quirements and resistances of individual designs of coils. A most important factor in the performance of extended-surface coils is the bond between the fin and the tube. An intimate contact between the tube and the fin must be maintained permanently in order to assure a continuing rated performance after the heating units have been in service for a period of time. In some coils, fins are wound on the tubes under pressure, in order to upset the metal slightly at the fin root, and then are given a coating of solder while the fin and tube are still revolving, for the purpose of assuring a uniform coating of solder. In other types, the spiral fin may be knurled into a shallow groove on the exterior of the tube. The tube may be expanded after the fins are assembled, or the tube-hole flanges of a flat or corrugated fin may be made to override those in the preceding fin and so compress them upon the tube. There are also types of construction where the fin is formed out of the material of the tube itself.

For *heating coils*, materials most generally used are copper and aluminum. Steel is occasionally used where sodium or calcium chloride brine is circulated in the tubes. Aluminum fins on copper tubes are a common con-

FIG. 1. TYPES OF FIN COIL ARRANGEMENT

struction. Generally speaking, brass does not serve as a satisfactory fin material because of corrosion difficulties. *Cooling coils* for water or for volatile refrigerants most frequently have copper fins and tubes, although aluminum fins on copper tubes are also used. There are many makes of heating and cooling coils of the light weight extended surface type for both heating and cooling with tubes commonly  $\frac{1}{2}$ ,  $\frac{3}{8}$ ,  $\frac{3}{4}$ , and 1 in. outside diameter, and with fins spaced three per inch up to eight per inch. The tube spacing generally varies from about  $1\frac{1}{2}$  to  $2\frac{1}{2}$  in. on centers, depending upon the width of individual fins and on other considerations of performance. Fin spacing should be chosen for the duty to be performed, with special attention being paid to possibility of lint accumulation and, especially in dehumidifying, the consideration of frost accumulation.

#### Steam Coils

For proper performance of steam heating coils, condensate and air must be continuously eliminated and the steam must be evenly distributed to the individual tubes. This distribution is usually accomplished by individual orifices in the tubes, by distributing plates and orifices in the steam header, or by perforated internal steam-distributing pipes extending into the individual tubes. The latter arrangement has the advantage of distributing the steam throughout the length of each tube, and is conducive to uniform temperature of delivered air. The tendency of condensate to freeze at the bottom of the coil with cold entering air and light heating

loads, is also minimized. This is especially valuable for outside air pre-heaters.

### Water Coils

The performance of water coils, for heating or cooling, depends on the elimination of air from the system and proper distribution of water. Air elimination is taken care of in the system piping as described in Chapter 22. To assure a pressure drop sufficient for adequate distribution, but at the same time to provide against excessive pumping head where large water quantities are handled, water coils are provided with various water circuit

FIG. 2. VARIOUS WATER CIRCUIT ARRANGEMENTS

arrangements. For instance, a typical coil 18 tubes high and 6 tubes deep in the direction of air flow can be arranged for 6, 9, 18, 24, or 36 parallel water circuits, as conditions may require. Orifices in individual tubes are occasionally employed, but are usually unnecessary as the resistance of individual water circuits is generally sufficient to effect a satisfactory distribution. In precooling coils using well water, where there may be considerable sand and other foreign matter in the water, provision for cleaning of individual tubes is of advantage. It is important to arrange water coils for complete drainage (see Fig. 2). The drains are usually provided in the water piping at the coil header.

### Direct-Expansion Coils

Coils for volatile refrigerants present more complex problems of fluid distribution than do water, brine or steam. It is desirable that the coil be effectively and uniformly cooled throughout, and necessary that the compressor be protected from entrained, unevaporated refrigerant. There are two types, namely, flooded systems, and thermal expansion valve systems, as shown in Figs. 3 and 4. In a flooded coil, the circulation is similar to that in a water tube boiler. The liquid is maintained at the proper level by the action of a float regulator as shown in Fig. 3. The thermal expan-

sion valve system depends upon the thermal valve automatically feeding just as much liquid to the coils as is required to maintain the superheat at the coil suction outlet within predetermined limits, which vary from about 6 to 10 deg. The thermal valve arrangement is in common use for the type of coils covered by this chapter, while the flooded system is rarely used.

With the flooded system the refrigerant distribution through the tubes depends on properly selecting the length of the feeds, and the head of liquid imposed upon the liquid inlets. No auxiliary distributing devices are required. With the thermal valve system, there are two factors to consider. There must be, generally, more than one refrigerant feed through the coil per thermal valve to keep the pressure drop through the refrigerant circuit within practical limits, and to reduce the corresponding penalty in increased

FIG. 3. DIRECT-EXPANSION COIL WITH FLOODED SYSTEM

FIG. 4. DIRECT-EXPANSION COIL WITH THERMAL VALVE SYSTEM

evaporating temperature. At the same time the coil must be so arranged that the required suction superheat can be attained with a minimum sacrifice in the performance of the coil as a whole. It is general practice to attain this superheat within the coil itself, and not by the use of external heat exchangers or other auxiliary devices.

With thermal expansion valves it is advantageous to keep the pressure drop through the refrigerant feeds as low as possible. The feeds are laid out to expose each to the same mean temperature difference so that it handles the same refrigerating load. Here, a distributing means is imposed between valve and coil liquid inlets to divide the refrigerant equally among the feeds. Such a distributor must be effective for distributing both liquid and vapor, because the entering refrigerant is a mixture of the two. Fig. 5 shows three typical types of distributors. In distributor A the liquid and gas mixture from the thermal valve is led tangentially into a chamber. The coil feed connections extend outward radially at the top of this chamber. In distributor B the refrigerant is discharged at a high velocity through a central jet against the end plate, forming a uniform mixture of gas and liquid within the distributor, from which individual connections are led as shown. In type C the refrigerant enters at high velocity from the thermal valve and is discharged against the end plug in which the individual liquid feeds are closely arranged. These distributors can be used in either vertical or horizontal position. There are also other types of headers such as the centrifugal and weir type. The individual liquid connections from the distributor to the coil inlet are commonly made of small diameter tubing, and are all of the same length and diameter in order to impose the same friction between the distributor and the coil. Since the

thermal valves act in response to the superheat at the coil outlet, this superheat should be produced with the least possible sacrifice of active evaporating surface. Sometimes a single thermal valve is used per coil. In other cases, multiple valves are used, with the coil divided across the air flow or parallel to the air flow as shown in Fig. 6. The arrangement of Fig. 7 should be avoided, since it offers the disadvantage of unequal load on the two parallel circuits.

### Flow Arrangement

In all heat transfer processes, the relative directions of flow of the fluids influence the performance of the heat transfer surface. In air-heating and cooling coils, the air usually flows at right angles to the tubes. In a coil having only one row in the direction of air flow, the relative directions of

FIG. 5. TYPES OF REFRIGERANT FEED DISTRIBUTING HEADS

flow would all be at right angles. In coils having more than one row in the direction of air flow, the media in the tubes may be variously circuited as illustrated for water or steam coils in Fig. 8. It is the usual practice to designate a coil that is circuited and employed as in Fig. 8A as a *parallel flow* coil. Figs. 8B and 8C show the general arrangements that are termed *counter-flow* and *cross-flow* respectively. Cross flow is common in steam heating coils, the temperature within the tubes being substantially uniform, and the mean temperature difference the same whatever the direction of flow, relative to the air. The parallel and counter-flow arrangements as illustrated in Figs. 8A and 8B are common in brine or water coils, with the counter-flow arrangement being the preferred arrangement to secure the advantage of highest possible mean temperature difference. Most direct-expansion coils also follow the general scheme of counter flow but the circuiting requirements for proper loading sometimes result in a combination of the other flow arrangements with counter flow in the same coil. Cross flow is generally avoided in the volatile refrigerant coils because of the unequal loading of the parallel circuits.

### Applications

Heating coils in field-assembled banks are used for a number of purposes as described in Chapter 30. They may be arranged with the air flow

FIG. 6. ARRANGEMENT FOR FACE CONTROL

FIG. 7. ARRANGEMENT FOR DEPTH CONTROL

vertical or horizontal, although the latter is more common. For steam heating, the coils may be set with the tubes vertical or horizontal. In the latter case the coil should be sloped to provide for condensate drainage. Because of the multi-circuit feed arrangement and the necessity for avoiding air and water pockets, water heating coils are generally arranged with the tubes horizontal. Certain precautions must be taken against freezing. Where steam coils are used with entering air below freezing temperature, throttling the steam supply may cause freezing of the condensate in the bottom of the coil, if the tubes are of the variety not provided with internal distributing pipes or an equivalent arrangement.

There are coils available having inner distributing tubes, and having the supply and return headers cast in one piece. In this type of coil the condensate that forms in the outer tube has resulted from steam fed from

FIG. 8. FLOW OF MEDIA IN TUBES IN RELATION TO AIR FLOW

the inner tube orifices. This condensation flowing back along the warm inner tube is prevented from freezing. A wide range of modulation at very low temperatures without danger of freezing, is therefore obtained. As an added precaution, with both steam and water coils, the outside air inlet dampers are often closed automatically when the fan is stopped to avoid trouble caused by very cold outside air drifting in during off periods.

A typical arrangement of coils is shown in Fig. 9. All of the air should be filtered to prevent dirt, insects and foreign matter from accumulating on the coils. The cooling coil and humidifier must be provided with a drip pan to catch the condensate formed during the cooling cycle and the excess water from the humidifier. The drain connection should be on the downstream side of the coils, made of ample size (not less than 1½-in. pipe), provided with accessible clean-outs, a deep seal trap, and discharge to an indirect waste, so that there will be no possibility that sewer gas may enter

FIG. 9. TYPICAL ARRANGEMENT OF COOLING COILS IN A CENTRAL SYSTEM

the system. Precautions against freezing must be taken with the humidifier piping and drain connections.

Water coils and large steam coils are also subject to freezing. Cold outside air must be provided with tempering coils or mixing vanes. They must be installed to insure thorough mixing of the outside and return air to prevent this hazard.

Face and by-pass damper have proven to be satisfactory means of capacity reduction for cooling coils using non-volatile refrigerants. The use of such face and by-pass damper arrangements on volatile refrigerant coils poses difficult refrigerant control problems which are most severe when a change of setting at the thermostat imposes a rapid change in the dampers at the coils. On many installations, the coil bank is divided into 2, 3, or 4 sections and each section is connected to an individual compressor, or connected to a modulating compressor or compressors which will adjust to the load as each succeeding coil section is cut out by the thermostat.

The design features of the coil (fin spacing and type of fins, whether circular fins or plate) determine at what air velocity condensed moisture will be blown off the coil. Water blows off some coils below 400 fpm face velocity, while this does not occur on others at face velocities in excess of 500 fpm. Where there is a likelihood of water being blown off the coil face, eliminator plates should be placed on the down-stream side of the coil. Plate coils are most frequently installed without eliminator plates. When a number of coil sections are stacked one above another, there is a tendency for the condensate to be carried out into the air stream as it drips

from one coil to the next one. In such cases, drip troughs as are shown in Fig. 10 are used to collect the water and conduct it to the drain pan.

The enclosure around a coil or filter bank should be corrosion resistant and should have adequate access doors to provide for changing of air filters, cleaning of coils, adjusting expansion valves, oiling motors, etc.

Sometimes cooling and dehumidifying coils are sprayed with water to increase the rate of heat transfer and to provide leaving air approaching saturation. This arrangement requires a collecting tank and recirculating pump to maintain water circulation whenever the apparatus is in operation. Fig. 11 illustrates this arrangement with a bypass around the coil. This bypass is often used to facilitate thermostatic control. It is advantageous

FIG. 10. COIL ARRANGED WITH DRIP TROUGH

FIG. 11. RECIRCULATING SPRAY SYSTEM FOR CLEANING COILS

to direct only return air through the bypass rather than a mixture of return and outdoor air in order to hold the humidity ratio under thermostatic control.

Although both heating and cooling coils are made of sufficient strength to take up expansion and contraction arising within themselves, care should be taken to avoid imposing strains from the piping on the coil connections. (See Chapter 21.)

### COIL SELECTION

In the selection of a coil it is necessary to consider various factors:

1. The duty required: heating, cooling, dehumidifying, and the capacity required to maintain balance with other system components such as compressor equipment in the case of direct expansion coils.
2. Temperature of entering air—dry-bulb only if there is no dehumidification; dry- and wet-bulb if moisture is to be removed.
3. Available heating and cooling media.
4. Space and dimensional limitations.
5. Air quantity limitations.
6. Allowable resistances in air circuit and through tubes.
7. Allowable resistance between the inlet and the outlet of the coil tubing circuits.
8. Characteristics of individual coil designs.
9. Individual installation requirements, such as, for example, the type of automatic control to be used.

The duties required may be determined from information in Chapters 9,

11, 12, 13 and 30. There may, or may not, be a choice of cooling and heating media, as well as temperatures available, depending upon whether the installation is new or is in combination with present sources of heating or cooling. Space limitations are dictated by the requirements of individual cases. The air quantity is influenced by a number of considerations. The air quantity through heating coils is often made the same as that necessary to handle the summer cooling load. The air handled may be limited by the use of old ventilating ducts as the air distribution system or may be dictated by requirements for satisfactory air distribution or ventilation. The resistance through the air circuit influences the fan horsepower and speed. This resistance may be limited to allow the use of a given size of fan motor, or to keep the operating expense low, or it may be limited because of sound level requirements. The allowable friction through the water or brine circuit may be dictated by the head available from a given size of pump and pump motor. The performance of a surface heating or cooling coil depends upon correct choice of the original equipment, and upon proper application and maintenance.

Coil ratings are based on a uniform face velocity. Interference with uniform air flow through the coil will affect performance. Such air flow interference may be caused by air being brought in at odd angles or by inadvertent blocking of a portion of the coil face. To obtain rated performance it is necessary that the air quantity be adjusted on the job to that used in determining the coil selection, and that it be kept at this value. The most common causes of a reduction of air quantity are the fouling of the filters and collection of dirt in the coils. These difficulties can be avoided by proper design and regular servicing. There are a number of ways in which coils may be cleaned. A common method is to wash them with water. They can sometimes be brushed and cleaned with a vacuum cleaner. In bad cases of neglect, especially on restaurant jobs where grease and dirt have accumulated, it is sometimes necessary to remove the coils and wash off the accumulation with steam, compressed air and water, or hot water. The best practice, however, is to keep the filters serviced, and to inspect and wash the coils at regular intervals.

The proper selection of coils requires an understanding of the requirements of each case, and should be based on an economic analysis of the plant design as a whole. While no general rule can be established for the selection of heating or cooling coils, it is possible, however, to point out the limits of usual practice and to indicate the influence of the variables involved in the coil selection.

### Heating Coils

*Steam and hot water heating coils are usually rated within these limits:*

Air Face Velocity—200 to 1200 fpm, sometimes up to 1500 fpm.  
 Steam Pressure—2 to 200 psig, sometimes up to 350 psig.  
 Hot Water Temperature—150 to 225 F.  
 Water Velocity—2 to 6 fps.

Individual cases may deviate widely, but the tabulation given herewith will serve as a guide to usual *heating installation practice*:

Air Face Velocity—500 to 800 fpm face, 500 being a common figure.  
 Delivered Air Temperature—varies from about 72 F for ventilation only, to about 150 F for complete heating.  
 Steam Pressure—2 to 10 psig, 5 psig being common.  
 Hot Water Temperature—150 to 225 F.  
 Water Velocity—2 to 6 fps.

### Air Heating and Cooling Coils

*Water Quantity*—Based on about 20 deg temperature drop through a hot-water coil.

*Air Resistance*—The total resistance through heating coils is usually limited to from  $\frac{3}{8}$  to  $\frac{5}{8}$  in. of water for public buildings, to about 1 in. for factories.

The selection of heating coils is relatively simple as it involves dry-bulb temperatures and sensible heat only, without the complication of simultaneous latent heat loads, as in cooling coils. For a given duty, entering air temperature, and steam pressure, it is possible to select several arrangements of the same design of coil depending upon the relative importance of space, cross-sectional area, and air resistance.

### Cooling Coils

*Cooling and dehumidifying coils are usually rated within these limits:*

Entering Air Dry-Bulb—60 to 100 F.  
 Entering Air Wet-Bulb—50 to 80 F.  
 Air Face Velocities—300 to 800 fpm (sometimes as low as 200 and as high as 1200).  
 Volatile Refrigerant Temperatures—25 to 55 F, at coil suction outlet.  
 Water Temperatures—40 to 65 F.  
 Water Quantities—2 to 6 gpm per ton, or equivalent to a water temperature rise of from 4 to 12 deg.  
 Water Velocity—2 to 6 fps.

The ratio of total to sensible heat removed varies in practice from 1.00 to about 1.65, i.e., sensible heat is from 60 to 100 percent of total, depending on the application. (See Chapter 30.) Since required ratios may demand wide variations in air velocities, refrigerant temperatures, and coil depth, general rules as to their values may be misleading. On most comfort installations air face velocities between 400 and 600 fpm are frequent, 500 being a common value. Refrigerant temperatures ordinarily vary between 35 and 50 F where cooling is accompanied by dehumidification. Water velocities range from 2 to about 6 fps.

When no dehumidification is desired, for which condition the dew point of the entering air is equal to or lower than the cooling coil surface temperature, the coil selection is made on the basis of dry-bulb temperatures and sensible-heat transfer only, the same as with heating coils. It is possible also to choose various arrangements of face area, depth, air velocity, etc., for the same duty.

### Dehumidifying Coils

The performance of coils accomplishing both cooling and dehumidification is determined by a series of tests carried on under laboratory conditions. Coil ratings can be prepared from such laboratory test data to facilitate the selection of coils for cooling and dehumidifying duty. The coil capacity should be in balance with the capacity of related equipment, such as compressors, and the temperature of the circulating medium.

The selection of cooling coils for factory-assembled self-contained air conditioners is generally accomplished in conjunction with laboratory testing. The current industry standards call for ratings at 33.4 cfm per thousand Btu of cooling capacity and this is approximately 400 cfm per ton of refrigeration. The use of an entering air condition of 80 F dry bulb and 67 F wet bulb is representative of the entering air conditions actually encountered in many comfort operations because, while the indoor conditions are usually lower than 67 wet bulb, the introduction of outside air will usually bring the mixture of air to the cooling coil up to an approximation of the 67 wet bulb entering air condition at design conditions.

The selection of cooling coils for field assembled projects is usually ac-

completed by the use of coil rating tables. The practice of selecting coils from the load division indicated by the load calculation has worked out satisfactorily for the usual human comfort applications. Additional design precautions and refinements are being used for more exacting industrial applications and for improved results on all types of air conditioning in the more humid areas. One of these refinements is the use of a separate cooling coil to cool and dehumidify the ventilation air before admixture with recirculated air. This procedure takes care of one of the main sources of moisture in the usual application. Provision for reheat is required for some industrial applications, and is used for better results on very special commercial applications.

In checking the operating results obtained from cooling coils in various air conditioning installations, it is necessary to keep in mind the influence of the climatic conditions of the various areas encountered. The majority of problems are encountered at *light load* conditions when the cooling requirement is considerably less than at design conditions. In the hot dry climates, where the outside dew points are so constantly low that dehumidifying is not generally a problem, the *light load* condition does not pose any special problems. In the hot humid climates, where the outside dew points are generally high and close to the dry-bulb temperatures, the *light load* condition has a higher proportion of moisture and a correspondingly lower proportion of sensible heat. These climatic conditions result in higher dew points in the conditioned spaces during the *light load* conditions unless some of the special means for controlling the inside dew points are used. In the geographic locations where warm weather occurs with both high and low dew points, such as around the Great Lakes, the *light load* operating conditions with the higher percentage of moisture loading will be encountered less frequently and consistently than in the south coastal areas.

Care should be taken to avoid freezing at light loads. In general, freezing occurs when the coil surface temperature falls to 32 F. With usual coils for comfort installations, this does not occur unless the evaporating temperature at the coil outlet is about 20 to 25 F. The exact value depends on the design of the coil and the amount of loading. Although it is not customary to choose coil and condensing units to balance at low temperatures at peak loads, there is danger of this occurring when the load decreases. This is further aggravated if a by-pass is used so that less air is passed through the coil at light loads.

### HEAT TRANSFER AND AIR FLOW RESISTANCE

The transfer of heat between the heating or cooling medium and the air stream is influenced by several variables:

1. The temperature difference.
2. The design and surface arrangement of the coil.
3. The velocity and character of the air stream.
4. The velocity and character of the medium in the tubes.

The driving force is usually taken as the logarithmic mean temperature difference for heating or cooling without dehumidification. The rating of cooling coils for combined cooling and dehumidification is discussed later in this chapter. With volatile refrigerants there is often an appreciable pressure drop and corresponding change in evaporating temperature through the refrigerant circuit. The problem is further complicated by the fact that the refrigerant is evaporating in part of the circuit, and superheating in the remainder. In the case of volatile refrigerants, a cooling coil is tested and rated in conjunction with a specific distributing and liquid

metering device, and the capacities are stated for a given superheat condition of leaving vapor.

The design and surface arrangement of the coil include such items as materials, type, thickness, height, and spacing of the fins, and the ratio of this surface to that of the tube, the use of the staggered or in-line tube arrangement, and provisions to increase the air turbulence such as the use of corrugated as against flat fins. Staggered tubes increase the total heat transfer, as against the in-line arrangement, and corrugated fins may be more effective than flat. This design and surface arrangement has a large effect on the air film heat transfer resistance.

The velocity of the air usually considered is the coil *face* velocity. This bears a *varied relation to the actual velocity* over the surface, depending upon the individual coil design. As long as a fixed design of coil is under consideration face velocities may be used, but they may be unsatisfactory in comparing different designs, as it is the *actual surface velocity that is significant*. The air volume is often based on standard air at 70 F and a barometric pressure of 29.92 in. Hg.

At the same mass air velocity, varying performance can be obtained depending upon the turbulence of the air flow into the coil, and upon the uniformity of distribution of air over the coil face. The latter is very important in obtaining reliable test ratings, and in realizing rated performance in practical installations. The resistance through the coils will assist in distributing the air properly, but where the inlet duct connections are brought in at sharp angles to the coil face, the effect is frequently bad and there may even be reverse air currents through a portion of the coils. This reduces the capacity, but can be avoided by proper layout or by the use of vanes or baffles.

Heat transfer information on plain pipe coils has been developed and verified through many tests. In the case of finned coils, the heat transfer from the cooling or heating medium to the air stream is dependent on so many factors that reliable rating and performance information for any design of coil must be based upon actual tests of the specific coil. Mathematical comparisons of different designs of coils on a square foot of surface and face area basis may be misleading. The selection of finned coils should be made from curves or tables of coil performance prepared from a series of adequate and reliable tests. There are cases in which the engineer must extend available data or design for a single unique installation. For such purposes the following coil calculations will be useful.

### PERFORMANCE OF HEATING AND DRY COOLING COILS

The performance of heating and dry cooling coils depends in general upon:

1. The overall coefficient of heat transfer from the fluid within the coil to the air it heats or cools.
2. The mean temperature difference between the fluid within the coil and the air flowing over the coil.
3. The physical dimensions of the coil.

Thus, for any one definite operating condition, the heating or cooling capacity of a given coil is expressed by the following basic formula:

$$q_t = U \times (\Delta t_m) \times A \times N \quad (1)$$

where

$q_t$  = total heat transfer the coil, Btu per (hour) (square foot of coil face area).

$U$  = overall coefficient of heat transfer, Btu per (hour) (square foot of external coil surface) (Fahrenheit degree temperature difference between the fluid within the coil and the air flowing over the coil).

$\Delta t_m$  = mean temperature difference, Fahrenheit degrees, between the fluid within the coil and the air passing over it. (This is commonly taken as the logarithmic mean temperature difference).

$A$  = external surface area of the given coil, square feet per (square foot of coil face area) (row of coil depth).

$N$  = number of rows of coil depth.

### Overall Coefficient of Heat Transfer

While the overall coefficients of heat transfer for plain pipe coils have been defined by numerous tests within close limits, the verification of a plain coil design by a series of tests is an accepted commercial practice. The overall coefficients of heat transfer for finned coils should always be obtained from tests. The data from a series of tests may be used for purposes of extending coil data beyond test range but such data should later be verified by test.

Considering any coil, whether of bare pipe or of finned type, the overall heat transfer coefficient for a given size and design of coil can always be considered as a combined effect of three individual heat transfer coefficients, namely:

1. The film coefficient of heat transfer between air and the external surface of the coil, usually given in Btu per (hour) (square foot external surface) (Fahrenheit, degree mean temperature difference).

2. The conductivity of the coil material—tube wall, fins, ribs, etc., usually given in Btu per (hour) (square foot of surface) (Fahrenheit degree per inch).

3. The film coefficient of heat transfer between the internal surface of the coil and the fluid flowing within the coil, usually given in Btu per (hour) (square foot internal surface) (Fahrenheit degree mean temperature difference).

These three individual coefficients acting in series result in an overall coefficient of heat transfer in accordance with the basic laws given in Chapters 5 and 9. For a *bare pipe* coil the overall coefficient of heat transfer, whether for heating or for cooling (without dehumidification), can be expressed by a simplified basic formula as follows:

$$U = \frac{1}{\frac{R}{f_i} + \frac{L}{k} + \frac{1}{f_o}} \quad (2)$$

where

$U$  = overall coefficient of heat transfer, Btu per (hour) (square foot external surface) (Fahrenheit degree mean temperature difference between air and fluid within the coil).

$f_i$  = film coefficient of heat transfer between the internal surface of the coil and the fluid flowing within the coil, Btu per (hour) (square foot internal surface) (Fahrenheit degree mean temperature difference between that surface and the average fluid temperature).

$f_o$  = film coefficient of heat transfer between air and the external surface of the coil, Btu per (hour) (square foot external surface) (Fahrenheit degree mean temperature difference between the mass of air and the external surface).

$k$  = conductivity of material from which the bare pipe is constructed, Btu per (hour) (square foot) (Fahrenheit degree per inch thickness).

### Air Heating and Cooling Coils

$L$  = thickness of tube wall inches.

$R$  = ratio between external and internal surface of the bare tube, usually varying from 1.03 to 1.15 for the tube used in typical heating or cooling coils. This ratio  $R$  is inserted in the formula in order to place internal fluid coefficient of heat transfer on the basis of external surface.

Frequently, when pipe or tube walls are thin and of material having high conductivity (as is the case in construction of typical heating and cooling coils) the term  $L/k$  in Equation 2 becomes negligible and is generally disregarded. (The effect of the term  $L/k$  in typical bare pipe heating or cooling coils seldom exceeds 1 to 2 percent of the overall coefficient). Thus, in its simplest form, for bare pipe:

$$U = \frac{1}{\frac{R}{f_i} + \frac{1}{f_o}} \quad (3)$$

For finned coils the formula\* for the overall coefficient of heat transfer can be conveniently written:

$$U = \frac{1}{\frac{R}{f_i} + \frac{1}{\eta f_o}} \quad (4)$$

in which the term  $\eta$ , called the *fin efficiency*, is introduced to allow for the resistance to heat flow encountered in the fins.

The term  $R$ , in this case, is the ratio of *total* external surface to internal surface. For typical designs of finned coils for heating or cooling, this ratio varies from 10 to 30. Term  $R$  is again introduced to place the internal surface coefficient of heat transfer on a basis of external surface.

The performances of all heating and dry cooling coils are influenced by these same factors. But, when cooling coils operate wet or act as dehumidifying coils, the performance cannot be predicted on the basis of overall coefficients.

### PERFORMANCE OF DEHUMIDIFYING COILS

When the dew point of the air leaving a cooling coil is lower than the dew point of the air entering the coil, some moisture removal has been accomplished. A coil that normally accomplishes (or is designed to accomplish) moisture removal in addition to sensible heat cooling is termed a dehumidifying coil.

In most air conditioning processes, the air may be considered as a mixture of water vapor and the dry components. Both dry components and the water vapor enter an air conditioning coil at the same dry-bulb temperature; both the dry components and the water vapor lose sensible heat during the contact with the first portion of the cooling coil in the same manner as in a dry cooling coil. As the dry-bulb temperature of the mixture approaches the dew point of the water vapor components, moisture removal starts.

The psychrometric path of air through a cooling coil is generally agreed to follow a path similar to that shown in Fig. 12. When the dry-bulb

\* Rational Development and Rating of Extended Air Cooling Surface, by H. B. Pownall (*Refrigerating Engineering*, October, 1935, p. 211).

temperature of the air mixture in the coil falls below the entering dew-point temperature, moisture removal proceeds. The indications are that the lower the leaving dry-bulb temperature below the entering dew-point temperature, the less will be the difference between the leaving dry-bulb temperature and the leaving dew-point temperature.

The first portion of a cooling coil (in the direction of air flow) may function in the same manner as a dry cooling coil. Where the moisture removal starts, the cooling surfaces also continue the removal of sensible heat, thereby carrying the load due to both. As saturation is approached in the cooling coil, each degree of sensible cooling is approximately matched by a

FIG. 12. PERFORMANCE OF DEHUMIDIFYING COIL

corresponding degree of dew point decrease. However, while the sensible heat removal from the dry air remains approximately constant per degree change, the amount of latent heat removal per degree of dew point change varies considerably because moisture content varies widely at different temperatures.

For example, the following tabulation compares the amount of moisture removal involved in a reduction of one degree of dew point from 60 to 59 F with the removal from 50 to 49 F:

| DEW POINT  | $W_s \times 10^3 \text{ lb/(lb)}$ | DEW POINT  | $W_s \times 10^3 \text{ lb/(lb)}$ |
|------------|-----------------------------------|------------|-----------------------------------|
| 60         | 11.080                            | 50         | 7.658                             |
| 59         | 10.690                            | 49         | 7.374                             |
| DIFFERENCE | 0.390                             | DIFFERENCE | 0.284                             |

The above values are given in Table 2, Chapter 3.

When cooling coils act as dehumidifying coils, the performance can be predicted accurately only from tests at a sufficient number of points to establish the definite performance characteristics of the coil under varying conditions of loading and of entering air. Dehumidifying coils employing volatile refrigerants are generally rated in conjunction with specific refrigerant distributing and flow control equipment. The combination of the coil with its refrigerant control equipment (such as distributor and expansion valve, and capillary tube or float valve) must be tested at both the higher and lower capacities of its rated range. The lower capacities

impose a test on the distributor to provide equal distribution and on the control to modulate without hunting at the lower capacities. The higher capacities result in a greater pressure drop through the coil system and a test of the maximum feeding capacity of the flow control device at various head pressures.

Most coil manufacturers have their own methods of producing performance rating tables from a suitable number of coil performance tests. Several such methods have been reported in the literature of the industry. A standard titled Standard Methods of Testing and Rating Forced-Circulation Air-Cooling and Air-Heating Coils has been completed by the Heating and Cooling Coil Manufacturers' Association and the Air-Conditioning and Refrigeration Institute.

FIG. 13. PSYCHROMETRIC ARRANGEMENT OF COOLING COIL IN CENTRAL SYSTEM

### DETERMINING REFRIGERATION LOAD

The following determination of the refrigeration load shows a division of the true *sensible* and *latent* heat loss of the air, which is accurate within the limitations of the data. These divisions will not correspond to load determination obtained from approximate factors or constants.

The total refrigeration load  $q_t$  of a cooling and dehumidifying coil (or air washer) is indicated on Fig. 13 and consists of the following components:

1. The *sensible heat*  $q_s$  removed from the dry air and moisture in cooling from entering temperature  $t_1$  to leaving temperature  $t_2$ .
2. The *latent heat*  $q_e$  removed to condense the moisture at the dew-point temperature  $t_d$  of the entering air.
3. The heat of *subcooling*  $q_w$  removed from the condensate in cooling it from the condensing temperature  $t_c$  to the leaving condensate temperature  $t_3$ .

Items 1, 2, and 3 may be related by

$$q_t = q_s + q_e + q_w \quad (5)$$

If only the *total heat* value is desired, it may be computed by

$$q_t = (h_1 - h_2) - (W_1 - W_2)h_{w2} \quad (6)$$

where

$h_1$  and  $h_2$  = enthalpy at points 1 and 2 respectively.

$W_1$  and  $W_2$  = humidity ratio at points 1 and 2 respectively.  
 $h_{w2}$  = enthalpy of saturated liquid at the final temperature,  $t_2$ .

If a breakdown into *latent* and *sensible heat* components is desired, the following relations may be used:

The *latent heat* may be found from

$$q_e = (W_1 - W_2)h_{fg4} \quad (7)$$

where

$h_{fg4}$  = enthalpy at the condensing temperature,  $t_4$ .

The *sensible heat* may be shown to be

$$q_s + q_w = (h_1 - h_2) - (W_1 - W_2)h_{fg4} + (W_1 - W_2)(h_{w4} - h_{w2}) \quad (8)$$

where

$h_{fg4}$  = enthalpy at the condensing temperature,  $t_4$ .

$h_{w4}$  = enthalpy of saturated liquid at condensing temperature,  $t_4$ .

The last term in Equation 8 is the heat of *subcooling* the condensate from the condensing temperature  $t_4$  to its final temperature  $t_2$ . Then,

$$q_w = (W_1 - W_2)(h_{w4} - h_{w2}) \quad (9)$$

All values for solving the foregoing equations may be found on the ASHAE Psychrometric Chart and Tables 2 and 3 of Chapter 3.

**Example 1:** Air enters a coil at 90 F dry-bulb, 75 F wet-bulb; it leaves at 61 F dry-bulb, 58 F wet-bulb; leaving water is assumed to leave at a temperature between the leaving air dew point and coil surface temperature of 54 F. Find the total, latent, and sensible cooling loads on the coil.

**Solution:** From the ASHAE Psychrometric Chart, find the following:

$h_1 = 38.42$  Btu per lb of dry air.  $W_1 = 0.01525$  lb per lb of dry air.  
 $h_2 = 25.10$  Btu per lb of dry air.  $W_2 = 0.00960$  lb per lb of dry air.  
 $t_4 = 69$  F wet-bulb of entering air.

From Table 3, find:

$h_{w4} = 37.11$  Btu per lb.  $h_{fg4} = 1054.27$  Btu per lb.  
 $h_{w2} = 22.12$  Btu per lb.  $h_{g4} = 1091.34$  Btu per lb.

The total heat from Equation 6 is

$$q_t = (38.42 - 25.10) - (0.01525 - 0.00960) \times 22.12 = 13.32 - (0.00565 \times 22.12) = 13.32 - 0.12 = 13.20 \text{ Btu per lb dry air.}$$

The *latent heat* from Equation 7 is

$$q_e = 0.00565 \times 1054.27 = 5.96 \text{ Btu per lb of dry air.}$$

The *sensible heat* by difference, is

$$q_s + q_w = q_t - q_e = 13.20 - 5.96 = 7.24 \text{ Btu per lb of dry air.}$$

Or the *sensible heat* may be computed from Equation 8 as

$$\begin{aligned} q_s + q_w &= (38.42 - 25.10) - (0.00565 \times 1091.34) + 0.00565(37.11 - 22.12) \\ &= 13.32 - 6.16 + 0.00565 \times 14.99 \\ &= 13.32 - 6.16 + 0.08 = 7.24 \text{ Btu per lb of dry air.} \end{aligned}$$

The *sub-cooling* of the condensate as a part of the sensible heat is indicated by the last term of the equation, 0.08 Btu per lb of dry air.

## CHAPTER 37 REFRIGERATION

Refrigeration Theory: Definitions and Basic Concepts, Refrigerants, Vapor Compression Refrigeration Cycles, Clearance and Volumetric Efficiency, Complex Refrigeration Cycles, Air Cycle, Steam Jet, Absorption and Ice Systems, Heat Pump; Basic Refrigeration Equipment: Compression Machines, Condensers, Evaporators and Coolers; Refrigeration Controls, Piping and Accessories; Equipment Characteristics and Selection

WITH the increasing use of all-year comfort air conditioning installations, the importance of refrigeration to the air conditioning engineer has been greatly magnified. The details of equipment operation, maintenance and design remain problems for the refrigeration engineer, but the air conditioning engineer does retain a responsibility to the customer which requires on his part some knowledge of the different refrigeration cycles and the relative merits of each. In order to assist in meeting this need, the present chapter has been divided into four parts, the first covering the fundamental technical relationships which govern the selection and analysis of an operating cycle, the next two presenting brief discussions of basic refrigerating equipment and auxiliaries, and the last, information on selection criteria.

### REFRIGERATION THEORY

#### Definitions and Basic Concepts

The *ton of refrigeration* is a quantity unit which originated in the days when harvested ice was the principal source of summer cooling. By definition the *ton* is the cooling effect realized when one ton of 32 F ice melts to water at 32 F; since the latent heat of fusion of ice is 144 Btu per pound, the *ton* represents a unit cooling effect of  $144 \times 2,000 = 288,000$  Btu. In common practice the *ton* is usually considered a rate (rather than quantity) unit, and is taken as 288,000 Btu per day (24 hours), or 12,000 Btu per hour, or 200 Btu per minute. Thus for air conditioning calculations, the size of the requisite refrigeration machine, expressed in tons, can be obtained by dividing the heat gain of the structure, expressed in Btu per hour, by 12,000. In equation form:

$$H_t = (\text{Btu per hour heat gain}) \div 12,000 \quad (1)$$

where

$H_t$  = load in tons.

The *working substance*, or *refrigerant*, is the fluid which carries heat through the refrigeration cycle from the evaporator, where heat enters the refrigerant, to the condenser where the heat is discharged to some cooling medium. The great majority of modern refrigeration systems use a liquefiable vapor as the working substance. By altering the pressure of the refrigerant its boiling temperature is changed, allowing the material to *boil* in the evaporator at a temperature sufficiently lower than that of the conditioned space, to insure maintenance of an effective heat transfer rate from

the space (or in some cases from a secondary cooling fluid such as brine or cold water) to the refrigerant. The vapor formed in the evaporator is then raised in pressure (by a compressor, or by the absorber-generator combination of the absorption system) until its new boiling temperature exceeds the temperature of the available cooling medium. Under these conditions, heat transfer is established from the refrigerant vapor to the cooling medium with resultant condensation of the refrigerant. When condensed, the high-pressure liquid refrigerant is reduced in pressure and again allowed to boil in the evaporator.

In order to permit evaluation of the effectiveness with which any given cycle operates, some term is desirable which would be comparable to the *efficiency* that is used for heat engines. In refrigeration the desired effect is heat extraction, and the cost of achieving this extraction is the amount of energy which must be supplied as shaft work. Thus the ratio of refrigerating effect to the heat equivalent of the compressor work is used as a measure of effectiveness, and is defined as the coefficient of performance.

If the desired effect is the rejection of heat through the condenser instead of heat extraction through the evaporator, the refrigeration system is then termed a heat pump. In this case the coefficient of performance is the ratio of the heat rejected from the condenser to the heat equivalent of the compressor work. The coefficient of performance for the heat pump is greater than that for a system operating as a refrigerating machine, because all mechanical shaft work required to operate the compressor is dissipated as useful heat through the condenser.

The Carnot cycle, an ideal, thermodynamically reversible cycle consisting of an adiabatic expansion and an isothermal expansion, followed by an adiabatic compression and an isothermal compression to form a closed cycle, may be shown to be a measure of the maximum possible conversion of heat energy into mechanical energy. In its reversed form it is a measure of the maximum performance possible for any refrigeration cycle operating either as a refrigerator or as a heat pump. Although it cannot be applied in an actual machine because of the impossibility of obtaining complete reversibility, it is, nevertheless, extremely valuable as a criterion of inherent limitations. The coefficient of performance (CP) of a reversed Carnot cycle system operating as a refrigeration system is

$$(CP) = \frac{T_e}{T_c - T_e} \quad (2)$$

where

$T_e$  = evaporator temperature, Fahrenheit degrees, absolute.  
 $T_c$  = condenser temperature, Fahrenheit degrees, absolute.

With the ideal Carnot cycle operating as a heat pump, the coefficient of performance is

$$(CP) = \frac{T_c}{T_c - T_e} \quad (3)$$

The Carnot cycle coefficient of performance for both a refrigerating machine and a heat pump increases as the spread between the evaporator and the condenser temperatures decreases. In general, the same is true for an actual system operating as either a refrigerating machine or a heat pump.

### Refrigerants

A desirable refrigerant should possess chemical, physical, and thermodynamic properties which permit its efficient application in refrigerating systems. In addition, when the volume of the charge is large, there should be little or no danger to health or to property in case of its escape.

Thermodynamically, a material for use as a refrigerant should have a large latent heat of vaporization since it is this heat quantity—subject to minor variations—which constitutes the working effectiveness of the refrigerant. Further, since the work required to compress a vapor increases rapidly with the pressure ratio, the thermodynamic characteristics of the fluid should be such that the required low-to-high temperature range can be achieved with only a moderate change in ratio. A further consideration, from the standpoint of practical operating effectiveness, is that the suction pressure should not be below atmospheric (to prevent leakage of air into the refrigerant lines) nor should the condenser pressure be excessively high (to prevent need for extra-heavy construction). The specific volume-specific enthalpy relationship is also important because some materials would have such low density, when in vapor form, that impractical compressor displacements would be needed to handle the suction vapor.

Properties of refrigerants are usually given either in tabular or graphic form. In contrast to the temperature-entropy plotting which is used almost exclusively in steam-power work, refrigeration problems are usually referred to a pressure-enthalpy chart. The advantage of pressure-enthalpy plotting is that linear distances on the chart correspond to energy gains or losses, and the two types of processes, constant-pressure and constant-enthalpy, which occur most frequently in refrigeration cycles, can both be represented by straight vertical or horizontal lines. Figs. 1 and 2 present pressure enthalpy charts for dichlorodifluoromethane,  $\text{CCl}_2\text{F}_2$ , and monochlorodifluoromethane,  $\text{CHClF}_2$ , respectively. Although tabular arrangements of refrigerant properties require interpolation between values, they have the advantage of an accuracy greater than that obtainable from a chart. Tables 1, 2, and 3 give the thermodynamic properties of three of the more common refrigerants used in air conditioning installations: dichlorodifluoromethane, monochlorodifluoromethane and monofluorotrichloromethane,  $\text{CCl}_3\text{F}$ , the first two of these are commonly used in reciprocating compressors; the last refrigerant is used in centrifugal machines.

Referring to Table 1, the first column gives the range of saturation temperatures likely to occur in practice. The second column gives the saturation pressure expressed in pounds per square inch absolute corresponding to a given temperature, while the next six columns give the three fundamental specific properties, volume, enthalpy, and entropy, of the saturated liquid and saturated vapor, respectively. The last four columns give values of enthalpy and entropy for gases with 25 deg and with 50 deg of superheat; note particularly that the column heading 50 F *superheat* means, not that the gas is at a temperature of 50 F, but that its temperature exceeds by 50 deg the saturation temperature corresponding to its actual pressure. Thus,  $\text{CCl}_2\text{F}_2$  vapor at 38.0 psig and 91 F possesses 50 deg of superheat, since its saturation temperature corresponding to 52.7 psia is 41 F.

The tabular arrangements of refrigerant properties are literally for saturated or superheated materials only. In many cases, however, the engineer must work with sub-cooled liquids. With an accuracy sufficient for all practical purposes, the specific volume and the enthalpy of any sub-cooled

Fig. 1. PRESSURE-ENTHALPY DIAGRAM FOR DICHLORODIFLUOROMETHANE ( $\text{CCl}_2\text{F}_2$ )  
Temperature—F; Volume—Cu Ft per Lb; Enthalpy—Btu per Lb.

refrigerant can be taken as equal to the values read from the tables for a saturated liquid at the same temperature. Thus, if  $\text{CCl}_2\text{F}_2$  at 121 psia and 40 F is passing through a pipe, its volume and enthalpy can be determined from Table 1 as 0.0116 cu ft per pound and 17.0 Btu per pound.

Frequently it is necessary to determine the properties of a wet vapor or of a mixture of liquid with some added vapor, such as is found at discharge from an expansion valve. This can be done from the tables by noting that the specific enthalpy of the mixture must be equal to that of the saturated liquid, plus a fraction of the latent heat of vaporization equal to the fraction

FIG. 2. PRESSURE-ENTHALPY DIAGRAM FOR MONOCHLORODIFLUOROMETHANE (CHClF<sub>2</sub>)  
Temperature—F; Volume—Cu Ft per Lb; Enthalpy—Btu per Lb (F deg).

of refrigerant which is present in vapor form. Consider, for example, CCl<sub>2</sub>F<sub>2</sub> with a quality (the percent in vapor form) of 30 percent; the enthalpy of this material would be equal to

$$h_m = h_l + 0.30 (h_v - h_l) \quad (4)$$

where

- $h_m$  = specific enthalpy of the mixture.
- $h_l$  = specific enthalpy of the liquid.
- $h_v$  = specific enthalpy of the saturated vapor.

TABLE 2. PROPERTIES OF MONOCHLORODIFLUOROMETHANE (CHClF<sub>2</sub>)

Values of  $v_s$  and  $v_d$  for use in Equation 4 can be obtained directly or by calculation from the tables of properties of refrigerants.

By a reversal of this same procedure the tabular data can be used to determine the state of a mixture leaving an expansion valve. Consider a valve to which saturated liquid at pressure  $p_s$  is admitted, and a mixture of saturated liquid and vapor at pressure  $p_d$  is discharged. The quality of the material at discharge is then determined by making use of the fact that the expansion process is completely irreversible, is a throttling process, and hence, occurs without change in enthalpy. Thus, the enthalpy of the mixture,  $h_m$ , is equal to the enthalpy of the saturated liquid at the entrance state,  $h_{fs}$ , and can therefore be read from the table.

Thus,

$$h_{fs} = h_m = h_{vd} - (1 - x)(h_{vd} - h_{fd}) \quad (5)$$

or,

$$x = (h_m - h_{fd}) / (h_{vd} - h_{fd}) \quad (6)$$

where

$h_{fs}$  = enthalpy of saturated liquid at entrance to expansion valve.

$h_m$  = enthalpy of mixture.

$h_{vd}$  = enthalpy of saturated vapor at discharge.

$h_{fd}$  = enthalpy of liquid at discharge.

$x$  = proportion of liquid in the mixture, decimal.

### Vapor Compression Refrigeration Cycle

**Simple Cycle.** The refrigerant cycle is the series of state changes (which occur in the conditioning processes) needed to restore the refrigerant to a condition in which it will possess the ability to extract heat from the space to be cooled. For all compression-type systems the cycle consists of four processes: heat gain in the evaporator; pressure rise in the compressor;

heat loss in the condenser; pressure loss in the expansion valve. The compression process is accomplished at the expense of energy added to the compressor in the form of shaft work, and the expansion process could be carried out, if the economics of the system would permit, in an expanding engine with consequent release of energy as shaft work. In ordinary systems, however, the additional first cost and maintenance costs of an expanding engine so greatly exceed the advantage resulting from the work realized, that such engines are not used, and the pressure reduction is allowed to occur irreversibly in an expansion valve. Basically, then, a refrigeration cycle consists of two heat transfer processes and two pressure change processes, no work entering into the heat transfer processes and—in the simple cycle—no heat transfer occurring during the pressure-change processes.

The most common and least complicated type of refrigeration cycle is called the simple saturation cycle, and is shown diagrammatically in Fig. 3 and plotted upon pressure-enthalpy coordinates in Fig. 4. For this system,

FIG. 3. MECHANICAL REFRIGERATION SYSTEM

saturated vapor flows without gain or loss of heat from the evaporator to the suction of the compressor. During passage through the compressor the energy added as shaft work goes entirely to increase the enthalpy of the refrigerant, and the compression process, which is assumed to occur irreversibly and without external heat transfer, is characterized by constant entropy. Thus, the state of the superheated vapor leaving the compressor can be determined from the tables of thermodynamic properties by noting the discharge pressure and fixing, also, the entropy of the saturated vapor at entrance to the compressor.

Superheated vapor from the compressor flows to the condenser where de-superheating and condensation take place. From the condenser the refrigerant flows to the expansion valve, undergoes a constant-enthalpy pressure reduction, and returns to the evaporator where it again removes a quantity of undesired heat. When the evaporator is arranged to permit direct cooling of room air by the refrigerant, the system is said to be of the *direct expansion* type, while a system in which the evaporating refrigerant cools water or brine, which in turn cools the air, is said to be *indirect*. Although many differences exist between most actual systems and that of the simple saturation cycle, this latter is, nonetheless, of great value in that it provides an extremely simple method of rapidly achieving an approximate

analysis of probable power requirements, compressor size, etc. Further, the equations used in analysis of a simple saturation cycle form the basis of the more complex treatments required for compound refrigeration cycles. For these reasons a typical simple saturation problem will be worked in detail.

**Example 1:** A simple saturation cycle carries a 7 ton load when operating between suction and discharge pressure of 52.7 psia and 121 psia with dichlorodifluoromethane,  $\text{CCl}_2\text{F}_2$ , as the refrigerant. Determine: (a) the cooling effect provided by each pound of refrigerant; (b) the refrigerant circulating rate; (c) the horsepower required; (d) the quantity of heat to be dissipated from the condenser; (e) the required condenser cooling water, in gallons per minute, if temperature rise of water passing through the condenser is 8 deg; (f) the bore and stroke of a double acting cylinder (neglecting the effect of the piston rod) if speed of compressor is 500 revolutions per minute; (g) coefficient of performance.

**Solution:** (a) Saturated liquid  $\text{CCl}_2\text{F}_2$  at 121 psia leaves the condenser and enters the expansion valve. The enthalpy of this material (from Table 1) is 29.68 Btu per pound, and this must also be its enthalpy at entrance to the evaporator. Leaving the evaporator as a saturated vapor at 52.7 psia, its enthalpy is 82.82, so the refrigerating effect must be  $82.82 - 29.68 = 53.14$  Btu per pound.

FIG. 4. PRESSURE-ENTHALPY DIAGRAM FOR SIMPLE SATURATION CYCLE

(b) The refrigerant circulating rate is equal to the total heat to be picked up in unit time, divided by the pick-up per pound of refrigerant or,

$$W_r = (7 \text{ ton} \times 200) + 53.14 = 26.3 \text{ lb per minute.}$$

(c) The horsepower required is equal to the increase in energy of the refrigerant passing through the compressor (expressed in Btu per minute) divided by the conversion factor 42.42, which is the number of Btu per minute corresponding to 1 hp,

$$(\text{hp}) = W_r (h_d - h_{vs}) \div 42.42 \quad (7)$$

where

hp = horsepower.

$W_r$  = refrigerant circulating rate in pounds per minute.

$h_d$  = enthalpy of vapor at condition of discharge from compressor.

$h_{vs}$  = enthalpy of saturated vapor entering compressor.

$W_r$  is known from (b) and  $h_{vs}$  is the enthalpy of refrigerant as it enters the compressor in a saturated vapor state at 52.7 psia; thus  $h_{vs} = 82.82$ .

In order to determine  $h_d$ , the state of the refrigerant must first be determined at the compressor discharge. At the known suction state the entropy (from Table 1 for saturated vapor at 52.7 psia) is 0.16828 and, since the compression is assumed to occur isentropically, it therefore follows that the discharge stage must have the same entropy at 121 psia. From the table the entropy of vapor superheated 25 deg is

## Refrigeration

0.17330, so the superheat,  $t_{sd}$ , possessed by the actual gas discharged from this compressor can be obtained by interpolation as;

$$\frac{t_{sd}}{25} = \frac{0.16828 - 0.16608}{0.17330 - 0.16608}$$

from which  $t_{sd} = 7.6$  deg.

As the saturation temperature at 121 psia is 94 F the actual temperature,  $t_d$ , of the vapor leaving the compressor is,  $t_d = 94 + t_{sd} = 94 + 7.6 = 101.6$  F. By the same kind of interpolation the enthalpy of the discharged vapor can be determined from the enthalpies given for vapor superheated 25 F and for saturated vapor,

$$\frac{(h_d - 88.10)}{(92.16 - 88.10)} = \frac{(0.16828 - 0.16608)}{(0.17330 - 0.16608)}$$

from which,  $h_d = 89.34$  Btu per pound.

Then substituting in Equation 7,

$$(\text{hp}) = 26.3 (89.34 - 82.82) \div 42.42 = 4.03.$$

(d) The rate of heat loss from the condenser,  $Q_c$ , must be equal to the sum of the energies picked up by the refrigerant in the evaporator and the compressor,

$Q_c = 53.14 + (89.34 - 82.82) = 53.14 + 6.52 = 59.66$  Btu per pound or  $26.3 \times 59.66 = 1569$  Btu per minute. This same figure can, of course, be determined more directly by subtraction of the enthalpy of liquid leaving the condenser from the enthalpy of superheated vapor going into it, thus,

$$Q_c = 26.3 (89.34 - 29.68) = 1569 \text{ Btu per minute.}$$

(e) The cooling water rate (based on a gallon as 8.34 lb) is  $1569 \div (8 \times 8.34) = 23.5$  gpm.

(f) The compressor size is fixed by the volume of gas which must be drawn into the machine per unit time. Saturated vapor at 52.7 psia has a specific volume, from Table 1, of 0.779 cu ft per pound, hence  $26.3 \times 0.779 = 20.49$  cu ft of gas must be handled. Assuming a volumetric efficiency of 90 percent, the compressor must then displace  $20.49 \div 0.9 = 22.8$  cu ft. The speed is given as 500 rpm and, as the unit is known to be double-acting, the displacement is therefore  $(22.8 \times 1728) \div (2 \times 500) = 39.4$  cu in. If the unit were designed so that bore  $d$  and stroke were the same,

$$(\pi d^3) \div 4 = 39.4 \quad d = 3.69 \text{ in.}$$

$$(g) (\text{CP}) = (h_{vs} - h_{lc}) \div (h_d - h_{vs})$$

$$= (82.82 - 29.68) \div (89.34 - 82.82) = 8.17$$

where  $h_{lc}$  is the specific enthalpy of liquid at discharge from the condenser.

The coefficient of performance of *Example 1* may be compared with that of an ideal system operating on the Carnot cycle between the same temperature limits. Then  $T_s = 501$  F (which is  $41$  F +  $460$ ) and  $T_c = 554$  F (which is  $94$  F +  $460$ ) and,

$$(\text{CP}) = \frac{501}{554 - 501} = 9.6$$

The actual cycle is therefore  $8.17 \div 9.6$  or 85 percent as effective as a Carnot cycle between the same temperature limits.

## Influence of Suction Pressure

Brief consideration of the analytical procedure used in discussion of the simple saturation cycle will bring out the need for maintaining the suction pressure on any refrigeration system as high as the load will permit. As the suction pressure increases, for fixed discharge pressure, the enthalpy

of refrigerant entering the evaporator remains unchanged, but the leaving enthalpy increases and, hence, the refrigerating effect increases. Further, compressor energy input is reduced not merely because of the greater enthalpy of the gas at suction, but also because of a reduction in the enthalpy of the superheated gas at discharge. Since the refrigerating effect is greater and the work less, it is obvious that there will be a substantial gain in the coefficient of the performance.

The actual value of suction pressure on any system is obviously determined by the required temperature which must be maintained in the conditioned space. For a direct expansion system the evaporator can be held at a temperature not much less than that of the conditioned enclosure, except in cases where lower temperatures may be needed in order to establish a desired ratio of dehumidifying to cooling load. When dehumidification requirements dictate the use of unusually low evaporator temperatures, the increased operating cost should properly be charged against the dehumidification rather than the sensible cooling.

#### Influence of Discharge Pressure

In contrast to the suction pressure, the compressor discharge pressure should be kept as low as operating conditions will allow. This pressure must be high enough to provide a saturation temperature of refrigerant within the condenser which is greater than the exit temperature of the cooling water. The discharge pressure therefore is a direct function of the temperature of the cooling fluid, and will automatically rise whenever the temperature of cooling water (or air) rises; it will also rise when the flow rate of the cooling medium is decreased.

Increase in discharge pressure (for fixed suction pressure) raises the enthalpy of the gas leaving the compressor; hence, increases the work of compression. Further, as the enthalpy of saturated liquid leaving the condenser increases with pressure, the refrigerating effect must decrease. Thus the effect of such a pressure rise is to require more work per pound of refrigerant handled, and at the same time to necessitate an increase in the refrigerant flow rate.

#### Influence of Water Jacket

The preceding discussion has, in every case, assumed isentropic compression. Where exact performance data are not available, this assumption is a desirable one since it leads to a conservatively large determination of the power required. In most actual systems, the compression process departs from isentropic due to irreversible heat transfers which occur between the vapor in the cylinder and the cylinder wall, and also because of intentional heat dissipation from the outside of the cylinder walls to the surroundings, or to a cooling fluid passing through a water jacket around the cylinder. Compressor cooling is highly desirable as a method of reducing power consumption.

#### Influence of Superheating and Subcooling

The most common departure from conditions of the simple saturation cycle is that resulting from admission of superheated vapor to the compressor. Thermodynamically, superheat is undesirable because the enthalpy increase required to compress a vapor through a given pressure range increases with superheat. Further, superheated vapor leaving an evaporator is usually an indication that the suction pressure is lower than

necessary. Under practical operating conditions, however, superheat is almost universally used as a means of assuring complete vaporization of the refrigerant going to the compressor. With modern compressors operating at high speed, and with relatively small clearance space, it is particularly necessary to avoid admission through the suction valves of liquid refrigerant.

Another common departure of actual systems from the simple saturation cycle occurs because of subcooling of refrigerant in the condenser. Thermodynamically, such subcooling is advantageous since it increases the refrigerating effect without affecting the unit energy requirements of the compressor. Further, it can be shown that for a fixed ratio of condenser cooling water to refrigerant circulating rate, the total compressor power requirements will be greater when operating at simple saturation than when operating with maximum sub-cooling. What is even more surprising is that condenser pressure may be lower for the sub-cooling cycle than for the saturation cycle. This condition results from the fact that,

FIG. 5. PRESSURE-ENTHALPY DIAGRAM FOR REFRIGERATION CYCLE WITH SUBCOOLING AND SUPERHEATING

for the same capacity on a heavily loaded condenser, the refrigerant flow rate is less when there is sub-cooling.

Because of the advantages attendant upon the use of sub-cooling, many methods are in use for obtaining some sub-cooling effect outside of the condenser. One common procedure is to use the cold vapor leaving the evaporator to cool the liquid flowing from condenser to expansion valve.

Another somewhat unusual sub-cooling cycle allows cold refrigerant from the downstream side of the expansion valve to cool liquid refrigerant from the condenser down to the evaporator temperature. Fig. 5 shows the pressure-enthalpy diagram for a typical refrigeration cycle operating with both sub-cooling of the refrigerant from the condenser and superheating of the refrigerant leaving the evaporator.

#### Clearance and Volumetric Efficiency

*Clearance*, like displacement, is a characteristic—usually fixed—of a given compressor. In some cases clearance pockets are provided which place within the operator's control the ability to alter the clearance of the machine, but most moderate size compressors are built with fixed clearance. By definition, the clearance is the percentage of the volume swept by the piston, which is represented by spaces in the end of the cylinder (including valve spaces, etc.) when the piston is at the end of its stroke.

Because of the trapping of high pressure vapor in the clearance space, and its subsequent re-expansion, the suction valves of the compressor

do not open until the piston has completed part of its stroke. Hence, the volume of fresh vapor introduced into the compressor per stroke is less than the volume swept by the piston. The ratio of actual volume of fresh gas to swept volume is, by definition, the clearance volumetric efficiency, CVE. In equation form,

$$(CVE) = 100 - V_c \left[ \frac{v_s}{v_d} - 1 \right] \quad (8)$$

where

CVE = clearance volumetric efficiency.

$V_c$  = clearance, percent of volume swept by piston, which is contained in spaces at end of cylinder when piston is at end of stroke (clearance includes valve spaces, etc.).

$v_s$  = specific volume of gas at compressor inlet.

$v_d$  = specific volume of gas at compressor discharge.

Values of  $v_s$  and  $v_d$  can be obtained directly or by calculation from the tables of properties of refrigerants.

In addition to clearance, there are several other factors which tend to reduce the volumetric efficiency. The suction gases from the evaporator are heated and expanded upon contact with the hot cylinder walls during the suction stroke. This results in a reduction of the actual charge drawn into the cylinder. Wire-drawing through the suction and discharge valves reduces the suction pressure in the cylinder below that in the evaporator, and increases the discharge pressure above that in the condenser. Leakage of gases around the pistons also decreases the volumetric efficiency. The total volumetric efficiency (TVE) includes all of these factors and is reliably obtained only by laboratory measurements. It is too difficult to predict the effects of these factors to any degree of accuracy comparable to actual tests.

### Complex Refrigeration Cycles

The preceding sections have dealt only with refrigeration systems in which there is but one evaporator; compression is accomplished through but a single stage, and expansion proceeds through a single expansion valve. In large systems or in low temperature systems in which the compression ratio is high, the compression process can be carried out in stages, with the refrigerant passing through several cylinders arranged for operation in series. The thermodynamic advantage of such compound compression arises from the fact that intercoolers can be placed between the stages of compression to extract heat from the vapor, and thereby cause the overall compression process to approach more closely the ideal condition of isothermal compression. Essentially, such intercoolers serve the same purpose as a cooling jacket, but with greater effectiveness because of the more satisfactory heat transfer conditions.

In the simple saturation cycle the saturated liquid entering the expansion valve commences to vaporize as soon as its pressure starts to drop. The vapor produced during the expansion process has no further use, in terms of refrigerating effect, since it has already picked up its latent heat of vaporization as a result of heat which it has extracted from the unvaporized residue. Thus the instant such vapor forms, its usefulness is at an end, and to allow such material to undergo a further drop in pressure is uneconomical. With compound compression, there is at least one intermediate pressure

at which flash vapor can be extracted. In such cases several expansion valves can be utilized with all of the refrigerant from the condenser passed through a first expansion valve to the higher suction pressure, and the flash vapor then extracted and returned to the condenser through the high compression stage. The remaining refrigerant can then pass through a second expansion valve where the pressure is dropped to that corresponding to the low-pressure evaporator. The number of expansion valves is limited by the number of stages of compression.

Further cycle complications may arise if more than one evaporator is to be operated with a single compressor, and particularly, if the pressures in these evaporators are to differ. The most common solution is to operate the compressor at the suction pressure of the lowest pressure evaporator, and to equip all other evaporators with back-pressure regulating valves or throttling devices between the evaporator and the compressor suction.

### The Air Cycle System

Fundamentally, the air cycle<sup>1</sup> is essentially the same as the vapor cycle. Compression is accomplished by a reciprocating or centrifugal compressor, and, since there is no change of phase of the refrigerant upon expansion, an *air cooler* replaces the condenser, and a *refrigerator*, the evaporator. Although some cooling would result from the expansion of the gas through an ordinary expansion valve, a much greater drop in air temperature is accomplished if the expansion is controlled to approach the isentropic by replacing the valve with an expansion engine or turbine. Furthermore, the work recovered by such an expansion engine can be utilized to supply part of the work of compression or to drive other devices.

### The Steam Jet System

The *steam jet* system, under certain circumstances, is desirable for use in air conditioning.<sup>2</sup> Steam supplies directly the power used for compressing the refrigerant, thus eliminating the losses connected with other methods of supplying energy. As the compression ratio between the evaporator and condenser under normal circumstances is large, the mechanical efficiency of the equipment is somewhat lower than that of the positive mechanical type compressor. The condensing water requirements are considerably greater, as both the refrigerant and the impelling steam must be condensed.

The steam jet system functions on the principle that water under high vacuum will vaporize at low temperatures. Steam jet boosters or compressors of the type commonly used in power plants for various processes, will produce the necessary low absolute pressure to cause evaporation of the water.

A diagrammatic representation of a typical steam ejector water cooling system is shown in Fig. 6. The figures correspond to an average representative system. The water to be cooled enters the evaporator and is cooled to a temperature corresponding to the vacuum maintained. Because of the high vacuum, a small amount of the water introduced in the evaporator is flashed into steam. As this requires heat, and the only source of heat is the rest of the water in the evaporator tank, this other water is almost instantly cooled to a temperature corresponding to the boiling point determined by the vacuum maintained. The amount of water flashed into steam is a small percentage of the total water circulated through the evaporator, amounting to approximately 11 lb per (hr) (ton)

of refrigeration developed. The remainder of the water at the desired low temperature is pumped out of the evaporator and used at the point where it is required.

The ejector compresses the vapor which has been flashed in the evaporator, plus any entrained air taken from the circulated water, to a somewhat higher absolute pressure. The vapor and air mix with the impelling steam on the discharge side of the jet, and the total mixture then passes from the ejector into the condenser.

The slight amount of air which may be entrained in the cooled water is removed by a small secondary ejector which raises the pressure sufficiently so that the air can be discharged to the atmosphere. A secondary condenser is then necessary to condense the steam in the secondary jet.

While a single booster of smaller than 15 tons capacity is difficult to build, steam jet vacuum cooling units have been built for as small as 5 to 6 tons capacity. They can readily be built for steam pressures of from

FIG. 6. DIAGRAMMATIC ARRANGEMENT OF STEAM JET VACUUM COOLING UNIT

5 to 200 psig, and condenser water temperatures as high as 90 F. The steam consumption in pounds per hour per ton of refrigeration increases rapidly as the booster steam pressure is lowered. For example, the lowering of the booster steam pressure from 200 to 90 psig results in an increase in steam consumption of approximately 5 percent, whereas a further decrease in booster steam pressure to 10 psig increases the steam consumption by approximately 72 percent over that required at 200 psig.

The capacity of a steam jet system is usually controlled by controlling the number of boosters in use since the unit usually has several boosters operating on the same evaporator. Usually one booster is automatically controlled, whereas the others are manually operated. The capacity is dependent, as for all compressors, upon the evaporator temperature, or in other words, the suction pressure. For example, the capacity is lowered approximately 17 percent if the evaporator or chilled water temperature is lowered from 50 to 45 F. The capacity therefore can be controlled to some extent by regulating the evaporator temperature.

### The Absorption System

The absorption and compression refrigeration cycles differ only with respect to the method of compression. Each cycle requires a condenser, expansion valve, and evaporator, but the absorption cycle utilizes three major equipments in place of the mechanical compressor; these equipments are the *absorber*, the *pump*, and the *generator*. Vapor from the evaporator is absorbed by a low temperature absorbent fluid which is then pumped to the generator where heat is supplied to boil off the refrigerant. The absorbent is now cooled and readmitted, through a pressure-reducing valve, to the absorber.

In addition to the three primary equipments of the absorption cycle it is necessary to provide auxiliary equipment, usually an analyzer and a rectifier, to remove from the refrigerant leaving the generator, insofar as is possible, the absorbent which vaporizes and leaves the generator with the refrigerant. Removal of this material is of great importance to effective operation of the system, since even a small concentration of absorbent

FIG. 7. CLOSED ABSORPTION SYSTEM

in the refrigerant will suffice to reduce greatly the evaporator pressure required for maintenance of a given evaporator temperature. Thermodynamic analysis of absorption cycles is relatively complex, and requires the use either of tables or graphs showing the equilibrium relationships and thermodynamic properties of the refrigerant-absorbent combination. Data of this kind are given in the first book in the bibliography. A discussion of various absorbents is given in the sixth book. Thermodynamically, the effectiveness of a refrigerant-absorbent combination increases directly with its negative deviation from Raoult's Law.

Fig. 7 shows a typical absorption cycle flow diagram. Cooling water first goes through the absorber (where it extracts the heat of absorption which is liberated by the refrigerant vapor as it goes into solution), then through the condenser, and finally through the rectifier. Refrigerant from the evaporator enters the absorber where it goes into solution in the absorbent; the high concentration solution is then pumped to the generator where heat is supplied; the refrigerant (with some absorbent vapor) leaves for the rectifier and the warm low concentration solution is returned to

the absorber. In the rectifier selective condensation occurs, the concentration of the absorbent in the condensate being much greater than its concentration in the entering vapor mixture; rectifier condensate is dripped back to the generator.

The ratio of refrigerating effect to heat input (the performance ratio or commonly used efficiency measure of absorption machines) is only 40 to 45 percent with the ordinary ammonia absorption system and, aside from the inherent disadvantages involved in the use of a toxic and explosive refrigerant, this is not sufficiently high to make it competitive with other types of systems when used in air conditioning applications. Therefore, recently, several absorption systems using hygroscopic brines of salts such as lithium chloride or lithium bromide<sup>3</sup> (solids in the pure state) as absorbents and water as the refrigerant have been developed. Such systems are limited to higher temperature applications but, thermodynamically, have

FIG. 8. DIAGRAM OF LITHIUM BROMIDE WATER ABSORPTION SYSTEM

the advantages of a refrigerant with a high latent heat of vaporization and nonvolatile absorbents with a large negative deviation from Raoult's Law. None of the absorbent is carried off with the refrigerant from the generator and the performance ratio ranges as high as 75 percent. Both the refrigerant and the absorbent are non-toxic and non-explosive and the performance ratio does not vary greatly between 20 percent of capacity and full load. This increased efficiency places operating costs in competition with other forms of refrigeration in many high temperature applications such as air conditioning.

One form of lithium-bromide-water absorption system is shown schematically in Fig. 8 with the generator and condenser shown located in a high pressure shell and the evaporator and absorber in a low pressure shell. The water to be cooled flows to the evaporator 1 from the load where a small portion of it is flashed into vapor thus cooling the remaining water which is then returned by pump 2 to the load. The pressure in the low side shell and, therefore, the temperature of the water passing through the shell is controlled by the temperature and concentration of the lithium

bromide brine sprayed over absorber coil 3. The water vapor flashed in the evaporator chamber is absorbed by the strong salt solution to form a weak solution which drains from the low pressure chamber and passes through solution pump 4. From pump 4 a portion of the weak brine is delivered through the heat exchanger 5 to the high pressure shell and the remainder is mixed with the strong solution through eductor 6 and delivered back to the low pressure shell. Heat applied at the generator 7 boils off the water vapor earlier condensed in the absorber and returns the brine to its original concentration. The condenser 8, also located in the high pressure shell, liquifies the water boiled off by the generator and this condensate is returned through a liquid loop to the evaporator. The re-concentrated solution is returned from the high pressure shell through the heat exchanger 5 to the eductor 6 where it is mixed with a portion of the weak solution and pumped to the absorber with the mixture at a still relatively high concentration.

### Ice Systems

Cold water systems using ice as the cooling agent have been installed in some theaters, restaurants, funeral homes, churches and other places where short hours of operation and high peaks of cooling demand make this type of system desirable. A comparatively small quantity of ice in the water cooling tank of such a system can release refrigeration at a relatively rapid rate. For instance, neighborhood theaters having a peak demand of 1,200,000 Btu per hr (100 tons refrigeration) have found 8 ton capacity ice bunkers satisfactory.

In operation, the water in the air conditioning system is circulated over ice placed in an insulated box, and is cooled to the 38 or 40 deg range or higher, if desired. This cold water is pumped from the ice bunker to air cooling coils or spray type air washers. The blowers, coils, air washer or air handling sections are the same as those parts in any system employing cold water as a refrigerant.

The ice water cooler or ice bunker is usually built at the installation in a location where it can easily be iced. It can be constructed of any desired material such as concrete, steel, or wood with an adequate amount of insulation to save the ice from one period of use to the next. The basic requirement is that the tank be durable and water-tight.

The temperature of the water is controlled at a predetermined point by a thermostat in the supply line. If the temperature drops too low, a part of the return water is by-passed directly to the sump and is not cooled over the ice. In the larger systems it is customary to install an overflow control which, as the ice melts, discards the excess water through an economizer coil, the surface of which is large in relation to the flow so that the water is warmed to 60 F or more as it is discharged from the system.

In an attempt to lower initial equipment cost and operating expense, or increase the refrigeration capacity of an existing air conditioning system, storage refrigeration has been utilized in a few applications. Some of the methods which have been adopted include the storage of refrigeration in the form of chilled water, chilled brine, ice on evaporator coils<sup>4</sup> and the accumulation of thin sheets of ice on copper plates in a steel tank.<sup>5</sup> If the peak load factor is low as compared with a long period of operation, such as in a restaurant, or if the hours of operation are short but the usage factor high, as in a church, then it is possible to consider storage refrigeration. This method of accumulating refrigeration frequently makes it possible to use low cost off-peak electric power. Power costs may also be reduced by

TABLE 4. HEAT PUMP HEAT SOURCES AND SINKS

| HEAT SOURCE                                                                                                | AIR                                                                                                                                                                                                                            | CITY WATER                                                                                                                                                               | WELL WATER                                                                                                                                                               | SURFACE WATER                                                   | WASTE WATER                                                                                                         | EARTH                                                                                                                                                                                                                                                                  | SOLAR                                                                                                                                                                                                                                                                                                                                                                                                               |

installing a smaller refrigeration plant, augmented by a storage system, and by operating it for longer periods.

### The Heat Pump

It has been almost 100 years since Prof. William Thomson (Lord Kelvin) first proposed the use of a compressor as a "warming engine" and as a means of heating buildings to replace equipment for direct burning of fuels. Several early working models were constructed, but the device has remained essentially of laboratory interest until the last 20 years.

Although frequently referred to incorrectly as the reverse cycle system, the heat pump cycle is identical with the ordinary refrigeration cycle, and differs only in the sense that the desired effect is rejection of the heat from the condenser rather than absorption of heat in the evaporator. A discussion of the coefficient of performance for the heat pump is found earlier in this chapter.

The first actual residential heat pump installation was probably made in Scotland in 1927 and since that time, a number of commercial and residential systems have been made in this country. Both progress and growth of interest have been particularly rapid in recent years and, consequently, at the present time there are several hundred residential installations and probably a greater number of commercial systems. However, much research is needed before the residential heat pump installation can successfully emerge to compete economically and with equal reliability with the more common forms of heating and fuels.

From an analysis of the equation for the coefficient of performance, it is evident that the economical adaption of the heat pump as a practical means of heating, requires that the temperature of the source from which the heat is extracted be as high as possible, and that the temperature of the sink to which the heat is rejected for heating purposes, be as low as possible. Thus, with a small temperature spread between the evaporator and the condenser, six or more times as much heat may be obtained theoretically (and three to five times practically) as the heat equivalent of the work necessary to operate the system. There are a number of limitations, however, the most serious of which is the lack of ready availability of a practical source of heat.

One of the major problems in the development of the heat pump involves research on, and the compilation of reliable design data for, the various heat sources and sinks available. The four principal potential sources of heat are air, water, earth, and solar energy. Of these, the first three are primary sources of heat which may be used alone. The fourth, solar energy, while of tremendous potentiality, will probably be developed in most localities as auxiliary to the other three. In addition, there are other minor sources such as process waste heat, sewage, etc., which may be used under special circumstance.

There are also a number of industrial applications of heat pumps, for purposes other than space heating, which are practical largely through economic considerations of the particular process involved. Table 4 presents a summary of the advantages and disadvantages of each of these major heat sources.

By reference to Table 4, it will be seen that, to date, the most satisfactory heat sources are air, water, and earth, and that air and water are the most satisfactory heat sinks. There are, therefore, six possible combinations of source and sink in application: air to air, air to water, water to air, water to water, earth to air, and earth to water. In addition, it should be recog-

nized that heat storage devices may be used with any of these systems involving either a single or a dual heat source. One promising possibility involves the utilization of a storage pit or cistern operating upon a heat of fusion cycle and supplied by supplementary heat from air or solar sources. Heat of fusion may, for example, also be utilized with city water and sewage disposal to increase the practicability of these sources.

When heat is to be obtained from a ground coil it should be emphasized that, in general, the heat extracted must be replaced by heat from the sun, received by radiation to the ground or by heat carried into the ground by rain.

Combinations of heat sources, such as air and water, air and ground, air and solar energy, or ground and solar energy, may also be used and will frequently improve the coefficient of performance over an entire heating season; but they will probably result in considerably greater initial cost.

FIG. 9. SCHEMATIC OPERATION OF REVERSED CYCLE CONDITIONING SYSTEM

A typical arrangement of a heat pump system with air as the heat source is shown in Fig. 9.

Both water and air are practical media to which the condenser heat may be rejected; but the generation of steam requires too high a condenser temperature. Practical operation, therefore, dictates that the heat pump be used in conjunction with either an air or water heating system with actual distribution of the heat to the rooms through either air ducts, convection radiators, or panels.

In general, it is believed that the future of this device is very promising, and it is recognized that there are a number of practical and economical systems in operation at the present time. However, design data for the majority of types of systems are inadequate, and it is therefore recommended that the enthusiasm and the interest which have greeted the emergence of the heat pump from the category of a scientific toy to one of practical application, should be tempered with caution, since it will probably be several years before proper development and design information will enable the widespread satisfactory application of the heat pump. It is for this reason that no design information is presented at this time in THE GUIDE. A wealth of literature concerning individual installations is available, and reference to the many articles which have appeared

in current technical magazines should form sufficient information for those interested in the development of this type of heating.

## BASIC REFRIGERATION EQUIPMENT

### Compression Refrigeration Machines

Compression of the refrigerant gas drawn from the evaporator may be accomplished by one of several means. Positive displacement may be used as in the reciprocating, rotary or gear types of compressors; centrifugal force may be applied as in the centrifugal compressor; an ejector may be used as in the steam jet refrigeration cycle; or absorption of a low pressure refrigerant gas in a secondary fluid, followed by the absorbent's release upon application of heat, may be utilized. A detailed discussion of the equipment required for each of these types of systems is beyond the scope of this chapter. For a more comprehensive treatment, reference may be made to the bibliography. The present discussion is limited to positive displacement reciprocating compressors, rotary compressors and centrifugal compressors.

### Reciprocating Compressors

Reciprocating compressors may be classified according to (a) cylinder design, (b) compressor drive, (c) valves, and (d) lubrication and cooling.

**Cylinder Design.** Cylinder design may vary as to number, arrangement, and action (i.e., single-acting or double-acting). Single-acting compressors usually have their cylinders arranged vertically, radially, or in a V or W shaped arrangement. Double-acting compressors, with refrigerant gas drawn in, and compressed on both the head and crank ends of the cylinder, are usually arranged horizontally. Reciprocating units are available with from one to sixteen cylinders with the V, W, or radial arrangements best adapted to the greatest numbers. The present trend is toward higher operating speeds with a low displacement per cylinder, together with an increase in the number of cylinders. Whereas the original reciprocating compressors were slow speed (50 to 55 rpm) steam driven devices, modern electric motor-driven compressors range up to 3500 rpm. Cylinder heads are usually bolted tight to the cylinders, but in some large compressors where there is danger of wet compression or of foreign materials entering the compressor space, a secondary head known as a safety head, may be seated at the end of the cylinder and held in position with heavy springs. Normally, this head remains stationary, but excessive pressures in the clearance space are relieved by movement of the safety head, and thus prevent damage to the cylinder.

**Compressor Drives.** Reciprocating compressors may be subdivided on the basis of source of motive power, and whether they are open or hermetic. Practically all modern compressors are electric motor-driven, although a few large, steam-driven compressors are still being installed where steam forms the most economical source of energy. In a few cases, as with truck transportation, the compressor may be driven by an internal-combustion engine.

The division of compressors into open or closed types is dependent upon whether the motive power is received from an external source, or whether the motor is direct drive and sealed within the housing. In the open type, power is received from an external source with one end of the compressor crankshaft extending through the crankcase, and usually V-belt driven. The point of emergence of the shaft from the crankcase forms a weak point of refrigerant leakage, and is most frequently sealed with a bellows type crankshaft seal. Horizontal double-acting compressors operate with a sliding piston rod, moving back and forth through a stuffing box. If the motor is direct-drive and enclosed within the compressor housing, the compressor is classified as closed or hermetic. This eliminates the necessity of any shaft seal, and not only prevents refrigerant leakage at this point, but reduces operating noise. One disadvantage is the inaccessibility of moving parts for repairs, but lubrication is greatly simplified since both the motor and compressor operate in a sealed space with the lubricating oil.

**Compressor Valves.** All refrigeration compressor valves are dependent for their

operation upon a difference in pressure between the inside of the cylinder and the suction or discharge line. Although mechanically-operated valves might have some advantage, they have proved unsatisfactory because each change in the evaporator or condenser operating pressures requires a change of valve setting. The pressure differentials required for operation of the valves depend upon the valve design and the compressor speed. The suction and discharge valves may be arranged with both located in the compressor head, or with the suction valve on the top of the piston and the discharge valve in the compressor head (uniflow arrangement). The valves themselves are usually classified as either poppet, ring-plate or flexing.

**Lubrication and Cooling.** Lubrication of modern compressors is accomplished by either splash lubrication or forced lubrication. The latter is used on large compressors, while simple splash lubrication is used in the smaller units.

Large compressors are usually water cooled with the water jacket either cooling the cylinder walls, or both the cylinder walls and the compressor head. Small compressors are either water cooled or air cooled with extended finned surfaces cast on

FIG. 10. DIAGRAMMATIC VIEW OF ROTARY COMPRESSOR WITH FLOODED EVAPORATOR AND CAPILLARY TUBE

the exterior of the cylinder. In a few cases small compressors may be found in which there is no attempt to add any purposive cooling other than through non-finned surfaces to the lower temperature air.

Water cooling is more effective than air cooling, but even under the best conditions cylinder cooling removes only a portion of the superheat in the refrigerant gas. This removal of heat from the cylinder results in some decrease in the work of compression, as well as reduction in condenser load.

### Rotary Compressors

In recent years rotary compressors, usually hermetically sealed, have become quite popular for fractional tonnage applications and are being designed in increasingly larger sizes. Of the various designs attempted, the single blade rotary compressor, shown diagrammatically in Fig. 10, is the most popular. An eccentric driven rotor revolves within a housing in which the suction and discharge passages are separated by means of a sealing blade. When the rotating eccentric first passes this blade and the suction opening, the compressor suction space is very small. As the eccentric rotates, this crescent-shaped space becomes increasingly larger, thereby drawing in a charge of suction gas. When the eccentric again passes the blade, the gas charge is cut off from the suction inlet, compressed, and discharged from the compressor. Such rotary compressors are quiet in operation and reasonably free from vibration. In common with other types of hermetically sealed units, they have the advantages of comparatively low loss of refrigerant and sealed-in lubrication.

### Centrifugal Compressors

*Centrifugal compressors* are used with very low pressure refrigerants; usually both evaporator and condenser work below atmospheric pressure. Water and monofluorotrichloromethane ( $\text{CCl}_3\text{F}$ ) are the refrigerants commonly used in centrifugal machines.

Compression of the refrigerant is accomplished by means of centrifugal force; therefore, this type of compressor is inherently suitable for large volumes of refrigerant at low pressure differentials. Two or more stages are usually required and high speeds are necessary to obtain good efficiency.

The evaporator is usually constructed as an integral part of the centrifugal type condensing unit, to chill water which is then circulated to the

FIG. 11. ENCLOSED TYPE CENTRIFUGAL CONDENSING UNIT

air conditioning system. This is done because it would not be economical to pipe these large volumes of refrigerant any distance.

Centrifugal compressors, like reciprocating compressors, can be divided into two general types, open and enclosed. In general, the open type compressor is geared to the driving mechanism, and operates at higher speed than the driving motor or turbine. A modern, completely enclosed, direct-driven centrifugal compressor is illustrated in Fig. 11.

Centrifugal refrigeration compressors are particularly well suited to direct steam turbine drive because of their high operating speed. Water cooling equipment of one design is operated between 3500 and 4000 rpm for units developing 1000 to 2000 tons capacity, and from 7000 to 8000 rpm for units developing 100 to 200 tons capacity. However, a great many applications, particularly in the smaller sizes, are electric motor-driven and equipped with standard gear-type speed increasers. Centrifugal systems are particularly well adapted to large capacities (up to 3000 tons) although it is also possible to secure units as low as 50 tons in rating. Because centrifugal units operate best with refrigerants possessing a high specific volume, and because of the simplification of lubrication difficulties, they are frequently used for extremely low temperature applications. They are adaptable to a wide range of temperatures from  $-130^\circ\text{F}$  to  $50^\circ\text{F}$ . One important advantage is their flexibility under varying loads, since units may be

designed to operate with reasonable efficiency at capacities as low as 20 percent of normal load.

### Condensers

Condensers used for liquefying the refrigerant are of three general designs: (1) *air cooled*, (2) *water cooled*, and (3) *evaporative* (combination air and water).

1. *Air cooled condensers* are seldom used for capacities above 3 tons of refrigeration, unless an adequate water supply is extremely difficult to obtain, as, for instance, in railway air conditioning. Even on fractional tonnage installations, air is used as the condensing medium only where water is expensive, or where simplicity of installation warrants the higher condensing pressure and consequent power costs higher than would be obtained using water as the condensing medium.

The conventional air cooled condenser consists of an extended surface coil across which air is blown by a fan. The hot discharge gas enters the coil at the top and, as it is condensed, flows to a receiver located below the condenser. Air cooled condensers should always be located in a well ventilated space so that the heated air may escape and be replaced by cooled air.

The principal disadvantages of air cooled condensers are the power required to move the air, and the reduction of capacity on hot days. This loss of capacity, due to high condensing pressures on hot days, requires that equipment of increased capacity be selected to meet the peak load. Thus at normal loads the equipment is oversized. The principal advantages are low installation costs and simplicity, and for these reasons they are frequently used in small self-contained units.

2. *Water cooled condensers* are commonly used with compressors of one horsepower or larger in size, and they are found almost exclusively on large installations. They usually prove to be the most economical choice if an adequate water supply and means for its disposal are available. Although water cooled condensers may be of many designs, the shell and coil and the shell and tube are most commonly found in present day practice.

The amount and temperature of the condensing water determine the condensing temperature and pressure, and indirectly the power required for compression. It is therefore necessary to determine a balance so that the quantity of water insures economical compressor operation.

Because there is a decided tendency to conserve the water in city mains, and because most large cities are restricting the use of water for air conditioning and refrigeration equipment, it is often necessary to install cooling towers or evaporative condensers. Cooling towers, unfortunately, produce the warmest condensing water at the time when the load on the system is greatest, so that the refrigeration equipment must be designed to meet the maximum load at abnormal condensing water temperatures. If properly designed, this makes little difference in the efficiency of operation throughout the year, except at those times when the condensing water temperature is highest. As this occurs only for 5 percent of the entire cooling period, it can be disregarded as a factor in establishing yearly operating costs. For further information on cooling towers, reference may be made to Chapter 35.

3. *Evaporative condensers* were developed to alleviate the over-burdened water supply and drainage facilities of communities where many small air conditioning systems using water cooled condensers were applied. The adaptation of cooling towers to small installations is not practicable. The evaporative condenser combines the functions of the two by using a minimum amount of water on a finned surface, cooling it to approximately the wet-bulb temperature of the surrounding atmosphere.

The end view of a typical evaporative condenser is shown in Fig. 12. The fan draws the air over a finned tube condenser which is kept wet by a water spray. The discharge refrigerant gas from the compressor enters the top of the condenser coil, and the liquid refrigerant is drained from the bottom of the coil into a liquid receiver, and then circulates through the remaining portion of the system in the usual way.

The water is circulated through the spray nozzles, and the level is maintained in the sump by means of a float valve. The eliminator plates are placed in the path of

the water-air mixture so as to remove the entrained water. The air leaving the unit is almost completely saturated, so that care must be taken in locating discharge ducts to prevent condensation.

Evaporative condensers are available in sizes up to 100 tons or more. These units use only a small portion of the water required for a water cooled condenser. The water is vaporized by the heat of the refrigerant so that each pound of water used extracts approximately 1000 Btu from the refrigerant, whereas under standard rating conditions where the water temperature rise is 20 F, each pound of water extracts only 20 Btu from the refrigerant. Including the water lost by entrainment

FIG. 12. SCHEMATIC VIEW OF AN EVAPORATIVE CONDENSER

in the discharge air, by overflow and stand-by evaporation, the water used is about 3 to 5 percent of the amount that would be required for a water cooled condenser.

The evaporative condenser requires more maintenance, occupies greater space (must be located where air is available), and has a higher first cost than the water cooled condenser, but where the use of water is restricted or expensive, the evaporative condenser has become widely accepted. Compared with a water cooled condenser and cooling tower, which combination uses about the same quantity of water, the evaporative condenser has the advantage of lower cost and smaller space requirements.

### Evaporators and Coolers

Refrigeration evaporators must be designed for efficient removal of heat from the medium being cooled, as well as effective boiling of the refrigerant and a minimum drop of pressure through the coil. There are two general types of evaporators, dry and flooded. In the dry evaporator the refrigerant enters in the liquid state, and the design provides for complete

evaporation with the vapors leaving slightly superheated. In flooded evaporators not all of the refrigerant is evaporated, the liquid-vapor mixture leaving the evaporator flows into a surge drum from which the vapors are drawn into the compressor suction line, and the liquid is recirculated through the evaporator.

The types of coolers used in connection with air conditioning work fall into three general groups: (1) direct water coolers, (2) direct air coolers, and (3) brine coolers for circulation of the brine in a closed system, and thus cooling indirectly either water or air.

1. *Water coolers.* One method of the direct cooling of water is to install direct expansion coils in the spray chamber so that the water sprayed into the air comes in direct contact with the cooling coils. Another common and efficient method of cooling spray water is to use a Baudelot type of heat absorber where the water flows over direct expansion coils at a rate sufficiently high to give efficient heat transfer from water to refrigerant.

Another type of spray water cooler is the shell and tube heat exchanger in which the refrigerant is expanded into a shell enclosing the tubes through which the water flows. The velocity of the water in the tubes affects the rate of heat transfer, and as the refrigerant is in the shell completely surrounding the tubes at all times, good contact and a high rate of heat transfer are insured. The disadvantage of such a system is that with the falling off of load on the compressor, the suction temperature or the temperature in the evaporator drops, and there is a possibility of freezing the water in the tubes, which, of course, might split the tubes and allow the refrigerant to escape into the water passage. This danger can be eliminated by automatic safety devices.

Another system of cooling spray water is to submerge coils in the spray collecting tank, or in a separate tank used for storage. The heat transmission through the walls of the coils, however, is low and a great deal more surface is required than for any other type of cooler. However, with large storage tanks this type of cooling can be utilized to advantage.

2. *Air coolers.* When direct cooling of air is employed, the refrigerant is inside the coil and the air passes over it. Cooling depends upon convection and conduction for removing the heat from the air. The type of coil used can be either smooth or finned, the finned coil being more economical in space requirement than the smooth coil. The fins, however, must be far enough apart so as not to retain the moisture which condenses out of the air.

When refrigeration evaporators are used for cooling air or other gases by forced convection, they are usually termed blast coils or unit coolers. A blast coil may be placed in a duct or in an assembled unit, and the air forced across the coil and discharged through distributing ducts or directly into the space to be conditioned. Unit coolers, designed much like unit heaters, consist of a finned coil, propeller fan, and controls suspended directly in the space to be cooled.

3. *Indirect brine coolers.* The indirect cooler, where brine is cooled by the refrigerant and the resulting cold brine is used to cool either air or water, introduces several other considerations. It is not the most economical from a power consumption standpoint, as it is necessary to cool the brine to a temperature sufficiently low so that there is an appreciable difference between the average brine temperature and that of the substance being cooled. This requires that the temperature of the refrigerant must be still lower, and consequently the amount of power required to produce a given amount of refrigeration increases due to the higher compression ratio. There are other considerations which make such a system desirable. In the first place, where a toxic refrigerant is undesirable or cannot be used because of fire or other risks, especially in densely populated areas, the brine can be cooled in an isolated room or building and can then be circulated through the air conditioning equipment. This arrangement eliminates any possibility of direct contact between the air and refrigerant.

### REFRIGERATION CONTROL

In addition to the compressor, evaporator, and condenser, several auxiliaries are required for proper operation of a refrigeration system. Some device must be supplied for the controlled expansion of the refrigerant from

the high condenser pressure to the low evaporator pressure; controls are required for the on-off operation of the compressor, the flow of the condensing medium, and for safety devices; proper piping is required for connecting the various portions of the systems. Where refrigerating apparatus is used for the cooling of rooms, additional controls are required.

### Expansion Devices

Some form of expansion device must be provided to control the rate of flow of the liquid refrigerant between the high and low side pressures of the system. This device is usually an expansion valve and may be either manual or automatic; however, with few exceptions, manual valves are obsolete and no longer used.

*Automatic Expansion Valves.* An automatic or pressure controlled expansion valve operates to maintain a constant pressure in the evaporator. The liquid refrigerant passes through an orifice, the opening size of which is controlled by means

FIG. 13. TYPICAL THERMOSTATIC EXPANSION VALVE

of a needle valve connected to a flexible bellows. This bellows expands or contracts with variations in the evaporator pressure transmitted to the expansion chamber through the refrigerant outlet from the evaporator. The position of this needle valve is controlled by the degree of compression in an adjustable spring, balanced against the bellows, and these two forces operate to maintain a constant pressure in the evaporator by increasing or decreasing the flow of liquid refrigerant. Such an expansion valve is usually applied to evaporators of the direct expansion type, but is not satisfactory for fluctuating loads such as are encountered in air conditioning installations.

*Thermostatic Expansion Valves.* A thermostatic expansion valve controls the flow of liquid refrigerant to the evaporator so as to maintain the entire coil filled with evaporating refrigerant, and to keep a constant superheat in the refrigerant gas leaving the coil. The construction of such a valve is shown in Fig. 13 and is similar to that for an automatic expansion valve but incorporates, in addition, a power element responsive to changes in the degree of superheat of the refrigerant gas leaving the coil. This power element consists of a bellows connected by means of a capillary tube to a feeler bulb fastened to the suction line from the evaporator. The bulb, bellows, and tube are usually charged with the same liquid refrigerant used in the evaporator itself. A starved condition in the evaporator results in a greater superheat in the gas leaving the evaporator, and this in turn operates through the power element to increase the flow of liquid refrigerant. A flooded evaporator reduces the discharge superheat, and thus tends to reduce the flow of liquid refrigerant. Such an expansion valve is satisfactory for operation with fluctuating loads since this type of control tends to keep the evaporator filled with refrigerant at all times.

*Low-Side Float Valves.* A liquid refrigerant control of the low-side float valve type consists of a ball float located in either a receiver or the evaporator itself on

the low pressure side of the system. A needle valve, operated through a simple lever mechanism attached to the float, permits the passage of more or less refrigerant, as the level in the receiver or the evaporator fluctuates. Such a control must be used in conjunction with a flooded evaporator, and has been applied extensively to household refrigerators and, to some extent, in commercial and industrial installations.

**High-Side Float Valves.** A high-side float valve differs from a low-side float valve in that the float is located in a receiver or container on the high pressure side of the system. Proper operation again depends upon metering of the refrigerant through a controlled opening, depending upon the level of the liquid refrigerant in the container. Such a control has the disadvantage that the evaporator must be placed directly adjacent to the float container, or some intermediate pressure device must be applied to prevent flashing of the refrigerant upon pressure drop.

**Capillary Tubes.** A capillary tube may be used as a liquid refrigerant expanding device. Such a device consists of an extremely small bore tube (in the order of 0.04 inch in diameter) of five to twenty feet in length. Although such a restricting device operates as a very simple means of expanding the liquid refrigerant, it has the disadvantage that no modifications are possible to adjust the rate of expansion under various operating conditions. The bore and length of the tube, as well as the proportions of the rest of the system, are critical. It is for these reasons that its application has been limited to factory assembled domestic and commercial units.

### Refrigeration Control Devices

In addition to automatic control of expansion of the liquid refrigerant, a completely automatic refrigeration system requires (1) some means for on-off operation of the compressor motor, (2) control of the flow of the condensing medium, and (3) safety devices for prevention of damage to the equipment. In addition, special controls designed for specific applications are frequently required. The various types of devices used to accomplish these purposes are so numerous that it would be impossible to describe all of their modifications. Only the general purposes and operating characteristics of the more typical mechanisms are here discussed.

**Compressor Motor Controls.** Two types of controls are used for intermittently starting and stopping compressors. The first of these is a pressure motor control responsive to the evaporator pressure, and the second a thermostatic motor control responsive to the temperature of the load surrounding the evaporators. In the first case the compressor operation is indirectly dependent upon the temperature of the load, and is controlled by the refrigerant pressure at the point of control location. The second type is dependent upon the temperature of the load being cooled.

With the pressure actuated device, the control is frequently located directly on the condensing unit, and the low pressure in the suction line or the crankcase of the compressor is used to control motor operation. Such a control usually consists of a low pressure bellows, connected through tubing directly to the low pressure control source, and an electrical switch operated through linkage by the movement of the bellows. The electrical circuit is closed on rising pressure, and opened on falling pressure. The thermostatic type of motor control is usually similar in construction to the pressure control, with the exception that a temperature bulb and capillary tube replace the pressure line, and the temperature bulb is located adjacent to the evaporator itself. In this case motor control is directly responsive to changes in the temperature of the load surrounding the evaporator. Frequently, a high pressure safety cutout switch is combined with the motor control, and operates to cut off the power from the motor in case the high side pressure exceeds a predetermined limit.

**Solenoid Valves.** Solenoid or magnetic stop valves are frequently used in refrigeration systems for control of gas and liquid flow. When applied as liquid stop valves, they are placed in the liquid line between the condenser or receiver and the evaporator, and the line is open to passage of the refrigerant only when the compressor is in operation. When the compressor is not in operation, leakage of liquid refrigerant in the evaporator is prevented. In some cases such a magnetic stop valve is operated directly by a thermostat located at the point of the load, and the compressor motor operation is controlled independently by a low pressure switch.

Magnetic liquid stop valves are also widely used for the control of the refrigerant flow to individual evaporators in a multiple evaporator system operated by one compressor. In some installations magnetic liquid line and suction line valves are used to isolate completely an evaporator for defrosting purposes. A magnetic valve may be installed in a by-pass around one or more cylinders of a multiple cylinder compressor, and thereby be used to unload a compressor during starting to reduce load. Additional applications are found in control of the circulation of brine in a secondary refrigeration system.

**Suction Pressure Valves.** Suction pressure control valves, frequently called back pressure regulators or two-temperature valves, are sometimes placed in the suction line to prevent the evaporator pressure and temperature from dropping below a predetermined level. Typical applications of such controls occur in water cooling or milk cooling systems, where freezing and other damage would result if the evaporator pressure dropped too low, or in multiple systems where several evaporators are supplied by one condensing unit. Thus, different evaporators may be kept at different temperatures by maintaining a pressure drop between the evaporator and the suction line.

**Condensing Water Control.** The majority of the refrigeration systems, other than fractional horsepower, use water cooled rather than air cooled condensers, since the lower condensing temperatures result in more economical operation. Automatic control of the water flow to the condenser must be maintained if water wastage is to be eliminated. Such control may be provided through the use of either an electric solenoid water valve or by means of a pressure control valve. With a solenoid valve, the flow is two-position, either *off* or *on*, and its operation is simultaneous with starting and stopping of the compressor motor. With a pressure operated valve, the flow is modulated and is dependent entirely upon condenser pressure rather than condensing unit operation. Similar water valves controlled thermostatically by the temperature of the water discharged from the condenser are also available.

**Safety Controls.** Many controls are designed not to aid in proper operation of the system, but to prevent damage in case of improper operation. One such safety control is the high-pressure cutoff frequently combined with the low-pressure motor control as previously described. Another safety control often used is a low voltage cut-off which shuts down the system automatically in case the line voltage drops below a minimum value. High pressure relief valves are used for safety purposes to prevent damage in case excessive condensing pressures are encountered.

### Refrigeration Control for Air Conditioning Equipment

When refrigerating equipment is used for space cooling, two major control problems exist: one is control of the temperature and the other, control of the humidity. In some applications the amount of latent heat to be removed is small compared with the sensible heat. In such cases, sufficient dehumidification will usually occur without any special provisions. In other cases, such as theaters, where the latent load is relatively high, the air must be cooled below its dew-point temperature, and sometimes rewarmed to return it to the comfort range. Chapter 39, Automatic Control, discusses, among other topics, control systems for unit coolers, well water and ice cooling systems, central fan systems, and all-year air conditioning systems.

### REFRIGERATION PIPING

The pressure drop which occurs during passage of the refrigerant through connecting piping is similar in effect to that which occurs through suction and discharge valves of the compressor. Thus, the effect of the pressure drop in the suction line between evaporator and compressor requires that a lower pressure be maintained inside the compressor during suction than is maintained in the evaporator. The pressure drop through the connecting piping between the compressor and the condenser requires that a higher pressure be maintained inside the compressor during discharge than in the

condenser. These losses result in a greater compression ratio, and therefore greater power requirements, as well as a lower volumetric efficiency and higher displacement requirements. Pressure losses in the liquid line between condenser or receiver and the expansion valve may result in some flashing of the liquid refrigerant, unless the liquid is subcooled. In all cases, frictional losses should be kept to a minimum, and piping should be selected which will give the smallest loss consistent with overall economy in the system.

Refrigerant liquid lines from the receiver to the expansion valve should be preferably designed with a pressure drop of less than 5 psi, and with 10 psi as the maximum. A velocity of 100 to 250 fpm is recommended to prevent a pressure drop great enough to cause vaporization of the refrigerant ahead of the expansion valve. If the evaporator is to be located at a higher elevation than the condenser or receiver, account should be taken

| 1 $\frac{1}{2}$ IPS | 62.0                                            | 80.2 | 114.  | 160.  |
| 2 OD                | 124.                                            | 161. | 231.  | 328.  |
| 2 IPS               | 230.                                            | 297. | 426.  | 607.  |
| 2 $\frac{1}{2}$ OD  | 364.                                            | 469. | 676.  | 972.  |
| 2 $\frac{1}{2}$ IPS | 539.                                            | 704. | 1005. | 1430. |
| 3 OD                | 753.                                            | 972. | 1385. | 1945. |

Note: Tonnage values above those underlined give velocities of 300 fpm or less.

of the pressure drop for each foot of static liquid lift. Approximate values are 0.26 psi per foot for ammonia, 0.57 psi per foot for dichlorodifluoromethane, 0.51 psi per foot for monochlorodifluoromethane, and 0.64 psi per foot for monofluorotrichloromethane. Where there is a possibility of vaporization of some of the liquid before reaching the expansion valves, means for subcooling should be provided.

Since a reduction of suction pressure at the compressor results in an appreciable reduction in capacity and more power input per ton of refrigeration, great care should be given to the proper sizing of suction lines between the evaporator and the compressor. Although comparatively high velocities, 500 to 5000 fpm, may be used, the optimum value will depend upon the refrigerant and the operating pressure range. Since return of the oil to the compressor must be considered in the case of the fluorinated hydrocarbons and methyl chloride, for these refrigerants the minimum velocity should be 500 fpm for horizontal runs and 1000 fpm for vertical runs. For the former, the usual design velocities range between 1000 and 2000

fpm. Too high velocities create noise problems and excessive pressure drops. The total pressure drop in the suction line should be between one and two psi, if the velocity can be kept to within the specified limits.

Compressor discharge or hot gas lines may be designed with velocities from 1000 to 5000 fpm, except for dense gases such as carbon dioxide, where noise considerations will reduce the upper limit. A pressure drop of 2 to 4 psi is recommended for the discharge lines. Extensive tables are available in the literature for the determination of pressure drops through refrigerant lines with various refrigerants. The capacities listed in Tables 5, 6 and 7 are published in *ARI Equipment Standards-1946*, of the *Air-Conditioning and Refrigeration Institute*, and are used by permission.

Table 5 shows the tonnage capacity normally allowed for  $\text{CCl}_2\text{F}_2$  liquid lines per foot equivalent length of pipe, and Table 6 the maximum tonnage for suction and discharge  $\text{CCl}_2\text{F}_2$  lines. Table 7 presents suction-line capacity factors for equal pressure drop.

### ACCESSORIES

Dehydrators, oil separators, strainers, vibration eliminators, sight glasses, and various types of valves are accessories frequently needed for the proper

FIG. 14. PERFORMANCE CHARACTERISTICS OF COMPRESSION REFRIGERATION MACHINES AT CONSTANT SPEED

installation and operation of refrigeration systems. Refrigerant-line dehydrators or dryers usually consist of copper containers fitted with tubing connections at either end, and contain a desiccant such as silica gel, activated alumina, or calcium chloride. The liquid refrigerant is circulated through the dryer during operation of the system, and the moisture content of the refrigerant charge is thus kept to a minimum.

Oil separators are installed between the compressor and condenser to prevent excessive oil removal from the compressor crankcase and its passage into the condenser and evaporator. The oil is separated from the gaseous refrigerant by gravity during its passage through a chamber of sufficient size to reduce the velocity. A float-operated valve maintains a maximum oil level in the separator, and additional oil is forced by pressure difference through a line back to the crankcase.

Screen strainers are frequently installed in the liquid line piping before solenoid valves and expansion valves, as well as before regulating valves

in water lines leading to water cooled condensers. Sight glasses which permit visual inspection of the condition of the refrigerant are sometimes installed on factory assembled commercial unit systems. It is particularly advisable to place such a fitting before the expansion valve, if the evaporator is located above the condenser.

Flexible vibration eliminators, usually consisting of a bellows design covered with woven copper wire, are sometimes installed in copper lines where units such as compressors are installed on flexible mountings, or where vibration is otherwise a problem. Packed or packless shut-off valves are necessary where it may be required to isolate portions of a system.

FIG. 15. PERFORMANCE CHARACTERISTICS OF COMPRESSION REFRIGERATION MACHINES AT CONSTANT SPEED

### EQUIPMENT CHARACTERISTICS AND SELECTION

The various types of compression systems have quite different characteristics of capacity and power with varying evaporator and condenser temperatures, as may be noted from curves in Figs. 14 and 15.

From Fig. 14 it may be observed that power requirements for the centrifugal compressor increase much more rapidly than for the reciprocating compressor, with increase in evaporator temperature. Similarly, the capacities of the steam ejector and centrifugal compressors increase more rapidly than those of the reciprocating compressor with increase in evaporator temperature. Thus, both the steam jet and centrifugal machines tend to be more self-regulating than the reciprocating. It is also evident from Fig. 14 that the steam jet equipment is best suited for operation at high evaporator temperatures.

The effect of condenser temperature upon the power and capacity of the different types of compressors is shown in Fig. 15. It may be noted

that the power required by the reciprocating compressor increases rapidly with increase in condenser temperature, while the power curve for the centrifugal compressor is relatively flat. It is also evident that the capacity of the steam jet compressor is independent of condenser temperature until a certain point is reached, where it drops to zero. As previously stated, steam jet equipment requires more condensing water than other types of compression systems. Consequently, steam jet systems are well suited to those applications where condensing water is cheap, or where condensing water is rather high in temperature.

The selection of proper refrigeration equipment for any air conditioning

job is of utmost importance for satisfactory results. The most important factors in the selection of the equipment are:

1. Loads (as determined by the conditions of the space to be cooled).
2. Economics (both initial and operating costs).
3. Codes (local safety codes must be adhered to and influence the type of system to be used).

A broad division of equipment to be used for a particular installation or application may be made on the basis of the magnitude of the load. Current general practice is outlined in Table 8.

Unit or *packaged* systems, consisting of a reciprocating compressor, condenser, evaporator, and fans, are generally used in the smaller sized jobs where electric power is available, as they are manufactured complete, ready to install, and are the most economical (see Chapter 26).

The reciprocating compressor in the built-up central system (see

Chapter 30) covers the widest range of application since it is applicable to either the direct expansion or indirect systems, and can be driven by steam or gas engines, or by electric motors. The quantity of condensing cooling medium required is also less than for any other system, with the exception of the centrifugal compressor, which uses the same amount.

Centrifugal compressors are used for large installations, and usually where the indirect system is required. The driving mechanism can be a steam turbine or electric motor. The steam jet system is used where steam is available and cooling water can be had in large quantities.

It will be noted by referring to Fig. 14 that all systems using compressors have a common characteristic, namely, that the capacity varies with the evaporating temperature. Not only can the equipment be selected to

FIG. 16. COMPRESSOR AND COIL PERFORMANCE

produce a given result, but the performance can be predicted under varying load conditions by the simple expedient of using the variable of evaporating temperature as the abscissa, and the load or capacity as the ordinate in a series of curves.

Manufacturers of compressors and cooling coils furnish performance data for apparatus that can be plotted in the form of curves similar to those shown in Fig. 16. The performance of a compressor is plotted as a series of curves, each curve being drawn for a given condensing pressure. The performance of a direct expansion coil at two different air velocities is plotted on the same graph. The operating point will be, of course, where the two curves cross.

Data given in Table 9 illustrate two types of conditioned enclosures having the same total load of 148,000 Btu per hour, but with two different ratios of sensible to total heat. In the case of the office with a ratio of 82 percent sensible to total heat, the operating point A in Fig. 16 is found to be 42.2 F evaporating temperature, with a face velocity of 500 fpm. In the case of the restaurant, with a ratio of 69.5 percent sensible to total heat, the air velocity is lowered to 300 fpm, and the evaporating tempera-

ture is lowered to 34.4 F as shown in point B of Fig. 16. In order to obtain the same capacity, a larger condensing unit is used. This illustration assumes zero pressure drop through the suction line. The pressure drop can be taken into account by shifting the compressor performance curves by the amount of pressure drop expressed in Fahrenheit degrees.

## CHAPTER 38

## DEHUMIDIFICATION BY SORBENT MATERIALS

Definitions and Principles, Adsorbents, Dehumidification by Solid Adsorbents, Dehumidification Equipment Using Solid Adsorbents, Absorbents, Dehumidification by Liquid Absorbents, Dehumidification Equipment Using Liquid Absorbents, Calculation of Moisture Load, Vapor Transfer to Dehumidified Space

**D**E HUMIDIFICATION as used herein is the reduction of the water vapor content of a given volume of air or other gas. The term thus describes a special case of dehydration which covers the removal of moisture in any form from matter. The degree of dehumidification required varies greatly with different applications, and is one of the prime considerations influencing the choice of a method. Dehumidification may be accomplished by latent heat removal, together with sensible heat removal, as described in Chapters 30, 35, and 36, or by the use of sorbents.

Sorbents are substances which have the property of extracting and holding other substances (usually gases or vapors, e.g., water vapor), brought into contact with them. All materials are sorbents to a greater or lesser degree. The weight of water held by a substance will increase or decrease, depending upon whether the vapor pressure of the water held by the substance is less or greater, respectively, than the partial pressure of water vapor in the surrounding atmosphere. As generally used, however, the term sorbents refers to those materials having a capacity for moisture which is large compared to their volume and weight. Such materials are divided into two general classifications:

1. *Adsorbent*—A sorbent which does not change physically or chemically during the sorption process. Certain solid materials, such as activated alumina, silica gel, activated bauxites, and activated charcoal have this property. The action of adsorbents, most of which adsorb some gases and condensable vapors besides water vapor, is selective. Thus, in the case of a mixture containing both water and organic vapors, silica gel would remove the water vapor in preference to the organic vapors, while the reverse would be true in the case of activated carbon. The selective property of adsorbents is made use of in some instances for the removal of objectionable and contaminating vapors from an air or gas mixture. (See Chapter 8.)
2. *Absorbent*—A sorbent which changes either physically, chemically, or both, during the sorption process. Calcium chloride is an example of a solid absorbent, while liquid absorbents include solutions of lithium chloride, calcium chloride, lithium bromide, and the ethylene glycols.

## ADSORBENTS

The ability of an adsorbent to remove water vapor from a gas is explained by the fact that the vapor pressure of the water in the adsorbent (when in the reactivated condition) is less than the partial pressure of the water vapor in the surrounding atmosphere. For instance, when an active adsorbent is brought into contact with a gas of high humidity, there is a tendency for the vapor pressure of the water in the adsorbent to reach equilibrium with the partial pressure of the water in the surrounding gas, with

the result that water is extracted by the adsorbent and its weight increased, while the moisture content of the gas is correspondingly reduced. (The adsorbent is said to be saturated for a given condition when equilibrium is attained.) The weight of water a given adsorbent will extract is dependent upon the relative humidity (ratio of the partial pressure in the gas to the saturation pressure at a given temperature) and the temperature of the adsorbent. The process is reversible; if the temperature of the adsorbent is raised until the vapor pressure of the adsorbed water becomes greater than the partial pressure of the vapor in the surrounding atmosphere, water will be released by the adsorbent. After the adsorbent cools to room temperature, for instance, the vapor pressure of the water in the adsorbent falls below the partial pressure of the vapor in the atmosphere, and the adsorbent will again start extracting water. The elimination of water by the addition of heat is known as reactivation, and is a means of regenerating the adsorbent so that it may be used repeatedly.

Adsorption is proportional to the amount of surface (internal and external) of the sorbent. The materials that are used commercially as solid adsorbents have a porous structure of sub-microscopic dimensions, which gives them extensive surface area. An adsorbent should meet the following requirements in order to be satisfactory for dehumidification purposes:

1. Have a high adsorptive capacity under normal atmospheric conditions.
2. Be chemically stable, resisting contamination from impurities.
3. Be physically rugged to resist breakdown from handling and use.
4. Be capable of reactivation at temperatures generally obtainable.
5. Be heat-stable at reactivation temperatures.
6. Have a weight per unit volume such as to avoid excessive bulk.
7. Be available at reasonable cost.

#### Activated Alumina

Activated alumina is a granular porous material which removes by adsorption substantially 100 percent of the moisture from gases, vapors, and certain liquids. Regeneration or reactivation may be accomplished by employing a heating medium at temperatures ranging from 350 to 600 F. After many cycles of adsorption and reactivation it is substantially as effective as originally, and retains its original size and shape.

Activated alumina is produced by chemically controlled precipitation from a sodium aluminate solution resulting from the extraction of alumina from bauxite by the Bayer process. By subsequent processes this precipitate is converted into a highly porous adsorptive material. It is low in iron and silica, each normally less than 1/10 of 1 percent. Commercially produced material is uniform in analysis and physical form.

Activated alumina is a partially dehydrated aluminum trihydrate containing about 7 percent water and small amounts of soda, oxides of iron, silicon, and titanium, as well as very minor amounts of other elements indicated spectrographically. Substantially all of the soda is combined with silica and alumina as an insoluble constituent.

Activated alumina is inert chemically to most gases and vapors, is non-toxic, and will not soften, swell or disintegrate when immersed in water. High resistance to shock and abrasion is one of its more important physical characteristics. Commercial sizes range from a powder passing through 300 mesh screen to particles 1 in. in diameter. The sizes commonly used are 8-14 mesh and  $\frac{1}{4}$  in. to 8 mesh. The average weight for most forms is 50 lb per cubic foot. Its high degree of purity warrants classification among commercially pure chemicals.

#### Silica Gel

Silica gel is a prepared form of silicon dioxide (silica) having an extremely porous structure which makes it an efficient adsorbent. It is made by mixing predetermined concentrations of an acid, such as sulfuric acid, and a soluble silicate, usually sodium silicate, and allowing the mixture to set to a jelly-like mass called hydrogel. The product takes its name from its condition as a colloid at this stage of its manufacture. After setting, the hydrogel is broken into small lumps, washed, dried, crushed, and screened to the desired particle sizes and then given a final heat treatment or activation. The surface area of silica gel has been found to be in excess of 50,000 sq ft per cubic inch of product. Silica gel has high adsorptive capacity per unit weight, and may be reactivated repeatedly at temperatures up to 600 F. Reactivation is generally accomplished by blowing gases through the silica gel at approximately 300 F, or by heating in a well vented oven maintained at this temperature until no more moisture is given off. Silica gel is a high purity, rugged, non-toxic, heat-stable material, having a specific heat of 0.2, and is most inert. There is no change in the size or shape of the particles as it becomes saturated, and no corrosive or injurious compounds are given off. It is available commercially in a number of grades, ranging in particle size from a 3 to 8 mesh product to an impalpable powder passing through a 325 mesh screen. The product generally used for dehumidification applications has a particle size of 6 to 12 mesh, and a bulk density of between 40 and 45 lb per cubic foot.

#### Activated Bauxite

Activated bauxites are certain natural products which, after controlled heat treatment, have properties which make them suitable for use as solid adsorbents. They are marketed under different trade names by several processors. The activated bauxites consist primarily of  $Al_2O_3$ ,  $Fe_2O_3$ ,  $SiO_2$ ,  $TiO_2$ , and  $H_2O$  in varying percentages. The surface area, adsorptive capacity, and other properties of the several products differ to some extent, depending upon the source of the original material and its subsequent treatment. The available activated bauxites are durable products having a specific heat of about 0.24, and can be regenerated at temperatures between 300 F and 500 F. They are usually supplied in a number of particle sizes, and have a bulk density of between 55 and 65 lb per cubic foot.

There are other solid substances having marked adsorbent properties, but details concerning them are not available.

#### DEHUMIDIFICATION BY SOLID ADSORBENTS

Since adsorption is primarily a condensation process, heat, equivalent to the latent heat of evaporation of the vapor, plus the heat of wetting (which is an additional amount of heat, depending upon the vapor being adsorbed and the adsorbent used) is liberated. The sum of the latent heat of evaporation and the heat of wetting is known as the heat of adsorption. During adsorption it might be said that latent heat is transformed into sensible heat, which is dissipated into the adsorbent, into the metal of the adsorbent container, and into the gas mixture, resulting in a rise in temperature. Fig. 1 shows the relationship between temperature, vapor pressure, and moisture content of a solid adsorbent. These curves indicate the general performance of solid adsorbents, although the exact values vary for the different adsorbents, and may vary even for different types of the same compound. The effects of vapor pressure and temperature upon the moisture content of an adsorbent may be observed by referring to Fig. 1. When the given type of solid adsorbent is in equilibrium with air having a dry-

bulb temperature of 70 F and 70 percent relative humidity, that is, having a dew-point of 60 F or a water vapor pressure of 13.2 mm Hg, the water content of the adsorbent is 33 percent. With air having the same dry-bulb temperature and a dew-point of 37 F, or a vapor pressure of 5.6 mm Hg, the water content is 20 percent. The increase in weight for an activated solid adsorbent, after it reaches equilibrium with a gas of any given water vapor content, may be found by subtracting the residual water content (for example 6 percent) from the equilibrium value. In the case of the two examples cited, the actual water gain would be 27 percent and 14 percent,

FIG. 1. TEMPERATURE—VAPOR PRESSURE—CONCENTRATION CHARACTERISTICS FOR A TYPICAL SOLID ADSORBENT

respectively. The effect of temperature upon the adsorptive capacity may be observed by following the 5.6 mm Hg vapor pressure line. At a temperature of 70 F, the moisture content of the adsorbent is 20 percent, while at 100 F, the equilibrium water content is 11 percent.

In practice, the temperature rise in the dehumidified air caused by the adsorption heat, is approximately 10 deg F for each grain of moisture removed per cubic foot of air at atmospheric pressure. This temperature rise occurs progressively through the adsorbent bed, and is an important consideration in predetermining the performance of a given design of apparatus. Data such as these, together with information covering other characteristics such as specific heat, resistance to air flow, etc., are of value in the basic design of adsorption apparatus. In the solution of air conditioning problems, however, reference must be made to performance data on established apparatus designs.

#### DEHUMIDIFICATION EQUIPMENT USING SOLID ADSORBENTS

A typical solid adsorbent dehumidification unit air flow diagram is shown in Fig. 2. The apparatus consists of two adsorbent containers (adsorbers)

FIG. 2. A TYPICAL SOLID ADSORBENT DEHUMIDIFICATION UNIT AIR FLOW DIAGRAM

with necessary interconnecting piping, valves, and auxiliaries consisting of filters, fans, activation air heater, controls, and, in some instances, a cooler for the dehumidified air. Before entering the adsorber, the air to be dehumidified is drawn into a filter to remove dust and other impurities. In passing through the adsorbent bed, the moisture content of the air is reduced and the dehumidified air is then introduced into the space or process requiring it. While the first adsorber is dehumidifying the air, the second adsorber is being reactivated by means of outside air drawn through a filter and heater in which its temperature is raised to 300 F. The heat may be supplied by electric heating elements, steam coils, the direct products of combustion of gas, oil, waste heat, or any other convenient source. In passing through the adsorbent bed, the hot gases supply the necessary heat for releasing adsorbed water from the adsorbent, and then carry it out of the adsorber to the activation gas outlet, where it is exhausted to the outside atmosphere. In some instances a thermostat placed in the activation outlet connection shuts off the activation fan and heater when the adsorbent is completely reactivated, as indicated by a rapid rise in the temperature of the outlet activation gas. The length of the adsorption period may be controlled by a timing device which changes the valves or dampers from the adsorbing to the activating position, or by a humidistat located in the dehumidified air connection or in the dehumidified space. The majority of commercial units are time controlled.

In applications where a continuous stream of dehumidified air is not required, a single adsorber type unit may be used, while in other cases where a continuous stream of dehumidified air is required, a multiple number of adsorbers, or even a continuously rotating system, may be used.

If the air to be dehumidified is very warm, and especially where exceedingly low dew-point dehumidified air is required, it is advantageous to install a pre-cooler to reduce the temperature of the inlet air. In this way the working temperature in the adsorber is lowered, and the overall performance appreciably increased. Some equipment manufacturers install cooling coils in the adsorbent beds for the same purpose, while others divide the adsorbent bed and install coolers between the sections.

Dehumidification equipment is employed to the best advantage where the air conditioning problem is primarily one of obtaining low relative humidity control rather than temperature control. This requirement is found in the case of the preservation of inactive naval vessels where the interior of the ship must be kept at a relative humidity below 30 percent to avoid corrosion, mold, mildew, and other moisture damage that occurs at humidities substantially in excess of this figure. Other advantageous applications for dehumidification systems are found in industrial processes where low relative humidity atmospheres are required during the manufacture, as well as for preservation of the finished products. Dehumidification with cooling may be used to advantage in work-rooms or other spaces occupied by humans, where the moisture load is high in comparison to the sensible heat load. In many instances, where independent control of temperature and humidity is important, dehumidification is used to advantage in conjunction with cooling.

#### ABSORBENTS

Any absorbent substance may be used as a dehumidifying agent if it has a vapor pressure with respect to water lower than the partial pressure of the water vapor in the mixture from which the moisture is to be removed.

*Solid Absorbents.* The substances used are generally the solid forms of the liquid absorbents. At present they are used principally in small desiccating chambers

and in small dryers of the cartridge type, through which air is forced under pressure. Calcium chloride is frequently used because of low cost.

**Liquid Absorbents.** These are primarily water solutions of materials in which the vapor pressure is reduced to a suitable level by controlling the concentration and temperature of the dehumidifying solution. Water solutions of the chlorides or bromides of various inorganic elements and certain organic compounds, are the liquid absorbents used in air conditioning.

In addition to having suitable water vapor pressure characteristics, an absorbent, to be satisfactory, should also meet the following requirements:

1. Be widely available at low cost.
2. Be non-corrosive, odorless, non-toxic, and non-inflammable.
3. Be chemically inert against any impurities in the air stream.
4. Be stable over the range of use.
5. Must not precipitate at the lowest temperature to which the apparatus is exposed.
6. Have low viscosity, and be capable of being economically regenerated or concentrated after having been diluted by the moisture absorbed.

### DEHUMIDIFICATION BY LIQUID ABSORBENTS

In liquid absorption systems the air-vapor stream is brought into intimate contact with the absorbent solution by passing the air stream through a tower into which the brine is introduced as a finely divided spray, or by passing the air through a tower or contactor which is continuously sprayed with the brine, thereby presenting a large surface of absorbent to the air to be dehumidified. The difference in the partial pressure of the water in the concentrated brine and the partial pressure of the water vapor in the air, causes the water vapor to be given up by the air to the brine until equilibrium is approached. The water vapor is condensed during this operation, and its addition to the absorbent solution results in a decrease in the concentration of the solution. As the water vapor condenses, the latent heat of condensation is released in the absorbent solution. An additional, frequently appreciable, quantity of heat known as the heat of solution or heat of mixing, is also released. The heat released as the result of condensation and mixing, is directly transferred to the liquid absorbent, equipment, and air being dehumidified, thereby causing a rise in temperature.

A modified system includes means for removing heat from the absorbent solution, either within the contactor or externally. Thus the temperature of the solution may be higher than, equal to, or lower than that of the air, depending on the chemical employed and the ultimate use of the dehumidified air.

Fig. 3 shows the relationship between temperature, vapor pressure and moisture content of a typical absorbent of the *inorganic* type. These curves indicate the general performance of such absorbents, although the exact values vary for the different compounds.

When the given absorbent is in equilibrium with air having a dry-bulb temperature of 70 F and a relative humidity of 70 percent, i.e., having a dew-point of 60 F, or a water vapor pressure of 13.2 mm Hg, the water content of the solution is 4.8 lb water per pound of anhydrous absorbent. With air having the same dry-bulb temperature and a dew-point of 37 F, or a vapor pressure of 5.6 mm Hg, the water content is 2.1 lb per pound of absorbent. Therefore, when a solution of 2.1 lb water per pound of absorbent is exposed to an atmosphere of 70 F and 70 percent relative humidity, it will absorb an additional 2.7 lb of water in reaching equilibrium.

The effect of temperature on the absorptive capacity may be observed by following a constant vapor pressure line in Fig. 3. At a temperature of 70 F and a vapor pressure of 13.2 mm Hg, the moisture content is 4.8 lb

water per pound of absorbent. At 100 F, the moisture content is 1.8 lb water per pound of absorbent.

Fig. 4 shows the relationship between temperature, vapor pressure, and moisture content of a typical liquid absorbent of the *organic* type.

### DEHUMIDIFICATION EQUIPMENT USING LIQUID ABSORBENTS

One type of system utilizing liquid absorbents includes an external inter-changer having essential parts consisting of a liquid contactor, a solution

FIG. 3. TEMPERATURE—VAPOR PRESSURE—CONCENTRATION CHARACTERISTICS FOR A TYPICAL INORGANIC ABSORBENT (HALOGEN SALT GROUP)

FIG. 4. TEMPERATURE—VAPOR PRESSURE—CONCENTRATION CHARACTERISTICS FOR A TYPICAL ORGANIC LIQUID ABSORBENT

concentrator, a solution heater and a cooling coil, all as shown in Fig. 5. The contactor and cooling coil are located in the wet air stream. The air to be conditioned is brought into contact with a liquid absorbent having a vapor pressure below that of the entering air, resulting in a transfer of moisture from the air to the brine solution. This results in a conversion of latent heat to sensible heat, which raises the solution temperature and consequently, the air temperature. The temperature change of the air being processed is determined by the cooling water temperature and the amount of moisture removed in the equipment. Control of leaving air temperature may be obtained by precooling the absorbent solution in a suitable surface cooler, by tap, well, or chilled water.

The excess water of condensation, which dilutes the liquid absorbent, is removed in the solution concentrator. This is a low pressure steam heat exchanger which over-concentrates a portion of the weak liquor, and returns it to the main reservoir for re-cycling. The concentrator operates in the manner of an evaporative condenser, whereby moisture is evaporated from the liquid absorbent by the heating coils into a stream of regeneration air taken from, and rejected to, the outside atmosphere. Low pressure

steam is normally used for heating the liquid absorbent. When it is desirable or necessary to use gas or electricity, an auxiliary low pressure steam boiler is usually added to the equipment. Concentrators operating on a simple boiler principle have not as yet been commercially practical.

It should be noted that the solution concentration phase is the reverse of the absorption process. During concentration, the aqueous vapor pressure of the solution is greater than that of the surrounding air, while during dehumidification, the reverse is the case. Utilization of this principle permits winter humidification by heating (instead of cooling) the solution pumped to the contactor. Water is thereby evaporated into, rather than condensed out of, the conditioned air stream. This requires dilution of the liquid absorber externally to the contactor.

### CALCULATION OF MOISTURE LOAD

Calculation of the dehumidification required to maintain lower than normal moisture content in a given room begins with determination of the

FIG. 5. LIQUID ABSORBENT EQUIPMENT IN WHICH SOLUTION COOLER AND CONCENTRATOR ARE COMBINED

rate of moisture gain in the room from all sources. It is common practice, when maintaining a low humidity ratio, to recirculate a large percentage of the air in the room through the dehumidifier, and to add only enough outside air to meet the needs of the problem. The humidity ratio of the mixture of outside and recirculated air and the dehumidifier performance data can be used to calculate the humidity ratio of the air leaving the dehumidifier. The difference between the humidity ratio of the air in the room and that of the dehumidified air entering the room represents the effective dehumidification per pound of air. The rate of internal moisture gain in grains per minute, divided by the effective dehumidification in grains per pound of air, equals the air quantity required in pounds per minute. The following typical example using arbitrary values shows a general method of determining the dehumidifying requirements. Sensible heat determination considerations are discussed in other chapters, and are purposely omitted here.

**Example 1:** A solid absorbent dehumidifier having performance characteristics as shown in Fig. 6 is to be used to maintain inside conditions of 73 F and 20 percent relative humidity, i.e., 24.1 grains per pound of dry air, 30 F dew-point, in a room 20 ft x 30 ft x 10 ft high, having a total wall, ceiling, and floor surface area of 2200 sq ft. Outside design conditions are 72 F dew-point (118.4 grains per pound).

### Dehumidification by Sorbent Materials

Internal sources of moisture are: 4 occupants; an open natural gas burner using 15 cu ft of natural gas per hour; an open top water tank, having an area of 2 sq ft exposed surface, in which water is maintained at 87 F, with air movement over the water surface being 100 fpm. Determine the quantity and condition of the dehumidified air to be supplied to the room.

**Solution:** The internal moisture gain consists of items 1 to 5.

- |                                               |                                                                                                                                  | Grains per Minute |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|-------------------|
| 1. From occupants:                            | $4 \times 1800/60 =$                                                                                                             | 120               |
|                                               | 1800 grains per person per hour is obtained from Fig. 7, Chapter 6, by interpolation between curves C and D.                     |                   |
| 2. From burned gas:                           | $15 \times 650/60 =$                                                                                                             | 162               |
|                                               | 1 cu ft natural gas produces approximately 650 grains of moisture.                                                               |                   |
| 3. From exposed water surface:                | $2 \times 20 =$                                                                                                                  | 40                |
|                                               | Evaporation from water surface is assumed to be 20 grains per (minute) (square foot) at 87 F water with air movement of 100 fpm. |                   |
| 4. From infiltration:                         | $\frac{6000}{60 \times 13.56} \times (118.4 - 24.1) =$                                                                           | 696               |
|                                               | One air change, 6000 cu ft, assumed per hour (see Chapter 11).                                                                   |                   |
| 5. Moisture transmitted through room surface: | $\frac{2200}{60} \times 3 \times (0.783 - 0.176) =$                                                                              | 67                |
|                                               | Permeability assumed to be 3 grains per (square foot) (hour) (inch Hg vapor pressure difference on two sides of wall).           |                   |

Total moisture gain from internal sources

1085

Let  $q$  be the air delivered to the room, pounds per minute. Let it be assumed for this problem that 85 percent of the air is recirculated and 15 percent is outside air. Enough air must be supplied to replace leakage from the system or to satisfy normal ventilating requirements for the occupants of the room as given in Chapter 6, whichever is greater. The amount is estimated from experience or obtained by test.

The humidity ratio of the mixture of recirculated and outside air entering the dehumidifier is then:

$$\frac{0.85q(24.1) + 0.15q(118.4)}{0.85q + 0.15q} = 38.3 \text{ grains per pound entering dehumidifier.}$$

For the dehumidifier whose performance is shown in Fig. 6, for 38.3 grains per pound in entering air, the leaving humidity ratio will be 6.5 grains per pound.

Effective dehumidification in the room is  $24.1 - 6.5$  or 17.6 grains per pound of supply air.

Then  $q = \frac{1085 \text{ grains per minute}}{17.6 \text{ grains per pound}} = 61.6 \text{ lb air per minute minimum}$  that must be supplied to the room to maintain 30 F dew point.

Note that this figure represents the minimum requirement for the arbitrary conditions set forth and that in practice, safety margins should be added to the outside air percentage figure and to the calculated internal moisture gain.

### VAPOR TRANSFER TO DEHUMIDIFIED SPACE

The walls enclosing a dehumidified space are subjected to a vapor pressure differential. The pressure of the vapor outside the walls tends to force moisture through the walls into the dehumidified zone of relatively low vapor pressure. As this process can be an unnecessary load on the

FIG. 6. PERFORMANCE DATA FOR TYPICAL COMMERCIAL SOLID ADSORBENT DEHUMIDIFIER

dehumidifying equipment, provisions should be made for keeping the vapor transfer to a minimum. Also, if the space is cooled below the ambient dew point, there is a possibility that condensation may occur within the walls, unless vapor transfer is controlled. For these reasons a vapor barrier should be located within the wall construction as near to the high vapor pressure side as feasible. To be effective, a barrier must be continuous and should be so located within the structure that it will be protected from rupture. (See Chapter 10, Moisture In Building Construction).

## AUTOMATIC CONTROL

**Fundamentals:** Type of Control Systems and Action, System Components, Controlled Devices, Auxiliary Control Equipment; **Control Applications:** Automatic Fuel Burning, Residential Heating and Air Conditioning, Zoning, Individual Room Control, Central-Fan Systems, Outdoor Air, Reheater Coil, Humidity, Cooling and Dehumidification, Static Pressure, Space Condition, Typical System, Unit Heaters, Unit Ventilators; **Design Coordination:** Size of Controlled Area, Equipment Selection and Layout, Location of Space Controllers, Control of Steam or Water Flow.

PRESENT-day standards of comfort combined with the capacity and rapid response of modern heating and cooling equipment make automatic controls an essential part of heating, ventilating, and air conditioning systems. These automatic controls respond to variables such as temperature, relative humidity, and pressure. They operate individually or in sequence to maintain the desired conditions throughout the system and in the occupied space. A factor which has made the subject of automatic control somewhat confusing has been the matter of terminology. Many different expressions or words have sometimes been used to convey a single idea or concept. This chapter, therefore, attempts to use and define the terms which are most common and suitable so that they will be more precise and readily understood. The terms and definitions used are also selected so as to conform, as nearly as possible, to automatic control terminology used by engineers in other realms of engineering endeavor.

### PART I—FUNDAMENTALS OF AUTOMATIC CONTROL

A control system, Fig. 1, consists essentially of (1) a controller, (2) a controlled device, and (3) a source of energy.

A controller is a device which measures a variable condition such as temperature, humidity, pressure, and liquid level, and produces a suitable action or impulse for transmission to the controlled devices. Thermostats, humidistats, and pressure controllers are examples.

A controlled device reacts to the impulse received from a controller and varies the flow of the control agent. It may be a valve, damper, electric relay, or a motor driving a pump, fan, etc.

The control agent is the medium manipulated by the controlled device. It may be air or gas flowing through a damper, gas, steam, water, etc., flowing through a valve, or an electric current.

The controlled variable is the condition such as temperature, humidity, or pressure, being controlled.

Most control systems, of which Fig. 1 is typical, form a closed loop. That is, the controller measures and responds to changes in the controlled variable and actuates the controlled device to bring about an opposite change which is again measured by the controller. This system of transmitting information about the results of an action or operation back to its origin is known as feedback, and makes true automatic control possible.

An open-loop system is sometimes employed in control circuits, but it does not provide complete control. An outdoor thermostat arranged to control the flow of heat to a building in proportion to the load caused by

changes in outdoor temperature is an example. This system depends for its operation on a prearranged relationship between outdoor temperature and heat input to the building, and room temperature has no effect on the controller.

As there is no feedback, the control corrects only for those disturbances of room temperature caused by changes in outdoor temperature.

### TYPES OF CONTROL SYSTEMS

Control systems are divided into five main groups according to the primary source of energy:

1. A *self-contained system* combines the controller and controlled device in one unit and employs the power of the measuring system to effect the necessary corrective action. The measuring system derives its energy from the process under control without amplification by any auxiliary source of energy, and may be of the sealed-bellows or remote-bulb type as described under Types of Measuring Elements

FIG. 1. ESSENTIALS OF A CONTROL SYSTEM

Temperature changes at the bellows or the remote bulb result in pressure or volume changes of the enclosed media which are transmitted directly to the operating device of the valve or damper.

2. A *pneumatic system* utilizes compressed air, usually at a pressure of 15 to 25 psig, as a source of energy. This is supplied to the controller which in turn regulates the pressure supplied to the controlled device.

3. A *hydraulic system* utilizes a suitable liquid under pressure as the source of energy. The pressure often is considerably higher than in a pneumatic system, but in other respects the systems are similar. Hydraulic systems find their chief use in applications where large forces are required for operation of the controlled devices.

4. An *electric system* utilizes electric energy, either low or line voltage as the energy source. The electric energy supplied to the controlled device is regulated by the controller either directly or through relays.

5. An *electronic system* also utilizes electric energy, but employs an electronic amplifier to increase the minute voltage variations of the measuring element to values required for operation of standard electrically-controlled devices. Measuring elements usually are of the resistance type, but thermocouples also are employed. Combination electronic-pneumatic systems utilize compressed air for operation of the controlled device by converting the output of the electronic amplifier into suitable air pressure changes by means of an electronic-pneumatic transducer.

### TYPES OF CONTROL ACTION

Control action may be divided into five types:

1. *Two-position action*, Fig. 2, is the type in which the controlled device can be positioned only to a maximum or minimum position, or can be either *on* or *off*. A thermostat which opens and closes a valve, or starts and stops a burner, is an example.

2. *Timed two-position action* is a common variation of two-position control action in which the time of *on* periods are prematurely shortened. This type of action usually is employed only in room thermostats, and is accomplished by a heater element

in the thermostat which is energized during the *on* periods. The percentage of time *on* is varied in proportion to the system load.

*Controller differential* applying to two-position control action, is the difference between the setting at which the controller operates to one position and the setting at which it operates to the other position. As an example, if a pressure controller starts a pump at 12 psi and stops it at 15 psi, the differential is 3 psi. It is sometimes

FIG. 2. TWO-POSITION CONTROL

FIG. 3. FLOATING CONTROL SHOWING VARIATIONS IN CONTROLLED VARIABLE AS LOAD CHANGES

FIG. 4. PROPORTIONAL CONTROL SHOWING VARIATIONS IN CONTROLLED VARIABLE AS LOAD CHANGES

desirable to have a controller in which the differential can be changed by manual adjustment. This is designated as an adjustable differential.

3. *Floating action*, Fig. 3, is the type, as with two-position action, where the controller can perform only two operations: moving the controlled device usually at a constant rate either towards its open or its closed position. Generally there is a neutral zone between the two positions which allows the controlled device to stop at any position whenever the controlled variable is within the differential of the controller. When the controlled variable gets outside the differential of the controller, the controller moves the controlled device in the proper direction. An example of floating control is a fire box draft controller positioning a damper in the breeching of a boiler.

4. *Proportional action*, Fig. 4, is the type where the controlled device is positioned proportionately in response to slight changes in the controlled variable. It does not run through its complete stroke, as is the case with two-position control, nor does it continue to move until the change in the controlled variable resulting from that movement is felt by the controller, as is the case with floating control, but it immediately assumes a position in proportion to the system requirement.

An example of proportional control is a thermostat in a fan discharge duct actuating an automatic valve in the steam supply to a coil to regulate the air temperature leaving the coil. This control would be similar to that shown in Fig. 1.

*Throttling range* is the total amount of change in the controlled variable required

to move the controlled device through its complete stroke, from one extreme to the other. It is often adjustable to meet job requirements.

*Set Point* is the value at which the controller is set and represents the desired value of the controlled variable.

*Control Point* is the actual value of the controlled variable at which the instrument is controlling. It will vary within the throttling range of the controller according to the demand on the system and other variables.

*Offset* is the difference between the set point and the actual control point under stable conditions. This is sometimes also called *drift*, *deviation*, or *droop*.

5. *Proportional plus Automatic Reset Action*, Fig. 5 combines floating action with proportional action to achieve both the stability of proportional control, with a relatively wide throttling range, and the invariable control point of floating control. The system functions the same as proportional action, the automatic reset serving to shift the control point back to the set point whenever any offset occurs.

*Reset rate* is the number of times per minute the proportional action is duplicated by the reset action, and usually is expressed as *repeats per minute*. The reset rate in most controllers is adjustable and must be carefully matched to the system characteristics to avoid unstable operation. Because automatic reset is necessarily slow-acting, it should be used only when load changes are of reasonably long duration and when the maximum offset resulting from proportional control alone is outside of acceptable limits.

Figs. 4 and 5 show the results of rather abrupt demand changes, which usually result in two or three cycles before stability is restored. More gradual demand changes will result in a smoother curve.

### AUTOMATIC CONTROL SYSTEM COMPONENTS

In addition to controllers and controlled devices, many control systems include auxiliary apparatus such as switches and relays of various kinds, clocks or timers, thermometers, gauges, pilot lights, and other indicators for observing the operation of the system. Only those more commonly used will be described here.

#### Controllers

Automatic controllers have both a measuring element and a controlling element.

The *measuring element* measures changes in the controlled variable and produces a proportional effect on the controlling element. This effect usually is a change in position, force or electrical resistance.

The *controlling element* converts the effect produced by the measuring element into an effect suitable for operation of the controlled device. (In self-contained controllers the measuring element produces a force which is directly applied to the controlled device. In pneumatic or electric controllers the controlling element regulates the application of energy such as compressed air or electricity.)

#### Types of Measuring Elements

*Temperature measuring elements* usually consist of (1) a bimetal strip, (2) a rod and tube of dissimilar metals, (3) a sealed bellows, with or without a remote bulb or (4) an electrical resistance.

1. A *bimetal element* is composed of two thin strips of dissimilar metals fused together. Because the two metals have different coefficients of thermal expansion, the element bends as the temperature varies and produces a change in position. Depending on the space available and the movement required, it may be in the form of a straight strip, U-shaped, or wound into a spiral. This element finds its most common application in room thermostats, but is also used in insertion and immersion thermostats.

2. A *rod-and-tube element* consists of a high-expansion metal tube inside of which is a low-expansion rod with one end attached to the rear of the tube. The tube changes length with changes in temperature, causing the free end of the rod to move. The

rod-and-tube element is commonly employed on certain types of insertion and immersion thermostats.

3. A *sealed bellows-element* is either vapor filled, gas filled, or liquid filled, after being evacuated of air. Changes of temperature cause changes in pressure or volume of the gas or liquid, resulting in a change in force or a movement. This element is often employed in room thermostats.

A *remote-bulb element* is a sealed bellows or diaphragm to which a bulb or capsule is attached by means of a capillary tube, the entire system being filled with vapor, gas or liquid. Changes of temperature at the bulb result in changes of pressure or volume which are communicated to the bellows or diaphragm through the capillary tube. The remote-bulb element is useful where the temperature measuring point is remote from the desired thermostat location. It usually is provided with fittings suitable for insertion into a duct or into a pipe or tank.

4. A *resistance element* is made of wire whose electrical resistance changes with temperature changes. It is used with electronic controllers. It is available in forms suitable for measuring room temperature or for insertion into a duct or into a pipe or tank.

FIG. 5. PROPORTIONAL PLUS AUTOMATIC RESET CONTROL SHOWING HOW CONTROL POINT IS RETURNED TO SET POINT AFTER A LOAD CHANGE

*Humidity measuring elements* are made of (1) hygroscopic organic materials or (2) an electrical resistance.

1. An *organic element* usually is made of human hair, wood, paper, or animal membrane. Changes in relative humidity cause the element to expand and contract.

2. A *resistance element*, for use with electronic controllers, frequently consists of a thin coating of hygroscopic salt on an insulating form. The resistance of the salt varies with the relative humidity.

*Pressure measuring elements* can be divided into one of two general classes depending upon pressure range.

1. For pressures or vacuums measured in pounds per square inch or inches of mercury, the element usually is a bellows, diaphragm, or Bourdon tube. One side of the element may be open to atmosphere in which case the element responds to pressures above or below atmospheric. A differential pressure element has connections to both sides so that it will respond to the difference between two pressures.

2. For low ranges of pressure or vacuum which are usually measured in inches of water, such as the static pressure in an air duct, the measuring element may be an inverted bell immersed in oil, a large slack diaphragm, or a large flexible metal bellows. The element usually is of the differential type, and when employed in conjunction with orifices, pitot tubes, and similar accessories, may be used to measure flow, velocity or liquid level as well as static pressure.

Measuring elements for other purposes, such as flame detection or for measuring smoke density, specific gravity, CO<sub>2</sub>, CO, etc., often are necessary for the complete control of a heating, ventilating or air conditioning system.

#### Types of Controlling Elements

Controlling elements differ because some regulate the application of pneumatic energy while others regulate the application of electrical energy. They also differ according to the type of control action produced.

An *electric controlling element* is used in several of the common types of control action.

For *two-position control* it may simply make and break an electrical contact, to start a burner, motor, etc., or to actuate a spring-return valve or damper operator. Another type makes one contact while breaking another and is used to control unidirectional valve or damper operators. Either type may be used for timed two-position action by the addition of a small resistance heater.

For *floating control* two contacts are employed, but there is a neutral zone between the two contacts where neither is made. This type is commonly used with reversible valve or damper operators.

For *proportional control* a contact is moved across a potentiometer to vary the voltage applied to a relay. The relay controls the operation of a reversible valve or damper operator and is re-balanced as the controlled device is positioned. In another arrangement the controlling element has two contacts and a neutral zone as described for floating control and is re-balanced by a small solenoid which is energized by a variable voltage feedback from the reversible valve or damper operator which it positions.

An *electronic controlling element* consists of an electronic amplifier and an electric relay or relays. The amplifier receives the minute electrical signals from the measuring element and amplifies them sufficiently to actuate the relays. The electronic controlling element may be two-position, floating, or proportional, depending upon the amplifier and relay arrangement.

A *pneumatic controlling element* is most often of the proportional-action type but may also be used for the other types of control action. It may be classified as non-relay type and relay type.

A *non-relay type* of pneumatic controlling element is the simplest form and employs a restricted air supply and a nozzle or control port. The measuring element varies the opening of the nozzle and the resulting variable pressure is applied to the controlled device. This type is limited to applications requiring small volumes of air.

In a *relay-type* pneumatic controlling element the relay contains both a supply and an exhaust valve usually arranged so that the exhaust valve must close before the supply valve opens. Both valves are closed except when the control pressure is required to change. The variable force for operating the valves may be supplied directly by the measuring element or it may be supplied by a diaphragm actuated by air pressure from a very small nozzle and restrictor arrangement, this air pressure being varied by the measuring element. In either case the control pressure, operating on a diaphragm within the relay, produces a force which balances the force produced by the measuring element.

Pneumatic controllers may be either direct or reverse acting.

A *direct-acting controller* increases the control air pressure as the controlled variable increases. For example a direct-acting thermostat increases the air pressure as the temperature increases.

A *reverse-acting controller* decreases the control air pressure as the controlled variable increases. A reverse-acting thermostat decreases the air pressure as the temperature increases.

### Indicating and Recording Features

Controllers may be of the indicating or recording type.

The *non-indicating controller* is most common in heating, ventilating, and air conditioning work, and includes all those in which the measuring element does not provide a visual indication of the value of the controlled variable. If an indication is desired, a separate thermometer, relative humidity indicator, pressure gauge, etc., is required. With room thermostats, for example, a separate thermometer often is attached to the cover.

An *indicating controller* has a pointer added to the measuring element or attached to it by a linkage so that the value of the controlled variable is indicated on a suitable scale.

A *recording controller* is similar to an indicating controller except that the indicating pointer is replaced by a recording pen which provides a permanent record on a chart driven by a clockmotor.

*Proportional band* is a term used in connection with indicating and recording con-

trollers and has the same meaning as throttling range. It is usually expressed in per cent of the scale or chart range of the controller.

### Types of Controllers

Controllers are mainly (1) thermostats, (2) humidistats, and (3) pressure types.

1. Many thermostats are of the simple, single-purpose type, but there are many others for various special purposes. Various types are indicated in paragraphs (a) to (k) which follow.

a. The *room type* is designed for mounting on a wall and responds to room temperature.

b. The *insertion type* is designed for mounting on a duct with its measuring element extending into the duct.

c. The *immersion type* is designed for mounting on a pipe or tank. It has a fluid-tight connection to allow the measuring element to extend into the fluid. A separable socket or well is often used with immersion thermostats to avoid the need for draining the system when removal of the thermostat is required. Since the separable socket will reduce the response rate of the thermostat, the socket should be no heavier than necessary and should fit snugly around the element.

d. The *remote bulb type* is designed for applications where the point of temperature measurement is at some distance from the desired thermostat location. It is often used for centralized panel mounting of the controller. The remote bulb element may be of either the insertion or immersion type.

e. The *surface type* is designed for mounting on and measuring the temperature of a pipe or similar surface.

f. The *day-night, or dual room thermostat* controls at a reduced temperature at night. It may be indexed (changed from day to night operation) individually or in groups from a remote point by a manual or time switch. Some electric types have an individual clock and switch built into the thermostat.

g. The *pneumatic day-night thermostat* uses a two-pressure air supply system, the two pressures often being 13 and 17 psi or 15 and 20 psi. Changing the pressure at a central point from one value to the other actuates switching devices in the thermostat and indexes them from day to night or vice versa. Supply-air mains often are divided into two or more circuits so that switching can be accomplished in various areas of the building at different times, in accordance with use. For example a school building may have the separate circuits: for classrooms, offices and administrative areas, auditorium, and gymnasium and locker rooms.

h. The *heating-cooling or summer-winter thermostat* can have its action reversed and, if desired, have its set point changed by the indexing means. It is used to actuate controlled devices, such as valves or dampers, that regulate a heating source at one time and a cooling source at another time. It is often indexed in groups manually by a switch or automatically by a thermostat measuring the temperature of the control agent, the outdoor temperature, or other suitable variable.

i. The *pneumatic heating-cooling thermostat* uses a two-pressure air supply system as described for day-night thermostats.

j. A *two-stage thermostat* is arranged to operate in two successive steps.

k. A *submaster thermostat* has its set point raised or lowered over a predetermined range in accordance with variations in output from a master controller. The master controller can be a thermostat, manual switch, pressure controller or similar device. For example, a master thermostat measuring outdoor air temperature can be used to readjust a submaster thermostat controlling the water temperature in a heating system. Master-submaster combinations are sometimes designated as *single cascade action*. When such action is accomplished by a single thermostat having more than one measuring element, it is known as *compensated control*.

2. *Humidistats* are of either the room or insertion type. Submaster humidistats of either type are sometimes used in conjunction with an outdoor master thermostat to reduce the humidity in cold weather and prevent condensation on windows.

A *wet-bulb thermostat* is often used for humidity control in conjunction with proper control of the dry-bulb temperature. A wick or other means for keeping the bulb wet is required, and rapid air motion to assure a true wet-bulb measurement is essential.

3. A *pressure or static-pressure controller* is made for mounting directly on a pipe

or remotely on a panel or wall. A small pipe or tube may be used for transmitting the pressure signals to the instrument.

### Controlled Devices

Controlled devices consist of (1) automatic valves (2) valve operators, (3) automatic dampers, and (4) damper operators. Other controlled devices include electric heaters, and motors on such equipment as fans, pumps, burners, refrigeration compressors and similar apparatus.

1. An *automatic valve* is designed to control the flow of steam, water, gas, and other fluids and may be considered as a variable orifice which is positioned by an electric or pneumatic operator in response to impulses from the controller. It may be equipped with a throttling plug or v-port of special design to provide the desired flow characteristics.

Renewable composition discs are common. They are made of materials best suited to the media handled by the valve, and its temperature and pressure. For high pressures or for superheated steam, metal discs are often employed. Internal parts of valves such as the seat ring, throttling plug or v-port skirt, disc holder, and stem sometimes are made of stainless steel or other hard and corrosion resistant metals for use in severe service. Automatic valves should be properly selected and sized for the specific applications. See the section on Design Coordination in this chapter for further details.

The functions of various types of automatic valves are as follows:

a. A *single-seated valve* is designed for tight shut-off. Appropriate disc materials for various pressure ranges and media are used.

b. A *pilot piston valve* utilizes the pressure of the control agent as an aid in operating the valve. It usually is single-seated and is used where large forces are required for valve operation.

c. A *double-seated or balanced valve* is designed so that the media pressure acting against the valve disc is essentially balanced thereby reducing the force required of the operator. It is widely used where the fluid pressure is too high to permit a single-seated valve to close. It cannot be used where tight shut-off is required.

d. A *three-way mixing valve* has two inlet connections and one outlet connection and a double-faced disc operating between two seats. It is used to mix, as required, two fluids entering the inlet connections and leaving through the common outlet.

e. A *three-way diverting valve* has one inlet connection and two outlet connections and two separate discs and seats. It is used to divert the flow to either of the outlets or to proportion the flow to both outlets.

f. A *butterfly valve* consists of a heavy ring enclosing a disc which rotates on an axis at or near its center, and in principle is similar to a round single-blade damper. The disc usually seats against a ring machined within the body.

2. Valve operators are of three general types:

a. A *solenoid* consists of a magnetic coil operating a movable plunger. It is used for two-position operation. The most common use of a solenoid-operated valve is to control the flow of gas, water, air and refrigerants and generally it is limited to relatively small sizes.

b. An *electric motor* operates the valve stem through a gear train and linkage. Electric motor operators are classified in three distinct types. *Unidirectional*, for two-position operation. The valve opens during one-half revolution of the output shaft and closes during the other one-half revolution. Once started, it continues until the half revolution is completed, regardless of subsequent action by the controller. Limit switches built into the operator stop the motor at the end of each stroke. If the controller has been satisfied during this interval the operator will continue to the other position. *Spring-return*, for two-position operation. Electric energy drives the valve to one position and holds it. When the circuit is broken, the spring returns the valve to its normal position. *Reversible*, for floating and proportional operation. The motor can run in either direction and can stop in any position. It is sometimes equipped with a return spring. For proportional control applications, a potentiometer for rebalancing the control circuit is also driven by the motor.

c. A *pneumatic operator* consists of a spring-opposed flexible diaphragm or bellows attached to the valve stem in such a way that an increase in air pressure moves the valve stem and at the same time compresses the spring. Springs of various ranges in terms of air pressure can be employed to provide sequence operation of two or more

devices by proper selection or adjustment of the springs. Springless pneumatic operators, using two opposed diaphragms or two sides of a single diaphragm, also are used but generally are limited to special applications involving large valves or high pressures. Pneumatic operators are designed primarily for proportional control. Two-position control is accomplished by use of a two-position controller, or a two-position pneumatic relay to apply either full air pressure or no pressure to the valve operator.

Pneumatic valves and valves with spring-return electric operators can be classified as normally open or normally closed.

A *normally-open* valve will assume an open position when all operating force is removed.

A *normally-closed* valve will assume a closed position when all operating force is removed.

3. *Automatic dampers* are designed to control the flow of air or gases and function like valves in this respect. Steel blades and frames are most common, but other materials are used for special applications such as those involving corrosive fumes. Large dampers often are made in two or more sections for strength and convenience in handling, the sections being inter-connected so as to operate as a unit. The damper types commonly used are:

a. *Single-blade*, which is generally restricted to small sizes because of the difficulty of securing proper operation with high velocity air.

b. *Multi-blade or lower damper* which has two or more blades linked together. It may be arranged for (a) *parallel operation*, in which all blades rotate in the same direction or (b) *opposed operation*, in which adjacent blades rotate in opposite directions and provide more linear air flow characteristics than obtained with parallel operation.

c. *Mixing dampers*, composed of two sections interlinked so that one section opens as the other closes.

4. *Damper operators* of the electric type may be unidirectional, spring-return, or reversible similarly to electric-motor valve operators. Pneumatic damper operators are similar to pneumatic valve operators except that they usually have a longer stroke or the stroke is increased by means of a multiplying lever. Damper operators are mounted on the damper frame and are connected with linkage directly to a damper blade or are mounted outside the duct and connected to a crank arm attached to a shaft extension of one of the blades. On large dampers two or more operators may be required, and usually are applied at separate points on the damper. Normally-open or normally-closed operation is obtained according to the method of mounting the operator and connecting the linkage.

### Auxiliary Control Equipment

In addition to the conventional controllers and controlled devices described, many control systems require auxiliary devices to perform various functions. Auxiliary controls for electric systems include:

1. *Transformers* to provide current at the required voltage.

2. *Electric relays* for control of electric heaters or to start and stop oil burners, refrigeration compressors, fans, pumps, or other apparatus for which the electrical load is too large to be handled directly by the controller. Other uses include time delay, circuit interlocking safety applications, and similar functions.

3. *Potentiometers* for manual positioning of proportional controlled devices or for remote set point adjustment of electronic controllers.

4. *Manual switches* for manually performing a variety of operations. These may be of two-position or multiple-position type or may be of single or multiple-pole type.

5. *Auxiliary switches* on valve and damper operators for providing a selected sequence of operations.

Auxiliary control equipment for pneumatic systems include:

1. *Air compressors and accessories*, to provide a source of air at the required pressure.

2. *Electro-pneumatic relays*, which are electrically-actuated air valves for operating pneumatic equipment when an electrical circuit is energized or de-energized.

3. *Pneumatic-electric relays*, which are actuated by air pressure and make or break an electrical circuit.

4. *Pneumatic relays*, which are actuated by the pressure from a controller and perform numerous functions. They may be divided into two groups:

a. *Two-position relays*, which permit a controller actuating a proportional device to also actuate one or more two-position devices. They also are used in various automatic switching operations.

b. *Proportional relays*, which are used to reverse the action of a proportional controller, select the higher or lower of two pressures, average two or more pressures, respond to the difference between two pressures, add or subtract pressures, amplify or retard pressure changes, and perform other similar functions.

5. *Positioning relays*, which are devices for assuring accurate positioning of a valve or damper operator in response to changes in pressure from a controller. They are affected by the position of the operator and the pressure from the controller, and whenever the two are out of balance will change the pressure applied to the operator until balance is restored.

6. *Switching relays*, which are pneumatically operated air valves for diverting air from one circuit to another or for opening and closing air circuits.

7. *Pneumatic switches*, which are manually operated devices for diverting air from one circuit to another or for opening and closing air circuits. They may be of two-position or multiple-position type.

8. *Gradual switches*, which are proportional devices for manually varying the air pressure in a circuit.

Auxiliary control devices common to both electric and pneumatic systems include:

1. *Sequence controllers* for operating a number of electric switches in sequence by means of a proportional electric or pneumatic operator. They are commonly used for controlling a number of steps of refrigeration capacity and may be arranged to prevent simultaneous starting of compressors and to alternate the sequence to equalize wear. They may also be used for sequence operation of electric heaters and other equipment in response to the demands of a proportional controller.

2. *Clocks or timers* for turning apparatus on and off at predetermined times, for switching control systems from day to night operation, and for other time sequence functions.

## PART II—CONTROL APPLICATIONS

Applications of controls to systems or apparatus of a general nature will be found in this chapter. Applications pertaining to specific systems or apparatus will be found in the chapters covering those subjects.

### CONTROLS FOR AUTOMATIC FUEL BURNING EQUIPMENT

Controls for the automatic fuel burning equipment described in Chapter 15 are outlined here. The basic requirements for oil burners, gas burners and coal burners (stokers) are included and the term *burner* refers to all three types of fuel burning equipment. Controls for these burners can be classified as *operating controls*, *limit controls* and *primary controls*. The schematic diagrams shown in Fig. 6 indicate the relationships of the basic components. The *power supply* may be line voltage for each type of burner. In control systems for domestic burners the line voltage may be stepped down by means of a transformer for those portions of the circuits indicated by dotted lines. Such transformers are usually built into the stoker and oil burner *primary controls*. Control systems for domestic gas burners frequently use a separate transformer as shown. There are domestic gas burner control systems which obtain their electrical power supply from the conversion of heat to low voltage electrical energy, in which case no transformer would be required. As the burner sizes increase, the tendency to use all line voltage controls increases in each of these general categories.

### Operating Controls

*Operating controls* initiate the starting and stopping of the burner and on larger burners they usually vary the fuel and air input to the combustion chamber in response to varying load demands. For residential and small commercial heating plants with fuel inputs up to approximately 500,000 Btu per hour, the *operating controller* is usually some form of room thermostat which automatically starts and stops the burner through the *primary control* as the *limit controls* permit. As the size of the heating system increases, the use of a room thermostat as the *operating controller* for the burner becomes less common. An insertion thermostat (for furnaces), immersion thermostat (for hot water boilers) or pressure controller (for steam boilers) may be applied as an *operating controller*. Also, such

FIG. 6. SCHEMATIC DIAGRAMS OF SOME TYPICAL BURNER CONTROL SYSTEMS (O = Operating Control; P = Primary Control; L = Limit Control)

devices as submaster and compensated controllers (which are reset from outdoor temperature for governing the bonnet temperature in large furnaces or the water temperature in a boiler) come into more frequent use on the larger installations. The still larger burners are usually equipped to vary the rate of fuel and air input in response to varying load demands.

### Limit Controls

Limit controls guard against unsafe temperature, pressure or water level to assure that safe conditions prevail for the operation of the burner. Draft controls protect the firebox against excessive drafts, regardless of the type of fuel being burned, to increase combustion efficiencies and reduce stack losses. For fuel input requirements above approximately 1,000,000 Btu per hour some additional factors become common to all types of burners. For example, the draft in the firebox is controlled at a suitable constant for all firing rates, including the *off* period, by measuring the draft conditions in the firebox and actuating a *damper operator* to position the damper at the boiler outlet. Where necessary, provision may be made to open the boiler outlet damper wide before permitting the burner to start and then return this damper to automatic control after the burner has been started. Also, the firing rate of these larger burners is frequently automatically adjustable and provisions are made for always starting the burner on its low firing rate, with facilities for increasing the firing rate slowly after the burner has been started. It is not recommended and codes seldom permit the use of one and the same instrument as both an *operating controller* and a *high limit control*. In such cases an *operating controller* will be adjusted to control at the desired set point while the *high limit*

control will be adjusted to stop the burner at some higher point in the event that the *operating controller* fails to stop the burner before the higher shut-off point is reached. For example, to maintain a constant water temperature in a hot water boiler, the operating controller may be set to stop the burner when the boiler water temperature reaches 180 F. The *high limit control* should then be set to stop the burner at a higher temperature, say 200 F.

Various interlocks or limit controls are usually included to assure safe operation of these larger burners. A latch switch interlock prevents burner operation if the burner is not in its proper firing position. Another interlock must prove that the burner is in its low-fire position before the burner can be started. Safe draft conditions should be proved before the burner can be started or allowed to run, especially where induced draft fans are involved. A smoke detecting device may sound an alarm and stop the burner if excessive smoke is produced. Also, protection against electrical overloads must be provided.

### Primary Controls

*Primary controls* provide for the safe start and operating procedure of the burner. They are somewhat different for each of the three types of fuel burners.

1. *Stokers.* Stokers are equipped with refueling, or *hold-fire*, controls. These *primary controls* cause the stoker to intermittently feed a predetermined amount of coal during the long off periods of the *operating controller* to maintain ignition and to reduce the possibility of having idle fuel beds damage stoker castings. In some cases the *primary control* system includes an *out-fire* feature which stops the feeding of coal into the firebox if the fire goes out.

2. *Oil Burners.* *Primary controls* required for oil burners depend on the size and type of burner. Some of the more common *primary controls* are discussed in following paragraphs a to d.

a. Domestic oil burners of the vaporizing type usually require a *primary control* which will (1) meter the correct amount of oil into the burner to maintain the pilot flame; (2) regulate the required amount of oil into the burner for its high flame operation; and (3) completely shut off the flow of oil in the event of a flame failure.

b. Domestic oil burners of the pressure atomizing type require a *primary control* which will (1) energize the burner motor and electric ignition; (2) test for the establishment of main burner flame and stop the burner and ignition if flame has not been established; (3) cut off the ignition after a safe burner flame has been established (does not apply to constant ignition type burners); (4) monitor the flame continuously during burner operation and stop the burner in the event of flame failure (manual reset is necessary following a flame failure lock-out); and (5) stop the burner when either the *operating controller* or *limit control* requires it.

c. Commercial and industrial oil burners of the pressure atomizing type have *primary controls* that are essentially the same as those outlined for domestic oil burners of the pressure atomizing type. In addition, some models are equipped with a solenoid oil-shut-off valve to provide a pre-purge period, if desired, and a quick shut-off of the oil flow when the burner is stopped.

d. Commercial and industrial oil burners of the horizontal rotary cup type are usually equipped with a more elaborate *primary control* system. The *primary control* is often described as a programming combustion safety control. Its most important operations include (1) starting the burner upon a call for heat; (2) providing a pre-purge period before activating the gas-electric ignition; (3) proving the presence of proper ignition before permitting the flow of oil to the main burner; (4) proving the presence of a stable main burner flame within a predetermined period of time; (5) shutting off the gas-electric ignition after a predetermined length of time has elapsed; (6) monitoring the main burner flame during its entire on period and stopping the burner quickly in the event of a flame failure (it is usually required that the flow of oil through the burner be stopped within four seconds following a flame failure); (7) stopping the flow of oil through the burner when either the *operating controller* or a *limit control* requires it; (8) operating the burner for a predetermined length of time

after the main fuel valve has been closed; and (9) locking out on a flame failure shut-down (the programming control then must be manually reset prior to a restart).

When steam, air or mechanical atomizing burners are automatically controlled, their sequence of control is similar to that described for horizontal rotary cup burners.

3. *Gas Burners.* Some of the more common *primary controls* for gas burners are as follows.

a. Domestic gas burners of the atmospheric type require a *primary control*, to insure safe starting and operating conditions, which will (1) prevent opening of the gas valve unless the pilot is operating properly, and (2) stop the flow of gas through the burner if safe ignition conditions do not prevail at all times.

b. Commercial and industrial gas burners of the atmospheric type require a *primary control* whose function is similar to that for domestic sizes of these burners except in the rate of response to a pilot flame failure. The pilot flame burns constantly and, in general, the *primary control* system will (1) assure operation only when ignition of the main burner will be safe; (2) start and stop the main burner when required to do so by either the *operating controller* or a *limit control*; and (3) close the safety shut-off valve in the gas supply line to the burner upon a flame failure or an electrical power failure.

c. Commercial and industrial gas burners of the power type equipped with electric ignition require a *primary control* whose most important operations include: (1) starting the burner motor upon a call for heat by the *operating controller*; (2) providing a pre-purge period before activating the gas-electric ignition; (3) proving the presence of proper ignition before allowing gas to flow to the main burner or shutting off the electric ignitor; (4) closing the safety shut-off valve in the event of a flame failure (it is usually required that the flow of gas be stopped within four seconds following a flame failure); (5) stopping the burner when either an *operating controller* or a *limit control* requires it; and (6) locking out on a flame failure shut-down (the programming control then must be manually reset prior to a re-start).

### RESIDENTIAL HEATING AND AIR CONDITIONING

The control equipment function in the residence may vary from the regulation of a coal fired heating plant to the completely automatic control of a year-around heating and cooling system. Regardless of the type of heating or air conditioning system used, the control system should be selected carefully to insure safety and comfort of the occupants as well as economy of operation.

The simplest type of domestic control is one in which the room thermostat starts and stops the burner, as described in the preceding section. It may be used on gravity or forced warm air, hot water or steam systems. In forced warm air or forced hot water systems the fan or circulator usually is controlled by a thermostat in the furnace or boiler and runs whenever the air or water temperature is above a minimum value, as discussed in Chapter 20. If straight two-position control is used for this application, the *on* and *off* periods are relatively long and there is a tendency towards cold drafts on the floor during off periods. If timed two-position control is used, the burner may be cycled (started and stopped) often enough to provide results very comparable to proportioning control. The heat input to the home is proportioned continuously to the heat loss from the home. The fan of a forced warm air system or the circulator of a forced hot water system may be run almost continuously, thus minimizing the possibility of cold drafts.

Proportional control is used on residential applications when provisions are made for it in the design of the system. Face and bypass dampers on warm air systems, throttling valves on steam systems and three-way mixing valves on hot water systems are typical examples of controlled devices which permit proportional control. With these arrangements the burner usually is controlled by a thermostat in the furnace or boiler. Proportional control will permit nearly continuous circulation of warm air or hot water, thus reducing cold drafts.

Automatic night set-back through the use of a day-night type room

thermostat is a refinement frequently added to residential control systems. Though opinions vary regarding the amount of fuel that can be saved by automatic night set-back, tests made both in the warm air heating research residence and the I=B=R research home at the University of Illinois indicate that, on thermostatically controlled systems, a possible fuel saving of from 7 to 10 percent may be obtained by reducing the house temperature 6 to 10 F from about 10:00 p.m. to 5:30 a.m.

It is often desirable to divide the house into two or more zones for greater accuracy of control and comfort. Each zone may then be maintained individually at the desired temperature level. The division into zones should be based upon exposure or occupancy; the most common division is usually found to be (1) the living section such as living room, dining room, den; (2) the sleeping section; (3) the service section such as kitchen, pantry, servants' quarters; and (4) the recreational areas.

Further discussion of zone control will be found in the following section on Zone Control and Zone Control Systems.

Year-round residential air conditioning systems which provide for heating in winter and cooling in summer should be given the same consideration in selecting the control system as required for commercial air conditioning systems. See Chapter 30. The basic principles are the same and the final results must provide for the comfort of the occupants. A reduction in investment for automatic controls may result in wasteful operation of the system and discomfort for the occupants.

Special thermostats have been designed to take care of the year-round residential air conditioning systems. These thermostats offer manual, semi-automatic, and automatic changeover from heating to cooling as selected by the unit manufacturer. Generally speaking, the heating unit is controlled by timed two-position action and the cooling unit by straight two-position action. Some form of humidity control may be added.

When an *add-on* unit is installed to obtain a year-round air conditioning system by change of straight heating system, it may be controlled separately or integrated with the heating control system. However it is accomplished, the control system should be simple enough for the user to understand how to operate it effectively.

### ZONE CONTROL

Zone control for any heating, ventilating or air conditioning system is employed where it is desired to control the heating or cooling effect in a number of rooms or areas, having similar orientation or occupancy, through one set of controls. For zone control to be successful the requirements must be approximately consistent throughout the extent of the zone. Whether zoning a building for heating or cooling the following factors should be considered in determining the number and arrangement of the zones:

1. *Exposure.* Solar effect, prevailing winds, and the shelter afforded by surrounding structures affect the heat gain or loss.
2. *Occupancy.* Indoor temperature requirements for the various activities carried on in different portions of the building and the hours of occupancy of the various spaces impose definite control problems.
3. *Building Structure.* The physical characteristics of the building will influence the subdivisions of the system into zones since satisfactory temperature conditions throughout a single zone of given extent may not be enjoyed equally in buildings of dissimilar types of construction. Other factors are the height of the building and its horizontal extent and form.
4. *Floors.* Even though several floors have the same wall exposure, it is advisable

to have separate zones on the lowest and highest floors due to variations of basement or ground floor requirements and those with roof exposure. It is also desirable to have a separate zone or zones for the intermediate floors.

The initial investment will often influence the decision as to the final number of zones to be employed. In larger buildings accepted practice is to have at least one zone for each exposure. Each exposure may require subdivision vertically into two or more zones for the higher structures. Also, the presence of two or more wings having the same general exposure may suggest the desirability of more restrictive zoning. When the street floor or any other portion of the building is used for public occupancy or activities which differ from those carried on in the remainder of the building, it is desirable to provide separate thermostats and controls for each individual area.

Zone controls alone may not provide satisfactory temperature conditions in all rooms or areas within the zone because occupancy, lighting load, space arrangements and similar factors cannot always be predicted with accuracy. A combination of zone controls with individual room control in critical areas may be necessary to achieve complete satisfaction.

### ZONE CONTROL SYSTEMS

This section is concerned with zone controls for steam or hot water heating systems.

Most zone control systems are designed to supply heat to a zone at a rate equal to the heat loss. This rate of heat input may be established by room thermostats, by controllers responsive to outdoor conditions, or by a combination of both. The outdoor controller responds to temperature and may respond to solar radiation and wind velocity and direction. Features which may be added to the basic zone control system include:

1. Means for automatically or manually varying the heat input to the zone to compensate for variations in internal heat gain. The automatic arrangement requires a thermostat at a representative location within the zone. The manual arrangement usually consists of a switch located where convenient.
2. Means for maintaining a lowered economy temperature or shutting off the heat completely at night or at other times when the zone is unoccupied. This may be accomplished manually or by means of a clock.
3. An arrangement providing rapid warm-up following a period at the non-occupancy temperature. During this warm-up period full heat may be admitted to the system or the heat input may be controlled at a higher-than-normal rate. The warm-up may be accomplished by a manual switch or may be part of the clock program. A warm-up thermostat located within the zone may be arranged to terminate the warm-up period independently of the switch or clock when the zone approaches the desired occupancy temperature.
4. A manual switch to provide full heat or no heat independently of other controls and to permit manual selection of the various clock functions.
5. Means for shutting off the heat completely when the outdoor temperature reaches a point where heat no longer is needed.
6. A high limit thermostat in the zone to shut off the heat completely when the zone becomes overheated.

### Steam Heating Systems

In *continuous-flow steam systems* the quantity of steam supplied to the zone is varied in accordance with the demands of the control system. To obtain equalized distribution of the steam, metering orifices are generally required on the inlets to all radiators or convectors. Supplementary controls for low heat output are often desirable. The following two arrangements are common:

1. Varying the difference in pressure between the supply and return which results

in partially filling the heating units in accordance with demand. This method can be used on atmospheric or vacuum return systems.

2. Varying the pressure in the system while maintaining a constant differential pressure between the supply and return. This results in the heating units being filled with steam at a temperature which is proportional to demand. A vacuum pump maintaining a vacuum slightly below the supply pressure is required, and vacuums as high as 20 in. Hg during mild heating weather are common.

In *intermittent systems* steam at full pressure is supplied intermittently to the zone, the length of the *on* and *off* periods being varied in accordance with the demands of the control system. Two common arrangements are:

1. A timing device controlled by an outdoor thermostatic element which can be used to vary the on-off periods of boiler operation or the opening and closing of a steam valve as a function of outdoor temperature.
2. A control responding to an outdoor element and an element attached to a radiator or convector, so that it varies the length and frequency of the on-off intervals in such a way that the radiator or convector temperature is varied in accordance with outdoor temperature.

FIG. 7. CONTROL OF HOT WATER HEATING WITHOUT DOMESTIC HOT WATER SERVICE  
(Limit and primary controls not shown)

For proper operation of zone control equipment the heating system must be carefully designed and installed, and maintained in good operating condition. Vents, traps, vacuum pumps and valves must be given a careful inspection and repaired or replaced when required. Piping must be of adequate size graded and dripped. Return piping must be vented and any pockets or lifts removed.

### Hot Water Heating Systems

A common method of obtaining zone control of hot water systems consists of varying the temperature of water supplied to the zone inversely as the outdoor temperature varies. This may be accomplished by a submaster thermostat in the zone supply line readjusted by an outdoor master thermostat, or by a single controller having one measuring element in the supply line and another compensating element outdoors. On single zone installations the controller may actuate the burner directly as shown in Fig. 7. If the boiler is also used for domestic hot water the controls may be arranged as in Fig. 8. In this case the boiler is controlled at a fixed temperature and the zone controller is arranged to operate a valve to proportion hot water from the boiler with cooler return water to obtain the desired zone water temperature. On multiple zone installations the boiler usually is controlled at a fixed temperature, and each zone is controlled by a separate valve and outdoor compensated controller. Each zone should be equipped with a

separate pump because in many cases the return water from some zones is warmer than the required supply water for other zones. By using individual zone pumps the returns can be separated and thus prevent overheating that would otherwise occur.

To compensate for variations in internal load, the action of the zone control may be modified by a room thermostat in each zone which either starts and stops the zone pump, modifies the relationship between outdoor temperature and water temperature, or operates an automatic valve in the zone supply or return line. Each zone may be further subdivided by providing a separate thermostat and valve for each subdivision.

Another zone control method for hot water systems consists of maintaining a constant water temperature and varying the volume of water supplied to the zone by means of a room thermostat which either starts and stops the zone pump or operates a two-position valve in the zone supply or return line.

Whenever flow control valves are employed in water circuits it is necessary to employ a relief valve or pressure-regulating valve in a bypass connection around the pump.

FIG. 8. CONTROL OF HOT WATER HEATING WITH PROVISIONS FOR DOMESTIC WATER HEATING  
(Limit and primary controls not shown)

### PANEL HEATING SYSTEMS

Automatic controls for panel heating differ somewhat from those described for convective heating because of the thermal inertia characteristics of the panel heating surface and the increase in the mean radiant temperature within the space under increasing loads for panel heating. However, many of the same control principles for hot water heating systems will also apply to panel heating.

Panels such as concrete slabs have large heat storage capacity and continue to emit heat long after the room thermostat has shut off the supply of heating medium. In addition, there is a considerable time lag between thermostat demand and heat delivery to the space due to the large part of the heat which must first be stored in the thermally heavy radiant surface. This inertia will cause uncomfortable cycling of space conditions unless controls for detecting load changes as early as possible are provided.

In general, the temperature of the heating medium supplied to the panel surface should be varied in accordance with outdoor temperature, as described in the first paragraph under Hot Water Heating Systems in the section on Zone Control Systems. Controls indicated in Figs. 7 and 8 apply and, in addition, consideration should be given to preventing the introduction of excessively hot water in the event of control failure which might

damage the panels, and to a manual boiler bypass or other means of reducing the water temperature to prevent too rapid drying out of new panels (see Chapter 24, Panel Heating). Due to the increase in MRT (mean radiant temperature) within a panel heated space which necessarily takes place as the heating load increases, the air temperature under such conditions, theoretically, should be lowered in the order of 1 or 2 degrees to maintain comfort. In ordinary structures with normal infiltration loads the required reduction in air temperature is small and, consequently, a conventional room thermostat may be used.

In panel heating systems, lowered night temperatures will produce unsatisfactory results with heavy panels such as concrete floors. These panels cannot respond to either quick increase or decrease in heating demand within the relatively short time required, with the result that there will be a very slow reduction of space temperature at night and a correspondingly slow pick-up in the morning. Panels of light weight construction, such as plaster or metal ceilings and walls, may respond to changes in demand with sufficient rapidity that moderately satisfactory results can be expected from lowered night temperatures. However, very little fuel saving can be expected even with the light panels unless the lowered temperature is maintained for long periods. If reduced non-occupancy temperatures are employed, some means of providing a higher-than-normal rate of heat input for rapid warm-up is necessary, or a long warm-up period should be provided for, as explained under Zone Control Systems.

### INDIVIDUAL ROOM CONTROL

The ideal temperature control system for any building is one that promotes maintenance of the desired temperature in every room at all times regardless of location and occupancy. Individual room temperature control is desirable for securing proper thermal environment in schools, hospitals and offices.

Control of the temperature in each room, or possibly of adjacent rooms having the same orientation (as in an apartment), overcomes many of the problems encountered when attempting to regulate the temperature of a building as a whole or of large areas or zones. Each individual thermostat controls the heat input to its particular space regardless of occupancy or exposure to sun and wind. The advantage of individual room control is in fuel economy and comfort for the occupants. Each room should have a thermostat that controls valves or dampers on all the controllable sources of heating and cooling. One such uncontrolled source may prevent proper operation of the control system.

### CONTROL OF CENTRAL FAN SYSTEMS

Local practice, local climatic conditions and economic factors influence control system design.

The following sections describe some of the more common methods of controlling the different pieces of equipment used in central fan systems. The complete control system is made up by combining the selected method for each item into an integrated arrangement with proper consideration being given to the interrelation of the several parts, necessary sequence of operations, etc.

#### Outdoor Air Damper Control

Outdoor air for ventilation is usually controlled by a damper arrangement to provide a homogeneous mixture of outdoor air and recirculated air. Outdoor air to meet minimum ventilation requirements should be available

whenever the fan is running and is usually provided in one of the following ways:

- By a minimum outdoor-air damper which opens when the fan is started. A maximum outdoor-air damper may also be provided if additional outdoor air for natural cooling is desired.
- By an outdoor-air damper opening to a minimum position when the fan is started. Additional outdoor air is provided by further opening of the damper under automatic control.

Recirculated-air and exhaust-air dampers are synchronized to operate with the outdoor air dampers. Mechanical interconnections are preferable but separate operators on each of the dampers can be used when mechanical interconnections are impractical. Control of outdoor air quantities beyond the minimum amount can be accomplished by:

- A thermostat set for about 55 F and having its bulb located where there is a true mixture of outdoor air and return air.
- A thermostat in the outdoor air which will gradually open the outdoor-air damper as the outdoor-air temperature increases during mild heating weather.
- A combination of outdoor-air and return-air thermostats operating to select the cooler source of air when cooling is required.
- The preheater thermostat, arranged so that after the preheat valve is closed the outdoor-air damper gradually opens.
- The apparatus dew-point thermostat, arranged so that the outdoor-air damper opens before mechanical cooling is used.

In most arrangements provisions are made to prevent admission of more than minimum outdoor air required for ventilation both during heating operation and when the outdoor-air temperature is too high to provide some natural cooling. Provisions should also be made to close the outdoor-air damper and open the return-air damper whenever the fan is stopped.

#### Preheater Coil Control

The function of a preheater is to temper the outdoor air to prevent the possibility of freezing beyond the coil. Care must be taken to avoid freezing in the coil itself. The proper selection, installation and sizing of steam traps are very important to assure rapid elimination of condensate to prevent freezing.

Steam-distributing-type coils usually are controlled by a thermostat located downstream from the coil and operating a valve in the steam supply line. Where a large temperature rise is required, two or more coils in series should be used, each having a separate valve. The valves should be arranged to operate in sequence, with the valve on the upstream coil opening first.

Non-distributing-type coils should be controlled by a thermostat located ahead of the preheat coil and adjusted to completely open the valve before the incoming air temperature drops to 35 F, to avoid freezing in the coil.

It is important that the preheat coil and its valve be selected so as to prevent overheating the conditioned space when the valve is fully open at 35 F incoming temperature. The use of preheat coil-face and bypass dampers will permit proportional control from a thermostat located beyond the preheat coil, and will prevent such overheating. The coil valve should be wide open whenever the incoming air temperature is below 35 F.

Hot water preheat coils should be controlled by face and bypass dampers operated by a thermostat downstream from the coil, with continuous water circulation when the outdoor air is below freezing. A pressure switch to stop the fan in case of pump failure is often employed. Further freeze protection can be accomplished by a thermostat in the coil outlet arranged

to stop the fan if the water temperature approaches 35 F. In all applications where face and bypass dampers are used, precautionary measures must be taken to prevent stratification of the mixture beyond the coil.

#### Reheater Coil Control

Reheat coils when used for tempering air for ventilation can be controlled by a proportional insertion thermostat, preferably located in the fan discharge to minimize the effect of stratification. This thermostat operates the reheat coil valve or valves, or face and bypass dampers, to maintain a constant discharge air temperature. When face and bypass dampers are used it is good practice to have a valve on the coil which closes after the face damper is closed to prevent overheating due to radiation from the coil or to damper leakage. When used for space heating, reheat coils are controlled by valves or face and bypass dampers actuated by a thermostat in the space or the return air. Usually a low-limit discharge thermostat is used in conjunction with the space or return-air thermostat to maintain the delivered air temperature above the design minimum. To avoid the lag associated with room or return-air control of the reheat coil, it often is preferable to use a controller in the fan discharge which is compensated by space temperature.

#### Humidity Controls

Steam-pan or grid type humidifiers usually are controlled by a valve actuated by a proportional room or return air humidistat or wet-bulb thermostat. The valve should close when the fan stops.

Single-bank sprays, when used primarily for humidification, are usually controlled by a two-position room or return-air humidistat or a wet-bulb thermostat operating a valve in the water line or starting and stopping the pump. Air washers should be run continuously and are usually controlled by varying the temperature of the washer water or the air entering the spray chamber. An apparatus dew-point thermostat with its measuring element located in the air washer water, or in the outlet of the washer beyond the eliminator plates, may be used to (1) operate a mixing valve, or a steam valve on the water heater, to control the washer water temperature; (2) control a valve on the tempering coil ahead of the washer; (3) operate outdoor-air and return-air dampers to control the mixed air temperature entering the washer; or (4) operate a combination of these arrangements.

#### Cooling and Dehumidification Controls

Dehumidification by condensation is so closely related to sensible cooling that it is convenient to discuss them together. Three typical applications of controls are discussed.

**Direct Expansion Systems.** A thermostat measuring the space temperature may be used to open and close a solenoid refrigerant valve on the coil inlet; control the starting and stopping of one or more refrigerating compressors, or otherwise control the compressor capacity; position face and bypass dampers, or a return-air bypass damper, in combination with the opening and closing of the refrigerant coil valve or the starting and stopping of the compressor; control a back pressure regulating valve with proportional action; or control a liquid-refrigerant valve on the inlet to the coil with proportional action. The positive opening and closing of the refrigerant valve or the starting and stopping of the refrigeration compressor will result in wide variations in discharge temperature and dehumidification. When such variations are objectionable, it is desirable to employ proportional damper controls or proportional control of refrigerant flow in conjunction with refrigeration equipment capacity controls as discussed in Chapter 37.

**Chilled Water and Brine Coils.** A thermostat measuring the space temperature may be used to control a valve on the inlet or outlet of the cooling coil; control a

#### Automatic Control

three-way mixing valve; position face and bypass dampers at the coil; or position a return-air bypass damper. An apparatus dew-point thermostat may also be used to control the cooling coil valve.

**Air Washers.** Since the air leaving an efficient washer is practically saturated, the temperature of the spray water will determine the dew-point temperature of the air leaving the washer. With this condition it is possible to maintain very accurate dew-point temperatures and consequently accurate relative humidities under a given ratio of sensible-to-latent heat gain in the conditioned space, provided the space dry-bulb temperature is accurately controlled. In general, the water pump operates continuously and a thermostat measuring the dew-point temperature is used to position a three-way valve to mix refrigerated water with bypassed washer water. To compensate for variations in latent load, a humidistat measuring the space relative humidity may be employed as a master controller to readjust the set point of a dew-point submaster controller.

#### Static Pressure Control

Since fans are selected to produce the desired results for a certain system characteristic, any change in the system characteristic will change the output of the fan. Such changes occur, for example, on single-duct systems in which the volume of air delivered is varied and in double-duct systems where quantities of air are shifted from one duct to the other to obtain final space control. System characteristics may also change when the relative quantities of outdoor air and recirculated air are varied, when exhaust fans are run intermittently, and for other reasons. Such changes result in a changing static pressure in the system, a changing noise level, and changing velocities at air outlets which upset the air flow patterns.

Static pressure control of some form is usually required on such systems, and it is accomplished by a static pressure controller measuring the pressure at a selected point in the system with respect to an atmospheric reference point or some other point inside the building. It can be used to actuate a damper operator on fan inlet vanes, on a multi-blade damper on the suction or discharge side of the fan, or on a damper in a bypass connection between the fan discharge and the fan suction.

#### Control of Final Space Conditions

It is sometimes satisfactory to control the entire area or zone served by a central fan system from a single point as described in previous sections relating to reheat coils, humidifiers and to cooling and dehumidification. The factors to be considered in properly zoning the building are discussed in the section on zone control. Where the entire area does not meet the requirements of a single zone, it may be subdivided so that the air distribution system can be arranged for individual control of each smaller area. This may be accomplished by a thermostat in each space operating warm- and cold-air mixing dampers in the duct serving the space, or operating valves on individual reheat or cooling coils for each space. By providing a sufficient number of subdivisions of the area served by a central fan system, individual room control can be achieved.

#### Control of a Typical System

Fig. 9 shows a complete control arrangement for a typical central-fan air conditioning system in which individual room control is not provided. The controls can be pneumatic, electric, or electronic.

When the fan is started relay E-1, actuated by the fan-motor starter, opens outdoor-air damper D-1, places humidistat H in service, and allows insertion thermostat T-1 to operate preheat coil valve V-1, maximum-outdoor-air damper D-2, return-air damper D-3 and exhaust damper D-4. When the fan stops, E-1 is de-energized and closes the outdoor-air dampers and humidifier valve V-4.

The sequence of operation described will in general also apply to high-pressure

fan systems except that it is considered desirable to open the outdoor-air damper before starting the fan. With this arrangement, a manual switch operates damper D-1. A mercury contactor mounted on the damper starts the fan when the damper is fully open. It also stops the fan when the damper starts to close.

Insertion thermostat T-1 maintains a temperature of 65 F at the preheat coil discharge by operating preheat coil valve V-1. This serves as a low limit for the fan discharge temperature during heating operation. When V-1 is closed, thermostat T-1 then gradually opens maximum-outdoor-air damper D-2 and closes return-air damper D-3 proportionately. At 65 F outdoor temperature D-2 is wide open and D-3 is closed. Exhaust air damper D-4 opens and closes in synchronization with D-2. At 75 F outdoors, when the outdoor air is no longer useful for natural cooling, T-2 closes D-2 and D-4 and opens D-3.

Reheater coil valve V-3 is controlled by submaster thermostat T-3 in the fan discharge. This thermostat is automatically readjusted over an appropriate range of temperature by room thermostat T-4 so that the discharge temperature matches

FIG. 9. CONTROL DIAGRAM FOR TYPICAL CENTRAL FAN AIR CONDITIONING SYSTEM

the space requirements. When the room temperature tends to rise above a predetermined value, T-3 has been readjusted downward far enough to keep reheat valve V-3 closed. T-4 then controls cooling coil valve V-2 directly to maintain the desired space temperature.

Humidistat H operates humidifier valve V-4 to maintain the desired humidity in the conditioned space. It is usually adjusted to maintain 30 to 40 percent relative humidity, and therefore keeps the humidifier off during cooling operation when the humidity is higher.

### AUTOMATIC CONTROL OF UNIT HEATERS

The controls for a unit heater can either provide (1) on-off operation of the unit fan or (2) continuous fan operation with modulation of the heat output.

For on-off operation a room thermostat is used to start and stop the fan motor. A limit thermostat, often strapped to the supply pipe, prevents fan operation in the event heat is not being supplied to the unit coil.

Continuous fan operation practically eliminates the intermittent blasts of hot air resulting from on-off operation, and the stratification of tempera-

ture from floor to ceiling which often occurs during the off periods. In this arrangement a proportional room thermostat controls a modulating valve in the steam or hot water supply line to the coil. A limit thermostat or auxiliary switch stops the fan when the valve is closed.

Unit heaters may be used in summer as a means of circulating air to give some measure of comfort due to air motion. In such cases the source of heat should be shut off and the thermostat should be provided with a bypass switch which will permit fan operation independently of the controls.

### AUTOMATIC CONTROL OF UNIT VENTILATORS

Many different control cycles are available. The principle difference in the various cycles pertains to the amount of outdoor air delivered to the room during normal periods of heating. The choice may be governed by compulsory ventilation codes.

Usually a room thermostat controls both a valve to regulate the heat supply and a damper to regulate the supply of cool outdoor air. An insertion thermostat at the unit ventilator prevents the discharge of air below the desired minimum temperature. Any auxiliary heating devices in the same room should be controlled, by the room thermostat, in the proper sequence to fit into the unit ventilator cycle during the following stages:

**Warm-up Stage.** All control cycles function to provide rapid warm-up by having all heating valves wide open and the outdoor damper closed. Thus 100 percent room air is recirculated and heated until the room temperature approaches the desired temperature level.

**Heating and Ventilating Stage.** As the room temperature rises into the operating range of the thermostat, ventilation is accomplished by the partial or complete opening of the outdoor damper according to the cycle used. Valves on auxiliary heating devices are often closed at about the same time. As the room temperature continues to rise the unit ventilator valve is throttled as required to control the heat supply.

**Cooling and Ventilating Stage.** When the room temperature rises above the normal level, cool air is discharged into the room. The room thermostat accomplishes this by throttling the valve further, and then closing it and opening the outdoor damper, if necessary, to prevent the room from overheating. The insertion thermostat frequently takes control during this stage to prevent the discharge of objectionably cold air.

The three basic control cycles commonly used are as follows:

**Cycle X.** A fixed percentage (often 100 percent) of outdoor air is admitted at all times except during the warm-up stage.

**Cycle Y.** A minimum amount of outdoor air (normally 25 to 50 percent) is admitted during the heating and ventilating stage. This percentage is gradually increased to 100 percent, if needed, during the cooling and ventilating stage.

**Cycle Z.** Except during the warm-up stage a variable amount of outdoor air is admitted as needed to maintain a fixed temperature of air entering the heating coil. This is controlled by the insertion thermostat which must be set low enough (often 60 F) to provide cooling when needed.

Day-night thermostats are often used with unit ventilators. Separate switching circuits are used to permit daytime temperatures in some areas and lowered temperatures in others for maximum economy. Several day-night arrangements are in common use. One uses the unit as a convector. Another turns the fan on and off like a unit heater. More elaborate arrangements are available.

### PART III—DESIGN COORDINATION

A heating or cooling system is designed to meet maximum conditions but functions at partial capacity much of the time. The ability to properly

control the system at all times is one of the most important factors having to do with the design of the system and for this reason the proper use and application of controls should be considered at the time the heating or cooling system is being designed. Wherever possible the system should be designed to facilitate control operation. This section includes factors which should be considered in the design of a new heating or cooling system, or the modernization of an existing one, to enable the control system to produce the best possible results.

The design of the system and its controls should take into consideration the nature and type of the building in which it is to be used and the results it is desired to accomplish. Quality of the control equipment should be consistent with the accuracy of control required. Where results more precise than those for normal comfort applications are required, such as in certain manufacturing areas, constant temperature rooms, etc., both the air conditioning system and the control system should be given special consideration so that the required results can be produced. Controls can be made to produce almost any degree of accuracy required, but it is useless to provide such controls unless the air conditioning system is capable of properly responding to the demands of the controllers. For example, it is virtually impossible to maintain close control of temperature and humidity by starting and stopping a refrigeration compressor or opening and closing a refrigerant valve. It is necessary instead to employ refrigeration equipment which will permit proportional control by one of the methods discussed in Chapter 37, or to use a chilled-water system with a cooling coil or air washer that will permit proportional control. Neither is it good practice or economical to select equipment capable of producing far more precise control than the application requires, or to unnecessarily complicate the system to obtain special sequences or cycles of operation. It is well to remember that the system must be adjusted and maintained in operation for many years, and the simplest system that will produce the necessary results is usually the best.

### SIZE OF CONTROLLED AREA

No individually controlled area should be excessively large because the difficulties of obtaining good distribution and of finding a representative location for the space controls become greater as the area increases. Each individually controlled area must have similar load characteristics throughout and otherwise should conform to the recommendations given in the section on Zone Control. For uniform conditions throughout the area equitable distribution must be provided by competent engineering design, careful sizing of equipment and proper balancing of the system. The control can measure conditions only at the point where it is located, and it cannot compensate for variable conditions throughout the area caused by improper distribution or inadequate design. Areas or rooms having dissimilar load characteristics, or having different conditions to be maintained, should be individually controlled. The smaller the controlled area the better will be the control obtained and the more nearly will the system approach the optimum in performance and flexibility.

Even when individual room control is employed it often is well to consider some form of overall zone control of the whole system in accordance with the major factor influencing system load. Thus the water temperature in a hot water heating system, the steam temperature or pressure in a steam heating system, or the delivered air temperature in a central fan system may be varied inversely as the outdoor temperature varies. This obtains a fair share of the necessary control on the system as a whole, relieves the indi-

vidual space controls of a part of their burden and makes more accurate space control possible. Furthermore, modifying the basic rate of heating or cooling input to the system in accordance with system load reduces losses in the distribution system. The cost of the additional controls is often justified by the reduction in operating costs.

Where such overall system controls are employed, accurate zoning, while desirable, is not necessary. The system must always be able to satisfy the area or room having the greatest demand. The individual controls take care of the variations in demand within the area served by the system. The more accurately the system is zoned the larger will be the share of the control accomplished by the overall system controls, the smaller will be the system distribution losses, and the more accurately will the individual space controls be able to maintain the space conditions.

### EQUIPMENT SELECTION AND LAYOUT

Heating and cooling coils should be carefully selected to avoid oversizing. A coil that is too large is not only more difficult to control but may increase air temperature stratification. When temperature measuring elements are to be placed between coils, ample space between the coils must be provided. The measuring element should be located as near as possible to the coil it is controlling. For example, an idle water coil interposed between a thermostat and the coil it is controlling introduces enough thermal inertia to make it difficult to produce stable control.

The elimination of stratification in an air handling system is essential not only in producing good control but in obtaining equitable distribution of heating or cooling. Outdoor-air and return-air dampers should be arranged in such a way as to help blend the outdoor air and return air. Face dampers should be placed far enough from coils to allow for equalization of air flow over the coil surface. The controller for face and bypass dampers must be located far enough downstream so that the air has become thoroughly mixed before reaching the controller. Other sources of stratification are coils which heat or cool unevenly and coils arranged in parallel and controlled in sequence. Whenever stratification cannot be eliminated by proper design or arrangement of equipment, special baffles, mixing chambers or other mechanical devices should be used for this purpose. If stratification still exists at a point where the measuring element of a thermostat is to be located, the use of a long averaging element, or one made up of a number of small elements, may make a suitable temperature measurement possible. This does not solve the other problems relating to stratification which can cause discomfort or, in extreme cases, freezing of equipment.

Good air distribution and properly spaced diffusers and grilles will greatly assist in maintaining even temperatures throughout an area. A space temperature controller cannot prevent drafts. This can be accomplished only by proper attention to such factors as balancing the system, by introducing air in the correct manner, and by providing a suitable low-limit control on the delivered-air temperature. A system that employs constant air volume with variable air temperature results in more uniform distribution than one which requires variations in air volume to achieve temperature control. Varying the volume of air affects both ventilation and distribution, two factors which usually have little relation to thermal requirements. Return air grilles usually can and should be located so as to aid both the distribution and control of the system.

A further aid to both distribution and control is the provision of adequate facilities for exhausting air from the building. The larger the percentage of outdoor air introduced the more important becomes the provi-

sion for adequate exhaust. To prevent drafts due to infiltration, it is quite common to provide for positive exhaust of less air than is brought in. On systems where the quantity of outdoor air is large but constant, this may be accomplished by use of a properly sized exhaust fan. Systems having large internal heat gains, or large solar gains, may use a variable amount of outdoor air up to 100 percent when cooling is required during cool weather. In such cases the outdoor-air quantity may be controlled from space conditions and the quantity of exhaust air may be controlled by a static-pressure controller set to maintain the space under a slight positive pressure.

### LOCATION OF SPACE CONTROLLERS

Space controllers such as room thermostats must be placed where they will measure the variables they are to control and where the condition is representative of the whole area served by the controller. If the return-air duct is used to represent space conditions, the controller should be located as near the space as possible to eliminate the effect of any heat gain or loss in the duct.

Room thermostats should usually be placed in occupied areas on inside walls or columns. They should never be placed in spaces such as corridors, lobbies, and foyers unless they are used for the control of these areas only.

In a typical home which is not zoned a satisfactory location for a room thermostat can usually be found on an inside wall of the living room or dining room. It should always be located toward the center of a relatively open room on the coolest rather than the warmest side of the building. It should not be mounted on an outside wall or other cold surface where it is exposed to cold drafts from an outside door. Neither should it be mounted where it will be affected by direct rays of the sun, by heat from a nearby warm surface such as a chimney, pipes or ducts in the wall, or radiators, or by direct air currents from a register. The location should provide ample air circulation unimpeded by furniture or other obstructions, and should afford protection from mechanical injury.

### THE CONTROL OF STEAM FLOW

The size of an automatic steam valve is based on the required capacity at maximum load, under the conditions which will exist at that time. Equation 52, Chapter 4, for mass flow through an orifice or nozzle can be rewritten as

$$w = C_A \sqrt{P_1 - P_2} \quad (1)$$

where

$w$  = the flow of steam in pounds per hour.

$A$  = the area of the port opening in square inches.

$P_1$  = the steam supply pressure, pounds per square inch, absolute.

$P_2$  = the downstream pressure, pounds per square inch, absolute.

$C$  = a constant for a given steam supply pressure and a given valve body.

Valves for two-position operation usually are selected of a size adequate to supply the required maximum capacity with a reasonably low pressure drop ( $P_1 - P_2$ ). It is necessary only to be sure that the valve will close against the system pressure and will have ample capacity when fully open.

Proportional valves for steam service must be carefully sized if stable control is to be achieved. In general the tendency is to oversize such valves and no controller can produce its best results if handicapped by a valve which is too large. The function of the valve is to vary the value of

area  $A$  in Equation 1 and it is desirable that the flow vary in proportion to the value of  $A$ . The correct maximum required capacity must first be determined. There should be no factor of safety in this determination, and it should be based on actual heating requirements rather than on the condensing capacity of the coil, since the coil may be larger than necessary. It is also necessary to base the valve size on the actual supply pressure ( $P_1$ ) which will exist at the valve, since this supply pressure affects both the density of the steam and the pressure drop which will be selected.

Selecting the proper pressure drop ( $P_1 - P_2$ ) across the valve when it is wide open and is supplying the maximum steam requirement is the most important consideration in determining the valve size. For purposes of discussion it will be assumed that  $P_1$  is constant and that the valve is supplying steam to a heating coil which has air entering at a constant temperature and velocity. Any pressure drop between the valve and the coil will be neglected so that  $P_2$  represents the pressure in the coil. The condensing capacity of the coil varies with changing values of  $P_2$ . When the valve is fully open,  $P_2$  assumes a value such that the capacity of the valve and the condensing rate of the coil are in balance. If this value of  $P_2$  is relatively large, then as the valve is partially closed  $P_2$  will decrease until the capacity of the valve and the condensing rate of the coil are again in balance. Reducing the value of  $A$  in Equation 1 results in an increase in the value of  $\sqrt{P_1 - P_2}$  and partially offsets the effect of closing the valve. This effect is greatest when  $P_2$  is nearly equal to  $P_1$  and diminishes as  $P_2$  decreases.

The minimum value which  $P_2$  can assume is established by the return line pressure (or vacuum) of the system. However,  $P_2$  may reach a value which results in the critical velocity through the valve before it has been reduced to its minimum value. If so, any reduction of  $P_2$  beyond this value has no further effect on the valve capacity. The critical velocity exists when  $P_2$  is approximately 58 percent of  $P_1$ . The undesirable effect caused by variations in  $P_2$  can be eliminated by selecting a valve size such that  $P_2$  is at or near its minimum value, or the value corresponding to the critical velocity, whichever is higher, when the valve is wide open.

On low pressure steam applications it is good practice to base the valve size on a pressure differential equal to 75 or 100 percent of the gauge supply pressure. When the supply pressure is high enough so  $P_2$  at the critical velocity (58 percent of  $P_1$ ) is above atmospheric pressure, the valve size can be based on a pressure differential of 42 percent of  $P_1$  absolute. All valves of the same size do not have the same capacity for a given pressure differential. Having established the supply pressure and the pressure differential, the valve manufacturer's tables or charts should be consulted in selecting the proper size of valve for the required capacity.

It is important that the supply pressure to an automatic steam valve be constant because it is difficult for a thermostat to produce stable results if the pressure is constantly changing. This situation arises, for example, when a steam boiler is operated by a two-position pressure controller. A pressure reducing valve, which will supply a constant pressure to the steam mains while permitting the boiler pressure to fluctuate between the limits of the pressure controller, is recommended. Lacking this, the differential of the pressure controller should be set as narrow as is consistent with efficient boiler and burner operation. On vacuum return systems the vacuum pump also should operate on a narrow differential.

The use of two automatic control valves in parallel will often provide more stable control than a single larger valve, especially on large coils or steam-to-water heat exchangers. The valves should be sized so that one

valve handles about one-third of the total capacity and the other about two-thirds. They are controlled in sequence so that the small valve operates during periods of light load and the large valve begins to open only after the load exceeds the capacity of the small valve.

The steam piping from the valve to the coil inlet, and from the outlet to the trap should be the full size of the coil tapping or size specified by the manufacturer of the coil and should conform to good standard practice as illustrated in Chapter 21. It is very important that condensate be promptly drained from the coil. When the coil is at reduced pressure, as it will be much of the time, there will not be sufficient difference in pressure between the coil and the return line to obtain any lifting of the condensate.

### THE CONTROL OF WATER FLOW

The capacity of a proportional valve for water service is not influenced by the supply water pressure but only by the pressure differential. If a certain water circuit has a total resistance of 30 psi at maximum flow, of which 1 psi is through the valve, the resistance of the rest of the circuit is 29 psi. When the valve is closed and there is no flow, the entire 30 psi resistance is across the valve. Thus the pressure drop across the valve increased by a ratio of 30:1 as the valve closed. This increase in pressure drop as the valve opening is decreased offsets partially the effect of closing the valve. It is obviously impracticable to design a water system such that there will be no increase in pressure drop across the valve as it closes. However, it is important to design the system, including the valve, in such a manner that the ratio of this increase in pressure drop as the valve closes is kept as low as possible. Thus, if the design pressure drop across the valve is 5 psi instead of 1 psi, the ratio of increase is only 6:1 instead of 30:1 and the performance of the valve will be improved accordingly. This discussion assumes a circuit in which the entire flow is controlled by a single valve. The same reasoning will apply to the more complicated systems involving a multiplicity of parallel circuits, each having a valve. In general it can be said that the pressure drop across a water valve at full flow should be a reasonable percentage of the resistance of the circuit in which the valve controls the flow. Due consideration should be given to any resultant increase in pumping head and operating costs.

Water circuits involving variable flow are subject to variable pressures in accordance with the pressure vs flow characteristic of the pump. On such circuits it is desirable to provide pressure control by means of a bypass connection around the pump. This bypass connection either has a spring-loaded relief valve, subject to the system pressure difference, or an automatic control valve operated by a differential pressure controller. The total resistance through the bypass connection at full flow should be equal to the total system resistance.

## CHAPTER 40

### MOTORS AND MOTOR CONTROLS

Fundamentals of Motor Selection; Alternating Current Motors, Types and Control Equipment; Motor Rating; Functions of Motor Control Equipment; Glossary of Motor Terms, Enclosures, Speed Classification and Mounting

THE electric motor, available in many different types suitable for various services, is now the most widely used form of motive power. The equipment for starting, controlling and protecting these motors varies with the type and with the functions it is desired to attain. Motors are divided into two general classifications, *alternating-current* or *direct-current*, depending on the power source to be used.

### FUNDAMENTALS OF MOTOR SELECTION

The following characteristics of the *power supply* should be determined:

- (1) whether current is alternating or direct, (2) voltage, (3) alternating current phase, (4) alternating current frequency, (5) voltage regulation, (6) continuity of power.

1. *A-C vs. D-C Systems.* For most applications, a-c supply is satisfactory since suitable performance can usually be obtained with a-c motors and control. Where special characteristics, such as an extra wide speed range and severe accelerating or reversing duty are involved, conversion by means of motor generator sets, by rectifiers, or in special cases by converters, may be justified.

2. *Voltage.* Standard conditions of voltage and frequency are the values listed on the name plate of the motor. Reasonable horsepower design limits are given in Table 1. Power lines are often given voltage ratings known as *nominal system voltages* which are numerically slightly different from the standardized motor voltages.

3. *Phases.* Three-phase power supply is most desirable, but only single phase is offered for most residential and rural districts.

4. *Frequency.* Sixty-cycle systems predominate in the United States. In foreign countries, 50-cycle systems are common and nominal system voltages are frequently different.

5. *Voltage Regulation.* The voltage regulation of the power supply should be known in order to select motors which will deliver sufficient torque even with the probable drop in voltage, to start and carry the load. All induction motor torques and synchronous-motor starting and pull-in torques vary as the square of the voltage.

6. *Continuity of Power.* Dips in voltage from switching or other line disturbances may necessitate time-delay undervoltage protection, and, in case of synchronous-motors, high torque designs and resynchronizing control. Sustained low voltage may necessitate higher torque motors.

The following characteristics of the *driven machine* should be determined:

- (1) mechanical arrangement including position of motor and shaft, portability desired, drive connection, and space limitations; (2) speed range desired; (3) horsepower requirement; (4) torque; (5) inertia; and (6) frequency of starting.

1. *Mechanical Arrangement.* Arrangement of the driven machine usually determines whether a *horizontal* or *vertical* motor is needed. Horizontal motors are more generally available and less expensive; most grease-lubricated ball-bearing motors will operate in either position. Fractional-horsepower waste-packed sleeve-bearing

TABLE 1. REASONABLE HORSEPOWER DESIGN LIMITS FOR STANDARD MOTOR VOLTAGES

| POWER SUPPLY        | STANDARD MOTOR VOLTAGE | SUGGESTED MINIMUM HORSEPOWER | SUGGESTED MAXIMUM HORSEPOWER |
|---------------------|------------------------|------------------------------|------------------------------|
| Alternating 1-phase | 115                    | None                         | 1                            |
|                     | 230                    | None                         | 15                           |
| Alternating 3-phase | 110                    | None                         | 15                           |
|                     | 220                    | None                         | 200                          |

|                     | 2300                   | 1                            | 6000                         |
|                     | 4000                   | 50                           | 7500                         |
|                     | 4600                   | 100                          | 8000                         |
|                     | 6600                   | 250                          | None                         |
|                     |                        | 400                          |                              |

motors are satisfactory for short periods of vertical operation where no thrust is involved.

If shaft is tilted for momentary operation, special construction of bearing housings will be required for oil-ring-lubricated sleeve-bearing motors, to avoid loss of lubricant. In case of long periods of tilted operation, bearings suitable for end thrust may be necessary. Ball-bearing motors with grease lubrication are suitable for tilted operation.

Most motors are suitable for mounting with base above a horizontal shaft or to one side of the shaft, provided the end shields are rearranged. If, during operation, the angle of the motor (with regard to the horizontal shaft) changes more than 10 or 12 deg, a ball-bearing motor will usually be required. Sleeve-bearing motors are also applicable within the angle given if modified oil gages are provided.

On portable machines, motors of greater compactness and less weight than standard may be required, and special bearing construction may be needed, except for ball-bearing motors. Direct connection should always be considered where machine speed coincides with available motor speed.

Maintenance, efficiency, power factor, space and initial cost, will determine the choice between direct connection and other methods, such as belt, chain or gear drive. When direct connection is possible (where parts of the driven machine, such as shaft or bearings, are common with the motor structure) a built-in construction may be advantageous.

**Belt Drive.** Diameters and widths of pulleys or sheaves and center distances are factors in determining motor-bearing pressures and shaft deflection. Flat belts should not run at greater speeds than about 5000 fpm. Application of flat belting to vertical-shaft motors is difficult.

**Chain Drive.** The chain manufacture should be consulted so that the best drive on a basis of quietness and economy of operation may be selected.

**Gear Drive.** Compactness and arrangement of drive often indicate gear motors, which are obtainable in a variety of mechanical constructions with speed ratios of 3 to 1 upwards, and are generally limited to about 75 hp maximum. Where the pinion of ordinary spur gearing is mounted on the motor shaft, two-bearing motors

TABLE 2. SPEED RANGES FOR VARIOUS TYPES OF MOTORS

| POWER SUPPLY     | TYPE                                                         | SPEED RANGE            |
|------------------|--------------------------------------------------------------|------------------------|
| Single Phase a-c | • Brush-shifting repulsion motor                             | 3:1                    |
|                  | • Capacitor-motor with tapped winding                        | 2:1                    |
|                  | Multi-speed capacitor-motor                                  | 2 or 3 fixed speeds    |
| Poly-phase a-c   | Multi-speed squirrel-cage                                    | 2, 3 or 4 fixed speeds |
|                  | • Wound-rotor motor                                          | 2:1                    |
|                  | • 2-speed wound-rotor motor                                  | 4:1                    |
|                  | • Brush-shifting shunt motor                                 | 20:1                   |
|                  | • Brush-shifting series motor                                | 3:1                    |
|                  | Squirrel-cage motors with variable frequency supply          | Very wide range        |
| d-c              | Motor-Generator Set—D-c Drive Motor                          | Very wide range        |
|                  | Rectifiers—D-c Drive Motor                                   | Very wide range        |
|                  | Shunt-wound standard constant-speed motor with field control | 2:1 in some cases      |
|                  | • D-c motor with armature control                            | Wide                   |
|                  | Adjustable-speed motor                                       | From 3:1 to 6:1        |
|                  | Shunt motor with adjustable voltage supply                   | Very wide              |

\*Speed regulation relatively wide. Unsuitable for some loads.

are limited in horsepower ratings. Maximum pitch-line speed with steel pinions is about 1400 fpm.

The selection of the motor part of a gear-motor is the same as for a conventional motor.

Space limitations may affect the choice of motor and require (a) built-in construction; (b) a gear-motor; (c) forced ventilation using an external blower; or (d) a small frame with Class B or H insulation permitting higher temperature rise.

**2. Speed Range.** Where more than one speed or a range of speeds is required, one of the motor types listed in Table 2 may be applicable, depending upon the power supply and the speed range required.

**3. Horsepower Requirement.** The horsepower required by the driven machine determines the motor rating. Where the load varies with time, a horsepower vs. time curve will permit determination of the peak horsepower required. The calculation of the root-mean-square (rms) horsepower indicates the proper motor rating from a heating standpoint. In case of extremely large variations in load, or where shut-down, accelerating, or decelerating periods constitute a large portion of the cycle, the rms horsepower may not give a true indication of the equivalent continuous load, and the motor manufacturer should therefore be consulted.

Where the load is maintained at a constant value for an extended period (varying from 15 min to 2 hr, depending on the size), the horsepower rating required will usually not be less than this constant value, regardless of other parts of the cycle.

If the driven machine is to operate at more than one speed, the horsepower required at each speed must be determined.

**4. Torque.** The torque required to operate the driven machine at every moment between initial breakaway and final shutdown is important in determining the type of motor. A torque-speed curve is desirable and sometimes essential.

The starting torque or breakaway torque required by the driven machine may be as low as 10 percent, as in the case of medium-sized centrifugal pumps, or as high as 225 to 250 percent of full-load torque, as in the case of a loaded reciprocating two-cylinder compressor. The breakaway torque may vary greatly at different times because of frequency of start, temperature changes, type and amount of lubricant, etc. The motor torque available at the shaft must be well above the torque required by the driven machine, taking into consideration these variables as well as the possibility of low voltage and the type of starter used.

The torque required after breakaway for acceleration to full speed varies with different driven machines, remaining at a rather high value throughout acceleration for such machines as loaded compressors and plunger pumps. The torque delivered by the motor must at all points, up to full speed, be in excess of the torque required by the driven machine. The greater this excess torque, the faster will be the acceleration. The approximate time required for acceleration from rest to full speed is:

$$\text{Time in seconds} = (\text{rpm}) \times WR^2 \div (T \times 308) \quad (1)$$

where

(rpm) = full-load speed in revolutions per minute.

$T$  = average torque available for acceleration, foot-pound.

$WR^2$  = inertia of rotating parts, pound-foot square.

If the time to accelerate on full voltage is greater than about 20 sec, special motors or starters may be required to avoid overheating.

**5. Inertia of Driven Machine.** The inertia or flywheel effect  $WR^2$  of the rotating parts of the driven machine affects the accelerating time and, therefore, the heating of motors and control, particularly where reversing duty or frequent starting is involved.

Where synchronous motors are applied, the  $WR^2$  must be known, since the pull-in torque required of this motor varies approximately as the square root of the total  $WR^2$  of motor and load.

The  $WR^2$  of a rotating member of the driven machine which operates at a speed different from that of the motor may be converted to an equivalent value at the motor shaft by multiplying by

$$[(\text{rpm of rotating member}) \div (\text{rpm of motor})]^2 \quad (2)$$

**6. Frequency of Starting.** The frequency of starting the driven machine affects the motor and control by increasing their heating, particularly where accelerating

TABLE 3. CLASSIFICATION OF MOTORS

TABLE 3. CLASSIFICATION OF MOTORS

| TYPE                         | SPEED CHARACTERISTICS                  | FULL VOLTAGE            |                                           | HP RANGE         | APPLICATION<br>SEE FOOTNOTES<br>(a) to (e) |                                                                                       |

a. Drives having medium or low starting torque and inertia ( $WR^2$ ) such as fans and centrifugal pumps or reciprocating pumps and compressors started unloaded.  
 b. Drives having high starting torques, such as reciprocating pumps and compressors started loaded.  
 c. Similar to (a) except where frequent or hard starting (large  $WR^2$ ) requires a higher starting and accelerating torque.  
 d. Fans direct connected.  
 e. Starter drives.  
 f. Torque depends on hp rating and speed. See NEMA Standard MG1-4.10 on Motors and Generators.

time is prolonged by high  $WR^2$  and high load torques. In general, driven machines starting more than 4 to 6 times per hour may require special motors and control.

## ALTERNATING CURRENT MOTORS

Alternating current motors are divided into two main classifications: *polyphase* and *single phase* (see Table 3), according to the type of power supply. They are further subdivided by type of motor winding.

When polyphase power is available it is usually found more economical to apply polyphase motors in preference to single phase motors. A typical 5 hp, 1200 rpm capacitor start-induction run single phase motor, for instance, will cost approximately twice as much as the corresponding three phase *Design B* squirrel-cage motor. In addition, the polyphase motor has the advantage of higher efficiency.

TABLE 4. LOCKED-ROTOR CURRENT OF THREE-PHASE, 60-CYCLE MOTORS: AT 220 VOLTS<sup>a, b</sup>

<sup>a</sup> The locked-rotor current of three-phase, 60-cycle, constant-speed, induction motors, measured with rated voltage and frequency impressed and with rotor locked, shall not exceed the tabulated values.

<sup>b</sup> Locked-rotor current at other voltages shall be inversely proportional to the voltage.

<sup>c</sup> For 1 hp or less the value is given per hp.

## Polyphase Motors

The three types of polyphase motors are: *squirrel-cage induction* motors, *wound rotor induction* motors, and *synchronous* motors.

*Squirrel-cage* motors are specific by NEMA standards providing a variety of speed and torque characteristics. *Design A* motors provide normal starting torque at starting current in excess of *Design B* motors, and are suitable for constant speed application to equipment such as fans and blowers. *Design B* motors provide normal starting torque with NEMA starting current values shown in Table 4, which are acceptable by many power companies for full voltage starting. They are used for the same type of application as *Design A*. *Design C* motors provide high starting torque with starting current same as *Design B*, and are used on compressors started without unloaders, and on reciprocating pumps. *Design D* motors have high slip\* and are used with flywheels for widely pulsating loads on equipment such as reciprocating compressors and pumps where other motors would draw high peak currents. *Design F* Motors have low starting current and low torques. They are used on power systems of limited capacity. Careful application must be made since the low breakdown torque provides only limited safety margin for overload or low voltage conditions. A drop in voltage, for instance, could cause the motor to stall.

Figs. 1 and 2 illustrate the characteristics of squirrel-cage motors. The motor operates under load from near synchronous speed at light load to

\* Refer to Glossary at end of chapter.

about 95 percent synchronous speed at full load. Overloads decrease the speed further until the maximum torque point is reached. If the load torque exceeds this point the motor will stall. The motor torque varies as the square of the voltage. If the voltage drops 10 percent, the motor torque will be only 81 percent of rated value. Both power factor and efficiency are improved if the motor is operating as near rated load as possible. In addition, as shown in Fig. 2, power factor and efficiency are better for higher speed motors.

*Wound Rotor* motors are used for applications requiring high starting torque at low starting current, because a wound rotor motor with its controller and resistance can develop full load torque when starting with about full load current. For comparison, a squirrel-cage motor would require from 3 to 5 times as much current to develop full load torque at starting. The wound rotor motor is also used for varying speed service to drive fans, blowers, and other continuous duty apparatus.

The addition of resistance to the secondary winding of the wound rotor motor changes the speed torque characteristics. The motor speed, with

FIG. 1. SPEED TORQUE CHARACTERISTICS OF SQUIRREL-CAGE MOTORS

the resistance added, is dependent on load, and consequently, the motor has very poor speed regulation when secondary resistance is added to reduce the speed to values below 50 percent. Fig. 3 illustrates the characteristics of wound rotor motors.

*Synchronous* motors are used for continuous duty applications at constant speed where efficiency and power factor are important. Another advantage of these motors is that of lower initial cost in large sizes and for low speeds when compared with squirrel-cage type motors.

The outstanding advantage of the synchronous motor is that its power factor can be changed to compensate for the low power factor of other drives in the same location. Lagging power factor is an inherent characteristic of all induction apparatus, such as induction motors and neon signs. Unless synchronous motors or capacitors are installed, the plant power factor may be comparatively low. This does not necessarily mean that corrective equipment must always be installed, but in most cases it

\* Refer to Glossary at end of chapter.

is desirable to determine what advantages may be gained by improving the power factor. With purchased power, if the rates include a clause embodying a penalty for low power factor, or a bonus for high power factor, the saving in power costs may often make a very good return on the investment required for the corrective equipment.

Synchronous motors are used to drive fans, blowers, pumps, compressors and other applications. Compressor applications having a high peak torque require the use of flywheels to smooth out power peaks, and should always be referred to the electrical manufacturer for recommendations.

Synchronous motors are provided with built-in damper windings on the rotor and operate during the starting period similarly to squirrel-cage

FIG. 2. EFFICIENCIES AND POWER FACTORS FOR SQUIRREL-CAGE INDUCTION MOTORS

motors. After the motor is nearly up to speed, field excitation is applied and the motor draws into step at synchronous speed. After excitation is applied, the motor runs at exactly constant speed and will remain at this speed until a load approaching the pull-out load is reached, whereupon the motor pulls out of synchronism and stops.

In applying synchronous motors consideration must be given to the torque the motor can develop on pull-in, that is, at the instant when field excitation is applied. Table 5 shows typical application requirements of synchronous motor drives, listing starting, pull-in, and pull-out torques.

*Multi-Speed* motors provide flexibility in many types of drives. Synchronous motors can be furnished only with a 2 to 1 ratio in speed, single

winding. Squirrel-cage induction motors may be 2, 3 or 4 speed. Two-speed induction motors are usually of single winding type, having a 2 to 1 speed ratio such as 600 rpm and 1200 rpm, or may be double winding. Three-speed induction motors are always two winding, and four-speed motors are usually two winding with a 2 to 1 speed ratio in each winding. Motors can be provided in constant torque, varying torque, or constant horsepower ratings. The constant horsepower type of motor is considerably larger than the constant torque motor, due to the fact that the same horsepower must be developed at either reduced speed or high speed.

In selecting two-speed motors for fan, pump, blower, or compressor applications, it is usually found that two winding motors are more expensive than the single winding type. The control cost for two-speed, two winding motors, however, is more economical, and therefore the combined

FIG. 3. SPEED-TORQUE SPEED-CURRENT CHARACTERISTICS OF WOUND ROTOR MOTORS

price of both motor and control for the two winding motor is only slightly higher. Because of the improved performance of the two winding motors, and because of the factor of safety provided by two independent windings, the increased cost is frequently worth the difference.

### Single Phase Motors

Single phase induction motors have auxiliary windings or devices for starting, and are classified by the method used.

**Capacitor start** motors develop high starting torque in fractional horsepower ratings, and moderate starting torque in larger ratings. They are used for constant speed drive such as fans, blowers and centrifugal pumps. During the starting period, a winding with a capacitor in series is connected to the motor circuit and when the motor comes up to speed, a centrifugal switch cuts the capacitor and second winding out of the circuit.

**Two-value capacitor** motors develop high starting torque employing a starting capacitor and a running capacitor. The starting capacitor gives high starting ability, but is suited for short time operation only, and is cut out for the running condition by a centrifugal switch. The running ca-

### Motors and Motor Controls

pacitor gives high efficiency at full speed. These motors are used on compressors, reciprocating pumps and similar equipment which may start under heavy load.

**Permanent split capacitor** motors have low starting torque and are ideally suited for small fan drives. Operation is similar to the capacitor start motor, except that the capacitor is not cut out when running.

**Repulsion-Start Induction-Run** motors develop high starting torque. The motors have a wound rotor connected to a commutator for starting. A centrifugal switch shorts the commutator bars when the motor comes up to speed to obtain a winding approximately like the squirrel cage in its function.

**Repulsion-Start Induction-Run** motors are suitable for applications, such

as industrial compressors, requiring high breakaway torque, and where commutator and brush noise are not factors.

**Split Phase** motors have a high resistance auxiliary winding which is in the circuit during starting, but is disconnected through the action of a centrifugal switch as the motor comes up to speed. Under running conditions it operates as a single phase induction motor with one winding in the circuit. These units are available for the small horsepower ratings, and when equipped with a high slip rotor, may be used for adjustable varying speeds through line voltage control. The motors are ideally suited for fan duty.

Speed-torque characteristics of single phase motors are shown in Fig. 4.

**Full voltage starting** of single phase motors is general practice, but since most of these motors are connected to secondary distribution systems located in light load density areas, power companies check carefully the starting currents in order to prevent objectionable voltage dips. This is particularly important for motors started frequently, such as those controlled by pressure or temperature sensitive devices and applied to refrigerators, stokers, oil burners, and water pumps.

The report of a joint committee of *AIEC-EEI-NEMA*\* recommended three application rules taking into account the greater annoyances resulting from frequent motor starting during lighting hours against infrequent starting at any time. Table 6 shows typical applications of these rules which are becoming widely accepted for full voltage starting. Rules 1 and 2 apply to general use.

Rule 1 limits the locked-rotor current to 20 amp at 115 volts, and 25 amp at 230 volts when automatically controlled (usually frequently started) motors are used. Rule 2 permits twice these values when manually controlled (usually infrequent starting) motors are used. Rule 3 applies to

FIG. 4. SPEED-TORQUE CHARACTERISTICS OF SINGLE PHASE MOTORS

special conditions where larger currents may be allowed above Rules 1 and 2 upon approval of the electric company.

*Hermetically enclosed* single-phase a-c motors are widely used in appliances such as domestic and commercial refrigerators, room air conditioners, beverage coolers, freezer chests, and water coolers. In such appliances, the motors are sealed inside the compressor, and the gas and oil circulate freely within and around the motor. Centrifugal starting switches are not used on such motors because any arcing in the gas and oil atmosphere would be detrimental, and also because the units are permanently sealed and cannot be serviced or repaired in the field. In place of a centrifugal switch, an external relay is used to start hermetically enclosed motors.

Hermetically enclosed motors for refrigeration compressors will, in the future, have the horsepower rating eliminated. The full load current is to be the operating current in amperes, when the compressor is deliver-

\* Refer to Glossary at end of chapter.

ing rated output. The motors for hermetically enclosed service are usually of the split-phase type or of the capacitor-start (or two-value capacitor) type.

For starting the split-phase type of motor, two methods are generally acceptable. In one method a thermally-operated time delay is used. When the motor is started, a contact which is normally closed applies power to the starting winding. A thermal element which controls these contacts is in series with the motor and carries line current. Due to the current flow through this element, it is heated until, after a definite period of time, it is warmed sufficiently to open the contacts and remove power from the starting winding. The running current then heats the element enough to keep the contacts open. The setting of the time for the starting contacts to open is determined by tests on the system components, i.e.,

A refers to automatically controlled devices.

M refers to manually controlled devices.

\* These values of Locked-rotor current are the same as the NEMA standard for single-phase Design M motors.

the relay, the motor, and the compressor, and is based on a prediction of the amount of time delay required to bring the motor up to speed.

The second method of starting split-phase motors utilizes a series-coil or current-operated relay. This device is affected indirectly by motor speed.

In this type of connection, a relay coil carries the line current going to the motor. When the motor is started, the inrush current to the running winding, passing through the relay coil, causes the contacts to close, and applies power to the starting winding. As the motor comes up to speed, the current decreases until at a definite calibrated value of current corresponding to a pre-selected speed, the magnetic force of the coil diminishes to a point which allows the contacts to open, removing power from the starting winding.

*Capacitor-start* and *two-value capacitor hermetically sealed* motors are usually started with a voltage-type relay. In this method of starting the relay coil is connected in parallel with the starting winding. When power is applied to the line, the relay does not operate because it is calibrated to operate on a higher voltage. As the motor comes up to speed, the voltage across the starting winding and relay coil increases in proportion to the motor speed. At a definite voltage corresponding to a pre-selected speed, the relay operates and opens its contacts, thereby opening the starting

winding circuit. The relay then keeps these contacts open because there is sufficient voltage induced in the starting winding, when the motor is running, to hold the relay in the open contact position.

### CONTROL FOR ALTERNATING CURRENT MOTORS

*Squirrel-Cage* motors are usually linestarted where power company limitations permit. In sizes up to 5 hp at 220 volts, or  $7\frac{1}{2}$  hp at 440 volts, polyphase motors may be started by means of manual switches having overload current elements for motor protection. In larger ratings a linestarter is usually provided with either an additional safety switch or circuit breaker for disconnecting and short circuit protection. Reduced voltage starting may be used when the current inrush on full voltage exceeds the limitations set by the power company. The magnitude of this inrush current is entirely independent of the load on the motor, and is the same whether the motor is lightly loaded or heavily loaded.

TABLE 7. COMPARISON OF SQUIRREL CAGE AND SYNCHRONOUS MOTOR STARTING METHODS

| TYPE OF STARTER       | PERCENT OF MOTOR RATED VALUES |                 |              |
|-----------------------|-------------------------------|-----------------|--------------|

| Reactor               |                               |                 |              |
| 50 percent tap        | 50                            | 25              | 50           |
| 45 percent tap        | 45                            | 20              | 45           |
| 37.5 percent tap      | 37.5                          | 14              | 37.5         |
| Part Winding          | 60                            | 50              | 60           |

Restrictions on starting current may limit the maximum current inrush or may limit the increments of current inrush which may be drawn on each step. Table 7 shows a comparison of the various methods of reduced voltage starting. The choice may depend upon the limitation to be met. Fig. 5 shows examples for maximum current limitations. Fig. 6 shows examples for increment limitations. The increment starters would not be satisfactory for meeting maximum current limitations as they exceed the maximum value before the motor reaches full speed. Both Curves B and C of Fig. 6 would be satisfactory if the increment limitation were 400 percent but only the starter illustrated by Curve C would meet a limitation of 200 percent increments.

When increment starters are used the motor may not develop enough torque to start until the last step. Fig. 6 shows that with the resistor step starter the motor does not start until step 3 or after 2 seconds on Curve C. Part-winding motors may start and then stall at about half speed until the second step which applies full torque.

The load inertia ( $WK^2$ ) may also affect the selection of reduced current starting method since the reduced torques may not be sufficient to accelerate the load without overheating the motor or in the case of synchronous motors, may not reach sufficient speed to pull into synchronous speed.

FIG. 5. STARTERS FOR MAXIMUM CURRENT LIMITATIONS

In these cases the solution may be to use the wound-rotor induction motor or some means of reducing the load such as suction dampers on compressors. Fig. 7 illustrates recommended control practice for squirrel-cage motors.

*Wound-Rotor* motors require control of both primary and secondary circuits. The primary\* control may be the same as for squirrel-cage motors, manual or magnetic, at full voltage. Secondary\* control provides means of varying secondary resistance for starting and speed control. The secondary controller should be specified for starting duty only, or for speed regulating duty. If the secondary controller is to be used for speed regulating duty, the percent speed reduction, the number of speed control points, and the type of load (variable or constant torque) should be specified. Fig. 8 illustrates recommended control practice for wound rotor motors.

*Synchronous* motor starters should provide pull-out protection, automatic synchronization or automatic stopping of the motor after pull-out, and insurance of complete starting sequence, as well as overload and low voltage protection. The control may be either magnetic or semi-magnetic at full or reduced voltage. Semi-magnetic starters provide automatic field control, but require hand operation for closing the line contactors to start and transfer to full voltage.

FIG. 6. STARTERS FOR INCREMENT LIMITATIONS

\* Refer to Glossary at end of chapter.

In applying reduced voltage starters to synchronous motors it should be remembered that, since these motors are started on damper windings and function during the acceleration period similarly to squirrel-cage motors, the starting torque varies as the square of the applied voltage. Consideration should be given to insure development of sufficient motor torque to accelerate the load.

**Multi-Speed** control may be either manual or magnetic, and at full or reduced voltage. When using automatic magnetic control with two-, three-, and four-speed separate winding or consequent pole motors, control may be obtained from a remote point by means of a push button master switch. The various speeds of the motor are obtained from the master switch by simply depressing the correct push button. This is known as selective speed control. It is commonly used in the smaller theater installations where the fan and motor are located backstage and the speed control is located in the lobby.

Arrangements 2, 4 and 5 provide automatic push-button starting.

FIG. 7. RECOMMENDED CONTROLS FOR SQUIRREL-CAGE MOTORS

Multi-speed motor controllers may be provided with compelling relays which make it necessary for the operator to press the first speed button before regulating the motor to the desired speed. This insures that the motor is always started at low speed before adjusting to a higher speed.

Timing relays which provide for automatic acceleration may be used for control. With this feature the motor will always start at low speed and automatically accelerate to the desired speed. Decelerating relays may be used to reduce the shock effect of the braking action on the motor and drive when the speed is reduced from a higher to a lower speed.

**Single Phase** motor control usually consists only of a line starter, either manual or magnetic. In some cases it is desirable also to provide a disconnect switch. Fig. 9 illustrates the recommended controls.

### MOTOR RATING

The rating of an electric motor depends upon the total temperature which the motor attains under operating conditions. This total temperature depends on both the ambient temperature and the temperature rise of the motor. As motor temperature rise is in turn determined by the ability of the motor to dissipate heat, circulation to the motor should not

be restricted. Improper selection of motors with regard to temperature ratings may result in high motor operating temperatures and accompanying reduction in motor life.

### FUNCTIONS OF CONTROL EQUIPMENT FOR MOTORS

In general, control equipment for all types of motors should provide (1) means of disconnecting the motor from the power supply, (2) means for starting the motor, (3) overload protection for the motor, (4) protection against low voltage, and (5) means for varying the motor speed.

Full voltage starting for motors is preferable because of its lower first cost and simplicity of control. Except for d-c machines, most motors are mechanically and electrically designed for full voltage starting. The starting inrush current, however, is limited in many cases by regulations of power companies because of the voltage fluctuations which may be caused by heavy current surges. It is therefore often necessary to reduce

FIG. 8. RECOMMENDED CONTROLS FOR WOUND ROTOR MOTORS

the starting current below that obtained by across-the-line starting. The power supplier should be consulted to determine the allowable inrush current for any given location.

The choice between full voltage and reduced voltage starting is governed almost entirely by inrush current limitations. The starting torque of all motors varies with the starting current, and it is therefore necessary to insure that the motor is supplied with sufficient current to develop enough torque to accelerate the load.

In present practice overload protection of motors is obtained by use of thermal overload inverse time limit type protection. The usual setting of such protection devices is not to exceed 125 percent of rated full load current for open 40 C rise motors, and not to exceed 115 percent of rated full load current for all other motors, the element tripping after a definite interval of time. The *National Electrical Code* requires the addition of fuses or circuit breakers to protect the overload elements from severe short circuit currents.

Two types of protection are available against low voltage at the motor terminals. One type, called low voltage release, permits the motor line contactor to drop out on low voltage and to close again when the voltage returns to normal, thereby restarting the motor when the abnormal condi-

tion is ended. The second type, called low voltage protection, causes the motor line contactor to drop out on low voltage, but prevents restarting when the voltage returns to normal except by the action of an operator. This latter type of protection is desirable where it is necessary for the operator to make initial starting adjustments on the machine.

Manual control for an alternating or a direct current motor is usually located near the motor. When so located an operator must be present to start and stop or change the speed of the motor by operating the control mechanism. Manual control is sometimes employed only as a device to give overload protection, and another device is employed to start and stop the motor. Manual control is used particularly on small motors which operate unit heaters, small blowers, and room coolers in an air conditioning system. In other cases manual control in the form of drums, when used with multi-speed motors, is used only as a speed setting device, while the

Arrangements 2, 3 and 4 are optional for motors up to 7½ hp, 220 volts.

FIG. 9. RECOMMENDED CONTROLS FOR SINGLE PHASE MOTORS

starting and stopping functions operate automatically through thermostats and pressure switches.

Because of the increasing complexity of air conditioning systems, the equipment is operated preferably by automatic control, and less dependence is placed on manual operation and regulation.

Automatic control of motor starters may be accomplished by the use of remote push button stations, by a thermostat, float switch, pressure regulator, or other similar pilot devices. An added advantage of automatic control is that the main wiring for the starter may be installed near the motor, while the starter may be operated by a remote control device.

## GLOSSARY

### General Definitions

**NEMA** is the abbreviation for the *National Electrical Manufacturers Association*.

**AEIC** is the abbreviation for the *Association of Edison Illuminating Companies*.

**EI** is the abbreviation for the *Edison Electric Institute*.

**Speed Regulation** (d-c motors) is the change in speed between no-load and full-load, expressed in percent of full-load speed; for example, a motor having a no-load speed of 1200 rpm and a full-load speed of 1140 rpm would have a speed regulation of 5.26 percent.

**Slip** (a-c induction motors) is the difference between the motor speed and synchronous speed expressed in percent of synchronous speed, e.g., a 1200 rpm motor operating at 1140 rpm would have a slip of 5 percent.

**Torque** is an expression of the turning effort developed by the motor at the shaft, and is usually expressed in ounce-feet for fractional horsepower motors, and in pound-feet for motors of larger ratings.

**Primary** is the term usually applied to the high voltage or line side of a transformer or motor. In the case of the wound rotor motor the primary is the stator winding.

**Secondary** is the term usually applied to the low voltage or load side of a transformer or motor. In the case of the wound rotor motor the secondary is the rotor winding.

## NEMA Classification of Motor Enclosures

**Open motors** (40 C rise, rated load, 50 C rise, service factor load) are self-ventilated machines having no restriction to ventilation other than that necessitated by mechanical construction.

**Guarded motors** (50 C Rise) have all ventilating openings limited in size by either design of structural parts, perforated covers or screens preventing direct access to live or rotating parts.

**Semi-Guarded motors** (50 C rise) have the ventilating openings in the top half of the frame only protected by perforated covers.

**Drip Proof motors** (50 C rise) are so constructed that drops of liquid or solid particles falling on the machine at any angle not greater than 15 deg from the vertical, cannot enter the machine either directly or by striking and running along a horizontal or inclined surface.

**Splash Proof motors** (50 C rise) are so constructed that drops of liquid or solid particles falling on the machine or coming toward it in a straight line at any angle not greater than 100 deg from the vertical, cannot enter the machine either directly or by striking and running along the surface.

**Totally Enclosed Non-Ventilated motors** (55 C rise) are so constructed as to prevent exchange of air between inside and outside of the case, but are not air tight and are not equipped with external cooling means.

**Totally Enclosed Fan-Cooled motors** (55 C rise) are similar to totally enclosed, non-ventilated machines, except that exterior cooling is provided by means of a fan or fans integral with the machine.

**Explosion Proof motors** (55 C rise) have an enclosing case designed to withstand an explosion of a specified gas or vapor which may occur within it, and to prevent ignition of the gas or vapor surrounding the motor by sparks, flashes, or explosions of the gas or vapor which may occur within the machine casing.

**Dust Explosion Proof motors** (55 C rise) have an enclosing case designed and constructed so as not to cause the ignition or explosion of an atmosphere of the specific dust, or to cause ignition of dust on or around the machine. (Proper overload protection and cleanliness are required for successful operation).

**Water Proof motors** (55 C rise) are so constructed as to exclude water applied in the form of a stream from a hose.

## Motor Speed Classifications

A **Constant Speed** motor is one in which the speed remains practically constant with changes in load; e.g., a d-c shunt wound motor or a-c squirrel-cage motor with low slip.

A **Varying Speed** motor is one in which the speed varies with the load, usually decreasing when the load increases; e.g., a d-c series motor or an induction motor with large slip.

An **Adjustable Varying Speed** motor is one in which the speed can be adjusted gradually, but when once adjusted for a given load will vary in considerable degree with change in load; e.g., a shunt wound d-c motor adjusted by armature resistance control.

An **Adjustable Speed** motor is one in which the speed can be varied gradually over a considerable range, but when once adjusted remains practically unaffected by the load; e.g., a d-c shunt motor with field resistance control. The standard ratings for open type, adjustable speed motors, having a speed range of 3 to 1 and greater are in accordance with the following:

- (1) A standard continuous horsepower rating at 150 percent of minimum speed with a temperature rise of 40 C.
- (2) The next higher standard continuous horsepower rating at 3 times minimum speed with a temperature rise of 40 C.

- (3) Between 150 percent of minimum speed and 3 times minimum speed, the standard continuous horsepower rating with a temperature rise of 40 C will vary with the speed along a straight line connecting these two horsepower ratings. No further increase in horsepower is recognized above 3 times minimum speed.
- (4) Below 150 percent of minimum speed the lower continuous horsepower rating (see preceding item 1) will apply with a temperature rise of 50 C.  
*Example:* 20/25 hp, 400 to 1600 rpm. This motor may be rated 20 hp, 40 C at 600 rpm and 25 hp, 40 C from 1200 to 1600 rpm. Between 600 and 1200 rpm the rated horsepower increases directly with speed from 20 to 25 hp.
- (5) Motors may also be rated 1 hour with temperature rise of 50 C with the higher horsepower rating (see preceding item 2) throughout the entire speed range.  
*Example:* 20/25 hp, 400 to 1600 rpm. This motor may be rated 25 hp, 50 C 400/1600 rpm; 1 hour.

### Mechanical Modifications

*Vertical Mountings* are available for such applications as pumps and agitators. This type of application may require a special umbrella-type hood to protect against dripping liquids.

*Flanged Mountings* are available for use where motors are built in as part of machines. Motors may also be supplied with flush plate mountings, suitable for close coupled pump and similar applications.

## CHAPTER 41

### SOUND CONTROL

Unit of Noise Measurement, Apparatus for Measuring Sound, General Problem, Kinds of Noise, Noise Transmitted Through Ducts, Design Room Noise Level, Noise Generated by Fans, Natural Attenuation of Duct System, Duct Sound Absorbers, Air Supply Noises, Cross Transmission Between Rooms, Controlling Vibration from Machine Mountings

IN ventilating and air conditioning a building or a room, consideration must be given to the effect of the mechanical system on the acoustics of the space conditioned. It is important to consider also that the use of air conditioning often permits keeping the windows closed, thus giving relief from certain external noises, but at the same time increasing the necessity of providing adequate sound control.

It is assumed that in a given space the architect and acoustical engineer have produced a room or rooms which are satisfactory for speech, music, or other uses. The ventilating engineer's sole function is to ventilate and air condition these rooms properly so that they will be physically comfortable without adding any acoustical hazards.

### UNIT OF NOISE MEASUREMENT

According to an international standard, the *decibel (db)* is the unit for expressing sound pressure levels. The *sound pressure level*, in decibels, is given by the relation:

$$db = 20 \log_{10} \left( \frac{P}{0.0002} \right) \quad (1)$$

where  $P$  = the sound pressure in dynes per square centimeter.

The reference pressure (0.0002 dynes per square centimeter) is a sound pressure which is slightly less than the threshold of audibility, at the frequency of 1000 cycles per second, for the person of average hearing. This reference point is approximately the minimum sound pressure that would be audible in a very quiet room to an observer having acute hearing. The ear is essentially a pressure operated device; hence, the sensation of loudness, or magnitude of sound is governed by the sound pressure existing at the point of reception.

The sound level meter measures sound level pressure, the measurement being expressed as *sound level* on a decibel scale with zero corresponding to the reference pressure of 0.0002 dynes per sq cm at 1000 cycles. In the higher ranges of the decibel scale, approaching 120 db, the sensation is one of feeling, and at higher levels the sensation becomes painful.

Associated with sound pressure level is the *sound intensity level*, expressed in decibels above a standard reference intensity. Sound intensity is the average rate of sound energy transmitted through a unit area normal to the direction of propagation, commonly expressed in watts per square centimeter. The *sound intensity level*, in decibels, is given by the relation:

$$db = 10 \log_{10} \left( \frac{I}{10^{-16}} \right) \quad (2)$$

where  $I$  = the sound intensity in watts per square centimeter.

The reference intensity is  $10^{-16}$  watts per square centimeter, coinciding with the reference pressure of 0.0002 dynes per sq cm or  $2 \times 10^{-4}$  microbar. A microbar is the unit of pressure commonly used in acoustics, one microbar being equal to one dyne per sq cm.

The relationship of the decibel scale to sound pressure and sound intensity is shown in Table 1. A stated sound level in decibels, under standardized procedure, will thus be related to a threshold of 0.0002 dynes per square centimeter, or to a threshold of  $10^{-16}$  watts per sq cm. The standardization upon terminology, procedures and reference levels may be found in Standards<sup>1</sup> published by the *American Standards Association*.

#### APPARATUS FOR MEASURING SOUND

The measurement of sound or noise is conventionally made by means of a sound-level meter<sup>2</sup> consisting of a microphone, an amplifier, a variable attenuator, weighting networks, and an indicating meter which reads directly in decibels. The approved sound-level meter must comply with the specifications of the American Standard for Sound Level Meters for Measurement of Noise and Other Sounds, Z24.3-1944, approved and published by the *American Standards Association*. The meter is designed to indicate sound level above the standard reference level. Three measuring networks are generally provided: (1) flat response, (2) 70 db network and (3) 40 db network. The various networks are approximations of the equal-loudness contours relating intensity and frequency sensation response of the normal human ear.<sup>1</sup> Where there are no specific codes which specify the particular network to be used, general practice would indicate use of the 40 db network for sound levels up to about 55 db, the 70 db network for sound levels from about 55 db to 85 db, and the flat response network for higher levels. When sound level measurements are stated, the specific weighting network used, i.e., 40 db, 70 db or flat response, should always be reported. Complexity in design and calibration, and variations in component parts of the sound level meter impose some deviation from design objective response. Allowable deviations in response or acceptable tolerations recognized in the Standard, vary from  $\pm 2$  db in the 1000 cycle range to  $\pm 5$  db, or more, below 100 cycles and above 1200 cycles per second.

#### GENERAL PROBLEM OF SOUND CONTROL

The problem confronting the air conditioning engineer is to design a system which will operate without increasing the noise level in the conditioned space. It is therefore necessary:

1. To determine the noise level existing without the equipment.
2. To ascertain the noise level which would exist if the equipment were installed without sound control.
3. To provide as a part of the installation, sufficient sound control appliances and treatment to reduce the sound level due to the installation to a sound level at least three decibels, and preferably five decibels, below that found in Item 1.

To accomplish this the engineer should have information of three kinds:

1. A knowledge of the noise levels currently considered acceptable in various rooms, in order that he may have a basis on which to proceed.

TABLE 1. DECIBEL SCALE VS. SOUND PRESSURES AND SOUND INTENSITIES

| DECIBEL LEVEL | PRESSURE<br>dynes per sq cm | INTENSITY<br>watts per sq cm | DECIBEL LEVEL | PRESSURE<br>dynes per sq cm | INTENSITY<br>watts per sq cm |
|---------------|-----------------------------|------------------------------|---------------|-----------------------------|------------------------------|
| 0             | 0.000200                    | $1.000 \times 10^{-16}$      | 40            | 0.0200                      | $1.000 \times 10^{-13}$      |
| 1             | 0.000224                    | $1.259 \times 10^{-16}$      | 50            | 0.0631                      | $1.000 \times 10^{-11}$      |
| 2             | 0.000252                    | $1.585 \times 10^{-16}$      | 60            | 0.200                       | $1.000 \times 10^{-10}$      |
| 3             | 0.000282                    | $2.000 \times 10^{-16}$      | 70            | 0.631                       | $1.000 \times 10^{-8}$       |
| 4             | 0.000317                    | $2.520 \times 10^{-16}$      | 80            | 2.00                        | $1.000 \times 10^{-6}$       |
| 6             | 0.000399                    | $4.000 \times 10^{-16}$      | 90            | 6.31                        | $1.000 \times 10^{-7}$       |
| 8             | 0.000503                    | $6.310 \times 10^{-16}$      | 100           | 20.0                        | $1.000 \times 10^{-6}$       |
| 10            | 0.000631                    | $1.000 \times 10^{-15}$      | 110           | 63.1                        | $1.000 \times 10^{-5}$       |
| 20            | 0.00200                     | $1.000 \times 10^{-14}$      | 120           | 200.0                       | $1.000 \times 10^{-4}$       |
| 30            | 0.00631                     | $1.000 \times 10^{-13}$      |               |                             |                              |

2. A knowledge of the nature and intensity of the noise created by the various parts of the equipment.

3. A knowledge of how, when necessary, to vary and control the noise level between the equipment and the conditioned space.

In addition, the engineer should have sufficient information to predict the levels produced by noises which may be transmitted by the duct system from one conditioned space to another, or from an outside space to the conditioned space. In either case, the designer must know the probable noise level at the point where the noise originates. From this he can compute the attenuation or transmission loss required in order to bring this level down to that required in the conditioned space. If there is likelihood of direct transmission through a duct, the attenuation required may be computed as shown in section Noise Transmitted Through Ducts. If the transmission is through dividing walls, it will be necessary to refer to published data on losses through standard building constructions.<sup>3</sup>

Information concerning the sound levels created by ventilating and air conditioning equipment such as fans, motors, air washers and similar items, has not yet been completely established. However, numerous manufacturers are in a position to supply such data for many of their products. Additional information is being collected. Uniformity in method of test and presentation of sound measurement data for fans, has been standardized in the Sound Measurement Test Code for Centrifugal and Axial Fans, developed by the *National Association of Fan Manufacturers*. The Code prescribes that the sound level shall be measured by the flat response network of the sound-level meter. Readings on the 40 db and 70 db networks may also be taken and reported, but the flat response reading is required to comply with the Code requirement. General practice is to use the *slow* or damped needle reading of the meter. The *fast* or undamped needle of the indicating meter generally reads one to two db lower than the *slow* or damped meter needle. The same Code prescribes a method of determining the sound level reading at each of seven stations, spaced at 5 ft from the outside of the fan housing, and located in a horizontal plane passing through the fan shaft. The sound level of the fan is the average of the seven readings. The level so determined is valuable primarily for comparative purposes rather than absolute values. Of more value to the design engineer would be the sound level at the fan outlet and at the beginning of the distribution duct system.

The technique of sound measurement in a moving air stream of ap-

preciable velocity has not yet been mastered, although it is a subject of current investigation. Development tests indicate that the sound level at the fan outlet is in the order of 10 to 15 db higher than the average value determined by the seven-station traverse around the fan. Where sound treatment of a distribution duct is required, the initial level should be taken as approximately 12 decibels higher than the reported Code rating sound level.

### KINDS OF NOISE

In solving a sound problem, it is desirable to consider, separately, the several means by which noise reaches the room. This avoids to some extent the necessity of knowing the noise level at the source, and instead, places the emphasis on ascertaining the level at the point where the sound enters the room.

The noise introduced into a room or building by ventilating or air conditioning equipment may be divided into two general kinds, depending on how it reaches the room:

1. Noise transmitted through the ducts.
  - a. From equipment such as fans, motors, pumps, sprays, etc.
  - b. From outside, and transmitted through duct walls into air stream.
  - c. From duct wall vibrations, transmitted into air stream.
  - d. From air currents, including eddying noises.
  - e. Cross talk and cross noises between rooms connected by the same duct system.
  - f. Noise produced by the grilles.
2. Noise transmitted through the building construction.
  - a. From machine mountings as vibration.
  - b. From equipment through room wall surfaces.

The next step in the solution of this problem is to present data and discuss methods whereby solutions of the noise problem can be obtained when the allowable room noise level, and the path through which the noise reaches the room, are known.

### NOISE TRANSMITTED BY AIR THROUGH DUCTS

Operation of an air distribution system results in the generation of noise which may be transmitted by air through the ducts to the ventilated or conditioned room. The transmission of this noise may be controlled by the proper application of sound absorptive material within the ducts. The application of the absorptive material is a problem in balancing the room noise level requirements against the intensity of the noise generated. The four steps in the problem are:

1. Determination of acceptable room noise level resulting from the operation of the equipment.
2. Determination of noise level generated by the equipment.
 

Add 5 decibels to the difference between items 1 and 2 to obtain the overall noise reduction required between the equipment and the room. In the discussion which follows, reduction of noise will be referred to as *attenuation* of noise.
3. Determination of the natural attenuation of the duct system.
4. Selection of the proper sound treatment for the duct system.

The difference in decibels between the overall attenuation required and the natural attenuation (3) is the additional sound attenuation to be provided by absorptive materials installed in the duct system, or by special constructions designed to absorb sound. Experience has shown, for example, that where ventilating requirements permit, introduction of an expansion chamber or a change in area in the duct will frequently provide further reduction in low frequency noise.

\* These values are tentative. More detailed measurements by D. F. Seacord, Bell Telephone Laboratories (*Journal Acoustical Society of America*, Vol. 12, pp. 183-187, 1940) give average values and standard deviations of room noise in residences, offices, stores, factories, etc., in large American cities.

<sup>b</sup> For train standing in station, a level of about 45 db is the maximum which can ordinarily be tolerated.

### DESIGN ROOM NOISE LEVEL

Measurements of sound levels in various types of rooms and locations have been observed by numerous investigators. However, close agreement upon these values has not been realized, and more detailed measurements are needed to accurately establish the normal sound levels in occupied spaces and enclosures subject to sound analysis and control. Typical sound levels, of a tentative nature, based upon earlier determinations, are listed in Table 2. The levels listed are weighted levels by the 40 db or 70 db network, depending upon the range of level existing. Levels taken upon the flat response network may be from 5 db to 20 db higher, as governed by the predominating frequencies which may influence the weighting level.

Table 3 lists sound levels based upon more recent surveys than Table 2, and upon the basis of the flat response network. The flat response network offers a more logical correlation of space sound level to fan sound level which, under present practice, is reported upon basis of the *flat response* reading.

The values listed were determined with the air conditioning or ventila-

TABLE 3. AVERAGE SOUND CONDITIONS IN VARIOUS TYPES OF ROOMS AND BUILDINGS\*

\* Values based on recent surveys.

tion equipment out of operation, unless such equipment presented no acoustical addition to normal conditions. The windows and doors were closed to simulate the conditions of normal occupancy. In Table 2, minimum, representative and maximum levels are given for each type of space, classified as shown in the following paragraph. In Table 3, the minimum to maximum range is shown, with the same general classification.

**Minimum sound level** refers to spaces within well-constructed buildings, typified by double windows, carpeted floors, and acoustically-treated walls and ceilings. In such spaces heavy upholstered furniture is also usually used.

**Representative sound level** refers to spaces within average construction with average furnishings, and exposed to external sounds typical of the locality in which the space is usually found.

**Maximum sound level** refers to (1) any space within inexpensive construction where bare furnishings are used, and where noise is normally not an important factor, or (2) spaces in close proximity to very intense street traffic or industrial noise.

In general, if the sound level in the space resulting from the operation of the air conditioning equipment only, is equivalent to, or less than, the typical level (from Tables 2 or 3 or, better still, determined by actual site measurement) the installation will prove satisfactory. If the space level and the equipment level are equal and heard together, the resultant level will be 3 db higher than either space or equipment level alone. However, to minimize possible annoyance due to introduction of single or distinctive frequency components from the equipment, it is desirable to design for an equipment sound level of at least 5 db below the typical space level.

#### NOISE GENERATED BY FANS

Noise generated by fan wheels may be divided into two classifications, rotational noise and vortex noise. The rotational noise may be described

FIG. 1. SOUND LEVEL CHARACTERISTICS OF TYPICAL CENTRIFUGAL, MULTI-BLADE VENTILATING FAN

as that due to the thrust and torque applied to the air. Vortex noise is that due to the shedding of vortices from the blade, and is dependent on the angle of attack, velocity, air turbulence, and blade shape. Vortex noise is due to pressure variations on the blade as a result of variations of air circulation. Given the noise level at the outlet or inlet of one type of fan construction under specific conditions of size, tip speed, and total pressure, the noise levels at other values of tip speed, total pressure, and size may be approximated by the relationships:

1. For constant size and point of rating, the noise level of a fan will increase with increasing speed.

$$db \text{ (change)} = 50 \log_{10} \left( \frac{RPM_2}{RPM_1} \right) \quad (3)$$

2. For constant pressure and tip speed, the noise level of a given type of fan will increase with increasing fan size.

$$db \text{ (change)} = 20 \log_{10} \left( \frac{Size_2}{Size_1} \right) \quad (4)$$

Fan size refers to wheel diameter, housing height or some dimension that is directly proportional to linear units. Fan sizes based on arbitrary systems or systems of preferred numbers, have no significance.

The noise of a given fan is not constant at constant speed if the air delivery changes due to change of resistance. In general, a backward curved blade fan is lowest in noise at or near the point of maximum efficiency; a forward curved blade fan at or between the point of maximum efficiency and shut-off; an axial flow fan at or between the point of maximum efficiency and free delivery. The noise level of a double width fan may be taken as 3 db higher than for a similar single width fan operating under the same conditions of speed and pressure.

The sound level characteristic curve of a typical ventilating fan of the centrifugal multi-blade type is shown in Fig. 1. The accented portion of the curves denotes the range of minimum sound emission. The selection and application of the fan should be made within such good application range where quietness of operation is of major consideration. The various types of fans available possess individual sound level characteristics throughout their range of possible operation. Recourse to standard

FIG. 2. SOUND LEVEL CHARACTERISTICS OF TYPICAL VANEAXIAL FAN

test rating information should be made to arrive at the sound emission of a particular type.

In general, that size of fan which is so selected as to operate at or near peak static efficiency, will also provide the lowest sound level attainable with the particular type and design of fan.

The characteristic trend of the sound level curve of a typical vaneaxial fan, adaptable to moderate pressure ventilation requirements, is shown in Fig. 2. The sound level of a particular fan is primarily governed by the operating speed required to produce a desired delivery against the system static pressure. Fig. 3 illustrates the variation of fan sound level in decibels with operating speed, the fan operating in connection with a conventional fixed system. The influence of high static pressures is evident in increased operating speed and higher sound level.

The range of sound levels to be experienced in fan application is widespread due to volumetric and pressure requirements which extend over a broad field. Fig. 4 illustrates the general scope of sound levels of centrifugal ventilating fans over a wide range of volumetric capacities and static

FIG. 3. RELATION OF SOUND LEVEL TO OPERATING SPEED OF A CENTRIFUGAL VENTILATING FAN

FIG. 4. TYPICAL SOUND LEVELS AT POINT OF MINIMUM SOUND EMISSION FOR CENTRIFUGAL VENTILATING FAN

pressures. The sound levels are based upon a general average of the sound emission that can be anticipated from the several types of fans adaptable to ventilating and air conditioning duties. The sound levels are typical of the centrifugal fans as a class, and specific types may exhibit sensible departure from the charted values. Exact application should be based upon applicable test data derived from the particular equipment under consideration.

#### NATURAL ATTENUATION OF DUCT SYSTEM

**Straight Sheet Metal Ducts.** The attenuation of sound in straight sheet metal ducts is a function of the length, shape, and size of the duct.<sup>4</sup> Attenuation values are given in Table 4. In general this attenuation is so negligible, except for long runs, that it may be disregarded for all practical purposes.

**Elbows and Transformations.** Due to reflective interference, attenuation will take place at elbows and transformations. The magnitude of the attenuation will depend on the size and abruptness of the elbow or transformation as shown in Table 5.

When the area of a duct increases abruptly, an attenuation of noise level takes place in the duct. In duct design practice the total area of the branch ducts is greater than the supply duct. Similarly with outlets, the area of the outlet, plus the area of the duct after the outlet is greater than the duct area before the outlet. Therefore in an outlet run, attenuation occurs in the duct as it passes each outlet. Table 6 gives the db reduction for various ratios of total branch duct and outlet area to supply duct area.

**Grilles to Room.** The large abrupt change in area between the grilles and the surfaces within a room results in an appreciable noise attenuation.

TABLE 4. ATTENUATION IN STRAIGHT SHEET METAL DUCT RUNS

| DUCT   | SIZE, IN. | ATTENUATION PER FT. db |
|--------|-----------|------------------------|
| Small  | 6 x 6     | 0.10                   |
| Medium | 24 x 24   | 0.05                   |
| Large  | 72 x 72   | 0.01                   |

TABLE 5. ATTENUATION OF ELBOWS<sup>a</sup>

| ELBOW           | SIZE IN. <sup>b</sup> | ATTENUATION<br>PER ELBOW, db |
|-----------------|-----------------------|------------------------------|
| Very small..... | 2 wide                | 3                            |
| Small.....      | 3 to 15               | 2                            |
| Medium.....     | 15 to 36              | 1.5                          |
| Large.....      | 36 plus               | 1                            |

<sup>a</sup> The attenuation in vanned elbows should be considered the same as in elbows having the same dimensions as the radius of curvature of the vanes. If the vanes are lined for the purpose of damping any vibrations in them, one third may be added to the attenuation values listed.

<sup>b</sup> These attenuation values are based on elbows having a center line radius 1.5 to 2 times the diameter or width of the duct. The attenuation will be greater if the ratio is less than 1.5 and less when the ratio is greater than 2.

This attenuation is a function of the total grille area (supply and return) and the total sound absorption of the room in *sabins*. (The sound absorption of a room in *sabins* is the summation of the products of each surface of the room measured in square feet multiplied by its corresponding absorption coefficient. The *sabin* is a unit of sound absorption equivalent to the absorption of one square foot of a totally sound-absorbent surface). The attenuation is given in Equation 5 as:

$$db \left( \begin{array}{l} \text{Attenuation between} \\ \text{grilles and room} \end{array} \right) = 10 \log_{10} \frac{\text{Total Room Absorption in Sabins}}{\text{Total Grille Area}} \quad (5)$$

Values in Table 7 approximate the attenuation for various rates of air change, and general types of room surfaces.

#### DUCT SOUND ABSORBERS

The difference between the required sound attenuation and the natural attenuation must be supplied by the proper sound treatment of the ducts.

#### Selection of the Absorptive Material

When a sound wave impinges on the surface of a porous material, a vibrating motion is set up within the small pores of the material by the alternating sound waves. As the ratio of the cross-sectional area of the pores to their interior surface is small, the resistance to the movement of air in the pores is large. This viscous resistance within the pores of the material, converts a portion of the sound energy into heat. The decimal fraction representing the absorbed portion of the incident sound wave is called the absorption coefficient. Considerable absorption may also result, particularly in the low frequency range, from the flexural vibrations of the duct. In the selection and application of the absorptive material, the following points should be considered:

TABLE 6. ATTENUATION AT DUCT BRANCHES OR OUTLETS

| $\frac{\text{BRANCH DUCT + OUTLET AREA}}{\text{SUPPLY DUCT AREA}}$ OR $\frac{\text{SUM OF BRANCH AREAS}}{\text{SUPPLY DUCT AREA}}$ | ATTENUATION<br>PER<br>TRANSFORMATION, db |
|------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------|
| 1.00                                                                                                                               | 0.0                                      |
| 1.20                                                                                                                               | 0.8                                      |
| 1.35                                                                                                                               | 1.3                                      |
| 1.50                                                                                                                               | 1.8                                      |
| 1.75                                                                                                                               | 2.5                                      |
| 2.00                                                                                                                               | 3.0                                      |

1. For the absorption of the low frequencies below 500 cycles per second the material should be at least 1 to 2 in. thick. Thin materials, particularly when mounted on hard solid surfaces, will absorb the high frequencies and reflect the low.

2. In order to provide as much low frequency noise absorption as possible by means of flexural vibration, it is desirable to fasten the absorptive panels discontinuously. This result may be attained to some extent by spot cementing, but better results are obtained when it is possible to fasten the absorptive panels to furring strips, leaving an air space behind. However, the exact resonance characteristics of the panels, and thus their absorption, are so unpredictable that flexural vibration cannot be relied upon for a specific value of attenuation.

Requirements for a good sound absorption material are: (1) high absorption at low frequencies;<sup>5</sup> (2) adequate strength to avoid breakage; (3) fire resistance and compliance with national and local code requirements; (4) low moisture absorption; (5) freedom from attack by bacteria

and algae; (6) low surface coefficient of friction; (7) particles should not fray off at the higher design velocities; and (8) freedom from odor when either dry or wet.

With every application, the use of sound absorptive material should be considered in the dual function of insulation and sound absorption. It has been shown theoretically<sup>6</sup> that the reduction (in decibels per linear foot) of sound transmitted through a duct lined with sound absorbing material, is related in a rather complicated manner to the size and shape of the duct, to the frequency of the sound, and to the sound absorbing characteristics of the lining. Experimental evidence likewise indicates that there is no simple formula involving the variables which will apply accurately to all cases. However, it may be stated generally that the attenuation in decibels at a given frequency is directly proportional to the length of

lined duct. It decreases as the cross-sectional area increases, and increases as the aspect ratio is increased.

The noise reduction varies to a considerable extent with the frequency of the sound. In calculating noise reduction, consideration should be given both to the comparative efficiency of the duct lining material at different frequencies, and to the frequency distribution of the noise to be quieted. In the case of fan noise, it is recommended that calculations be based upon the predominant frequency component in the fan sound level spectrum. Normally, most of the sound energy is in the region of this frequency, which generally corresponds to the blade frequency and is equal to  $\text{rpm} \times \text{no. of blades} \div 60$ .

Where the noise reduction is calculated upon the basis of the fundamental frequency component, the treatment indicated as required should be ample for the harmonics which are more easily absorbed than the fundamental. In quieting noise due to air turbulence and eddy currents where high frequencies predominate, the frequency 1024 should be used.

Since ventilating system noise contains many frequencies, an exception should be noted to the previous statement that attenuation in decibels is directly proportional to length of duct. Most sound absorbent materials are more efficient at high frequencies than at low frequencies. In consequence, the attenuation in the first five or ten feet of lined duct will be greater because the high frequencies are being absorbed. Thereafter, since low frequencies will be predominant, the overall noise attenuation per foot will gradually be less.

#### Duct Lining

By far the most commonly used method of obtaining sound absorption in ventilating systems is to line the duct with absorbing material. It is usually more convenient to line all four sides of the duct, but a lining on one side over a longer length of the duct will, in general, give the same effect for the same area of applied acoustical material. Subject to certain restrictions, the attenuation of a fully lined duct to single-frequency sounds may be expressed by the approximate Equation 6:<sup>7</sup>

$$R = 12.6L \frac{P}{A} a^{1.4} \quad (6)$$

where

$R$  = attenuation, decibels.

$L$  = length of lined duct, feet.

$P$  = perimeter of duct, inches.

$A$  = cross-sectional area of duct, square inches.

$a$  = absorption coefficient of lining.

This formula was empirically developed for a set of duct sizes ranging from 9 x 9 in. to 18 x 18 in., for cross-sectional dimension ratios of 1:1 to 2:1, for frequencies between 256 and 2048 cycles, and for absorption coefficients between 0.20 and 0.80. The duct lining material used was 1 in. rock wool sheet. In Table 8 are listed the absorption coefficients of a material of this type in one-half and one inch thickness.

It is also possible to calculate the absorption by a very complicated mathematical theory.<sup>8,9</sup> Such calculations are in substantial agreement with Equation 6. This equation may be in error when applied to other

types of duct lining and to duct sizes and shapes greater than those specified. An empirically-derived chart<sup>10</sup> representing the average experimental data on a number of different types of materials, is shown in Fig. 5. Since individual materials vary, the curves of Fig. 5 are given only as representing the best available averages for duct sizes of cross-sections from 6 x 6 in. to 48 x 48 in. The dotted lines are plotted from Equation 6 and show that the slope is materially different from the average values.

#### Rectangular Cells (Plate or Cell Absorbers)

If the length of duct from the main duct to the grille is shorter than the length of lining indicated by Equation 6, the duct may be subdivided into smaller ducts as shown in Fig. 6, or it can also be even more subdivided by an egg-crate construction. In such a construction in which all the subdivided ducts are the same size, sound will be equally absorbed down each channel. It is, therefore, only necessary to calculate the sound attenuation of an individual channel. For this, Equation 6 is adequate.

When the number of splitter plates or cell partitions is large, the percentage free area of the gross duct size may be materially reduced. This leads to a further sound attenuation. Values of the attenuation possible, due to this cause, are given in Table 9.

### Sample Calculations for Duct Treatment

**Example 1:** An air conditioning installation is to be installed in a small theater. Determine the necessary sound treatment for the air distribution system to provide a satisfactory noise level in the theater utilizing these conditions:

|                                                                                           |         |
|-------------------------------------------------------------------------------------------|---------|
| Fan tip speed 4000 fpm, total pressure 1.25 in. ....                                      | 77 db   |
| Acceptable room noise level (Table 2) .....                                               | 40 db   |
| Required attenuation .....                                                                | 37 db   |
| <b>Solution:</b> Natural attenuation of supply duct.                                      |         |
| Sheet metal duct 50 ft long 48 in. x 36 in. (Table 4) 50 x 0.01 .....                     | 0.5 db  |
| Elbows, two size 48 in. x 36 in. (Table 5) 2 x 1 .....                                    | 2.0 db  |
| Attenuation grilles to theater air change 10 min (Table 7) outlet velocity 1000 fpm ..... | 22.0 db |
| Total natural attenuation .....                                                           | 24.5 db |

Difference between required and natural attenuation, 37 minus 24.5, is 12.5 db. This attenuation must be supplied by sound treatment in the duct, either in the form of duct wall lining or rectangular cells of the plate or cell absorber arrangement.

A similar analysis of the return duct system shows that 15 db attenuation is to be furnished by absorptive material. An inspection of the installation shows that the lining of the plenum on the suction side of the fan would prove the most economical, where it would secure the dual function of heat insulation and sound absorption.

**Example 2:** A 10 x 20 in. duct is connected to a private office space in a quiet location. Determine the length of lining necessary to attenuate average fan noise satisfactorily, using a lining material of a type to which Equation 6 applies, and having an absorption coefficient of 0.40 at 256 cycles. Assume that the duct is only 12 ft long as shown in Fig. 6, and that a 30 db reduction is required in this length.

**Solution:**

**Case 1.** (No splitters, duct lining only). From Equation 6,

$$R = 12.6 \times 12 \times \frac{60}{200} \times 0.40^{1.4} = 13 \text{ db.}$$

TABLE 9. END REFLECTION OF PLATE OR CELL ABSORBERS

| Percentage free area of absorber ..... | 50 | 40 | 30 | 25 | 20 |
|----------------------------------------|----|----|----|----|----|
| Attenuation db .....                   | 1  | 2  | 4  | 5  | 6  |

FIG. 7. ABSORPTION PLENUMS WITH AND WITHOUT SOUND CELLS

**Case 2.** (Two 1 in. splitter plates, 3 channels each 20 in. x 1/2 in.). From Equation 6,

$$R = 12.6 \times 12 \times \frac{46.7}{66.7} \times 0.40^{1.4} = 29 \text{ db.}$$

Additional attenuation may be obtained by using additional splitter plates or use of egg-crate arrangement of absorbing material and application of Equation 6.

### Plenum Absorption

In systems where individual ducts are directed to a number of rooms, and sound treatment is required in every duct, a sound absorption plenum on the fan discharge as shown in Fig. 7 will often prove the most economical arrangement. The absorption in the plenum may be approximated by Equation 7.

$$db \text{ (Attenuation)} = 10 \log_{10} \frac{\text{Plenum Absorption in Sabins}}{\text{Area Fan Discharge}} \quad (7)$$

The area of the plenum should be at least ten times as great as the fan discharge area. The plenum should be lined with 2 in. of muslin covered rock wool blanket, or 1 in. sound absorbing board preferably nailed to wood strips on the inside of the plenum. With such a lining the plenum is particularly effective in reducing low frequency fan noise. The absorption of the plenum in sabins is the sum of the products of each interior area of the plenum measured in square feet multiplied by its corresponding absorption coefficient.

### Outlet Sound Absorbers

Outlet sound absorbers are rectangular or plate cells installed directly behind an outlet or they may be the lining of a pan or plaque outlet. They are particularly effective in the elimination of high frequency whistles which are generated by air flow in the ducts. They are also employed in large systems with long runs where only a few outlets near the fan require treatment. Frequently outlet cells are the only means of correcting existing noisy installations, as the duct sections directly behind the outlets may be the only sections accessible for treatment. (See Fig. 8).

### AIR SUPPLY OPENING NOISES

When air is introduced into a room through a grille or register at a constant velocity, sound energy is being introduced into the enclosure at

FIG. 8. OUTLET CELLS FOR PAN OUTLETS OR GRILLES

a constant rate.<sup>11</sup> Due to partial reflection at the boundaries of the enclosure, the intensity of sound at any point in the space builds up to some maximum value. In a large room at a point remote from the source of sound (the supply opening) the intensity can be shown to be substantially proportional to the rate at which sound energy is generated, and inversely proportional to the number of sound absorption units (sabins) in the room. It would thus appear that doubling the sound absorption of the room would halve the intensity and result in a noise level decrease of 3 db.

Grille noise is similar in character to fan vortex noise. Knowing the noise level at the face of a grille for a given grille blade setting, the noise will vary as given in Equation 8 where  $V$  is the velocity of the air through the grille.

$$db \text{ (change)} = 50 \log_{10} \left( \frac{V_2}{V_1} \right) \quad (8)$$

For a change in blade setting Equation 9 applies, and in this case the total pressure is measured directly behind the face of the grille. For a typical air conditioning grille the noise level at the grille face may be approximately 48 db with a total pressure behind the grille of 0.1 in.

$$db \text{ (change)} = 25 \log_{10} \left[ \frac{(\text{Total Pressure})_2}{(\text{Total Pressure})_1} \right] \quad (9)$$

The resultant room noise level can be approximated by Equation 10.

$$\text{Room Level} = \left[ \text{Noise Level at Face of Grille} \right] - 10 \log_{10} \frac{\text{Total Room Absorption in Sabins}}{\text{Total Grille Area}} \quad (10)$$

#### Grille Selection

In practice the allowable total sound and the required air flow are usually known, and it is desired to determine the maximum allowable velocity. In comparing sound ratings of various grilles several factors must be known if the information is to be properly applied:

1. The threshold intensity on which the decibel ratings are based.
2. The distance from the grille at which data were taken.
3. If stated as sound level versus velocity for a given grille, the *core area* (not nominal area) must be known.
4. The sound absorbing characteristics of the test room.
5. Whether or not corrected for test room sound level; if not, the room level (without grille noise) must be known.
6. Methods used for recording data. (Characteristics of sound meter).

Since total sound and air flow are both functions of velocity and area, the solution of the problem implies a trial and error method. It has been

FIG. 9. AIR FLOW AND SOUND LEVEL CHART

found possible to present these data with sufficient practical accuracy as a family of uniform curves, as illustrated in Fig. 9, which are based on these assumptions:

1. Threshold intensity =  $10^{-12}$  watts per square centimeter.<sup>1</sup>
2. Microphone location 5 ft from lower edge of supply opening on a line downward at 45 deg, and in a plane bisecting the supply opening perpendicularly.
3. Where data are given as sound level versus velocity, the rating is per square foot of core area.
4. The room is assumed to have 100 sabins absorption.
5. Plotted data are sound levels of *supply openings only*, correction having been made for test room level.
6. Data taken with a direct reading sound-level meter with frequency weighing network intended to approximate the response of the human ear.

If the published ratings are in terms of decibels per square foot, correction must be made for area to secure the total sound level of supply openings of more or less than one square foot area from Equation 11.

$$\text{Decibel Addition} = 10 \log_{10} A \quad (11)$$

where

$A$  = core, square feet.

With Fig. 9 it is possible to find directly the velocity in feet per minute which will give a predetermined total sound at a predetermined rate of flow expressed in cubic feet per minute. The values used are arbitrarily chosen for the purpose of discussion, and do not necessarily represent data referring to any particular design of air supply opening. A correction chart is shown in Fig. 10 for a room having a sound absorption other than 100 sabins.

**Example 3:** Determine the core area (see Chapter 31) of an air supply grille which will maintain a noise level of not more than 40 db in a room having 100 sabins of sound absorption, if an air volume of 2400 cfm is required to maintain the proper air conditioning.

**Solution:** Assuming a grille noise rating of at least 5 db below the noise level of the room, Fig. 9 shows that the limiting grille velocity for a total sound level of 35 db is about 725 fpm, and the core area becomes fixed at  $2400 \div 725$  or 3.31 sq ft.

If the room absorption had been greater, the previously selected velocity of 725 fpm would be safe, since the sound level reduces. If the room absorption had been 200 sabins, a correction of plus 1.3 should be made by reference to Fig. 10, and the

permissible velocity becomes that corresponding to a total sound level of 36.3, or approximately 800 fpm.

If the room had been highly reflective with an absorption of less than 100, the correction would be much more important. For instance, for a room of 35 sabins, a correction of minus 3 db should be made, and the maximum velocity corresponding to the 32 db total sound level would be approximately 600 fpm.

Where more than one supply opening must be considered, the problem is more complicated. If a similar supply opening is added in a far corner of a highly absorbent room, the change in noise level at the 5 ft station at the first supply opening is small; however, if the room is small, or highly reverberant or both, the intensity at the 5 ft station may be almost doubled and the noise level increased nearly 3 db thereby. The simplest method of handling this problem is to treat the room as though all the air were being supplied by one supply opening. Thus, if two outlets, each supplying 1000 cfm are used, the value 2000 cfm should be used with Fig. 9. Although this method may place an unwarranted limit on velocity when used in a large room, it is seldom that such a room has a noise level low enough to justify a more complicated, though more exact procedure.

In general, return grilles are selected for velocities about half the supply velocity, and when this is done, they may be neglected in sound computations. However, if supply and return grilles are the same size, resulting in the same face velocity, they must be treated as two supply openings. That is, if 1000 cfm are supplied and exhausted through grilles of the same area, 2000 cfm must be used in the solution with Fig. 9.

#### CROSS TRANSMISSION BETWEEN ROOMS

Ducts serving more than one room permit cross talk between the rooms and should be lined with acoustical material. Where the rooms are close together and the ducts short, the ducts should be sub-divided to provide ample acoustical treatment. Lagging material similar in character to acoustical board, when placed on the outside of ducts, serves to prevent noise, originating outside the ducts, being carried inside the ducts and into the air stream.

A case where outside lagging is desirable occurs when ducts originate at the fan in the equipment room and pass through this room on the way to the room being conditioned or ventilated. Unless the ducts are lined, some of the mechanical noise from air in the equipment room may be transmitted through the wall of the duct into the air stream, and thereby carried into the room. In such cases, that portion of the duct which is exposed to the sounds in the equipment room should be lagged with material, such as cork, pipe covering or other sound damping material, to prevent the sound from entering the duct at this point. Numerical data are not available to permit a simple and practical calculating procedure to determine thickness of covering which should be used for this purpose.

Laboratory measurements have shown that the loss through a sheet of No. 22 gage metal is 24 db. When a sheet of rock wool insulation 1 in. thick and weighing 1.4 lb per square foot is added to this, the insulation value is increased to 29 db. In general, however, adding a layer of insulation or pipe covering does not materially increase the sound insulation value unless the material is dense, or unless it is surfaced with another sound impervious layer such as metal or board. Standard reference books should be consulted for sound insulating properties of various materials. Inside lining material, used in the case previously mentioned, would serve as an absorber of the sound transmitted through the duct walls, and thus act as a

FIG. 10. ROOM ABSORPTION CORRECTION CHART

means of preventing the transfer of noise into the air stream. Inside lining may also be used in ducts to absorb noise which reaches the air stream from equipment such as fans, sprays and coils; noise due to eddying currents set up by elbows, dampers and similar obstructions; and noise transmitted from room to room where there is a common duct system.

#### CONTROLLING VIBRATION FROM MACHINE MOUNTINGS

It is impossible to select equipment which will operate without producing some mechanical noise and, since the equipment must be mounted in a building, it is probable that a part of this noise will be transmitted to the building to such a degree as to make noisy conditions in the rooms which are to be air conditioned.

Much of this noise may be transmitted by the duct if it is rigidly connected to the fan outlet. It is common practice to make the connection between the fan and the duct with a canvas sleeve which effectively restricts noise at this point. Noise may also enter the building through the mounting of the motor and the fan. Flexible mountings should be provided in all installations, but these mountings must be carefully designed so that they will actually reduce the energy transmitted between the machinery and the supporting floor. If a flexible material is used, it is desirable to investigate the installation so that it is not short-circuited by through bolts which are improperly insulated, and by electrical conduit which is not properly broken and is attached both to the equipment and to the building. The flexible mounting, if improperly engineered, may actually increase the energy transmitted between the equipment and the supporting floor.

In the proper isolation of vibration, which is usually in the lower range

of frequencies and does not include the *airborne* vibrations known as sound, there is one basic formula which is important in the solution of the problem. It is the formula of transmissibility as governed by the equation:

$$T = \frac{1}{\left(\frac{f}{f_n}\right)^2 - 1} \quad (12)$$

where  $T$  = transmissibility of the support.  
 $f$  = frequency of the vibratory force.  
 $f_n$  = natural frequency of the machine unit on its support (damping = 0).

Equation 12 shows that the transmissibility approaches unity for disturbing frequencies considerably lower than the natural frequency of the mounting. As the disturbing frequency is increased, the transmissibility is also increased until at the resonant frequency, where  $f = f_n$  the transmissibility becomes infinite. This is not true in practice because all materials have some internal damping effect. However, operating at or very close to the resonant frequency is always serious as forces and stresses may be multiplied 10 to 100 times. As the disturbing frequency becomes greater than the natural frequency, the transmissibility becomes a smaller quantity, and at the value of  $f/f_n = \sqrt{2}$  it again has the value of unity. Beyond this point true isolation is first accomplished. At a ratio of 3 to 1 for  $f$  to  $f_n$  the isolation is effective enough for practical application, and experience and economical design have shown that a ratio of 5 to 1 is good. For high speeds, higher ratios for  $f$  to  $f_n$  are easily attained and give better results for effective vibration control, but for the lower speeds as experienced with compressor work the higher ratios become uneconomical.

For a given installation, the speed of the compressor is fixed by the specifications; therefore the value of  $f$  is fixed. That leaves only  $f_n$  to be determined, and that is accomplished by the choice of mounting material and design for the support of the machine. It is well to keep in mind that when trying to isolate vibration, no attempt should be made to isolate the driving and driven piece of equipment separately. The two should be mounted on a rigid frame, and then the entire assembly isolated according to the rules presented in this chapter.

The value of  $f_n$  can be controlled by the flexibility of the machine support, and when the deflection of the machine support is proportional to the load applied (such as with springs or nearly so with rubber in shear) the value of  $f_n$  can be determined by Equation 13:

$$f_n = \frac{1}{2\pi} \sqrt{\frac{g}{d}} \quad (13)$$

where  $g$  = gravitational constant.  
 $d$  = static deflection of supporting material.  
 $f_n$  = natural frequency of the machine unit on its support (damping = 0).

By the use of Equation 13 a set of curves may be plotted as shown in Fig. 11. The first line  $AB$ , plotted as the critical frequencies for the various static deflections, is a curve showing the worst possible conditions or resonant conditions.

Plotting another curve  $CD$ , which is  $\sqrt{2}$  times curve  $AB$ , shows the area  $MCDN$  in which the resilient material or mounting does more harm

FIG. 11. STATIC DEFLECTION FOR VARIOUS FREQUENCIES

than good. Plotting curves  $EF$  (3 times curve  $AB$ ) and  $GH$  (5 times curve  $AB$ ) shows area  $EGHF$  which represents efficient and economical isolation. Area  $GPOH$  is excellent isolation, but for all except the highest speeds, becomes rather uneconomical because of the large deflections required.

**Example 4:** An electric motor driven compressor unit is to be isolated. The compressor is partially balanced and operates at a speed of 360 rpm. The speed of the motor is 1160 rpm, and it is belt connected to the compressor. Total weight of the compressor and motor is 4500 lb.

**Solution:** The minimum disturbing frequency to be isolated is 360 cycles per minute. Assume that the desired ratio of forced to natural frequency is 3 as a minimum, and that 5 is desired. The desired natural frequency of the mounting is  $360 \div 5 = 72$  cycles per minute.

From Fig. 11 a deflection of 7 in. is required to attain a natural frequency of 72 cycles per minute. This value may be obtained from critical curve  $AB$  for 72 cycles, or from curve  $GH$  (5 times critical) for 360 cycles. For the minimum ratio of 3 the deflection would be 2.5 in.

The next step is to determine the total weight to be supported by the springs. For low speed partially balanced compressors, it has been found necessary to add a foundation weighing 2 to 3 times the weight of the motor and compressor, in order to maintain the machine movement below 0.03 in.

|                      |           |
|----------------------|-----------|
| Compressor and motor | 4,500 lb  |
| Concrete foundation  | 9,000 lb  |
| Total                | 13,500 lb |

Practical application dictates the number of springs to be used, which is based on the design of the machine foundation and the supporting floor structure. However, it is desirable to design for at least 8 springs and one or two spares for cases of unknown weights. As many as 50 springs have been used on one installation. The distribution of the springs must be balanced against the masses to be supported, otherwise the foundation design and supporting structure determine the location of the springs.

The choice of the material used in the design of the resilient mounting is also important. For the slow-speed type compressor, a common speed found in practice is 360 rpm. For speeds below this, isolation should not be attempted except under careful supervision. Referring to Fig. 11, it is

found that for 360 rpm the static deflection required for a ratio of  $f/f_n$  of 3 to 1 (line *EF*) is 2.5 in., and for a ratio of 5 to 1 (line *GH*) it is 7 in. For these values of deflection the only choice of material is the coil spring. This is also true for speeds up to about 700 rpm. In consideration of the transverse spring constant (so as to maintain good ratios among the various degrees of freedom) experience has shown that the spring should be designed with a *working height* equal to 1.0 to 1.5 times the outside diameter. A long spring of small outside diameter has very low transverse rigidity, and therefore requires some additional means of preventing side drift of the unit, and on very sensitive applications this may tend to destroy the isolation efficiency. For speeds of 700 to 1200 rpm the required deflections range from 0.22 in. to 1.75 in. For these conditions rubber in shear serves as a rather satisfactory material if protected from oil. For speeds higher than 1200 rpm cork specially made for vibration damping can be applied with good results. These limitations are by no means absolute, because certain liberties may be taken without impairing the result if all possible degrees of freedom have been taken into account in the design of the installation.

When a machine unit is properly isolated it will have a definite amount of movement which is determined by the ratio of the unbalanced forces to the total mass of the machine. If this resultant machine movement is too great for the necessary connections or the satisfaction of the customer, it can be reduced only in two ways without destroying the quality of the isolation; first, adding mass or dead weight to the machine (such as concrete) common in the application of low speed, partially balanced machinery; second, accurately balancing (both statically and dynamically) all moving parts so as to eliminate the vibration at the source. This latter method is the best engineering practice and is the modern trend. However, even with well balanced machinery, installed in the vicinity of quiet offices, it is usually necessary to isolate properly the equipment to prevent the transmission of vibration likely to cause complaints.

Where limitation of machine movement is desired during the starting and stopping periods, the application of friction or hydraulic damping will serve without seriously interfering with the efficiency of the isolation.

## CHAPTER 42

### ELECTRIC HEATING

Resistors, Heating Elements, Electric Heating Units, Applications of Electric Heat, Types of Electric Heating Systems, Equipment and Installation Methods, Calculating Capacities, Heating Water by Electricity, Induction and Dielectric Heating, Power Problems

**E**LECTRICITY as a source of heat represents thermal energy in a refined form, easily applied to space heating by a variety of methods, and readily distributed and controlled. However, it usually is more expensive on a direct-heat-equivalent basis than heat from conventional fuels, and for economical service requires careful application in the design of system, adaptation of building structure, choice of control devices, and in method of operation by the user. For special applications and particularly when used to supplement heating systems of other types, the compactness, simplicity, responsiveness, accuracy of control, safety, and other characteristics of electric heating may carry greater weight in choice of method, than operating expense or initial investment.

The basis of all electric heating methods and devices, except so-called heat pumps, is in the power-to-heat conversion constant: 1 kilowatt equals 3413 Btu per hr. Because ratings of electric heating equipment are expressed in terms of watts input and volts at the terminals, heating capacity calculations are translated directly to electric power requirements without the necessity of considering ampere currents or ohm resistances.

Definitions of *Resistor*, *Heating Element*, *Electric Heating Unit* and other terms applying to heating practices will be found in Chapter 1.

It is strongly recommended that compliance with the National Electrical Code and approval by *Underwriters' Laboratories Inc.*, or other recognized certifying agency, be required in the specifications for all equipment, materials, and construction used in electric heating systems.

### RESISTORS AND HEATING ELEMENTS

Electric resistors usually are composed of metal alloys such as nickel-chromium wire or ribbon, or non-metallic compounds containing carbon formed into rods or other shapes. Heating elements may have resistors either in the form of exposed coils mounted on insulators or of metallic conductors embedded in a refractory insulating material, encased in a protective sheath of metal. Fins or extended surfaces may be used to add heat-dissipating area. Elements are made in many forms, such as wires, strips, rings, tubes, plates and panels. Strip elements are used for clamping to surfaces requiring heat transfer by conduction, in some types of convection air heaters, and in low-temperature radiant heaters. Ring and plate elements are common in electric ranges and many small air heaters. Metal or oxide conductive films on glass and ceramics have been applied, usually in the form of panels. Tubular elements may be immersed in liquids, and when cast into metal or formed into coils, are used in water heaters, electric ranges and air heaters.

Cloth fabrics, woven from flexible resistor wires and asbestos or glass

fiber thread, are employed for many low-temperature purposes such as heating pads, blankets, aviators' clothing, and some radiant panel heating installations.

Special incandescent lamps are used as heating elements in certain applications where radiant heat alone is desired. These may have tungsten or carbon filaments as resistors, and are designed to produce maximum energy in the infra-red portion of the spectrum.

### ELECTRIC HEATING UNITS

In general, an electric heating unit is considered to be a structure containing one or more heating elements, electric terminal connections or leads, electrical insulation, and a frame, casing or other supporting means, all assembled together into a unit. There are many varieties, designated by such characteristics as shape and size of housing, material and arrangement of heating elements, operating temperature of resistors, ratio of radiant to convective heat delivery, directional control for radiation, natural or forced convection air circulation, thermostatic or manual control, and electric load-limiting features.

So-called *electric unit heaters* include a built-in fan which circulates room air over heating elements; they are employed for the same uses as other forms of unit heaters (steam, hot water, gas, oil), if conditions are favorable to electric heating. They are especially adaptable for supplemental heating, for small occupied rooms in otherwise unheated buildings and for unattended equipment enclosures in which temperature must be maintained above freezing. Location and arrangement of such unit heaters are discussed in Chapter 25. The typical wiring connection for a heater with single-phase power supply, shown in Fig. 1, has a safety thermal trip wired in series with the magnetic contactor, thermostat, and manual switch.

Forced-air duct heaters have collar frames designed to fit into rectangular cross-section ducts, within which are mounted closely nested resistors all wired to the terminal connections. Choice of resistor type and spacing depends on requirements for heat transfer to the air and on obtaining low air-flow resistance.

### APPLICATIONS OF ELECTRIC HEAT

Until recently the predominating applications of electric space heating have been for convenience service, such as: (a) to supplement an existing system, locally, at times when the main system is shut down, (b) for local use, where the main system may be inadequate, (c) for temporary service requirements, (d) for special conditions involving separate or remote control, (e) for isolated locations, (f) where minimum initial cost is the dominant factor. Some of these requirements are readily satisfied with portable heating units. However, complete electric heating systems are now finding wide application, mainly in residences, but also in many commercial and industrial establishments.

Small electric duct heaters or compact strip heaters are useful in balancing heat distribution in central fan heating systems operated with steam and hot water, and in improving temperature and humidity control for summer air conditioning. Such heaters can be installed in branch ducts or behind the air inlet grilles in each room.

In control of heating systems, employing electric units of the forced-air duct or similar types, a basic difference between electric heating and

steam should be taken into account. Steam is approximately a constant-temperature source of heat, at any given pressure, and a change in air quantity flowing over steam coils does not greatly alter the temperature of the coil surface. The amount of steam condensed (heat input) varies in proportion to the air volume, but the surface temperature of the steam coils remains about the same. Electric heat is quite different, having a constant rate of energy input. If the air flow over electric heating elements is changed, but no change is made in the electric power input, there will be a corresponding change in temperature of the air delivered. This occurs because the electrical energy input remains constant, and the surface temperature of the heating elements will vary as is necessary to compel the air to accept all the heat.

Thus, with electric heat the total heating effect is constant unless some compensating action is performed by controls. Automatic variation of

FIG. 1. WIRING DIAGRAM FOR UNIT HEATER

the electrical heat input synchronized properly with the air flow, can be successfully accomplished by certain special methods of control. By-pass dampers as used with steam units cannot control electric heat.

### TYPES OF ELECTRIC HEATING SYSTEMS

The principles employed in electric house heating for heat transfer and distribution, and for temperature control and cyclic operation, and the variety of equipment that has found application, outnumber those for systems utilizing fuel. This can be ascribed to the inherent adaptability of electric energy for transmission, conversion and regulation, and more importantly to the relatively high unit cost in terms of thermal equivalent as compared with fuels traditionally used for house heating; this necessitates and justifies greater attention to efficient utilization.

Types of electric heating equipment and complete heating systems in current use are listed in Table 1. The sequence shown is for convenient reference only, and does not indicate the relative extent of use, quality of performance, or installation cost and operating expense. Installations of all types listed are in successful operation, but performance and cost depend in large measure on proper application to the local conditions.

### EQUIPMENT AND INSTALLATION METHODS

#### Convactor with Metallic Resistors

Standard heating units for wall mounting, of either recessed or surface type, are made with resistors of incandescent bare-wire or low-temperature

(black) types and the general construction already described. A metal inner liner or reflector, usually placed between resistors and casing, provides a secondary air passage to promote circulation and reduce casing surface temperature at the rear. Depending on ratio of horizontal to

vertical dimension, pattern of face grille, and arrangement of resistors and deflector, the convection heat delivery constitutes between 40 and 60 percent of total output.

Ratings usually are from 1000 to 8000 watts (3400 to 27,300 Btu per hr) with some models down to 500 and up to 15,000 watts. Voltages are the standardized values between 110 and 240. Similar models equipped also with air circulation fans of axial type, are available; these give convection heat delivery up to 80 percent. Other types, using the same components but without a fan, are arranged as *floor furnaces* to be installed

between floor joists. A manual switch and thermostat integral with the unit are optional.

Portable units of the foregoing types, except floor furnaces, are obtainable with plug-in extension cords for convenience and occasional service. Ratings are 500 to 1200 watts at 110 volts; special models rated up to 5000 watts are also made, but can be used only on branch circuits having special wiring and receptacles.

### Convector Type Unit

The location of built-in electric heating units of convector type, generally along the exterior walls beneath or alongside windows, is governed by the same principles that determine arrangement of steam and hot-water convectors, with respect to movement of warm and return air. Positions on interior walls are sometimes permissible, so long as interference from opened doors and from furniture placement is avoided. A thermostat of high-sensitivity type and a conveniently located manual switch are recommended for each unit or at least each room.

### Radiant Convector Unit

Glass electric heating units, sometimes designated as radiant panels, depend on the heating effect produced by passage of current through a thin coating of conductive material fused to one face of a panel of  $\frac{1}{4}$ -in. thick special glass. The conductive layer may be sprayed-on aluminum or *printed* metallic oxide patterned to form a grid several thousandths of an inch thick, or fused-on material to give a uniform coating less than 0.0001 in. thick over the entire active face of panel. Normal glass operating temperatures are 300 to 400 F, with maximum permissible temperature around 650 F.

Electric wiring connections are made to the panel coating at its opposite extremities by wires soldered to the coating, by metal strips held in place with springs, or by other methods that assure low electrical resistance. The panel is supported on insulators within a metal frame which also carries a reflector behind the glass and is arranged to provide space for air circulation. A protective guard prevents accidental contact with the hot glass.

Glass units have standardized ratings, usually 1000 watts; with smaller units extending down to 200 watts, for the common voltages ranging between 110 and 240 volts. Starting current for some types exceeds running current by 10 and by 50 percent. Frame sizes vary from about 30 x 24 in. for 1000-watt size to 42 x 6 in. for 300-watt baseboard model; frame types are for either recessed or surface mounting. Thermostats integral with the frame assembly are optional. Portable units equipped with plug-in extension cords are of similar construction.

### Baseboard Type Unit

Metal casing proportioned to resemble and replace the conventional wood baseboard along plastered or masonry walls, contains 2 or 3 resistors placed horizontally, one above another. These usually are of low-temperature type, with ratings 80 to 120 watts (270 to 400 Btu per hr) per linear foot of baseboard unit, at 240 volts. The maximum surface temperature is 140 to 160 F. The vertical dimension is 6 to 8 in. above floor line, and the projection from face of plaster about 1.5 in. Placement within the room and method of control follow the same principles that apply to hot-water type baseboard installations described in Chapter 23.

Another type of baseboard unit has glass panels 6 to 8 in. high and 30 to 42 in. long, with surface operating temperature kept below 250 F.

#### Resistor with Focusing Reflector

An example of the focusing-reflector-type heating unit is the copper-bowl parabolic or circular *glow* heater for portable use. This has an incandescent wire-coil resistor on a conical ceramic core, screwed into a lamp-type central receptacle. Usual ratings are 600 and 1000 watts for 110 or 120 volt service. Heat emitted by radiant effect is 75 to 85 per cent of total delivery.

For permanent installation, low-temperature focusing units are made with tubular resistors mounted within sectional trough-type reflectors resembling industrial fluorescent lighting fixtures. They may be suspended from ceiling or bracketed from a wall. Rated capacities are 500 to 1500 watts per linear foot of unit. Installations of this kind are mainly in public and industrial buildings, to handle the perimeter heat loss at windows, doors or wall openings. In a modified form, such units are employed for infra-red heating and drying in industrial processes.

#### Steam Radiator with Immersion Element

For portable use, radiators (convectors) of light-weight 2-column construction are equipped with an immersion element screwed into a bottom opening at one end. Usually, after charging with water and antifreeze compound the radiator is sealed. A safety valve or thermal relief plug is provided, to protect against excessive pressure in case heat dissipation is unduly curtailed by clothing, bedding or other insulating material placed over the unit. The steam-and-water intermediate heat-transfer medium has no effect on overall thermal efficiency, but gives the unit operating characteristics adapted for certain applications.

Many recent models of window-type air conditioners are provided with resistors, enabling them to be used also for heating service in moderate weather. Electric input for heating is usually kept the same as for cooling. Consequently, the units normally give only convenience heating and are intended for use at times when the main heating system is shut down.

#### Ceiling Panel-Type Installations with Conductive Rubber

Panels of laminated construction containing electrically conductive rubber, with rating of 22 watts (75 Btu) per sq ft, for 115 and 230 volt service, are built in standard sizes 3 x 4 ft, 4 x 4 ft, and 4 x 6 ft. They consist of a layer of special rubber about  $\frac{1}{4}$  in. thick sealed between layers of phenolic resin-impregnated electrical insulating paper. The assembly is covered on each side with a sheet of aluminum foil. Overall thickness is  $\frac{1}{8}$  in.; weight is 0.4 lb per sq ft. Metal strips embedded along edges of the rubber sheet serve as potential leads. Electric terminal blocks are provided on each panel and standard raceway mouldings are furnished for wiring connections. An earlier type of construction using asbestos-board backing to form rigid panels  $\frac{1}{4}$  in. thick has been discontinued.

Under normal operating conditions that cause cycling under thermostat control, the surface temperature is about 100 F. When panels are turned on in a cold room or with continuous operation, the maximum temperature reached is 120 F.

The position of panels on the ceiling of a room should be as near as possible to exposed walls, especially at windows and doors, to counteract

cold-wall effect and to keep the occupants never farther than 3 ft horizontally from a heated area. The preferred location is with the terminal-block edges close to the walls and with 1-ft spaces between panels. Since it is not permissible to cut heating panels, the entire pattern for ceiling must be planned in advance both for appearance and for economy. Attachment to ceiling plaster, plaster-board or other smooth surface is made by a special adhesive applied on the ceiling along a  $1\frac{1}{2}$  in. fastening margin, provided around the four sides of each panel, which carries a dry adhesive tape bonded to the panel. Lighting fixtures must not be fastened or cut into the active area of a panel.

Adequate thermal insulation above panels is mandatory to protect all wiring from excessive temperature and to assure economical heating service. The minimum thickness of mineral or fiber insulation (glass or rock wool, cellulose fibers, loose asbestos, etc.) is 4 in. at top story and 2 in. for intermediate floors, whereas 6 in. and 3 in., should be the minimum corresponding thicknesses of expanded mica insulation.

A thermostat of high sensitivity type with an integral manual cut-off device should be provided in each room. To obtain economy of operation, a time switch or clock is advocated for lowering the room temperature to 55 F at night or when rooms remain unoccupied.

#### Ceiling Panel-Type Installations with Embedded Conductors

Resistors or *cables* for embedding in plastered ceilings to form panel-type heating installations are electrically insulated with a special compound resistant to high temperature, water absorption, aging effects, and chemical action with plaster, cement and soil. Cable units are furnished in standardized lengths between 20 ft and 1000 ft, rated from 50 to 3000 watts per unit, for 120, 220 and 240 volts. They have an outside diameter about  $\frac{1}{2}$  in., the maximum safe operating temperature is about 165 F, and the test voltage is 2500. Non-heating leads 8 ft long are attached to each unit, allowing the unit to be terminated at thermostats or in switch boxes without causing erratic operation of thermostat by heat from cable. Units are identified in regard to rating, by label and by color code. It is not permissible to alter the length of cable or leads, nor to install any cable unit lacking a visible identification label.

For plastered ceilings, the lathing used is of gypsum or other non-metallic fire resistant type. The cable is temporarily secured to lath with strips of  $\frac{3}{4}$ -in. cotton tape spaced not over 16 in. apart. Each element is tested immediately after fastening on lath, for completeness of circuit and for insulation resistance of at least 100,000 ohms measured to adjacent plaster or structural members.

The minimum spacing between cable passes or turns should be  $1\frac{1}{2}$  in. Leads from cable to junction boxes should be placed in loom. A clearance of at least 2 in. is required from any metal lath, such lath being permissible only for reinforcement along corners at walls. Clearance is likewise necessary at any metal objects, and this applies also to non-heating leads, as a precaution against magnetic hum. Cables must be kept away from local areas of ceiling that would be additionally heated by recessed or surface-type lighting fixtures. All general wiring for power and light is run above thermal insulation over the heat panel areas, or at least 4 in. above the heated ceiling surface.

Plaster should be applied in three coats with the first coat trowled in the same direction as the elements. A superfine sand finish is recommended, since a putty finish coat has a tendency to crack. While new

plaster is drying out, the range and rate of temperature changes (either increase or decrease), should be kept low. Vermiculite or other insulating plaster must not be used, since it causes cables to overheat.

Thermostats should be of high sensitivity type with a manual switch and have other characteristics like those described for conductive rubber panel installations.

### Electric Wall Panels

Although less common than ceiling or floor panel systems, walls may similarly be utilized for electric panel heating. However, possibility of damage to the electrical conductors or to their insulation, from nails driven for hanging pictures and from building alterations, as well as radiation interference caused by furniture placement and interior decorations, requires consideration. Care must be exercised to assure compliance with any applicable codes or safety regulations.

### Electric Floor Panels

Resistor cables of the same types which are used for ceiling panels are employed also for floor panel systems in concrete slabs. The thickness of the concrete slab is usually made a minimum of 3 in. when placed directly on soil. Precautions to be observed in construction of floor slabs for panel heating are covered in Chapters 12 and 24. Cement finish  $1\frac{1}{8}$  in. thick is poured and trowled above the cables. They are stapled at the specified spacing to wood nailing strips laid on the rough concrete slab. It is desirable that cables be secured in place either with a  $\frac{1}{8}$  to  $\frac{1}{4}$ -in. layer of cement wash or thinned grout before the final  $1\frac{1}{2}$ -in. cement or ter-razzo finish is applied, or by tacking at 2 ft intervals with daubs of cement, plaster-of-Paris, strips of masking tape or other non-conductive material. When the slab is made of light-weight insulating concrete, cables should be secured by tape or cord stapled directly to the slab as in the case of plastered ceilings. With monolithic finish, nailing strips are omitted and the cable is strung on frames with nail spacers; frames are removed when enough concrete has been poured to hold the cable in place. If desired, magnesite flooring, asphalt tile or wall-to-wall carpeting may be used on the floor.

Spacing between adjacent turns or loops of cable, and clearance from reinforcing steel bars or other metal bodies embedded in concrete, for prevention of magnetic hum, are the same as for plaster ceilings. Non-heating leads should have rigid conduit between the wall outlet box and floor. They terminate beneath the surface of the final coating. Porcelain or phenolic bushings to separate the leads should be placed with the leads pass from raceway into the slab. Cable circuits should be tested for continuity during the time they are being laid and again while the top concrete layer or cement finish is being poured.

Under ceramic tile floors, the cables are embedded in grout before tiling is laid. In the case of bathrooms, laundry rooms, basements subject to flooding, or other locations where wet floor conditions are likely, soil heating cable of lead-sheathed or other special water- and corrosion-resistant types may be required under local regulations.

### Central Hot-Water Systems

Heating systems of hot-water type using conventional radiator or convector units, discussed in Chapter 22, may be operated electrically by means of heat exchangers containing immersion elements (resistors) of

the required capacity. Control of the resistor circuit by a thermostat within the exchanger is usually desirable. The water holding capacity of exchanger should be made sufficient to minimize frequency of cycling of the heavy electric load from the resistor, and for safety. Resistors may be interlocked with the circuit of the water circulating pump, so that they can be energized only when circulating pump is in operation under control of the room thermostat.

For off-peak operation, where rate schedules for electric power make this desirable, a water heating tank of large storage capacity is employed. The system may be designed for a maximum water temperature of 250 to 275 F at pressures of 60 to 75 psig. An automatic valve is required to provide 140 to 160 F temperature at the pump, by mixing hot water from the tank outlet with cool water from the return main. Another method for heat delivery employs the *flash* principle, withdrawing water at high storage temperature into a low-pressure separating chamber where steam is obtained as a result of the pressure reduction; however, power for pumping is substantially greater with this steam-accumulator method. In practice, tanks up to 1200 gal with immersion elements of 25 to 30 kw have been used for installations with design heat requirements up to 90,000 Btu per hr. Thermal insulation on the tank piping must have low heat transmission in order to cut down the daily and seasonal standby losses. Design of such off-peak systems requires careful analysis of all factors, both thermal and economic. High investment, space required for equipment, and other practical considerations tend to limit the application of this type of electric heating.

### Central Warm-Air Systems

These systems usually employ heaters consisting of resistors mounted in a frame or housing, as mentioned under Electric Heating Units earlier in this chapter. In many cases, arrangement of the supply and return duct system can be planned advantageously to facilitate future addition of equipment for summer air conditioning.

### Conversion of Existing Heating Systems

Changeover of existing conventional fuel-type house heating systems to electric operation, by substituting resistors in place of the fuel equipment in the combustion chamber of a warm-air furnace or boiler, is seldom desirable. Excessive thermal losses from such central equipment and lack of adequate refinements in the distribution facilities and controls, will usually cause high operating cost. However, where heat delivery into the system is accomplished by a steam or hot-water coil assembly located within a duct system, replacement or supplementing with a bank of resistors like those employed in electric unit heaters is sometimes advantageous. A case of this kind occurs where standby heating is needed to maintain safe or comfortable temperature in isolated rooms, during emergency conditions or when the normal electric service for lighting and motors is not in use.

### Heat Pump Systems

Where summer air conditioning is wanted in addition to heating, the heat-pump type of all-year system, which utilizes a refrigeration compressor unit in conjunction with a central-plant installation, is finding a number of applications. It reduces electric input demand and consumption for heating to about one-half or one-third that with the resistance method, the reduction depending mainly on temperature level of the heat source

used and on the type of heat distribution system and its controls. In general, the conditions most favorable to heat pumps occur where, due to climate or operating requirements, the compressor capacities needed both for heating and for cooling service are the same, or nearly so. Customary methods of conveying the heat output from heat pumps to the space served are indicated in Table 1. The main types of heat pumps and the characteristics of heat sources utilized are discussed in Chapter 37.

Some recent models of window-type air conditioners are being equipped for operation as heat pumps. They have refrigerant reversing valves and controls, provided either at the factory or optionally by the installing contractor. Such units are intended for between-season or convenience heating only, since they do not give good performance when the outdoor temperature falls below 35 to 40 F, and they lack means for defrosting the evaporator coil.

In the case of heat pumps using air as heat source, it is shown theoretically and found in practice that heat delivery capacity falls off rapidly as outdoor temperature decreases, whereas the heat requirement increases directly with indoor-outdoor temperature difference. Deficiency at temperatures below the *balance point* can be made up by supplementary electric resistance elements, but this adds disproportionately to power demand. Moreover, seasonal energy consumption by such resistance heating, per kilowatt of demand established, is much less than for the heat-pump cycle itself, and the combination gives load characteristics unfavorable to the utility company for rendering low-cost electric service. An alternative provision for cold-weather peaks is thermal storage in chemical salts and by other devices; such processes are still in the development stage.

The installed cost of residential heat-pump systems is two to three times that of resistance types. However, in practically all cases the summer air-conditioning service obtained with conventional heat pumps is as valuable to the user as the winter heating. Resistance heating systems, except the minority using mechanical air circulation through ducts, do not lend themselves to consolidation with summer air conditioning features, and consequently, an independent cooling installation is necessary. Heat pumps thus have an advantage over such dual systems.

### CALCULATING CAPACITIES

The procedure outlined in Chapter 12 for calculating the heating load should be used for electric systems. Load expressed in Btu per hour is converted to kilowatts by the divisor 3413 Btu per kilowatt. All the energy applied to a resistor transforms itself into heat, unaffected by temperatures of the surrounding air and of surfaces receiving radiated heat. However, both electric power input and heat output are directly affected by voltage at the resistor terminals, being proportional to square of the voltage. Thus, a resistor rated 1000 watts at 240 volts, if used on a circuit at 220 volts, delivers 840 watts or 16 percent under the rated value, while at 208 volts the shortage is 25 percent.

Selection of proper indoor and outdoor temperatures for design of electric heating systems is more critical than for those using fuel, since in case the installed heating capacity is found deficient, the only recourse is to add more electric heating units or to bring the supply voltage up to the permissible maximum. On the other hand, fuel-operated systems ordinarily

permit raising the rate of combustion somewhat above the nominal rating, although there may be some penalty on efficiency, operating or maintenance expense, or overall performance.

Indoor temperatures usually specified are shown in Table 2 of Chapter 12, subject to the indicated notation concerning effect of radiant or panel heating. Moreover, allowance is required for radiation effect of cold surfaces if there are large windows, and for the continuing trend toward adoption of higher indoor temperatures. Concerning outdoor temperature for design, attention is directed in the case of electric heating systems to the cautionary remarks relating to winter climatic conditions in Table 1 of Chapter 12. Judgment must be exercised in choice between values *In Common Use* and *TAC 97.5 Percent Basis*, which show differences as large as 15 deg for some cities. If indoor temperature is taken at 70 F, it may be inadvisable to select outdoor temperature as high as the TAC 97.5 percent value.

The arbitrary addition of a percentage *safety margin* on the calculated heating load or on the specified rated capacity of heating units to be installed, is not recommended, especially in case the outdoor temperature for design is taken at or near the *In Common Use* value instead of *TAC 97.5 Percent Basis*. Such practice increases the peak electric demand and usually the cost of electric service. It also tends to produce excessive on-and-off cycling, impaired temperature regulation, and needless voltage variation or *flicker* disturbances with bad effect on lighting and other electric devices.

Many electric heating systems are of decentralized type, with a thermostat provided on each convector or for each room as recommended by manufacturers of such heating equipment. This practice compensates for variability of heat contributed by auxiliary sources such as sunshine, lighting and appliances. It also gives opportunity for *diversity* of power demand, i.e., the non-coincidence of electric load from all the convectors, panels or heating units of an installation. Manual switches are also commonly provided in such decentralized installations to permit cutting off heat or reducing temperature in rooms when not occupied. Such decentralized operation, advocated as an economic measure with electric heating, requires that consideration be given to adequate capacity for warm-up, as against the uniform-temperature operation with a fully centralized system.

It is essential that buildings intended to be heated electrically should be well constructed, with adequate thermal insulation having impervious vapor barriers, and with storm windows or double-glazed window units and weather stripping to minimize heat loss and air infiltration. Open fireplaces should be eliminated wherever possible, because they induce excessive infiltration. The relatively high electric cost for thermal energy, about \$6.00 per million Btu at \$0.02 per kwh, for example, as compared with about \$1.20 for oil at \$0.12 per gal when utilized with 70 percent efficiency, gives economic justification for substantial expenditure to reduce heat consumption. The large majority of dwellings heated economically by electricity have heat factors (quotient of seasonal energy consumption in kilowatt hours, divided by degree-days and by volume of gross heated space expressed in thousands of cubic feet) between 0.2 and 0.3. The features necessary to hold consumption within these limits result in construction that for 5000 degree-day climate with 0 F outside design temperature, gives a calculated heating load of 4000 to 5000 Btu per hr per 1000 cu ft gross volume. Heat factors up to 0.4 are not uncommon, but

experience shows that such high heat requirement may result in excessive operating cost.

### HEATING WATER BY ELECTRICITY

Electric water heaters for hot-water service in residences and commercial buildings are predominantly of the automatic storage type. These generally have a cylindrical tank mounted vertically, with a primary electric heating element or resistor near the bottom and a secondary unit located within the upper one-quarter of the tank. Water heaters of single-heating-unit type have an element only at the bottom. The first cost of automatic electric heaters is somewhat higher than that of fuel-fired types, owing to the need for larger tank storage to compensate for the limitation of recovery rate, since for economical electric service the connected load should be kept low. Large tank capacity is necessary also with off-peak operation, where there are low electric rates for this class of service.

Instantaneous heaters are used in special cases only, because of the high electric power input required, for example, 15 kw to deliver 1 gpm with 100 deg temperature rise.

Capacities of household automatic storage-type water heaters, as partially standardized within the electrical industry, range from 30 to 140 gal nominal tank capacity with input 1600 to 7000 watts. Wattage input ratings of two-unit heaters are based on approximately 30 watts per gallon of tank capacity for secondary unit and 20 watts for primary unit. Single-unit heaters have tank sizes up to 80 gal with an input of 4000 watts, the ratings being based on 50 watts per gallon. The schedule of heater capacities shown in ASA Standard C72.1-1949 is reproduced in Table 2.

The wattages listed in Table 2 are minimum recommended values for continuous service. Some departure from the standardized watts-per-gallon ratios is to be expected, as experience indicates that increased hot-water use with automatic laundry machines and dishwashers may call for larger heating units than have heretofore been found desirable. With off-peak operation the watts-per-gallon ratio likewise must be raised.

Rated voltage for water heaters is 240 volts, with a range 220 volts minimum to 248 volts maximum, but specified test performance is required to be met only at the 236 volts taken as normal design voltage. Thermostats controlling the heating units are normally set for 150 F, with upper limit of adjustment range of 170 to 180 F.

Heating units are of three general types, all of which give approximately the same service efficiency if selected to suit the operating conditions, as follows:

1. Immersion element, inserted horizontally through a threaded or flanged opening in side of tank.
2. Strap-on unit, externally mounted directly against the tank shell and held in close contact by a band or strap encircling the tank.
3. Side-arm or *outside circulation* unit, consisting of a vertical cylindrical housing or heat exchanger which contains an immersion heating element, connected by pipes into top and bottom of the storage tank.

For the third type, which is less commonly used, thermostats separate from the heating units are mounted within the storage tank.

A fourth type of heater, applied only in exceptional cases and for large installations with alternating current, employs the water itself as a re-

sistor in which electrodes are immersed. Close temperature regulation and compensation for the effect of variable amount and composition of solids and gases in the water are difficult to obtain with small unattended heaters of this kind. The electrode type of construction has in the past been used also for generating steam in so-called electric boilers, mainly for industrial plants; however, in only few instances today is electric energy obtainable at cost low enough to make it competitive with fuel-fired boilers for steam production.

Tanks of electric heaters are regularly constructed to withstand a 300 psig hydrostatic test pressure and are rated for a safe working pressure of 127.5 psig. Materials in contact with the water are selected to resist corrosion caused by solid and gaseous impurities occurring in some locations. It may be desirable also to provide *sacrificial metal* anodes of magnesium, zinc or alloys to protect the tank and its piping connections. A safety relief valve of pressure-actuated type must be included; it may optionally be actuated also by internal temperature. A heat trap at the hot-water

TABLE 2. STANDARD RATED CAPACITIES OF ELECTRIC WATER HEATERS

| TANK SIZE<br>GALLONS |            | RATED INPUT, WATTS |           |                    |
|----------------------|------------|--------------------|-----------|--------------------|
|                      |            | Two-Unit Heater    |           | Single-Unit Heater |
| Nominal              | Range      | Primary            | Secondary |                    |
| 30                   | 30 to 35   | 600                | 1000      | 1500               |
| 40                   | 35 to 45   | 750                | 1250      | 2000               |
| 52                   | 45 to 55   | 1000               | 1500      | 2500               |
| 66                   | 55 to 70   | 1250               | 2000      | 3000               |
| 80                   | 70 to 90   | 1500               | 2500      | 4000               |
| 110                  | 90 to 115  | 2000               | 3000      |                    |
| 120                  | 115 to 135 | 2500               | 4000      |                    |
| 140                  | 135 to 175 | 3000               | 4000      |                    |

outlet, if not provided by manufacturer within or outside the tank shell and inside the insulated jacket, may be placed in the external piping. The trap consists of vertical pipe at least 6 in. long having downward flow, to retard circulation of hot water within the distribution piping system under standby conditions.

Occasionally, an uninsulated tempering tank is installed ahead of an electric water heater, enabling the cold inlet water to absorb heat from the basement or room air—if conditions are such that objectionable sweating does not occur. The practice of connecting a tempering tank with a fire-box coil, the electric heater then furnishing heat only when there is deficiency from the boiler or furnace, is not recommended.

Delivery performance efficiency of heaters meeting the electrical-industry standard 24-hour operation test is 90 percent minimum, which allows 10 percent for thermal loss through the jacket insulation. In service, the quantity of water withdrawn from an automatic storage heater has considerable influence on overall efficiency. With increasing quantities, service efficiency rises and approaches the upper limit fixed solely by the jacket thermal loss; on the other hand, if little or no water is drawn, efficiency approaches zero since no useful work is done. Hence oversizing

a water heater by having too large a tank impairs the service efficiency. Excessive heating-unit wattage causes undesirably high electric demand. Undersizing of heaters obviously results in inadequate and unsatisfactory hot-water service.

Selection of electric heater capacity for residences is made by reference to rating tables which take into account the number of occupants, number of bathrooms or plumbing fixtures, and presence of appliances such as laundry equipment, dishwashers, and the like. Information of this kind is in Chapter 49 and in design manuals issued by the electric utility industry and by heater manufacturers. For commercial applications, the hourly hot-water requirements must be analyzed and the best combination of tank capacity and heating element rating determined, with due consideration of electric power demand created in relation to the user's other electric demands.

A common type of electric service for water heating is the so-called

FIG. 2. DOMESTIC HOT-WATER HEATER FOR OFF-PEAK SERVICE

*off-peak* service under which the charge for energy consumed during designated hours is lower than for normal or unrestricted service. With this system, the operation of heaters is confined to such hourly intervals during the 24 hours as will (a) avoid creating peak electrical demands by the customer in excess of the demand resulting from the customer's other uses of electricity, or (b) keep the water heating load off the electric utility system during peak hours. In general, Case (a) occurs where rate schedules contain a demand charge component, and Case (b) where a special low rate applies to off-peak consumption. Water heater circuits are controlled with relays actuated by an electric-clock mechanism or by a *carrier-current* impulse impressed at suitable intervals on the electric distribution system, or by an automatic load-limiting type of control.

One arrangement of domestic hot-water heater for off-peak service, shown in Fig. 2, has the lower heating unit under control of an off-peak switch. Upper unit is connected directly to the line, so that in case the reserve of hot water becomes depleted, the top thermostat brings its heating unit into operation only until the upper portion (usually about 25 percent) of tank contents reaches the thermostat temperature.

Water heaters employing the heat-pump principle are now in limited trial use, obtaining annual performance factor (sometimes called coefficient

of performance) approaching 2.5. This value represents the ratio of useful heat delivered, to the direct heat equivalent of total electric input. The predominant models have tank capacity of approximately 55 gal, hermetic type compressors rated  $\frac{1}{4}$  or  $\frac{1}{2}$  hp, and small circulating fans. So-called *vagrant* heat occurring within the basement or utility room is generally the heat source. In some cases there is secondary benefit from dehumidifying, and an appreciable cooling effect is produced. Present limitations include high initial cost, low recovery rate, restricted maximum temperature, and necessity of condensate drain connections, compared with conventional electric resistance-type and fuel-fired water heaters.

### INDUCTION AND DIELECTRIC HEATING

These methods, employed for industrial processes requiring extreme speed or close control of heat location, do not lend themselves to space or water heating. However, since they are sometimes proposed for consideration, the operating principles are described briefly.

Any electrically conducting material placed in an alternating magnetic field develops eddy currents that generate heat. The rate of internal heating is so high that conduction away from the zone to be treated does not unduly lower the temperature. The field is created by coils connected to an alternating-current power source such as motor-generator set, a mercury arc, or an electronic-tube or spark-discharge oscillator, producing frequencies usually between 250 and 10,000 cycles per second, but for some applications up to 500,000 cps. The coils are generally copper tubes through which cooling water is circulated. Induction heating apparatus must be specifically designed for each application such as melting metals, brazing, heat treating internally or in zones, and surface hardening without oxide scale formation or distortion.

Dielectric heating, for materials that are non-conductors of electricity and are poor thermal conductors, requires a high-frequency electrostatic field produced at high voltage and very high frequencies reaching 50 million cps. The method is well adapted to continuous-flow production process including manufacture of bonded plywood, drying of deep-pile fabrics, dehydration of granular or crystalline materials, and sterilization of foods.

### POWER PROBLEMS

#### Rates for Electric Service

The cost of electricity varies due to several factors. The main elements are the annual charges, including taxes, on capital invested and those expenses necessary to keep the electric utility system at all times in a state of *readiness to serve* the load. The cost of generating the energy is secondary. Electricity is not stored, but must be produced instantaneously when and as required by the user. Consequently, the time of power use, both daily and seasonally, and relation between rate-of-use or demand and the energy consumed within a period (load factor) have large effects on costs and the rates charged. Special low rates sometimes are available during certain prescribed *off-peak* hours of use, when the system load is low.

Space heating is a load whose magnitude is determined basically by weather, and is affected to a much lesser extent by the electric customer's use of his premises. Most of the heating loads in a region occur simultaneously, thereby tending to create peaks for which the capacity of the electric system must be adequate. Accordingly, rates contain in one way

or another, charges both for demand and energy. Demand may be indicated directly by a demand meter or be derived from manufacturers' rating data shown on nameplates of the heating equipment. In block-type rates, where demand is not specifically mentioned, it is in part reflected by higher charges per kilowatt-hour in the earlier blocks.

#### Control of Electric Demand

To obtain electricity for space heating at minimum cost, it is necessary to keep the user's kilowatt demand as low as possible, by provisions in original design of the installation and by judicious methods of operation. Excess heating capacity should be avoided, but without jeopardizing satisfactory performance in cold weather. A variety of control methods can be applied to minimize both demand and consumption. Decentralized control with a thermostat in each room or on each heating unit, together with manual switch to cut off any unoccupied room, is one method. Sequence switching whereby electric service to individual rooms or circuits is shifted in rotation by an automatic timing device and sequence is modified by outdoor thermostat or by total electric load, is another.

Load-limiting controls of several types have come into use. These are generally arranged to measure the customer's total power demand, which for a residence may be grouped as lighting and miscellaneous appliances, refrigerator and water heater, cooking range, and the space heating system. When the demand exceeds a preset value, one or more heating circuits are cut off progressively in rooms least affected by the interruption. Experience shows that with electric floor or ceiling panel heating, temperature drop occurs slowly, at the rate of about 1 deg per hour for concrete slabs and 2 deg for plaster construction or rigid panels properly backed with thermal insulation. Moreover, electricity consumed by lighting, appliances and cooking ranges is contributing some useful heat at such times.

Another form of limiting control for 120/240-volt 3-wire circuits provides complete or sequence transfer of space heating units from 240 volts to 120 volts, thereby reducing the electric input to one quarter whenever the total load or general-service component exceeds a preset limit. This method lends itself to use of an outdoor thermostat actuating a relay, whereby in mild weather the entire heating system operates at 120 volts and with lengthened cycles obtains more uniform room temperature. For reducing temperature at night, if desired, a clock-operated master thermostat can be provided to lower the heating-system voltage. On some electric utility systems, centralized control by means of a pilot-wire or carrier-current actuating a relay is applied to house-heating installations.

With any type of control, time-delay relays should be used in order that upon restoration after an emergency service interruption or whenever a master thermostat calls for heat, the individual circuit or units will come on non-simultaneously over a period of a few minutes. This is advisable especially for types of resistor units that have a power input, when cold, as much as 50 percent above the rated value at normal operating temperature.

#### Operating Costs

The range of electric costs for house heating, on residential rate schedules typical of country-wide conditions, is from something over two cents per kilowatt-hour where house-heating consumption comes mainly on the

bottom step of a block-type residential rate, to as little as half that figure in areas served by large hydroelectric systems. Since the range of heat factors for houses of differing construction types with various methods of resistance electric heating and with a variety of occupancy is likewise more than 2-to-1, costs of house heating for dwellings of the same size in similar winter climates may vary through a range of nearly 5-to-1. However, an

TABLE 3. RELATION OF RESISTOR VOLTAGE TO HEAT DELIVERY

| CONDITION                                | VOLTS   | HEAT DELIVERED<br>% |
|------------------------------------------|---------|---------------------|
| Electric system, nominal value           | 120/240 | 103.3               |
| For design of equipment, at terminals    | 118/236 | 100                 |
| Range, as basis for design               |         |                     |
| Minimum                                  | 110/220 | 86.8                |
| Maximum                                  | 124/248 | 110.5               |
| On secondary distribution system         |         |                     |
| Favorable zone, as to voltage conditions |         |                     |
| Minimum                                  | 110/220 | 86.8                |
| Maximum                                  | 125/250 | 112.0               |
| Tolerable zone                           |         |                     |
| Minimum                                  | 107/214 | 82.2                |
| Maximum                                  | 127/254 | 116.8               |
| Emergency conditions                     | 90/180  | 58.3                |

8000-cu ft house can be heated with 8000 kilowatt-hours of electrical energy annually in 5000 degree-day climate, if a heat factor of 0.2 is attained by means of good construction and adequate insulation.

#### Voltage Requirements

The preferred nominal system voltage at point of electric utilization by equipment, for single-phase 3-wire systems necessary with space heating, is 120/240 volts, as stipulated by standards of the electrical industry (*EEI* publication R-6 and *NEMA* publication No. 117 issued May 1949). For household heating appliances mentioned in the standards, such as air heaters, water heaters, and cooking ranges, the *equipment voltage rating for design* is specified as 118/236 volts, and the range of *voltages to be used as a basis of design* extends from 110/220 minimum to 124/248 maximum. However, naturally variations exist from time to time in the conditions at different points in any secondary distribution system and will affect both voltage level and range of fluctuations. Under emergency conditions on electricity supply systems, voltages of the order of 90/180 may be encountered. Heat delivery by resistors with these voltage values, expressed in percent of rated delivery with the normal 118/236 volts (at terminals) is given in Table 3.

Voltages stipulated for secondary distribution systems are at point of service entrance to the building; the drop of voltage in the house supply wiring to terminals of the heating equipment may be 2 to 3 percent, thus reducing heat delivery by some 5 to 8 percentage points below the *favorable zone* and *tolerable zone* values included in the last column of Table 3. Ac-

cordingly, it is necessary the designers of electric heating installations obtain specific information from the local electric utility company on both existing and anticipated future conditions at the location, before specifying the capacity and voltage for equipment, wiring and controls.

### CHAPTER 43

## CORROSION AND WATER FORMED DEPOSITS, CAUSES AND PREVENTION

Definitions, Classification and Characteristics of Water, Causes and Prevention of Scales and Sludges, Causes and Prevention of Slimes, Underwater Corrosion, Atmospheric Corrosion, Buried Pipe Lines, Handling Water Treating Chemicals, Legal Regulations

THE surfaces of heating and ventilating equipment that are in intimate contact with water sometimes are affected by the chemical characteristics of contacting waters to such an extent that prohibitive amounts of insoluble materials are formed or corrosion ensues at an insufferable rate. To avoid or to correct such troubles; it is desirable that heating and ventilating engineers have a general appreciation of industrial water chemistry. The principal purpose of this chapter is to provide those criteria by which the average engineer may judge whether a problem is one that will yield to rather simple remedies, or will require the skill of an experienced water technologist.

### DEFINITIONS

The following definitions for water-formed deposits, corrosion, and closely allied terms have been proposed:

**Water-Formed Deposits.** A water-formed deposit<sup>1</sup> is any accumulation of insoluble material derived from water or formed by the reaction of water upon surfaces in contact with water.

Deposits formed from or by water in all of its phases may be further classified as scale, sludge, corrosion products, or biological deposits.

**Scale.** Scale<sup>1</sup> is a deposit formed from solution directly in place upon a confining surface. It is a deposit which will retain its physical shape when mechanical means are used to remove it from the surface on which it is deposited. Scale, which may or may not adhere to the underlying surface, is usually crystalline and dense, frequently laminated, and occasionally columnar in structure.

**Sludge.** Sludge<sup>1</sup> is a water-formed sedimentary deposit. It usually does not cohere sufficiently to retain its physical shape when mechanical means are used to remove it from the surface upon which it deposits. Sludge is not always found at the place where it is formed. It may be hard and adherent, and baked to the surface on which it has been deposited.

**Biological Deposits.** Biological deposits<sup>1</sup> are water-formed deposits of biological organisms or the products of their life processes. Biological deposits may be microscopic in nature, such as slimes, or macroscopic, such as barnacles or mussels. Slimes are usually composed of deposits of a gelatinous or filamentous nature.

**Corrosion.** Corrosion<sup>2</sup> is destruction of a metal by chemical or electrochemical reaction with its environment. In the corrosion process, the reaction products formed may be soluble or insoluble in the contacting environment. Insoluble corrosion products may deposit at or near the attacked area, or be carried along and deposited at a considerable distance from the attacked area.

**Corrosivity.** Corrosivity<sup>3</sup> is the capacity of an environment to bring about destruction of a metal by the process of corrosion. Corrosivity is a property of the environment, but it has no significance until the metal in question is specified.

### CLASSIFICATION AND CHARACTERISTICS OF WATER

For industrial use there is no accepted conventional classification of water. Rather, each industry usually develops a body of ideas applicable to its own water problems.<sup>4</sup> For heating and ventilating engineers, it is perhaps most convenient to distinguish between mineralized waters and condensates.

#### Mineralized Waters

All the waters found in streams, wells, lakes, and the ocean are mineralized. The same is true of all municipal supplies even though they may have been treated. For a given area, ground waters are likely to be more highly mineralized than are surface waters. Conversely, surface waters

TABLE 1. MINERAL ANALYSES TYPIFYING COMPOSITION OF WATERS AVAILABLE AND USED INDUSTRIALLY IN THE USA

| SUBSTANCE              | UNIT              | LOCATION OR AREA <sup>a,b</sup> |       |     |       |     |     |     |     |        |

<sup>a</sup> All values are parts per million of the unit cited to nearest whole number (see Reference 5).

<sup>b</sup> Numbers indicate location or area as follows:

- |                                                            |                                           |
|------------------------------------------------------------|-------------------------------------------|
| (1) Catskill supply—New York City                          | (6) Well Water—Maywood, Illinois—2090 ft. |
| (2) Swamp Water (Colored) Black Creek, Middleburg, Florida | (7) Well Water—Smithfield, Va.—330 ft.    |
| (3) Niagara River (Filtered) Niagara Falls, New York       | (8) Well Water—Rosewell, N. Mexico        |
| (4) Missouri River (Untreated) Average                     | (9) Ocean Water—Average                   |
| (5) Well Waters—Public Supply—Dayton, Ohio—30-60 ft.       |                                           |

are more likely to be contaminated with municipal sewage and trade wastes. Virtually all mineralized waters also contain biological organisms.

**Mineralogical Characteristics.** The character and amount of extraneous inorganic materials—including deleterious gases—dissolved and suspended therein, describe the mineralogical characteristics of any water. Revealing such information is the function of a mineralogical chemical analysis.

The analyses in Table 1 disclose the composition of the public water supplies used by about 45 percent of the total population of the cities, in the United States, having more than 20,000 inhabitants.<sup>5</sup>

All values recorded are in terms of parts per million.\* This is the approved standard terminology for reporting the results of mineral analyses.<sup>6</sup> Values reported in the other terms commonly used may be converted into the standard form by using the factors listed in Table 2.

Data for dissolved gases or pH values have been omitted in Table 1 because even waters of the same mineral contents may vary widely in these respects. Unpolluted natural waters usually have pH values within the range 5 to 8, depending upon their free CO<sub>2</sub> contents. Polluted waters,

\* Parts per million are hereinafter abbreviated ppm. A part per million signifies a unit weight of material per million unit weights of the solution.

TABLE 2. CONVERSION FACTORS FOR WATER ANALYSES

| TO CONVERT                 | INTO | MULTIPLY BY |
|----------------------------|------|-------------|
| Grains per U. S. gallon    | ppm  | 17          |
| Grains per Imperial gallon | ppm  | 14 1/4      |
| Grams per liter            | ppm  | 1000        |
| Mg per liter               | ppm  | 1           |

which include those derived from wells or swamps in marshy ground, may have pH values well below 5.

**Biological Characteristics.** The slime-forming organisms are mostly lower plants, grouped by botanists into the phylum thallophyta. This group is distinguished by the absence of leaves, roots, or stems from the mosses, ferns, and seed plants which comprise the three other phyla of the plant kingdom.

The thallophyta (see Table 3) are divided into algae, which can synthesize chlorophyll for the production of sugar, and the fungi which lack chlorophyll, and must therefore secure already synthesized carbohydrates.

All thallophyta are of universal distribution and many of them are slime forming. Of the five divisions of algae, only three (the green, the blue-green, and the diatoms) are found in fresh water. Of the five divisions of fungi, all may occur in fresh water, the principal slime formers being indicated in Table 3.

The methods of analysis commonly used in the sanitary examination of a water have, as their principal object, to identify and count pathogens.

Most slime-forming organisms are not pathogens. When a water is subjected to a biochemical analysis for the purpose of evaluating its slime producing characteristics, tests, widely different from sanitary bacteriological tests, must be made. Tests upon the water itself are seldom satisfactory, and true indications of the sliming characteristics of a water can only be determined by the analysis of deposits on surfaces having a temperature close to the temperature of the final design equipment. The results of such a test are commonly reported in the manner illustrated in Table 4.

#### Condensates

All condensates result from the chilling of water vapor. Such chilling may result from natural causes, thus producing *dews, sweats, rain, and snow*, or from artificial causes, as in steam condensing equipment, producing condensate or return water.

TABLE 3. PRINCIPAL SLIME FORMERS

| PHYLA | ROUGH DIVISION OF PHYLA                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Algae | Single celled, sometimes forming slimy sheets.<br>Many celled in either sheets or fronds.                                                                                                                                                                                                                                                                                                                                                                                   |
| Fungi | <i>Bacteria</i> (Schizomycetes) frequently forming slimy surface coatings.<br><i>Slime Molds</i> (Myxomycetes) forming slimy sheets as one stage of their life history.<br><i>Sac fungi</i> (Ascomycetes) of which one division, the yeasts, occasionally form slimy aggregates.<br><br>The alga-like fungi ( <i>Phycomycetes</i> ) and the stalked fungi ( <i>Basidiomycetes</i> ) rarely form slimes but their filaments may hold together the slimes of other organisms. |

TABLE 4. PLANT WATER SUPPLIED FOR EXAMINATION

| TOTAL COUNT                                         | 100,000 organism/cc.                                                                                                                                                                                                                                                                                                  |
| ORGANIC CONTENT (by WEIGHT, DRY BASIS)—60%          |                                                                                                                                                                                                                                                                                                                       |
| DISCUSSION—                                         | The presence of common slime-forming organisms in the deposit combined with high organic content indicates that the deposit is bacterial in origin. Heat transfer reductions would be caused by such a deposit. These deposits, combined with crenothrix, can cause corrosion of both ferrous and non-ferrous metals. |
| RECOMMENDATIONS—                                    | It is recommended that the water be treated at the suction side of the deep well pump with chlorine in quantities sufficient to maintain a free chlorine residual of 1.0 ppm at the discharge of the shell and tube cooler. This treatment can be scheduled on an intermittent basis.                                 |

In the heating and ventilating field, the biological characteristics of condensates are likely to be of concern *only* where the condensate is used as cooling water in recirculating systems. The deleterious gas contents of condensates, however, very often create serious corrosion troubles.

The data in Table 5 typify the chemical composition of the atmosphere in rural and metropolitan areas, and of stack gases when various types of common fuels are used. The curves in Fig. 1 disclose the solubility of the major deleterious gases present in such atmospheres in otherwise pure water, when the partial pressure of the gas is one psia.

The most common deleterious gases entrained by steam are oxygen and

carbon dioxide. In rare instances, hydrogen sulphide, sulphur dioxide, or ammonia are present.

In most steam condensing equipment,<sup>7,8</sup> the non-condensable gases entrained with steam accumulate so that the amount present in the vapor space is several hundred times higher than in the incoming steam and the amount dissolved in the condensate may therefore approach, or even exceed for short periods, the amount entrained by the steam.

### CAUSES AND PREVENTION OF SCALES AND SLUDGES

Scales may be formed on surfaces of equipment in contact with water, and sludges in the body of the water, by the separation from the water of dissolved or suspended solids. According to the nature of a particular

Fig. 1. SOLUBILITY OF GASES AT PARTIAL PRESSURE OF 1 PSI

piece of equipment and the method of its operation, such separation may be promoted by one or more than one, of several factors:

- The concentration of solids may be increased by the evaporation of water.
- The dissolved solids may be rendered less soluble in the water by changes in temperature.
- Conditions may favor the decomposition of unstable compounds with the formation of less soluble compounds.

Figs. 2 and 3 show that the solubilities of both calcium carbonate and calcium sulphate decrease with the rising temperature within a moderate range of temperatures. Surfaces transferring heat into water, such as

FIG. 2. SOLUBILITY OF CALCIUM CARBONATE IN DISTILLED WATER CONTAINING CARBON DIOXIDE

(pH Values at Approximately 73 F)

Fig. 2 Adapted from (1) *Ind. & Eng. Chem.*, 20 (1928) 1197—by Baylis. (2) *J.A.C.S.* 50 (1929) 2086—Frear & Johnson.

condensers and coolers, are more susceptible to scale and sludge formation than are the cold parts of the same system using the same water.

The most common of the unstable soluble salts are the bicarbonates of calcium, magnesium, and occasionally iron. Under conditions favoring the removal of carbon dioxide, as when the water is strongly aerated or when it is boiled, the bicarbonates are readily converted to the relatively insoluble carbonates. The type of scale most usually encountered is calcium carbonate (often called alkalinity) from the decomposition of calcium bicarbonate according to the following chemical reaction:

Conversely, carbonates are readily converted to the more soluble bicarbonate by the addition of carbon dioxide or other acidic materials. This explains the increase in the apparent solubility of calcium carbonate

at decreasing pH values (increasing concentration of hydrogen ion) shown in Fig. 2, the carbonate really going into solution largely as bicarbonate.

In special cases, primarily with well waters possessing a high natural iron content, deposition of iron oxide from the decomposition of ferrous bicarbonate takes place according to the following reaction:

Low water velocity in heat transfer equipment often causes sludges to settle out in the tubes. This has the same effect on heat transfer as scale

FIG. 3. SOLUBILITY OF CALCIUM SULFATE AND OF CALCIUM CARBONATE FOR COMPARISON

(CaCO<sub>3</sub> in Equilibrium with Normal CO<sub>2</sub> Content of the Atmosphere)

Fig. 3 Adapted from Bull. No. 15, *Univ. of Mich.* Formation and Properties of Boiler Scales by P. E. Partridge.

formation. When this occurs, increasing the water velocity often cures the condition.

It is sometimes desired to evaluate the tendency in a particular water toward the separation of calcium carbonate, which may be desirable as a means of establishing a corrosion-resistant film on metal surfaces, or in other circumstances may be undesirable because of the impedence of the calcium carbonate film to heat transfer. This tendency is indicated approximately by the Langelier Index,<sup>9</sup> which is obtained by subtracting the actual pH of a particular water from the pH at which it is estimated precipitation of calcium carbonate would just begin. This estimate may be made by the use of Fig. 4.

There are various expedients which may be employed for avoiding or mitigating difficulties due to scales:

- The water may be treated before use to remove elements such as calcium, magnesium, and iron, which form relatively insoluble compounds. In the various softening processes this removal of these elements is accompanied by the addition of other elements, particularly sodium, the compounds of which are relatively soluble.
- The water may be treated within the equipment to promote the separation of

dissolved solids as sludges, rather than as scale which is, in most cases, more objectionable.

c. The increase in total solids, due to the evaporation of water, may be controlled by the displacement, continuously or intermittently, of some of the used water by fresh supply.

d. Substances, such as the polyphosphates, having the property of inhibiting the precipitation of calcium carbonate from solutions supersaturated with it, may be added.

e. The *pH* of the water may be lowered (hydrogen ion concentration raised) to reduce the tendency for precipitation of carbonate. This is permissible only to such an extent as will not cause a serious increase in rate of corrosion.

The choice of the best expedient or combination of expedients must be made for each type of equipment, and will be affected by operating and water considerations. Item c above must be used, regardless of which other items are used, for all recirculating water systems from which evaporation takes place.

### Once-Through Equipment

Where abundant supplies of water are available at low cost, the cooling water may pass through the equipment once, undergoing a rise in temperature. Little difficulty from scale should be encountered if the Langelier Index is lower than +0.5, based on the highest water temperature encountered in the system. This often corresponds to a carbonate hardness of less than 200 ppm when water temperatures are lower than 100 F. However, since many municipal supplies are softened so that incipient calcium carbonate precipitation is induced, the Langelier Index is a more reliable indication of scaling tendency.

Prevention of scale in once through systems is based primarily on the adjustment of *pH*, the application of surface-active agents, or a combination of the two. Normally the addition of a few parts per million of a surface-active agent such as a polyphosphate<sup>10</sup> fed proportionately to a water with a scaling tendency is all that is required to control scale.

Where a given water does not respond satisfactorily to surface-active agents, reduction of *pH* with sulfuric acid or carbon dioxide is often employed. The *pH* is reduced only sufficiently to have it fall within the effective range of the surface-active agent. The use of acid or carbon dioxide is sometimes permitted without polyphosphates when corrosion will not be severe. In this case the *pH* is reduced so that the Langelier Index is less than +0.5. The acid or carbon dioxide must be added with care. Use of automatic *pH* controllers is required if corrosion is to be prevented.

A special case of scale from ferrous bicarbonate decomposition was mentioned previously. Ferrous bicarbonate is considerably less stable than calcium bicarbonate. The prevention of this decomposition can be accomplished by the addition of polyphosphate in low concentrations.<sup>11</sup> The use of polyphosphate in the ratio of two parts by weight to one part by weight of iron is usually most effective. The polyphosphate must be added to the water before exposure of the water to air or chlorine if effective stabilization of the iron is to occur.

### Closed Recirculating Systems

The closed recirculating system is one in which water circulates through one heat exchanger where it absorbs heat, has its temperature elevated, and circulates through another heat exchanger in which its temperature is lowered. In cold water or chilled water systems scaling is seldom a

FIG. 4. GRAPH AND NOMOGRAM FOR DETERMINATION OF *pH* SATURATION BY LANGELIER'S FORMULA  
(Applicable within *pH* Range 7.0-9.5)

Based on article in Oct. 1938 issue of American Water Works Association Journal and later corrections for Tables 2 and 4 of article. Prepared for Charles P. Hoover of the Columbus, Ohio, Water Softening and Purification Plant by M. L. Riehl.

#### Instructions for Using Chart:

1. Knowing temperature and total dissolved solids, find temperature and total solids constant on Col. 1.
2. Align this constant with given value of calcium on Col. 3 of Chart, then locate point on Col. 2 of Chart (Pivot Line).

3. Align this point on Pivot Line with given alkalinity on Col. 5; read *pH* saturation on Col. 4.
- Saturation index is *pH* actual minus *pH* saturation.  
e.g. - *pH* actual, *pH* saturation. Saturation index.  
7.6 8.1  
-0.5 (corrosive)  
+0.5 (scale forming)

problem. In hot water systems scaling is seldom a problem unless there is a large amount of makeup water.<sup>12</sup> In these cases the use of surface-active agents such as polyphosphate are used.

### Open Recirculating Systems

Where water from condensers and similar equipment is passed through a spray pond or cooling tower and then returned to the equipment, there is an increase in the concentration of solids because of the evaporation of some of the water into the cooling air, and, moreover, the aeration removes carbon dioxide. Both factors promote the tendency to deposit scale.

This condition is also true for air washers during periods of operation when air is humidified. Evaporation of recirculated water occurs, causing concentrations of scale forming minerals. (There are cases, such as in New York City, where water supplies have extremely low solids content. Aeration in air washers and cooling towers causes absorption of acid gases

FIG. 5. RELATION OF BLEED-OFF REQUIREMENT TO  $\text{CaCO}_3$  IN MAKE-UP WATER

such as sulfur dioxide,  $\text{SO}_2$ , from the air. Serious corrosion rather than scale occurs.)<sup>13</sup>

The concentration of scale-forming minerals in open recirculated cooling water is limited by natural drift or windage loss. This is the loss of water droplets from the system. Windage losses from typical systems may be classified as follows, based on recirculating rates:

|                                              | Percent of Recirculating Rate |
|----------------------------------------------|-------------------------------|
| Evaporative Condensers and Air Washers ..... | 0 to 0.1                      |
| Mechanical Draft Cooling Towers .....        | 0.1 to 0.3                    |
| Atmospheric Cooling Towers .....             | 0.3 to 1.0                    |
| Spray Ponds .....                            | 1.0 to 5.0                    |

To show the effect of concentration in a typical mechanical draft system assume:

1. Recirculating Rate = 100 gpm.
2. Drift loss = 0.2 percent of recirculating rate = 0.2 gpm.
3. Evaporation Rate = 1 percent of recirculating rate = 1.0 gpm.
4. Calcium bicarbonate in make-up water = 100 ppm.
5. Calcium bicarbonate in evaporated water = 0 ppm.

### Corrosion and Water Formed Deposits, Causes and Prevention

Let  $K$  = concentration of calcium bicarbonate in recirculating water = concentration of calcium bicarbonate in drift loss.

The process of concentration in the system may be represented diagrammatically as follows:

The concentration may be obtained from the equation

$$(\text{Make Up}) [\text{Ca}(\text{HCO}_3)_2 \text{ conc.}] = (\text{Evap.}) [\text{Ca}(\text{HCO}_3)_2 \text{ conc.}] + (\text{Drift}) [\text{Ca}(\text{HCO}_3)_2 \text{ conc.}]$$

$$(1.2) (100) = (1) (0) + (0.2) (K)$$

substituting,

$$120 = 0 + 0.2 K$$

whence,

$$K = 600 \text{ ppm}$$

Therefore the concentration of calcium bicarbonate in the recirculating water equals 600 ppm. This far exceeds the allowable concentration of 170 ppm at which scaling will occur.

To correct this situation, it is imperative to provide a continuous bleed-off or blow down from the recirculating water circuit. Typical bleed-off requirements are shown in Fig. 5. Reference to the No Treatment curve shows that a bleed-off rate of 1.2 times the evaporation rate is required when a make-up water contains 100 ppm calcium bicarbonate (or alkalinity) if scale is to be prevented. Calculation by a material balance will show that the bleed-off plus drift loss will limit the calcium bicarbonate to 171 ppm.

It can be seen from Fig. 5 that very large amounts of bleed-off are required as a make-up water approaches or exceeds 150 ppm of alkalinity. When alkalinity exceeds 175 ppm, bleed-off alone is no longer effective. The use of 5 ppm or less of polyphosphate is extremely effective in reducing the required bleed-off and making possible the use of make-up waters which will not respond to bleed-off alone.

Occasionally, waters are encountered which have exceptionally high alkalinities or which develop high  $\text{pH}$  values when recirculated. The use of sulfuric acid is common in these cases to maintain  $\text{pH}$  values between 7 and 8. Polyphosphates are most always used when acid is required.

It is very important to control acid feeding carefully to avoid serious corrosion. Automatic  $\text{pH}$  controllers are often employed for such purpose.

### Heating System

In hot water heating systems or in steam heating boilers where all condensate is returned, troubles from scaling should not be severe. If necessary, sodium phosphate or sodium carbonate may be added to the water to prevent the formation of adherent calcium sulphate scale.

### Boilers and High Temperature Equipment

Where temperature exceeds 250 F, complete softening of the water is the only practical method for minimizing sludge formation. This is usually accomplished by artificial or natural zeolites (called also ion-exchange materials) or by hot-process precipitation softeners.

In boilers operating at pressures above 100 psig virtually all the calcium, magnesium, silica, iron, and manganese salts entering with the feed water are potential scale or sludge formers.

In boilers operating at 100 to 250 psig, the formation of adherent calcium sulphate (anhydrite) scales is most to be feared. Such deposits form on the *hottest* evaporative surfaces. The scale has a low heat conductivity. Even a layer of egg shell thickness may so impede the rate of heat transfer as to bring about over-heating of the metal.

The ortho-phosphates of sodium are most frequently used to prevent sulphate scales. The concentration of phosphate required is such as to cause the precipitation of calcium phosphate as sludge, thus keeping the boiling water under-saturated with respect to calcium sulphate. To a lesser extent, sodium carbonate (called also soda ash and sal soda) is also used. Most of the effective boiler compounds contain either phosphates or soda ash, or both. Certain organic materials and colloids are sometimes found to minimize scale formation. Where chemicals are introduced directly into the boiler in amounts adequate to prevent scale, sludge is formed in amounts proportionate to the calcium and magnesium salts entering with the feed water. To prevent troublesome accumulation of this sludge, as well as soluble salts, as evaporation occurs, some *blowdown* of boiler water is necessary.

### CAUSES AND PREVENTION OF SLIMES

A water containing slime-producing organisms will produce prohibitive amounts of slime *only* when the conditions of use are such as to propagate their life processes. Whenever sufficient food material from normal water or from airborne dust combines with optimum temperature conditions, such as exist on cooling surfaces and air washers, serious quantities of slime will be produced.

Some natural well waters do not contain sufficient foods to support luxuriant slime-growths. Algae, which require light for carrying on their life processes, are likely to cause difficulty in cooling towers and other areas where sunlight is abundant. The ordinary slime-forming bacteria are capable of using a wide variety of nitrogenous and cellulose material as food sources. These bacteria thrive best under dark conditions such as exist in condensers and other heat transfer surfaces. Other organisms capable of causing similar difficulties use such a wide variety of food material as algae,<sup>14</sup> iron compounds,<sup>15</sup> and inorganic sulphates.<sup>16</sup>

At present, the use of toxic chemicals and irradiation are the two general means employed in slime control. The value of ultra-violet light, used so broadly in the beverage industry, is somewhat in dispute.

Anti-fouling paints have been developed and are fairly satisfactory for the prevention of the growth of macro-organisms such as *barnacles* and *mussels*, but these paints must be renewed at frequent intervals, and are not applicable to inaccessible areas such as the inside of pipe lines and cooling towers. Satisfactory *anti-sliming* paints have *not* been found.

Names and other pertinent data relating to some of the more common chemicals used in slime control are shown in Table 6.

Chlorine is the only chemical to which is attributed the ability to destroy slime-forming organisms. The others are presumed to poison marine organisms, most of which *recover* when the chemical is not used regularly.

While chlorine is the most generally used chemical, the use of others may occasionally prove to be more practicable. Choice of the chemical is conditioned largely by the design and operation of the system.

### Open Recirculating Systems

In spray ponds and cooling towers of the open type, light-loving algae growths are likely to cause blocking of the distribution piping and troughs. These organisms are most troublesome in areas accessible to sunlight. Algae slimes are usually stringy in character.

In open recirculating systems, continuous use of small quantities of chlorine is generally most satisfactory. In once-through systems, where

\* As Shipped.

large quantities of water are used, intermittent treatment a few times each day will usually result in satisfactory slime removal and chemical economies.

Neither the phenols nor copper sulphate may be used for the removal of slime already formed. For this purpose, chlorine gas is used. After being cleaned, the other chemicals may be used to prevent the reestablishment of slime in the system. The removal of green algae from a cooling tower should never be used as an indication that the true slime-forming organisms on heat exchanger surfaces have been removed. The more resistant slime formers, which so materially reduce heat transfer efficiency, will often be unaffected by treatment which completely eliminates algae.

Copper sulphate must be used with care because it can cause serious corrosion of steel in a system. It is also ineffective in alkaline water because the copper is precipitated from the water.

### Closed Once-Through Systems

In equipment where light is excluded, slime formations are due to fungi. Usually, they predominate on the heat exchange surfaces. Bacteria form thick, soft slime. Yeast and molds form tough rubbery slimes. Chlorine and hypochlorite solutions, fed intermittently, are usual preventatives.

### UNDERWATER CORROSION

When deleterious substances are present in water, the corrosivity of the solution is increased in proportion to the amount of deleterious substances present, the temperature, and usually the rate of flow of the solution over

the metal surfaces. There are other relevant factors, but their influence in general is subordinate to those mentioned. Dissolved oxygen, acid gases, and chloride salts are the corrosion accelerators most frequently encountered.

Neutral and slightly alkaline waters saturated with air, corrode iron at a rate about triple that for the same water free of air. Hot water containing oxygen will corrode iron at a rate three to four times that for the same water when cold.

Corrosion of iron decreases as the *pH* of water solutions increases, and practically ceases at a *pH* of 11. If the metal contains film forming agents, such as chromium, nickel, and silicon, or if the water contains inhibitors such as silicates and chromates, corrosion may in some instances be minimized.

Soft water, as for example the effluent from zeolite softeners, is likely to be several times more corrosive to iron than hard waters. In small installations, the use of copper or brass pipe usually is a practical expedient. Cement-lined pipe and tanks suitably resist attack.

Where the water contains slime-forming organisms, especially those bacteria that thrive on iron, chlorination of the water is imperative to inhibit tuberculation and subsequent pitting.

Bitumastic paints, applied at regular intervals upon well cleaned surfaces, will measurably prolong the life of equipment handling cold waters.

**Pipe Materials.** Brasses with 60 to 67 percent copper are dezincified in some corrosive waters, and in certain localities are not much more serviceable than galvanized iron or steel pipe. The zinc in brass pipes is leached out locally, leaving a plug of porous copper. The weakening of such pipe is especially noticeable under the threads. Dezincification is retarded by the use of silicate of soda (8 ppm added silica).<sup>17</sup>

In salt or fresh water, there is no material difference in rate of pitting of wrought iron, steel, low metalloid steels, or copper bearing steels. This is contrary to the relative performance of these metals in atmosphere.

#### Once Through Systems

Corrosion prevention in once through systems is obtained by any one of or a combination of the following methods.<sup>12</sup>

1. Forming a protective film of calcium carbonate on the metal surfaces.
2. Mechanical or chemical deaeration, or both, of the water.
3. Use of organic or inorganic corrosion inhibitors, or both, in low concentrations.

Formation of a thin protective calcium carbonate film is accomplished by adjustment of the water until the Langelier Index has a value greater than +0.5. This is rather difficult in systems which have a wide variation in temperature. Since the Langelier Index is dependent on temperature, when a water is adjusted to form a protective film on those surfaces of higher temperature, no film will form on colder surfaces. Therefore, this method of corrosion control is more applicable to large municipal distribution systems. Where heat transfer is involved, the method is usually impractical except under unusual circumstances. When this method is used, *pH* is increased by using an inexpensive alkali such as lime, caustic soda, or soda ash. Lime is usually used for waters of low calcium content. Caustic soda or soda ash are used for waters of high calcium content.

Mechanical<sup>18</sup> and chemical deaeration are not often used in once through

systems because of relatively high operating costs. Mechanical deaeration also requires the use of costly equipment. Chemical deaeration is usually accomplished by raising *pH* with caustic soda and by continuously feeding catalyzed sodium sulfite in proportion to water flow. The use of catalyzed sulfite is not permitted in water to be used for potable purposes.

There are several corrosion inhibitors such as chromate, polyphosphates, and silicates which are effective in once through systems.<sup>19</sup> Chromates are not usually used because, when maintained at an effective concentration of 300-500 ppm, their cost is prohibitive. It has been found that the use of polyphosphate at a concentration of 2-5 ppm is effective in controlling tuberculation of iron pipe and in reducing overall corrosion.

The use of chromate-polyphosphate concentrations at less than 60 ppm has also proved effective. Under no circumstances may chromates be used in potable water systems.

Sodium silicate is often used in relatively soft waters by increasing the silica content about 8 ppm. It is used primarily to reduce corrosion in potable water supply systems.

#### Open Recirculating Systems

Corrosion in open recirculating systems, such as air washers and cooling towers, is usually controlled by use of corrosion inhibitors such as chromates polyphosphates, a combination of chromate and polyphosphate, and nitrites.<sup>20, 21</sup> Mechanical or chemical deaeration is not practicable in open systems because of the high rate of aeration. It is not practicable to use high *pH* values of 11 or more in systems containing wood. High *pH* will cause serious delignification of wood. High *pH* values also prevent control of scale. Corrosion control is usually carried out in the *pH* range of 6.5-8.

Chromates are by far the most effective corrosion inhibitors. It is extremely important, however, to maintain an adequate concentration of 300-500 ppm, which is effective for most systems. If for economic reasons substantially lower concentrations are used, serious pitting corrosion may occur.

Polyphosphates are most effective in reducing tuberculation. It is not usually possible to reduce overall corrosion to anywhere near the degree possible with chromate.

Where economy of treatment is of primary importance, a substantial reduction of pitting and overall corrosion can be obtained by using as little as 60 ppm of a mixture of polyphosphate and chromate. Close control over *pH* is a requirement for good corrosion control by this process.

Sodium nitrite has not had widespread use as a corrosion inhibitor in open recirculating systems. It has been reported that difficulty may be encountered in maintaining effective concentrations. Considerable field experience is needed to further qualify this inhibitor.

#### Closed Recirculating Systems

The term Closed Recirculating System is in reality a misnomer. Except for relatively small systems, most closed systems are open because they most usually require make-up water. Recently, tests conducted on 84 closed systems indicated that more than 50 percent of the systems had one or more water changes per month because of leakage. Weekly water changes were found in more than 10 percent of the systems.<sup>22</sup> Continuous make up, of course, replenishes oxygen in the system, thus promoting

corrosion. It is imperative, therefore, that corrosion control be provided for most closed systems. The age old assumption that closed systems are closed is no longer valid.

Corrosion control is usually accomplished by (1) mechanical or chemical deaeration or (2) use of corrosion inhibitors such as chromates and nitrites.

The use of polyphosphates is not generally recommended for closed systems because they will revert to ineffective orthophosphates unless there is a large replacement of water containing polyphosphate.

Higher concentrations of chromate are usually maintained in closed systems as compared with open systems. This is primarily due to the fact that, since water losses are usually small, the cost of maintaining excess chromate as a safety factor is small.

### Treating Chemicals

Whenever chemicals are used to control scale, corrosion, algae, and slime, competent advice from a water chemist is desirable. Often factors considered irrelevant to the layman, will be of much importance in secur-

TABLE 7. QUANTITIES OF SODIUM DICHROMATE TO BE ADDED TO MAINTAIN INITIAL CONCENTRATION

ing effective treatment. Very often troubles are created through improper use of chemicals and are more serious than if they were not used.<sup>23</sup>

### Refrigerating Systems

Corrosion in refrigerating systems is confined to surfaces in contact with brines or those in contact with the refrigerant.

**Brines.** Refrigerating brines usually are comprised of sodium chloride, calcium chloride, or calcium and magnesium chlorides. The corrosivity of dilute brines is higher than their more concentrated solutions. The corrosivity of sodium brines, other conditions being fixed, is about 1.5 times greater than brines of the alkaline earth metals.

Brines are excellent electrolytes. Contact of dissimilar metals of wide potential differences, when in contact with brines, results in rapid corrosion by galvanic action.

The leakage of air, acid refrigerants, or both, accelerates the corrosivity of brines. Ammonia precipitates calcium and magnesium salts, thus clogging the system at restricted points.

The addition of caustic soda and sodium dichromate to brine solutions to inhibit corrosion of iron, is a more or less general practice. Sodium sili-

cate and sodium phosphate are also used at times, but tests indicate they are not as effective as is sodium dichromate. It has been suggested<sup>24</sup> that 125 lb of sodium bichromate per 1000 cubic feet of calcium chloride brine, and 200 lb per 1000 cubic feet of sodium chloride brine, be added to inhibit brines; that when salt or calcium chloride is added to "strengthen" brine, sodium dichromate also be added in the amounts shown in Table 7.

**Refrigerants.** The common refrigerants, except those of the hydrocarbon type, will attack the common metals and alloys if *moisture is present*. Even a very small amount of water may cause severe corrosion with certain refrigerants. The amount required need only be sufficient to produce a water film on the metal surface.

With the halogenated hydrocarbons, complete elimination of water is much to be desired. Where ammonia is used, copper and its alloys, aluminum and zinc, are attacked especially at elevated temperatures. When sulphur dioxide is used, more than 50 ppm (0.005 percent) of water will cause appreciable corrosion of virtually all the common materials.

### Minimizing Condensate Corrosiveness

There are four expedients that may be utilized to minimize corrosion in steam condensate systems: (1) treatment of the boiler feedwater so as to eliminate deleterious gases entrained with the steam, (2) design of the condensing equipment to minimize dissolution in the condensate of the deleterious gases entrained with the steam, (3) chemical treatment of the condensate, (4) use of resistant metals.

**Boiler Feedwater Treatment.** Elimination of oxygen from boiler feedwater and, therefore, from the steam developed, can be accomplished either mechanically or chemically. In some steam generating stations, both expedients are employed.

Tests<sup>25</sup> have indicated that in small low-pressure heating boilers, where the boiler input contains less than about 50 ppm of carbonate hardness, the CO<sub>2</sub> in the steam can be controlled by adding calcium hydroxide to the boiler. In Fig. 6 are shown the equilibria conditions proposed for boilers operating at pressures up to about 5 psi gage. This expedient may *not* be used in higher pressure boilers, because of the possibilities of scale and sludge formations. In the latter, the only method used to date for treating the feedwater consists of removing the alkaline earth salts, *i.e.*, softening, and subsequent acidulation followed by deaeration at temperatures near the atmospheric boiling point of water.<sup>26</sup>

**Design of Condensing Equipment.** In the design of water heaters and comparable types of condensing equipment,<sup>27</sup> it is possible to shift the accumulation of non-condensable gases to a location away from the condensate level and, subsequently, vent these gases to the atmosphere. Venting an amount of steam equal to about one-half percent of the total steam entering the condenser is the optimum vent rate.

Venting is of little practical value when the CO<sub>2</sub> content of the incoming steam is below about 5 ppm. When the steam contains more than 5 ppm, venting provides a means of producing a condensate containing a minimum of about 3 ppm. However, even as little as 3 ppm of dissolved CO<sub>2</sub> can produce active corrosion if large amounts of condensate are flowing.

**Chemical Treatment of Condensate.** Condensates containing comparatively large amounts of oil, are practically non-corrosive, due to the protective film provided by the oil. When oil is intentionally added to con-

densate,<sup>28</sup> inadequate quantities may accelerate rather than decelerate corrosion on those surfaces not covered by the oil. Sodium silicate added to  $CO_2$ -bearing condensate has been shown to decrease, but not entirely prevent, corrosive action. It is not known whether the protection afforded by silicate solutions is due to the establishment of a protective film on the metal surface or to neutralization of the  $CO_2$  by the alkali in the silicate solution.

It has been postulated that ammonia,<sup>29</sup> cyclohexylamine,<sup>30</sup> ethylene diamine, and morpholine<sup>31</sup> will retard corrosion of condensate lines. Tests with benzylamine have also been reported.<sup>32</sup> Where copper and its alloys are involved, the use of alkaline inhibitors is believed inadvisable. The use of small amounts of sodium hexametaphosphate has been suggested

FIG. 6. RELATION OF HYDRATE/CARBONATE CONTENT IN *Hard* BOILER WATER AND  $CO_2$  IN STEAM AT ABOUT 5 PSI OPERATING PRESSURE  
(All analytical values are ppm by weight)

too, but tests<sup>33</sup> indicate that this salt accelerates rather than decelerates, the rate of attack of steel by condensate containing  $CO_2$  and oxygen. Whether chemical treatment of steam or condensate is feasible, must be determined not only upon the basis of the acuteness of corrosion troubles, but also upon the uses to which the steam or condensate is put.

**Use of Resistant Metals.** For economic reasons, the metals known to resist corrosion can seldom be used exclusively for condensate lines in any sizable enterprise. Nevertheless, there may be instances where the use of a limited amount of the more costly, but resistant, materials can be justified. The data in Fig. 7 are the results of tests<sup>34</sup> designed to reflect the corrosion resistance of the more commonly used metals to attack by condensate containing oxygen and  $CO_2$ .

In contemplating the use of a resistant metal, as a section of a condensate line, it should be remembered that, if other conditions are *right*, corrosive attack will merely be transferred down stream in the system. Galvanic corrosion resulting from the contact of dissimilar metals in a condensate line seldom occurs. No paint or similar protective coating

has thus far proven satisfactory. Tests of cement-lined and vitreous-lined pipe have shown the linings to be readily dissolved by hot condensates.

### ATMOSPHERIC CORROSION

Most of the problems originated by atmospheric corrosion occur in connection with the fire-side of boilers and furnaces (including their flues and stacks), sewer vents, air ducts, coal and ash handling equipment. Usually such equipment is fabricated from common types of ferrous metals.

Generally little or no atmospheric corrosion occurs at temperatures higher than the boiling point of water, because at such temperatures little or no condensate is formed. If it does form at the higher temperatures, only negligible amounts of carbon dioxide and oxygen present in the

FIG. 7. COMPARATIVE CORROSION RESISTIVITY OF 10 MATERIALS EXPOSED TO CONDENSATE

atmosphere, will dissolve in the hot liquid, but sulphur gases may dissolve and cause rapid attack. Oxygen, sulphur dioxide, sulphur trioxide, and carbon dioxide are the deleterious gases most frequently accountable for corrosion in moist atmospheres.

### Coal Storage and Handling Equipment

Virtually all coals contain sulphur in the form of pyrite, and some moisture. In storage, the pyrite is likely to be decomposed by oxidation. Moisture dissolves the products of decomposition forming sulphurous and sulphuric acid. The acid solutions vigorously attack the supporting metal.

Rubber linings have been developed for coal chutes and bins to effectively resist corrosion and the abrasive action of the coal, but they are expensive.<sup>35</sup> Concrete linings for steel bunkers have also been effectively employed.<sup>36</sup>

The use of high chromium steels is not always a sure cure, especially with coals treated with dust allaying agents high in chlorides.

### Flues, Stacks, and Fire-side of Boilers

The surfaces of flues and boilers contacting the products of combustion, seldom experience corrosive attack when the equipment is in operation.

Breechings, smoke hoods and canopies in contact with flue gas may, however, be subject to attack during the warming-up period of an appliance, or when the rate of operation is so low that the temperature of the flue gas is below the dew-point. It is common practice to use cast-iron or acid resistant vitreous enameled steel in flue gas connections to appliances, to prolong the life of these parts. The shut-down period, when condensation of moisture occurs on the metal surfaces, is usually the time when most damage is done.<sup>37</sup> In those sections of the stacks where flue gas temperature drops below the dew-point, corrosion is inevitable during operation.

It is clear that where long shut-down periods are anticipated, a practical method for mitigating corrosion is to clean the surface thoroughly and to provide adequate clean, dry air circulation to prevent condensation. (See also Care of Idle Heating Boilers, Chapter 16).

Protective coatings with organic binders are destroyed rather rapidly above 400 F because of the decomposition of the organic materials. The surfaces of metals, whose temperature does not exceed 400 F, may be protected by periodically applying paints such as those specified in the following paragraphs entitled Air Ducts.

#### Air Ducts

The most practical method for protecting air duct surfaces made of steel from atmospheric corrosion, is to apply protective paints. One of the most effective protective coatings is red lead paint.

Three coats of paint should be applied, of which the first two coats should be rust inhibitive paint such as red lead paint, with the second coat tinted to a light brown color with carbon black, and the finishing coat may be red lead paint tinted to a black or brown color, black paint made according to Federal Specification TT-P-61; red iron oxide paint conforming to Federal Specification TT-P-31, or white or light tinted paint made according to Federal Specification TT-P-40.

Another paint which has had some use for priming iron and steel is zinc chromate paint.

Under some conditions, a chlorinated rubber base paint made according to Federal Specification TT-P-91 may be used for the finishing coat, particularly where the presence of highly corrosive gases or contact with strong alkaline water would injure the standard paints. Rubber base paints should be used only for the finishing coat over regular priming and second coats.

#### BURIED PIPE LINES

Lines that are cold and in intimate contact with the earth are corroded from the same causes as in mineral waters, but pitting is usually more intense due to variations in concentration of salts and oxygen in solution, acidity, drainage, and presence of solid materials (such as cinder) in contact with metal pipe. Galvanic currents, induced by contact of certain dissolved constituents in the soil, often act over a large area, and accelerate corrosion where they leave the pipe line.

Certain bacteria that thrive in the absence of oxygen have the power to obtain hydrogen and dissociate sulphates in the soil, with a resultant production of hydrogen sulfide which attacks the iron to form iron sulphide.

Stray electric currents from electric power generating stations sometimes find their way into buried steel structures, and do damage in proportion to the current density where the current leaves the metal to enter the ground.

#### Pipe Materials

Under many conditions where steel would be corroded, the use of corrosion-resistant metals other than steel may be desirable, even if greater in first costs. Wholly austenitic stainless steels are very resistant to underground corrosion. In most environments copper, red brass, and copper-silicon alloys will resist corrosion and may, at times, be used to advantage. However,<sup>38</sup> soils with a high content of organic matter, or alkaline soils in which the ratio of chlorides and carbonates to sulfate is high, may be corrosive. Copper should not be embedded directly in cinders or in tidal marshes where it may be subjected to attack by sulfur compounds. Lead<sup>39</sup> corrodes chiefly in soils deficient in oxygen or containing cinders. Because lead is corroded to a considerable extent in most soils, lead coatings applied to steels are not adequate for underground use.

Galvanized iron pipe will resist corrosion for various periods of time, depending on the soil and how long the galvanized coating lasts. The zinc used for the galvanized coating is on the electrochemical protective side of the iron, and the zinc is corroded and changed to zinc compounds before the iron is attacked. This accounts for the protection afforded by galvanized iron. Even if some protection is obtained, eventually the galvanized coatings are destroyed by chemical action and the corrosion of the steel begins.

#### Protective Coating

Protective coatings for buried pipe lines are in a class by themselves because of the unusual service conditions, and because it is not possible to maintain them by recoating when necessary. Buried steel pipe lines have been protected against corrosion with considerable success by the use of very thick bituminous coatings applied in molten condition. The best results are obtained by applying the bituminous coatings over a standard priming coat such as red lead or a bituminous paint, and for long service it has been found that after the bituminous coatings are applied, a wrapping of asbestos fabric saturated with bitumens will prevent movement and displacement of the bituminous coatings, and add greatly to the length of time satisfactory protection will be maintained.

#### Cathodic Protection

Protection is obtained by rendering the structure cathodic to the surrounding water or soil by means of a controlled difference of potential. This method, which has proved satisfactory and economical on a number of gas and oil pipe lines underground, has also been applied with some success to the protection of the inside of water storage tanks and other structures that are in contact continuously with water. Protective coatings that insulate a large portion of the metal surface will reduce very materially the total amount of protective current that must be impressed on bare anodic areas to arrest corrosion.

Because of differences in environmental conditions, it is necessary to determine or estimate the minimum current density required for each structure, and design the anode or anodes so that the necessary protection can be obtained most economically. In water having relatively high electrical conductivity such as in sea water, this is comparatively easy compared with fresh water. In the latter, the composition of the water is a major factor. It is therefore desirable to obtain an accurate estimate of the minimum current density required. The current is then controlled by the potential between the anode and the structure to be protected.

Rectifiers have generally proved to be the most practical means for supplying the necessary current for protection of surfaces in contact with neutral waters.<sup>40</sup>

### HANDLING WATER TREATING CHEMICALS

Virtually all the chemicals used in water conditioning are injurious if taken internally in large doses. Many also cause severe skin irritation. Thus, they should be handled with caution.

Caustic soda, lime, and concentrated sulphuric acid will burn the flesh. In addition, if mixed with small amounts of water, sufficient heat may be generated so that spattering occurs or the container becomes too hot to handle.

The chlorophenol compounds, even in the low concentrations used in water conditioning, have been reported<sup>41</sup> to produce dermatitis. Chrom-itch is not uncommon among workers handling chromates. The amines are said to be absorbed through the skin.<sup>42</sup> Morpholine is said to cause kidney and lung trouble when so absorbed.

Chlorine gas irritates the skin, eyes, and mucous membranes. Concentrations as low as 0.004 percent by volume in air cause dangerous illness in 0.5 to 1 hour.

When relatively large amounts of the non-gaseous chemicals are to be handled, protective clothing, including goggles, should always be provided, and a shower head or its equivalent provided at or very near the point where the chemicals are mixed. *Chemicals should always be washed from the skin with large volumes of water.*

For the handling of chlorine and chlorinators, the *U. S. Public Health Service*<sup>43</sup> stipulates the following safety requirements:

1. Suitable gas masks and a small bottle of ammonia for testing for leaks should be kept at convenient points immediately outside the room or enclosure in which chlorine is being stored or is in use. Gas masks should be inspected at regular intervals and kept in serviceable condition. Note:—All-purpose masks offer adequate protection only when the concentration of acid gases does not exceed two percent—see Safe Practices Pamphlet #64 National Safety Council.

2. Chlorinating equipment and cylinders of chlorine should be housed preferably in separate buildings above the ground level.

3. The room or building housing chlorinators in service should be maintained at a temperature above 60 F, but never in excess of the normal summer temperature. The cylinders of chlorine should be shielded, where necessary, from excessive heat or cold. Direct heat should not be applied to cylinders of chlorine, nor should hot water be poured over them or come in contact with the cylinder valve.

4. Adequate ventilation should be provided for all enclosures in which chlorine is being fed or stored.

5. All joints of tubing connecting chlorine cylinder and chlorinators should be kept absolutely tight and inspected frequently to insure tightness. Tubing should slope upward from the cylinder.

### LEGAL REGULATIONS

In a number of states, the water used for humidification, even in industrial plants, is required to meet drinking water standards insofar as bacteriological quality is concerned. A ruling of the *U. S. Department of Agriculture, Meat Inspection Division*, prohibits the use of chromate in water used for air washing when the air later contacts foodstuffs.<sup>44</sup>

There is an ever growing consciousness on the part of public health officials, of the necessity for regulations to protect potable water supplies. Attesting this is an ordinance<sup>45</sup> now in effect in Detroit, Michigan, which stipulates in part:

"No physical connection shall be maintained between lines carrying city water and pipes, pumps, or tanks supplied from any other source. Where dual supplies are necessary or desired, lines carrying city water must be protected against back flow of polluted water by an *atmospheric gap*. Secondary supplies and emergency sources shall include: surface waters from rivers, lakes, ponds, lagoons, and reservoirs; well waters both deep and shallow; any supply of water which has been stored, held, or reserved after being used for industrial purposes; cooling water, or water which has in any way been treated, processed, or has been subjected or exposed to any contamination of a bacteriological or chemical nature; and water from any other source than the city supply."

The *U. S. Public Health Service* stipulates:

"Salts of barium, hexavalent chromium, heavy metal glucosides, or other substances with deleterious physiological effects, shall not be allowed in the water supply system."

The same agency recommends that the concentration of the substances listed be held below the values cited in Table 8. The Board of Directors

TABLE 8. RECOMMENDED MAXIMUM ALLOWABLE CONTENT IN WATER SUPPLY\*

| SUBSTANCE                     | MAX. CONCENTRATION, ppm | SUBSTANCE                     | MAX. CONCENTRATION, ppm |

\* *U. S. Public Health Service.*

of the *American Water Works Association* has accepted these values as standard for all public water supplies in the United States.<sup>46</sup> While their action is not binding, prudence dictates that no form of treatment should be used that will result in raising the concentration of the substances listed above the value cited.

Since virtually all of the permissible chemicals used for scale, slime, and corrosion control have deleterious, physiological effects if taken internally in *relatively large doses*, they should always be carefully *proportioned*. To insure this, the Detroit ordinance stipulates that the chemical feeding device must have the following major characteristics:

- "1. There shall be a visible means of checking the quantity of material being applied by the feeding device.

2. A water metering device, sealed to prevent tampering, shall be installed to measure the flow of water being treated.

3. The device shall be constructed so that in the event of back-flow or vacuums, the maximum amount of material that may be possibly back-siphoned from the device or any of its attachments or parts shall not exceed one fluid ounce.

4. Should there be a failure of the water metering device or the water supply, the feeding device shall automatically cease operating."

## CHAPTER 44

## OWNING AND OPERATING COSTS

Fixed Charges: Amortization, Interest, Taxes, Insurance, Rent; Maintenance Costs;  
Labor for Operation; Energy and Water Costs: Operating Refrigerating  
Equipment, Condenser Water, Heating

THE total cost for the use of heating, ventilating, and air conditioning systems may be divided into two classifications. The first of these is the relatively fixed and unvarying expense of ownership, and the second is the variable and somewhat controllable expenditure for actual operation of the equipment. Owners and prospective purchasers of this equipment are particularly concerned with both since the actual expenditure is generally predicated upon the possible return on the investment resulting from increased patronage, greater efficiency on the part of the employees, meeting of competition, or the improvement and maintenance of quality in a manufactured product. These costs may be grouped under four headings: (1) *Fixed Charges*, (2) *Maintenance Costs*, (3) *Labor for Operation*, and (4) *Energy and Water Costs*.

## FIXED CHARGES

Fixed charges are the annual expenses arising from the ownership of the installation, including use of the owner's money, and protection of the equipment in the form of insurance. Such costs are usually unchanged from year to year regardless of whether the equipment is in or out of service. Fixed charges may be grouped under five headings: (1) *Amortization*, (2) *Interest*, (3) *Taxes*, (4) *Insurance*, and (5) *Rent*.

## Amortization

As air conditioning equipment becomes older, its ability or capacity to perform present and future service is reduced. Provision must be made for the owner to recover each year a portion of the initial value of the equipment as an expense to be charged against revenue, or to amortize the cost. This decrease in the value of property is usually determined by an accountant or engineer using some theoretical method and will depend upon (1) the total first cost, and (2) the amortization period.

The total first cost of an installation is the actual capital expenditure required to buy and install the air conditioning, heating, or ventilating system ready for operation. It represents the first cost of the equipment combined with additional costs incurred because of the installation of the system.

The first cost of air conditioning, heating, or ventilating systems includes the following:

1. Heat producing equipment including boilers, burners, controls, etc.
2. Heat distributing equipment including direct radiation, piping, etc.
3. Air handling equipment including fans, air heaters, air conditioners, filters, controls, etc.
4. Air distribution system including ducts, outlets, grilles, etc.
5. Refrigerating equipment including piping, pumps, etc.
6. Water conservation devices including towers, evaporative condensers, etc.

\* These cost figures (based on 1950 prices which may be adjusted by using current building cost index) cover only the average type of comfort air conditioning in open spaces as in department store, or for industrial air conditioning involving large areas. Where a multiplicity of small spaces must be individually controlled, as in office buildings, hotels and apartment houses, the cost of the equipment will be increased accordingly.

<sup>b</sup> Includes on 10 and 11 recent costs where well water or city water is available for condensing purposes. Where conservation of water is required, add column 12 or 13 to column 9 to obtain total cost per ton.

<sup>c</sup> Does not include cost of structural reinforcement, if required to support the weight of cooling towers or evaporative condensers.

## Owning and Operating Costs

7. Insulation of pipes, ducts and equipment.

8. Building alterations, furring-in ducts and pipes, structural work, etc.

To estimate the first cost of any system prior to installation, the best procedure is to determine the heating and cooling load, and then after thorough engineering study, select the type of system. The installed cost of systems will vary widely, depending upon the type of equipment selected, and the design of the distribution system, equipment and labor costs in the locality, demands for the particular installation, etc. A reasonable approximate cost may be determined for a selected design in a given locality from the sum of the estimated unit costs of the component parts of the system. A reasonably precise estimate of the cost of the components may be obtained from cost records of recent installations of a comparable design, or from quotations submitted by manufacturers and contractors.

Approximate costs are given in Table 1 for mechanical air handling systems including heating and cooling coils for distributing  $1\frac{1}{2}$  cfm per square foot of floor area and refrigeration equipment based upon a requirement of one ton for every 333 sq ft of floor area. Different types of service demand may change the floor area per ton of refrigeration and air volume per square foot between wide limits and, consequently the table should be used with caution.

Other first costs may be incurred because of the installation of the air conditioning or heating and ventilating system. These will include such items as electrical work, plumbing, miscellaneous piping, building alterations, cutting, patching, furring-in of ducts or pipes, foundations, structural supports, remodeling or redecorating after installation, consulting engineer's fees, licenses, and permits. As these costs vary widely no approximations are practicable. Therefore, each case must be considered individually. If a quotation can be secured from a manufacturer or contractor covering the complete job, it will usually include the items which have been mentioned.

The length of the amortization period to be used depends upon (1) the type and remaining life of the building or space for which the system is to be used; (2) the type of equipment to be employed as a part of the system; (3) the character of the business; and (4) the lease or ownership conditions.

Depreciation, due to deterioration or obsolescence, must be considered in arriving at the amortization period. Maintenance and deterioration usually have the effect of offsetting one or the other. If a long depreciation period is to be used, then the item for maintenance, repair, and the replacement of wearing parts must be greater than for a short depreciation period.

In determining the length of the amortization period, the owner's accounting practices will have considerable bearing upon the number of years used in the calculation. For taxation purposes, this period depends upon the use and the service to which the equipment is placed. At the present time indications are that varying interpretations on depreciation will be made by the *Bureau of Internal Revenue*. While most air conditioning equipment may be considered as having a normal, useful life of 20 years for depreciation purposes, no final value for depreciation should be determined without consultation with the owner's tax consultant or perhaps

referral to Schedule F which is issued by the *Bureau of Internal Revenue* and summarized in Table 2.

### Interest

The interest charged to the cost of ownership may be based upon the average interest rate for the period during which the first cost of the equipment will be amortized. While some accountants do not include interest in the annual fixed charges and consider it a negligible item, the money invested in air conditioning, heating, or ventilating equipment, must be either borrowed or diverted from the owner's funds and converted to the

TABLE 2. PROBABLE USEFUL LIFE OF EQUIPMENT\*

purpose of making the installation. Whether it is borrowed or taken from surplus funds, the money that might have been earned as interest is properly chargeable to the operation of the system.

The formulas for computing interest and amortization are given in Table 3. This table also serves as a check list for the various items to be considered in calculating the cost of ownership and operation.

### Taxes

The taxes which may be charged to the property as a result of the improvement due to the installation of an air conditioning system will vary according to the practice of the official agencies levying property taxes.

### Insurance

Insurance against losses by fire is ordinarily secured by increasing the building fire insurance coverage to cover all or part of the first cost of installing the air conditioning and other mechanical systems. Various types of extended coverage are available for protection against a number of other types of losses.

Boiler insurance may be extended to cover the air conditioning equipment to protect against losses due to explosion, rupture of piping, and similar hazards. Since insurance rates vary widely depending upon the type of structure in which the equipment is located and the nature of the owner's business, the rates are usually set by rating organizations specializing

ing in this work. Exact figures on insurance cannot be determined without consultation with the owner's underwriter.

### Rent

If the equipment under consideration is to be located in rented or leased quarters, or if additional space must be rented, such expense becomes a fixed charge.

### MAINTENANCE COSTS

Maintenance charges consist of expense for labor and material necessary to make repairs and replace parts, as well as cleaning, painting, inspection, etc. for the purpose of eliminating or minimizing the need for repairs. Generally, routine maintenance labor requirements will be the function of an operating engineer or staff. If the responsibility of this group may

extend to other facilities beyond the equipment being discussed here, it is important that only an equitable share of the group's time be charged to maintenance.

Extraordinary repairs are quite often handled by separate maintenance divisions and the expense charged back to air conditioning, heating, and ventilating. In other cases, all maintenance is handled by outside service firms and the cost considered as maintenance. These costs vary considerably with factors such as the type of system and the proficiency of the installing and servicing organization. Therefore, any forecast of maintenance costs should include consideration of the equipment as a part of the engineering study. The charges should be based upon the entire period under study rather than the early years of operation when repairs may be expected to be at a minimum.

Various estimates of maintenance costs vary from 5 percent to 10 percent of the installation cost. Table 4 is based upon an average of  $7\frac{1}{2}$  percent for about a 75-ton installation. This probably would apply to most installations using high quality equipment. The maintenance cost must be

TABLE 4. APPROXIMATE MAINTENANCE COST FOR LARGE AIR CONDITIONING INSTALLATIONS, USING HIGH QUALITY EQUIPMENT\*

\* Estimated for 1955.

modified for size of job and quality of equipment. With lower cost equipment, higher maintenance costs can be expected.

The accounting practices of the owner and the rules of the *Bureau of Internal Revenue* affect the charges for major overhauling or complete replacement which may restore the capital value of certain equipment items. In these cases the expenditure may not necessarily be charged as maintenance but will become a fixed charge spread over the remaining years of equipment life. Table No. 4 gives some approximate costs for maintaining large air conditioning installations using high quality equipment.

#### LABOR FOR OPERATION

In some cases with the installation of automatic equipment, operating labor may be non-existent, but where such labor is required, the cost is readily calculated. Where operators are required, the expense is often considered maintenance, but since they may have other functions which are not properly charged to operation of the air conditioning, heating, or ventilating installations the charges should be properly allocated. The cost of experienced and competent operators is well justified in medium and larger plants by economies that can be achieved in maintenance and energy costs.

#### ENERGY AND WATER COSTS

Energy costs include the costs for power, water, steam, coal, oil, etc. consumed to operate the system.

From the selected equipment and type of installation, it is possible to segregate the relatively constant power loads and the total brake horsepower. Annual power cost can then be figured from the following formula:

$$\text{annual power cost} = \frac{0.746(\text{bhp})HR}{\eta} \quad (1)$$

\* *Modern Air Conditioning, Heating and Ventilating*, by W. H. Carrier, R. E. Chrene and W. A. Grant Pitman Publishing Corp. 1940, p. 73).

where

bhp = brake horsepower.

H = annual operating hours.

R = power rate, dollars per kw-hr.

$\eta$  = motor efficiency (decimal).

In using Equation 1 it must be pointed out that the electric rate, R must reflect the proper combination of energy and demand rates. These vary widely between the utility companies, and sometimes the rate structure is such that it is largely the demand charge which determines the proper value of R to use in Equation 1.

#### Operating Refrigerating Equipment

In an air conditioning system the refrigerating equipment is usually the largest power consuming item to be considered. Also, the prediction

of operating cost is more difficult because the power required for summer cooling is affected by many factors of a variable nature.

Table 5 gives the equivalent full load operating hours of refrigerating equipment used for summer cooling for the period of May 15th to October 15th. This table was calculated from the following equation:

$$H_e = m(b + cf) \quad (2)$$

where

- $H_e$  = equivalent full load operating hours of refrigeration equipment used for summer cooling during period May 15 to October 15.  
 $m$  = total hours during period May 15 to October 15 that the establishment is open for business.  
 $b$  = fraction of maximum load from internal heat under average operating conditions.  
 $c$  = fraction of maximum load which is due to external sources at maximum design conditions.  
 $f$  = ratio of the number of hours for a particular city, when the outside wet-bulb exceeds 65 F, during the period June 1 to October 1 to the total number of hours during that same period. Total hours are assumed as 8 hr per day period for barber shops, department stores, funeral parlors, offices, short hour restaurants, and specialty shops, and 12 hr per day period for drug stores, long hour restaurants, and theaters.

It should be pointed out that certain southern cities may have seasons longer than the 5-month period indicated in Table 5. If it is desired to consider a longer season of operation, the ratio of full load operating hours to hours open for business is smaller; in other words, the *refrigeration load factor* is lower. This is true because the extra increment of days added will be a relatively light load, since the table already includes the more severe part of the season.

The season electrical power cost for refrigerating equipment is then given by the following equation:

$$\text{season power costs} = \frac{0.746 (\text{bhp}) TH_e R}{\eta} \quad (3)$$

where

- bhp<sub>t</sub> = brake horsepower per ton (see Fig. 1) for *average* load during period. (Due allowance should be made for poorer compressor efficiency at light load.)  
 $T$  = maximum refrigeration design load, tons.  
 $H_e$  = equivalent full load refrigeration operating time, hours (from Table 5).  
 $R$  = power cost, including demand and energy charges, dollars per kwhr.  
 $\eta$  = motor efficiency at average load (decimal).

In considering refrigeration power consumption, it should be noted that the use of weather records for a specific year may lead to large inaccuracies in estimating operating costs, since there may be wide variations from year to year, and therefore, average yearly weather records should be used rather than those for any individual year.

If the refrigeration compressor is steam turbine driven, the same general method can be followed, taking into account average water rate per brake horsepower-hour and the cost of steam.

### Condenser Water

Condenser water cost estimates can also be based on equivalent full load operating hours of the refrigeration equipment. The varying temperature of the water at its source, as well as the temperature of the discarded water, must, however, be taken into account. In general, when water is purchased, control is provided to hold the leaving water temperature (or condensing temperature) constant; and in such case the entering water temperature becomes the major variable, and the gallons per minute per ton can readily be calculated for any water temperature rise.

FIG. 1. TYPICAL BRAKE HORSEPOWER REQUIREMENTS FOR REFRIGERATION\*

\* Values given are representative of dichlorodifluoromethane reciprocating machines of about 25 tons capacity in air conditioning applications. Requirements of smaller machines are usually higher, and for larger machines may be lower. Values shown are for liquid refrigerant at condenser temperature (no subcooling). Subcooling of the liquid may decrease these values approximately 0.3 percent to 0.5 percent for each Fahrenheit degree the liquid temperature is lowered.

The following equation for cost of condenser water is useful:

$$B = 0.060 a TH_e C \quad (4)$$

where

- $B$  = cost of water for refrigeration during period, dollars.  
 $a$  = average gallons per (minute) (ton).  
 $T$  = tons of refrigeration at maximum design load.  
 $H_e$  = equivalent full load refrigeration operating hours (Table 5).  
 $C$  = water cost, dollars per 1000 gal.

The average gallons per minute per ton must take into account the variable water temperature. When well water is used as a source, and entering and leaving temperatures are considered constant, the average gallons per minute per ton obviously are equal to the design gallons per minute per ton. However, when the source is river or lake water, its maximum seasonal temperature will generally be reached at the same time that

the refrigeration load factor is highest. The average gallons per minute per ton should be calculated from known or estimated water temperatures, because they vary through the season. Maximum water main temperatures are given in Chapter 35, but should always be verified locally. In lieu of this tedious work, the average gallons per (minute) (ton) may be taken as 80 percent of design gallons per (minute) (ton) with reasonable accuracy, for the condition of variable temperature of entering water obtained from rivers and lakes.

Cooling towers and evaporative condensers virtually eliminate condensing water charges since the windage and evaporation losses are seldom over two or three percent of the water circulated.

The savings in water consumed often times will not in itself justify the installation of water economizing equipment since the cost for pumping and the fixed or ownership charges may be in excess of the annual cost for once through condensing operation. If operating costs are to be the basis for selection, then fixed charges should be determined when studying application of this equipment which usually has a shorter life than the other components.

Usually the primary factors influencing the installation of water conservation equipment are the lack of an adequate water supply or local regulations intended to conserve an existing water supply.

Another factor influencing the installation of such equipment is the increasing trend toward the enactment of taxes and service charges for condensing water wasted into city sewers. Certain municipalities will remit the sewer taxes or service charge if the condensing water is submetered and discharged into a storm sewer or used for process purposes.

### Heating

The method of estimating fuel consumption to balance the building heat loss is given in Chapter 18. It is important to include the fuel required to heat ventilation air as used in ventilating and air conditioning systems. In estimating fuel consumption for ventilation air, the tendency of the conventional control systems to use less than the estimated quantity of outside air in cold weather should be considered in its effect in lowering fuel consumption. In addition, the heat required to accomplish winter humidifying must not be neglected, when this feature is included in the equipment.

## INDUSTRIAL AIR CONDITIONING

General Requirements for Manufacture, Processing and Preservation; Design Conditions and Application Data; Classification of Problems; Moisture Content and Regain; Conditioning and Drying; Chemical and Biochemical Reactions; Crystallization; Control for Machining, Polishing, and for Static Electricity Elimination; Laboratory Conditions; Calculations; Safeguarding Health and Maintaining Safety; Contaminant Control; Dilution Systems for Contaminants; Heat Storage; Radiation; Local Relief and Spot Cooling; Odors

INDUSTRIAL air conditioning is concerned with the design and application of equipment for obtaining proper conditions for (1) the manufacturing, processing, and preserving of material, equipment, and commodities; and (2) maintaining the health, safety and efficiency of workers. This chapter includes a general discussion of these conditions and also a comprehensive list of specific requirements for various types of products.

### GENERAL REQUIREMENTS FOR MANUFACTURE, PROCESSING AND PRESERVATION

In order to apply air conditioning to industrial processes, the air conditioning engineer must have a thorough understanding of the processing problems involved. Individual processes and machines are changing rapidly, and air conditions must be revised constantly to meet the new conditions.

Table 1 lists the temperatures and relative humidities required for storage of certain commodities, and for manufacturing and processing of others. In some cases the temperatures and relative humidities listed in Table 1 have no direct influence upon the product itself, but do affect the efficiency of employees, and in turn affect workmanship, uniformity and the cost of production. Sometimes, a compromise between the known optimum condition for processing and that required for worker comfort is unavoidable.

Air conditioning for industrial processes is so extensive and involved that a detailed treatment is beyond the scope of this chapter. It is possible to cover only a few salient points of the general subject. In many industries the exact conditions to be maintained are determined and known only by the manufacturer who specifies them. In other industries there is a wide variance between manufacturers' requirements, depending on results desired, experience, and cost considerations.

### CLASSIFICATION OF PROBLEMS

In general, any industrial air conditioning problem in processing may be classified under one or more of the following:

1. Control of regain.
2. Control of rate of chemical reactions.
3. Control of rate of biochemical reactions.
4. Control of rate of crystallization.
5. Control of temperature for close tolerance machining and grinding.

(Continued on page 1026.)

TABLE 1. TEMPERATURES AND HUMIDITIES APPLICABLE TO INDUSTRIAL AIR CONDITIONING\*

| PROCESS                                           | TEMP. F | R.H. % |
|---------------------------------------------------|---------|--------|
| <b>BAKERY</b>                                     |         |        |
| Mixer (bread dough).....                          | 75-80   | 40-50  |
| Fermenting.....                                   | 75-80   | 70-75  |
| Proof box.....                                    | 92-96   | 80-85  |

| Cake oven.....                                    | 300-430 |        |
| Bread cooler (room or tunnel) Vacuum 28.6 in..... | 70-75   | 80-85  |
| Cold room.....                                    | 40-45   |        |
| Make up room.....                                 | 75-80   | 65-70  |
| Cake mixing.....                                  | 70-75   | 65     |
| Cake mixing (sponge).....                         | 95-110  |        |
| Crackers and biscuits.....                        | 60-65   | 50     |
| Wrapping.....                                     | 60-65   | 60-64  |
| Dried ingredients, storage.....                   | 70      | 55-65  |
| Fresh ingredients, storage.....                   | 30-45   | 80-85  |
| Flour storage.....                                | 65-80   | 50-65  |
| Shortening (depending on type), storage.....      | 45-70   | 55-65  |
| Sugar, storage.....                               | 80      | 35     |
| Water, storage.....                               | 32-35   |        |
| Wax paper, storage.....                           | 70-80   | 40-50  |

## METHODS OF MIXER COOLING

1. 35-40 F water circulated through mixer jacket.
2. 15-25 F brine.
3. Direct expansion, refrigerant circulated through mixer jacket.
4. Cracked ice added to dough in mixer.
5. Cold air introduced into mixer during mixing process.
6. Cooled agitators are used in mixers.

## MIXER LOAD CALCULATIONS

Refrigeration is required to remove: excess ingredient, if any; heat generated by the heating and mixing of dough; excess heat in mixer body; heat of hydration of flour and water; and heat absorbed by mixer from atmosphere during mixing process.

Additional factors are the design and speed of mixer, consistency, kind and mass of dough.

Data Used in Calculations:

1 bbl. flour = 200 lb  
 Heat of hydration = 6.5 Btu per lb of flour  
 Specific heat of flour = 0.42 Btu per lb  
 Water is 65% of weight of flour  
 Flour is 65% of batch  
 Sponge is 60% of batch  
 Total motor output is converted to heat in the mixer.

In fermenting rooms recent practice is to use direct radiation for heating, atomizing sprays for humidifying, and gravity convection cooling surfaces for temperature reduction and dehumidifying thereby eliminating objectionable air currents.

Proof box and bread cooler conditions vary slightly for dark bread.

Cakes are sterilized by ultra-violet rays before wrapping.

| PROCESS        | TEMP. F  | R.H. %   |
|----------------|----------|----------|
| <b>BANANAS</b> |          |          |
| Ripening.....  | 68       | 90 to 95 |
| Storage.....   | 60       | 85 to 90 |
| Shipping.....  | 54 to 56 | 85 to 90 |

Forced ripening is accomplished in 4 to 5 days while slow ripening is extended to 7 to 9 days with lower temperatures.

The green fruit with a pulp temperature of 56 F is placed in a ripening room at 68 F and 90 to 95 percent relative humidity until it begins to change color. The temperature is then lowered sharply to 60 F (or slightly less) dependent upon how quickly the fruit is to be moved.

Typical refrigeration load for ripening room per carlot, with an 85 F ambient temperature:

Insulation & electric load = 0.4 ton  
 Live load = 0.9 ton  
 Pull down load (from 68 F to 60 F) = 1.6 ton

Minimum carlot—20,000 lb which represents about 300 stems.

Since bananas give off minute quantities of ethylene and possibly other gases necessary for ripening, ventilation during the early stages of ripening is undesirable.

Cooling unit to be sized to provide a complete air change every 1½ to 2 min.

\* Information in Table 1 is drawn from many sources. See bibliography at end of chapter.

TABLE 1. TEMPERATURES AND HUMIDITIES APPLICABLE TO INDUSTRIAL AIR CONDITIONING—(Continued)

## BANANAS (Continued)

Provide a heating system with a rated capacity to warm the fruit at a rate of not less than 2 deg per hr. Specific heat—0.9 Btu per (lb)(F deg).

Approximate rate of evolution of heat by bananas when stored at temperatures indicated:

Bananas at 54 F = 3,300 Btu (per ton) (24 hr).  
 green at 68 F = 8,360 Btu (per ton) (24 hr).  
 turning at 68 F = 9,240 Btu (per ton) (24 hr).  
 ripening at 68 F = 8,360 Btu (per ton) (24 hr).

| ROOM                          | TEMP. F  | R.H. %   |
|-------------------------------|----------|----------|
| <b>BREWING</b>                |          |          |
| Storage: Hops.....            | 30 to 32 | 55 to 62 |
| Grain.....                    | 80 max.  | 60 max.  |
| Liquid yeast.....             | 32 to 34 |          |
| Lager.....                    | 32 to 34 | 75 min.* |
| Ale.....                      | 40 to 46 | 75 min.* |
| Fermenting Cellar: Lager..... | 40 to 45 | 75 min.* |
| Ale.....                      | 55       | 75 min.* |
| Racking Cellar.....           | 32 to 35 | 75       |

\* If wooden tankage is used, otherwise humidity controlled to prevent condensation on walls and ceiling.

Wort cooled to 47 F for lager, 54 to 59 F for ale, by evaporative cooling or use of double pipe or plate type coolers with counter flow of cooling medium.

Fermentation produces 250 Btu per lb of sugar fermented. Lager fermented five days at 55 to 60 F, ale at 68 to 75 F, then cooled to storage temperature.

Bottled beer pasteurized by heating to 140 F in twenty minutes, maintaining temperature for eighteen minutes, then cooling to 80 F in twenty minutes. Canned beer requires one-third less time.

Cold water, brine, direct expansion ammonia or propylene-glycol and water solutions may be used as the cooling medium.

| PROCESS                           | TEMP. F  | R.H. %   |
|-----------------------------------|----------|----------|
| <b>CANDY (CHOCOLATE)</b>          |          |          |
| Candy centers for coating.....    | 80 to 85 | 40 to 50 |
| Hand dipping room.....            | 60 to 65 | 50 to 55 |
| Enrober room.....                 | 75 to 80 | 55 to 60 |
| Enrobing.....                     |          |          |
| Loading End.....                  | 80       | 50       |
| Enrober.....                      | 90       | 13       |
| Stringing.....                    | 70       | 40 to 50 |
| Tunnel.....                       | 40 to 45 |          |
| Packing.....                      | 65       | 55       |
| Panned specialty room.....        | 70 to 75 | 45       |
| General candy storage.....        | 65 to 70 | 40 to 50 |
| Tempering room = Ventilation only |          |          |

Tunnel discharge room requires a dew point lower than the temperature of the product leaving the tunnel.  
 During the summer months the product is usually held in the tempering room for 24 hours prior to shipping.

Recovery of sugar fly in coating kettle rooms is accomplished with the use of cyclone type dust collecting devices. Supply air to coating kettles is maintained at 85 F dry-bulb and 61 F wet-bulb temperature.

Bacteriological control is employed.

Load calculations for hand dipping rooms are based on 100 lb of 90 F chocolate per (worker) (hr).

Specific heat of chocolate = 0.30 to 0.56 Btu per (lb)(F deg).

Latent heat of fusion = 34 to 40 Btu per (lb)(F deg).

Freezing point =

Sweet milk chocolate = 86 F.

Dark chocolate = 90 to 92 F.

| PROCESS                        | TEMP. F  | R.H. %   |
|--------------------------------|----------|----------|
| <b>CANDY (HARD)</b>            |          |          |
| Manufacturing.....             | 75 to 80 | 30 to 40 |
| Mixing and cooling.....        | 75 to 80 | 40 to 45 |
| Tunnel.....                    | 55       |          |
| Packing.....                   | 65 to 75 | 40 to 45 |
| Storage.....                   | 65 to 75 | 45 to 50 |
| Tempering = (Ventilation only) |          |          |

TABLE 1. TEMPERATURES AND HUMIDITIES APPLICABLE TO INDUSTRIAL AIR CONDITIONING—(Continued)

## CANDY (HARD) (Continued)

Hot rooms used in the drying of jellies and gums are maintained at 120 to 150 F. A purge system using 100 percent outside air, bypassing the heating coil, is incorporated to produce rapid cooling of both the product and the room.

Cold rooms for cooling marshmallows and cast creams are maintained at 75 to 80 F with a relative humidity of 45 to 50 percent. Uniform air distribution is essential.

Standard starch drying equipment is employed.

Filtration of air is required.

| PROCESS            | TEMP. F | R.H. % |
|--------------------|---------|--------|
| <b>CHEWING GUM</b> |         |        |
| Manufacturing..... | 77      | 33     |
| Rolling.....       | 68      | 63     |
| Stripping.....     | 72      | 53     |
| Breaking.....      | 74      | 47     |
| Wrapping.....      | 74      | 58     |

| PROCESS                      | TEMP. F    | R.H.     |
|------------------------------|------------|----------|
| <b>CERAMICS</b>              |            |          |
| Refractory.....              | 110 to 150 | 50 to 90 |
| Molding room.....            | 80         | 60 to 70 |
| Clay storage.....            | 60 to 80   | 35 to 65 |
| Decalcomania production..... | 75 to 80   | 48       |
| Decorating room.....         | 75 to 80   | 48       |

Relative humidity has no effect on the manufacture of the products.

Temperature and humidity must be controlled in the decorating shop in the whiteware plants, and the decalcomania production room.

Dust control is essential, and the dust count must be held down to four million particles per cubic foot due to the danger of silicosis.

| PROCESS        | TEMP. F | R.H. % |
|----------------|---------|--------|
| <b>CEREAL</b>  |         |        |
| Packaging..... | 75-80   | 45-50  |

| PROCESS                    | TEMP. F | R.H. %   |
|----------------------------|---------|----------|
| <b>CITRUS FRUIT</b>        |         |          |
| Lemons (storage)*.....     | 58      | 84 to 88 |
| Grapefruit (storage)*..... | 60      | 88 to 88 |

\* Prior to transcontinental shipment

Careful consideration must be given to air volumes, air temperatures, humidity, ventilation and distribution.

In regions where end rot is prevalent, it may be necessary to store grapefruit at temperatures of 32 to 34 F for a period not exceeding six weeks.

Lemon and grapefruit storage requires an air conditioning system to (1) maintain a constant temperature, (2) maintain a high relative humidity, (3) ventilate to maintain 0.1% CO<sub>2</sub> content, (4) obtain uniform air distribution, and (5) provide air washing or air filtration.

Load calculations include (1) transmission losses, (2) internal load-fruit cooling and respiration, cooling fruit boxes, electric load, and people, and (3) outside air load—72 cfm per carlot.

Specific heat—Btu per (lb) (F deg):

Lemons 0.94, Grapefruit 0.87, Boxes 0.40

## HEAT OF EVOLUTION IN BTU PER (TON) (24 HR)

| TEMP. | LEMONS | GRAPEFRUIT |
|-------|--------|------------|
| 32    | 580    | 460        |
| 40    | 810    | 1070       |
| 60    | 2070   | 2770       |
| 80    | 6200   | 4180       |

TABLE 1. TEMPERATURES AND HUMIDITIES APPLICABLE TO INDUSTRIAL AIR CONDITIONING—(Continued)

## CITRUS FRUIT (Continued)

Approximately 10 percent of the cooling load is considered as latent heat load.

In a conventional system the air required is one cfm per storage box or 650 cfm per carload, resulting in a small temperature rise in the supply air making possible the required high humidities.

In a combination system the air required is one cfm per sq ft of floor area or 300 cfm per carlot with the addition of auxiliary humidifying nozzles to maintain the required high humidities.

Installation of metal ducts is required. Ductwork made of insulation board is sometimes preferred.

| PROCESS                    | TEMP. F  | R.H. %   |
|----------------------------|----------|----------|
| <b>DISTILLING</b>          |          |          |
| Storage:                   |          |          |
| Grain.....                 | 60       | 35 to 40 |
| Liquid Yeast.....          | 32 to 34 |          |
| General Manufacturing..... | 60 to 75 | 45 to 60 |
| Aging.....                 | 65 to 72 | 50 to 60 |

Mashing done at 150 to 155 F, then cooled to 64 to 68 F.

Yeast culture fermented at 170 F, then cooled to 70 to 72 F.

Yeast propagated at 150 to 154 F.

Mash heated to 165 F and then cooled to 80 F, then pitched with yeast and fermented at maximum temperature of 85 F.

Cooling for various distilling processes normally accomplished by use of river or well water depending on temperatures and availability.

Low humidity and dust control important where grains are ground.

Viscous filters preferred as mold spores and bacteria are trapped in the viscous film, preventing propagation.

| PROCESS                                          | TEMP. F  | R.H. %   |
|--------------------------------------------------|----------|----------|

\* grains per pound abs. hum.

Some operations are stabilized against possibility of mold growth.

Precise control of temperature and humidity is required for mechanical oxidizing of linseed oil. The rate of flow and the temperature of cooling water in the jacket surrounding the tank must be controlled.

Air filtration is recommended for the stoving process.

TABLE 1. TEMPERATURES AND HUMIDITIES APPLICABLE TO INDUSTRIAL AIR CONDITIONING—(Continued)

| PROCESS            | TEMP. °F |  |
|--------------------|----------|--|
| <b>FOUNDRIES</b>   |          |  |
| Core making.....   | 60 to 70 |  |
| Mold making:       |          |  |
| Bench work.....    | 60 to 70 |  |
| Floor work.....    | 55 to 65 |  |
| Pouring.....       | 40       |  |
| Shakeout.....      | 40 to 50 |  |
| Cleaning Room..... | 55 to 65 |  |

\* Winter design temp.

The charging room is usually unheated.

In core making fume exhaust hoods are required for oven and for cooling areas adjacent to ovens.

In mold making provide hoods at transfer points with wet collector dust removal system. Use 600 to 800 cfm per hood.

Pouring rooms require two-speed powered roof ventilators. Design for minimum of two cfm per sq ft floor area at low speed. Shielding is required to control radiation from hot surfaces. Proper introduction of air will minimize preheat requirements.

In shakeout room provide hoods with wet collector dust removal system. Exhaust 400 to 500 cfm per sq ft grate area. Roof ventilators are generally not effective.

In cleaning room provide hoods for grinders and cleaning equipment with dry cyclones or bag type collectors.

Winter ventilation (preheated) is required to the extent of replacing exhausted air. Summer ventilation is usually supplemented by use of pedestal fans.

Spot coolers are sometimes used in larger installations.

| PROCESS              | TEMP. °F | R.H. %   |
|----------------------|----------|----------|
| <b>FUR</b>           |          |          |
| Drying.....          | 110      | ....     |
| Shock treatment..... | 18 to 20 |          |
| Storage.....         | 40 to 50 | 55 to 65 |

Shock treatment, for eradication of any insect infestations, requires the lowering of the temperature to 18-20 °F for 3 to 4 days, then raising it to 60-70 °F for 2 days, then lowering it once again to 18-20 degrees for 2 days and raising it to the storage temperature.

Furs remain pliable, oxidation is reduced and color and luster are preserved when stored at 40 to 50 °F.

Mold growth is prevalent with humidities above 80 percent, while hair splitting is common where humidity is lower than 55 percent.

| PROCESS               | TEMP. °F | R.H. % |
|-----------------------|----------|--------|
| <b>LEATHER</b>        |          |        |
| Drying:               |          |        |
| Vegetable tanned..... | 70       | 75     |
| Chrome tanned.....    | 120      | 45     |
| Storage.....          | 50-60    | 40-60  |

After leather is moistened in preparation for rolling and stretching, it is placed in an atmosphere held at room temperature with a relative humidity of 95 percent.

Leather is usually stored in warehouses without temperature and humidity control. However, it is necessary to keep humidity below 85 percent to avoid mildew.

Air filtration is recommended for toggle machines.

| PROCESS                 | TEMP. °F | R.H. % |
|-------------------------|----------|--------|
| <b>LENSES (OPTICAL)</b> |          |        |
| Fusing.....             | 75       | 45     |
| Grinding.....           | 80       | 80     |

The air must be free of dust and temperature held constant.

To acquire desired cleanliness of air a combination of impingement and electrostatic filters are used. Dust collectors are required for grinding operations.

TABLE 1. TEMPERATURES AND HUMIDITIES APPLICABLE TO INDUSTRIAL AIR CONDITIONING—(Continued)

| ROOMS                        | TEMP. °F | R.H. % |
|------------------------------|----------|--------|
| <b>LIBRARIES AND MUSEUMS</b> |          |        |
| Museum.....                  | 70-80    | 40-50  |
| Book storage.....            | 70-80    | 40-50  |

Spray type dehumidifiers used to eliminate SO<sub>2</sub>. Water treatment is essential to maintain between 8.5 and 9.0 pH.

Reheat is usually needed for refrigeration cycle due to the low sensible heat load.

In extremely cold weather a lower relative humidity is required to prevent condensation on walls.

Positive high and low limit relative humidity controls are used. Do not locate water or steam piping where leakage can cause damage.

#### Check Figures for Cooling Estimates:

|                                              | Low  | MEDIUM | High |

| Grand total heat, Btu per (hr)(sq ft).....   | 30   | 51     | 75   |
| Sensible heat factor.....                    | 0.73 | 0.83   | 0.90 |
| Cooling load per person, tons.....           | 0.12 | 0.23   | 0.40 |
| cfm per sq ft of floor area.....             | 0.92 | 1.60   | 2.10 |

#### MALTING (BREWING)

Steeped 24 to 72 hr in 45 to 65 °F water.

Germinated six days at 55 to 75 °F.

Kilned at temperatures of 120 to 175 °F.

#### MALTING (DISTILLING)

Germinated twenty days at 63 °F.

Germination produces total heat of 16,000 Btu/bushel at varying rate depending upon grain and process.

| PROCESS          | TEMP. °F | R.H. % |
|------------------|----------|--------|
| <b>MATCHES</b>   |          |        |
| Manufacture..... | 72 to 74 | 50     |
| Drying.....      | 70 to 75 | 40     |
| Storage.....     | 60 to 63 | 50     |

Water evaporated is 18 to 20 lb per million matches simultaneously with the setting of the glue.

The match machine will turn out about 750,000 matches per hour.

| PROCESS                  | TEMP. °F   | R.H. %      |
|--------------------------|------------|-------------|
| <b>MUSHROOMS</b>         |            |             |
| Sweating-out period..... | 120 to 140 |             |
| Spawn added.....         | 60 to 75   | nearly sat. |
| Growing period.....      | 48 to 60   | moderate    |
| Storage.....             | 32 to 35   | 80 to 85    |

As spawn starts to grow, it is necessary to abruptly cool the mushroom house by 15 deg in a 12 hr period (approx.). Usually, this is the controlling factor in selection of refrigeration equipment, unless there is portable equipment available for such a purpose.

Ductwork is usually of wood, due to the deterioration of ferrous metals during sweating-out period.

Air filtration is essential in spawn rooms. Viscous filters are preferred, as mold spores are trapped in the viscous film. Odorless oil should be used.

Heat of emission is 4 Btu per (hr)(sq ft of growing surface).

| Biological manufacturing.....                                                                                                                                                                           | 70 to 80 | 20 to 30 |
| Liver extracts.....                                                                                                                                                                                     | 74 to 78 | 50       |
| Serums.....                                                                                                                                                                                             | 75 to 80 | 40       |
| Animal rooms.....                                                                                                                                                                                       | 75 to 78 | 47 to 48 |

Gelatin capsules require varying relative humidities, depending upon size of capsule. Moisture content should not exceed 0.25 gr per cu ft. Various kinds of gelatin require different temperatures.

Penicillin incubation process requires holding temperature within  $\frac{1}{2}$  deg F, with temperatures and humidity rigidly controlled during all manufacturing phases.

Ampule filling requires a 20 percent relative humidity when especially fine powders are used.

Uncoated tablet manufacturing requires accurate control of temperature and relative humidity, since low relative humidity causes formation of a hard outer layer, and high relative humidity retards drying at the proper rate.

Liver extracts require a low relative humidity after they are dried. Temperatures higher than 80 F will cause the extracts to deteriorate.

Tablet coating requires the control of the temperatures of all ingredients and the temperature of air introduced to coating pans.

Sterile conditions are essential in many pharmaceutical processes. Provide suitable air exhaust to remove surplus material from tablet compressing machine.

Air filtration is generally required, with positive air filtration in some areas.

#### ANIMAL ROOMS IN PHARMACEUTICAL LABORATORIES

In the following tabulation each of the items mentioned is equivalent in metabolism to one man:

| QUANTITY | ANIMAL      | WEIGHT EACH |
|----------|-------------|-------------|
| 872      | White Mice  | 21 g        |
| 110      | Rats        | 200 g       |
| 73       | Rats        | 400 g       |
| 70       | Guinea Pigs | 410 g       |
| 21       | Rabbits     | 2.6 kg      |
| 16       | Cats        | 3.0 kg      |
| 16       | Monkeys     | 3.0 kg      |
| 5        | Dogs        | 14.0 kg     |

Dogs are generally the worst offenders as far as odor generation is concerned.

Decontamination of exhaust air is recommended in populated areas.

For good air quality conditions the following space per animal and total air circulation (all outdoor or decontaminated in recirculation) should be provided:

| Animal      | cu ft | cfm  |
|-------------|-------|------|
| Mice        | 3     | 0.5  |
| Rats        | 4     | 0.75 |
| Guinea Pigs | 6     | 1.0  |
| Rabbits     | 10    | 1.9  |
| Hamsters    | 8     | 1.5  |
| Cats        | 35    | 10.0 |
| Dogs        | 150   | 28.0 |

TABLE 1. TEMPERATURES AND HUMIDITIES APPLICABLE TO INDUSTRIAL AIR CONDITIONING—(Continued)

| PROCESS              | TEMP. F | R.H. % |
|----------------------|---------|--------|
| <b>PHOTO STUDIO</b>  |         |        |
| Dressing Room.....   | 74      | 30-40  |
| Drying Room.....     | 75-80   | 50     |
| Printing Room.....   | 70      | 70     |
| Setting Room.....    | 72      | 65     |
| Developing Room..... | 70-75   | 60     |
| Storage Room.....    | 60      | 45     |

Heat liberated during printing, enlarging and drying processes is removed through an independent exhaust system, which also serves the lamp houses and dryer hoods.

Dust control is essential, and absolute filtration is required in some areas.

| PROCESS                          | TEMP. F | R.H. % |
|----------------------------------|---------|--------|
| <b>PHOTO MATERIAL</b>            |         |        |
| Drying.....                      | 20-125  | 40-80  |
| Cutting & Packing.....           | 65-75   | 40-60  |
| Film Base & Paper Storage.....   | 70-75   | 40-65  |
| Coated Paper & Film Storage..... | 70-75   | 40-65  |
| Safety Base Film Storage.....    | 60-80   | 45-50  |
| Nitrate Film Storage.....        | 40-50   | 40-50  |

Spray water must have algae inhibitor. Positive dust control must be maintained and absolute filtration is essential.

In nitrate film area take proper precautions against fires.

Recirculated air used for film drying is passed through activated carbon filters.

Relative humidity for film storage should never exceed 60 percent with a minimum of 25 percent.

| PROCESS                                | TEMP. F  | R.H. %   |
|----------------------------------------|----------|----------|
| <b>PLASTICS</b>                        |          |          |
| Manufacturing areas:                   |          |          |
| Thermo setting moulding compounds..... | 80       | 25 to 30 |
| Cellophane wrapping.....               | 75 to 80 | 45 to 65 |

Absolute filtration is required in some areas.

Collection and removal of dust and fumes is essential.

| PROCESS                   | TEMP. F | R.H. %   |
|---------------------------|---------|----------|
| <b>PLYWOOD</b>            |         |          |

|------------------------|---------|--------|
| <b>POULTRY RAISING</b> |         |        |
| Incubator.....         | 70-75   | 30-60  |
| Brooder:               |         |        |
| 1st week.....          | 70-75   | 60     |
| 2nd week.....          | 50-60   | 60     |
| Battery room:          |         |        |
| Starting.....          | 70      | 70-75  |
| Growing.....           | 50-60   | 50-60  |
| Egg storage.....       | 45-60   | 70-80  |

Maximum ventilation is required for laying quarters during the summer months, while an attempt is made to maintain a temperature 10 deg above or below outdoor temperature during the winter, to minimize condensation on the exterior walls. This applies to houses not having forced ventilation systems.

| PROCESS                                    | TEMP. F | R.H. % |
|--------------------------------------------|---------|--------|

| Precision parts—honing                  | 75-80   | 35-45  |

For product improvement and increased personnel efficiency some manufacturing areas are being provided with summer air conditioning. Where air conditioning is not provided, an ample supply of outdoor air and air motion are relied upon to provide acceptable working conditions.

Low relative humidity is usually maintained to prevent corrosion.

Temperature control within a narrow range is more important than temperature maintained.

Dust control is required wherever polishing operations occur.

Air distribution is important to maintain constant conditions throughout the area.

| PROCESS                                          | TEMP. F | R.H. %                 |
|--------------------------------------------------|---------|------------------------|
| <b>PRINTING</b>                                  |         |                        |
| Pressroom:                                       |         |                        |
| Multicolor offset lithography                    | 75-80   | 46-48                  |
| Other sheet fed printing                         | 75-80   | 45-50                  |
| Newspaper & other web printing                   | 75-80   | 50-55                  |
| Stock room:                                      |         |                        |
| Multicolor offset lithography                    | 73-80   | * 5-8% above pressroom |
| Other paper storage                              | 70-80   | b                      |
| Binding, cutting, drying, folding and gluing     | 70-80   | 45-50                  |
| Roll storage                                     | 73-80   | 50                     |
| * 5 to 8% above pressroom<br>b same as pressroom |         |                        |

Lithography requires constant humidity control of entire pressroom with paper conditioned 5 to 8 percent higher relative humidity at start. All printing requires conditioned paper otherwise it will not lie flat, with 40 to 45 percent R.H. low limit to eliminate static electricity; and 60 percent R.H. high limit to prevent swelling of the rolls and slow ink drying. Temperature is not critical, but extremes should be avoided due to softening of the rolls at high temperature and improper ink distribution at low temperatures.

Hoods must be provided for gas dryers, with solvent recovery recommended for all except job shops. Exhaust system with dust collectors incorporated is required for type and plate cleaning areas. Check use of gasoline and other solvents. Normal air cleaning is adequate. Air distribution must prevent drafts on paper in storage or process. Gas flame dryers impose unusual loads.

Air from press and storage rooms should not be recirculated through office areas.

| PROCESS                        | TEMP. F  | R.H. %   |
|--------------------------------|----------|----------|
| <b>REFRIGERATION EQUIPMENT</b> |          |          |
| Valve Manufacturing            | 75       | 40       |
| Compressor Assembly            | 70 to 76 | 30 to 45 |
| Refrigerator Assembly          | 75       | 30 to 50 |
| Testing                        | 65 to 82 | 47       |

| PROCESS                      | TEMP. F | R.H. % |
|------------------------------|---------|--------|
| <b>RUBBER DIPPED GOODS</b>   |         |        |
| Manufacture                  | 80      |        |
| Cementing                    | 80      | 25-30  |
| Dipping surgical articles    | 75-80   | 25-30  |
| Storage prior to manufacture | 60-75   | 40-50  |
| Laboratory (ASTM Standard)   | 73.4    | 50     |

Solvents used in manufacturing processes are usually explosive and toxic, requiring positive ventilation. Volume manufacturers usually install a solvent recovery system.

Cotton: Relative humidity maintained in ring spinning depends on staple, twist and whether leather aprons are used for conveying long draft stock. Aprons readily absorb moisture causing cotton to stick when relative humidity is above 55 percent.

With conventional 3 or 4 roll spinning, relative humidity may be as high as 70 percent dependent upon draft, twist and staple.

Relative humidity carried in cotton weaving depends upon construction of the cloth. When automatic machines are to be tended and the warps are heavily sized, it may be as high as 90 percent.

Woolen: In woolen spinning, the relative humidity maintained for mules is generally 55 percent, with conditions over frame spinning at 55 to 60 percent. Both types of spinning depend on the class of stock spun, also the regain in the roving.

TABLE 1. TEMPERATURES AND HUMIDITIES APPLICABLE TO INDUSTRIAL AIR CONDITIONING—(Concluded)

## TEXTILES (Continued)

**Worsted:** Top storage temperature depends on whether cellar long period conditioning at low temperature or quick conditioning at high temperature is used. Weaving relative humidity depends upon staple, quality and construction.

Filtration of air is essential.

**Rayon manufacture:** The steeping room, where sheets of raw material are dipped in caustic soda then broken into a fine matted crumb, is held at 70 F and 55 percent relative humidity. Relative humidity is held down to prevent condensation on cold pipes and jackets.

In chum room, where sodium cellulose is converted into cellulose xanthate, temperatures of 75 to 80 F are maintained while humidity control is not important. Room temperatures are held below 85 F during the summer months.

The crumb is dumped into aging tanks located in a room held at 73 F with no humidity control.

For spinning operations it is desirable to limit the temperature to 90 F with a minimum relative humidity of 70 percent for the summer, while 70 percent and 75 F are desirable for the winter months.

The storage room, where the material is held for later processing design conditions, are 85 F and 100 percent relative humidity.

The material is washed, desulfurized, bleached and then washed again. It is then placed in a drier where controlled conditions of 100 deg and 65 percent relative humidity are required to bring the rayon back to the proper regain.

In the coning room, where winding machines place the rayon yarn on cones, temperature is held at a maximum of 80 F. Relative humidity is held at 55 percent.

| PROCESS                                  | TEMP. F  | R.H. %   |
|------------------------------------------|----------|----------|
| TOBACCO                                  |          |          |
| Cigar and cigarette making               | 70 to 75 | 55 to 65 |
| Softening                                | 90       | 55 to 85 |
| Stemming and stripping                   | 75 to 85 | 70 to 75 |
| Packing and shipping                     | 74 to 78 | 65       |
| Filler tobacco casing and conditioning   | 75       | 75       |
| Filler tobacco storage and preparation   | 78       | 70       |
| Wrapper tobacco storage and conditioning | 75       | 75       |

In preparation for stripping, the tobacco undergoes a softening operation, whereby it is automatically heated, moistened and then cooled.

Control of moisture regain, and of chemical and biological reactions is required in tobacco processing.

Exact temperature and humidity conditions maintained are usually trade secrets as they affect the finished product.

(Continued from page 1015).

- Control of dew-point for protection of highly polished surfaces.
- Control of humidity for static electricity elimination.
- Control of conditions for material test laboratories.

## Moisture Content and Regain

In the manufacture or processing of hygroscopic materials such as textiles, paper, wood, leather, tobacco and foodstuffs, the temperature and relative humidity of the air have a marked influence upon the rate of production and upon the weight, strength, appearance, and general quality of the product. The moisture content of materials having a vegetable or animal origin, and to a lesser extent minerals in certain forms, comes to equilibrium with the moisture of the surrounding air. This moisture content is known as *regain*. Standards of *regain* are fixed in the trade, and are the fundamental basis for the control of certain physical qualities of the material during manufacture.

Manufacturing economy requires that the moisture content be maintained at a level favorable to rapid and satisfactory manipulation, and to a minimum loss of material through breakage. A uniform condition is desirable in order that high speed machinery may be adjusted permanently for the desired production with a minimum loss from delays, wastage of raw material, and defective product. *Moisture content* refers to free moisture (as in a sponge) and to hygroscopic moisture (which varies with atmospheric conditions). It is usually expressed as a percentage of the

total weight of material. *Regain* is more specific and refers only to hygroscopic moisture. It is expressed as a percentage of the *bone-dry* weight of material. For example, if a sample of cloth weighing 100.0 g is dried to a bone-dry weight of 93.0 g, the loss in weight, or 7.0 g, represents the weight of moisture originally contained. This expressed as a percentage of the total weight (100.0 g) gives the moisture content of 7 percent. The regain, which is expressed as a percentage of the bone-dry weight, is  $(7.0/93.0) \times 100 = 7.5$  percent.

The use of the term *regain* does not imply that the material as a whole has been completely dried out and has re-absorbed moisture.

A basis for calculating the regain of textiles is obtained by drying, under standard conditions, a sample from the lot, and the dry weight thus obtained is used in the calculations to determine the regain.

Table 2 shows the regain or hygroscopic moisture content of several organic and inorganic materials when in equilibrium at a dry-bulb temperature of 75 F and various relative humidities. The effect of temperature as compared to the relative humidity is comparatively unimportant, although sudden changes in temperature cause a slight change in regain even when the relative humidity remains stationary. Changes in temperature do, however, affect the rate of absorption or drying, although this property generally varies with the nature of the material, its thickness and density.

When hygroscopic materials absorb moisture from the surrounding air, they deliver to the air sensible heat equivalent to the latent heat released by the moisture to the material. This amount of heat should be included in the load estimate.

## Conditioning and Drying

In general, the materials may be exposed to desirable humidities for treatment coincidentally with the manufacture or processing of the materials, or they may be treated separately in special enclosures. This latter treatment may be classified as conditioning or drying. The usual purpose of conditioning or drying is to establish a desired condition of moisture content and to regulate the physical properties of the material. When the final moisture content is lower than the initial one, the term *drying* is applied (See Chapter 47). If the final moisture content is to be higher, the process is termed *conditioning*. In the case of some textile products and tobacco, for example, drying and conditioning may be combined in one process for the dual purpose of removing undesirable moisture, and accurately regulating the final moisture content. Frequently, conditioning or drying is made a continuous process in which the material is conveyed through an elongated compartment by suitable means, and subjected to various controlled atmospheric conditions.

## Control of Rate of Chemical Reactions

A typical example of control of the rate of chemical reactions occurs in the manufacture of rayon. The pulp sheets are conditioned, cut to size, and passed through a mercerizing process. It is essential that, during this process, close control of both temperature and relative humidity should be maintained. The temperature controls the rate of reaction directly, while the relative humidity maintains a constant rate of evaporation from the surface of the solution, and maintains a solution of known strength throughout the mercerizing period.

Another well-known example in this class is the *drying* of varnish which

TABLE 2. REGAIN OF HYGROSCOPIC MATERIALS  
Moisture Content Expressed in Percent of Dry Weight of the Substance at Various  
Relative Humidities—Temperature, 75 F

is an oxidizing process dependent upon temperature. High relative humidities have a retarding effect on the rate of oxidization at the surface, and allow the internal gases to escape freely as the chemical oxidizers cure the varnish from within. This produces a surface free from bubbles and a homogeneous film throughout. Desirable temperatures for drying varnish vary with the type. A relative humidity of 65 percent is beneficial for obtaining the best processing results.

#### Control of Rate of Biochemical Reactions

In the field of biochemical control, industrial air conditioning has been applied to many different and well-known products. All problems involving fermentation are classed under this heading. As biochemistry is a subdivision of chemistry, subject to the same laws, the rate of reaction may be controlled by temperature. An example of this is the dough room of the modern bakery. Yeast develops best at a temperature of 80 F. A relative humidity of 70 percent is maintained to hold the surface of the dough open to allow the carbon dioxide gases formed by the fermentation to pass through and produce a loaf of bread, when baked, of even, fine texture without large voids.

The curing of fruits, such as bananas and lemons, also comes under this classification. Bananas require a cycle of temperatures and relative humidities for ripening. The starches in the pulp of the fruit must be changed and the skin cured and colored, after which the fruit is cooled to maintain as low a rate of metabolism as possible. Ideal storage conditions range between 56 and 60 F, with about 85 percent relative humidity, and ventilation at the rate of three or four air changes per hour.

The curing of lemons is an entirely different problem. Bananas are cured for a quick market, while lemons are held for a future market. The process, therefore, varies in the temperature used. Temperatures from 54 to 59 F have been found to be best suited for this process. A high relative humidity of 84 to 88 percent is necessary to hold shrinkage to a minimum and, at the same time, develop the rind so it will be sufficiently tough to permit handling.

Tobacco from the field to the finished cigar, cigarette, plug or pipe tobacco, offers another interesting example of what may be done by industrial air conditioning in the control of color, texture and flavor. In the processing of tobacco, control of moisture regain, and of chemical and biochemical reactions, is involved, and only through close atmospheric control can the best quality of leaf be developed.

#### Control of Rate of Crystallization

The rate of cooling of a saturated solution determines the size of the crystals formed. Both dry- and wet-bulb temperatures are of importance, as the one controls the rate of cooling, while the other, through evaporation, changes the density of the solution.

In the coating pans for pills, gum, and nuts, a heavy sugar solution is added to the tumbling mass. As the water evaporates, each separate piece is covered with crystals of sugar. A smooth, opaque coating is only accomplished by blowing into the kettle the proper amount of air at the right dry- and wet-bulb temperatures. If the cooling and drying are too slow, the coating will be rough and semi-translucent, and the appearance unsightly; if too fast, the coating will chip through to the interior. Only by balancing temperature, relative humidity, and volume of air to the sugar solution, can the proper rate be obtained and a perfect coating assured.

### Control of Temperature for Close Machining Tolerances

Where tolerances must be held within 2 or 3 ten-thousands of an inch, as in the manufacture of precision instruments, tools, and high quality lenses, temperature variations may cause expansion and contraction of material to an extent that will seriously affect the quality of the work. This type of work usually requires close temperature control to assure accuracy and uniformity of the product.

Usually the temperature level with respect to the product is not as important as controlling the temperature within close limits. For this reason, conditions are usually selected within the comfort range.

### Control of Dew-Point for Protection of Polished Surfaces

In the manufacture of certain metal articles, the presence of finger prints, tarnish, or *etching* can not be tolerated in the finished article. If these articles are manufactured under conditions of effective temperatures that will cause the hands to perspire, an unsatisfactory product will result. The salt and acid contained in body perspiration, when deposited on the highly polished article, can show corrosion and rust within a few hours if examined under a microscope.

It is therefore important to maintain temperatures and relative humidities (dew-point) low enough to prevent sweating of the hands. In addition, the manufacture of polished surfaces usually requires a better-than-average job of air filtering to avoid abrasion of the surfaces.

### Control of Humidity for Reduction of Static Electricity

The presence of static electricity is often detrimental to the satisfactory and economical processing of many light materials, such as textile fibers, paper, etc. It is also extremely dangerous where explosive atmospheres or materials are present. Fortunately, this hazard is minimized by increasing the relative humidity to at least 55 percent, if the material being processed is not damaged thereby.

It must be borne in mind that for successful elimination, the air that actually comes in contact with the material in the machine must be at a relative humidity of 55 percent or more. As some machines consume a great deal of power, which is converted directly into heat, the temperature in the machine may be considerably higher than the temperature adjacent to the machine where the relative humidity is normally measured. In such cases, the relative humidity in the machine will be appreciably lower than that elsewhere in the room, and it may therefore be necessary to maintain a room relative humidity of 65 percent, or even more, to maintain the desired humidity.

### Control of Conditions for Material Test Laboratories

Laboratories having controlled conditions of temperature and humidity, are becoming more common, not only for the purposes of scientific research, but also for routine testing and for quality production control. A control of temperature and humidity within fairly close plus or minus limits is usually required. Laboratories designed for scientific research may require control of conditions over a wide range, whereas the routine testing laboratory or quality control laboratory will usually be designed to maintain the A.S.T.M. Standard Conditions of 50 percent relative humidity and 23 C (73.4 F) temperature.

## CALCULATIONS

The methods for determining the heating and cooling loads for the various industrial processes are similar to those outlined in Chapters 12 and 13. Some factors affecting heating or cooling requirements are given in Table 1. Because of the large number of motors and heat producing units usually found in an industrial application, it is particularly important that operating allowances, for the latent and sensible heat loads, be definitely ascertained and used in the calculations to determine the total design load.

## GENERAL REQUIREMENTS FOR HEALTH, SAFETY AND EFFICIENCY

### Control of Atmospheric Contaminants

Safeguarding the health and maintaining the safety and efficiency of workers, require control of dusts, fumes, smokes, mists, fogs, vapors, and gases, and control of the effective temperature, which includes temperature, humidity and motion of air about the worker.

General ventilation may be relied upon in some cases to control air contaminants. Chapter 11 gives information on natural ventilation. If mechanical ventilation is to be used, Chapter 33, Fans; Chapter 31, Air Distribution; Chapter 32, Air Duct Design; Chapter 34, Air Cleaning; and Chapter 35, Spray Apparatus, furnish information on a broad range of industrial design conditions.

Specialists in the field of industrial hygiene should be consulted in case of doubt concerning the presence of airborne industrial hazards to health. Chapter 8, Air Contaminants; Chapter 6, Physiological Principles; and Chapter 7, Air Conditioning in the Prevention and Treatment of Disease, will be of help in determining the atmospheric conditions which should be maintained around the worker. Local codes, ordinances, or state labor laws must likewise be observed, particularly for ventilation requirements for hazardous trades. Comfortable conditions are desirable because they are likely to increase the efficiency of workers. For purposes of analysis, both sensible and latent heat should be included as contaminants of industrial atmospheres. A recent small scale survey has indicated that more than half of the air conditioning and ventilation installations in a typical industrial plant were concerned with removal of either sensible or latent heat as a source of air contamination.

### Contaminant Control Systems

In general, systems for control of atmospheric contamination in industrial plants will be of three types:

1. *Local exhaust systems* will be indicated where the contamination originates at concentrated areas and is characterized by low or imperceptible air motion, or where the contaminant is a dust, mist or fume requiring a capture velocity exceeding 25 fpm. Design of this type system is discussed in Chapter 46, and will not be further treated in this chapter.
2. A system employing the *dilution* method will usually be indicated where the contamination originates at scattered points dispersed generally throughout the area.
3. Combination of *local exhaust* and *dilution* methods is often economical, since well designed exhaust hoods or openings, removing from the space that portion of the contamination load which is susceptible to such treatment, will often reduce greatly the air volumes required for dilution purposes. The choice of the type of system should be made on the basis of economic comparisons.

### Design of Dilution Systems

The first step in the design of a system employing the dilution method is to determine as exactly as possible the nature and extent of the contaminating load. This will often be difficult, and may require construction of pilot production models. Often, however, the required data will be available from production records, showing the weight or volume rate of loss of the contaminating agent to the atmosphere, or it may be estimated from parallel operations in other plants, or by applying experienced engineering judgment. However obtained, the determination of the nature and magnitude of the contaminating load is an indispensable step in the proper design of the corrective system. Designs based on number of air changes per hour, or other rule-of-thumb methods, are hopelessly inadequate, and lead either to unsuccessful operation or to excessive and unnecessarily high cost of installation.

1. *Gases and Vapors.* Once having established the nature and magnitude of the contamination load, it is rarely necessary to completely remove contaminating agents from the atmosphere. For cases involving diffusible vapor or gas contaminants, maximum allowable concentrations (MAC) of commonly encountered gases and vapors have been established, and these data are tabulated in Chapter 8. From these data, and the previously established rate of addition of the contaminant to the space, the volume of air required to dilute the addition to a tolerable level can be calculated by the equation:

$$Q = \frac{V \times 10^6}{(\text{MAC}) - (\text{SAC})} \quad (1)$$

where

$Q$  = quantity of air circulated, cubic feet per minute.

$V$  = rate of generation of contaminant, cubic feet per minute.

$\text{MAC}$  = maximum allowable concentration, ppm by volume.

$\text{SAC}$  = concentration in supply air, ppm by volume.

The rate of generation of the contaminating vapor will often be available as a *weight or volume* of liquid evaporated into the space per unit time. These may be converted to the units of Equation 1 by applying the principle that a pound-mol of a gas or vapor will occupy approximately 359 cu ft at standard pressure and temperature. Thus,

$$\text{cfm (vapor)} = \frac{W}{M_w} \times 359 \times \frac{t + 460}{492} \quad (2)$$

where

$W$  = rate of generation of contaminant, pounds of liquid solvent per minute.

$M_w$  = molecular weight.

$t$  = air temperature, Fahrenheit.

A special case occurs where local concentrations of solvent vapors *at the breathing zone*, resulting from concentrated sources of contamination, are intolerably higher than the average design concentration when using dilution methods. Data are available for calculations, but involve many assumptions regarding boundary conditions, such as convection area and random air movement in the vicinity.

2. *Dusts and Fumes.* Maximum allowable concentration of various dusts, fumes and mists are also tabulated in Chapter 8. However, the dilution method as a means of treating particulate contaminating agents should be used with care, since the allowable air movement in spaces will ordinarily be lower than the capture velocity required for such particles. Exhausting at the source (see Chapter 46) will generally be the recommended treatment for these particulate contaminants.

3. *Sensible Heat.* Excessive sensible heat contamination is subject to treatment, similar to that for vapors, by the dilution method, the difference being that the rate of generation of the contaminant must be expressed in units of energy rather than volume or weight, and that the effect will be expressed as excessive temperature. In this case, the circulated air required will be:

$$Q = \frac{H}{(t_1 - t_o) \times d \times c} \quad (3)$$

where

$Q$  = quantity of air circulated, cubic feet per minute.

$H$  = rate of generation of heat, Btu per minute.

$t_1$  = allowable temperature in the space, Fahrenheit.

$t_o$  = temperature of supply air, Fahrenheit.

$d$  = density of air in pounds per cubic foot.

$c$  = specific heat of air.

In some cases, such as ventilation systems not employing refrigeration, unusually large and uneconomical air quantities may be required when the desired or tolerable temperature  $t_1$  approaches too closely the temperature  $t_o$  of the dilution air. This condition may sometimes be corrected by a combination of treatment by dilution and central exhaust, large sources of heat load being eliminated by exhaust through hoods at the source.

### Heat Storage in Structure

A special condition is sometimes encountered in large masonry structures when, due to the heat storage capacity and time lag of the structure, a prolonged period of hot weather may cause storage of such large quantities of heat in the structure that they continue to be a source of heat load after the outside weather has moderated.

In general, the solution to ventilation problems by the simple *dilution method* is limited to cases where a practical and economical equilibrium may be established between the maximum rate of generation of the contaminant distribution and cost of the air required for its removal.

### LOCAL RELIEF IN HOT AND HOT HUMID INDUSTRIAL ENVIRONMENTS

In many areas in industrial buildings, it is not economically feasible to provide acceptable working conditions by the conventional means of ventilation and air conditioning. In such cases, local control of the environment (spot cooling) may be provided by means of shielding, air cooled booths, and spot cooling by means of air motion to provide a relatively cool area for the worker. These methods of local control may be used in conjunction with the natural or mechanical ventilation systems of the building to obtain the desired conditions for the worker, process or equipment.

Spot cooling may be defined for the purposes of industrial environment control as heat relief of a local area within a larger space, independently of the general surroundings; a so-called oasis to provide conditions of relative comfort.

### Environmental Considerations

In the preliminary design for hot environments the following should be considered:

1. Estimate the conditions of dry-bulb temperature, humidity, air motion, radiant

heat, effective temperature, and body heat balance. For buildings with low ceiling heights, the possibility that heated air may accumulate under the ceiling or that the ceiling may absorb heat and become a radiant heating panel should be explored. (See Chaps. 5 and 24.) Such radiant heat loads may represent other heat loads considered but not dissipated to the outside. In addition to the pertinent chapters in *THE GUIDE*, the designer should refer to the articles by Small<sup>1</sup>, and Haines and Hatch<sup>2</sup> on the subject of heat relief in industry, in evaluating the above factors.

2. Consider the practicability of reducing the heat loads imposed on the area and worker by:

- a. Designing a building structure of adequate height, reducing the glass area exposed to sun radiation, and utilizing heat-reflecting glass to shield the high intensity radiant sources.
  - b. Changing the process in such manner as to provide lower operating temperatures, thereby lowering the heat release to the area.
  - c. Providing air cooled booths, possibly in conjunction with remote operating controls and visual aid devices, so that the hot areas may be avoided except for short exposures.
  - d. Insulating all surfaces above 125 F in temperature where these surfaces are extensive enough to add appreciably to the ambient air temperature or mean radiant temperature.
  - e. Using canopy hoods for hot equipment or providing local hoods at flues and doors of furnaces and similar hot equipment to reduce the heat dissipated to the work area.
  - f. Shielding hot equipment (often used in conjunction with hoods) so as to reduce sources of radiant heat.
3. Give careful consideration to the type of clothing used by the workers.<sup>3</sup> Lightweight, open-weave fabrics in white, will frequently reduce the heat received by the worker to a small extent and will materially increase the workers' ability to lose heat by convection and evaporation. Also, reflective clothing can be provided, as noted hereinafter under the heading Radiation Shielding.
4. Heat removed from exchangers, motors, generators and similar equipment can be used to temper necessary make-up air or to heat the building in the winter. This heat can be discharged outdoors in warm weather.

### Physiological Considerations

In hot environments, the major physiological considerations are the degree of activity of the occupants (this affects their metabolic rate or rate of heat production), the length of the period of activity and occupancy, and the ambient environmental factors (dry-bulb temperature, mean radiant temperature, humidity and air motion) which control the dissipation and reception of heat by the occupants. The subjects of work activity, and the correlated effective temperature limitations are covered in detail in Chapter 6. While effective temperature is a good index for hot areas (when mean radiant temperature effects are included), it must be realized that the allowable effective temperature which can be considered for a particular area must be dependent upon the degree of activity or work rate, and, consequently, on the body heat balance. It is essential that body heat balance (metabolic rate plus heat received by the body, versus the heat dissipated by the body) be maintained except for relatively short exposures to hot environments. The subject is treated to some extent in Chap. 6, but Haines and Hatch<sup>2</sup> have recently provided detailed data for estimating the maximum heat removal that can be expected for various environmental conditions. These data and calculations will also provide a means of estimating the maximum practical work rate for the area under consideration, and will indicate the best means for providing relief for the worker.

Too little information is available on the effect of air motion (draft) on human comfort. An understanding of the subject is of great importance in designing areas for local cooling. The comfort reaction to a draft is a function of (a) the physiological factors of work activity, position, age, sex, health and acclimatization; and (b) the environmental conditions of

temperature, air movement (over the body), and humidity. In hot atmospheres with high mean radiant temperatures and with high degrees of activity, a draft may be pleasant. In cooler conditions with less active work, a draft may be unpleasant. The body extremities are sensitive to draft and the head, neck, and shoulders have been found particularly sensitive if subjected to continued or excessive air movement in conjunction with low humidity, sweating, and the impingement of low temperature air.

The position of the worker is important. A person sitting, at rest, will produce less heat than a person standing, but because of the increased convection and evaporation surface exposed, the latter can lose more heat. Likewise, a person whose job requires him to stay at a fixed point, cannot be comfortable under the same conditions of air movement as a person who is moving about and exposed intermittently to the same air movement. Yaglou<sup>4</sup> among others, has pointed out that minimum body stress occurs with uniform cooling or heating over the body area. On the basis that the maximum work rate which can normally be maintained for an 8 hr day is 88 Btu per (sq ft)(hr) or 1700 Btu per hr for a surface area of 19.5 sq ft, the following stress factors may be used as guides in determining the design of local relief areas in hot industries.

1. The effective temperature should be maintained below 85 F. (See Ref. 2 also.)
2. The relative humidity should not exceed 80 percent for normal temperatures nor should the wet bulb temperature exceed 83 F. (See Chap. 6, Fig. 9.)
3. The skin temperature should not exceed 95 F.
4. The pulse rate should not exceed 125 beats per minute (from an initial rate of 70 to 80).
5. The rectal temperature should not exceed 100 F (from an initial level of 98 to 99 F).

These are neither rigid nor exact limitations but do provide guides for design purposes. Generally, the designer will do well to stay reasonably below these limits. If the limits of paragraphs 3, 4, and 5 are not exceeded within the first two hours of work they probably will not be exceeded during the work day provided there is no change in the rate of work or the environmental conditions.

### Radiation Shielding

Shielding is an all-important method for reducing radiant heat exposures and the one technique that has been largely neglected in industry.

A shield consists of a sheet of suitable material placed between a hot object, such as a furnace, and its cooler surroundings. The closer it is placed to the hot object, the greater the effective coverage. Hot surfaces emit infra-red waves which reach all objects within visible range. Essential to all shielding is the presence of an air space between the hot object and the shield to avoid conduction to the shield or a thermal short circuit.

Radiation shields in the following forms are very effective:

1. Sheets of reflective metal or insulating board, either semi-permanently attached to the hot equipment (such as furnace buck stays) or arranged as semi-portable floor stands.
2. Aluminum foil faced cloth curtains which can be raised or lowered on spring rolls.
3. Transparent shields, including heat reflecting tempered plate glass, reflective metal chain curtains and close mesh wire screens. These have lower efficiency than opaque shields described in preceding paragraphs 1 and 2.
4. Reflective garments, such as aprons, or in the form of a sandwich in cases of

continuous front and back exposures. For continuous wear the apron or sandwich width should be limited to 14 to 18 in. to assure adequate continuous side openings for air circulation and body ventilation. In addition gauntlets and face shields are particularly applicable to operations such as the pouring and casting of hot metal. Supply houses dealing in safety clothing for industry offer suitably lightweight flame proofed foil-faced cotton drill or denim of excellent reflectivity.

For repairs inside hot coke ovens and industrial furnaces, a complete suit is available using forced ventilation from a small blower or a compressed air source. These suits may be made of asbestos cloth, faced with a reflective metal in atomized form.

If the shield is a good reflector, it will remain relatively cool in the presence of severe radiant heat. This reflectivity is a surface characteristic. Hence a thin sheet is as effective as a thick one. Tinplate, stainless

FIG. 1. DIRECTIONAL OUTLETS FOR SPOT COOLING

steel and ordinary flat or corrugated aluminum sheets are efficient and long-lived. Foil-faced plaster board, though less durable, obtains good reflectivity on one side.

### Spot Cooling By Air Motion

The previous paragraphs have described the steps which should be taken to reduce the heat load on the worker or the work area. When these factors have been considered and the heat load has been minimized to a practical degree, the designer may then resort to spot cooling by air motion to cool the worker himself. Such cooling may be provided by supplying air to the local areas or into suitable working enclosures or booths, or to ventilated coverall suits. The air supplied should be at such conditions of temperature, relative humidity and air motion as to provide a cooling effect on the worker.

These systems may also be used to provide make-up air for industrial exhaust systems, or to provide spot heating in the winter time.

Such installations may be provided to improve the conditions around the

worker continuously, or else to provide a relief area where the worker will be in a cool zone intermittently. The designer should keep this in mind in selecting the proper method of air cooling.

Spot cooling may be provided by means of recirculated (man-coolers), direct outside, dehydrated, evaporatively cooled or mechanically cooled air, the solution depending upon the environmental conditions existing in the working area, and the economic factors. Generally, recirculated air will be effective only for areas of moderate heat release. Other systems will be required for areas having high heat release.

A great variety of outlets may be used for spot cooling. Several different types are shown by Fig. 1. In addition, several manufacturers make remotely adjustable ceiling diffusers such that the air patterns may be altered from horizontal (parallel to the ceiling) to vertical, down. A number of manufacturers also make double deflection grilles that are good for this service. Such outlets can be provided in conjunction with an elbow type outlet and slip joint (see lower right diagram in Fig. 1) so as to provide directional discharge at any desired angle. The latter is very important to the worker because he may frequently want the air discharging into the space but may not want it to blow on him.

Perforated panels may also be used for the supply air. Such panels have low induction characteristics and, used in conjunction with a booth could provide a low velocity blanket of air which should be effective for local heat relief, if supplied with cooled air. A booth would shield the worker from radiant heat and would permit effective cooling by means of the air supplied through the panel.

The outlet air velocities used for spot cooling systems may vary from 50 to 2000 fpm. The higher velocities are frequently used but should be used with caution as noted hereafter. The data in Chap. 31 Air Distribution, should be studied in determining the required outlet velocities corresponding to the desired velocity at the worker or the operating station.

The following items are particularly important in designing spot cooling installations:

1. Where the personnel are engaged in work requiring little activity and where the exposure is continuous, the air velocity at the personnel should be low, approaching the normal room velocities. The maximum velocity for such cases is sometimes given as 200 fpm. With greater worker activity, and where the worker is in the air current intermittently, higher velocities may be used. See Chap. 6, Effective Temperature Chart, Fig. 9.
2. Generally the temperature of the air impinging on the worker should exceed 80 F.
3. When the temperature of the air impinging on the worker exceeds the skin temperature the critical point is approached where too high an air velocity will add to the body heat load and too low a velocity will fail to remove the sweat, and thus fail to provide the maximum evaporative cooling for the existing conditions. (See Ref. 2.)
4. The outlets should be placed as close as practicable to the worker in order to take advantage of the lower discharge air temperature and the relatively larger core of air at the discharge air temperature. Installations in which the air is discharged from outlets 4 to 8 ft. from the worker are effective with small volumes of air, 200 to 1000 cfm. per outlet. At hot metal furnace working stations, 2000 to 3000 cfm. will be adequate. At greater distances more air is required due to the increased entrainment of room air. However, the effect of the lower velocity air would be more tolerable.
5. In selecting the outlets it should be kept in mind that large outlets have greater cooling effect because of the larger core of cool air. Slot outlets by comparison have high induction ratios, thus higher impinging temperature (at the worker). Per-

forated panels have low induction ratios and thus will provide lower impingement temperatures.<sup>5</sup> See Chap. 31.

6. Generally the outlets should have remote directional or volume control or, preferably, both. The worker should be able in most cases to operate the outlet damper, vanes or louvers (or to turn the outlet) from the floor by some convenient means.

The damper control should provide at least 80 percent reduction in velocity. The workers may desire the full air velocity in hot weather, but may wish to reduce the velocity or to direct the air above the head zone in cold weather.

7. Generally the spot cooling air should be directed to the front and to the torso of the worker. If possible the air should not be directed at the head, shoulders or the back of the worker.

8. When providing spot cooling with evaporatively cooled air, be sure that conditions of high humidity will not exist and cause conditions detrimental to the comfort of the personnel or cause rusting or other difficulty with the equipment or process.

Generally the evaporatively cooled air should be limited to 20 to 50 percent of the total outside air circulated through the building.

### Odors

There is little information available either on the rate of generation of common odors, or on the maximum concentration which would be tolerated by a majority of persons. Thus a quantitative specification covering systems for locker rooms and toilet rooms, or other applications where odors constitute the contaminant, is not now possible. Pending research in this important field, it is suggested that the data in Table 1, Chapter 6, showing the outside air supply required per person, at various socioeconomic levels, be used.

## CHAPTER 46

### INDUSTRIAL EXHAUST SYSTEMS

Elements of Exhaust Systems, Hoods or Enclosures, Capture Velocities, Air Volume, Duct System Design, Calculations, Construction of System, Materials, Details, Air Flow Producing Equipment, Air Cleaning Equipment, Make-Up Air, Maintenance of Performance, Materials for Corrosion Resistance

**I**n industrial plants, some type of exhaust system designed to collect and remove dusts, fumes, mists, vapors, and gases is installed to protect health and safety of industrial personnel, promote worker efficiency, salvage usable material, or improve plant housekeeping. This chapter will not include consideration of systems similar in design, but used to convey heavy loadings (100 or more grains per cu ft) of materials. Definitions of various air contaminants, their particle sizes, maximum allowable concentrations, and upper and lower explosion limits are included in Chapter 8, Air Contaminants.

Exhaust systems are extensively used for control of contaminants from:

1. Mechanical cutting and abrading operations including abrasive blasting and rock cutting.
2. Fuel burning and exhaust gas producing operations.
3. Molten materials handling operations.
4. Welding, burning, and soldering operations.
5. Fiber handling operations.
6. Volatile and gaseous material handling operations.
7. Chemical processes.

Local exhaust systems should be considered whenever possible rather than general ventilation methods which allow contaminants to be dispersed within the workroom. More positive control, great reduction in exhaust volume handled, and reduced cost of air cleaning equipment will result.

#### ELEMENTS OF EXHAUST SYSTEMS

An exhaust system will consist of (1) hoods or enclosures at all sources of air contamination, (2) branch and main ducts through which an air stream transports the contaminant to air cleaning device or to the outside atmosphere, (3) air moving equipment to produce required air flow into hoods or enclosures, and (4) air cleaning equipment when required. See Chapter 34, Part II, for discussion of types, applications, and principles of operation.

#### HOODS OR ENCLOSURES<sup>1 to 10</sup>

Basically, hood design requires sufficient knowledge of a process or operation so the most effective hood or enclosure can be installed to provide minimum exhaust volumes for effective contaminant control. The more complete the enclosure, the more economical and effective will be the installation. Many designers develop their hoods by mentally enclosing the operation completely and then providing access and working openings as indicated. From this complete enclosure concept are developed the familiar hood shapes like booths, side or downdraft hoods (with or without side shields). All

openings are kept to a minimum size and are placed away from the natural path of the contaminant travel wherever possible. Inspection and maintenance openings are provided with doors whenever practicable.

### Capture Velocities and Air Volume Exhausted

Only after the hood design has been determined can exhaust volume requirements be calculated. With enclosures, volumes are calculated from the known open area of the hood and the selection of the capture or indraft velocity sufficient to prevent outward escapement. Where enclosure of the process is impracticable, the air flow pattern in front of the hood must be such that selected capture velocities will be maintained in the area of generation, conveying the contaminant to the hood opening.

Usual capture velocities for typical operations are listed in Table 1 and

TABLE 1. MINIMUM AIR VELOCITIES REQUIRED AT POINT OF ORIGIN TO CAPTURE CONTAMINANT EFFECTIVELY

| CONDITION OF GENERATION OF CONTAMINANT | MINIMUM CAPTURE VELOCITY, FPM | PROCESS                                                                                                                                                      |
|----------------------------------------|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Released without noticeable movement   | 50-100                        | Evaporation of vapors, exhaust from pickling, washing, degreasing, plating, welding, etc.                                                                    |
| Released with low velocity             | 100-200                       | Paint spraying in booth; inspection, sorting, weighing, packaging, low speed (less than 200 fpm) conveyor transfer points, blending, mixing, barrel filling. |
| Active generation                      | 200-500                       | Foundry shakeout, high speed (over 200 fpm) conveyor transfer points, crushers, screens.                                                                     |
| Released with great force              | 500-2000                      | Grinding, tumbling mills, abrasive cleaning.                                                                                                                 |

refer in the case of remote hoods to the air movement required at the zone of air contaminant generation. Required capture velocities for any operation will vary with the magnitude of the air volume handled, with uncontrolled air movement in the area, and oftentimes with the location of the process or operation and size of the workroom. Larger remote hoods exhausting large air volumes will provide effective control at lower maintained capture velocities than in the case of small remote hoods handling lower exhaust volumes. A hood at one end of a small narrow room with air supply at opposite end will provide control with lower capture velocities than that required from the same hood in a large room where no perceptible air flow will be obtained except in the immediate area of the hood.

The method for determining, approximately, the quantity of air that must be exhausted from an unobstructed hood, without flanges, to produce these capture velocities at the point of origin, is given in Equation 1:

$$Q = V(10X^2 + A) \quad (1)$$

where

$Q$  = quantity of air exhausted, cubic feet per minute.

$V$  = air velocity in feet per minute at  $X$  distance in feet from the hood and on the centerline of the hood.

$X$  = distance in feet, along the hood centerline, from the face of the hood to the point where the air velocity is  $V$  feet per minute.

$A$  = area in square feet of the hood opening.

Fig. 1 shows lines of equal velocities (velocity contours) for a rectangular hood opening with a side ratio of one-half. The velocities are expressed as percentages of the velocity at the opening. Studies have established the principle of *similarity of contours* which states that the positions of the velocity contours for any hood (when the contours are expressed in terms of the average velocity at the hood opening) are purely functions of the shape of the hood. Extensive studies<sup>2, 11, 12</sup> have revealed variations in values of such velocity contours for long narrow slots and for hoods with one or more planes shielded against air flow.

For smaller hoods, flanges which are usually 3 to 6 in. wide surrounding the hood opening usually will improve the air flow in front of the hood

FIG. 1. VELOCITY CONTOURS FOR RECTANGULAR OPENING WITH A SIDE RATIO OF ONE-HALF. CONTOURS ARE EXPRESSED AS PERCENTAGES OF THE VELOCITY AT THE OPENING

and will reduce the air volume required to provide desired capture velocity by as much as 25 percent.

### Special Exhaust Requirements

It is important to note that certain operations may require exhaust volumes in excess of the quantities based on design data from Table 1 and Equation 1. Typical reasons for increased ventilation rates include:

1. Induced air flow caused from falling granular material in large quantities through considerable height, or from internal rotating parts like some types of crushers, knives, macerators.
2. Induced air flow caused by the thermal or stack effect from sources of extreme heat.

TABLE 2. A GUIDE TO VENTILATION RATES FOR TYPICAL INDUSTRIAL EQUIPMENT.  
State or Local Regulations Should be Consulted and Followed Where Higher Ventilation Rates are Specified

| OPERATION                                                  | VENTILATION                                             |                                                                                                                                                                                                                | USUAL TRANSPORT VELOCITY (FPM) | REMARKS AND REFERENCES                                                                                                                                    |
|------------------------------------------------------------|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                            | Type of Hood                                            | Air Flow                                                                                                                                                                                                       |                                |                                                                                                                                                           |

3. Exhaust volumes insufficient to dilute mixtures of combustible vapor and air to less than 20 percent of the lower explosive limit of the combustible.

4. Room air currents caused by cross drafts, spot cooling, motion of machinery or operators.

5. Local or State regulations may specify larger exhaust volumes for specific operations.

Exhaust volume requirements for many specific operations have been listed in Tables 2, 3, 4, and 5.

#### GRINDING OR POLISHING BELTS:

To 3 in. wide—3 in. branch, add ½ in. to branch diameter for each 2 in. or fraction increase in belt width over 3 in.

\* Increase branch diameter 0.3 in., but not less than ¼ in., for each 1 in. increase in width over dimension noted.

#### Duct System Design

The duct system will consist of branch ducts connected to a main duct which will convey the air from the hoods to the exhaust fan and the air cleaning equipment, if used. Round ducts should be used wherever possible. Their gage size and construction differ from air supply practice due to the rougher usage encountered, and in the case of dusts, to the abrasive effect. (See later section on Exhaust System Design and Construction Features.) Usual conveying velocities are shown in Table 6. Where solid contaminants are handled, recommended velocities must be maintained throughout the system to prevent material from settling in the ducts and obstructing the air flow. For conveying of solid particles, velocities shown in Table 6 include a reasonable factor of safety, and design velocities may therefore be adjusted to use commercial pipe sizes which are available generally in ½-in. diameter steps through 6-in. diameter and 1-in. steps through 16-in. diameter or larger with 2-in. diameter steps for large diameters. For contaminants that are not solids, conveying velocities are based on a balance

Note 1—Column A refers to tank with hood along one side or two parallel sides when one hood is against a wall or a baffle running length of tank and as high as tank is wide; also to tanks with exhaust manifold along center line with  $\frac{W}{L}$  becoming tank width in W/L Ratio.

Column B refers to free standing tank with hood along one side or two parallel sides.

Note 2—Complete control of the vapors and mist from degreasing operations requires the same ventilation rates as recommended for pickling. However, the solvents employed in degreasing operations are relatively volatile, and the solvent loss caused by evaporation increases rapidly as the exhaust rate at the tank increases. For this reason perfect control is usually sacrificed in favor of lower solvent evaporation rates. Where solvent loss does not present an important cost or operating problem, the exhaust rates given for pickling should be adhered to, but where solvent loss must be kept at a minimum, an exhaust rate of 50 cfm per sq ft of tank area is commonly employed. Where this rate is used, control will be adequate only if the tank is located in an area free of drafts and if the degreasing operations are carried out in accordance with a rigid schedule.<sup>44</sup>

between the higher resistance and lower first cost of smaller diameter ducts against higher first cost and lower resistance of larger diameter ducts.

Main ducts connecting two or more branches are sized by the same procedure. The main should be designed for the total exhaust volume to be handled through all branch ducts.

Where exhaust systems handling solids are to provide for a substantial increase of future capacity, required conveying velocities can be maintained by:

1. Providing open end stub branches in main through which air will be admitted into system until future connection is made. The volume admitted into the main

TABLE 5. EXHAUST REQUIREMENTS FOR WOODWORKING OPERATIONS<sup>16</sup>  
(Air Velocity: 4000 fpm in all branches unless noted otherwise)

| Note: One branch of size indicated required for each drum. Fewer branch pipes may be used as long as total branch pipe cross sectional area is not reduced. Some manufacturers use 1 extra branch of equal size on feed side. 1-4 in. branch may be required for exhausting bed rubber cushions or mechanically operated brush. |                                     |

| Pulley pockets and chain mortises-3 in. branch; dovetail and lock corner machines, dowel machines, duplex molding sanders, forming lathes, panel raisers (each head), ploughs, rail shears, routers, sash stickers (each head) 4 in. branch; pulley stiles-5 in. branch; glue jointer-6 in. branch. |                                                         |

can be adjusted to required air flow rate, cfm, by use of a blast gate or orifice plate in such stub branch.

2. Arranging system layout so future points can be picked up by a separate main which will run directly to the fan or air cleaning equipment inlet.

### CALCULATION OF SYSTEM PRESSURE LOSS

The pressure loss of the system includes entrance loss<sup>17</sup> as air is accelerated through the hood to a branch duct connection, resistance loss of ducts,<sup>18</sup> elbows, and junctions, and acceleration or deceleration losses from velocity changes within the system. Chapter 32 includes data on duct resistance and on resistance of elbows, and provides sample calculations. In exhaust systems, either the equal friction method (illustrated in Chapter 32) or the use of blast gates in the branches to equalize pressure loss of all runs is employed.<sup>8, 11, 12, 18</sup>

Data on losses for hood entrance and branch entry, transitions and weather hoods are given in Fig. 2. The static pressure in branch ducts close to the hood connection is frequently referred to as *hood suction*. It is the sum of the velocity pressure in the branch and the hood entrance loss.

TABLE 6. APPROXIMATE CONVEYING VELOCITIES

| MATERIAL CONVEYED                             | DESIGN VELOCITY<br>FPM |

FIG. 2. EXHAUST SYSTEM DESIGN DATA<sup>13</sup>

Tapered hood data from Reference 37  
 Weather hood data from Reference 38

EXHAUST SYSTEM CONSTRUCTION SPECIFICATIONS AND DESIGN DETAILS<sup>13</sup>

Correct design and competent installation of sheet steel ducts and hoods are necessary for the proper functioning of any exhaust system. The following specifications are mainly those recommended in the manual Industrial Ventilation.<sup>13</sup>

## General Requirements

All exhaust systems shall be constructed with the materials recommended here-with and shall be installed in a permanent and workmanlike manner. The interior of all ducts shall be smooth and free from obstructions; with joints either welded, flanged, or soldered air-tight.

## Materials

a. Ducts shall be constructed of black iron welded or of galvanized sheet steel riveted and soldered unless the presence of corrosive gases, vapors and mists makes use of such material impracticable. Galvanized construction is not recommended for temperatures exceeding 400 F. Welding of black iron of 18 gage and lighter is not recommended for field fabrication.

b. For average exhaust systems on non-corrosive applications the metal thickness in the following table shall be supplied.

| DIAMETER OF STRAIGHT DUCTS (INCHES) | U. S. STANDARD GAUGE FOR STEEL DUCT |          |           |
|-------------------------------------|-------------------------------------|----------|-----------|
|                                     | Class I                             | Class II | Class III |
| Up to 8                             | 24                                  | 22       | 20        |
| Over 8 to 18                        | 22                                  | 20       | 18        |
| Over 18 to 30                       | 20                                  | 18       | 16        |
| Over 30                             | 18                                  | 16       | 14        |

Class 1. Includes ducts non-abrasive applications such as for paint spray, wood-working, pharmaceutical, and food products.

Class II. Includes ducts for non-abrasive material in high concentration (low pressure pneumatic conveying); moderately abrasive material; and highly abrasive materials in light concentrations. Typical examples are chemicals and wood dust; exhaust of foundry shakeouts and sand handling systems, grain dusts; coal crushing and screening; exhaust of grit blast cabinets; and grinding, buffing and polishing.

Class III. Includes ducts for conveying all highly abrasive materials in moderate to heavy concentrations and moderately abrasive materials in heavy concentrations as in: low pressure conveying of tobacco; and exhaust systems from abrasive cleaning operations, rock and ore screening and crushing, dryers and kilns, and flyash from boiler stacks.

Where aluminum duct is indicated, the following equivalent B & S gage thickness of sheets should be used:

|                           |    |    |    |    |    |
|---------------------------|----|----|----|----|----|
| Steel—U. S. Standard Gage | 26 | 24 | 22 | 20 | 18 |
| Aluminum—B & S Gage       | 24 | 22 | 20 | 18 | 16 |

c. Elbows and angles shall be a minimum of two gages heavier than straight lengths of equal diameter.

d. Hoods shall be a minimum of two gages heavier than straight section of connecting branches.

e. Where flexible piping is necessary, a non collapsible type of flexible piping shall be used and its length shall be kept at a minimum.

## Construction

a. Longitudinal joints of ducts shall be lapped, and riveted or spot-welded on 3-in. centers, maximum.

b. Girth joints of ducts unless flanged or butt welded shall be made with lap in direction of air flow with not less than 1-in. lap.

c. Elbows and angles should have an inside or throat radius of two pipe diameters whenever possible, but the radius shall never be less than one pipe diameter. Large radii are recommended for heavy concentrations of highly abrasive dusts. Construct elbows 6 in. or less in diameter of at least five sections, over 6 in. diameter of seven sections. Angles shall be pieced proportionately.

d. Hoods must be free of sharp edges or burrs and shall be reinforced to provide necessary stiffness.

e. Provide dead end caps within 6 in. from last branch of all mains and sub-mains.

f. Provide cleanouts every 10 ft and near each elbow, angle, or duct junction in horizontal sections.

g. Support ducts sufficiently to prevent placing of any load on connecting equipment and to carry weight of system if plugged with material. Use maximum supporting interval 12 ft for 8 in. or smaller ducts and 20 ft for larger ducts.

h. Provide 6 in. minimum clearance between ducts and ceiling, wall, or floor.

i. Rectangular ducts can be used only when clearances prevent the use of round construction. Rectangular ducts must be as nearly square as possible. Weight of metal, lap and other construction details are to be the equal of round duct construction whose diameter equals the longest side.

j. All branches shall enter the main at the large end of the transition at an angle not to exceed 45 deg (30 deg is recommended). Connect branches only to top or sides of main, with no two branches entering diametrically opposite.

#### System Details

a. Connect duct to fan inlet with split sleeve drawband one pipe diameter long but not less than 5 in.

b. Transitions in mains and sub-mains are to be tapered; taper 5-in. long for each 1-in. change in diameter is recommended.

c. Place blast gates for adjustment of system near connection of branch to main. Provide means for locking gates after adjustments have been made.

d. Fire dampers, explosion vents, etc., should be installed in accordance with NFPA Codes or local fire ordinances.

#### Deviation From Specifications

Where State or local laws conflict with the specifications given, the more stringent regulation shall be followed. Any other deviation must be approved before installation.

#### AIR FLOW PRODUCING EQUIPMENT

The principal types of air moving equipment are centrifugal fans, axial flow fans, and venturi ejectors. Chapter 33 includes information on fan types, arrangements, and application. Gravity stacks have application for some systems handling higher air temperatures or steam where no air cleaning equipment is installed.

Centrifugal fans are most frequently used for the bulk of exhaust system applications due to the system pressures involved. Where air cleaning equipment is included, fans are usually located on the clean air side. The paddle wheel or modified paddle wheel designs are heavily constructed and have few blades to make them more suitable if wear, corrosion, or accumulations are a factor. The higher efficiency backward curved blade designs find application where relatively clean, non-corrosive air is handled. Forward curved blade designs have limited application due to the number, shape, and metal thickness of the short curved blades.

Belt driven fans are recommended by many designers because a change in fan speed is often needed where future changes of the system may be involved, where added pressure losses from air cleaning equipment improvements are anticipated, or where the fan may be used at some later date for another application.

The axial flow fan is used for systems having low pressure losses. Pro-

PELLER or disc designs develop pressures under 1 in., the vane axial designs develop higher pressures but seldom are used where pressures exceed 3 in.

The venturi ejector<sup>39</sup> is an inefficient method of air movement, but has the advantage of causing air flow without the exhaust air passing through the air flow producing equipment. It minimizes the explosion or corrosion potentialities in certain types of system.

Fans, motors, and drives should be located so that safe and easy access for periodic inspection, servicing, and maintenance is possible.

#### AIR CLEANING EQUIPMENT

As discussed in detail in Chapter 34, air cleaning equipment should be considered in all systems to prevent property damage, neighborhood pollution, re-entry to the working space; to salvage usable material, reduce fire and explosion hazards or to make possible some recirculation of air to the working spaces. The present growing emphasis on air pollution control makes it desirable to remove all contaminants to the greatest practical degree based on reasonable cost and maintenance.

#### MAKE-UP AIR REQUIREMENTS

A correctly designed exhaust system may be ineffective during periods when windows and doors are closed. This condition should be anticipated and prevented by making provision for an adequate air supply. Poor performance of exhaust hoods is caused by: absence of air supply systems; cold drafts due to high indraft velocities through cracks and openings in building construction especially at windows and doors; reverse air flow through low pressure systems of roof ventilators or general ventilation systems; downflow through heater vent stacks preventing exhaust of flue gases to the outside. Systems for conditioning make-up air do not necessarily increase heating requirements for the space, as cold air due to infiltration from the outside must be heated somehow to maintain comfortable temperatures in the area. The cost will depend on the ratio of exhaust air to that required for ventilation of the space occupied.

#### MAINTENANCE OF PERFORMANCE

Periodic inspection and checking of exhaust systems are necessary if control is to be maintained at the effective level of the original installation. Continued effectiveness depends on maintained design air volume flowing through the exhaust hoods. A checking procedure, therefore, must include some data to indicate at least relative air flow through the hoods. The static pressure or hood suction measurement will prove useful for such checking if data are available on air volumes and pressures at the time the system was installed. Testing and recording of such data for each new installation are of the utmost importance.

While hood suction readings have rightfully been discarded as a means of measuring air flow, they do offer a quick and accurate method of measuring relative air flow. If the hood suction is known while an exhaust system is functioning properly, its continued effectiveness can be assured so long as the hood suction is not reduced from its original value.

Unless the hood design is altered or there are accumulations in the hood or branch pipe between hood and point of hood suction reading, the air volume

| 100               |                          |                 |            |                 |       |             |          |             |                |              |          |             |        |

Notes: 1. Ratings are based upon collated field service reports. Indefinite ratings are given where reports are inconsistent due to varying operating conditions (such as dilution, exposure to weather, etc.). Blank spaces denote insufficient information, not poor service. 2. Mild soaps, detergents, water soluble oils, 140–180 F. 3. Cresote oil, kerosene, ethylene dichloride. 4. To 20 percent; E: 50–70 percent, 150 F; S: 5. To 50 percent; plating; E: 20 percent anodizing, agitated 80 F; S: 6. To 50 percent plating; S: over 50 percent pickling, 20 percent anodizing; E: 7. 5–22 percent, 135–215 F pickling; S: plating, pickling, anodizing; E: 8. Except acid. 9. Acid.

CLASSIFICATION

APPROXIMATE SERVICE LIFE

Note: Ratings are based upon collated field service reports. Forward curved fans are not recommended for open-tank ventilation service. Cleanout doors and bottom drains are recommended on all fans on open-tank operations. The deposits which build up on fan wheels and casings should be removed by regular cleaning. Repaint where any coating has been broken and removed.

Combinations: Variable performance

exhausted from a hood cannot change without a change in hood suction reading.

The Pitot tube can be used for routine check purposes instead of the static pressure method.

Difficulty from plugging may be encountered where heavy dust loads or moist air is encountered. In any case, the hood suction method of checking can more readily be delegated to an assistant having no technical training, whereas the Pitot tube method requires care in reading velocity pressures in an exact position with the tube paralleling the flow of air. U-gages have been standard plant equipment long enough to eliminate any feeling of uncertainty in their use.

Since pressure readings vary as the square of the velocity or volume of flow, a slight change in flow is magnified by a comparison of gage readings. Normally, a reduction of volume or velocity of 10 to 15 percent will not be sufficient to reduce the effectiveness of the exhaust system. This range is equivalent to a reduction in static pressure readings of 19 to 30 percent.

A marked reduction in hood suction can often be traced to one or more of the following items:

1. Reduced performance by the exhaust fan caused by reduced speed due to belt slippage, wear on rotor or casing, or an accumulation of material in the rotor or casing, obstructing the air flow.
2. Incorrect direction of exhaust rotation.
3. Reduced performance caused by defects in the exhaust piping, such as accumulations of material in branch or main ducts due to insufficient conveying velocities, condensation of oil or water vapors on duct walls, adhesive characteristics of material exhausted.
4. Leakage losses caused by loose clean-out doors, broken joints, holes worn in duct (most frequently in elbows), or poor connection to the exhaust inlet.
5. Losses in suction due to additional exhaust points added to the system or a change of setting of blast gates in branch lines.
6. Increased pressure loss through the dust collector due to lack of maintenance, improper operation, wear, etc.

### MATERIALS REQUIRED FOR CORROSION RESISTANCE

In many cases, exhaust systems including hoods, ducts, air flow producing equipment, and air cleaning equipment will require protective coatings if carbon steel is used, or other materials of construction will be required. Need for such materials will be determined by (a) the corrosion rates on interior or exterior duct surfaces, (b) protection against product contamination, and (c) explosion hazards.

Of the above groups, construction for corrosion protection is the most difficult due to the complex factors that influence rate of corrosion. It is seldom possible to predict the concentration, composition, and dry- and dew-point temperatures that will exist in actual operations. A guide for selecting corrosive resistant materials based on a survey of actual experiences has been reproduced in Tables 7 and 8.<sup>40</sup>

## CHAPTER 47

## INDUSTRIAL DRYING SYSTEMS

Drying Terminology, Mechanism of Drying, Internal and External Conditions, Periods of Drying, Approximate Equations for Estimating Drying Time, Equilibrium Moisture Content, Applications of Hygrometry to Drying, Dryer Calculations, Drying Methods and Equipment; Radiant, Conduction and Convection Drying; Solution of Drying Problem

THE term *drying*, in a broad sense, encompasses the removal of water, and occasionally other liquids, from gases, liquids, or solids. However, the common usage of the word confines the meaning principally to the removal of water or solvent from solids by thermal means. *Dehumidification* is the term that is commonly assigned to the drying of gases. This is usually accomplished by condensation or adsorption by various drying agents, and is treated in Chapter 38. *Distillation*, and more particularly *fractional distillation*, is associated with the drying of liquids.

It is usually more economical to employ, whenever possible, mechanical means of separating as much water as is practicable from the solid materials before undertaking drying or dehydration steps. These mechanical methods such as filtration, screening, pressing, centrifuging, or settling usually require much less power, and frequently less capital outlay, thereby making the operation cheaper in terms of cost per pound of water removed.

DRYING TERMINOLOGY<sup>1</sup>

The generally accepted definitions of terms used in drying technology follow:

*Bound moisture* refers to liquid (held by a solid) which exerts a vapor pressure less than that of the pure liquid at the same temperature. Liquid may become *bound* by retention in small capillaries, by solution in cell or fiber walls, by homogeneous solution throughout the solid, and by chemical or physical adsorption on solid surfaces. Bound moisture can be removed from a solid only under specific conditions of humidity in the external surroundings.

*Capillary flow* refers to the flow of liquid through the interstices and over the surface of a solid. It is caused by liquid-solid molecular attraction.

*Commercial-dry basis* expresses the moisture content of a product as pounds of water per pound of solid as it leaves the dryer, i.e., per pound of commercially dry solid.

*The constant-rate period* is that drying period during which the rate of water removal per unit of drying surface is constant.

*The critical moisture content* is that obtaining when the constant-rate period ends and the falling-rate period begins.

*Dry basis* indicates the moisture content of a wet solid as pounds of water per pound of bone-dry solid. The advantage of using this basis is that the absolute amount of moisture loss is obtained simply by subtracting the moisture contents before and after drying. (See definition of *Wet Basis*.)

*Dryer efficiency* is that fraction of the total heat, supplied by fuel, used to evaporate water. *Overall efficiency* is sometimes used to distinguish overall system efficiency from the efficiency of the drying space or evaporative efficiency.

*Equilibrium moisture content* is that to which a given material can be dried under specific conditions of air temperature and humidity.

*Evaporative efficiency* compares the amount of evaporation actually obtained in a dryer with that which would obtain by saturation of the air.

*The falling-rate period* is that drying period during which the instantaneous drying rate continually decreases.

**Fiber saturation point** is the moisture content of cellular materials (wood, etc.) at which the cell walls are completely saturated while the cavities are liquid-free. It may be defined as the equilibrium moisture content as the humidity of the surrounding atmosphere approaches saturation.

**Free moisture content** is that liquid content which is removable at a given temperature and humidity. Free moisture may include both bound and unbound moisture.

**The funicular state** is that condition in drying a porous body when capillary suction causes air to be sucked into the pores.

**Humidity** denotes the amount of water vapor actually present in a gas, and is generally expressed as weight of vapor per unit weight of any gas.

A **hygroscopic material** is one that may contain bound moisture.

**Initial moisture distribution** refers to the moisture distribution throughout a solid when drying begins.

**Internal diffusion.** Diffusion is a single-phase phenomenon; internal diffusion must therefore occur as solid through solid, liquid through liquid, or gas through gas. Internal diffusion occurs when the moving phase obeys the fundamental laws of diffusion.

**The moisture content** of a solid is usually expressed as moisture quantity per unit weight of volume of the dry or wet solid. A weight (dry or wet) basis is preferred.

**Moisture gradient** refers to the internal distribution of water in a solid at a given moment in the drying process, the nature of which depends on the characteristics of the solid involved.

A **non-hygroscopic material** is one that can contain no bound moisture.

**Pendular state** is that state of a liquid in a porous solid when a continuous film of liquid no longer exists around and between discrete particles and, therefore, flow by capillarity cannot occur. This state succeeds the funicular state.

**Unaccomplished moisture change** refers to the ratio of the free moisture present at any time to that initially present.

**Unbound moisture** in a hygroscopic material is that moisture in excess of the equilibrium moisture content corresponding to saturation humidity. All water in a non-hygroscopic material is unbound water.

**Wet basis** expresses the moisture in a material as a percentage of the weight of the wet solid. This basis is less satisfactory than the dry-weight basis on which the percentage change of moisture is constant for all moisture contents. Fig. 1 shows the relationship between the dry- and wet-weight bases, and indicates that when the wet-weight basis is used to express moisture content, a 2 or 3 percent change at high moisture content (above 70 percent) actually represents a 15 to 20 percent change in evaporative load. An evaporative increase of this amount might well increase the load above the capacity of a dryer.

### MECHANISM OF DRYING<sup>1</sup>

When a solid dries, two fundamental processes are involved: (1) the transfer of heat to evaporate the liquid, and (2) the transfer of mass as vapor and internal liquid. These two processes occur simultaneously, and the factors governing the rate of each process determine the rate of drying.

In any commercial drying problem, a principal objective is to supply the required heat in the most efficient manner. Consequently, heat transfer may occur by convection, conduction, or radiation, or by any combination of these mechanisms. The various types of industrial dryers may be shown to differ fundamentally with respect to the method used for transferring heat to the solid. In general, heat must flow first to the outer surface of the solid and then into the interior. An important exception is drying with high frequency electrical currents where heat is generated within the solid, producing a higher temperature at the interior than at the surface, and consequently, causing heat to flow from inside the solid to the outer surfaces.

Mass transfer in drying occurs as liquid or vapor flow, or both, within

the solid, and as vapor flow from the external wet surfaces. The nature of liquid concentration gradients in solids during drying depends on the mechanism of internal liquid flow, and this mechanism, in turn, depends to a large extent upon the physical and chemical characteristics of the solid being dried.

### Internal vs. External Conditions

A study of how a solid dries may be based on the *internal* mechanism of liquid flow, or on the effect of the *external conditions* of temperature, humidity, air flow, state of subdivision, etc., on the drying rate of the solid. The former procedure involves a fundamental study of the liquid flow conditions within a solid during drying. The latter procedure, although less fundamental, is more generally used because the effects are

FIG. 1. RELATION BETWEEN WET-WEIGHT AND DRY-WEIGHT BASES

easier to establish and the results have greater immediate application in dryer design and operation.

**Internal Mechanism of Liquid Flow.** Internal liquid flow may occur by several mechanisms, depending on the structure of the solid. Several mechanisms of flow are as follows:

1. Diffusion in continuous, homogeneous solids.
2. Capillary flow in granular and porous solids.
3. Flow caused by shrinkage and pressure gradients.
4. Flow caused by a vaporization-condensation sequence.
5. Flow caused by gravity.
6. Flow caused by an electrical potential, electro-osmosis.
7. Flow caused by temperature gradients, thermal diffusion.

Although more than one of these mechanisms of flow may be effective at one time, only one predominates as a rule at a given time in a solid during drying. However, a different mechanism may predominate at a different time in the cycle. The mechanism of moisture flow is usually established experimentally from a study of moisture gradients.

**External Variables.** The principal external variables involved in any drying problem are: temperature, humidity, air flow, state of subdivision of the solid, agitation of the solid, method of supporting the solid, and the contact between hot surfaces and wet solid. All these variables do not necessarily occur simultaneously in one problem.

FIG. 2. MOISTURE CONTENT  $W$  vs. DRYING TIME  $\theta$ 

### Periods of Drying<sup>1</sup>

A typical drying time curve for a wet solid is shown in Fig. 2. This curve is a plot of the moisture content at any time in a solid undergoing drying. It is the usual method of presenting experimental drying data. Although Fig. 2 shows that the moisture content is subject to a continuous variation with time, a more precise illustration of the nature of this variation can be obtained by differentiating the curve and plotting the drying rate (pounds of water per hour per pound of dry material) against the moisture content (pounds of water per pound of dry material) as shown in Fig. 3, or plotting the rate of drying against time as shown in Fig. 4. These *rate curves* show that the drying process is not a smooth, continuous one in which a single mechanism controls throughout. The rate curve in Fig. 4 has the advantage of showing how long each drying period predominates.

Section AB on each curve represents a *constant-rate period*. In Fig. 2, it is shown by a straight line of constant slope  $dW/d\theta$ , which becomes a horizontal line on the rate curves in Figs. 3 and 4.

FIG. 3. RATE OF DRYING  $\frac{dW}{d\theta}$  vs. MOISTURE CONTENT  $W$ 

The curved portion of Fig. 2 is termed the falling-rate period, and, as shown in Figs. 3 and 4, it is typified by a continuously changing rate. Point A, where the constant rate ends and the drying rate begins to decrease, is termed the *critical moisture content*.

The portion of the curves designated by CB represents a warming-up period, and it may, or may not, be a significant item depending on the total time involved.

**Constant-Rate Period.** Drying during the constant-rate period is equivalent to evaporation from a free-water surface on the surface of the solid. The rate of drying in this period is determined by the rate of diffusion of water vapor through an air film at the wet surface of the solid. A constant rate of evaporation on the surface of the solid maintains the surface at a constant temperature, which, in the absence of other heat effects, is very nearly the wet-bulb temperature of the air. If heat flows to the surface of evaporation by radiation and conduction, or both, in addition

FIG. 4. RATE OF DRYING,  $\frac{dW}{d\theta}$  vs. TIME  $\theta$ 

to convection, the surface temperature will be constant at some value between the air temperature and the wet-bulb temperature. This higher temperature in turn produces a higher constant rate of evaporation.

In those dryers in which heat is transferred to a wet solid by conduction through hot surfaces, and heat transfer by convection is not a factor, the wet surfaces approach the boiling point temperature rather than a wet-bulb temperature.

When all the heat for evaporation in the constant-rate period is supplied by a hot gas, a dynamic equilibrium is established between the rate of heat transfer to the material and the rate of vapor removal from the surface. This equilibrium between heat and mass transfer rates can be expressed as follows:

$$\frac{dw}{d\theta} = \frac{h_t A \Delta t}{\lambda} = k_g A \Delta p \quad (1)$$

where

$\frac{dw}{d\theta}$  = drying rate, pounds of water per hour.

- $h_t$  = total heat transfer coefficient, Btu per (hour) (square foot) (Fahrenheit degree).  
 $A$  = area of heat transfer and evaporation, square feet.  
 $\lambda$  = latent heat of evaporation at  $t_s$ , Btu per pound.  
 $k_s$  = mass transfer coefficient, pounds per (hour) (square foot) (atmosphere).  
 $\Delta t = (t_s - t_a) =$  temperature difference between air and surface of evaporation, Fahrenheit degrees.  
 $t_a$  = air temperature, Fahrenheit.  
 $t_s$  = temperature of surface of evaporation, Fahrenheit.  
 $\Delta p = (p_s - p_a) =$  vapor pressure difference, atmospheres.  
 $p_s$  = vapor pressure of water at  $t_s$ , atmospheres.  
 $p_a$  = partial pressure of water vapor in air, atmospheres.

When  $h_t = h_c$ , the coefficient of heat transfer by convection only, then  $t_s$  under equilibrium conditions becomes  $t_w$ , the wet-bulb temperature of the air, and  $p_a$  is the vapor pressure at this temperature. If heat is also supplied by radiation, then  $h_t$  is the sum ( $h_c + h_r$ ) where  $h_r$  is the radiation coefficient and  $h_c$  is the convection coefficient, and  $t_s$  becomes higher than the wet-bulb temperature. A similar result occurs when heat reaches the surface of evaporation by convection and conduction. When the surface is at the wet-bulb temperature, the value of  $\Delta p$  in millimeters of mercury, is almost exactly one-half the wet-bulb depression ( $t_a - t_w$ ), in Centigrade degrees.

**Effect of Air Velocity.** The principal effect of air velocity is on  $h_c$  and  $k_s$ , since the rate of transfer of heat and mass in the constant-rate period depends mainly on the rate of diffusion of heat and vapor through the air film at the surface of the solid, and air velocity is the chief factor affecting the thickness of this film. The influence of air velocity may be expressed by the following relationship:<sup>3</sup>

$$h_c = 0.0128 G^{0.8} \quad (2)$$

where

- $h_c$  = convection heat transfer coefficient, Btu per (hour) (square foot) (Fahrenheit degree).  
 $G$  = mass velocity of dry air, pounds per (hour) (square foot).

For estimating the constant rate in drying from plane surfaces with air flow parallel to the surface of evaporation and with no radiation or conduction effects, the following heat transfer expression can be used:

$$\frac{dw}{d\theta} = \frac{0.0128 G^{0.8} A}{\lambda} (t_a - t_w) \quad (3)$$

where

- $t_w$  = wet-bulb temperature of the drying air, Fahrenheit degrees.

Heat transfer coefficients, rather than mass transfer coefficients, should be used to estimate drying rates, because heat transfer coefficients are generally more reliable, and, unless the temperature of the drying surface is measured, it must be calculated from heat transfer considerations before mass transfer coefficients can be applied for drying-rate predictions. The assumption that the surface of drying is at the wet-bulb temperature of the air, introduces a more serious error in the computation of mass transfer than of heat transfer.

**Determination of True Surface Temperature.** Frequently, radiation and conduction are of sufficient magnitude to cause the temperature of evaporation to exceed the wet-bulb temperature of the air. When this occurs, it is necessary to estimate the true surface temperature in order to calculate

the constant rate. This may be done by means of a heat balance equating the total heat transferred by convection, conduction, and radiation to the latent heat of evaporation.

**Constant-Rate Period in Through-Circulation Drying.** The equation for estimating the rate of evaporation when air flows across a free-water surface must be modified for the case of air-flow through a permeable bed of solids. The constant rate in through-circulation drying depends on the air rate, air temperature, air humidity, size of the particles making up the permeable bed, and physical characteristics of these particles.<sup>4</sup>

The following general expression for the constant rate in through-circulation drying for the system water and air, was developed<sup>5</sup> from experiments on the rate of evaporation of water from the surface of wet spheres and cylindrical particles with through-circulation of air:

$$\frac{dW}{d\theta} = \frac{0.42 a G^{0.59} (\Delta H)_m}{D_p^{0.41}} = \frac{0.37 c_s a G^{0.59} \Delta t_m}{\lambda a D_p^{0.41}} \quad (4)$$

where

- $\frac{dW}{d\theta}$  = constant rate, pounds of water per (hour) (pound of dry stock).  
 $a$  = drying area, square feet per cubic foot of bed volume.  
 $G$  = superficial mass velocity, pounds of dry air per (hour) (square foot).  
 $\Delta H_m$  = logarithmic mean of inlet and outlet humidity driving force across the air film adjacent to the particle through which the water vapor diffuses, pounds per pound (the surface humidity is taken as the humidity corresponding to the wet-bulb temperature of the drying air).  
 $\rho_s$  = bulk density of dry granular bed, pounds per cubic foot.  
 $D_p$  = average diameter of particle, feet.  
 $\Delta t_m$  = logarithmic mean difference between temperature entering and leaving the bed and the wet-bulb temperature, Fahrenheit degree.  
 $c_s$  = humid heat, Btu per (pound of dry air) (Fahrenheit degree).  
 $\lambda$  = latent heat of evaporation, Btu per pound.

Equation 4 applies when the Reynolds number  $D_p G / \mu$  is greater than 300, where  $\mu$  is the viscosity of the air stream. For values less than 300, a modification of Equation 4 has been presented.<sup>6</sup>

**Evaporation from Liquid Drops.** For the important problem of spray drying, evaporation rates of liquid drops must be estimated. Below a value of Reynolds number ( $D_p G / \mu$ ) of 10 for spherical particles, the heat transfer coefficient across the gas film surrounding the drop is given by

$$h = \frac{2k_f}{D_p} \quad (5)$$

where

- $h$  = film heat transfer coefficient, Btu per (hour) (square foot) (Fahrenheit degree).  
 $k_f$  = thermal conductivity of gas film, Btu per (hour) (square foot) (Fahrenheit degree per foot).

Equation 5 is applicable when the Reynolds number for liquid drops is less than 10. Drop diameters are almost always less than 500 microns, and usually in the range of 20 to 150 microns.

The rate of evaporation of drops may be expressed in terms of heat transfer or mass transfer. In terms of heat transfer, the evaporation rate is given by the equation:

$$\frac{dw}{d\theta} = \frac{2\pi k_f D_p}{\lambda} (t_a - t_s) \quad (6)$$

where

$\frac{dw}{d\theta}$  = evaporation rate, pounds per hour.

A similar expression based on mass transfer is

$$\frac{dw}{d\theta} = \frac{2\pi M d_v D_p}{RT} (p_a - p_s) \quad (7)$$

where

$M$  = molecular weight of the diffusing vapor.

$d_v$  = diffusivity of the vapor, square feet per hour.

$T$  = absolute temperature of the gas, Fahrenheit degrees.

$R$  = gas constant, (cubic feet) (atmosphere) per (Fahrenheit degree).

$p_a$  = vapor pressure at the particle surface corresponding to the liquid temperature, atmospheres.

$p_s$  = vapor pressure of liquid in the drying medium, atmospheres.

Both Equations 6 and 7 are based on the assumption that Equation 5 applies. If Equation 6 is integrated for a constant drop diameter (*i.e.*, if it is assumed that the solid being dried in the liquid drop creates a structure which becomes rigid at a fixed  $D_p$ ) and evaporation proceeds as from a pure liquid drop, an expression for the time of evaporation is obtained as follows:

$$\theta = \frac{W \lambda \rho_s D_p^2}{12 k_f (t_a - t_s)} \quad (8)$$

where

$\theta$  = time, hours.

$W$  = water content of the drop as it enters the drying chamber, pounds per pound.

$\rho_s$  = density of dry particle, pounds per cubic foot.

The temperature difference between drop and gas ( $t_a - t_s$ ) is essentially constant for a single drop evaporating in a large mass of gas. However, in spray dryers this is not true, and an overall average temperature difference must be used in Equation 8 in this case.

When the drop diameter varies as evaporation proceeds, the expression for the time of evaporation becomes

$$\theta = \frac{\rho_L \lambda [(D_{p1})^3 - (D_{p2})^3]}{8 k_f (t_a - t_s)} \quad (9)$$

where

$\rho_L$  = density of the evaporating liquid, pounds per cubic foot.

$D_{p1}$  = drop diameter at the start of evaporation, feet.

$D_{p2}$  = drop diameter of dry particle, feet.

Equation 9 assumes that the drop density is essentially that of the liquid.

*Drying at Air Temperatures above the Boiling Point of the Liquid.* When the temperature of the drying air is maintained above the boiling point of the liquid being evaporated, or when superheated vapors are used for drying, the usual equations for mass transfer, expressing rate of evaporation

as a function of the vapor pressure difference, lose significance, since large errors are introduced in the expression for vapor pressure driving force due to its apparently small value. Such cases can be treated conveniently on a basis of heat transfer, since a temperature difference must always exist in order that drying may proceed. At drying temperature above 260 F, recirculation has no retarding effect on the drying process.

*Constant-Rate Period When Heat Transfer Depends on Conduction and Radiation.* In indirect drying, where heat transfer and drying do not depend on the flow of heated gases, the drying rate depends either on heat conduction through retaining walls to wet material in contact with such surfaces, or on radiation, or both. This applies to drum dryers, agitated pan dryers, indirect continuous sheeting dryers, steam tube rotary dryers, vacuum rotary and vacuum tray dryers, and infra-red dryers.

A principal difference between indirect drying and direct drying is that, with the former, the material is usually at a higher temperature than the surrounding air, so that heat is actually transferred to the air instead of from the air.

Generally, the individual heat transfer coefficients for indirect dryers are difficult to determine or estimate, and therefore, an overall coefficient, as defined by Equation 10, is generally used:

$$q = UA (t_h - t_s) \quad (10)$$

where

$q$  = rate of heat transfer, Btu per hour.

$U$  = overall heat transfer coefficient based on the temperature difference between the heating medium and the product, Btu per (hour) (square foot) (Fahrenheit degree).

$t_h$  = temperature of the heating medium, Fahrenheit.

$t_s$  = temperature of the solid, Fahrenheit.

The overall coefficient is a function of dryer type. Thus, in agitated pan dryers,  $U$  depends on the degree of agitation, temperature of the surface, physical properties of the wet material, etc., and will sometimes vary throughout a drying cycle as the physical properties of the solid vary with a changing moisture content.

As long as  $U$  and the temperature difference in Equation 10 remain constant, a constant drying rate will be maintained. However, as drying proceeds the material temperature will begin to increase after some critical moisture content is reached, and, as in the case of direct dryers, a falling-rate period is encountered.  $U$  is frequently defined, for the entire drying period, on the basis of an overall mean temperature difference. Therefore,

$$q = UA (\Delta t)_m \quad (11)$$

*The Falling-Rate Period.* In the discussion of the periods of drying, it was shown that the drying process is discontinuous, consisting of a period of a constant rate of evaporation and a period in which the rate continuously decreases. (See Figs. 3 and 4). This latter period is usually designated as the falling-rate period. It begins when the constant-rate period ends at the critical moisture content. If the critical moisture content is less than the required final moisture content, the constant-rate period will constitute the whole of the drying process. On the other hand, if the initial moisture content is less than the critical moisture content, as

in the case of some slow-drying materials, such as soap and wood, then no constant rate will appear, and the whole of the drying process will be in the falling-rate period. This period, in the most general case, can be divided into two zones which may be termed (1) the zone of unsaturated surface drying, and (2) the zone where internal liquid flow controls.

The zone of unsaturated surface drying follows immediately after the critical point and results from a progressively decreasing wetted surface. With the surface no longer completely wetted, dry portions of the solid protrude into the air film, so that the rate of evaporation per unit of total surface is reduced. The effective wetted surface in this zone is frequently a linear function of the water content, so that the curve representing rate of drying *vs.* water content of the solid is straight in this region, as shown by line AD in Fig. 3. The mechanism of drying is essentially the same as during the constant-rate period.

The zone where internal liquid flow is in control, is usually the second zone of the falling-rate period. In this phase the rate of internal liquid movement controls the drying rate, and in drying to low moisture contents, this period may be the principal factor determining the drying time.

Studies of internal moisture flow have indicated the possibility of several controlling mechanisms, the more significant ones having been postulated previously as diffusion, capillarity and pressure gradients due to shrinkage. Of these mechanisms, internal moisture movement by diffusion has been treated extensively, while capillary flow and flow caused by shrinkage and pressure gradients, have received only preliminary consideration.

When diffusion does control in the falling-rate period, it obeys the same fundamental laws of diffusion as those applying to the diffusion of heat. On this basis, the integrated diffusion equation for the falling-rate period (for the case where the surface is dry or at its equilibrium moisture content and the solid has a uniform initial moisture distribution) expresses the average moisture content as a function of time as follows:

$$\frac{W - W_o}{W_o - W_o} = \frac{8}{\pi^2} \left[ e^{-\pi^2 d (\pi/2L)^2} + \frac{1}{9} e^{-9\pi^2 d (\pi/2L)^2} + \frac{1}{25} e^{-25\pi^2 d (\pi/2L)^2} + \dots \right] \quad (12)$$

where

$W, W_o, W_o$  = the moisture contents, on a dry basis, at any time  $\theta$ ; at  $\theta = 0$ , the start of the diffusional flow period; and in equilibrium with the external conditions, respectively, pounds of water per pound of dry solid.

$d$  = the liquid diffusivity, square feet per hour.

$L$  = one-half the thickness of the solid layer through which the liquid is diffusing, feet.

In Equation 12 it is assumed that evaporation is occurring from two opposite faces of the solid. When evaporation occurs from only one surface, substitute the total thickness of the solid layer for  $L$  in Equation 12.

Equation 12 is based on the assumption that  $d$  is constant. However, this is rarely true, and  $d$  has been shown to vary with moisture content, temperature and humidity.<sup>7</sup>

When the time becomes large, a limiting form of Equation 12 is obtained as follows:

$$\frac{W - W_o}{W_o - W_o} = \frac{8}{\pi^2} e^{-\pi^2 d (\pi/2L)^2} \quad (13)$$

From Equation 13 an expression for the rate of drying may be derived to give

$$\frac{dW}{d\theta} = -\frac{\pi^2 d}{4L^2} (W - W_o) \quad (14)$$

where  $dW/d\theta$  = drying rate, pounds per (hour) (pound dry material).

Equation 14 states that the rate of drying, when internal diffusion controls for long times, is directly proportional to the free moisture content ( $W - W_o$ ), the liquid diffusivity  $d$ , and that the time of drying varies as the square of the material thickness. However, Equation 14 holds only when  $(W - W_o)/(W_o - W_o) < 0.6$ . When this ratio exceeds 0.6, the curve of drying rate *vs.* moisture content is concave upward.

Equations 12, 13, and 14 hold only for a slab-shaped solid, the length of which is large compared with its thickness.

The falling rate frequently can be expressed with fair accuracy over the required range of moisture content by an equation similar to Equation 14:

$$\left( \frac{dW}{d\theta} \right)_t = -K(W - W_o) \quad (15)$$

where  $K$  is a function of the constant rate as follows:

$$K = \frac{(dW/d\theta)_c}{(W_o - W_o)} \quad (16)$$

where

$(dW/d\theta)_c$  = the constant drying rate, pounds per (hour) (pound dry material).  
 $W_o$  = the critical moisture content, pounds per pound dry material.

Substituting in Equation 16 the proper expression for  $(dW/d\theta)_c$  the value of  $K$  becomes

$$K = \frac{h_i(t_a - t_o)}{\rho_s L \lambda (W_o - W_o)} \quad (17)$$

and hence, the falling rate for this case is given by

$$\left( \frac{dW}{d\theta} \right)_t = -\frac{h_i(t_a - t_o)(W - W_o)}{\rho_s L \lambda (W_o - W_o)} \quad (18)$$

For materials obeying Equation 18, the drying time varies directly as the thickness. When the surface temperature in the constant-rate period is at the wet-bulb temperature,  $t_w$  can be substituted for  $t_o$  and 0.0128  $G^{0.8}$  can be substituted for  $h_i$  in Equations 17 and 18.

The drying time for each case of the falling-rate period may be obtained by integration of Equations 14 and 18, respectively, to give:

1. Diffusion law

$$\theta_t = \frac{4L^2}{\pi^2 d} \log_e \left( \frac{W_o - W_o}{W - W_o} \right) \quad (19)$$

2. Proportional-to-thickness law

$$\theta_t = \frac{\rho_s L \lambda (W_o - W_o)}{h_i(t_a - t_o)} \log_e \left( \frac{W_o - W_o}{W - W_o} \right) \quad (20)$$

Table 1 gives an approximate classification of materials which are most likely to obey Equations 19 and 20.

Equations 18 and 20 hold for cross-circulation drying. When through-circulation drying is involved, the appropriate constant-rate expression given by Equation 4 must be used to determine  $K$  in Equation 16. Thus, for through-circulation drying in the falling-rate period when Equation 15 holds, the rate is given by

$$\left(\frac{dW}{dt}\right)_t = -\frac{0.37c_s a G^{0.59}(\Delta t)_m}{\rho_s \lambda D_p^{0.41}(W_s - W_e)}(W - (W_e)) \quad (21)$$

where the symbols have been defined for Equations 4, 12, and 16.

**Critical Moisture Content.** In order to use the above equations for estimating the drying time in the falling-rate period, it is necessary to know values of the critical moisture content. Such values are usually difficult

TABLE 1. APPROXIMATE CLASSIFICATION OF MATERIALS MOST LIKELY TO OBEY EQUATIONS 19 AND 20

| MATERIALS OBEYING EQUATION 19                                                                                                        | MATERIALS OBEYING EQUATION 20                                                                                                                                       |
|--------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Single-phase solid systems such as soap, gelatin, glue.                                                                           | 1. Coarse granular solids, such as sand, paint pigments, minerals, etc.                                                                                             |
| 2. Wood and similar solids below the fiber saturation point.                                                                         | 2. Materials in which moisture flow occurs at concentrations above the equilibrium moisture content at atmospheric saturation, or above the fiber saturation point. |
| 3. Last stages of drying starches, textiles, paper, clay, hydrophilic solids, and other materials when bound water is being removed. |                                                                                                                                                                     |

to obtain without making actual drying tests which, in themselves, would give the required drying time and thereby obviate the necessity of the calculations.

It appears that the constant-rate period ends when the moisture content at the surface reaches some specific value. If the rate of drying is great, the moisture gradients within the solid will be steep and the average moisture content considerably greater than that at the surface. It is for this reason that the critical moisture content (average through the material) increases with increase in rate of drying, and with an increase in thickness of the layer being dried.

#### Approximate Equations for Estimating Drying Time

An estimate of the overall drying time for a given drying problem usually involves an estimate of the time required for the constant-rate period, plus an estimate of the time for the falling-rate period. An approximate equation for the overall drying time applicable to the cross-circulation drying of materials of the type listed in Table 1 as obeying Equation 20, may be written as follows:

$$\begin{aligned} \theta_t &= \theta_c + \theta_f = \frac{(W_s - W_e)\lambda L \rho_s}{h_i(t_s - t_a)} + \frac{\rho_s L \lambda (W_s - W_e)}{h_i(t_s - t_a)} \log_e \frac{W_s - W_e}{W - W_e} \\ &= B \left[ \frac{W_s - W_e}{W_s - W_e} + \log_e \frac{W_s - W_e}{W - W_e} \right] \end{aligned} \quad (22)$$

where

$$B = \frac{\rho_s L \lambda (W_s - W_e)}{h_i(t_s - t_a)} = \frac{1}{K}$$

$\theta_t$  = total drying time, hours.

$\theta_c$  = drying time for constant-rate period, hours.

$\theta_f$  = drying time for falling-rate period, hours.

$W_s$  = initial moisture content, pounds per pound of dry solid.

$W_c$  = critical moisture content, pounds per pound of dry solid.

$W_e$  = equilibrium moisture content, pounds per pound of dry solid.

$W$  = moisture content at time  $\theta_t$ , pounds per pound of material.

$h_i$  = total overall heat transfer coefficient Btu per (hour) (square foot) (Fahrenheit degree).

$t_s$  = air temperature, Fahrenheit.

$t_a$  = temperature of surface of material, Fahrenheit.

$L$  = depth of material in tray, feet.

$\lambda$  = latent heat of evaporation at  $t_s$ , Btu per pound.

$\rho_s$  = density of dry solid, pounds per cubic foot.

Equation 22 will apply to those materials satisfying Equation 20 when drying to very low moisture content is not involved.

For through-circulation drying, an expression similar to Equation 22 is obtained. Thus, the total drying time for through-circulation drying is given by

$$\theta_t = B' \left[ \frac{W_s - W_e}{W_s - W_e} + \log_e \frac{W_s - W_e}{W - W_e} \right] \quad (23)$$

$$\text{where } B' = \frac{2.7 \rho_s \lambda D_p^{0.41} (W_s - W_e)}{c_s a G^{0.59} (\Delta t)_m}$$

The drying times estimated from Equations 22 and 23 apply only to cross-circulation drying and through-circulation drying, respectively. Drying times for other methods, such as rotary drying or drum drying, must be estimated by other methods.

#### Equilibrium Moisture Content

In the drying of solids it is important to distinguish between hygroscopic and non-hygroscopic materials. A hygroscopic material is one which retains a definite percentage of moisture under definite conditions of air humidity. This bound moisture is in a state of equilibrium with the water vapor in the surrounding air, and a decrease in the water vapor content will decrease the amount of equilibrium bound water. Water so retained by a solid in equilibrium with the humidity of the surrounding air, is designated as the *equilibrium moisture content*. Such moisture may be held as adsorbed surface films or condensed in fine capillary structures at reduced vapor pressure.

The equilibrium moisture content varies with the temperature and humidity of the surrounding air. Consequently, any correlation of equilibrium moisture content should take these two factors into account. However, at low temperatures, e.g., 60 to 120 F, a plot of equilibrium moisture content vs. percent relative humidity, expressed as 100 ( $p/p_s$ ), is essentially independent of temperature. Such a plot usually results in a curve of double curvature with a point of inflection (see Fig. 5).

The equilibrium moisture content at a given relative humidity is not

independent of temperature for all temperature ranges. As the temperature increases at a given relative humidity, the equilibrium moisture content tends to decrease. A limiting condition exists when temperatures above the boiling point of the adsorbed liquid are encountered. In such cases, relative humidity loses its significance with regard to equilibrium moisture content, and complete dryness of most hygroscopic materials is possible, even when a large amount of vapor exists in the atmosphere. This makes possible drying by means of superheated vapors.

In the special case of the dehydration of hydrated inorganic salts, such as copper sulfate, sodium sulfate, and barium chloride, temperature and humidity are very important in obtaining the desired degree of dehydration. Thus, in the drying of wet salt crystals to obtain a product with the maximum number of molecules of hydrate water, it is necessary to dry under closely controlled conditions of air temperature and humidity. Generally, the temperature is low and the humidity is high.

The equilibrium moisture content of a hygroscopic material may be determined in a number of ways. The requirement for any method is a

FIG. 5. TYPICAL EQUILIBRIUM MOISTURE CONTENT CURVES<sup>1</sup>

source of constant humidity and constant temperature air into which the sample may be placed. The determination may be made under either static or dynamic conditions, the latter being preferred if the data are to be used for drying calculations.

Probably the simplest static procedure is to place a series of samples in ordinary laboratory desiccators over sulfuric acid solutions of known concentration, which thereby produce atmospheres of known relative humidity. The sample in each desiccator is weighed periodically until a constant weight is obtained. The moisture content at this final weight represents the equilibrium moisture content for the particular relative humidity involved. The value of equilibrium moisture content so obtained will depend on whether it is reached by losing moisture, as in drying, or by gaining it, *i.e.*, whether the sample is at a moisture content higher or lower than the equilibrium value. The equilibrium moisture content reached by losing moisture, *i.e.*, by drying, is generally higher than that reached when moisture is adsorbed, as shown in Fig. 5.

The equilibrium moisture content of a solid has particular significance in drying because it represents a limiting final moisture content for specific

conditions of air humidity and temperature. Drying costs can be unnecessarily high if a material is dried to a moisture content less than that which it normally possesses in equilibrium with atmospheric air. For example, if a dryer dries a material to 1 percent final moisture, and on standing under normal atmospheric humidities it regains moisture to 5 percent, the material is considered to be overdried, so that probably the dryer would be capable of a considerably higher capacity and efficiency with a 5 percent final moisture content.

### Applications of Hygrometry to Drying

Drying of a solid by hot air or hot gases may be divided into two processes: (1) transfer of heat to evaporate the water, and (2) removal of the

FIG. 6. PSYCHROMETRIC CHART

vapor by the air or gas stream. Likewise, two processes are involved in the *design* and *operation* of direct dryers: (1) the estimation of the drying rate or drying time, and the effect of the external variables on the drying rate; and (2) the calculation of the heat and air quantities required. The first estimates concerning drying time have been considered in the first part of this chapter. The second calculations are based on the use of the psychrometric chart, Fig. 6.

In drying, the humidity chart finds its greatest utility in analyzing the operation of existing dryers, in making design calculations, and in checking calculations of air quantities. It is equally useful in interpreting the humidity-temperature relations within the dryer. The adiabatic cooling lines on the humidity chart indicate the relation between the temperature and the humidity which are present in air passing through an adiabatic dryer, *i.e.*, one in which all of the sensible heat given up by the air in cooling is used to evaporate water from the wet stock. Referring to the section of the humidity chart shown in Fig. 7, where AB is one adiabatic saturation line, it follows that air entering an adiabatic dryer at temperature  $t_1$

and a humidity  $H_1$  will cool, following this cooling line toward point A. Air leaving with a humidity  $H_2$  will consequently have cooled to  $t_2$ , the wet-bulb temperature of the air throughout the dryer being  $t_w$ . When heat is lost to the surroundings, the operation is somewhat lower than  $t_2$ , so that the actual humidity-temperature relation is represented by the line Bb, having less slope than the adiabatic saturation line. The ratio  $(t_1 - t_2)/(t_1 - t_w)$  then gives a measure of the evaporative efficiency of the dryer. For the case of dryers containing steam coils maintained at a constant temperature, the humidity-temperature relation is obviously represented by the vertical line Bc, assuming the initial and final humidities to be  $H_1$  and  $H_2$  as before. The heat supplied within the dryer itself is usually less, but may be greater, than the total heat requirements of the dryer. If less, the cooling is indicated by some such line as Bd, and if greater, by a line such as Be having a positive slope.

FIG. 7. HUMIDITY-TEMPERATURE RELATIONS IN DRYERS<sup>1</sup>

### DRYER CALCULATIONS

As shown in the foregoing part of this chapter calculations for drying during the constant-rate period are different from those applying to the falling-rate period, and in contrast are subject to relatively simple mathematical analysis.

The constant rate of drying by convection is directly proportional to the temperature difference between air and wet solid, and also proportional to the 0.8 power of the air velocity as shown by Equation 3. Usually the wet surface is assumed to attain the wet-bulb temperature of the air passing over it, and evaporation takes place at a constant rate under equilibrium conditions. This is a conservative assumption, however, and when conduction and radiation effects occur, the constant rate may be increased by 30 to 60 percent over that for pure convection.

Fig. 8 permits a ready estimate of the constant drying rate for various air temperatures and humidities. The chart is based on the difference between the dry-bulb and wet-bulb temperatures of the entering stream of air, and on an air velocity of 300 fpm. It may be assumed satisfactory for tray drying of any material in the constant-rate drying period. It does not apply to rotary or through-circulation drying.

A curve for correcting the air velocity in any given problem is incorporated in Fig. 8. This curve is based on the variation of drying rate with the 0.8 power of the velocity, as given by Equation 3.

The use of Fig. 8 in practical drying problems is as follows: Since the drying conditions of temperature and relative humidity are fixed, the corresponding absolute drying rate is read from Fig. 8. This value is then multiplied by the correction factor corresponding to the air velocity employed. The rate so obtained, however, does not include any effects of radiation or of conduction through unwetted surfaces. These effects tend to increase the rate of evaporation so that the chart is conservative.<sup>3</sup>

It has been demonstrated empirically for certain materials that the rate of drying during the falling-rate period is approximately proportional to the free water content of the material. Actual calculations of drying time

FIG. 8. RATE OF EVAPORATION CHART<sup>3</sup>

during the falling-rate period for this case require only a knowledge of the critical moisture content and the constant rate. For other cases of the falling-rate period, calculations are not feasible. Consequently, it is best to determine drying times for design purposes by means of pilot tests. However, when tests are not feasible, drying times may often be estimated approximately from Equations 22 and 23.

The following nomenclature will be used in the discussion of design calculations:

- $H$  = humidity ratio of air, pounds of water vapor per pound of dry air.
- $N_a$  = pounds of dry air supplied to the dryer per unit of time.
- $S$  = pounds of stock dried per unit of time in a continuous dryer.
- $S'$  = pounds of stock charged per batch to a discontinuous dryer.
- $\theta$  = time, hours.
- $Q$  = total heat supplied to the dryer, Btu.

Actual dryer operation is somewhat more complicated because even if radiation and conduction losses are neglected, the wet-bulb temperature of the air remains constant only as long as surface evaporation of water is taking place. When sub-surface evaporation is occurring, some heat from the air is used to heat the material and hence, there is a drop in wet-bulb temperature. Fig. 10 illustrates the drying process in a tunnel dryer in which the air is flowing parallel to the product.<sup>2</sup>

In design calculations using Equation 26, the following steps outline the procedure:

1. The unit drying rate, pounds of water per hour, is determined from the experimental drying time curve and the amount of product to be dried per hour. The drying time may also be approximated from previous experience.
2. The experimental data or experience also determine the drying condition, *i.e.*, point L Fig. 9. This fixes  $H_2$ . Where experimental data are lacking L may be approximated from Regain Tables (see Chapter 45 Industrial Air Conditioning) since the relationship between the vapor pressure in the product and in the air at equilibrium for the desired final moisture content must prevail in the dryer. The air temperature must be not greater than the maximum permissible product temperature.

FIG. 10. TEMPERATURE AND MOISTURE CONDITIONS IN A TUNNEL DRYER  
Parallel Flow Air and Product

3. The rate of air circulation  $N_a$  must be determined and also the supply air condition S. In the design of some dryers, such as rotary or tunnel types, it is customary to determine S first and then to calculate the air rate  $N_a$ . In other types of dryers, such as tray dryers or through circulation dryers, where a fixed air velocity is maintained,  $N_a$  is calculated first and then point S is found. Because of the many variables involved, it is generally not possible to select S except on the basis of past experience or on the basis of experimental drying tests.
4. The prevailing outside air conditions establish point A and hence, the line AL. The percent of recirculated air can then be calculated.
5. The physical arrangement of the dryer must then be selected to handle the desired quantity of product, and at the same time circulate the calculated air quantity at the desired velocity.
6. Equation 26 can then be used to calculate the heat requirements.

### DRYING METHODS AND EQUIPMENT

Drying systems are sometimes classified according to the method of heat transfer that is employed, since the entire problem of drying resolves itself into individual problems of heat transfer and the thermodynamics of air and water vapor. The methods of heat transfer are radiation, conduction and convection. Many types of dryers have been built on these principles for different purposes.

Drying systems can also be classified, according to the method of product handling, as batch operation, semi-continuous and continuous.

#### Radiant Drying

Sun drying, the oldest form known to man, is still practiced where the material is amenable to such treatment, where the necessary time can be allowed, and where there is little danger of rain or atmospheric pollution.

In artificial systems, radiating surfaces, heated by steam, electricity or other means, afford a good method of heat distribution and control. Radiant heating sets up convection currents, and in low-temperature dryers only about one-third to one-half of the total heat for evaporation is actually supplied to the material by radiation. At high temperatures the radiation output increases rapidly, according to the *fourth-power law*. The total radiation may be computed by the equations and tables given in Chapter 5. In general, fins and irregular surfaces do not increase radiation, hence, the area to be used in calculations is the area of a smooth-surface envelope enclosing the radiating elements.

A certain amount of air circulation is required through a radiant dryer in order to carry off the vapor.

Radiant heat from infra-red lamps has been accepted by certain industries as practicable for their specific problems. An example of successful application is found in the drying of lacquers.

Lacquers and similar surface films can be very effectively dried by radiation. Special electric lamp units have been developed which give off a high percentage of infra-red and similar heat rays. For continuous manufacturing processes these units are mounted in tunnels through which conveyors pass. For local applications, as for example paint drying in automobile repair shops, they may be mounted on portable racks. Objects of relatively large surface area in proportion to their weight, and fabricated materials having a rather high heat absorption, may be satisfactorily heated by such a source.

For drying, baking, pre-heating and de-hydrating, where a low temperature infra-red heat source is desired, or where use of glass-enclosed radiant lamps is objectionable for safety reasons, electric heating units employing low temperature metal sheathed resistors, are available.

#### Conduction Drying

Drying rolls or drums, Fig. 11,<sup>8</sup> flat surfaces, open kettles and immersion heaters are examples of the direct-contact method. Intimate contact of the material with the heating surface is important, and in some cases agitation is desirable to increase the uniformity of heating or to prevent over-heating.

Greatest resistance to heat transfer occurs on the air side of the material being dried. The rate of heat transfer from the surface of the heated material to the air, and hence the rate of drying, may be increased by (a) forced convection or air circulation, and (b) vacuum operation to lower the boiling point of the liquid being evaporated.

A rather interesting method of conduction drying was put into practical use during the war for the drying of blood plasma, and has since been expanded to other fields such as the preservation of bacteria and other micro-organisms. This has come to be known as freeze drying or drying by sublimation. The material to be dried is first frozen and then placed in a high vacuum chamber connected to extremely low temperature condensers. The water is removed by vaporizing from the solid directly to the gas without ever becoming liquid.

#### Convection Drying (Direct Dryers)

A limited amount of convection drying takes place in almost any dryer such as those described in the preceding paragraphs. However, to be

FIG. 11. DRUM DRYER<sup>8</sup>

classified as a convection dryer the principal source of heat is the heated air or other gases circulated in the dryer. There are a number of mechanical means of accomplishing this circulation of air or gases, each of which has some particular virtue. Brief descriptions of some important types of convection dryers follow:

**Rotary Dryers.** These dryers are cylindrical drums which cascade the material being dried through the air stream. (See Fig. 12). The driers may be heated directly or indirectly, and the air circulation may be parallel or counter-flow. A variation is the rotating louver type dryer, which introduces the air beneath the flights thus securing very intimate contact.

**Cabinet and Compartment Dryers.** These are generally considered batch dryers wherein each charge is dried to completion before removal.<sup>8</sup> A wide range includes types from the heated loft with only natural convection, and usually poor and non-uniform drying, to the self-contained units with forced draft and properly designed baffles which give positive results. It is also possible to evacuate some of the systems for low temperature drying of delicate or hygroscopic materials. These dryers are usually loaded with material spread in trays to increase the exposed surface. The trays are loaded directly into the dryer or may be stacked on trucks which are wheeled in. (See Fig. 13)

**Tunnel Dryers.** Tunnel dryers are a modification of the compartment dryer, and as a rule are continuous or semi-continuous in operation. Heated air or combustion gas is usually circulated by means of fans, although a few natural draft units are still in use. The material is handled on trays or racks on trucks, and moves through the dryer either intermittently or continuously. The air flow may be parallel, counter-flow or a combination of the two, obtained by center exhaust. Further, the air flow may be across the surface of the trays or up or down through the bed, or in any

FIG. 12. CROSS SECTION AND LONGITUDINAL SECTION THROUGH CIRCULATION DRYER<sup>8</sup>FIG. 13. COMPARTMENT DRYER, SHOWING TRUCKS, WITH AIR CIRCULATION<sup>8</sup>

combination of directions. By reheating the air in this type of dryer or recirculating it, a high degree of saturation is achieved before exhausting the air. This reduces the waste of sensible heat.

A variation of this type dryer is the strictly continuous type having one or more mesh belts which travel through the dryer carrying the product, such as Fig. 14. Innumerable combinations of temperature, humidity and air direction and velocity are possible. The labor requirement is low on such a dryer, as it can be loaded and unloaded mechanically. There is the disadvantage of hot air leaks at the entrance and exit, although these can be minimized by means of baffles or inclined ends where the material enters and leaves from the bottom.

**Spray Dryers.** In recent years the spray dryer has become important for the drying of liquids in many fields, especially in the food industry.

The liquid is atomized by means of pressure nozzles, air jets or centrifugal bowls into the air stream of a tower or chamber. Inlet air temperatures may run from 250-300 F up as high as 1200 F. Drying times are very short because of the minute particle size. Particles as small as 5 to 10 microns are formed in spray dryers. The dry powder is separated from the air by cyclone separators which are sometimes followed by cloth bags or scrubbing towers.

Because of the high inlet temperatures and the relatively large volume of air required, the efficiency of the spray dryer is not too good and, consequently, is seldom used for dilute solutions (less than 30 percent solid). Fig. 15 shows a typical arrangement for a spray drying system.<sup>8</sup>

A common and important feature of all spray processing is the direct conversion of the spray liquid to a granular product suitable for packaging

FIG. 14. SECTION OF CONTINUOUS DRYER, BLOW-THROUGH TYPE

FIG. 15. SPRAY DRYER OF THE PRESSURE-SPRAY ROTARY TYPE<sup>8</sup>

without grinding or other intermediate handling. Another aspect is the unusually high rate of drying attained. In a well designed system 15 to 30 seconds is a fair time for the passage of the sprayed particle through the drying zone; the particle temperature need not rise materially above the wet-bulb temperature of the drying air. This makes the process particularly adaptable to the drying of heat-sensitive material, some of its most important applications being the drying of milk, eggs, potato flour, soap and blood.<sup>9</sup>

### SOLUTION OF TYPICAL DRYING PROBLEM

Since there are so many types of dryers which may be used, and so many special conditions surrounding each particular problem, it is usually recommended that those having experience with the dryer to be used be consulted. The following example, however, will serve as a guide for typical dryer calculations.<sup>10</sup>

**Example 1:** Assume 900 lb per hour of ceramic powder is to be produced. The powder has a specific heat of 0.22 and density of 98 lb per cu ft, wet. Initial moisture content is 19 percent on a wet basis; final moisture content is to be one-half of one percent on a wet basis.

A continuous belt dryer is a logical choice, and previous experience indicates that rubber belts will withstand temperatures up to 200 F, which is also about the highest desirable product temperature. Experience also indicates that a drying time of 45 min is possible at about 160 F dry-bulb and 100 F wet-bulb.

FIG. 16. CONTINUOUS BELT DRYER FOR CERAMIC POWDER<sup>10</sup>

**Step 1:** Let  $x$  = pounds moisture at final condition.

Then, 
$$\frac{x}{900} = 0.005$$

or, 
$$x = 4.5 \text{ lb moisture}$$

and therefore the solid will amount to 895.5 lb.

Likewise the weight of the initial moisture  $x$  can be found

from 
$$\frac{x}{895.5 + x} = 0.19$$

or, 
$$x = 210 \text{ lb.}$$

The weight of moisture to be removed is 205.5 lb per hour, and wet material entering dryer is 1105.5 lb per hr.

**Step 2:** Previous tests indicate that a  $\frac{1}{2}$  in. layer of powder gives satisfactory results, and that a desirable air velocity is 50 fpm applied at a right angle to the belt. Based on 45 min ( $\frac{3}{4}$  hr) drying time, the dryer holding capacity will have to be  $1105.5 \times 0.75 = 830$  lb of wet material or  $\frac{830}{98} = 8.45$  cu ft of material.

Assuming a 48 in. wide belt with an effective 42 in. width for the product, each foot of belt length carries 0.146 cu ft or 14.3 lb of wet material. Hence, the linear feet of belt must be  $\frac{830}{14.3} = 58$  ft and the total area of exposed product is 232 sq ft. Based on 50 fpm velocity directed at a right angle to the belt the total air circulation will be  $232 \times 50 = 11,600$  cfm.

For space economy and in order to expose periodically fresh layers of powder to air, a multiple vertical belt arrangement (Fig. 16) with belts traveling in opposite directions, is selected. Three belts each 19.4 ft long will be required. Fig. 16 illustrates the physical arrangement of the dryer.<sup>10</sup> The housing will be about 25 ft long, 8 ft wide and 7 ft high.

**Step 3:** At the drying conditions of 160 F dry-bulb and 100 F wet-bulb, the air moisture content (from Fig. 6) is 0.028 lb per pound of air. Make-up air will be assumed at 80 F dry-bulb and 72 F dew-point (summer weather), or a humidity of 0.0168 lb per pound of air. The pick-up is therefore  $0.0280 - 0.0168$  or 0.0112 lb per pound of air. Then  $\frac{205.5}{0.0112} = 18400$  lb of air per hour or 307 lb per min.

At the elevated temperature, the total air quantity of 11,600 cfm represents 675 lb of air per min. Hence,

$$\text{Make-up air} = 46 \text{ percent}$$

$$\text{Recirculated air} = 54 \text{ percent}$$

**Step 4:** Although the drying condition and drying rate should preferably be determined from experience or test results, the drying conditions can sometimes be estimated if the regain characteristics of the product or a similar product are known. In this case the regain characteristics of clay could be used as a guide. Inspection of regain data for typical clays indicates that at about one-half of one percent the vapor pressure of the moisture in the product is about 0.7 in. Hg less than the vapor pressure of free moisture at the product temperature. An assumption is made that the product temperature approximates the air wet-bulb temperature. If an assumption is made regarding the percent recirculated air the desired vapor pressure in the dryer can be estimated. For example assume a use of 46 percent outside air or 307 lb per min.

Then the moisture pick-up =  $\frac{205.5}{60 \times 307} = 0.0112$  lb per pound of air, with a consequent total of  $0.0168 + 0.0112 = 0.0280$  lb of moisture per pound of air in the leaving outside air, which has about 1.25 in. Hg vapor pressure. This is assumed to be the vapor pressure of the moisture in the product, and thus the vapor pressure of free water at product temperature can be  $1.25 + 0.7 = 1.95$  in. Hg. The temperature corresponding to 1.95 in. Hg is 100 F, and thus the air wet-bulb can be estimated to be 100 F. At 100 F wet-bulb temperature and 0.028 lb moisture per pound of air, the dry-bulb temperature is 160 F. Obviously, the assumed percentage of recirculated air affects the results, and therefore it is important that it be based on experience. About 50 percent recirculation is reasonable for the type dryer considered in this example.

**Step 5:** The pick-up of moisture per pound for the total air circulated is  $\frac{205.5}{60 \times 675} = 0.0051$  lb.  $0.0280 - 0.0051 = 0.0229$  lb moisture per lb of air for the supply air.

Assuming an existing wet-bulb of 100 F, the supply air dry-bulb will be 182 F. The mixture of recirculated air at 160 F dry-bulb and 100 F wet-bulb, with outside air at 80 F dry-bulb and 72 F dew-point, will be at approximately 120 F dry-bulb and 89 F wet-bulb.

**Step 6:** The heat required may be determined from Equation 26 by substitution of the following values:  $N_a = 307 \times 60 = 18420$  lb of air per hr;  $S = 900$  lb;  $c_s = 24 + 0.45 \left( \frac{0.028 + 0.0229}{2} \right) = 0.251$ ;  $t_1 = 80$  F;  $t_2 = 160$  F;  $t_2' = 100$  F;  $\lambda = 1100$  (approx.);  $W = 0.005$  lb;  $s_1 = 0.22$ .

$$Q = 18420 (0.251) (160 - 80) + 18420 (110 + 160 - 100) (0.028 - 0.0168) + 900 (100 - 80) (0.22 + 0.005) + Q_{rc}$$

$$= 609,000 \text{ Btu per hr} + Q_{rc}$$

The heat input requirement is therefore 609,000 Btu per hr plus radiation and convection losses ( $Q_{rc}$ ) which may be computed from the known construction of the dryer surfaces and the heat transfer coefficients.

Summer conditions were used in *Example 1* in order to obtain the maximum heat requirement which would be the case, except under the unusual condition where radiation and conduction losses are a large percentage of the total. In winter it is usually possible to take advantage of drier makeup air, and either speed up the process or operate at a lower dry-bulb temperature.

Controls for the system selected for *Example 1* would consist of a thermostat in the main return air duct controlling the heat input to maintain constant dry-bulb temperature. A wet-bulb controller in the return circulating duct would maintain constant desired wet-bulb temperature by simultaneous positioning of three sets of dampers in the makeup air, the exhaust air and the recirculated air ducts.

#### LETTER SYMBOLS USED IN CHAPTER 47

- $A$  = area of heat transfer and evaporation, square feet.
- $a$  = drying area, square feet per cubic foot of bed volume.
- $B$  = a constant (for use in Equation 22).
- $B'$  = a constant (for use in Equation 23).
- $c_s$  = humid heat, Btu per (pound of dry air) (Fahrenheit degree).
- $d$  = diffusivity of the liquid or vapor, square feet per hour.
- $D_p$  = average diameter of particle, feet.
- $D_{p1}$  = drop diameter at start of evaporation, feet.
- $D_{p2}$  = drop diameter of dry particle, feet.
- $e$  = Napierian base of logarithms = 2.718.
- $G$  = mass velocity of dry air, pounds per (hour) (square foot).
- $\Delta H_m$  = logarithmic mean of inlet and outlet humidity driving force across the air film adjacent to the particle through which the water vapor diffuses, pound per pound. (The surface humidity is taken as the humidity corresponding to the wet-bulb temperature of the drying air).
- $H_1$  = humidity ratio of entering air, pounds of water vapor per pound of dry air.
- $H_2$  = humidity ratio of leaving air, pounds of water vapor per pound of dry air.
- $h$  = film heat transfer coefficient, Btu per (hour) (square foot) (Fahrenheit degree).
- $h_c$  = coefficient of heat transfer by convection, Btu per (hour) (square foot) (Fahrenheit degree).
- $h_r$  = coefficient of heat transfer by radiation, Btu per (hour) (square foot) (Fahrenheit degree).
- $h_t$  = total gas film heat transfer coefficient, Btu per (hour) (square foot) (Fahrenheit degree).
- $K$  = a constant (a function of the constant drying rate).

- $k_t$  = gas film thermal conductivity, Btu per (hour) (square foot) (Fahrenheit degree per foot).
- $k_g$  = mass transfer coefficient, pounds per (hour) (square foot) (atmosphere).
- $L$  = material thickness, feet.
- $M$  = molecular weight of the diffusing vapor.
- $N_a$  = dry air supplied to the dryer, pounds per hour.
- $\Delta p$  =  $p_s - p_a$  = vapor pressure difference, atmospheres.
- $p_a$  = vapor pressure of water at  $t_s$ , atmospheres.
- $p_s$  = vapor pressure at the particle surface corresponding to the liquid temperature, atmospheres.
- $p_2$  = partial pressure of water vapor in air, atmospheres.
- $p_a$  = vapor pressure of liquid in the drying medium, atmospheres.
- $Q_{rc}$  = radiation and conduction loss, Btu per hour.
- $Q$  = total heat supplied to dryer, Btu.
- $q$  = rate of heat transfer, Btu per hour.
- $R$  = gas constant (cubic feet) (atmospheres) per (Fahrenheit degree).
- $S$  = weight of stock dried in a continuous dryer, pounds per hour.
- $S'$  = weight of stock charged in a discontinuous dryer, pounds per batch.
- $s$  = specific heat of stock, Btu per pound.
- $T$  = absolute temperature of the gas, Fahrenheit.
- $t_a$  = air or gas temperature, Fahrenheit.
- $t_h$  = temperature of the heating medium, Fahrenheit.
- $t_s$  = temperature of particle, solid or surface of evaporation, Fahrenheit.
- $t_w$  = wet-bulb temperature of drying air, Fahrenheit.
- $t_1$  = entering air temperature, Fahrenheit.
- $t_2$  = leaving air temperature, Fahrenheit.
- $t_1'$  = entering stock temperature, Fahrenheit.
- $t_2'$  = leaving stock temperature, Fahrenheit.
- $t''$  = average stock temperature over short interval of time, in batch dryer ( $t_1''$  = entering,  $t_2''$  = leaving) Fahrenheit.
- $\Delta t$  =  $(t_s - t_a)$  = temperature difference between air and surface of evaporation, Fahrenheit.
- $\Delta t_m$  = logarithmic mean between temperature entering and leaving the bed, and the wet-bulb temperature, Fahrenheit.
- $U$  = overall heat transfer coefficient, Btu per (hour) (square foot) (Fahrenheit degrees temperature difference between heating medium and product).
- $W$  = moisture content on dry basis at any time  $\theta$ , pounds of water per pound.
- $W_c$  = critical moisture content, pounds water per pound dry material.
- $W_d$  = water content, dry basis, of the drop as it enters the drying chamber, pounds per pound of dry solid.
- $W_e$  = moisture content at equilibrium with external conditions, pounds per pound dry material.
- $W_o$  = initial moisture or moisture content at start of diffusional period, pounds per pound.
- $w$  = pounds of water.
- $\frac{dW}{d\theta}$  = drying rate, pounds of water per (hour) (pound dry material).
- $\left( \frac{dW}{d\theta} \right)_c$  = constant drying rate, pounds per (hour) (pound dry material).
- $\left( \frac{dW}{d\theta} \right)_f$  = falling rate, pounds water per (hour) (pound of dry stock).
- $\frac{dw}{d\theta}$  = drying rate or rate of evaporation, pounds of water per hour (Eq. 1).
- $\theta$  = time, hours.
- $\theta_c$  = drying time for constant rate period, hours.
- $\theta_f$  = drying time during falling rate period, hours.
- $\theta_t$  = total drying time, hours.
- $\lambda$  = latent heat of evaporation at  $t_s$ , Btu per pound.
- $\mu$  = viscosity of the air stream, pounds per (hour) (square foot).
- $\rho_L$  = density of evaporating liquid, pounds per cubic foot.
- $\rho_s$  = bulk density of dry granular bed, density of dry particle, pounds per cubic foot.

## CHAPTER 48

## TRANSPORTATION AIR CONDITIONING

Railway Passenger Car Air Conditioning; Streetcar and Trolley Coach Heating and Ventilating; Passenger Bus Air Conditioning; Automobile Air Conditioning; Aircraft Air Conditioning; Ship Air Conditioning, Heating and Ventilating, Air Conditioned Space Treatment, Systems and Controls

THE principles of air conditioning applying to stores, restaurants, hospitals, theaters, and homes are applicable to railway passenger cars, passenger buses, automobiles, streetcars, trolley coaches, airplanes and ships. However, equipment used for mobile applications differs from that used for stationary purposes in that it must meet additional requirements. Equipment must be compact, accessible for quick inspection and servicing, light-weight and unaffected by vibration and impact. Freedom from vibration which could be transmitted to supporting vehicle and thus to passengers, is essential.

## RAILWAY PASSENGER CAR AIR CONDITIONING

The railway passenger car represents a very difficult air conditioning problem. Space is strictly limited so that all equipment and ducts must be reduced to minimum size. Electric power supply and water supply also are limited. All equipment must withstand severe vibration and shock, and must be very reliable since servicing points are frequently far apart.

During the heating season it is necessary to heat conventional cars with steam from the locomotive at pressures that may vary from 250 psig to only 5 or 10 psig on the last car in long trains. Passengers in window seats must sit only a few inches from cold outside walls and windows, and must also be very close to standing radiation installed along sides of cars. Sudden changes in load may be caused by changes in sun, wind, or train movement. Even in coldest weather, outside doors must be opened frequently.

During the cooling season, the problem is further complicated by a high concentrated internal load due to the passengers. Also, air distribution problems are increased by low ceilings and short air throws.

## Heating

The heating of passenger cars is accomplished by using a split system consisting of an overhead air circulating system with heating and cooling coils, and standing radiation (floor heat) along car sides. The floor heaters, which usually consist of finned tubing, may be made more efficient by using covers designed to increase gravity air circulation, and to direct the warm air from finned heating surface along cold outside walls and car windows. In some new cars, wall convector panels are used and extend the full length of the car, with air intakes along the floor and outlets at window sill height and at window head height in dead-light panels. The heated panel protects passengers from cold outside walls, and the chimney effect of the panel duct increases air flow and improves heating surface efficiency.

Floor heat is supplied by introducing steam into an inner tube within a finned tube or by means of a separate steam-to-liquid heat exchanger.

The liquid (usually an antifreeze) is mechanically circulated through plain finned tubing. When steam is used directly, the tube-within-a-tube construction makes it possible to obtain uniform distribution throughout the length of the car. It is achieved by means of heat transfer between the steam within the inner tube and the condensate returning in the annular space between the tubes.

The finned tubing at the floor must have sufficient capacity to offset effects of cold walls and windows during normal operation, and to heat the entire car to a minimum temperature of 60 F during standby when the overhead system is not operating. The maximum capacity required (determined by standby requirements) varies with car construction and design temperatures, but is approximately 90,000 Btu per hour. This requires a heating capacity in finned tube of approximately 650 Btu per linear foot.

The overhead air heating coil must have sufficient capacity to heat the outside air brought into the car for ventilation, and to supply approximately 20 percent of the internal heat loss of the car so as to permit supply of floor heat at all times at an output that will not be objectionable to passengers sitting near it. The usual capacity of the overhead heating coil is approximately 100,000 Btu based on 2400 cfm of circulated air, with 600 cfm of this being outside air for ventilation. All Btu figures are approximations of actual heating requirements, and do not include heat losses in the trainline (or leakage) or losses in the undercar piping. Recent car designs have enabled the car builder to run the steam supply lines in recesses within the car body, thus greatly diminishing under-car losses.

### Refrigeration

For cooling and dehumidification during summer, refrigeration may be obtained from ice bunkers, steam jet systems, or mechanical compressors (driven directly from car axle by electric motors or by gas engines). Refrigeration required varies with load conditions, but 7½ tons per car is one capacity frequently used. Evaporative type condensers are sometimes used in combination with the usual air condenser on either steam jet or mechanical refrigeration.

When an electric motor (approx. 10 hp) is used to drive the air conditioning compressor, the electric power source is a problem. If the power source is an axle-driven generator, there is an appreciable increase in the drag on locomotive, and the power available for refrigeration, when train is stopped at a station, is limited to storage batteries. One solution to this problem is to use a d-c generator driven by a gas engine. Another is to use a Diesel-driven alternator in a special head-end car to furnish power to the entire train. Recently there have been installations in which a Diesel-driven alternator is mounted on an individual passenger car to supply the power requirements of the car. The attractiveness of this type of installation can be increased by utilizing spare alternator capacity in winter for electric heating. If this capacity is supplemented by exhaust heat from the Diesel engine, there is sufficient capacity to heat the entire car and to provide hot water for wash rooms when outside temperatures are above approximately 30 F. This feature is important on trains using Diesel locomotives, since it eliminates the need for firing the steam heating boiler in the locomotive during a portion of the year.

### Air Distribution and Cleaning

Railway cars present critical problems in air distribution because air space per passenger is small (60 to 190 cu ft), and the sun load is great.

An average passenger car contains approximately 5000 cu ft of air, and may seat as many as 80 passengers. The occupants are continually liberating heat, carbon dioxide, moisture, odors, and some organic matter from their breath, skin and clothing. The heat and moisture can be removed by cooling and dehumidification, but other constituents can be successfully handled only by proper ventilation and air cleansing. In an average car, from 2000 to 2500 cfm are circulated by the air conditioning unit. Some of this air may be recirculated, but a portion of it should always be brought in from outside. The amount of outside air desirable depends upon the type of car, number of passengers, air temperature, humidity, odors, and whether or not the occupants are smoking, and will vary from 15 to 90 percent of the total air circulated.

Careful attention must be exercised in specifying the rate of outside air taken in so as to fit the type of service adequately, and yet not supply more ventilation than is necessary. Conditioning of this outside air is a major factor in determining size of both summer and winter equipment.

For normal conditions, 10 cfm of outside air per passenger are provided. When smoking is permitted, at least 15 cfm should be admitted. In some dining cars, and deluxe sleeping cars, outside air rates as high as 20 to 30 cfm per occupant are used. A ceiling duct lengthwise along the center of the car is usually used to distribute the air to the interior by fans or blowers. A perforated ceiling supplied from an overhead duct, or delivery grilles and plaques designed to give considerable entrainment and mixing, are used to deliver air to the car space.

Smoking rooms present a special problem. The cloud of smoke that usually hangs near the ceiling can be broken up by directing incoming air along the ceiling at a velocity somewhat higher than that used for the rest of car. The air is exhausted through the washroom or lavatory. For compartments, provision is made in the door or partition for removal of used air. Lower berths are provided with a low velocity air outlet.

Recirculating air grilles are usually of straight flow types. Outside air intakes are usually located in the vestibule, on the side of the car, or on the roof, depending upon location of the cooling coils. On many recently air-conditioned cars, there are no dampers or shutters at the outside air intakes; the percentage of the outside air is controlled by adjusting flow through the recirculating grille.

A considerable number of coach cars are now being equipped with return air ducts fitted in the structure of baggage racks. Part of the air circulated is returned to the blower unit through these ducts, and part through the car body. This arrangement reduces quantity and velocity of air returning through the car body, and removes smoke fumes at the source. This, and any other design features aimed at taking recirculated air at the floor and adjacent to both end doors (rather than drawing all recirculated air to one end of the car) also reduces infiltration of cold air in ankle height strata, when doors are opened during the heating season.

All air circulated by the blower is filtered before passing over the cooling and heating coils. In some cars outside air and recirculated air are filtered separately before mixing, while in others air from the two sources is mixed before passing through a common filter. Filters in use are combinations of metal, wool, cloth, spun glass, hemp, paper, hair and wire screen. Most filters have a viscous coating of oil for greater cleaning efficiency. Some types may be cleaned, re-treated, and re-used, while other types are discarded when dirty. Applications are also being made of electric precipitation for air cleaning. In this system the coarser particles are removed

from the air by mechanical separation; finer materials, by electrostatic action.

Activated carbon units sometimes are used in addition to the regular filters for adsorbing odors and other impurities, thus reducing the amount of outside air necessary for ventilation.

### Temperature and Humidity Control

Controls in a passenger car should be as automatic as possible. The regular train crew cannot be relied on to make adjustments for the comfort of passengers. For this reason the latest systems of temperature control have only an off-on switch to be operated by the train crew. When the system is in operation, heating or cooling is provided automatically as required.

When heating, it is important that floor-heat finned tubing be controlled at stable temperatures. Wide fluctuation in its temperature is highly objectionable because of location close to the passengers. Stable operation may be secured by cycling the floor heat on the basis of inside conditions in conjunction with an overhead air-circulating system to maintain final car temperatures.

Because of window condensation and other problems, usually no attempt is made to raise relative humidity in a railroad car in winter time.

When cooling, the steam jet refrigeration system is controlled in an on-off manner. Some means are ordinarily provided for operating mechanical compressor systems at partial capacity. In this case split evaporators are used, so that evaporator surface and compressor capacity can be reduced together under light load conditions.

Attempts have been made in the past, largely on an experimental basis, to control the relative humidity in railway cars. This was done by operating the air conditioning equipment according to outside temperatures and then re-heating the air to an acceptable temperature. This was found to be an expensive method of operating and the results did not justify the cost. A common method of controlling heating and cooling is to provide a thermostat to control heating only and a separate thermostat set at a slightly higher temperature to control the cooling equipment. This gives heating control, ventilation, and cooling control and the reverse, as the case may be. A car in service can go from heating into cooling in a very short time. An example of this is found on the full-dome cars in service on several railroads in the country. In the early morning hours before sunrise, the car may be requiring a considerable amount of heat. Shortly after sunrise, the car may go into the ventilating cycle and as the sun load increases, cooling may be required. On the majority of car heating systems, frequent cycling of the compressor is prevented by the one degree difference between the heating and cooling control points and by lag imposed on the system by applying artificial heat to the heating thermostat when cooling is required. On some car heating systems, a degree of modulation is obtained by the use of split evaporation. This requires two cooling thermostats with one of them set at a somewhat higher temperature than the other. The lower temperature cooling thermostat controls a portion of the cooling capacity and, if unable to maintain the car temperature, the higher thermostat adds the remaining capacity.

### STREETCAR AND TROLLEY COACH HEATING AND VENTILATING

Streetcars and trolley coaches present a special problem in the maintenance of satisfactory comfort conditions because of the frequent opening of the doors and highly fluctuating passenger load. Space limitations for ducts, and a desire to keep outlet grilles well above the floor to facilitate car cleaning, add further problems to the distribution system. Maintaining comfort conditions at the driver's station cannot be overlooked, since his term of occupancy is considerably longer than that of any passenger, and because he is usually dressed more lightly than passengers. A separate source of heat is usually provided for the operator, and is under his control.

#### Heating and Ventilating

Recently-built streetcars and trolley coaches obtain heat from air blown over the main accelerating resistors and track switch resistors, to heat the passenger space. In the modern streamlined streetcars, designated P.C.C., approximately 2400 cfm are drawn from the car and blown over these resistors to dissipate their heat. In trolley coaches, an amount of 800 cfm is customary. The heated air is then delivered to the passenger space or diverted to the outside by means of dampers, as required. If available heat from this source is insufficient, auxiliary electric heaters in the supply ducts may be cut in. The air distribution system is 100 percent recirculating when the maximum heating requirement is being met. At conditions other than maximum heating demand, part of the air drawn from the car is exhausted to the atmosphere. Outside air enters the car, under these conditions, by infiltration at all cracks and through doors when opened at stops.

The most recently-built streetcars have added ventilating fans in the roof structure to introduce outside air through ceiling diffusing grilles. By governing the outside air volume introduced through these roof fans in coordination with the heated air distributing system, it is possible to maintain a slight pressurization of the passenger space and avoid inrush of air when the doors are opened to load passengers. The roof fans also provide an effective means of maintaining lower inside temperature during summer operation. Ventilation tests on P.C.C. streetcars indicate that with 90 F outside temperature and above, 12,000 cfm are required to provide sufficient air change to keep inside temperature within a few degrees of outside air temperature, and to provide enough air movement over passengers for comfort. The best results have been obtained by operating the ventilating fans and keeping the windows closed. New cars provided with adequate ventilating capacity have been built with fixed sash.

#### Control

Temperature control, consisting of equipment especially designed to withstand the vibration present on transportation equipment, is used. Automatically operated dampers are used to control flow of heated air to the passenger space, or to direct heated air to the atmosphere. An automatically operated rheostat or multi-point switch is used to vary the speed of the ventilating fans. Recent control system applications employ one thermostat to operate both heating dampers and ventilating fans in a modulating or graduated manner, with a compensating thermostat in the heat supply duct to correct for wide fluctuations in temperature of air leaving the resistors. Ventilating fans are usually stopped or operated at lowest speed during the heating cycle, and then their speed is gradually increased as the car temperature rises above the heating-cycle control point.

## PASSENGER BUS AIR CONDITIONING

The passenger bus designed for urban transportation operation presents a greater problem to the designer of heating systems than does the inter-urban bus. More frequent stops, and rapidly changing passenger load create this problem on urban vehicles. Provision of heat for the driver independent of the passenger heating system, is a further problem. The inter-urban bus, however, is usually a deluxe vehicle and may require a comfort cooling system. Space and weight limitations and vibration must be considered.

## Heating

Recent designs of bus heating systems obtain improved air distribution. Heat in the engine coolant liquid is used to warm air by means of suitable finned coils and this heated air is distributed throughout the passenger space by ducts and outlets directed toward the floor. Some designs include finned surface near the floor in an application similar to that in railway passenger cars. Forced air circulation over this finned floor heating surface has been provided to increase its effectiveness. Oil burning booster heaters have been applied to many Diesel-powered buses to raise the temperature of the engine coolant for maximum engine operating efficiency, and to provide sufficient heat for the passenger space.

## Ventilation

Air for ventilation is usually brought into a bus at the front, and distributed throughout the length of the passenger space by a duct or ducts near the ceiling. Except for a few designs employing 100 percent outside air for heating, no heating of the ventilating air has been provided. One recently designed distribution system for an inter-urban bus provides for a fixed minimum of outside air, and is arranged to increase the percentage of outside air to 100 percent when the heating or cooling load diminishes. The distribution ducts and diversion damper arrangement of this system make available two supply ducts and one return duct for heating and for cooling, with a changeover to all three ducts to supply air during the intermediate ventilating cycle. This system permits utilization of atmospheric cooling and ventilation to the greatest degree when it can be most economically employed in the interval between the heating and cooling demand.

Conventional throw-away type filters or renewable filters are used in intake air ducts for many vehicles. Electrostatic filters have been successfully used in some installations. The need for elimination of dirt is great, but the problem is complicated by space limitations and limited power.

## Refrigeration

Summer conditioning systems for inter-urban vehicles range in cooling capacity from 36,000 to 48,000 Btu per hour. Mechanical compression systems using refrigerants are used, and are powered by water-cooled gasoline engines of approximately 14 hp.

Complete systems add from 800 to 1300 lb to weight of the coach. Sometimes an auxiliary generator driven by the refrigeration system engine is used and serves to help charge the bus battery, thereby offsetting power drain imposed by the ventilating blower. Belted reciprocating compressors and direct-driven V-type and rotary compressors are used, with engine speeds up to about 1800 rpm. Air-cooled condensers for this service re-

quire about 5000 cfm of outdoor air, and this is provided by either centrifugal or propeller type fans belted or direct-driven by the air conditioning engine. Preventing noise and vibration from affecting passengers is of vital importance. Installations must be made for quick daily engine servicing. In all cases fuel is obtained from the main bus tanks, and in some, the main engine cooling system cools the air conditioning engine.

## Control

Automatic temperature control is receiving more attention in the design of new vehicles. Some municipalities and states have enacted laws requiring that buses operated on their streets and roads be so equipped. The simplest control systems for heating of urban buses consist of a single thermostat to start and stop the blower of the heater unit. Improved heating systems employ a thermostat to control liquid flow to the heater cores by means of modulating valves, in combination with a means of stopping the heating blower when no heat is required. Heating and ventilating control is accomplished by controlling the volume of outside air, over and above the minimum required in accordance with the temperature in the passenger space, by means of automatic modulating dampers in the outside air intake, or by varying the speed of the ventilating air blowers.

In a large proportion of inter-city buses equipped with mechanical refrigeration, a single thermostat is used to start and stop the cooling operation. This may be accomplished by automatically starting an engine-driven compressor on the cooling demand or by engaging a clutch to drive the compressor. Modulated or graduated control of engine-driven compressors may be accomplished by automatic regulation of the engine throttle controlled from a thermostat in the passenger space. Complete control systems are available to coordinate operation of the heating, ventilating and cooling equipment from a single thermostat, with automatic change-over from heating to ventilating to cooling.

## AUTOMOBILE SUMMER AIR CONDITIONING

The first attempts to cool automobiles mechanically were made in south western United States 1930-1940 with systems assembled from commercial components. Between 1939 and 1942 one car manufacturer built about 1500 cars equipped with a mechanical system. Customer acceptance was mixed and the project was dropped to be reactivated again in 1953. In 1952 the major automobile manufacturers decided that time was ripe to offer summer comfort cooling in their higher priced cars. The 1953 models were introduced and well accepted. In 1953 and 1954 about 125,000 units were sold. In 1955 some of the lower priced cars were available with summer cooling systems.

The basic components used are fundamentally the same as in any stationary air conditioning system using the vapor compression cycle. The engineering problem is to design for automobile application in which case the source of power is always a major obstacle to overcome. The best solution to date for automobile applications is to operate the condensing unit by belt drive from the car motor and then control the variable refrigerating capacity caused by the variable car motor speed by suitable means.

One to seven or more horsepower are required. Compressors must be capable of operating at speeds of 4000 to 5000 rpm to last in this service. Refrigeration capacity required is about  $1\frac{1}{2}$  to  $1\frac{1}{4}$  tons. Radiant heat, as well as high conduction heat gain due to single-glazed large glass areas, and

lack of adequate insulation in car bodies require this much capacity. Proper air distribution to avoid undesirable drafts on passengers also requires careful design. Air distribution fans and electrical controls secure power from the car's electrical system which in some cases may require heavier generators and batteries to handle the load. Most systems weigh about 200 lb or less.

Early installations, and many current ones, have the cooling units installed in the rear of the car with the cooled air introduced through the package shelf at the rear of the passenger compartment. Cooled air is then distributed with or without ducts. Warm air is returned through a grill in the package shelf, or below the rear seat, thence through a filter into the cooling units. Refrigerant lines from condensing unit to cooling unit are carried from the engine compartment to the luggage compartment along the car frame under the body.

Current design objectives are to reduce weight and first cost, simplify installation, increase reliability, and improve performance, especially pull-

FIG. 1. TYPICAL FRONT END SYSTEM  
(All components ahead of fire wall)

down from a hot car standing in the sun. Recent systems have shown such improvements. Performance at open-road speeds have been very satisfactory (even with early systems—when they were operating properly). Twenty percent or more outside air should be supplied, especially if passenger smoke. This air is picked up by scoops on the side of the car or cowl (See Fig. 1) and carried into the cooling unit and mixed with returned warm air from the car.

Car temperature control, compressor capacity control to compensate for the variable compressor speed, and prevention of ice formation on the evaporators (a common fault of early systems) are accomplished by bypassing compressor discharge gas into the low pressure side of the system, or cycling the compressor with a magnetic clutch. The solenoid bypass valve or a magnetic clutch is electrically operated by a thermostat, usually controlled by the return air to the cooling unit. The bypass is opened or the compressor stopped when the air gets too cold.

A recent development is a complete factory-assembled system, charged with refrigerant and ready to run, which is dropped into position ahead of the fire wall of the car and bolted into place (see Figure 1). Flexible suction, liquid, and discharge lines are used to connect the refrigeration components together. This facilitates initial installation. It also simplifies removal for service and maintenance and eliminates the necessity to open the refrigeration components to the atmosphere with resultant loss of refrigerant or infiltration of moisture into the system.

This system combines winter heating with summer cooling. It also permits use of all or limited quantities of outside air, with or without heating or cooling. Outside air is taken in through cowl openings. This air is then pulled through a combined heating and cooling coil assembly by a fan inside the car on the firewall. Cooled air is discharged from adjustable nozzles on the dash inside the car. Hot air for heating is discharged onto the floor as with conventional car heaters. Dampers change the air distribution from heating to cooling, and dash controls activate or shut off either heating or cooling.

Temperature control, prevention of evaporator icing and compensation for variable compressor speed are controlled by a thermostat with bulb in the air leaving the evaporator. This cycles the compressor on a magnetic clutch.

Public acceptance of current offerings has been excellent. Performance has been very satisfactory. What service difficulties have been encountered have been readily cared for by car dealers who have trained personnel to render this type of service, or by competent refrigeration service organizations. Future demand is estimated as high as 10 percent of total car production by one major manufacturer, while another estimates a million or more of its cars will be equipped in the not too distant future.

### AIRCRAFT AIR CONDITIONING

In the space of a few years, heating, cooling and ventilating of airplanes has progressed from comparatively simple systems to highly complex multi-purpose designs. The attendant control problem has become correspondingly complex. On older, non-pressurized planes, the heating system consisted either of a steam boiler and radiator or a single stage or double stage heat exchanger. On both types, the cabin temperature was adjusted by positioning the face and bypass dampers. While these were sometimes moved by an automatic modulating control, in the majority of cases they were positioned by one of the ship's crew, with results which, while not satisfactory, were passable. As these planes cruised at less than 200 mph and normally operated at low altitudes, changes in outside air temperatures were generally gradual enough so that manual readjustment of controls could maintain reasonably comfortable cabin conditions. Nearly all of these heating systems were marginal in respect to heat available, and the main problem was lack of heat, rather than inadequate control.

### Non-Pressurized Cabins

With the advent of the combustion type heater, and use of larger and faster planes, use of manual controls became impracticable. The combustion type heaters reach full rating in less than a minute after being turned on, and as they are rated at 100,000 Btu per hr and up, and since several heaters are generally used, it would take full time of one crew

member to keep cabin temperature regulated. As ships of this type are not pressurized, the heating system is still comparatively simple.

In one type, two 100,000 Btu heaters are placed in parallel positions and the ram air from an external scoop is passed through the heaters and discharged through a series of distributing outlets located in the cabin ceiling. The cabin air is discharged through grilles located in the bottom walls of the cabin. An auxiliary nose heater is used by the crew to obtain additional heat for the cockpit or for windshield defrosting.

The cabin is maintained at the desired temperature by means of an automatic control which operates both heaters simultaneously. This control consists of two duct thermostats, one being mounted in the air inlet duct between the air scoop and the heaters so that it is affected by outside ambient temperatures, and the other being mounted in the heater outlet duct so that it is affected by the discharge air temperatures. A thermostat in the cabin is so located that a continuous stream of cabin air passes through it. This type of control has been found to respond to a 1 deg temperature change in less than a second. Its theory of operation follows.

As the outside temperature starts to drop, the outside air duct thermostat decreases in resistance, unbalancing an electronic bridge. This unbalance is amplified by vacuum tubes and causes a power tube to close a relay, turning on the combustion heaters. The resulting increase in temperature is sensed by the warm air duct thermostat which increases in resistance, thus re-balancing the bridge and causing the relay to open. If there were no loss by radiation or convection from the aircraft cabin, these two duct thermostats would be sufficient for adequate control. However, the cabin thermostat is given approximately 30 times more influence than the duct thermostats and so acts as the master controller, and the duct thermostats prevent over-heating or under-heating and keep the discharge air from alternating between extreme cold and extreme heat.

In a slightly more elaborate system, two combustion heaters supply a plenum chamber which is maintained at a constant temperature. Air from the plenum chamber is then mixed with outside air to maintain desired cabin temperature. All of the warm air is discharged into the cabin through the walls. The discharge grilles are located on the floor under seats, and a modulating type controller varies proportions of heated and outside air necessary to maintain desired cabin temperature. The same type of control system as previously described is used, except that an amplifier operates a two-phase motor capable of positioning control dampers instead of operating a relay which would merely open and close the fuel valve. An auxiliary duct, running from the plenum chamber, is used by the pilot as a source of windshield defrosting air.

#### Pressurized Cabins

With the advent of the new high speed pressurized transport planes, and the addition of cabin cooling in addition to heating, the control problem becomes more complex. On all of these airplanes, the heat of compression from cabin supercharger must be controlled, the air cycle or expansion turbines must be turned on and also, the heat exchanger or combustion heaters, which are used in the system when cooling is required for additional heat, must be automatically controlled.

Assuming that one of these airplanes is operating in an extremely cold climate, the sequence of operation would be as follows:

The automatic controller for the supercharged-air inter-cooler would be in full

closed position, so that none of the heat of compression would be removed, and the air would by-pass the expansion turbine and its compressor and the secondary after-cooler. An additional automatic controller would be operating the combustion heater and supplying the additional heat necessary to maintain the desired cabin temperature. If a heat exchanger were used as a supplemental source of heat, a modulating control operating a damper on this exchanger would run towards full heat position.

As the airplane enters a warm climate and heat requirements drop, the combustion heater would cease operation or the heat exchanger would go to full cold position, and the modulating control on the supercharger compressor would move towards the cold position. When the outside ambient temperature rises so high that cooling is desired, the cabin supercharger intercooler would be opened wide. If further cooling were required, the air would go into an air cycle turbine, which is modulated to deliver the required amount of cold air to maintain a comfortable cabin temperature.

Pressure in the cabin is maintained by providing a controlled, constant rate of air flow into the cabin sufficient to maintain ventilation, and adjusting the cabin-pressure relief valve setting, by means of a cabin pressure selector, to maintain the desired cabin pressure. Limits on maximum inside to outside pressure may be of the order of 4 or 5 psi, and safety controls should be provided to prevent exceeding this limit. There is a maximum rate at which the cabin can change to a newly selected value, this rate being in some cases also adjustable.

The requirements for controls of this nature are extremely rigid. It is commonplace for ships of this type to experience changes in outside ambient temperatures of as much as 100 deg in a space of 5 min. For this reason, speed of sensing a change and rapidity of response in the control system is essential if satisfactory control is to be accomplished. The older type thermostats cannot be used in airplanes, due to mass of the thermostat and to vibration experienced on all airplanes. All modern controls use some type of bridge system with temperature sensitive resistors as sensing elements. In some types of controls, the bridge system feeds a sensitive balanced relay, which in turn runs a modulating motor or controls an on-off power relay. A recent sensitive and quickly responding type uses an electronic amplifier, which in turn controls a two-phase motor, or, through relays, controls a d-c motor, or merely closes and opens a power relay for on-off applications.

In addition to extreme speed and accuracy which are required of all aircraft temperature controls, they must be able to operate under great extremes of temperature, pressure and humidity, and also withstand continuous extreme vibration. Heaters should have, in addition to control from thermostats, suitable limit controls to prevent over-heating due to failure of air supply, or any other cause. Also, there should be safety devices to shut off fuel in case of flame failure.

On the latest *high speed jet airplanes*, the temperature control problem is still more severe than on the latest transports; as in addition to the accuracy required, control response must be phenomenally fast. For example, on some, the air going to the cabin from the jet engine compressor can change the temperature at the rate of 150 deg per second. This, coupled with the fact that on smaller size pursuit ships air is changed in the cabin as much as four times per minute, makes the instantaneous sensing of change and an extremely rapid control movement essential. Also, in airplanes operating at Mach numbers in excess of 0.7, the control must react to the large adiabatic temperature rises encountered. Some of these problems are so new that controls still have not been developed to meet all of the desired conditions. However, present studies being made by control manufacturers should result in developments of such controls in the near future.

## SHIP AIR CONDITIONING

In air conditioning a ship, the designer is faced with all problems that would normally arise on shore installation plus additional factors. Mechanical ventilation is an absolute necessity for the comfort of passengers and ships' personnel, and for utility and preservation of cargo and stores. Ships are constructed with water-tight bulkheads dividing the vessel into several compartments. This complicates the running of duct work and results in a multiplicity of both supply and exhaust fans. Temperature and humidity requirements of various spaces aboard ship vary widely. Passenger staterooms and public spaces must have year-round air conditioning with is also being applied more and more to the quarters of the officers and crew. Boiler rooms, galleys, laundries, etc., must have ventilation, and some must have tempered air. Cargo spaces are quite likely to need dehumidification in addition to ventilation.

Inasmuch as ventilation is such a necessary factor aboard a ship, the majority of recently built vessels have been utilizing the air distribution system for heating purposes.

A ship is a self-contained structure quite likely to be away from repair ports for long periods. Adequate spare parts, therefore, form an integral part of equipment furnished. The same type of equipment should be used in as many places as possible throughout the ship, in order to reduce the number of spare parts to be carried.

Preliminary system design is simplified by uniformity of conditions which apply to most ships. Among such conditions are: (1) the necessity for the vessel to supply its own power, (2) the availability of an unlimited supply of low cost steam at suitable pressure, (3) limitations of available space and permissible weight.

The problem of heat transfer and insulation must be given careful consideration. The thermal conductivity of ship building material, such as steel, copper and brass, is many times the value of building material used ashore. The length of ducts between heat sources and fans necessitates extra duct insulation. Hull insulation must be of high quality, with attention given to fireproofness, low density, low thermal conductivity, ruggedness, vermin resistance, and ease of application. Board types are most common.

Duct insulation must have the same characteristics as hull insulation. Semi-rigid and rigid board are most common. Corrugated asbestos is not used because in the presence of moisture, it tends to disintegrate. There is a growing use of natural cork on chilled air ducts because of great difficulty in applying an adequate vapor seal due to space limitations.

## SHIP HEATING AND VENTILATING

It is usually most economical in weight and space to use steam duct heaters for heating spaces served by mechanical supply systems. Spaces which do not have mechanical supply, or do not require ventilation in cold weather, are heated by steam convectors or, where the load is large, by unit heaters. Ventilation air, except that supplied to auxiliary and main machinery spaces, is usually preheated to temperatures of 50 to 70 F. No recirculation is used in ventilation and heating systems, but a manual reduction (25 to 50 percent) of air quantity is made during the heating cycle. All heaters are automatically controlled, and preheaters are designed and installed to minimize possibility of freezing of condensate.

Preheaters are frequently located close to the outside air intake in order to conserve insulation and, for the same reason, zone reheaters are located as close as possible to each zone. Where a reheater serves only one space, it is commonly located in the space.

Combinations or variations of duct type and convection or radiant heaters are used, depending upon basic design requirements, such as weight and space limitations, and the economic justification of the cost of the type selected.

Because of many different requirements of various spaces aboard ship, some design temperatures and humidities are given in Table 1. The resulting quantities of air should be checked against typical heating and ventilation practices for ships.\*

TABLE 1. DESIGN CONDITIONS FOR SHIPS

| AREA                  | OUTSIDE DESIGN TEMPERATURES |               |               | INSIDE CONDITIONS |                    |         |
|-----------------------|-----------------------------|---------------|---------------|-------------------|--------------------|---------|
|                       | Heat-<br>ing                | Ventilating   | Cooling       | DB &<br>R.H.      | Effective<br>Temp. |         |
|                       | F                           | F             | F             | F                 | %                  | F       |
| Living Quarters . . . | 0                           | 95            | 95(DB) 80(WB) | 80                | 50                 | 73-74   |
| Public Spaces . . . . | 0                           | 95            | 95(DB) 80(WB) | 80                | 55                 | 73½-74½ |
| Naval Vessels . . . . | +10                         | 88(DB) 80(WB) | 88(DB) 80(WB) | 85                | 50                 | 75-78   |

## Living Spaces

The minimum quantity of ventilation air required for any sleeping or office space, including hospital space, should be that which will limit the temperature rise over the outside air to not more than 10 deg (a rise of 7 deg is more satisfactory), or a minimum of 30 cfm per person, whichever is the greater.

In spaces fitted for eating, recreation, or manual work, the rise may be taken at 10 deg with not less than 20 cfm per person. The same requirement applies to mechanical exhaust, although natural exhaust may be used where only a short run of duct exists.

Heat should be furnished to maintain the following temperatures:

|                                                           |            |
|-----------------------------------------------------------|------------|
| Staterooms, Berthing, Messing and Office Spaces . . . . . | 70 F       |
| Working Spaces and Shops . . . . .                        | 60 F       |
| Hospital Spaces . . . . .                                 | 75 to 78 F |

## Machinery Spaces

The prime purpose of machinery space ventilation is to maintain a habitable temperature for the operating personnel. It is more practicable to use *spot cooling* of personnel at working areas than to attempt to obtain uniform ambient temperature. The permissible temperature rise (above outside) at working stations is usually 15 deg, while the overall temperature rise is usually between 30 and 50 deg.

These spaces must be exhausted adequately, preferably by mechanical means. Every attempt should be made to remove air at or close to the heat sources. The capacity of the mechanical exhaust systems should be greater than the supply, taking into consideration the expansion of the supply air, to insure an indraft through access openings to the space.

Heat is not required for machinery spaces, except for those fitted with

\* See Ventilation and Heating of Maritime Commission Ships, by J. W. Markert (*Heating and Ventilating* Feb. 1943, p. 333).

electrically operated equipment, which may remain inactive during periods while in port when heating to about 50 F will be required.

### Storerooms and Cargo Spaces

The ventilation provided for these spaces depends on the type of vessel, location of space, and nature of cargo.

Ventilation is required for all closed spaces. Even if ventilation is not necessary to preserve the stores or cargo, it is required to prevent the accumulation of toxic or combustible gases and odors. One air change in 15 to 30 min is common practice, except where inflammable liquids or proximity to hot spaces requires additional ventilation. Mechanical supply and natural exhaust are usually used. However, where inflammable gases may exist, natural supply and mechanical exhaust are provided.

Many ships are fitted with dehumidification facilities for eliminating damage to the dry cargo by preventing condensation and dampness. The dehumidification load consists of moisture removed from the ventilation air passed through the dehumidifier, plus the moisture on, or given off by, the cargo, packaging, dunnage, battens, and other materials in the ship's holds. The most severe outside condition requires a moisture removal of 90 grains (140-50) per pound of dry air, with 88 F cooling water. The largest cargo ships are provided with equipment for removing about 250 lb of water per hour.

The dehumidification systems generally utilize silica gel or lithium chloride with inhibitor. (See Chapter 38). In most cases central drying equipment is provided. On large passenger ships consideration is given to the use of two dehumidifying units, because the cargo-carrying spaces are usually concentrated at the extreme ends of the vessel. A simple duct system distributes the dry air to the hold supply ventilation system. These ventilation systems use outside air when weather conditions are favorable. Recirculation and dehumidification are used only when necessary, i.e., when the weather dew-point approaches or exceeds the temperature in the hold. Two control stations are generally provided, one in machinery space and one in chart or wheelhouse. These stations are arranged so that either may change the cargo conditioning system controls from use of outside air to use of conditioned air.

### AIR CONDITIONED SPACE TREATMENT FOR SHIPS

The application of air conditioning to new American passenger ships is well established. All passenger staterooms, except steerage and third class, are usually air conditioned. This includes staterooms for ship's personnel and offices within conditioned passenger areas. Third class staterooms are air conditioned on some ships, depending on the particular trade. Theaters, lounges, smoking rooms, beauty shops, barber shops and similar closed public spaces are usually air conditioned.

All messrooms, recreation rooms, officers' offices, crew's inboard rooms, and those having fixed portlights are usually air conditioned on passenger vessels. The treatment depends on the requirements of the operator and the proposed itinerary of the vessel.

### SHIP SYSTEMS AND CONTROLS

The types of comfort conditioning systems used to date generally have followed conventional lines, except for those serving staterooms, offices, and similar small spaces. Large public spaces are fitted with individual

systems which supply dehumidified and cooled air during the cooling cycle, and warm air during the heating cycle. In many cases these rooms are fitted with large glass windows and doors, and require direct radiation to offset the downdraft which would occur in cold weather. Finned-tube radiation running the full length of the glass area is commonly used for this purpose. Introduction of warm air at the sill, in lieu of direct radiation, is also used.

Systems serving most public spaces are designed to provide all outside air as long as the refrigeration load is less than the capacity of the cooling equipment. Many central systems are simplified by using 100 percent outside air all-year-round. The important problem in ship air conditioning concerns the treatment of the small spaces such as passenger staterooms, offices, and crew quarters. Low headroom, congested quarters, double berths, and unsymmetric arrangements make each space a problem in air distribution and treatment.

The simplest system used for small spaces consists of a central filter bank, supply fan, preheater, and cooling and dehumidifying coil. The preheater steam valve and cooling coil water valve are controlled in sequence by a duct thermostat, in the fan discharge, set to maintain a constant outlet air temperature. Zone reheaters are provided to take care of variations in heating loads. The reheater steam valve is controlled by a sub-master thermostat at the reheater outlet. Control of room temperature is obtained by operating manual dampers in the air supply to the space. A recirculation exhaust fan is frequently provided, and operates in conjunction with automatic dampers to utilize the maximum quantity of outside air consistent with capacity of the cooling coils.

One system utilizes the same central supply equipment and recirculation exhaust system as the one just described, except that zone reheaters are replaced by individual space hot water reheaters. Each reheater is provided with a control valve, controlled by room thermostat. Generally, a forced circulation single pipe hot water system is used. This system is generally used for staterooms and small spaces devoted to first and second class passengers. The average total air per person is about 60 cfm, and average outside air per person is about 18 cfm.

A third system, used to a limited extent, is similar to the system just described, except that each room is provided with an induction unit (floor type where possible) which reheats the primary air supply. Control of heating coil in the induction unit is the same as noted for the system described in the previous paragraph. The average primary air supply is about 40 cfm per person. Recirculation is not always used. The amount of induced air varies with unit design.

A fourth less common arrangement is similar, but makes use of hot water in the induction unit in winter and cold water in the induction unit in summer. Control of the valve on the unit is obtained by use of a summer-winter type thermostat. The unit is provided with drip pan and drain piping to remove condensation. No recirculation is used.

On cargo ships, tankers and vessels not carrying passengers or not having air conditioning, heating of crews' spaces and officers' staterooms is usually obtained through a central system having filters, preheaters and reheaters. A minimum temperature of air leaving the preheater is controlled by a duct thermostat. The reheater is controlled by a sub-master discharge-duct thermostat, reset by outside master control. Relationship between sub-master and master control (wherein discharge temperature is raised as

outdoor temperature drops); is set according to a schedule based on the ship's itinerary.

Duct work for all systems described is designed for conventional velocity. However, if power is available, and suitably strong duct construction and adequate sound absorbing facilities are provided, high velocity systems may be used.

## CHAPTER 49

## WATER SERVICES

Sizing Cold Water Supply Piping, Procedure for Sizing Cold Water Systems, Cooling Water Piping, Estimating Heating Load and Storage Capacity, Methods of Heating Water, Computing Heat Transfer Surface, Hot Water Supply Piping, Control of Service Water Temperature, Safety Devices, Solar Water Heaters, Domestic Hot Water by Heat Pump

PROPER design of the water distributing system in a building is necessary in order that the various fixtures may function properly. The amount of either hot or cold water used in any building is variable, depending on the type of structure, usage, occupancy, and time of day. It is necessary to provide piping, water heating, and storage facilities of sufficient capacity to meet the peak demand without wasteful excess in either piping or equivalent cost.

### SIZING COLD WATER SUPPLY PIPING

One of the important items that must be determined before any part of the water-piping system can be sized, is the probable rate of flow in any particular reach of piping. The rate of flow in the service line, risers, and main branches, however, will rarely be equal to the sum of the rates of flow of all connected fixtures. In fact, the probability that every fixture in a large group will be in use at the same time is so remote that it would be very poor engineering practice to design the piping to take care of such simultaneous flow.

The demand load in building water supply systems cannot be determined exactly and is not readily standardized. The two main problems to be considered are: (1) the satisfactory supply of water for a given fixture, and (2) the number of fixtures which may be assumed to be in use at the same time.

The minimum flow that will be satisfactory to the consumer depends greatly on the consumer, his standard of living, his professional needs, size of family, garden requirements, and similar factors. Depending on these factors, the per capita water consumption for domestic use usually varies between 20 and 80 gal per day. Experience indicates that the type of dwelling also has considerable influence on the water consumption.

In *apartment houses* the per capita daily water consumption is generally higher than in single-family houses. This is due to the use of a central metering system which is not conducive to the saving of water, and to the long hot water lines which cause high heat losses and an increase in the wasting of the cooled water. In designing water supply systems for apartment houses, a daily per capita water consumption of 50 gal may be considered a safe design figure.

Although a considerable number of *housing projects* have been developed throughout the United States, conclusive water consumption data have not yet been gathered. Nevertheless, it seems that the daily per capita water consumption in housing projects falls in between the consumption in apartment houses and that in single dwellings at the same geographical location.

TABLE 1. PROPER FLOW AND PRESSURE REQUIRED DURING FLOW FOR DIFFERENT FIXTURES

| FIXTURE                                 | FLOW PRESSURE <sup>a</sup> | FLOW gpm           |
|-----------------------------------------|----------------------------|--------------------|
| Ordinary basin faucet.....              | 8                          | 3.0                |
| Self-closing basin faucet.....          | 12                         | 2.5                |
| Sink faucet— $\frac{1}{2}$ in.....      | 10                         | 4.5                |
| Sink faucet— $\frac{1}{4}$ in.....      | 5                          | 4.5                |
| Bathtub faucet.....                     | 5                          | 6.0                |
| Laundry tub cock— $\frac{1}{4}$ in..... | 5                          | 5.0                |
| Shower.....                             | 12                         | 5.0                |
| Ball-cock for closet.....               | 15                         | 3.0                |
| Flush valve for closet.....             | 10-20                      | 15-40 <sup>b</sup> |
| Flush valve for urinal.....             | 15                         | 15.0               |
| Garden hose, 50 ft, and sill cock.....  | 30                         | 5.0                |

<sup>a</sup> Flow pressure is the pressure in the pipe at the entrance to the particular fixture considered.

<sup>b</sup> Wide range due to variation in design and type of flush-valve closets.

In general, a daily per capita water consumption of 40 gal can be used as a safe design figure for *housing projects*.

Table 1 gives the rate of flow desirable for many common types of fixtures, and the average pressure necessary to give this rate of flow. The pressure necessarily varies with fixture design; with some, a much greater pressure is necessary to give the same rate of flow than with others. In general, the lower the quality of the faucet the greater will be the pressure required.

In estimating the load, the rate of flow is frequently computed in *fixture units*. One *fixture unit* is equivalent to 7.5 gal per min. Table 2 gives the demand weights in terms of fixture units for different plumbing fixtures under several conditions of service, and Fig. 1 gives the estimated demand in gallons per minute corresponding to any total number of fixture units. Fig. 2 shows an enlargement of Fig. 1 for a range up to 250 fixture units.

TABLE 2. DEMAND WEIGHTS OF FIXTURES IN FIXTURE UNITS<sup>a</sup>

| FIXTURE OR GROUP <sup>b</sup> | OCCUPANCY                | TYPE OF SUPPLY CONTROL      | WEIGHT IN FIXTURE UNITS <sup>c</sup> |
|-------------------------------|--------------------------|-----------------------------|--------------------------------------|
| Water closet.....             | Public                   | Flush valve.....            | 10                                   |

<sup>a</sup> For supply outlets likely to impose continuous demands, estimate continuous supply separately and add to total demand for fixtures.

<sup>b</sup> For fixtures not listed, weights may be assumed by comparing the fixture to a listed one using water in similar quantities and at similar rates.

<sup>c</sup> The given weights are for total demand. For fixtures with both hot and cold water supplies, the weights for maximum separate demands may be taken as  $\frac{3}{4}$  the listed demand for the supply.

No. 1 for system predominantly for flush valves.

No. 2 for system predominantly for flush tanks.

FIG. 1. ESTIMATE CURVES FOR DEMAND LOAD

The estimated demand load for fixtures used intermittently on any supply pipe will be obtained by multiplying the number of each kind of fixture supplied through that pipe by its weight from Table 2, adding the products, and then referring to the appropriate curve of Figs. 1 or 2 to find the demand corresponding to the total fixture units. In using this method it should be noted that the demand for fixture or supply outlets other than those listed in the table of fixture units is not yet included in the estimate. The demands for outlets (such as hose connections, air conditioning apparatus, etc.) which are likely to impose continuous demand during times of heavy use of the weighted fixtures, should be estimated separately and added to the demand for fixtures used intermittently, in order to estimate the total demand.

So far, the information presented makes possible the determination of the *design rate of flow* in any particular section of piping. The next general step is to determine the *size of piping*.

As water flows through a pipe, the pressure continually decreases along the pipe, due to loss of energy from friction. The problem is then one of ascertaining the minimum pressure in the street main, and the minimum

FIG. 2. SECTION OF FIG. 1 ON ENLARGED SCALE

FIG. 3. FLOW CHART FOR COPPER TUBING

pressure required for the operation of the topmost fixture. (A pressure of 15 psi is ample for flush valves, but reference should be made to the manufacturers' requirements. A minimum of 8 psi should be allowed for other fixtures.) The pressure differential thus obtained will be available for overcoming pressure losses in the distributing system, and in overcoming the difference in elevation between the water main and the highest fixture.

The pressure loss, in pounds per square inch, caused by the difference in elevation between the street main and the highest fixture, may be obtained by multiplying the difference in elevation in feet by the conversion factor 0.43.

When water flows through a pipe, friction occurs as the result of the sliding of water particles past one another. If the pipe wall is rough, the roughness projections cause additional friction, owing to the development of increased turbulence in the flowing water. As the water flows along a uniform pipe, the pressure decreases as a result of a dissipation of

FIG. 4. FLOW CHART FOR FAIRLY ROUGH PIPE

energy arising from the internal friction set up by viscosity of the water. This loss in energy is shown by the loss of pressure. The pressure loss is proportional to the length of straight uniform pipes, and varies greatly with flow velocity, pipe diameter, roughness of pipe, and water temperature.

On the basis of inside surface conditions, pipes may be classified as smooth, fairly rough and rough, as follows:

**Smooth.** The pipe surface shows no perceptible roughness. Pipes made of copper, brass, or lead may usually be classified as smooth.

**Fairly Rough.** All ordinary pipes, such as wrought iron, galvanized iron, steel and cast-iron, after a few years of usage, may be called fairly rough.

**Rough.** Pipes that have deteriorated fairly rapidly for some 10 or 15 years after being laid, are classified as rough.

Figs. 3, 4 and 5 give the pipe friction losses corresponding to these three types of pipes for various nominal diameters for a water temperature of 50 F.<sup>1</sup> Example 1 will illustrate the use of the charts.

FIG. 5. FLOW CHART FOR ROUGH PIPE

**Example 1:** A  $2\frac{1}{2}$  in. fairly rough pipe supplies 100 gpm of water. Find the friction loss in head if the pipe length is 200 ft.

**Solution:** Enter Fig. 4 at 100 gpm, and move along this line until it intersects the  $2\frac{1}{2}$  in. diameter line. From this intersection point, move vertically down and read 4.5 psi friction loss per 100 ft of pipe length. Then the total friction loss will be  $2 \times 4.5 = 9$  psi.

The pressure losses in the distributing system will consist of the pressure losses in the piping itself, plus the pressure losses in the pipe fittings, valves and the water meter, if any. Estimated pressure losses for disc-type meters for various rates of flow are given in Fig. 6.

Flow limits for disc-type meters, which may be regarded as the limits of recommended ranges in capacities, are given in Table 3. For information on other types of meters, the manufacturers should be consulted.

Fig. 7 shows the variation of pressure loss with rate of flow for various types of faucets and cocks, based on experimental data obtained at the State University of Iowa.

The loss of pressure through any fitting or valve can be expressed in

FIG. 6. PRESSURE LOSSES IN WATER METERS

pounds per square inch for any given rate of flow. Experience has shown, however, that the simplest method of expressing losses in fittings and valves is to use the concept of an equivalent length of straight pipe. Thus it has been found, for example, that a 1 in., 90 deg elbow introduces a loss equivalent to 2.2 ft of straight 1 in. pipe. Therefore, for each 1 in., 90 deg elbow, 2.2 ft of 1 in. pipe are added to the total length of 1 in. pipe.

Estimated pressure losses for pipe fittings and valves in terms of equivalent pipe length are shown in Table 4.

Table 5 lists the equivalent lengths for various special types of apparatus and fittings. The loss in water meters varies considerably with the design even in meters of the same nominal size. The values given in Table 5 are ample for the well-known meters now on the market.

| 4           | 28 to 500                      | 7                        |
| 6           | 48 to 1,000                    | 12                       |

\* American Water Works Association Standards:

Registration. The registration on the meter dial shall indicate the quantity recorded to be not less than 98 percent nor more than 102 percent of the water actually passed through the meter while it is being tested at rates of flow within the specified limits herein under normal test flow limits: There shall be not less than 90 percent of the actual flow recorded when a test is made at the rate of flow set forth under minimum test flow.

The water demand for hose bibbs or other large demand fixtures taken off the building main is frequently the cause of inadequate water supply to the upper floor of a building. This condition may be prevented by sizing the distribution system so that the pressure drops from the street main to all fixtures are the same. It is good practice to maintain the building main of ample size (not less than 1 in. where possible) until all branches to hose bibbs have been connected. Where the street main pressure is excessive and a pressure reducing valve is used to prevent water hammer or excessive pressure at the fixtures, it is frequently desirable to connect hose bibbs ahead of the reducing valve.

The principles involved in sizing either up-feed or down-feed systems are the same. The principal difference in procedure is that in the down-feed system, the difference in elevation between the house tank and the fixtures provides the pressure required to overcome pipe friction.

#### Procedure for Sizing Cold Water Systems

The recommended procedure for sizing piping systems is outlined in following paragraphs 1 to 6, inclusive.

1. Draw a sketch of the main lines, risers, and branches, and indicate the fixtures to be served. Indicate the rate of flow of each fixture.

TABLE 4. ALLOWANCE IN EQUIVALENT LENGTH OF PIPE FOR FRICTION LOSS IN VALVES AND THREADED FITTINGS

| 6                             | 20                                             | 12                              | 30                       | 6                                           | 4                   | 165                  | 80                   |

2. Using Table 2, compute the demand weights of the fixtures in fixture units.
3. Determine the total demand in fixture units and, using Fig. 1 or Fig. 2, find the expected demand in gallons per minute.
4. Determine the equivalent length of pipe in the main lines, risers, and branches. Since the sizes of the pipes are not known, the exact equivalent length for various fittings, etc., cannot be made. Add the equivalent lengths, starting at the street main and proceeding along the service line, the main line in the building, and up the riser to the top fixture of the group served.
5. Determine the average minimum pressure in the street main and the minimum pressure required for the operation of the topmost fixture. This latter pressure should be 8 to 15 psi.
6. Calculate, by means of Equation 1, the approximate design value of the average pressure drop per 100 ft of pipe in the equivalent length determined in paragraph 4.

$$p = [P - 0.43H - 10] \frac{100}{L} \quad (1)$$

where

$p$  = average pressure loss per 100 ft of equivalent length of pipe, psi.  
 $P$  = pressure in street main, psig.

TABLE 5. EQUIVALENT LENGTHS OF IRON PIPE TO GIVE SAME LOSS AS SPECIAL FITTINGS AND APPARATUS

| FITTING APPARATUS                                 | NOMINAL DIAMETER OF PIPE—INCHES |        |    |       |
|---------------------------------------------------|---------------------------------|--------|----|-------|
|                                                   | 1/2                             | 3/4    | 1  | 1 1/4 |

| 1 1/4 in. with 1 in. connections                  | —                               | 4.4    | 14 | 54    |
| Water softener                                    | —                               | 50-200 | —  | —     |

$H$  = height of highest fixture above street main, feet.  
 $L$  = equivalent length determined in paragraph 4, feet.

If the system is of the down-feed supply from a gravity tank, the height of water in the tank, converted to pounds per square inch by multiplying by 0.43, replaces the street main pressure, and the term  $0.43 H$  in Equation 1 is added instead of subtracted in calculating the term  $p$ . In this case,  $H$  will be the vertical distance of the fixture below the bottom of the tank.

7. From the expected rate of flow, determined as in paragraph 3, and the value of  $p$ , calculated as in paragraph 6, choose the sizes of pipe from Figs. 3, 4 or 5.

**Example 2:** Assume a minimum street main pressure of 55 psig; a height of topmost fixture above street main of 50 ft; a developed pipe length from water main to highest fixture of 100 ft; a total load on the system of 50 fixture units; and that the water closets are flush-valve operated. Find the required size of supply main.

**Solution:** From Fig. 2 the estimated peak demand is found to be 51 gpm. From Table 3 it is evident that several sizes of meters would adequately measure this flow. For a trial computation choose the 1 1/2 in. meter. From Fig. 6 the pressure drop through a 1 1/2 in. disc-type meter for a flow of 51 gpm is found to be 6.5 psi.

Then the pressure drop available for overcoming friction in pipes and fittings is  $55 - (15 + 50 \times 0.43 + 6.5) = 12$  psi.

At this point it is necessary to make some estimate of the equivalent pipe length of the fittings on the direct line from the street main to the highest fixture. The exact equivalent length of the various fittings cannot now be determined since the pipe sizes of the building main, riser, and branch leading to the highest fixture are not known as yet, but a first approximation is necessary in order to make a tentative selection of pipe sizes. If the computed pipe sizes differ from those used in determining the equivalent length of pipe fittings, a recalculation will be necessary, using

TABLE 6. COMPUTATION OF BRANCH SIZE IN EXAMPLE 2

| FIXTURES NO. AND KIND | FIXTURE UNITS (FROM TABLE 2 AND NOTE C) | DEMAND (FROM FIG. 2) GPM | PIPE SIZE (FROM FIG. 4) IN. |
|-----------------------|-----------------------------------------|--------------------------|-----------------------------|
| 3 flush valves.....   | 3 x 6 = 18                              |                          |                             |
| 2 bath tubs.....      | $\frac{1}{2}$ (2 x 2) = 3               |                          |                             |
| 3 lavatories.....     | $\frac{1}{4}$ (3 x 1) = 2.25            |                          |                             |
| Total.....            | 23.25                                   | 38                       | 1 $\frac{1}{2}$             |

the computed pipe sizes for the fittings. For the purposes of this example assume that the total equivalent length of the pipe fittings is 50 ft.

Then the permissible pressure loss per 100 ft of equivalent pipe is  $12 \times 100 / (100 + 50) = 8$  psi.

Assuming that the corrosive and caking properties of the water are such that Fig. 4 for fairly rough pipe is applicable, a 2 in. building main will be adequate.

The sizing of the *branches* of the building main, the *risers*, and *fixture branches* follow the principles outlined. For example, assume that one of the branches of the building main carries the cold water supply for 3 water closets, 2 bath tubs, and 3 lavatories. Using the permissible pressure loss of 8 psi per 100 ft, the size of branch determined from Table 2 and Figs. 1 and 4 is found to be 1 $\frac{1}{2}$  in. Items entering the computation of pipe size are given in Table 6.

### COOLING WATER PIPING

Water is very frequently used in refrigeration systems, cooling towers and other similar installations. In designing the piping system of such installations, the principles of hydraulics, as already outlined, are employed. Nevertheless, there are several practical items having particular application to cooling installations. They are outlined in the following paragraphs, and it is important that the designer be familiar with them.

In choosing pipe material, the problem of corrosion should be kept in mind to prevent defects in the system. If the water does not have drastic corrosion characteristics, wrought iron or steel piping may be used; otherwise, galvanized steel piping may be preferred. If sea water is used as the circulating medium, it is advisable to use alloys such as admiralty metal in pipe and tubing. In refrigeration condensers where water is the cooling medium, iron pipe is commonly employed.

In regard to assembly, cast-iron flanges or welded joints are to be preferred to screwed joints wherever possible.

Valves used in circulating systems may be of the globe, gate, or angle

TABLE 7. PIPE SIZES FOR COOLING TOWERS<sup>1</sup>

| RATED TONS OF REFRIG. | COOLING WATER GPM | PIPE SIZES (NOMINAL INCHES) |                   |
|-----------------------|-------------------|-----------------------------|-------------------|
|                       |                   | Inlet to Tower              | Outlet from Tower |
| 3 to 5                | 10 to 18          | 1 $\frac{1}{2}$             | 1 $\frac{1}{2}$   |
| 7 to 15               | 20 to 45          | 2                           | 2                 |
| 20                    | 65                | 2 $\frac{1}{2}$             | 3                 |
| 25                    | 86                | 2 $\frac{1}{2}$             | 4                 |
| 35                    | 115               | 3                           | 4                 |
| 50                    | 170               | 3                           | 4                 |
| 75                    | 225               | 5                           | 6                 |
| 100                   | 300               | 5                           | 6                 |
| 150                   | 450               | 5                           | 8                 |
| 200                   | 600               | 6                           | 8                 |
| 250                   | 750               | 8                           | 8                 |

types. If water is the circulating medium, brass valves are usually used. However, if the circulating medium is an electrolyte, such as brine, then it is preferable to use valves made of the same material as the piping itself.

The friction loss in the piping may be determined from Fig. 4 for fairly rough pipe. If the coolant is brine, a correction for the proper density must be made. Experience indicates that in sizing piping for cooling systems, a pressure drop of the order of 2 to 3 psi per 100 ft of pipe length, and a fluid velocity of 3 to 8 fps, yield most economical results.

In the case of cooling towers, the amount of circulating water is about 3 gpm per ton of refrigeration, when based on a design wet-bulb tempera-

ture of about 76 F. Table 7 gives pipe sizes frequently used for various sizes of cooling towers, assuming a hot-water temperature of 95 F and a cold-water temperature of 85 F.<sup>2</sup>

### ESTIMATING HEATING LOAD AND STORAGE CAPACITY

The maximum daily and the maximum hourly hot water demand form the basis for the selection of the heater and the storage tank.

In general, two thirds of the total daily water consumption is hot water. For residential dwellings, a design value of about 20 to 30 gal per capita per day may be assumed, but it should be remembered that the hot water used will depend on the number of rooms and the number of bathrooms in

any house or apartment. Table 8 gives estimates of the maximum hot water requirements in 24 hr in various types of buildings.

In estimating the size of hot water storage tank required, and the heating capacity to be provided, either from the boiler or from an independent domestic hot water heater, it is necessary to know the total quantity of water to be heated per day, and the maximum amount which will be used in any one hour, as well as the duration of the peak load.

In cases where the requirements for hot water are reasonably uniform, as in residences, apartment buildings, hotels, and the like, smaller storage capacity is required than in the case of factories, schools and office buildings, where practically the entire day's usage of hot water occurs during a very short period. Correspondingly, the heating capacity must be proportionately greater with uniform usage of hot water than with intermittent usage, where there may be several hours between peak demands during which the water in the storage tank can be brought up to tempera-

TABLE 9. ESTIMATED HOT WATER DEMAND CHARACTERISTICS FOR VARIOUS TYPES OF BUILDINGS

| TYPE OF BUILDING                     | HOT WATER REQUIRED         | MAX. HOURLY DEMAND IN RELATION TO DAY'S USE | DURATION OF PEAK LOAD HOURS | STORAGE CAPACITY IN RELATION TO DAY'S USE | HEATING CAPACITY IN RELATION TO DAY'S USE |
|--------------------------------------|----------------------------|---------------------------------------------|-----------------------------|-------------------------------------------|-------------------------------------------|
| Residences, apartments, hotels, etc. | 40 gal per person per day* | 1/7                                         | 4                           | 1/5                                       | 1/7                                       |
| Office buildings                     | 2 gal per person per day*  | 1/5                                         | 2                           | 1/5                                       | 1/5                                       |
| Factory buildings                    | 5 gal per person per day*  | 1/3                                         | 1                           | 2/5                                       | 1/8                                       |
| Restaurants                          |                            |                                             |                             | 1/10                                      | 1/10                                      |
| Restaurants 3 meals per day          |                            | 1/10                                        | 8                           | 1/5                                       | 1/10                                      |
| Restaurants 1 meal per day           |                            | 1/5                                         | 2                           | 2/5                                       | 1/6                                       |

\* At 140 F

ture. As a general rule, it is desirable to have a large storage capacity in order that the heating capacity, and consequently the size of the heater, or the load on the heating boiler, may be as small as possible.

In estimating the hot water which can be drawn from a storage tank, it should be borne in mind that only about 75 percent of the volume of the tank is available, since, by the time this quantity has been drawn off, the incoming cold water has cooled the remainder down to a point where it can no longer be considered hot water.

Where steam from the heating boiler is used to heat domestic hot water, the computed load on the boiler should be increased by 4 sq ft EDR (equivalent direct radiation) for every gallon of water per hour heated through a 100 deg rise. The actual requirement is  $(100 \times 8.33)/240 = 3.48$  sq ft per gal heated 100 deg. The value of 4 allows for transmission losses.

There are two methods in common use for estimating the hot water requirements of a building: (1) by the number of people, and (2) by the number of plumbing fixtures installed. Where the number of people to be served can be reasonably estimated, the data in Table 9 may be used.

**Example 3:** Determine the heater size and storage tank capacity for a residence housing five people.

**Solution:** From Table 9, a residence housing five people would have a daily re-

quirement of  $5 \times 40 = 200$  gal. per day, and a maximum hourly demand of  $200 \times 1/7 = 28.5$  gal. The heater should have a storage capacity of  $200 \times 1/5 = 40$  gal, and a heating capacity of  $200 \times 1/7 = 28.5$  gal per hr.

The conditions given in *Example 3* may be cited as average. It is possible to vary the storage and heating capacity by increasing and decreasing one over the other. Such a condition is illustrated in *Example 4*.

**Example 4:** Determine the required heater capacity for an apartment housing 200 people, if the storage tank has a capacity of 1000 gal. What heater capacity will be required if the storage tank is changed to 2500 gal capacity?

**Solution:** Assume an apartment house housing 200 people. From the data in Table 9: Daily requirements =  $200 \times 40 = 8000$  gal. Maximum hours demand =  $8000 \times 1/7 = 1140$  gal. Duration of peak load = 4 hr. Water required for 4-hr peak =  $4 \times 1140 = 4560$ .

If a 1000 gal storage tank is used, hot water available from the tank =  $1000 \times 0.75 = 750$ . Water to be heated in 4 hr =  $4560 - 750 = 3710$  gal. Heating capacity per hour =  $3710/4 = 930$  gal.

If instead of a 1000 gal tank, a 2500 gal tank had been installed, the required heating capacity per hour would be  $\frac{4560 - (2500 \times 0.75)}{4} = 671$  gal.

Table 10 may be used to determine the size of water heating equipment from the number of fixtures. To obtain the *probable maximum demand*, multiply the total quantity for the fixtures by the *demand factor* in line 11. The heater or coil should have a water heating capacity equal to this *probable maximum demand*. The storage tank should have a capacity equal to the *probable maximum demand* multiplied by the storage capacity factor in line 12. *Example 5* will illustrate the procedure.

**Example 5:** Determination of heater and storage tank size for an apartment building from number of fixtures.

|                       |               |                 |
|-----------------------|---------------|-----------------|
| 60 lavatories.....    | $\times 2 =$  | 120 gal per hr  |
| 30 bathtubs.....      | $\times 20 =$ | 600 gal per hr  |
| 30 showers.....       | $\times 75 =$ | 2250 gal per hr |
| 60 kitchen sinks..... | $\times 10 =$ | 600 gal per hr  |
| 15 laundry tubs.....  | $\times 20 =$ | 300 gal per hr  |

|                              |                      |                   |
|------------------------------|----------------------|-------------------|
| Possible maximum demand..... | =                    | 3870 gal per hr   |
| Probable maximum demand..... | = $3870 \times 0.30$ | = 1161 gal per hr |
| Heater or coil capacity..... | =                    | 1161 gal per hr   |
| Storage tank capacity.....   | = $1161 \times 1.25$ | = 1450 gal        |

Although, in private dwellings a water temperature of 140 F is reasonable for dishwashing, in public places sanitation regulations call for 180 F water. Most of the dishwashing machines now available on the market require 180 F water. The amount of 180 F water needed in restaurants per day may be determined according to the method outlined by the *American Gas Association*,<sup>3</sup> in the following paragraphs:

1. Multiply the number of meals per day by the number of dishes per meal (6 for low-price restaurants, 8 for medium-price restaurants, and 10 for high-price restaurants) to determine the total number of dishes per day.
2. Divide the total number of dishes per day, as determined by method in paragraph 1, by the average number of dishes per rack to find the number of racks per day.
3. Multiply the number of racks per day by the gallons of 180 F water (using 1.5 for single tank machines and 0.75 for two tank machines). This product will give the gallons of 180 F water per day for rinse sprays.
4. Multiply the number of meal periods per day (one, two or three) by the dish-

washing tank capacity in gallons, giving the gallons of 180 F water per day necessary to fill the tanks.

5. Add values from paragraphs 3 and 4 to obtain the total number of gallons of 180 F water required per day.

For purposes other than dishwashing, a considerable amount of 140 F water is also used. To find the daily 140 F water requirement in a restaurant, multiply the total number of meals served per day by the gallons of 140 F water per meal. Low priced restaurants on the average utilize 0.9 gal of 140 F water per meal, while medium- and high-price restaurants use 1.2 and 1.5 gal per meal, respectively.<sup>a</sup>

### METHODS OF HEATING WATER

Hot water may be heated either by the direct combustion of fuel, by an intermediate carrier such as steam or hot water, or by electrically heated

<sup>a</sup> Ratio of storage tank capacity to probable maximum demand per hour.

surfaces. The simplest method is to have the fire on one side of a metal barrier and water on the other. In such a method, if the surfaces for transferring heat are small, and if the water carries a heavy proportion of precipitable salts, the water passages may soon become clogged with resultant cracking or burning of the surface. A familiar example of such trouble is the water back in the kitchen stove, or the pipe coil inserted into the firebox of a warm air furnace or small boiler. The critical water temperature at which the lime, magnesia, etc., collect on hot surfaces, varies with the character and proportions of the solids, but generally such deposits are not a serious trouble below 140 F.

Coal-burning, direct-fired water heaters may be constructed of cored cast-iron sections, or of steel. In some cases the external appearance of the cast-iron sections is the same as in heating boilers, but internally the cores are changed to enable the sections to withstand the city water pressure. In small capacity water heaters, efficiency is not considered so important as low first cost and ability to maintain a fire at a low rate of combustion, and consequently, such heaters are generally built with a dry

section or fire-brick lining at the base of the fire-pot to prevent too much chilling of the fuel. While mud and scale will eventually clog the waterways of any direct-fired heater, increased life may be obtained by providing a three-way cock in the return line between the heater and the bottom of the storage tank, so that water can be blown through the heater or the tank separately, at full line pressure, to clean out loose sediment. Clean-out openings in the bottom of the heater are advantageous, if used by operators of water heaters for periodic cleaning out of sediment.

Oil-burning, direct-fired water heaters usually are of steel, and operate with higher flame temperature and better efficiency than commensurate sized coal-burning heaters. As they have the same tendency as coal boilers to accumulate lime deposits, the water passages should be large in cross-section and accessible for periodic cleaning.

Gas-burning, direct-fired water heaters may be of the instantaneous or storage type. Instantaneous heaters are generally constructed of spiral water tubes of copper, around which the products of combustion circulate upward from high capacity burners. Storage-type heaters may include

FIG. 8. INDIRECT WATER HEATER

in one unit an insulated storage tank, a combustion chamber, flues, burner equipment, and controls, or may consist of a separate storage tank and external direct-fired water heater, which may be a so-called *side-arm* heater for small capacity, or a gas-fired boiler for larger capacity. Gas boilers used for direct hot water supply must be able to withstand the city water operating pressure. While direct-fired gas heaters are used generally for residences and small installations of 100 gal storage capacity or less, indirect heaters are recommended for larger installations.

Chimney connections for all direct-fired, fuel burning water heaters are an important consideration. Refer to Chapter 17.

Electric water heaters for domestic hot water supply are described in the section Heating Domestic Water by Electricity in Chapter 42.

In the indirect method, either steam or hot water is used for heating the water. With steam, the water to be heated is preferably circulated around the outside of the steam tubes which are submerged within a tank. A typical indirect heater using steam is shown in Fig. 8. The coils usually are of copper, and are U-shaped to permit expansion and contraction. The shell may be of steel, with a protective coating or with a special inside protective lining, or may be of copper or copper alloy. Where straight heating tubes are used, one end of the tube is usually expanded into a floating head to take care of expansion. The coils should be capable of

FIG. 9. INDIRECT WATER HEATER MOUNTED ON SIDE OF BOILER

easy withdrawal for inspection and for removal of scale. Instead of steam, the heating medium may also be hot water inside the tubes.

Another method of transferring heat from a heating boiler to the domestic water is illustrated in Fig. 9. The water heater is generally a cast-iron shell within which there is located a spiral copper coil. Hot water from the boiler circulates inside the shell and around the coil, and returns to the boiler, while domestic water from the storage tank circulates inside the coil. The storage tank should be installed with the bottom of the tank as far above the boiler as possible. Horizontal storage tanks of less than 18 or 20 in. diameter are not recommended because of the difficulty of preventing the hot and cold water from mixing, and especially is this an important consideration when large quantities of water are withdrawn. In Fig. 10 the heat transfer surface is placed inside the boiler instead of in a separate vessel, but otherwise the operation is similar to that of Fig. 9. This arrangement with vertical tank is commonly used for small domestic installations.

Sometimes the heating element is located inside of the larger type fire tube boilers and small residential boilers. In this case the heat transfer surface is in the form of a number of straight copper tubes, with rear U-bends or a floating head, inserted through a special opening in the boiler. While the coil may be placed in the steam space above the water line of a steam boiler, it is usually placed below the water line. Long coils of small diameter tubing, immersed in the water, are widely used without storage tanks. The rate of flow through the coil is limited by the friction loss in the coil,

FIG. 10. INDIRECT WATER HEATER PLACED IN BOILER

and by fittings and restrictions, so that the water attains the desired temperature in one passage through the coil. This arrangement is frequently found in oil burner installations where the heating boiler, either steam or hot water type, is used to supply hot water during the summer. A thermostatic three-way mixing valve is frequently used to maintain a uniform temperature of the hot water supply to the plumbing fixtures.

In order to reduce clogging by precipitated solids, water heating plants sometimes develop steam in a closed circuit, transferring the heat through a tubular heater to the domestic water. The water in the primary heater, exposed to the high temperature of the fire, is repeatedly used and hence, has no appreciable tendency to deposit scale, while the domestic water, heated by steam at a much lower temperature than that of the fire, also exhibits a much reduced tendency to precipitate dissolved salts. Water characteristics, the effect of impurities and means of improving the quality of the water are important items, as brought out in Chapter 43.

### COMPUTING HEAT TRANSFER SURFACE

The area of the inside surface of a heating coil may be determined from Equation 2.

$$A = \frac{Q \times 8.33(t_2 - t_1)}{U \times t_m} \quad (2)$$

where

$A$  = surface area of coil, square feet.

$Q$  = quantity of water heated, gallons per hour.

$t_2$  = hot water outlet temperature, Fahrenheit.

$t_1$  = cold water inlet temperature, Fahrenheit.

$U$  = coefficient of heat transmission, Btu per (hour) (square foot) (Fahrenheit degree logarithmic mean temperature difference).

For copper or brass coils  $U = 240$  (steam) and 100 (hot water).

For iron coils  $U = 160$  (steam) and 67 (hot water).

$t_m$  = logarithmic mean of the difference between the temperature of the heating medium and the average water-temperature, and is approximately:

$$t_m = \frac{(t_2 - t_1)}{2}$$

$t_m$  = temperature of the heating medium, Fahrenheit.

Equation 2 may be used to check the heating coil ratings under temperatures other than those stated in the manufacturer's published ratings.

**Example 6:** What area of copper transfer surface will be required to heat 70 gal of water per hour from 40 to 180 F with boiler water at 220 F?

**Solution:**

$$t_m = \left[ 220 - \frac{(180 + 40)}{2} \right] = 110 \quad A = \frac{70 \times 8.33(180 - 40)}{100 \times 110} = 7.42 \text{ sq ft}$$

For instantaneous submerged heaters, the surface required will depend upon (1) the velocity of water in the tubes, (2) the boiler water temperature, (3) the inlet water temperature, (4) the outlet water temperature, (5) the cleanliness of the coil surface, and (6) the condition of the boiler water surrounding the coil. If the heater is located in the water of an ac-

tively steaming part of a boiler, the heat transfer may be twice as great as would be obtained if the water surrounding the coil were circulating slowly. Ratings of instantaneous water heating coils will therefore vary greatly, depending upon the assumptions made regarding the conditions of operation. The values of the coefficient of heat transmission for instantaneous heaters, shown in Table 11, are conservative.

For a coil in which heat is transferred from steam to water, the value of  $U = 300 \sqrt{v}$  may safely be used ( $v$  = velocity of water in feet per second).

The rate of heat transfer, between steam or water as the carrier, and the domestic water, is influenced by the rate of movement of both the carrier and the water which receives the heat. For this reason, where the transfer occurs from heating system water to domestic water, it is good practice to install a circulating pump to insure rapid movement of the boiler water.

In view of the high condensation rates obtained when steam is used with gravity circulation from the boiler, as when there is a sudden demand followed by an inflow of cold water, the bottom of a steam heating transfer element always should be at least 30 in. above the boiler water line, and the steam and condensate return pipes should be of liberal size. Otherwise,

TABLE 11. COEFFICIENT OF HEAT TRANSFER OF INSTANTANEOUS WATER HEATERS  
 $U = \text{Btu per (hr) (sq ft) (Fahrenheit degree logarithmic mean temperature difference)}$

|                               |     |     |     |
|-------------------------------|-----|-----|-----|
| Boiler water temperature..... | 210 | 200 | 180 |
| $U$ .....                     | 225 | 175 | 150 |

water hammer and reduced capacity may result, due to imperfect drainage of condensate.

When connecting a transfer-type hot water heater below the waterline of a cast-iron steam boiler having vertical sections, there should be a separate tapping for water circulation into every section of the boiler, as shown in Fig. 9, unless the boiler has large top nipple ports providing inter-sectional circulation. If the top nipples are entirely within the boiler steam space, no internal circulation occurs between sections. Steaming may then occur in the boiler sections not connected to the heater and, further, the unconnected sections will not deliver any heat to the water heater.

### HOT WATER SUPPLY PIPING

It is common practice to provide circulating piping in all hot water supply systems in which it is desirable to have hot water available continuously at the fixtures. In average-sized and small residences and systems, in which the piping from the heater to the fixtures is short, return circulating piping is generally omitted in order to reduce installation cost, and to reduce heat loss from the piping, particularly during periods of no water demand.

The hot water supply may be distributed by either an up-feed or down-feed piping system. Three common methods of arranging the circulating lines are shown in Fig. 11. Although the diagrams apply to multi-story buildings, the arrangements (a) and (b) are sometimes used in residential designs.

A check valve should be provided in the run-out from each return riser to prevent temporary reversal of flow in the piping when a faucet is open. Proper air venting of a circulating system is extremely important, particularly if gravity circulation is employed. In Fig. 11 (a) and (b), this is ac-

complished by connecting the circulating line below the top fixture supply. With this arrangement, air is eliminated from the system each time the top fixture is opened.

Where an overhead supply main is located above the highest fixture as in Fig. 11 (c), an automatic float type air vent is installed at the highest point of the system, or a fixture branch is connected to the top of the main where air venting is desired, and then dropped to the fixture outlet.

It is sometimes necessary to make an allowance for pressure drop through the heater when sizing hot water lines, particularly where instantaneous hot water heaters are used and the available pressure is low.

The principles involved in the sizing of the hot water supply pipes are the same as those for the sizing of cold water supply lines. For small and medium sized installations a  $\frac{3}{4}$ -in. hot water return will be ample. For larger installations, the size of the hot water return may be computed from considerations of the heat losses in the hot water piping.<sup>4</sup> A throttling

FIG. 11. METHODS OF ARRANGING HOT WATER CIRCULATION LINES

valve should be placed in the hot water return pipe so that the rate of circulation may be adjusted.

Where the hot water piping system is exceedingly long, a water circulator is frequently installed and controlled from an immersion thermostat (in the return line) set to start and stop the pump over approximately a 20 F deg temperature range.

### CONTROL OF SERVICE WATER TEMPERATURE

Coal-fired boilers are usually controlled by an immersion thermostat (located in the heated water) which opens or closes draft dampers at the boiler to adjust the rate of fuel combustion. With oil or gas-fired boilers, the immersion thermostat controls the oil burner or the automatic gas valve. The gas pilot flame usually burns continuously. With electric heaters, the immersion thermostat operates a switch on the source of energy.

When steam or hot water is the medium for heating the water in the tank, an immersion thermostat is used to control a valve in the steam or hot water supply line. In small residence installations, using water as the carrier, a combined immersion thermostat and butterfly valve in one simple

fitting may be installed in the transmitting circuit to prevent over-heating of the service water.

In residences heated by pump circulated hot water, the house temperature is controlled by operating the circulating pump intermittently, while domestic hot water is warmed by transfer from the house boiler, independent of the pump operation. The domestic water is heated from the heating boiler the year 'round. Under such an arrangement, to prevent overheating the house by thermal circulation when the pump is not running, it is usual to insert a weighted check-valve in the house heating main so that no circulation to the house heating system can occur unless the pump operates. In summer the fire may be controlled to maintain a boiler water temperature lower than when heating, and generally about 20 F warmer than that desired in the domestic hot water system.

The immersion thermostat in a hot water storage tank should be located no higher than the center of the tank, and possibly should be even closer to the bottom, since water in a tank stratifies proportionally to the temperature. When hot water is removed, the cold water entering to replace it quickly reduces the temperature in the lower parts of the tank.

### SAFETY DEVICES FOR HOT WATER SUPPLY SYSTEMS

There are still numerous plumbing codes which do not have regulations for the prevention of hot water storage tank explosions.

An ordinary storage tank is under certain water pressure, depending on the static pressure in the system. When the water in the tank is heated by circulation through an external heater, or by heating units in the tank, it gradually expands. For instance, if the entire contents of a 30-gal storage tank are heated from 70 F to 160 F, there will be an increase in volume of about one-half gallon. If the tank is connected to some supply without any intervening check valve, the increase in volume causes part of the water to be pushed back into the supply line. If the hot water reaches the water meter, it may ruin the composition discs.

If back-flow cannot occur, as for example, due to the use of a check-valve or a pressure-reduction valve in the line, or because of temporary shut-off of the cold-water line, the pressure in the tank rises as heating continues. Such a pressure rise, if the heating continues for any length of time, may result in rupturing of the tank.

If the tank water is not confined, continued heating would, of course, cause no increase in pressure beyond ordinary line pressure. However, the temperature would continue to increase. If this should happen at elevated temperatures, the flashing of the water into steam might cause a serious tank explosion.

In order to guard against the development of excessive pressure inside a hot water storage tank (owing to the thermal expansion of the water), it is customary to install a spring-loaded pressure-relief valve which is set to open at a pressure about 20 psi higher than the normal line pressure.

The amount of water discharged by any pressure-relief device is usually quite small, since it takes only a small quantity of water to relieve any pressure rise due to the thermal expansion of the water. The rate of discharge should be such as to limit the pressure rise for any given heat input to 10 percent of the pressure at which the valve is set to open. For any given installation, the discharging capacity should be in excess of the water to be discharged by the heater. The heater discharge  $Q_m$  in gallons per minute may be computed by Equation 3:

$$Q_m = 0.00005b$$

(3)

where  $b$  is the heat input of heater in Btu per minute.

To prevent danger of overheating, temperature-relief devices should be used. One type of such a device has a fusible plug of metal which melts at about 212 F. The hot water then runs from the opening until the device is serviced. A better type of relief device is one which incorporates a bellows or bimetallic disc, which opens at a temperature of 210 F and closes when the temperature drops to approximately 160 F.

Another type of safety device is a fuel cutoff switch or valve in which a fusible plug is melted by excessive water temperature. The fuel supply is cut off until the fusible plug is replaced.

FIG. 12. SOLAR HEATER TANK CONNECTIONS

FIG. 13. SOLAR HEATING COIL INCLINATION

The capacity of temperature relief devices may be calculated by Equation 4:

$$Q_m = 0.0008b$$

(4)

where  $Q_m$  and  $b$  denote the same quantities as in Equation 3.

Pressure relief valves should be installed in the cold water line near the tank out of contact with the hot water in order to prevent excessive corrosion and lime deposit on the valve seat. Temperature relief valves, in general, must be installed at the point of maximum water temperature.

### SOLAR WATER HEATERS

Solar heaters utilize the energy of the sun for heating water. The successful operation of such heaters requires the availability of sunshine practically every day in the year, which has limited their use to Florida and the southern portions of California. When supplemented with some other means of gas, coal, or oil water heating, solar heaters may be used in climates where sunshine may be more or less intermittent. They have been used in summer homes as far north as Chicago. When properly installed and proportioned, solar water heaters render satisfactory service, especially in climates where the outside temperatures are high and extremely hot water is not necessarily desirable. Such installations consist essentially of a storage tank, heating coil, and hot box. The coil is installed in the hot box, and is arranged to circulate water to and from the storage tank. The advantage in the use of this type of heater is the fact that it

requires no fuel. The same materials should be used for the coil, circulation lines, and tank. A copper coil is more efficient in absorbing heat in the box, but galvanized iron or steel may be substituted, depending on the local water conditions, cost, and other considerations.

The storage tank must be able to store sufficient heated water for the night period of about 16 hr when the coil is not functioning, or is operating under such poor sun conditions as to make its heating effect negligible. Due to the fact that the *no sun* period includes the night period when little or no hot water is used, an available storage of 50 percent of the average daily usage is considered adequate. Since about 25 percent of stored hot water cannot be drawn out of a storage tank before the incoming cold water reduces the temperature of all of the water in the tank to an unsatisfactory point for usage, the equation for calculating the storage capacity of the tank becomes:

$$S = \frac{Q_d \times 0.50}{0.75} = 0.666Q_d \quad (5)$$

where

$S$  = storage capacity of tank, gallons.  $Q_d$  = average daily usage, gallons.

Thus, for a family of four persons using an average of 40 gal of hot water per (person) (day), the size of the tank would be 4 persons  $\times$  40 gal  $\times$  0.666 or 106 gal, and the nearest standard size of tank would be used. The tank should be well insulated to prevent undue loss of heat during the 16-hour period when the coil is inoperative, and it should be located as high as possible in the building (under the peak of the roof if such exists) so as to secure a maximum circulation head from the coil. The hot water supply line to the house, as shown in Fig. 12, is connected to the top of the tank and serves to vent the air from the tank through the hot water faucets as fast as it accumulates.

The coil should be of the return-bend type (square or slightly rectangular in form), and should have the pipes running east and west, with the coil on the south side of the building where it can receive the full sun effect all day long without shadows from the building itself, or from the adjacent obstructions such as trees or other structures. The coil should be placed as low as possible in relation to the storage tank level, such as on a porch roof, the roof of a one-story extension or, if necessary, even on the ground. Both the coil and the circulation lines should be designed to facilitate the circulation flow as much as possible, using long radius copper fittings or recessed galvanized iron fittings to match the materials of the coil, circulation lines, and tank. The coil should be inclined, as shown in Fig. 13, so that the north end is raised above the south end to secure an angle with the horizontal of about 53 deg. This will result in the inlet end of the coil being on the south side (or bottom), and the outlet end being on the north side (or top). This will satisfy conditions along the 30-deg N latitude, which includes the portions of Florida and Southern California where these heaters are most frequently used.

The hot box is usually constructed of wood on the four sides and bottom, and is insulated. Glass sash are placed over the top of the box, and the box should be constructed as air-tight as possible. The interior surfaces should be painted white to reflect the heat, while the coil should be painted black to absorb the heat. The box need not be deeper than necessary to house the coil and to protect it from the weather.

\* Sun Effect and the Design of Solar Heaters, by H. L. Alt (A.S.H.V.E. TRANSACTIONS, Vol. 41, 1935, p. 131).

The addition, on the bottom of the box, of a light gage copper plate to which the pipe of the coil is soldered for good metallic contact, will add to the amount of heat received by the coil, due to the fact that this plate will receive all of the sun's rays which fail to directly strike the coil. The heat from this source is transmitted to the coil through the plate rather than from the heated air surrounding the coil. Otherwise, only part of the heat enters the coil, the balance being transmitted through the glass.

Design data given in Table 12 may be used with judgment in selecting the size of solar heater coil and box for a particular application. These data are based on consumptions of 30 and 40 gal of hot water per day per person.

### DOMESTIC HOT WATER BY HEAT PUMP

Hot water may suitably be obtained by using a heat pump installation. The hot water heater may be either a heat exchanger installed just ahead of the compressor of a heat pump installation, or may be a self-contained domestic-water heat pump.

Various designs of self-contained domestic water heat pumps are available, and one particular arrangement is shown in Fig. 14.

Hot water heating by means of a heat pump is not yet advisable where

FIG. 14. HEAT PUMP ARRANGEMENT FOR HOT WATER SUPPLY

high water temperatures are desired. This is due to the fact that higher water outlet temperatures result in lower coefficients of performance.

For coefficients of performance of 4 or higher, the heat pump water heater may be more economical to operate than a conventional water heater.

Although the first cost of domestic hot water heat pumps is somewhat high, they have the advantages of eliminating products of combustion, odors and soot, and not needing a chimney. A further advantage is that they may be used for cooling purposes. With a coefficient of performance of  $2\frac{1}{2}$  to 3, water temperatures of 140 to 150 F may be obtained.<sup>5</sup>

#### CHAPTER 50

### RESIDENTIAL SUMMER AIR CONDITIONING

Equipment Capacity Selection, Types of Equipment, Types of Application, Room Air Conditioners, Central Systems for Summer, Central Systems for Heating and Cooling, Location of Cooling Equipment, Noise, Air Distribution Methods, Operating Costs, Effects on Future House Design

IN RECENT years, summer air conditioning in residences has developed to the stage where it has become a major factor in the air conditioning field and has created a heavy interest among home-owners, builders, architects and business men. Residential cooling, particularly for the small home, received its initial impetus when equipment specifically designed for such purposes became available in the 1930's. Recently it has caught the public fancy resulting in a tremendous increase in the number of sales and installations.

The first installations were made by using the commercial and industrial methods as the estimating basis and did not prove as satisfactory as the installer or designer desired. Actually, the difference between estimating the residential summer air conditioning and commercial summer air conditioning loads is in the design temperature differences used, the type of internal load in the conditioned area, and the method of calculating equipment size.

#### EQUIPMENT CAPACITY SELECTION

With cooling, as with heating, the proper equipment capacity selection is that which, when properly installed, maintained, and operated, will satisfy the customer. Although at present an indoor design temperature of 75 F is used only on deluxe installations, it is felt that eventually this temperature will be used as the basis for design for both heating and cooling systems. At the present time, however, most summer air conditioning installations are designed on the basis of an 80 F indoor temperature. The outdoor design conditions commonly used in each locality are those listed in Chapter 13.

In calculating residential cooling loads, internal loads are not taken into consideration as much in domestic summer air conditioning as in commercial or industrial summer air conditioning. Lighting, electrical appliances, and so on, are not considered except in the cases where unusual loads are added to the conditioned area by means of certain types of appliances. These appliances, such as clothes dryers, and water heaters, should be vented to the atmosphere in order to limit their effect on the summer cooling load.

Although the methods of calculating the cooling load which are presented in Chapter 13 may be used for calculating residential cooling load, it has been found<sup>1</sup> that the load so calculated is much greater than that which is actually experienced in most residences. This is objectionable from at least two viewpoints: (1) it increases the capacity and consequently the

cost of the equipment installed, and (2) because of the increased size it results in less desirable humidity conditions within the residence.

A number of manufacturers, as well as several organizations, have been working on methods of calculating summer air conditioning loads for domestic applications. One of these is the method developed by the *National Warm Air Heating and Air Conditioning Association* in conjunction with the *Air-Conditioning and Refrigeration Institute*. This method is based on a load at a particular time of the day and takes into consideration the amount of solar radiation and heat gain due to the temperature difference between the conditioned area and the outside area on the assumption that the peak cooling load occurs from 3:00 to 4:00 o'clock in the afternoon.

Another method<sup>2</sup> evaluates the daily average cooling load on the design day rather than the maximum instantaneous heat gain. During the time the peak load occurs the room air temperature is allowed to rise from 72 F to about 78 F, thereby taking advantage of thermal storage in the structure and furnishings.

### TYPES OF EQUIPMENT

#### Low Side

Three types of low sides (the equipment that actually removes the heat from the conditioned space) have been developed for residential work as follows: (1) water-cooled coil, (2) chilled-water coil, and (3) refrigerated coils.

The water-cooled coil using water directly from the supply sources, such as city water or a well is the most simple type of installation. Cold water is circulated directly through the coil while air from the conditioned space is passed over the coil to remove heat and moisture. After the water has passed through the coil, it is wasted. To operate satisfactorily, an installation of this type requires water of sufficiently low temperature to chill the air enough to remove the desired amount of heat and moisture. Where a large supply of water at a cold temperature is obtainable, the water-cooled coil will operate with satisfactory results. As a general rule a water-cooled coil should not be used unless there is a supply of 52 F or colder water at the peak of the cooling season and in sufficient quantities to take care of the cooling load with a temperature rise of no more than 10 deg. Where water is not obtainable in sufficient quantities or at the required temperatures, it is necessary to chill the water to the desired temperature by using mechanical refrigeration. This is known as a chilled-water system.

In a chilled-water system, water is circulated through a closed circuit containing two coils. In one coil the water removes heat and moisture from the air in the conditioned space. In the other coil (water chiller) the heat is removed from the water by mechanical refrigeration. This type of system is called a duplex system in that the heat is picked up by chilled water and later removed from the water by means of a refrigeration system.

The third method of absorbing heat from the conditioned air is by means of direct evaporation of the refrigerant in a coil with the air to be conditioned passing over the outside of the coil surface. The heat is passed directly from the air into the refrigerant for removal.

#### High Side

The high side of a conditioning system, the section of equipment that removes the heat from the refrigerant and reclaims the refrigerant for further use in the system may be either the air or water-cooled type. The air-cooled high side is so constructed that the heat is removed from the

compressed or hot refrigerant by passing it into a cooling coil over which outside air (air taken from outside the conditioned area and returned to outside of the conditioned area) is circulated.

The major advantage of air-cooled equipment is that no water is required to accomplish the removal of heat from the refrigerant and only an electrical supply is needed. The disadvantage is that operating pressures are higher because of the inability to cool the refrigerant as much by air as by water. This results in an increase in electrical input to the compressor motor.

Water-cooled equipment can be of two types. In one type the water drawn from a well or from city mains is passed through the condenser of the high side and is allowed to flow to a drain, swimming pool, a wetted roof, or to other means of disposal. Where the water supply is sufficient and at low cost, this type of water-cooled unit is the better type installation because of lower equipment cost and lower operating costs and quieter operation. In a second type, if water is in short supply or is expensive, about 95 per cent of the cooling water can be reclaimed by evaporating sufficient water to rid the remaining water of the heat picked up in the condensing unit. This can be done by the use of an evaporative condenser or a cooling tower. These units are described in Chapters 35 and 37.

### TYPES OF APPLICATION

The common methods of cooling residences today make use of room air conditioners, central systems for cooling only, or central systems designed for both summer cooling and winter heating. The choice between these methods is largely one of cost and the relative heating and cooling loads.

### ROOM AIR CONDITIONERS

Window and cabinet-type air conditioning units can be used to cool small sections of a house.

The window units fit into an opening of a standard double-hung window and vary in size from  $\frac{1}{3}$  to 1 ton of cooling capacity. Room air is circulated through the unit where it is cooled, dehumidified, and filtered. No water pipes are necessary since the condenser is air-cooled; nor is a drain necessary inasmuch as the moisture condensed from the air is evaporated into the outdoor air. Electrically operated, the units can generally be plugged into existing electrical outlets although a voltage of 220 is required for units having one-horsepower motors.

Cabinet units stand on the floor and require an opening in the wall through which air to cool the condenser is brought in and discharged.

The room cooler is popular for use in offices or residences where the existing heating system does not contain provision for summer cooling or where cooling is not required in the entire space.

### CENTRAL SYSTEMS—SUMMER ONLY

In some areas there is little or no need for heating but there is a distinct need for summer cooling. Both air- and water-cooled package cooling units are available for such installations, ranging in size from one ton to at least 15 ton capacity. To install these units it is only necessary to make plumbing and electrical connections and add the duct work required to convey air to and from the conditioned space. These units can also be used to provide

central air conditioning to residences having heating systems which do not contain provision for attaching summer cooling equipment.

### CENTRAL SYSTEMS—HEATING AND COOLING

A summer air conditioner can be installed beside or near an existing warm-air furnace and can be connected to the duct work if the duct system has ample capacity for the cooling operation. If it does not, additional ducts and supply outlets will be required. The conditioner is about the same size or slightly smaller than a conventional forced warm-air furnace.

Year-round air conditioners require less space than a separate heating plant plus a separate summer conditioner. Usually the heating and cooling portions of a year-round air conditioner operate independently of each other. The air circulated by the fan passes through the cooling or heating portion of the equipment, only one of which is in operation at any one time.

Cool air supplied to rooms is usually 15 to 25 deg lower than the temperature of the rooms to be cooled. The size of the ducts of year-round air conditioning systems are often larger than those of equivalent winter heating systems because large quantities of cool air at 55 F to 65 F must be circulated through them. Duct systems should be designed and installed by competent engineers in accordance with such authoritative information as the design manuals of the *Air-Conditioning and Refrigeration Institute*<sup>3</sup> and the *National Warm Air Heating and Air Conditioning Association*.<sup>4</sup>

The cooled air is admitted to the room from the ducts through supply outlets. Since this air is colder, and therefore, heavier than the air within the room, it has a natural tendency to fall toward the floor. Unless the supply outlets are properly selected, located, and adjusted, the air distribution is likely to result in (1) a low velocity of cool air falling on the occupants, or (2) a high velocity stream of cool air striking a wall or other obstruction and splashing on the occupants. Research is being conducted to determine the most advantageous type and location of supply outlets.

The most commonly used outlets are registers with either fixed or adjustable vanes, and diffusers. Registers distribute the cooled air throughout the room. They are usually located either high or low in the sidewall or in the baseboard.

The diffuser type of outlet can be used in ceiling, wall, or floor. Different designs are available for each of these locations. The floor, baseboard, and sidewall diffusers blanket the walls with a curtain of cool air (or warm air in winter); the ceiling diffuser blankets the ceiling.

Air conditioning can be installed in homes having a hot-water heating system either by use of:

1. *Room units* resembling convectors and containing both heating and cooling coils. These units are used in place of the conventional radiator or convector. They can be installed in all rooms of the house to provide complete summer cooling, or they can be used in only one or two rooms. This arrangement is shown in Fig. 1.
2. A *split* system. The cooling coil is located in a duct through which air from the rooms is circulated, cooled, and returned to the rooms. The coil can be used for winter heating, or conventional radiators, convectors, or panels can be used to bring the heat to the rooms.

The cooling equipment is located in the basement or utility room near the boiler. Valves are provided so that the same piping system can be used to circulate heated water in winter and chilled water in summer. The piping must be insulated to prevent sweating when circulating cold water.

### LOCATION OF COOLING EQUIPMENT

The location of the summer cooling equipment will depend upon the type of unit. In a combination self-contained type unit, the location will depend upon accessibility to the duct system, the fuel supply, and the electrical supply. Too often, a heating or cooling unit is located by giving consideration to installation only, without considering the usability of the basement. This may result in breaking up the basement area to such an extent that it becomes practically useless for other purposes. In a remote type combina-

FIG. 1. COMBINATION SUMMER AIR CONDITIONING AND HOT WATER HEATING SYSTEM

tion unit, consideration must be given to the location of the condensing unit, whether it is located in the basement area or whether the unit is located in a remote area such as the garage breezeway. Preferences of the family and their habits of living must be given consideration so as to keep all space as useful as possible and still locate the equipment in such a place that it can do its intended job and be accessible.

### NOISE

One of the prime problems of domestic air conditioning is operating noise. Due consideration must be given to location of summer air conditioning equipment, with respect to areas under bedrooms or other rooms requiring very low noise levels. Equipment is often installed without due consideration to blower and duct sizes, with a resulting increase in noise level. Consideration should be given to the use of vibration absorbers in refrigerant and water lines, to anti-vibration padding under equipment, and to flexible duct connectors to isolate operating sounds.

### AIR DISTRIBUTION METHODS

Where cooling is installed with ducts and air outlets which serve the cooling function only, the practice and experience of comfort air conditioning for offices and commercial buildings apply directly to residential installation. Although cooling and heating by means of the same duct work and air outlets has been common practice in commercial and industrial applications, greater care must be taken in residential applications. It has been found that low air-flow rates are desirable for warm-air heating systems,<sup>5</sup> much lower than would be used for cooling systems. It is therefore recommended that in a residence located in a moderate or cold climate, provision be made for different air-flow rates for summer and winter. In warmer

climates, however, where air conditioning is the primary consideration, the summer air-flow rate may be used the year around.

The registers may be placed either in the high sidewall or in the perimeter location. For the high sidewall applications, it is necessary that the deflection of the air be different for summer than it is for winter to prevent the jet from dropping into the living zone (60 in. above the floor and below) where the velocity should be not greater than 35 fpm. For registers located at the perimeter of the residence,<sup>6</sup> it is not necessary to change the deflection from summer to winter.

The air distribution system should be designed for the largest air-flow rate which is to be used, as outlined in Manual No. 11<sup>4</sup> of the *National Warm Air Heating and Air Conditioning Association*. For small-pipe perimeter systems, it is necessary to have more outlets than for the larger duct systems. In some applications, it may be necessary to close off some registers during the winter so that adequate register-air velocities will be obtained. These registers would then be opened during the summer to give a sufficient number of outlets.

Recent investigations have shown<sup>7</sup> that the use of perimeter duct systems for air conditioning gives excellent results, and that objectionable air motion does not occur within the living zone except in the immediate vicinity of the registers. Care must be taken, however, to use only registers or diffusers that are specifically designed for perimeter application. This is necessary to permit the introduction of the air into the room in a pattern which does not cause drafts. Floor diffusers which distribute the air in a fan-shaped pattern along the wall or low sidewall diffusers which blanket the wall are recommended. For supply-air temperatures not more than 15 deg below room-air temperatures, diffuser face velocities of 500 fpm are recommended.<sup>8</sup> For supply-air temperatures 20 deg below room-air temperature, the diffuser face velocity should not be less than 700 fpm.

### OPERATING COSTS

The operating cost of residential cooling equipment during a particular summer depends on variables such as the amount of sunshine and rain, the number of abnormally hot or cool days, the efficiency of the equipment, and the local power rate. It is also influenced by human factors such as operation of equipment only during the hottest weather, opening windows at night<sup>9</sup>, and difference in preferred indoor temperatures. Nevertheless, it is important that lending agencies and prospective buyers of equipment be given a reasonably accurate estimate of the operating cost during normal summer weather and under usual operating conditions. Adjustments can then be made for any special conditions anticipated.

The basis of a method reported<sup>10</sup> is that the power cost  $S$  of residential cooling equipment, expressed in dollars, is predicted from the equation

$$S = \frac{RPT}{100} \quad (1)$$

where

$R$  = power rate, cents per kilowatt hour.

$P$  = average power input to the equipment over the season, kilowatts.

$T$  = predicted total operating time of equipment, hours.

Note: Symbols for Equations 1 and 2 are those used in paper.<sup>10</sup>

For a given application, the power rate is obtained from the local public utility. The average power input depends on the particular make of

equipment and condensing method, and consequently must be obtained from the manufacturer.

The operating time  $T$  to be used in Equation 1 is found from the equation

$$T = \frac{24HD}{C(t_m - 70)} \quad (2)$$

where

$D$  = number of cooling degree-days above 70, Fahrenheit.

$H$  = average hourly cooling load over the 24 hours comprising the design day, Btu per hour.

$C$  = average total cooling capacity (sensible plus latent) of equipment over the season, Btu per hour.

$t_m$  = design mean temperature = design outdoor dry bulb minus one half the daily range, Fahrenheit.

Tabulated values of cooling degree-days above 70 F for various localities are not yet available. Until they are, approximate values can be obtained from degree-day maps.<sup>11, 12</sup> Values of  $C$  must be obtained from the equipment manufacturer, whereas values of the daily range for computing  $t_m$  are given in the literature.<sup>13</sup>

It is emphasized that the value of  $H$  in Equation 2 is not the maximum instantaneous heat gain but the *average hourly cooling load over the 24 hours comprising the design day*. Consequently, it should be evaluated by a method similar to the one reported.<sup>2</sup> To facilitate application of the method, the original paper<sup>10</sup> contains charts from which values of  $T$  and  $S$  can be obtained directly.

If the evaporator fan cycles with the compressor, the power cost  $S$  also represents the total operating cost for air-cooled condenser applications. For continuous fan operation the value of  $T$  is subtracted from the number of hours in the cooling season to obtain the extra hours of fan operation. Equation 1 is then used with the appropriate value of  $P$  for the fan motor only, and the result is added to the power cost during compressor operation.

For water-cooled condenser applications the water cost, as determined from the operating hours, water rate and manufacturer's data on equipment water usage, is added to the power cost to obtain the predicted total operating cost.

### EFFECTS ON FUTURE HOUSE DESIGN

Air conditioning, like automatic heating, has brought about improved practice in residential construction, particularly in those regions where cooling is of primary importance. Although it is true that construction practices which reduce the heating load also reduce the cooling load, there are certain considerations which are unique in their effect upon the cooling load. Special attention must be paid to window orientation and means of shading the windows. South windows may be shaded by awnings or roof overhangs, but it is not practicable to shade large window areas having an east or west orientation except by exterior solar screening of some type. The use of insulation in the walls and ceiling of the residence will reduce the cooling load appreciably. In addition, attention should be paid to adequate ventilation of the attic. Double-glazed and weatherstripped windows, heat-absorbing glass, planned shade tree locations, and light colored exterior wall and roof surfaces, also help to reduce the cooling load.

## CHAPTER 51

## SCHOOLHOUSE HEATING AND VENTILATING

General Considerations; Factors Affecting Design: Classrooms, Other Spaces, Government and Fire Safety Regulations, Economic Considerations; Systems in Use: Open Window, Gravity and Mechanical Exhaust, Forced Air, Unit Ventilators, Panel Heating; Maintenance and Operation

SCHOOL buildings present certain special problems due to diversity of use of various spaces, differing times of occupancy, recent trends in building construction, and additional sources of odors. A school is generally a composite building, containing classrooms, large public meetings rooms which also serve as teaching spaces, offices and administrative areas, health departments, locker rooms, toilet rooms, laboratories, shops, cafeterias, and miscellaneous other spaces such as corridors, stairways and service areas. The heating and ventilating requirements are different for each type of space.

## GENERAL CONSIDERATIONS

The uses of spaces in schools vary widely in normal operation. The usual classrooms, assembly rooms, lecture halls, auditoriums, and other similar areas have occupants of relative inactivity. Consideration must also be given to areas such as music rooms, laboratories, shops, basketball courts and gymnasiums where various degrees of activity are found. All of these areas have different temperature and ventilation requirements. Most state laws require relatively large glass areas in classrooms, thereby imposing a real heating problem upon the designer. The lower mean radiant temperatures make these rooms particularly susceptible to objectionable drafts which the heating and ventilating system should be designed to combat or overcome.

The areas having higher levels of activity will require lower temperatures and, due to the increase in body odor, should have relatively more ventilation.

A major aspect of time of use of the various spaces is the dual use of the building by the school and by the community, not only of the auditorium and gymnasium, which may be planned for physical segregation during the evening, but also of any of the classrooms or the cafeteria. The room used by the board of education may be in use at any hour or time, and may require air conditioning.

The type of construction and its effect on comfort and condensation must be considered. The tendency, particularly in the Southern States, to encourage the use of one-story schools with outside corridors and concrete slabs on the ground has introduced many new heating problems. This construction greatly enhances the use of natural or window ventilation because the rooms are equipped with high windows on one side, usually the north or northeast, and low windows on the opposite side. The amount of ventilation air is thus regulated by the adjustment of the windows.

In the extreme South there is some tendency to design schools with very light wall construction and to omit any wall insulation, thus producing a

wall having a low heat capacity to obtain a fairly rapid heat dissipation. This results in more comfortable conditions on warm sunny days, but also imposes a requirement for more heating capacity on cool cloudy days. The roof constructions for these buildings are also designed for low heat capacity, but do require insulation because of the extended period of sun exposure. The exposed surfaces should be light in color for maximum reflection, and the under surfaces must be arranged so that the ventilation will remove the heat which penetrates through the construction. All parts of the structure must avoid high heat retention so that the heat of the afternoon sun will not be released into the building during the following morning.

The time of use, number of occupants, temperatures required, and degree or quantity of ventilation to be provided should of necessity be studied for each space, and equipment provided to maintain proper conditions. A complete analysis should be made of the requirements, and methods should be adopted that will provide for as many of the following functions as are indicated to be necessary: heating, ventilating, cooling, odor control, humidity control (to prevent or limit condensation).

Schools are usually constructed only after permissive referendums, approved by the taxpayers. School districts are mostly local public enterprises under state regulation but operating more or less individually in raising funds by taxation for school construction and operation. Most school district boards of education consider one of their greatest problems that of having the citizens of their communities vote the necessary taxes. Most boards are very susceptible to criticism from their constituents for seemingly (if not actually) spending large sums of money for *luxury* items. This one consideration alone has been a great factor leading to economy in construction and design. Heating and ventilating design is still strongly influenced by this consideration.

It should also be remembered by the designer of heating and ventilating equipment for school buildings that such equipment requires maintenance. The maintenance required may vary from merely dusting and cleaning to wholesale replacement of parts. The trend of modern architecture to reduce *wasted* space is frequently over-emphasized, and causes the spaces wherein mechanical equipment is to be installed to be so classified and consequently inadequate or inaccessible. The designer should always bear in mind that lengthy repairs to heating and ventilating equipment are always considered expensive nuisances.

#### FACTORS AFFECTING DESIGN

Some of the factors affecting design are the type and use of classrooms, types of other spaces, governmental and fire safety regulations, and economic considerations.

##### Classrooms

The number of occupants and sudden changes in occupancy should receive adequate consideration. In departmentalized schools, rooms may be unoccupied for a period and then be filled to over-ideal capacity within a few minutes. All rooms should be at the desired temperature when the students enter at the start of the school day. They should maintain such temperature when an internal heat gain is suddenly introduced in the form of body heat and lights.

Lighting in a typical classroom can be the equivalent of at least 8150 to 10,000 Btuh, depending on the type of lighting. Maximum heat gain from

lighting will not coincide with maximum sun load, but the modern tendency is to keep at least the row of lights farthest from the window *on* in order to compensate for loss of illumination.

Because of the large glass areas, solar heat is usually the largest single item of heat gain. Classrooms usually have separate shades for tops and bottoms of windows. In the South sunshades are increasingly being provided in the building construction. These shades often take the form of horizontal louvers, particularly on south exposures, and are so arranged that little, if any, direct sun rays reach the glass surfaces. The louver windows on the south exposure are often shielded from the sun by an outside corridor. Tinted glass, heat reflective glass, and glass blocks arranged with light reflective prisms are used to some extent.

The orientation of these windows requires careful study in order to take the greatest advantage of the shading devices during the normal period of occupancy. Some serious consideration must be given to the direction of the prevailing wind during the school term. Where there is a wide variation of direction during the school months, provision should be made to take advantage of the changes in wind direction.

In all climates the problem of compensation for lighting loads, sun loads, and occupant loads imposes a variable demand on all heating and ventilating systems. These can only be compensated for by adequate thermostatic controls.

It should be noted that while the heat gains are not too much affected by the passage of the seasons the heat losses mentioned are for the design condition only.

Due to the fact that there is no sun load on cloudy days and that before schools opens in the morning there are no lights or occupants, none of the heat gains mentioned can be deducted from the required design load. It is very desirable to have a classroom at required temperature when school starts, but these loads must be compensated for by control of the heating and ventilating equipment or by manual adjustment of windows.

Humidity conditioning is typical of dense occupancy applications, except that larger than average areas of low temperature surfaces make failure to control in cold weather more serious. Even in a room with an ideal occupancy of about 25, an hourly moisture gain of almost 26,000 grains must be removed.

Odor control is also required of dense occupancy applications with the additional sources of wet coats and packed lunches, if brought. It is advisable to locate exhaust inlets or relief openings adjacent to coat racks. Where wardrobes are used, their doors are undercut, and these inlets should be located in the wardrobes. This problem is particularly acute in schools of the *campus plan* type.

For the foregoing reasons classrooms should be provided with heating and ventilating installations that will respond rapidly to rapid changes in load.

##### Other Spaces

Auditoriums, laboratories, shops, office areas, service areas, kitchens (cafeteria and home economics), janitor's closets, swimming-pool rooms, toilets and locker rooms, present problems that are typical of similar spaces in other types of buildings. Chemical laboratories in high schools usually are equipped with fume hoods and have storage rooms that should be adequately ventilated. Shops in high schools may have special require-

ments, such as dust-collecting systems in woodworking shops, explosion-proof exhaust systems in wood-finishing rooms, and underfloor exhaust gas conveying systems in automobile shops. Locker rooms and toilets may be used in connection with outdoor sports activities during the summer.

Gymnasiums require lower temperatures and adequate ventilation without drafts. Ventilating and heating systems should take into account the ability to divide the gymnasium in half by means of folding partition, if provided. High school gymnasiums are often furnished with collapsible bleachers, indicating a greater occupancy and higher levels at which drafts should be avoided. Combination gymnasium-auditoriums (*general purpose* rooms) and gymnasium-cafeterias (*eating space*) should be treated so as to meet the requirements of each use. Football uniform drying rooms present a special problem of drying and odor control.

*Listening* rooms (for listening to records), an adjunct to the library, are usually interior rooms and, because of sound transmission, must be sound-proofed as well as ventilated. Visual-aid rooms should receive careful attention in ventilating or air conditioning because of the necessity for excluding light during use.

Panel heating is frequently used in kindergarten floors, since so much of the activity in these rooms takes place on the floor.

The room used by the board of education for its meetings is often air conditioned even in the northern part of the country, and even when it is the only space so treated. This is necessary because the board works during all months of the year. This room should be ventilated as recommended elsewhere for *smoking* conditions.

### Governmental Regulations

Almost every state or territory, and in some cases counties, cities, and towns as well, as its own set of regulations governing the heating and ventilating of school buildings. Unfortunately, most of these regulations have not been coordinated through any one central source, and consequently they vary tremendously. Each designer of heating and ventilating installations for schools should completely familiarize himself with the regulations of the locality in which the building is to be built and satisfy these regulations.

The regulations usually specify the minimum requirements. The designer can refer to Chapter 6, Table 1, for recommended air changes, to Chapter 11 for other ventilation requirements, and to Chapter 13, Table 3 and page 278 for recommended air changes for various types of occupancy.

### Fire Safety Regulations

Many states have fire safety regulations which limit the routing and arrangement of ducts and vary the requirements of fire dampers. Most of these regulations are based upon the *National Board of Fire Underwriters'* Pamphlet No. 90 which covers the regulations for the installation of air conditioning, warm air heating, air cooling, and ventilating systems. All installations should be made in accordance with these requirements.

### Economic Considerations

School building program budgets are often extremely marginal, especially if a succession of increases in building costs have occurred since the appropriation was voted. Under such circumstances, the board of education, its architect, and its engineers, in order to get the school built, are not

infrequently forced to adopt courses of action that are obviously not the most desirable or the most economical over the life of the building. Needless to say, the design of the mechanical systems should be consistent with the budget. However, the board is entitled to know precisely what penalty it will be paying for each departure from the optimum design.

### SYSTEMS IN COMMON USE

There are several different methods of complying with the foregoing requirements. All methods are not acceptable in all states, but all methods have been used in one form or another in this country.

#### Open Window Ventilation

The term *open window ventilator* usually means that there is no mechanical or gravity ventilating equipment. Air movement is caused by opening one or more windows at the top and raising some windows at the bottom. Where classrooms have windows only on one side this is not very effective and cannot be recommended for any part of the country. When the classroom has windows on two sides, particularly when they are at different levels, satisfactory conditions can be maintained if the teacher acts as the thermostat. In climates where heating is required for a large percentage of the time, open window ventilation should not be used.

#### Gravity Exhaust Ventilation

This is the next step in producing satisfactory conditions. Exhaust grilles are placed in the ceiling or wall away from the windows, and are connected to exhaust ducts or plenum spaces connected to roof ventilators. Due to the differential pressure, air is exhausted through these ventilators. It is, of course, necessary to open the windows in order to replace the exhausted air and the heating system must be designed to heat the air as it enters the windows. Satisfactory air changes can be obtained by this method, but it usually results in objectionable drafts. This type of system is reasonably satisfactory in mild climates but cannot be recommended where the design temperature is lower than 10 F.

#### Mechanical Exhaust Systems

A reasonably satisfactory arrangement for any mild climate can consist of a mechanical exhaust system where motor driven exhaust fans are connected to the exhaust grilles as previously described. With this arrangement, the fans can be operated on a schedule depending upon the outside temperature. When windows are closed the replacement air is drawn from the corridor or is greatly reduced.

This method usually consists of providing direct radiation along the window wall of a space to be heated and ventilated, and providing some means of positively exhausting air from the space to obtain ventilation. To make up the exhausted air, the windows are usually opened. To minimize drafts from open windows they are constructed with inside hoppers or baffles at the bottom to cause the incoming air to deflect upward and avoid blowing directly on the room occupants at desk level. To provide sufficient heat for tempering the incoming air, the radiation is designed for the total of the normal transmission plus the amount needed to offset the chilling effect of the entering air. The air quantity calculated to require such tempering is assumed to be the same amount as the amount exhausted. The amount of air exhausted from each space is established in each state code. The control of these systems is usually all manual or a combination

of manual and automatic operation. When they are all manual, the exhaust fans are started from some remote point, the teacher controls the opening and closing of the windows, and the radiation is either left uncontrolled or is manually controlled, again by the teacher. When controls are *manual-automatic*, all of these functions are controlled as described except that an automatic valve is installed to control the steam or hot water flow to the radiation in an attempt to maintain room temperature conditions. With this system, odors and humidity are presumed to be controlled by increasing or decreasing the window opening to admit more or less outdoor air (up to the amount being exhausted). Cooling is provided in a similar manner. The results, while passable, are frequently haphazard, drafty, or stuffy, and depend to a great extent on the individual preference of the teacher.

### Direct Radiation

Many schools employ direct radiation or, in some cases, convectors or continuous fin-type heating pipes in connection with all of the systems of ventilation described. The radiation should be well distributed along the outside wall. Where possible a radiator should be placed under each window or made practically continuous. Unless thermostatic control is to be installed, hand valves must be provided so that each teacher can regulate the amount of radiation being used.

The automatic control of these types of heating systems can be arranged by zones (where rooms have common orientation and common use) with the disadvantage of attempting to find the room with the average conditions, or by separate control for each room.

### Forced Air Systems (Central Direct-Fired)

Since schools require forced ventilation in many areas, many different types of central systems have been utilized. All of the available warm air furnaces have been used. These systems for schools are divided into as many zones, each having its own control, as possible. In addition to the common central system similar to the type used in homes without zoning, the two types most frequently used in school building have been:

1. The type which takes a mixture of outdoor and return air through a fan and filter, and discharges it in either of two paths, over the surfaces of a warm air heater or through a by-pass around the heater, with mixing at the outlet of the heater to control the temperature of the air supplied to the rooms. This requires one supply duct from the heater to each room or zone so controlled.
2. The type of system known as the double duct system which has in it one main duct from the heater and another one which has by-passed the heater, both ducts being run parallel to each other to a point just behind the room supply outlet where dampers are installed to mix warm air and cool air to obtain the desired outlet temperature.

These systems usually operate with a fixed (manually variable) outdoor air quantity, the balance of the air being obtained by returning it from the spaces. The air is released into the spaces either through wall grilles, ceiling outlets, or outlets in the window sills discharging upward. Excess air is removed from the spaces, or rather is allowed to escape from the spaces in many instances, through relief grilles into the corridors, the corridors returning the air to central points where connections are made to the suction side of the central fan unit. In some states return of air is not permis-

sible. Under these conditions the excess air is removed from the building through either gravity ventilators or power exhaust fans.

There have been some installations in which the return air is allowed to escape from the room, through wall grilles, into the corridors and thus back to the unit. While this arrangement is less expensive, it is not recommended because in case of fire all the smoke is drawn through the corridors which should be kept clear for the escape of the students and teachers. Corridor return is prohibited in many states and cities.

Proper design should avoid drafts from cold wall surfaces and from duct outlets. Air discharged toward cold surfaces should be designed for a terminal velocity of 50 fpm at approximately one-quarter the distance from a cold wall. Grille outlet velocities in excess of 600 fpm under 9 and 10 ft ceilings are likely to cause drafts at some points in the occupancy zone.

### Forced Air Systems (Central Steam)

In these systems the air supplied for ventilation is tempered by automatically controlled steam coils and the normal heat loss for each room is supplied by direct radiators or convection. Provision is made for exhaust equal to the amount of outdoor air supplied. There are many variations of these systems, and they may include any features of central systems described in Chapter 30. Hot water may also be used as the heating medium.

This type of system can also be designed to provide the entire heating requirement without using any direct radiation. This arrangement is quite satisfactory, but must be controlled for zones of similar occupancy which have exactly the same orientation. Where used as a two-duct system as described under Forced Warm Air Systems in preceding section, much more satisfactory results can be expected.

### Unit Ventilator Systems

Unit ventilators are used for supplying heat and ventilation for individual classrooms. These units and their controls are described in Chapters 25 and 39. They can be combined or furnished with storage cabinets, book shelves, extensions for additional direct radiation, and extended grilles to discharge upward along the window sills.

As in previous systems described, the excess air must be provided a means of escape.

### Panel Heating Systems

A number of schools have employed panel heating of various designs. It is particularly adaptable in the *slab-on-ground* type of school to overcome the cold floor. It is also quite adaptable to the *open corridor* type of school using natural or window ventilation in the warmer climates. In the cold climates it should be augmented by a tempered-air ventilating system as previously described.

Design data are given in Chapter 24, but the designer must include ample thermostatic control which employs some means of varying the water temperature in inverse ratio to the outside temperature. With well-insulated walls and ceilings this feature usually results in an appreciable anticipation of the heating requirements. Several control systems are outlined in Chapter 39. Individual room control is desirable but not mandatory. A separate zone control for each exposure and for each floor is absolutely necessary for satisfactory results.

When coils are installed in the floor slab, these systems must be operated continuously (day and night). Night setback is not desirable, but when used it must be placed on the room thermostats and the setback must not exceed 10 deg. Generally room temperatures, read on wall thermometers placed 60 in. from the floor, can be one to two deg lower than with other types of systems for equal comfort.

Floor temperature must not exceed 85 F on design days except that a perimeter band, not exceeding 15 in. from the walls, may have a surface temperature of 100 F. Floor panels should not be expected to warm the large volumes of air required for school ventilation, and for this reason a tempered air supply is required in all except mild climates.

### MAINTENANCE AND OPERATION

Controls, boilers and combustion equipment, fans and mechanical heating devices, traps and valves, all need attention at least annually. Every designer must use extreme care in selecting equipment that will require a minimum of attention, and see that it is accessible for service.

While school custodial forces may be competent, they frequently have more work than can be handled during normal working hours. Unusual maintenance problems may therefore result in deterioration of equipment and systems. While first cost is important, final selection of equipment should not be made without consideration of the overall cost which includes maintenance and service.

## CHAPTER 52

### INSTRUMENTS AND MEASUREMENTS

Temperature Measurement, Pressure Measurement, Air Flow Measurement, Air Change Measurement, Humidity Measurement, Heat Transfer Through Building Materials, Evaluation of Thermal Environment, Combustion Analysis, Smoke Density Measurements, Determination of Air Contaminants, Sound and Vibration Measurements

**H**HEATING and air conditioning engineers and technicians require instruments for both laboratory and field use. Somewhat more precision is attainable and essential in the laboratory, where research and development are undertaken, than in the field, where acceptance and adjustment tests are conducted. Some instruments have attained an adequate state of development, while others fall far short of the desirable. For instance, temperatures can now be measured readily with ample accuracy for most purposes, while a convenient and precise method for determining or comparing the dustiness of atmospheres is lacking, and improvement in existing hygrometers and humidity controllers is essential.

Codes and standards covering different types of heating and air conditioning devices and apparatus have been promulgated by various authoritative organizations, and instruments essential for performance or compliance testing are enumerated in the relevant publications.<sup>1, 2, 3, 4</sup> The present purpose is to discuss the use and characteristics of the more important instruments.

#### TEMPERATURE MEASUREMENT<sup>5, 6</sup>

##### Thermometers

Any device capable of indicating temperature is a thermometer, but in common usage the term *thermometer* without qualification has come to signify the ordinary mercury-in-glass temperature indicating device. This type has a useful range from -40 F, the freezing point of mercury, to about 1000 F, at or near which the glass usually softens. Lower temperatures can be measured with alcohol-filled thermometers for which the range is about -94 F to +248 F. The better thermometers have their scales, either Fahrenheit or Centigrade, etched with acid into the glass which forms their stems. The probable error for etched stem thermometers is plus or minus one scale division, and calibration is desirable for much test work. Thermometers are calibrated during manufacture at not less than two temperatures—the freezing and boiling points of water—and calibration is often accomplished with the instrument completely immersed in a bath at the known temperature. The intervening scale divisions are then applied to the stem. When such a thermometer is used with the stem incompletely immersed, a correction known as the stem correction is neces-

sary for accurate measurements, and its magnitude is usually computed by means of the following formula:

$$K = 0.00009 D (t_1 - t_2) \quad (1)$$

where

$K$  = correction to be added, Fahrenheit degrees.

$D$  = number of degrees on the thermometer scale which are not immersed.

$t_1$  = temperature indicated on the thermometer, Fahrenheit.

$t_2$  = temperature of the non-immersed mercury column, Fahrenheit.

0.00009 = difference in the coefficient of expansion of the mercury and glass.

When a thermometer is used in a liquid or in air or gas near room temperature, the effects of radiation can often be ignored, but when the temperature of hot air or gas is desired, means are usually provided for minimizing the effect of radiation.<sup>7</sup> These include bright metallic shields around the thermometer bulb, and the use of aspirated thermometers in which a stream of the air or gas is drawn at considerable speed across the bulb and increases the influence of the gas temperature on the thermometer indication. In any case, to prevent errors in temperature measurements, there should be ample circulation so that the thermometer will indicate a true temperature of the medium under observation, and ample time should be allowed for the thermometer to reach the same temperature as the medium. In reading a thermometer the eye should be at the same level as the top of the liquid to avoid parallax.

Industrial-type thermometers are available for permanent installation in pipes or ducts. These instruments are fitted with metal guards to prevent breakage, and are useful for many purposes. However, the considerable heat capacity and conductance of the guards or shields prevent such thermometers from following closely the fluctuations in a medium of varying temperature.

### Thermocouples

When two wires made of dissimilar metals are joined by soldering, welding or merely by twisting, a thermocouple or thermo-junction is formed. An electromotive force, which depends upon the temperature of the junction, is found to exist between the wires. When the wires are joined at two points a thermocouple circuit is formed. If one junction is kept at a temperature different from the other, an electric current flows through the circuit due to the difference in emf developed by the two junctions. This phenomenon is employed for temperature measurements in thermocouple systems, one junction being ordinarily kept at a constant temperature, as in an ice bath, while the other junction is placed at a point at which it is desired to observe the temperature. In practice it is desirable to utilize emf to indicate temperature because, at small or zero current flow, the resistance of the circuit is unimportant. A high resistance millivolt meter is useful in some cases but the potentiometer yields better results. In the potentiometer the electromotive force generated by the thermocouples is balanced against an electromotive force from the battery so that observations are made with no flow of current through the thermocouple circuit. A conventional arrangement is illustrated in Fig. 1. The thermocouple leads A-B are so connected that their polarity opposes that of battery C. If the position of E on the graduated slide wire rheostat DF is adjusted until galvanometer G shows no current flowing, resistance DE will indicate directly the voltage generated by the thermocouple. In order to calibrate

the instrument, switch S is thrown over to the standard cell circuit while rheostat R is adjusted so that the galvanometer shows zero current. Battery C then exerts the known voltage of the standard cell at DH.

The act of adjusting rheostat D-F (Fig. 1) for zero current flow is known as balancing the potentiometer. Automatic self-balancing instruments of both the indicating and recording types are on the market. They usually contain an automatically compensating cold junction to avoid the use of an ice bath, and special thermocouple wire is furnished with them from the factory.

The choice of materials for thermocouple wire is determined by the range of temperature to be measured, the protection from corrosion afforded the couple, and the precision and service life required. In general, copper *vs.* constantan is suitable for temperatures up to 700 F, iron *vs.* constantan up to 1500 F, and chromel *vs.* alumel up to 2200 F. Higher temperatures re-

FIG. 1. BASIC CIRCUIT AND CONNECTIONS FOR THERMOCOUPLE AND POTENTIOMETER

quire the use of noble metal thermocouples (platinum *vs.* platinum-rhodium). In addition to the higher initial cost of a noble metal couple, it does not develop as high an emf as the base metal couples do. Impurities make large differences in the performance of thermocouple wires and for this reason calibration of samples from each spool of wire is essential for precise work. Data on wire can usually be obtained from the manufacturer.

With a suitable potentiometer, small wires serve as well for thermocouples as large ones, and the fineness of the wires is limited only by consideration of mechanical strength and convenience in handling. Small couples respond more promptly to changes in temperature and are less affected by radiation than large ones. Heavy gage couples, however, are necessary for high temperature work where corrosion of the wire is a problem. For use in heated air or gases, thermocouples are often shielded,<sup>8</sup> as are thermometers, and aspirated thermocouples are sometimes used. An arrangement has been described for avoiding error due to radiation. It involves several thermocouples of different sizes, the true temperature being estimated by extrapolation of readings to zero diameter.<sup>9</sup>

By the use of thermocouples, temperatures at remote points may be indi-

cated or recorded on conveniently located instruments; average temperature may be readily obtained by connecting several couples in parallel or in series; and temperatures may be obtained within thin materials, narrow spaces, or otherwise inaccessible locations.

Thermocouples in series with every alternate junction maintained at a common temperature will give an emf which, divided by the number of couples to give the average emf<sup>10</sup> per couple, may be used to find the average temperature. This series arrangement of thermocouples, often called a thermopile, can have extreme sensitivity and is useful in detecting very small changes in temperature.

Thermocouples in parallel, having the similar metals of a number of couples connected together and run to a common cold junction, will cause an indication on a potentiometer which is the true average emf only if the electrical resistances of the parallel junctions are the same.<sup>10, 11</sup>

Temperatures of surfaces below red heat are difficult to determine by any other means than thermocouples. For this purpose, a thermocouple of fine wires is preferable to minimize the possibility of error due to the conduction of heat along the wires. It may be attached to a metal surface in any of several ways. For permanent installations, soldering, brazing, or peening may be desirable. A small hole is drilled for the peening operation; the thermocouple is inserted and the metal is peened to retain it. The fact that the thermocouple is in electric contact with the surface is unimportant in usual circuits. For temporary arrangements, couples may be attached by means of surgical or cellophane tape. For many boiler or furnace surfaces, furnace cement serves very well. The thermocouple may be attached by means of the cement when the surface is cold, and must be treated gently and usually supported until the cement dries, due to heat, and hardens—after which it has ample strength. It is good practice to use as little cement as possible, and also to plaster the wires to the surface for an inch or so from their junction to avoid errors due to heat conduction along the wire. Electric insulation between the wires should be perfect except at the junction since, otherwise, the indicated emf will be between those existing at the junction and at the short circuit.

### Resistance Thermometers

Resistance thermometers depend for their operation upon the change of electric resistance of metal with change in temperature. The resistance generally increases with rising temperature. Their use largely parallels that of thermocouples, although readings tend to be unstable above 950 F. Two-lead temperature elements are not recommended, since they do not permit correction for lead resistance. Three leads to each resistor are necessary to obtain consistent readings.

A typical circuit used by several manufacturers is shown in Fig. 2. In this design a differential galvanometer is used, in which coils L and H exert opposing forces on the indicating needle. Coil L is in series with the thermometer resistance AB; and coil H is in series with the constant resistance R. As the temperature falls, the resistance of AB decreases allowing more current to flow through coil L than through coil H. This causes an increase in the force exerted by coil L, pulling the needle down to a lower reading. Likewise, as the temperature rises the resistance of AB increases, causing less current to flow through coil L than through coil H. This forces the indicating needle to a higher reading. Rheostat S must be adjusted occasionally to maintain a constant flow of current.

As compared to the thermocouple, the resistance thermometer does not require a cold junction, and it can be simply scaled for more accurate measurements; but, generally because of its construction it is more costly and is apt to have considerable lag. It gives best results when used to measure steady or slowly changing temperature. For accurate results the entire thermometer coil must be exposed to the temperature to be measured.

### Pyrometers

The pyrometer is the usual instrument for measuring high temperatures such as those of incandescent bodies or furnace interiors. There are two types. In the radiation pyrometer the radiant energy from an observed surface falls on a thermopile, and the emf generated by the pile, measured

FIG. 2. TYPICAL RESISTANCE THERMOMETER CIRCUIT AND CONNECTIONS

by a galvanometer or potentiometer, is an index of the surface temperature. With the optical pyrometer a narrow spectral band, usually red, emitted by the surface, is matched visually with the filament of a special electric lamp. The emf necessary to cause the filament to match the surface in brightness is the index of the temperature of the surface. Pyrometers are calibrated by means of various metals with known melting or freezing points. Portable as well as laboratory models are manufactured.

### Color Indicating Crayons

Crayons are available, the marks of which change color or melt at specified temperatures. Such crayons have been sold in boxes covering the range from about 100 F to about 800 F in 100 deg steps, with a precision of some 10 deg. They are a rough but convenient means of determining temperatures, and of locating isothermal lines on surfaces below red heat.

## PRESSURE MEASUREMENT

### Pressure Gages

The Bourdon is the most common type of pressure gage, and its appearance probably is familiar to any one having an acquaintance with power plants or laboratories. The essential element of such a gage is the Bourdon

tube, a metal tube of oval cross-section curved along its length to form almost a complete circle. One end is closed and the other is connected to the vessel in which the pressure is to be measured. With an increase of pressure, the tube tends to straighten, and vice versa. The resulting motion of the closed end is communicated by suitable linkages to a needle moving over a graduated dial. If the range is above about 20 psi, such gages are usually calibrated by means of a *dead weight tester*, whereby known pressures are produced in a fluid by imposing known weights on a piston of known area. Gages are commonly set to read accurately at or near the pressure of probable use. Gages of several different types or qualities are available on the market.<sup>12</sup> Suction gages and pressure gages with ranges below about 20 psi are ordinarily calibrated against mercury manometers.

### Manometers

The manometer is a simple and useful means for measuring partial vacuum and low pressure. It is, moreover, a primary instrument; it does not require calibration, and it is often used as a standard for the calibration of other instruments. It is so universally used that both the inch of water and the inch of mercury have become accepted units of pressure measurement. In its simplest form, the manometer consists of a U-shaped glass tube partially filled with a liquid. A difference in height of the two fluid columns denotes a difference in pressure in the two legs, which is proportional to the difference in height.

For converting manometer readings into other pressure units, certain proposed standard factors are applicable for precise work. These are based on a standard gravitational acceleration of 32.1740 ft per (sec) (sec) and are as follows:

$$\begin{aligned} 1 \text{ Standard Atmosphere} &= 14.696 \text{ lb per sq in.} = 29.921 \text{ in. mercury at } 32^\circ \text{ F} \\ &= 33.96 \text{ ft water column at } 68^\circ \text{ F} \end{aligned}$$

For most ordinary purposes, the following figures are of ample accuracy:

$$\begin{aligned} 1 \text{ Atmosphere} &= 14.7 \text{ lb per sq in.} = 29.9 \text{ in. mercury} \\ &= 34.0 \text{ ft (408 in.) water column} \end{aligned}$$

Manometer tubes should be chemically clean. The bore is not important, except insofar as it affects the meniscus through wetting or surface tension. Bores of at least  $\frac{1}{8}$  in. for rough, and  $\frac{1}{4}$  in. for more precise, measurements are recommended. Liquids other than water are sometimes used for low pressure measurement and, when this is done, the readings must be corrected for the density of the fluid used.

For measuring pressure differences of a few inches of water, or less, U-gages are often set at an angle for scale amplification. In many gages of this type, commonly termed draft gages or inclined manometers, only one tube of small bore is used and the other leg is replaced by a reservoir. The scale is calibrated to read in inches of water, and it is necessary to use a fluid having the same gravity as that for which the gage was originally calibrated, or to apply a correction if another fluid is used. Such gages may be checked one against another. For more accurate calibration the gage may be checked against a micromanometer or a calibrating device known as a hook gage.<sup>13</sup> The accuracy of a draft gage is dependent on the slope of the tube, and consequently the base of the gage must be leveled carefully. It is not desirable to use a slope of less than 1 in 10. Where pressures are read under extreme conditions of temperature, and calibration is possible only at normal temperature, it is necessary to correct for the change in density of the

liquid in the manometer.<sup>14</sup> For measuring low pressure differences to within 0.001 in. of water, very sensitive micromanometers are available, such as the Illinois or Wahlen, the Meriam, the Trimount, and the Emswiler.<sup>15, 16</sup>

When using a manometer or other pressure gage for measuring air flow, by means of orifices, the type of duct openings used for manometer connections and their location are important. Where velocities are low, as in some plenum chambers, or where the flow is free of large eddies and parallel to the walls of a duct, a drilled hole cleared of burrs and at right angles to the stream, is satisfactory.<sup>17</sup> For higher velocities, it is common practice to provide four holes or taps around the periphery of the duct. Diamet-

FIG. 3. STANDARD PITOT TUBE

rically opposite pairs of taps are connected together, and then such pairs are manifolded together.

An alternate method involves the use of the Pitot tube, shown in Fig. 3. This instrument should be pointed up-stream, parallel with the air flow. Where the flow is not axial or parallel to the side walls of the duct, a very close approximation of the static pressure and the flow direction can be obtained by a Fechheimer tube.<sup>18</sup>

### Barometer

The simplest and earliest type of barometer consists of a glass tube somewhat more than 30 in. long filled with mercury, and inverted in a cup partially filled with mercury. The height of the mercury column in the tube above the mercury surface in the cup is a measure of the existing atmospheric pressure, except for the slight pressure of the mercury vapor in the space above the mercury in the tube. This can ordinarily be ignored.

Elaborate mercury barometers, fitted with vernier scales, are available. For precise work, corrections must be made for the thermal expansion of the mercury and of the scales.<sup>19</sup> The instruments are usually calibrated for 32 F mercury and 62 F scale temperature, and the correction

C to be subtracted from the observed barometer's height is obtained by means of Equation 2.

$$C = \frac{h(t - 28.630)}{(1.1123t - 10978)} \quad (2)$$

where

C = correction to be subtracted, inches of mercury.

h = observed height, inches of mercury.

t = observed temperature of the barometer, Fahrenheit degrees.

Standard atmospheric pressure at sea level is 29.921 in. Hg, and since normal atmospheric pressure decreases about 0.01 in. Hg for each 10 ft increase in elevation, it is important to make a correction if the elevation of the barometer is not that of the test apparatus. In many cases the barometric reading may be obtained from a nearby Weather Bureau Station, in which case inquiry should be made as to whether the value is for station or sea level pressure.

Atmospheric pressure may also be measured by an aneroid barometer which is easily portable. In this type, variations in atmospheric pressure deflect the thin surface of a sealed diaphragm capsule. Most commercially available aneroid barometers are not as accurate as the mercurial type, and the best require occasional recalibration. Open-scale aneroid barometers are more expensive than common mercurial barometers. Most of the pressure gages used in engineering work indicate gage pressures, that is, the difference between the pressure being measured and the atmospheric pressure. Such pressures are called gage pressures. Absolute pressure may be obtained by adding barometric pressure and gage pressure algebraically.

### AIR FLOW MEASUREMENT

The theory of various means for measuring the flow of fluids is discussed in Chapter 4, Fluid Flow. Heating and air conditioning engineers are called upon to measure the flow of air more often than that of other gases, and usually the air is measured at or near atmospheric pressure. Under this condition, the air can be treated substantially as an incompressible fluid which implies that simplified formulas can be used with sufficient accuracy for the solution of many problems.<sup>20</sup>

#### The Pitot Tube

The construction of the Standard Pitot Tube<sup>13</sup> is shown in Fig. 3. The formula for velocity used in conjunction with it, is as follows:

$$V_m = 1096.5 \sqrt{\frac{h_{aw}}{\rho}} \quad (3)$$

where

$V_m$  = velocity, feet per minute.

$h_{aw}$  = velocity pressure (Pitot tube manometer reading), inches of water.

$\rho$  = density of air, pounds per cubic foot.

Since the velocity in a duct is seldom uniform across any section, and since a Pitot tube reading indicates a velocity at only one location, a *traverse* is usually made to determine the average velocity so that the flow can be computed. Suggested Pitot tube locations for traversing round and rectan-

gular ducts are shown in Fig. 4. In general, the velocity is lowest near the edges or corners, and greatest at or near the center. For this reason a large number of readings should be taken (in the case of round ducts not less than 20) along two diameters at centers of equal annular areas. In rectangular ducts the readings should be taken in the center of equal areas over the cross-section of the duct. The number of spaces should not be less than 16, and need not be more than 64. When less than 64 are taken, the number of equal spaces should be such that the centers of the areas are not more than 6 in. apart. In determining the average velocity in the duct from the readings given, the calculated individual velocities or the square roots of the velocity heads must be averaged. It is incorrect to use the average

FIG. 4. PITOT TUBE TRAVERSE FOR ROUND AND RECTANGULAR DUCTS

velocity head for this purpose. Pulsating or disturbed flow will give erroneous results and therefore, if possible, the Pitot tube should be located at least  $7\frac{1}{2}$  diameters down-stream from a disturbance such as that caused by a turn; or a criss-cross type of flow straightener should be installed in the duct  $1\frac{1}{2}$  diameters ahead of the Pitot tube.<sup>13</sup> Flow straighteners do not equalize flow velocity across a duct. They merely serve to improve the precision of measurements. Equalization can be effected, if desirable, for measuring purposes by the use of wire netting, perforated plates or cloth screens across the duct.

Many forms of Pitot tubes, other than the one described, have been used and calibrated.<sup>21</sup> A double-ended tube,<sup>22</sup> one end pointing down-stream, and one up-stream, is sometimes used for low velocities, but it should be carefully calibrated for accurate results. A special form of this tube design consists of two straight  $\frac{1}{8}$  in. tubes soldered together, closed at the end, and with a 0.04 in. hole in each tube opposite the line of contact. This tube is useful in exploring velocities in exhaust inlets, such as hoods placed around grinding wheels. To meet special conditions, different sized Pitot tubes which are geometrically similar to the standard tube can be used.

#### Plate Orifices

Application of the Pitot tube is often inconvenient when velocities are low, because the resultant velocity pressures become so small that extraordinary means are necessary for measuring them. In addition, velocity

surveys of the whole cross-sectional area of a duct are inexpedient when numerous test runs are in prospect. Chiefly for these reasons orifices are favored for much test work. There are two types: the plate orifice and the shaped orifice or nozzle. Plate orifices are simple to construct and convenient to use, in that a frame can be made to support them in the duct such that one can be removed and another inserted when it is desirable to use an orifice of a different size.

### Formulas for Orifices

In the heating and air conditioning fields it is usually convenient to obtain orifice pressure drops in inches of water column, temperatures in Fahrenheit degrees and barometric pressure in inches of mercury. The air flow is usually desired in cubic feet per minute at the existing condition, so that velocities in various ducts can be computed, and in pounds per hour so that computations of heat transferred by the air can be based on weight, temperature change and specific heat. Equation 4 is applicable.

$$Q_M = 5.2KYD^2 \sqrt{\frac{T_i}{B_i} h_w} \quad (4)$$

where

- $Q_M$  = air flow, cubic feet per minute.
- $K$  = orifice coefficient.
- $Y$  = expansion factor, see Fig. 5.
- $D$  = orifice diameter, inches.
- $d$  = pipe diameter, inches.
- $T_i$  = temperature of air at orifice, Fahrenheit, absolute.
- $B_i$  = absolute pressure ahead of orifice, inches of mercury.
- $B_a$  = absolute pressure after orifice, inches of mercury.
- $h_w$  = pressure drop through orifice, inches of water.

As most laboratories are less than 1000 ft above sea level, precision is adequate in many cases if standard atmospheric pressure, 29.92 in. Hg, is assumed. Equation 4 then becomes

$$Q_M = 0.95 KYD^2 \sqrt{T_i h_w} \quad (5)$$

After the flow in cubic feet per minute is determined, it can be expressed in pounds of air per hour by means of the relation

$$W = 60 \frac{PQ_M}{RT_i} \quad (6)$$

- $P$  = pressure, pounds per square inch, absolute.
- $R$  = 53.3, the gas constant for air.
- $T_i$  = temperature of the flowing air, Fahrenheit, absolute.

The thin-plate square-edged orifice often has a discharge coefficient  $K$  near 0.60. The exact value depends on the location of the connections, the pressure drop, the diameter ratio of orifice to pipe, and the sharpness of the edge.<sup>23, 24</sup> Other information on orifices and their use is contained in Chapter 4, Fluid Flow.

Shaped orifices or nozzles have the advantage, if well made, that their discharge coefficients are close to unity so that the probability of large errors is less. Orifices of this type have been adopted for several specific

purposes, and designs are described in the Unit Heater Code<sup>1</sup> and Unit Ventilator Code,<sup>2</sup> and in A.S.R.E. Circular 13<sup>3</sup> entitled Standard Methods of Rating and Testing Air Conditioning Equipment. In some instances nozzles are used in multiple so that the capacity of the testing equipment can be changed by shutting off the flow through one or more nozzles. An apparatus designed for testing the air flow and capacity of air conditioning equipment is described by Wile<sup>25</sup> in an article in which pertinent information on nozzle discharge coefficients, Reynolds numbers, and the resistance of perforated plates is also presented. Such apparatus in some laboratories is commonly referred to as a *code tester*.

The Venturi meter is like the nozzle, except for the addition of a downstream transition section that reduces the pressure drop through the measuring apparatus.

In some cases air velocity through a duct, heater coil, or heating unit may

FIG. 5. EXPANSION FACTOR FOR AIR AND OTHER DIATOMIC GASES APPLICABLE TO FLANGE, RADIUS AND VENA CONTRACTA TAPS

be most conveniently estimated by computation from the heat given up by the coil, and the temperature rise (measured by thermocouples) of the air passing through. It is essential to have a uniform flow over the entire inlet and outlet of the heater at the plane of temperature measurement.

### Propeller or Revolving Vane Anemometer

The propeller or revolving vane anemometer consists of a light revolving wind-driven wheel connected through a gear train to a set of recording dials that read the linear feet of air passing in a measured length of time. It is made in various sizes, 3 in., 4 in., and 6 in. being most common. Each instrument requires individual calibration. At low velocities the friction drag of the mechanism is considerable. In order to compensate for this, a gear train that overspeeds is commonly used. For this reason the correction is often additive at the lower range and subtractive at the upper range, with the least correction in the middle range of velocities. Most of these are not sensitive enough for use below 200 fpm. Anemometers of this type are practically standard for wind measurements, and may be used in large

ducts where the air flow is not seriously altered by the presence of the instrument itself.

### Deflecting Vane Anemometer

The deflecting vane anemometer consists of a pivoted vane enclosed in a case. Air exerts a pressure on the vane as it passes through the instrument from an up-stream to a down-stream opening. The movement of the vane is resisted by a hair spring and a damping magnet. The instrument gives instantaneous readings of directional velocities on an indicating scale. With fluctuating velocities, it is necessary to average visually the swings of the needle to obtain average velocities. This instrument is very useful for studying motion of the air in a room,<sup>26</sup> and in locating objectionable drafts. Various attachments are available, such as the double tube arrangement for determining velocities in ducts, and a device for measuring static pressures. Each instrument, and the attachments for it, must receive individual calibration. For determining average velocity in a duct, it is necessary to *traverse* the duct as is done when using the Pitot tube.

### Measurement of Velocities at Inlets and Outlets of Ducts

In the field it is often desirable to make volume measurements at the face of the supply openings. It is rare to have access to the interior of duct sections where the flow is sufficiently uniform for measurement. For accuracy, the instrument and its application should be checked on a similar approach and grille in the laboratory before use in the field.

Tests have shown that the propeller type anemometer can be used successfully on most of the common types of supply grilles.<sup>27, 28</sup> The core area is divided into equal squares, and the anemometer is held against the face of the grille for the same length of time in each. To obtain the air volume in cubic feet per minute, the average corrected velocity in feet per minute thus obtained is multiplied by the average of the gross and net free area of the grille (core) in square feet.

On exhaust openings, the anemometer traverse is made as described previously. The air volume may be determined by multiplying the corrected velocity in feet per minute by the gross core area of the grille in square feet, and by a coefficient for average conditions of 0.85.<sup>2</sup>

When a propeller type anemometer is held in a stream of varying velocities, it tends to indicate higher than the true average, that is; the speed of the propeller is nearer to the top velocity in its area than it is to the minimum velocity. This is the main reason for the large difference in ratings of unit ventilators by the anemometer method, and by air volume measurements in a duct approach to the inlet.<sup>30</sup>

Anemometers can be used within their range at the face of supply grilles when properly applied. In principle, it is a case of finding the velocity at many points, and using the average thus found with the correct discharge area at that cross-section. The deflecting vane anemometer equipped with a jet on the end of a rubber tube has been found especially convenient and accurate on supply grilles.<sup>31</sup> On modern air conditioning grilles, the core area is used without a correction coefficient when the jet is held one inch away from the face of the grille. At this distance, the constriction due to the thin bars has disappeared, since the small air jets have reunited and the air stream has not yet spread beyond the core dimensions. With deflecting grilles the exploring jet should be turned to the angle giving a maximum reading. With suitable traversing tips and calibration, this instrument

may also be used on exhaust grilles if proper grille factors are applied.<sup>32</sup> Those contemplating such measurements should consult the references cited.

Smoke is a qualitative tool which is very useful in studying air movements. Satisfactory smoke can be obtained from titanium tetra-chloride (which, however, is very irritating to nasal membranes) or by mixing potassium chlorate and powdered sugar (a non-irritating smoke) and firing the mixture with a match. This latter process evolves considerable heat, and it should be confined in a pan away from flammable materials. The titanium tetra-chloride smoke lends itself to spot determinations, particularly for leakage through casings and ducts, as it can be easily handled in a small pistol-like ejector. The fumes of aqua ammonia and of sulfuric acid, if permitted to mix, form a white precipitate which is useful for some purposes. Two bottles, one containing ammonia water and the other acid, are connected to a common nozzle by means of rubber tubing. Air is forced over the surfaces of the liquids in the bottles by means of a syringe, and the two streams, upon mixing at the nozzle, form a white cloud.

### The Kata Thermometer

The measurement of air current velocities within enclosed spaces, such as the rooms of a house, is usually a tedious undertaking. However, useful data can be obtained by using the instruments described in following paragraphs if they are maintained in calibration, and the user understands the operation and limitations of the instruments.<sup>33</sup>

One of the instruments useful for determining the velocity of air currents in free spaces is the Kata thermometer which is essentially an alcohol thermometer with a large bulb. The instrument is heated above 100 F, and then the time in seconds required for it to cool from 100 to 95, when located in the air current, gives a measure of the air speed. It is important to have the Kata thermometer dry before taking the reading. Each Kata has its own factor etched on the stem, and this factor must be used with its cooling formula or chart for obtaining the velocity. The Kata thermometer is useful in exploring ventilated spaces to determine whether the proper air movement and distribution are being maintained. It is also used in determining the cooling power of the atmosphere, since it loses heat by radiation and convection when dry, and by radiation, convection, and evaporation when the bulb is equipped with a wetted cloth covering.<sup>34</sup>

### Thermal Anemometers

If a suitable sensing element is heated electrically at a fixed rate and exposed to an air stream, the temperature difference between the element and the stream becomes a measure of velocity by calibration. In the *hot-wire anemometer*, a very fine heated wire is employed as a resistance-thermometer element whose temperature may be determined accurately.<sup>35, 36</sup> In the *heated-bulb thermometer* type, a heating wire is wound around the bulb of a mercury-in-glass thermometer, and the temperature difference between this thermometer and a similar unheated one serves as an index of air speed.<sup>37</sup> The *heated-thermocouple anemometer* is calibrated to give velocity in terms of the differential *emf* between heated and unheated thermo-junctions exposed to an air stream.<sup>35, 38</sup> Combined measurements of air temperature and velocity are particularly useful for air distribution studies, and automatic recording potentiometers or resistance-thermometer devices facilitate spatial traverses. A correct calibra-

tion of thermal anemometers requires consideration of the effects of temperature, humidity and pressure upon the air properties which influence convective heat transfer.<sup>38</sup> With sensing elements of simple shapes for which convection data are known, thermal anemometers may be designed, both thermally and electrically, for desired characteristics. Directional sensitivity is controllable. Thermal anemometers are convenient and practical for low velocities.

#### Infiltration or Air Change Measurement

The total air leakage into an existing building caused by wind and temperature difference forces can be determined with considerable accuracy by determining the decrease in concentration of a tracer gas. Hydrogen and helium have both been used rather successfully as tracer gases in conjunction with a sensitive thermal conductivity comparator.<sup>39</sup> About one percent of tracer gas by volume is introduced into the room or building, and the tracer gas is thoroughly mixed with the air. The decrease in concentration of the tracer gas is observed at regular time intervals with a thermal conductivity meter as infiltration dilutes the mixture. The following formula is used to calculate the infiltration from the observed concentration measurements:

$$C = C_0 e^{-\frac{kt}{v}} \quad (7)$$

where

- $C_0$  = initial tracer gas concentration, percent.
- $C$  = concentration of tracer gas after  $t$  minutes, percent.
- $v$  = volume of room or building, cubic feet.
- $k$  = infiltration rate, cubic feet per minute.
- $e$  = 2.718, for natural logarithms.

Closets and cupboards should be left open during such infiltration tests so the entire space will have the same rate of change of tracer-gas concentration.

### HUMIDITY MEASUREMENT

#### Psychrometers

Any instrument capable of measuring the humidity or hygrometric state of the air is a hygrometer. A psychrometer is a particular kind of hygrometer which consists of two mercury thermometers, one of which has a cloth wick or sock applied to its bulb. For use, the wick is wetted with water and ventilated with air moving at a recommended rate of 900 fpm or more, relative to the instrument.<sup>40</sup> In the simpler and more common type, known as the sling psychrometer, the two thermometers are mounted side by side on a frame fitted with a handle by which the device can be whirled through the air. The motion is arrested for reading the thermometers, and continued until the thermometer readings become steady. Due to evaporation, the wet-bulb thermometer will indicate a lower temperature than the dry-bulb thermometer, and the difference is known as the wet-bulb depression. Charts and tables are available showing the relation between the thermometer readings and the humidity.<sup>19, 41</sup> Data are usually based on a total pressure of one standard atmosphere. For precise work, a correction is necessary for barometric pressure and is usually made by multiplying the observed relative humidity by the ratio of the observed to the standard atmospheric pressure.

For air temperatures below 32 F, the water on the wick may either freeze or super-cool, and its state must be known and a proper table or chart used,

since the wet-bulb temperature is different for ice and for water. Some operators remove the wick from the wet-bulb for freezing conditions and dip the bulb in water a few times, allowing the water to freeze on the bulb between dips and to form a film of ice. Since wet-bulb depression is slight at low temperatures, precise temperature readings are essential.

In the ventilated or aspirated psychrometer, the thermometers remain stationary, and a small fan or blower or a syringe is used to move the air across the thermometer bulbs. Various designs have been employed in the laboratories, and several commercial models are available.

#### The Dew-Point Hygrometer

In the usual form of these instruments, means are provided for cooling, and of observing the temperature of, a surface which is exposed to air. The temperature at which visible condensation occurs on the surface is considered the dew-point of the air. With the dew-point temperature known, the relative humidity and other properties of the air can be taken from tables and charts (See Chapter 3). A bright surface or metallic mirror is usually employed to improve the visibility of the dew deposit, and various means are used to cool the mirror from the back, including evaporating ether or another refrigerant, or a stream of air passed through dry ice. Dew-point temperatures, in some cases, are observed by means of thermometers in fluids in contact with the back of the mirror, but in modern instruments thermocouples are used, and are soldered or welded to the mirror itself. The dew-point apparatus is not so commonly used as the psychrometer, probably because it is less convenient. It is usable, however, for higher temperatures than the wet- and dry-bulb psychrometer, and should be considered for dew-points near or above the boiling point, as in the case of flue gases. Special apparatus for high precision has been constructed, in which the photronic cell and a light source are used for dew or frost detection instead of visual inspection.

#### Hair Hygrometers

Many materials, especially organic materials, change in dimensions with changes in humidity, and many devices have been designed in efforts to utilize this action in simple and effective humidity indicators, recorders and controllers. Unfortunately, no material has been found which can be relied upon to perfectly reproduce its action when exposed to repeated identical changes in humidity. The field has been well explored, and instrument and control manufacturers are practically unanimous in the selection of human hair for this service.

The hair hygrometer consists of from one to several strands of hair with a mechanism whereby changes in length of the strands, due to changes in humidity, cause an indicator to move across a dial. In the recording instrument, a pen is moved across and marks a moving paper ribbon, indexed in relative humidity. In a controller, or humidistat, the motion makes or breaks an electric contact governing the air conditioning equipment. Such devices require initial calibration and, for precise work, frequent recalibration or setting, especially if they are exposed to extremes of either high or low humidity. For continuous operation, with only slight changes in humidity, some operators report satisfactory reproducibility of results.

#### Electrolytic Hygrometers

The dampness, and therefore the electrical resistance of a salt film, varies with the humidity of the atmosphere to which the film is exposed, and at

least two types of instruments based on this fact have been developed. The Dunmore hygrometer was originally designed for use in radio-sondes or small balloons, and means were devised whereby the device transmits humidity data back to earth in the form of a radio signal. In the more usual form, this hygrometer consists of a dual winding of small wire on a non-conducting tube. The whole is coated with an electrolytic film, usually containing a salt such as lithium chloride, which forms an electric connection between the windings. Means are provided for determining the electrical resistance of the film, which is an indication of the humidity. In the radio-sonde, variations in the resistance of the film affect the frequency of an oscillating circuit. These hygrometers are usually calibrated by comparison with a wet- and dry-bulb psychrometer. For calibration for some purposes, particularly for use at sub-zero temperatures, means have been provided for producing atmospheres of known humidity.<sup>42</sup> Advantages of instruments of this type for some scientific and industrial purposes are becoming apparent, and some forms of them are on the market.

The Weaver type hygrometer is particularly useful for determining the humidity of air or other gas in pipes or closed vessels at various pressures and temperatures. It consists of a threaded plug carrying a central electrode insulated from the plug, except for a gelatinous electrolytic film. The film is exposed to the air or gas from the pipe or vessel, and provision is made for determining its electrical resistance. The hygrometer, or detector, is mounted in a manifold equipped with valves whereby the film can be alternately exposed to the test gas, and to a standard gas having a known absolute humidity. The pressure of the standard gas is varied until contact with it establishes the same resistance in the film as the test gas, and the humidity of the test gas is then determined by computation based on the gas laws.

### Chemical Hygrometry

The humidity of an atmosphere can be measured directly by extracting and weighing the water vapor from a known sample. For precise laboratory work, powerful desiccants such as sulphuric acid and phosphorus pentoxide are used for the extraction process, while for some purposes, calcium chloride, lithium chloride or silica gel are satisfactory. Freezing the water vapor out of a measured stream of air or gas with solid carbon dioxide, and weighing the resulting ice, is a similar operation. A thermal conductivity method for gas analysis can be used for temperatures above 212 F, or for very low humidities.<sup>43</sup>

## HEAT TRANSFER THROUGH BUILDING MATERIALS

### Thermal Conductivity

The thermal conductivity ( $k$  value) of an insulation, as defined in Chapter 9, is a unit heat transfer factor. Practically universally accepted for the conductivity determination of flat insulation is the guarded hot plate, which is described in *ASTM* test method C-177.<sup>44</sup> In its simplest form it consists of an electrically heated plate and two water cooled plates. Two identical specimens or slabs of a material are required for a test, and one is mounted on each side of the hot plate. A cold plate is then pressed against the outside of each specimen by a clamp screw. The heated plate is divided into two portions: the central or measuring section, and the outer or guard section. During tests the two sections are maintained as nearly as possible at the same temperature. The purpose of the guard section is to minimize errors due to edge effects. The electric energy required to heat the meas-

uring section is carefully observed and, converted to Btu per hour, is divided by the area and the temperature gradient to obtain the conductivity of a material tested. Hot plate apparatus accommodating specimens on the order of one foot square and an inch or more thick, is common. The apparatus at the *National Bureau of Standards* takes specimens 8 in. square, while plates as large as 3 ft square have been used. The thermal conductivity of cylindrical or pipe insulation (Chapter 28) is determined in a similar manner except that an equivalent thickness must be calculated to account for the cylindrical shape.<sup>45</sup>

Recently there has been considerable development of transient state conductivity apparatus utilizing a slender probe.<sup>46, 47, 48, 49</sup> These instruments are commercially available and have the advantages of rapidity and requiring a small test specimen. While useful as research and development tools, the probe has not been generally accepted as have the guarded hot plate and pipe insulation apparatus.

### Wall Conductances

The thermal conductances ( $C$  values) of many walls can be satisfactorily estimated from the conductivities of their components and their dimensions, but some walls are complicated by the inclusion of metal, for instance, and tests for conductance are required. The apparatus is required to accommodate large specimens representing actual construction. The shielded hot box apparatus was developed for this purpose.<sup>50</sup> Specimens for the apparatus at the *National Bureau of Standards* are 5 ft long and 8 ft high, while others require different sizes, some larger, others smaller.

The guarded hot box is described in the *ASTM* Standard Test Code for Built-up Sections, C-236-54T.<sup>50</sup> The apparatus consists essentially of three boxes: a cold box, cooled by a refrigerating machine; a hot box, heated electrically; and a metering box also heated electrically. Each box has an open side to be placed against the specimen. The cold box is clamped against one side of the specimen, and the hot box against the other. The hot box encloses the metering box and is kept at the same temperature to minimize heat exchanges to or from the metering box, except through the specimen. The electric energy necessary to heat the metering box is measured, converted to Btu per hour, and divided by the area and the temperature difference through the wall, from surface to surface, to yield the conductance of the wall. The transmittance or  $U$ -value of the wall is then computed by means of the surface coefficients from Chapter 9.

A heat flow meter is sometimes useful for measuring steady heat flow through a wall or other building member.<sup>51, 52, 53</sup> In essence, this meter consists of a plate or slab of material of known thermal resistance having attached thermocouples on both sides. For use, the device is pressed against or cemented to the wall to be tested. At steady state, the temperature difference through the slab, measured with the thermocouples, with the known thermal resistance of the slab, indicates the heat flow through the slab and hence, through the wall covered by it. For best results, such meters are calibrated by means of a guarded hot plate or other suitable apparatus. The chief precaution is to assure that the heat flow is steady at the time of measurement.

## EVALUATION OF THE THERMAL ENVIRONMENT

Advocates of radiant heating emphasize the fact that comfort depends on radiant heat exchanges, as well as air temperature. For this reason sev-

eral instruments have been devised to evaluate the comfort or warmth of rooms, taking radiant as well as convective effects into account. Prominent among these are the eupatheoscope, the globe thermometer, the thermal integrator and the heated globe.<sup>54, 55</sup> Descriptions are contained in the references, and are omitted here because these devices are not widely used in America for several reasons, among which is the fact that radiant heating with high temperature sources is not a chief method of comfort heating in this country.

### COMBUSTION ANALYSIS

There are two approaches to the problem of measuring the capacities of fuel burning devices, such as boilers and furnaces. The direct or calorimetric test consists in measuring the change in enthalpy or heat content of the fluid, air or water, heated by the device and multiplying by the flow rate in pounds per hour to arrive at the capacity in Btu per hour.<sup>56</sup> The indirect test consists in determining the heat lost in the flue gases and deducting it from the heat evolved by combustion of the fuel.<sup>57</sup> A heat balance consists in the simultaneous application of both tests to the same device. The indirect test almost invariably indicates the greater capacity, and the difference is credited to radiation from the boiler or furnace casing and *unaccounted for loss*.

In the case of some small equipment, the expense of the direct test is not considered justifiable, and the indirect test is relied upon with an arbitrary *radiation and unaccounted for factor*.<sup>57</sup>

### Flue Gas Analysis

The Orsat apparatus is commonly used for analyzing flue gases. In its ordinary form, it consists of three pipettes and a means for isolating a sample of flue gas in a graduate. After measuring, the sample is expelled from the graduate into the first pipette where the carbon dioxide is extracted by potassium hydroxide. The sample is then remeasured and successively passed into the second and third pipettes, where the oxygen and the carbon monoxide are respectively extracted by potassium pyrogallate and cuprous chloride.

For field testing and burner adjustment, simpler portable devices are available for carbon dioxide determination only. From curves, based on typical hydrogen content of several common fuels, efficiencies may be estimated from the carbon dioxide value obtained. More elaborate laboratory equipment is sometimes provided for precise determination of carbon monoxide content by burning the carbon monoxide to carbon dioxide in presence of a catalyst.<sup>58, 59</sup> In large plants, carbon dioxide recorders are used to obtain a continuous indication of the plant's efficiency.<sup>60</sup>

### SMOKE DENSITY MEASUREMENTS

*Ringelmann charts* are widely used for evaluating the density of smoke discharged from chimneys or stacks, and smoke ordinances are based on them in some cities. Each chart is composed of a series of crossed black lines on white paper which, at a distance of about 50 ft, is visually compared with the smoke under observation. Four charts are used with different degrees of blackness as shown in Table 1. The smoke density is specified by Ringelmann numbers from 1 to 4.

The *photoelectric cell* is used in some apparatus developed for smoke density recording in large plants. The same device is included in the test-

ing equipment for domestic oil burners described in *National Bureau of Standards, Commercial Standard CS75-42*.<sup>61</sup> Under *Laboratory Tests* this publication contains the following section: "Smoke Determination.—After combustion has reached equilibrium, the amount of smoke in the flue gases, when viewed lengthwise through 4 feet of the smoke pipe in accordance with the *Underwriters' Laboratories, Inc.*, Standard for Domestic Oil Burners (Subject 296), March 1934 and subsequent revisions, shall not reduce the output of a standard photoelectric cell from 9 microamperes, with a clear smoke pipe, to less than 8 microamperes." The Commercial Standard also requires that during a test after installation, the burner shall operate without visible smoke at the chimney top.

A method of evaluating smoke produced by pot type oil burners was developed for the *Institute of Cooking and Heating Appliance Manufacturers* by R. N. St. John. A glass rod is interposed between a light source and a photo-sensitive cell, both before and after being exposed to the flue

TABLE 1. RINGELMANN SMOKE CHART SPACINGS

| NUMBER OF CARD | THICKNESS OF LINES, MM | DISTANCE IN CLEAR BETWEEN LINES, MM |
|----------------|------------------------|-------------------------------------|
| 1              | 1.0                    | 9.0                                 |
| 2              | 2.3                    | 7.7                                 |
| 3              | 3.7                    | 6.3                                 |
| 4              | 5.5                    | 4.5                                 |

gases from a heating device. The diminution of the light transmitted by the rod, due to the deposit of soot on its surface, causes a reduction in the cell emf which is taken as an index of the concentration of smoke in the flue gases. A description of the method is contained in *National Bureau of Standards Commercial Standard CS104-46*.<sup>67</sup>

### DETERMINATION OF AIR CONTAMINANTS

Two measures of air dustiness are in use: particles per unit volume of air, and weight per unit volume of air. A comparative method consists in drawing known samples of air through a known area of filter cloth or paper, and comparing the density of the resulting spots with blackness charts or with spots from other sources.

For counting, particles are captured in a device such as the Smith-Greenburg impinger, the Owens jet dust counter, or in an electrostatic or a thermal precipitation device designed for the purpose.<sup>62</sup> Counting is done with a microscope, and the method yields important results when the nature or constituents of the dust are of interest.

For a weight determination, a known volume of air is drawn through a porous crucible or thimble, and the weight gained by the thimble during the operation is the weight of the dust captured from the air sample.<sup>63</sup> For precise work, the thimble must be dried in a desiccating chamber before weighing each time.

A test method based on weight determination was used in the A.S.H.V.E Code for Testing and Rating Air Cleaning Devices Used in General Ventilation Work.<sup>64</sup> This code was withdrawn by the Society in 1955 when it was evident that no manufacturer of filters was using equipment such as that specified in the code. This withdrawal was accompanied by a statement that it did not imply that any other code

was recommended to take its place. The subject of air cleaning is under investigation in cooperative research now being conducted at the University of Minnesota.

At the National Bureau of Standards a test method was developed for interested Government agencies, under which measured samples of the uncleaned air and of the air cleaned by a device under test are passed through filter papers.<sup>65</sup> The ratio of the flow rates through the two filter papers is adjusted during successive tests, until the resulting dust spots approach equality in density as shown by a photometer. The ratio of the flow rates is then indicative of the effectiveness of the cleaner in arresting dust. A statement of an air cleaner's efficiency by any test method, is meaningless unless the test dust is specified. Other instruments for determining gaseous and particulate air contaminants are described in industrial hygiene literature.<sup>62, 66, 67, 68</sup>

### SOUND AND VIBRATION MEASUREMENTS

Approximate measurements of sound intensity can be made by aural methods. The ear is used to compare the measured noise with sounds of known strength.

Electrical devices, in which the ear plays no part, furnish the most satisfactory means of measuring noise intensities. The sound meter consists essentially of a microphone coupled to an amplifier designed with an ear-like response. The output of the microphone is read on a sensitive direct current milliammeter graduated to read directly in decibels. Instruments of this type, if connected with suitable band pass filters, can be used to study the intensity of the sound over its entire range of frequencies.

Electrical instruments are available for measuring the frequency, amplitude and acceleration of a vibrating mass. They are usually more convenient and accurate than the vibrating reed tachometer, the seismic type displacement meters or the accelerometers which can also be used for this purpose. Sound level meters are discussed in several text books<sup>69, 70</sup> and standards.<sup>71</sup>

## CHAPTER 53 CODES AND STANDARDS

THE Codes and Standards listed in Table 1 represent accepted practice, methods, or standards prepared and accepted by the organizations indicated. They are valuable guides for the practicing engineer in determining test methods, ratings, performance requirements, and limits applying to equipment used in heating, ventilating, and air conditioning. Copies can usually be obtained from the organization listed in the reference column.

TABLE 1. CODES AND STANDARDS PREPARED AND ACCEPTED BY VARIOUS SOCIETIES AND ASSOCIATIONS

| SUBJECT                                   | TITLE                                                                                                                        | SPONSOR                              | REFERENCE                           |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|-------------------------------------|
| Acoustics (Terminology)                   | American Standard Acoustical Terminology. (1951)                                                                             | AS of A                              | ASA Z24.1                           |
| Air Conditioning                          | Code of Minimum Requirements for Comfort Air Conditioning (1938).                                                            | ASHVE ASRE                           | ASHAE                               |
| Air Conditioning (120,000 Btu/Hr or less) | Code and Manual for the Design and Installation of Warm Air Winter Air Conditioning Systems (1953).                          | NWAH & ACA                           | NWAH & ACA Manual No. 7 4th Edition |
| Air Conditioning (Above 120,000 Btu/hr)   | Code and Manual for the Design and Installation of Mechanical Warm Air Heating Systems (1950).                               | NWAH & ACA                           | NWAH & ACA Manual No. 9 4th Edition |
| Air Conditioning                          | Standards for the Installation of Air Conditioning, Warm Air Heating, Air Cooling and Ventilating Systems.                   | NFPA                                 | NFPA or NBFU Pamphlet No. 90 1952   |
| Air Conditioning (Equipment)              | ASRE Standard Methods of Rating and Testing Air Conditioning Equipment (1942).                                               | ASRE<br>ASHVE<br>NEMA<br>RMA<br>ACMA | ASRE Circular No. 13-42             |
| Air Conditioners                          | ASRE Standard Methods of Rating and Testing Air Conditioners (1949). (Supersedes ASRE Circular 13-42)                        | ASRE                                 | ASRE Standard 16-53                 |
| Airplane                                  | Air Conditioning Equipment, Airplane—General Requirements for (1948).                                                        | SAE                                  | SAE ARP 83B                         |
| Airplane                                  | Heaters, Airplane, Internal Combustion Heat Exchanger Type (1949).                                                           | SAE                                  | SAE ARP 143B                        |
| Airplane                                  | Heaters, Airplane, Steam Type                                                                                                | SAE                                  | SAE ARP 87                          |
| Attic Ventilation                         | Residence Ventilation Guide (1950).                                                                                          | PFMA                                 | PFMA                                |
| Boilers                                   | I=B=R Testing and Rating Code for Low Pressure Heating Boilers (1950).                                                       | IBR                                  | IBR                                 |
| Boilers                                   | Net Load Recommendations for Heating Boilers. Publ. semi-annually.                                                           | HP & ACCNA                           | HP & ACCNA                          |
| Boilers                                   | Net Square Feet Radiation Loads in 70 Deg Fahr. Recommended for Low Pressure Heating Boilers (1948).                         | HP & ACCNA                           | HP & ACCNA                          |
| Boilers                                   | Standard and Short Form Heat Balance Codes for Testing Low Pressure Steam Heating Solid Fuel Boilers (Codes 1 and 2) (1929). | ASHVE                                | ASHAE                               |
| Boilers                                   | ASHVE Performance Test Code for Steam Heating Solid Fuel Boilers (Code No. 3) (1929).                                        | ASHVE                                | ASHAE                               |
| Boilers                                   | ASHVE Standard Code for Testing Steam Heating Boilers Burning Oil Fuel (1932).                                               | ASHVE                                | ASHAE                               |

TABLE 1. CODES AND STANDARDS—(Continued)

| SUBJECT                 | TITLE                                                                                                                                                      | SPONSOR      | REFERENCE            |

| Wiring                                    | National Electrical Code, (1953).                                                                   | NFPA       | NFPA or NFBU Pamphlet No. 70.       |

## ABBREVIATIONS AND ADDRESSES

The Codes and Standards listed in preceding pages of this table can be obtained from the organizations listed in the *Reference Column*.

ACMA Air Conditioning Manufacturers Association, superseded 1940 by ACRMA.  
 ACRMA Air Conditioning and Refrigerating Machinery Association, Southern Bldg., Washington, D. C. superseded 1953 by ARI.  
 AFA American Foundrymen's Association, 616 S. Michigan Ave., Chicago, Ill.  
 AFI Air Filter Institute, 215 Central Ave., Louisville, Ky.  
 A.G.A. American Gas Association, 420 Lexington Ave., New York 17, N. Y.

## ABBREVIATIONS AND ADDRESSES (Concluded)

## INDEX TO MODERN EQUIPMENT

### OF ADVERTISERS APPEARING IN HEATING VENTILATING AIR CONDITIONING GUIDE, 1956

- ACCUMULATORS**  
 Domestic Pump & Mfg. Corp., 1605 Hoffman Specialty Mfg. Corp., 1622-1625  
 McQuay, Inc., 1288-1289  
 Worthington Corp., 1241
- ACOUSTICAL CONTROL**  
 Burgess-Manning Co., 1438  
 Korlund Co., Inc., The, 1687  
 Tectum Div., Peoples Research & Mfg. Co., 1676
- ADHESIVES**  
 Armstrong Cork Co., 1665  
 Goodyear Tire & Rubber Co., Inc., The, 1334  
 Miracle Adhesives Corp., 1654
- ADSORBERS, Odor**  
 Barnebey-Cheney Co., 1322-1323  
 Connor Engineering Corp., 1326-1327  
 Charles E. Manning Co., 1335
- ADSORPTION SYSTEMS**  
 Barnebey-Cheney Co., 1322-1323  
 Connor Engineering Corp., 1326-1327  
 Desomatie Products, Inc., 1228  
 Charles E. Manning Co., 1335  
 Pittsburgh Lectrodryer Corp., 1238  
 Pur Air Div., Barnebey-Cheney Co., 1322-1323
- AFTER COOLERS**  
 American District Steam Div., Adco Industries, Inc., 1505, 1594  
 Niagara Blower Co., 1235  
 Parks-Cramer Co., 1236-1237
- AIR CLEANING EQUIPMENT**  
 (See also *Filters, Air*)  
 Air & Refrigeration Corp., 1219  
 Air Devices, Inc., 1316, 1432  
 Air Filter Corp., 1317  
 Air-Maze Corp., The, 1318  
 American Air Filter Co., Inc., 1319-1321  
 American Moistening Co., 1222  
 V. D. Anderson Co., The, 1612-1613  
 Bahnsen Co., The, 1223  
 Barnebey-Cheney Co., 1322-1323  
 Buffalo Forge Co., 1382  
 Cambridge Filter Corp., 1324  
 Carey Electronic Engineering Co., 1325  
 Continental Air Filters, Inc., 1328  
 Dollinger Corp., 1330-1331  
 Electro-Air Cleaner Co., 1329  
 Farr Co., 1332-1333  
 Goodyear Tire & Rubber Co., 1334  
 Charles E. Manning Co., 1335  
 Owens-Corning Fiberglass Corp., 1336, 1658  
 Pittsburgh Plate Glass Co., Fiber Glass Div., 1337, 1664  
 Research Products Corp., 1338  
 E. H. Sheldon Equipment Co., 1412-1413  
 Somers Corp., 1339  
 Trion, Inc., 1340  
 Vortox Co., 1341  
 Westinghouse Electric Corp., Sturtevant Div., 1342
- AIR COMPRESSORS** (See *Compressors, Air*)
- AIR CONDITIONING COILS**  
 Acme Industries, Inc., 1358  
 Aeroform Corp., 1359-1361  
 Airtemp Div., Chrysler Corp., 1248-1249  
 American Blower Corp., 1220-1221  
 Bell & Gossett Co., 1598-1599  
 Carrier Corp., 1226-1227  
 Drayer-Hanson, Inc., Div. of National-U. S. Radiator Corp., 1229  
 Governair Corp., 1232  
 Hastings Air Conditioning Co., Inc., 1233  
 Kennard Corp., 1234  
 Marlo Coil Co., 1355  
 McQuay, Inc., 1288-1289  
 Modine Mfg. Co., 1290-1291  
 John J. Nesbitt, Inc., 1293-1295  
 Niagara Blower Co., 1295  
 Patterson-Kelley Co., Inc., The, 1293
- AIR CONDITIONING SCREEN** (See *Screening*)
- AIR CONDITIONING UNITS**  
 Acme Industries, Inc., 1358  
 Addison Products Co., 1243  
 Air & Refrigeration Corp., 1219  
 Airtemp Div., Chrysler Corp., 1248-1249  
 American Blower Corp., 1220-1221  
 American Moistening Co., 1222  
 American Radiator & Standard Sanitary Corp., (Plumbing & Heating Div.), 1523-1525  
 American-Standard, Air Conditioning Div., 1244-1245  
 Armstrong Furnace Co., 1246-1247  
 Bell & Gossett Co., 1598-1599  
 Bishop & Babcock Mfg. Co., The, (Massachusetts Blower Div.), 1377  
 Brunner Mfg. Co., 1368  
 Buensod-Stacey, Inc., 1224  
 Buffalo Forge Co., 1382  
 Burnham Corp., 1526-1527  
 Carrier Corp., 1226-1227  
 Clarage Fan Co., 1225, 1387  
 Curtis Mfg. Co., Refrigeration Div., 1370  
 Drayer-Hanson, Inc., Div. of National-U. S. Radiator Corp., 1229  
 Electromode Corp., 1305  
 Farr Co., 1332-1333  
 Pedders-Quigan Corp., 1286  
 Frick Co., 1371  
 General Automatic Products Co., 1513  
 General Electric Co., 1231  
 Governair Corp., 1232  
 Hastings Air Conditioning Co., Inc., 1233  
 Hydraline Products, Div. Borg-Warner Corp., 1251  
 S. T. Johnson Co., 1582-1583  
 Kennard Corp., 1234  
 Marlo Coil Co., 1355  
 McQuay, Inc., 1288-1289  
 Modine Mfg. Co., 1290-1291  
 Mueller Climatrol, Div. of Worthington Corp., 1254-1255  
 National-U. S. Radiator Corp., 1530-1533  
 Herman Nelson, American Air Filter Co., Inc., 1296-1297  
 John J. Nesbitt, Inc., 1293-1295  
 Niagara Blower Co., 1235  
 Norman Products Co., 1257  
 Parks-Cramer Co., 1236-1237  
 Patterson-Kelley Co., Inc., The, 1353  
 Pennsylvania Furnace & Iron Co., 1258  
 Ready-Power Co., The, 1372  
 Refrigeration Appliances, Inc., 1259  
 Refrigeration Engineering, Inc., 1373  
 Rheem Mfg. Co., 1260-1261  
 Rittinger Corp., The, 1364  
 Roberts-Gordon Appliance Corp., 1577  
 Servel, Inc., 1262-1263  
 Sheldons Engineering Ltd., 1404  
 Trane Co., The, 1298-1301  
 Union Asbestos & Rubber Co., 1265  
 Vulcan Radiator Co., The, 1367

Western Blower Co., 1409  
Worthington Corp., 1241  
York Corp., 1242  
York-Shipley, Inc., 1590  
Young Radiator Co., 1304

#### AIR COOLING EQUIPMENT (See Cooling Equipment, Air)

#### AIR COOLING, HUMIDIFYING AND DEHUMIDIFYING AP- PARATUS

Addison Products Co., 1243  
Aerofin Corp., 1359-1361  
Air & Refrigeration Corp., 1219  
Airtemp Div., Chrysler Corp., 1248-

#### RADIATION, Baseboard Non- ferrous

American Radiator & Standard  
Sanitary Corp., (Plumbing &  
Heating Div.), 1523-1525  
Columbia Boiler Co., 1546-1547  
C. A. Dunham Co., 1618-1621  
Fedders-Quigan Corp., 1286  
G & O Mfg. Co., The, 1362  
General Automatic Products Corp.,  
1513  
Hoffman Specialty Mfg. Corp., 1622-  
1625  
Kritzer Radiant Coils, Inc., 1514  
National-U. S. Radiator Corp.,  
1530-1533  
Herman Nelson, American Air  
Filter Co., Inc., 1296-1297  
John J. Nesbitt, Inc., 1293-1295  
Rittling Corp., The, 1364  
Sarcotherm Controls, Inc., 1633  
Shaw-Perkins Mfg. Co., 1515  
Slant-Fin Radiator Corp., 1366  
H. B. Smith Co., Inc., The, 1537  
Trane Co., The, 1298-1301  
Tuttle & Bailey, Inc., 1460-1461  
Union Asbestos & Rubber Co., 1265  
Vulcan Radiator Co., The, 1367  
Warren Webster & Co., 1638-1639  
York-Shipley, Inc., 1590

#### RADIATION, Cast-Iron

American Radiator & Standard  
Sanitary Corp., (Plumbing &  
Heating Div.), 1523-1525  
Burnham Corp., 1526-1527  
Crane Co., 1528-1529

### Index to Modern Equipment

D. J. Murray Mfg. Co., 1292  
National-U. S. Radiator Corp.,  
1530-1533  
Weil-McLain Co., 1540

#### RADIATION, Copper

Airtherm Mfg. Co., 1522  
C. A. Dunham Co., 1618-1621  
Fedders-Quigan Corp., 1286  
G & O Mfg. Co., The, 1362  
General Automatic Products Corp.,  
1513  
Hoffman Specialty Mfg. Corp., 1622-  
1625  
Modine Mfg. Co., 1290-1291  
Rittling Corp., The, 1364  
Shaw-Perkins Mfg. Co., 1515  
Slant-Fin Radiator Corp., 1366  
Trane Co., The, 1298-1301  
Union Asbestos & Rubber Co., 1265  
York-Shipley, Inc., 1590  
Young Radiator Co., 1304

#### RADIATION, Plain, Extended Surface

American Radiator & Standard  
Sanitary Corp., (Plumbing &  
Heating Div.), 1523-1525  
Burgess-Manning Co., 1438  
C. A. Dunham Co., 1618-1621  
Fedders-Quigan Corp., 1286  
G & O Mfg. Co., The, 1362  
General Automatic Products Corp.,  
1513  
Modine Mfg. Co., 1290-1291  
National-U. S. Radiator Corp.,  
1530-1533  
Herman Nelson, American Air  
Filter Co., Inc., 1296-1297  
John J. Nesbitt, Inc., 1293-1295  
Rittling Corp., The, 1364  
Sarcotherm Controls, Inc., 1633  
Shaw-Perkins Mfg. Co., 1515  
Slant-Fin Radiator Corp., 1366  
H. B. Smith Co., Inc., The, 1537  
Trane Co., The, 1298-1301  
Union Asbestos & Rubber Co., 1265  
Warren Webster & Co., 1638-1639  
Young Radiator Co., 1304

#### RADIATION, Underfloor

National Clay Pipe Mfgs., The,  
1516-1521

#### RADIATOR BRACKETS (See Brackets, Radiator)

#### RADIATOR ENCLOSURES AND SHIELDS

American Radiator & Standard  
Sanitary Corp., (Plumbing &  
Heating Div.), 1523-1525  
National-U. S. Radiator Corp.,  
1530-1533  
Sarcotherm Controls, Inc., 1633  
Slant-Fin Radiator Corp., 1366  
Somers Corp., 1339

#### RADIATOR HANGERS (See Hangers, Radiator)

#### RADIATOR HEAT REFLEC- TORS

Infra Insulation, Inc., 1679  
Reflectal Corp., 1682  
Silvercote Products, Inc., 1680-1681

#### RADIATORS, Cabinet

Airtherm Mfg. Co., 1522  
American Radiator & Standard  
Sanitary Corp., (Plumbing &  
Heating Div.), 1523-1525  
Crane Co., 1528-1529  
C. A. Dunham Co., 1618-1621

Fedders-Quigan Corp., 1286  
Modine Mfg. Co., 1290-1291  
National-U. S. Radiator Corp.,  
1530-1533

Herman Nelson, American Air  
Filter Co., Inc., 1296-1297  
Rittling Corp., The, 1364  
Shaw-Perkins Mfg. Co., 1515  
Slant-Fin Radiator Corp., 1366  
Union Asbestos & Rubber Co., 1265  
Weil-McLain Co., 1540  
Young Radiator Co., 1304

#### RADIATORS, Concealed

Airtherm Mfg. Co., 1522  
American Radiator & Standard  
Sanitary Corp., (Plumbing &  
Heating Div.), 1523-1525  
Burnham Corp., 1526-1527  
Crane Co., 1528-1529  
C. A. Dunham Co., 1618-1621  
Fedders-Quigan Corp., 1286  
Kritzer Radiant Coils, Inc., 1514  
Modine Mfg. Co., 1290-1291  
National-U. S. Radiator Corp.,  
1530-1533  
Herman Nelson, American Air  
Filter Co., Inc., 1296-1297  
Rittling Corp., The, 1364  
Shaw-Perkins Mfg. Co., 1515  
Slant-Fin Radiator Corp., 1366  
Union Asbestos & Rubber Co., 1265  
Warren Webster & Co., 1638-1639  
Weil-McLain Co., 1540  
Young Radiator Co., 1304

#### RANGES, Cooking, Hotel, Hos- pital, etc.

Air Devices, Inc., 1316, 1432  
Ray Oil Burner Co., 1584-1585

#### RECEIVERS, Air

Curtis Mfg. Co., Refrigeration Div.,  
1370  
Farrar & Trefts Div., Adco In-  
dustries, Inc., 1554  
International Boiler Works Co.,  
The, 1556  
Joy Mfg. Co., 1394-1395  
Worthington Corp., 1241

#### RECEIVERS, Condensation

Domestic Pump & Mfg. Corp., 1605  
Hoffman Specialty Mfg. Corp.,  
1622-1625  
Illinois Engineering Co., 1626-1627  
Worthington Corp., 1241

#### RECEIVERS, Refrigerants

Acme Industries, Inc., 1358  
Worthington Corp., 1241  
York Corp., 1242

#### RECORDERS, Humidity, Tem- perature

American Moistening Co., 1222  
Electric Auto-Lite Co., The Instru-  
ment & Gauge Div., 1478  
Johnson Service Co., 1484-1485  
Moeller Instrument Co., 1493  
Powers Regulator Co., The, 1498-  
1499  
Taylor Instrument Cos., 1503

#### REFRATORIES, Cement, Ma- terials

Armstrong Cork Co. (Building Ma-  
terials Div.), 1665  
Babcock & Wilcox Co., The, 1542  
Philip Carey Mfg. Co., The, 1656-  
1657  
Johns-Manville, 1670-1671

#### REFRIGERANT DRIERS (See Driers, Refrigerant)

### REFRIGERATING EQUIP- MENT, Absorption

Carrier Corp., 1226-1227

### REFRIGERATING EQUIP- MENT, Centrifugal

Bell & Gossett Co., 1598-1599  
Carrier Corp., 1226-1227  
Trane Co., The, 1298-1301  
Worthington Corp., 1241  
York Corp., 1242

### REFRIGERATING EQUIP- MENT, Steam Jet

Worthington Corp., 1241

### REFRIGERATING MACHIN- ERY

Addison Products Co., 1243  
Airtemp Div., Chrysler Corp., 1248-  
1249  
American Blower Corp., 1220-1221  
Brunner Mfg. Co., 1368  
Carrier Corp., 1226-1227  
Curtis Mfg. Co., Refrigeration Div.,  
1370  
Copeland Refrigeration Corp., 1369  
Frick Co., 1371  
Niagara Blower Co., 1235  
Ready-Power Co., The, 1372  
Refrigeration Engineering, Inc.,  
1373  
Servel, Inc., 1262-1263  
Trane Co., The, 1298-1301  
Worthington Corp., 1241  
York Corp., 1242

### REFRIGERATION CONTROLS

Aleo Valve Co., Inc., 1472  
General Controls, 1480-1481  
Hubbell Corp., The, 1483  
Meroid Corp., The, 1480  
Penn Controls, Inc., 1494  
White-Rodgers Electric Co., 1504

### REFRIGERATION TUBE, Cop- per (See Tubes and Tubing, Cop- per)

### REGISTERS (See Grilles, Registers and Ornamental Metal Work)

A-J Mfg. Co., 1426-1427  
Air Control Products, Inc., 1428-  
1431  
Air-Factors, Inc., 1433  
Auer Register Co., The, 1436  
Barber-Colman Co., 1437, 1473  
Dole Valve Co., The, 1640  
General Register Corp., 1442-1443  
Hart & Cooley Mfg. Co., 1444-1445  
Hendrick Mfg. Co., 1446-1447  
Independent Register Co., The,  
1448  
Lima Register Co., 1450-1451  
Louvra Mfg. & Sales Co., 1452  
National-U. S. Radiator Corp.,  
1530-1533  
Pyle-National Co., The, (Multi-  
Vent Div.), 1454-1455  
Register & Grille Mfg. Co., Inc.,  
1453  
Stewart Mfg. Co., Inc., 1457  
Titus Mfg. Corp., 1458-1459  
Tuttle & Bailey, Inc., 1460-1461  
United States Register Co., 1462-  
1463  
Waterloo Register Co., Inc., 1465  
Young Regulator Co., 1470-1471

### REGULATORS, Air Volume

A-J Mfg. Co., 1426-1427  
Barber-Colman Co., 1437, 1473  
Duro-Dyne Corp., 1466-1467

Hart & Cooley Mfg. Co., 1444-1445  
Powers Regulator Co., 1496-1498  
Young Regulator Co., 1470-1471

**REGULATORS, Back Pressure**  
Alco Valve Co., 1472  
Hubbell Corp., 1483

**REGULATORS, Damper**  
A-J Mfg. Co., 1426-1427  
Barber-Colman Co., 1437, 1473  
Duro-Dyne Corp., 1466-1467  
Field Control Div., of H. D. Conkey & Co., 1477  
Hart & Cooley Mfg. Co., 1444-1445  
Minneapolis-Honeywell Regulator Co., 1490-1491  
Powers Regulator Co., The, 1496-1498  
Spence Engineering Co., Inc., 1501  
Trane Co., The, 1298-1301  
Young Regulator Co., 1470-1471

**REGULATORS, Draft**  
Field Control Div., of H. D. Conkey & Co., 1477  
Simplex Mfg. Co., 1500

**REGULATORS, Evaporator Pressure**  
Alco Valve Co., 1472  
Hubbell Corp., The, 1483

**REGULATORS, Feed Water**  
Heller Laboratories, Inc., 1352  
McDonnell & Miller, Inc., 1570-1573

**REGULATORS, Furnace**  
Field Control Div., of H. D. Conkey & Co., 1477  
Mercoid Corp., The, 1489  
Minneapolis-Honeywell Regulator Co., 1490-1491  
Penn Controls, Inc., 1494  
White-Rodgers Electric Co., 1504

**REGULATORS, Gas**  
General Controls, 1480-1481  
Maxitrol Co., 1488  
Minneapolis-Honeywell Regulator Co., 1490-1491  
Penn Controls, Inc., 1494  
Webster Engineering Co., The, 1579

**REGULATORS, Humidity (See Humidity Control)**

**REGULATORS, Pressure**  
Alco Valve Co., 1472  
Bell & Gossett Co., 1598-1599  
A. W. Cash Co., 1617  
C. A. Dunham Co., 1618-1621  
Fulton Syphon Div., The Robertshaw-Fulton Controls Co., 1478-1479

General Controls, 1480-1481  
Hoffman Specialty Mfg. Corp., 1622-1625  
Hubbell Corp., The, 1483  
Illinois Engineering Co., 1626-1627  
Johnson Service Co., 1484-1485  
Leslie Co., 1487  
Jas. P. Marsh Corp., 1628-1629

April Showers Co., 1644

**SWITCHES, Float**  
Alco Valve Co., 1472  
McDonnell & Miller, Inc., 1570-1573  
Mercoid Corp., The, 1489

**SWITCHES, Flow Control**  
McDonnell & Miller, Inc., 1570-1573

**SWITCHES, Mercury**  
Mercoid Corp., The, 1489  
Minneapolis-Honeywell Regulator Co., 1490-1491

**SWITCHES, Pneumatic**  
Powers Regulator Co., The, 1496-1498

**SWITCHES, Stack Safety**  
Minneapolis-Honeywell Regulator Co., 1490-1491  
Penn Controls, Inc., 1494  
White-Rodgers Electric Co., 1504

**SWITCHES, Time**  
April Showers, Inc., 1844  
General Controls, 1480-1481

**TANK COILS** (See Coils, Tank)

**TANK COVERING** (See Covering Pipe)

**TANK HEATERS** (See Heaters, Tank)

**TANKS, Blow-off**  
American District Steam Div., Adco Industries, Inc., 1505, 1504  
International Boiler Works Co., The, 1558

**TANKS, Pressure**  
Farrar & Trefts, Div., Adco Industries, Inc., 1554  
International Boiler Works Co., The, 1558  
Killebrew Engineering Corp., 1597  
Trane Co., The, 1298-1301

**TANKS, Storage**  
Rheem Mfg. Co., 1260-1261  
Western Blower Co., 1409

**TEMPERATURE CONTROL**  
Barber-Colman Co., 1437, 1473  
Cam-Stat, Inc., Div. of the Paul Henry Co., 1474  
Combustion Control Div., Electronics Corp. of America, 1475  
Crane Co., 1528-1529  
C. A. Dunham Co., 1618-1621  
Fulton-Sylphon Div., The Robertshaw-Fulton Controls Co., 1478-1479  
General Controls, 1480-1481  
Hoffman Specialty Mfg. Corp., 1622-1625  
Illinois Engineering Co., 1626-1627  
Illinois Testing Laboratories, Inc., 1486  
Johnson Service Co., 1484-1485  
Leslie Co., 1487  
Jas. P. Marsh Corp., 1628-1629  
Mercoir Corp., 1489  
Minneapolis-Honeywell Regulator Co., 1490-1491  
Penn Controls, Inc., 1494  
Powers Regulator Co., The, 1496-1498  
Sarco-Sarcotherm, 1633-1635  
Spence Engineering Co., Inc., 1501  
Sterling, Inc., 1502  
Taylor Instrument Cos., 1503  
Warren Webster & Co., 1638-1639  
West Electric Heater Co., 1307  
Young Regulator Co., 1470-1471

**TEMPERING VALVES** (See Valves, Tempering)

**THERMOMETERS, Distance Type**  
Electric Auto-Lite Co., The Instrument & Gauge Div., 1476  
Illinois Testing Laboratories, Inc., 1486  
Jas. P. Marsh Corp., 1628-1629  
Minneapolis-Honeywell Regulator Co., 1490-1491  
Moeller Instrument Co., 1493  
Powers Regulator Co., The, 1496-1498

Sarco Co., Inc., 1634-1635  
Taylor Instrument Cos., 1503

**THERMOMETERS, Indicating**  
Electric Auto-Lite Co., The Instrument & Gauge Div., 1476  
Fulton-Sylphon Div., The Robertshaw-Fulton Controls Co., 1478-1479  
Illinois Testing Laboratories, Inc., 1486  
Johnson Service Co., 1484-1485  
Jas. P. Marsh Corp., 1628-1629  
Minneapolis-Honeywell Regulator Co., 1490-1491  
Moeller Instrument Co., 1493  
Powers Regulator Co., The, 1496-1498  
Sarco Co., Inc., 1634-1635  
Taylor Instrument Cos., 1503

**THERMOMETERS, Recording**  
Electric Auto-Lite Co., The Instrument & Gauge Div., 1476  
Johnson Service Co., 1484-1485  
Minneapolis-Honeywell Regulator Co., 1490-1491  
Moeller Instrument Co., 1493  
Powers Regulator Co., The, 1496-1498

**THERMOSTATS**  
Barber-Colman Co., 1437, 1473  
Cam-Stat, Inc., Div. of the Paul Henry Co., 1474  
Combustion Control Div., Electronics Corp. of America, 1475  
Crane Co., 1528-1529  
Fulton-Sylphon Div., The Robertshaw-Fulton Controls Co., 1478-1479  
General Controls, 1480-1481  
Hoffman Specialty Mfg. Corp., 1622-1625  
Johnson Service Co., 1484-1485  
Mercoir Corp., The, 1489  
Minneapolis-Honeywell Regulator Co., 1490-1491  
Penn Controls, Inc., 1494  
Powers Regulator Co., The, 1496-1498  
Sarco Co., Inc., 1634-1635  
Sarcotherm Controls, Inc., 1633  
H. A. Thrush & Co., 1600-1601  
West Electric Heater Co., 1307  
Edwin L. Wiegand Co., 1308-1309

**TIME SWITCHES** (See Switches, Time)

**TIMERS, Electric, Interval**  
Barber-Colman Co., 1437, 1473

**TOOLS, Sheet Metal**  
Duro-Dyne Corp., 1486-1487

**TOWERS, Cooling.** (See Cooling Towers)

**TRANSFORMERS**  
General Controls, 1480-1481

**TRAPS, Air**

## Index to Modern Equipment

Strong, Carlisle & Hammond Co., 1637  
Trane Co., The, 1298-1301  
Warren Webster & Co., 1638-1639

**TRAPS, Thermostatic**  
Barnes & Jones, Inc., 1616  
Crane Co., 1528-1529  
C. A. Dunham Co., 1618-1621  
Hoffman Specialty Mfg. Corp., 1622-1625  
Illinois Engineering Co., 1626-1627  
Jas. P. Marsh Corp., 1628-1629  
Powers Regulator Co., The, 1496-1498  
Sarco Co., Inc., 1634-1635  
Sterling, Inc., 1502  
Trane Co., The, 1298-1301  
Warren Webster & Co., 1638-1639

**TRAPS, Vacuum**  
V. D. Anderson Co., The, 1612-1613  
Armstrong Machine Works, 1614-1615  
Barnes & Jones, Inc., 1616  
Hoffman Specialty Mfg. Corp., 1622-1625  
Illinois Engineering Co., 1626-1627  
Jas. P. Marsh Corp., 1628-1629  
Sarco Co., Inc., 1634-1635  
Strong, Carlisle & Hammond Co., 1637

**TUBES, Boiler**  
Babcock & Wilcox Tube Co., The, 1542

**TUBES and TUBING, Copper**  
American Brass Co., The, 1310-1311  
Revere Copper and Brass Incorporated, 1313  
Wolverine Tube, 1314-1315

**TUBES, Pitot** (See Air Measuring and Recording Instruments)

**TUBING, Aluminum**  
American Brass Co., The, 1310-1311  
Revere Copper and Brass Incorporated, 1313  
Wolverine Tube, 1314-1315

**TUBING, Fabricated**  
Revere Copper and Brass Incorporated, 1313  
Wolverine Tube, 1314-1315

**TUBING, Finned**  
G & O Mfg. Co., The, 1362  
General Automatic Products Corp., 1513  
Kritzer Radiant Coils, Inc., 1514  
Rittling Corp., The, 1364  
Rome-Turney Radiator Co., The, 1365  
Wolverine Tube, 1314-1315

**TUBING, Flexible**  
Wiremold Co., The, 1469

**TUBING, Flexible, Metallic**  
Aeroquip Corp., 1312  
American Brass Co., The, 1310-1311  
Flexonics Corp., 1507

**TUBING, Insulation** (See Insulation, Tubing)

**TUBING, RESTRICTOR**  
American Brass Co., The, 1310-1311  
Wolverine Tube, 1314-1315

**TUBING, Steel**  
Revere Copper and Brass Incorporated, 1313  
Wolverine Tube, 1314-1315

**TUBING, Unicellular Rubber**  
B. F. Goodrich, Sponge Products Div., 1883

**TURBINES**  
Pyle-National Co., The, 1454-1455  
L. J. Wing Mfg. Co., 1302-1303  
Worthington Corp., 1241

**UNDERGROUND PIPE CONDUITS** (See Conduits, Underground Pipe)

**UNIT STEAM GENERATORS**  
(See Steam Generators, Unit)

**UNIT VENTILATORS** (See Ventilators, Unit)

**UNITS, Air Conditioning** (See Air Conditioning Units)

**VACUUM HEATING SYSTEMS**  
(See Heating Systems, Vacuum)

**VALVES, Air**  
V. D. Anderson Co., The, 1612-1613  
Crane Co., 1528-1529  
Desomat Products, Inc., 1223  
C. A. Dunham Co., 1618-1621  
Fairbanks Co., The, 1641  
Hammond Brass Works, 1642  
Hoffman Specialty Mfg. Corp., 1622-1625  
Jenkins Bros., 1643  
Jas. P. Marsh Corp., 1628-1629

**VALVES, Angle, Globe and Cross**  
Crane Co., 1528-1529  
Fairbanks Co., The, 1641  
Frick Co., 1371  
Hammond Brass Works, 1642  
Henry Valve Co., 1482  
Jenkins Bros., 1643

**VALVES, Automatic**  
Barber-Colman Co., 1437, 1473  
A. W. Cash Co., 1617  
Combustion Control Div., Electronics Corp. of America, 1475  
Dole Valve Co., 1640  
Fulton-Sylphon Div., The Robertshaw-Fulton Controls Co., 1478-1479  
Hubbell Corp., The, 1483  
Johnson Service Co., 1484-1485  
Leslie Co., 1487  
Jas. P. Marsh Corp., 1628-1629  
McDonnell & Miller, Inc., 1570-1573  
Minneapolis-Honeywell Regulator Co., 1490-1491  
Penn Controls, Inc., 1494  
Powers Regulator Co., The, 1496-1498  
Sarcotherm Controls, Inc., 1633  
White-Rodgers Electric Co., 1504

**VALVES, Back Pressure**  
Aco Valve Co., 1472  
A. W. Cash Co., 1617  
Hubbell Corp., The, 1483  
Illinois Engineering Co., 1626-1627

**VALVES, Balancing**  
Hammond Brass Works, 1642

**VALVES, Gate**  
Crane Co., 1528-1529

**VALVES, Gas**  
Combustion Control Div., Electronics Corp. of America, 1475  
Fairbanks Co., The, 1641  
Hammond Brass Works, 1642  
Jenkins Bros., 1643  
Penn Controls, Inc., 1494  
White-Rodgers Electric Co., 1504

**VALVES, Flow Control**  
Bell & Gossett Co., 1598-1599  
Crane Co., 1528-1529  
Dole Valve Co., 1640  
C. A. Dunham Co., 1618-1621  
Fulton-Sylphon Div., The Robertshaw-Fulton Controls Co., 1478-1479  
General Controls, 1480-1481  
Illinois Engineering Co., 1626-1627  
Jas. P. Marsh Corp., 1628-1629  
McDonnell & Miller, Inc., 1570-1573  
Powers Regulator Co., The, 1496-1498  
H. A. Thrush & Co., 1600-1601  
Warren Webster & Co., 1638-1639

**VALVES, Flow Control**  
Bell & Gossett Co., 1598-1599  
Crane Co., 1528-1529  
Dole Valve Co., 1640  
C. A. Dunham Co., 1618-1621  
Fulton-Sylphon Div., The Robertshaw-Fulton Controls Co., 1478-1479

# MANUFACTURERS' CATALOG DATA

(PAGES 1219-1696)

On pages 1219-1696 will be found the Catalog Data of 335 manufacturers whose products are described and illustrated.

For the convenience of the user of THE GUIDE 1956 there are eleven main divisions:

|                                          |           |
|------------------------------------------|-----------|
| Air Conditioning.....                    | 1219-1309 |
| Air Conditioning and Heating Piping..... | 1310-1315 |
| Air System Equipment.....                | 1316-1471 |
| Controls and Instruments.....            | 1472-1504 |
| Expansion Joints.....                    | 1505-1507 |
| Fittings and Flanges.....                | 1508-1511 |
| Floats.....                              | 1512      |
| Heating Systems.....                     | 1513-1643 |
| Insulation.....                          | 1644-1685 |
| Vibration.....                           | 1686-1688 |
| Publications.....                        | 1689-1695 |

On pages 1187-1216, under each of the index headings—Air Cleaning Equipment, Fans, Humidifiers, Ventilators, etc., will be found a list of manufacturers of any desired products, fully cross-indexed, and the page numbers in the Catalog Data Section where the products are described.

By reference to these indices, the manufacturers' names and the page numbers, any item of equipment or materials, and the producer's address, may be located quickly.

## Air & Refrigeration Corporation

439 Madison Avenue, New York 22, N. Y.

271 Milton Avenue, S. E., Atlanta, Ga.

Representatives in all major cities  
Air Conditioning, Humidifying, Dehumidifying, Cooling,  
Scrubbing, Air Washing and Purification Apparatus

Air & Refrigeration Corporation specializes in the design and manufacture of industrial and comfort-conditioning apparatus where maintenance of suitable humidity and temperature within closely controllable limits is essential. This specialization is based on technical knowledge and ingenuity born of extensive experience in the solution of the more difficult problems of air conditioning. A complete line of air conditioning equipment is available to contractors and owners for all phases of humidifying, dehumidifying, cooling and washing.

\* Capillary Air Washers provide a superior type humidifying, dehumidifying, air washing, cleaning and cooling unit for central station apparatus. For most purposes the Capillary Washer requires  $\frac{1}{2}$  the volume of water at  $\frac{1}{2}$  the pressure used by conventional spray equipment. They are available with factory insulated casings and tank for central station applications. For complete data, see Capillary Bulletin.

\* Capillary Unit Conditioners are factory insulated and assembled, ready for use. They include fan, motor, drive, heating coils, Capillary Cells with suitable sprays, spray pump and mixing dampers. Units are designed for floor mounting or for ceiling suspension, and can be arranged for the reception of cooling coils, if required. Complete description and engineering data will be found in Capillary Unit Bulletin.

Factory Insulated Class I  
Capillary Air Washer

Spray Type Air Washers for washing, humidifying and dehumidifying air are all basically the same. A & R Spray Washers include special features of design developed to insure more efficient and dependable operation, lower maintenance costs, and, in many cases, lower installation costs. Such features relate especially to eliminators, collecting tanks, flooded baffles, nozzle arrangement, etc. Spray Washers can be supplied with factory insulated casings and tank for central station applications. For details, see Air Washer Bulletin.

Sprayed Coil Dehumidifiers for year-round treatment of air are complete with cooling coils, sprays, circulating pump and glass mat eliminators. Sprayed coil dehumidifiers are factory insulated and complete, ready for assembly in the field. Special features in design insure continuous washing and cleaning of finned surfaces and easy accessibility to all parts. For engineering information and detailed description, see Sprayed Coil Bulletin.

A & R Insulated Panels consist of insulation between metal sheet on one side and hard fiber board on the other, the three laminated and cemented together. This unique panel design includes the structural frame to form units which require only bolting together to make enclosures of any required shape for plenum chambers and many other purposes. Panels are available in widths from 3 in. to 48 in., and in lengths to 12 ft. Their use insures tremendous economies in field labor. For details, see Panel Bulletin. Write for catalog and engineering data.

## American Blower Corporation

Detroit 32, Michigan  
CANADIAN SIROCCO COMPANY, LTD.  
310 Ellis Street, Windsor, Ontario  
Branch Offices in Principal Cities

Division of AMERICAN - Standard

AIR CONDITIONING — HUMIDIFYING — DEHUMIDIFYING — COOLING  
— VENTILATING — HEATING — VAPOR-ABSORPTION — DRYING — AIR  
WASHING AND PURIFICATION — EXHAUSTING EQUIPMENT AND  
MECHANICAL DRAFT APPARATUS

Capillary Air Washers—above, for high efficiency in cleaning, humidification, cooling and dehumidification of air. Air is forced at low resistance through long, irregular passages of small size formed by a large amount of thoroughly wetted glass surface. Write for *Bulletin 4023*.

Heating & Cooling Coils—above, American Blower heating and cooling coils offer a number of improvements in design and construction. Available in a complete range of sizes and types, including:

- Bulletin B-1218** Type S steam coils  
Type D double tube coils  
Type U return blend coils  
Type B booster coils  
Type W water coils  
Type C cleanable water coils  
Type X direct expansion coils  
**Bulletin B-1318** Type H heavy duty coils

"ABC" Utility Sets—complete packaged units, directly connected or V-belt short coupled drive for duct applications. Equipped with Aileron Control consisting of scroll sheet adjusted by connecting rod. Fan outlet is modified to give efficient operation over a wide range of air volumes and pressures. Sizes for a wide variety of ventilating problems. Quiet, compact. Complete technical information in *Bulletin 2814*.

Double Inlet "ABC" Multiblade Fan—above, is a heavy duty ventilating fan. The wheel has narrow, forward pitched blades. Low tip speeds assure quiet operation. Request *Bulletin A-801*. *Bulletin A-603* describes backwardly inclined, nonoverloading HS Fan.

## TYPES OF AMERICAN BLOWER CORPORATION AIR HANDLING AND CONDITIONING EQUIPMENT

All types of air handling and air conditioning equipment for industrial applications, process work, drying, cooling; also equipment for stores, offices, shops, public buildings, power plants, etc., and attic and kitchen ventilation for homes.

Unit Heaters—for many general purpose heating jobs. Wall or ceiling mounted. Streamline construction, rugged heating elements. Steam or hot water. Request *Bulletin 7517*.

Gas Fired Unit Heater—self contained—for clean, automatic, instantaneous heating. Adjustable louvers assure efficient heat distribution throughout the work area. A. G. A approved. Write for *Bulletin 8517*.

Centrifugal Type Unit Heaters—for use with or without duct systems, for large hard to heat areas. Ideal for floor mounting. Request *Bulletin 7727*.

Heating and Ventilating Units—with air filters and Aileron control. Ideal wherever attractive, quiet and economical heating and ventilation units are required. Wall, floor or ceiling mounting. Offer great flexibility of design and arrangement to meet specific needs. *Bulletin 7227*.

American Blower Air Conditioning Units.—Three basic types are available in twelve sizes, with capacities from 600 to 48,000 cfm. Type A (shown) is designed for all normal unitary-type commercial and industrial applications: Summer cooling and dehumidifying, using chilled water, direct-expanded refrigerant, or brines; winter heating, using steam or hot water. Type S is same basic unit as Type A, plus spray system, water recirculating pump and eliminators; combines the washing, air cleaning, humidifying, and evaporative cooling of an air washer with the cooling and heating of the basic unit conditioner. Type AB Multi-Zone Unit is furnished in a single arrangement for either horizontal or vertical air flow. Plenum and diffusion device between fans and coils provides even air distribution over coils. Request *Bulletin 8427*.

## American Moistening Company

Providence 1, R. I.

ATLANTA, GA. BOSTON, MASS. CAMDEN, N. J. CHARLOTTE, N. C.

# AMCO

Humidification Systems since 1888

### AMCO ATOMIZER NO. 6

The automatically self-cleaning Amco No. 6 micro-spray atomizer delivers a smoke-like spray to a great distance for balanced distribution of humidity. Its fine performance and ease of maintenance make this atomizer popular for new installations and replacements. These units require compressed air for operation and obtain their water supply from a constant level, float controlled tank.

### AMCO MODEL 35 HUMIDIFIER

Ideally suited for areas of light heat concentration, especially where cost of other types of humidification might be prohibitive. Propeller-type fan draws room air into rear of unit and forces it forward around periphery of atomizer disc—thus carrying atomized water into room where it quickly evaporates into surrounding atmosphere. Housed in stainless steel. Requires only simple water and electrical connections. May be adjusted to evaporate from zero to 22 pounds of water per hour while circulating 1200 cu ft of air per minute. Simple and reliable, it requires a minimum of maintenance.

### AMCO CYCLESTAT HUMIDITY CONTROL

The Amco Cyclestat is easily adjusted and provides exceptionally fine control of relative humidity within limits heretofore believed impractical. This improvement comes from a unique "change anticipating mechanism" which employs jeweled bearings and a principle of operation that converts microscopic changes in its humidity sensing membranes into instantaneous control signals. When properly adjusted and located all variations from the selected relative humidity are immediately counteracted.

## THE *Bahnson* COMPANY • WINSTON-SALEM, N. C.

Air Conditioning • Humidification • Cleaning

1. **AIR WASHER**—Bahnson Type Y and Type DC Air Washers cleanse, cool, and provide humidity control. Available in standard sizes from 6,000 to 250,000 cfm, they can be provided with spray systems best suited for the specific application. Write for Catalog 1A

2. **TYPE E HUMIDIFIER**—A self-contained unit with high evaporative capacity for installation in all types of industrial and commercial spaces requiring automatically controlled humidification. Evaporates up to 3 gallons per hour with 360 degree radial distribution of moisture. Requires only water supply and electrical connection. Write for Catalog 16A

3. **CENTRIFUGAL HUMIDIFIER**—A self-contained unit for industrial use. Evaporation up to 12 gph plus directional air flow with fractional horsepower motor. Installed singly or in groups with individual or group automatic control. Requires only water supply, drain, and electrical connection. Write for Catalog 2A

4. **TYPE BA-2 HUMIDIFIER**—A high-capacity unit for overhead suspension in commercial and industrial applications. Adjustable grilles give complete directional control of moist air delivered. Automatically regulated, the unit provides air flow, humidification and filtering. Requires only water supply, drain, and electrical connection; capacity up to 18 gph. Write for Catalog 17A

5. **TYPE ESC-2 ATOMIZER**—A self-cleaning pneumatic atomizer of superior design for direct humidification or supplementary evaporation. Uses air and water under pressure to provide high evaporation and fine spray quality, with minimum air requirements. Modulating control regulates evaporation in direct proportion to the room requirements. Write for Catalog 3A

Other equipment manufactured by Bahnson includes: portable humidifiers, steam humidifiers, air washer suction strainers, spray nozzles, automatic controls, grilles and complete industrial air conditioning systems. Write for descriptive literature on your requirements.

## BUENSOD-STACEY

60 East 42 St.

Richmond, Va.

New York 17, N. Y.

Charlotte, N. C.

Air Conditioning, Humidifying, Cooling, Ventilation Systems

**DUAL DUCT AIR CONDITIONING SYSTEMS.** In multi-story buildings with many separated occupied spaces, Dual Duct air conditioning allows each occupant to select the temperature at which he is most comfortable. For example, it allows one space to be cooled while an adjacent one is being heated. Air does all heating and cooling and insures proper ventilation.

Buensod-Stacey has devoted many years in the development of design techniques and apparatus improvement. In this long study it became apparent that the basic requirement of such a system is constant air flow to all areas. To accomplish this, air mixing units, each with self-contained volume regulators requiring no outside source of power, were developed for use in Dual Duct systems.

**TYPE V3 DUAL DUCT AIR MIXING AND DISTRIBUTING UNITS** are made in three parts for installation under windows or against walls. They supply air vertically through high velocity outlets. Mixing unit V3 contains pneumatically operated air mixing valve and self-contained volume controller. To this is attached a distributing header, VD, which can be varied in length to suit window width or building module. Part VFC provides a flush, finished front for the entire area under the distributing header and can also be varied in height and length to accommodate the space.

**TYPE H DUAL DUCT AIR MIXING UNITS** have a wider range of sizes than Type V3 and are designed for overhead or under-floor installation. Each one includes an automatic, pneumatically operated, air mixing valve, and self-contained volume controller. The units are arranged to supply air to conditioned spaces through conventional grilles, registers, or diffusers.

**BUENSOD-STACEY HIGH PRESSURE DEHUMIDIFIERS** for use in high pressure Dual Duct systems have been developed. A series of specially braced, factory insulated, sprayed coil dehumidifiers for use with pressure up to 10 in. wg are described in Bulletin DD-1.

Dual Duct Air Mixing and Distributing Units Under Windows

Type V3 Air Mixing Unit complete with Distributing Header and Front Cover

Type H Air Mixing Unit

## CLARAGE

**CLARAGE FAN COMPANY**  
Kalamazoo, Mich.

Air Handling and Conditioning Equipment  
Application Engineering Offices in All Principal Cities

For nearly a half century Clarage has been a leading manufacturer of equipment and units for ventilating, exhausting, cooling, air cleaning, humidifying and complete conditioning. Clarage equipment is designed to meet all types of industrial, commercial and public building requirements. For other equipment in the complete Clarage line see "Air System Equipment—Fans and Blowers."

Clarage Multitherms cool and dehumidify in summer, heat and humidify in winter. For comfort applications and process conditioning. Vertical and horizontal types, 10 sizes, capacities 600 to 20,500 cfm.

Clarage Air Washers are built in both capillary and spray types. Sizes range from 2000 to 193,000 cfm. Used for air cleaning, humidifying and dehumidifying purposes. Special constructions can be furnished.

Clarage Unicoil Units are ideal as an integral part of a central station system for heating or cooling, or both; or for complete air conditioning in comfort applications. Wide size range.

We welcome your inquiry on any air handling or conditioning problem. Contact our nearest branch office, or write us at Kalamazoo, Michigan.

## Carrier Corporation • Syracuse 1, N. Y.

Offices and Dealers in principal cities—refer to your telephone directory.

## **Carrier** AIR CONDITIONING

**Weathermakers**—completely self-contained air conditioners for commercial and industrial applications. Six sizes from 2 to 15 hp cooling capacity.

**Year-Round Weathermakers**—for heating and cooling in residential and commercial applications. Compact, efficient gas heating combined with summer cooling. Six combination sizes.

**Room Weathermakers**—fan-coil units for use with remote sources of refrigeration and heat. Each unit operates independently permitting individual room temperature control. Units are available in  $\frac{1}{2}$ , 1 and  $1\frac{1}{2}$  ton capacities with or without cabinets.

**Zoning Weathermakers**—blow-through fan-coil units for air conditioning systems using remote sources of heat and refrigeration. Six sizes for comfort and industrial applications, 6 to 80 tons.

**System Weathermakers**—fan-coil unitary air conditioners for applications to central cooling and heating systems for comfort and industrial use. Seven sizes from 5 to 125 tons, 2,000 to 23,000 cfm.

**Central Station Air Conditioners**—for application with fan and duct systems for large spaces such as stores, theatres, auditoriums and industrial plants.

**Weathermaster Systems**—for air conditioning of multi-story, multi-room buildings such as hotels, hospitals, office and apartment buildings. System consists of room units with individual temperature control, and central station air conditioning. Conditioned air distributed by high velocity conduits to individual Weathermaster units shown.

**Blast Freezers and Cold Diffusers**—for food freezing and storage, meat packing operations, and other industries requiring low temperatures. Units available in suspension or floor models, for use within space to be refrigerated or remotely located and connected by ducts.

Write for descriptive literature.

## **Carrier** REFRIGERATION

**Centrifugal Refrigerating Machines**—for large comfort and industrial air conditioning applications and for process cooling. High efficiency at peak or partial loads. Operate with any standard motor or turbine drive. Available in capacities from 100 to 4000 tons in a single unit.

**Absorption Refrigerating Machines**—for producing chilled water at 40 F or higher in fully automatic operation from 0 to 100 per cent capacity. Uses low pressure steam for operation. Available in eleven sizes with capacities from 100 to 700 tons.

**Water Cooling Machines**—Compact, packaged water cooling systems for air conditioning and for industrial process cooling. Direct or belt drive, capacities range from 5 to 200 hp.

**Commercial Refrigerating Machines**—for storage refrigerators, display cases, walk-in coolers and similar duty. Complete with compressor, drive, air or water cooled condenser and controls. All sizes.

**Reciprocating Compressors**—for refrigeration needs of air conditioning and process cooling. Adaptable to all drives and available for "Freon" and ammonia refrigerants. Sizes from 3 to 200 hp.

**Evaporative Condensers**—for use with refrigerating compressors in place of water cooled condensers. Simplify water supply and disposal problems. For indoor or outdoor use. Capacities 10 to 110 tons, for "Freon" or ammonia.

## **Carrier** INDUSTRIAL HEATING

**Unit Heaters**—for commercial and industrial space heating using steam or hot water. Complete range of sizes in three types: 46U Horizontal Discharge (13,400 to 200,000 Btu per hr), 46S Four-way Directed-flow (55,000 to 600,000 Btu per hr) and 46AE Cabinet Heaters (26,200 to 115,000 Btu per hr).

**Gas-Fired Unit Heaters**—for clean, economical heat in offices, stores, factories and similar spaces where gas is available. A.G.A. approved for manufactured, mixed, natural, LP and LP-air gases. Capacities: 50,000 to 230,000 Btu per hour.

**Heat Diffusers**—for ventilating as well as heating large commercial and industrial spaces. Floor, wall or ceiling mounted with coils for steam or hot water. Capacities 47,000 to 2,990,000 Btu per hour at 2 lb steam.

## Desomatic Products, Inc.

1109 West Broad Street  
Falls Church, Virginia

Designers • Engineers • Manufacturers

REPRESENTATIVES IN PRINCIPAL U. S. CITIES AND CANADA

**DESOMATIC MODEL 350.** This Desomatic unit protects materials in storage from corrosion, mold and mildew danger by maintaining low relative humidities in the space, over a temperature range from 0 F to 120 F. **DESOMATIC** Dehumidifiers use a solid sorbent, silica gel, and no replacement of adsorbent is necessary. Customer may specify other desiccants.

Desomatic equipment for dehumidification of air is your answer to efficient moisture control in storage areas, homes, industries and laboratories.

Five standard models to meet your needs. Also custom designed equipment and machines for Class 1, Group D, hazardous locations. All standard models may be modified to meet Military Specifications.

Manufacturers of Air Conditioning and Refrigeration Equipment

REFRIGERATION AND AIR CONDITIONING

### LEFT COLUMN READING DOWN:

**Multizone-type FZ**—Air conditioners, blow-through type, supply many zones individually by damper control. Horizontal, vertical types.

**Perma-Fan Series PF**—Complete line of blow-through type evaporative condensers, on principle developed by D-H in 1937. 5 to 110-ton capacities.

**HH and HHV types**—for horizontal or vertical air conditioning; central-type systems.

**Water Chiller**—Space-saving, self-contained water cooled or air-cooled units.

**Spotaire Series LRC**—Compact basic or cabinet types for air conditioning individual rooms of multi-room buildings. Overhead installation; takes little headroom.

### RIGHT COLUMN READING DOWN:

**Spotaire Series HRC**—Room unit air conditioning equipment for chilled water, hot water or DX. Concealed basic unit or cabinet models.

**Spotaire Series VRC**—Handsome, floor-mounted models for chilled or hot water, or "Freon."

**d-h Hot Shot Electric Defrost**—ceiling-type units using D-H's electric automatic defrost patents.

**d-h Spasaver**—Product cooling application for over 34F temperatures. Many sizes.

**d-h Flocold**—Product or produce coolers for under or over 34F; water or ammonia defrost.

**Extended Surface Coils**—Staggered tubes for steam, water, DX, "Freon" or ammonia; removable header or plug-type coils.

G-E Furnaces  
G-E Air Conditioning Equipment & Supplies

### 1. G-E OIL-FIRED BOILER

Compact, integrated steel boiler units designed exclusively for low-pressure oil burning. Ideal in multiple installation for both central heating and zone heating. High heat transfer rate with low water content and low metal mass. Exclusive G-E features give fuel savings up to 50 per cent: "Turnback Flame"; oil atomization for complete combustion; famous G-E "heat-trap" design. Built-in tank or tankless-type hot water coil. Five models: 100, 140, 200, 300 and 450,000 Btuh output. Listed by *Underwriters' Laboratories, Inc.* Constructed in accordance with ASME Code. Also GAS-FIRED BOILERS—96, 144, 192, 240, 288, 336, and 432,000 Btuh input—Cast Iron Heat Exchanger. For natural, manufactured or mixed gas.

### 2. G-E OIL AND GAS-FIRED WARM AIR FURNACES

Oil-Fired. Fuel savings up to 50 per cent reported by users. Features: G-E Atomized Oil burning, "Turnback Flame," "Spira-Flow" heat transfer surface. 60 to 155,000 Btuh bonnet output. Listed by *Underwriters' Laboratories, Inc.* Gas-Fired. G-E's long-life, cast-iron "Pinpoint" heat transfer sections give superior heating action. Compact, quiet. Listed by *Underwriters' Laboratories, Inc.* approved by A.G.A. Burn manufactured, mixed, natural, natural-SUR or LP gases. 60 to 210,000 Btuh input. Models. G-E Oil and Gas-Fired Furnaces are available in Upflow, Downflow and Horizontal models. Each is "Pre-Paired" to permit addition of G-E Home Cooling at any time.

### 3. G-E'S COOLING UNITS AND YEAR-ROUND AIR CONDITIONERS

Self-contained central system heats, cools, filters, dehumidifies, ventilates and circulates conditioned air. Cooling capacity: 2 to 5 tons. Heating capacity: with gas firing, 60 to 210,000 Btuh input; with oil firing, 60 to 155,000 Btuh, bonnet output. Over 4,784 heating-cooling combinations—permitting accurate sizing of units to fit any home size and design—all climatic conditions. Upflow, Downflow, Horizontal models. Cooling with water-cooled or air-cooled condensers.

### 4. G-E AIR-WALL\* SYSTEM FOR HEATING AND COOLING

Air-Wall—The Air-Wall register spreads a wall of conditioned air over insides of windows and outer walls, protecting against extremes of winter and summer weather. With G-E Year-Round Air Conditioning, or G-E Furnaces or G-E Home Cooling, same registers deliver both heat and cooling. Engineers and architects especially acclaim the coordinated design of the Air-Wall SYSTEM—heating and cooling units, ducts and registers designed to function as a single unit.

GENERAL ELECTRIC AIR CONDITIONING

## CEILING-MOUNTED UNITS

The latest additions to the complete G-E Line of Packaged Air Conditioners require no floor space. Instead, these compact, self-contained units are fastened to the ceiling or mounted on shelves. And there are no remote parts to complicate operation or increase danger of refrigerant leakage. Available in water-cooled and air-cooled models—latter designed to eliminate problem of water restriction. For offices, factories, shops, supermarkets, etc. Water-cooled model in 3, 5, and 7½ ton capacities; Air-cooled model in 3 and 5 ton capacities.

## FLOOR-MOUNTED UNITS

These popular G-E Packaged Air-Conditioners are famous for quiet, reliable performance—as they filter, cool, dehumidify and circulate air. They can be installed step-by-step to fit limited budgets—without extensive alterations. Modern, functional styling blends in with any decor. Units can be located in-space or out-of-space. For stores, offices, hotels, restaurants, plants, etc. Capacities: 3, 5, 7½, 10 and 15 tons.

BOTH ceiling-mounted and floor-mounted units have entire cooling system—motor, compressor, condenser—sealed-by-flame to keep dirt and moisture out, vital refrigerant in. Both have completely adjustable air distribution. Both can be supplied with coils for winter heating. And both carry G-E's 5-year warranty covering entire refrigeration system.

## Governair Corporation

513 North Blackwelder, Oklahoma City 4, Oklahoma

**GOVERNAIR**

Self-Contained Air Conditioners

**TYPE SC CONDITIONERS**—for stores, offices, hospitals, homes—3, 5, 7½, 10, 15 ton sizes—heating optional—plenum or duct air distribution for city water or cooling tower use—with quiet hermetic compressor.

**EVAPORATIVE CONDENSERS**—3 to 100 ton—all prime or fin surface—corrosion resistant steel or non-ferrous construction—internal jacket liner.

**SELF-CONTAINED AIR CONDITIONERS**—completely packaged air conditioners with evaporative condenser. Ready for connection to duct system—3 to 60 ton—single or two separate refrigeration systems—non ferrous condenser available.

**FAN AND COIL CABINETS**—cooling, heating, humidifying, dehumidifying, ventilating, 1 to 100 ton, 500 to 30,000 cfm, vertical or horizontal types. Governair multi-zone fan and coil units are available in sizes ranging from 5 to 60 ton capacities, suitable for individual zoning.

**BLAST COILS**—direct expansion, water steam—hydraulically expanded tubes for close fin spacing—mechanically expanded tubes for wide fin spacing—copper or aluminum fins—complete range of sizes.

Also: Multi-Zone Fan and Coil Units, Cooling Towers, Packaged Water Chillers and Low Temperature Coolers.

## Hastings Air Conditioning Co., Inc.

Hastings, Nebr.

Manufacturers of

Cooling, Heating and Ventilating Equipment.  
Water, DX and Steam Coils.  
Gas and Steam Unit Heaters.  
Gas Power Conversion Burners.

A complete line of air conditioners for chilled or well water, cold city water, and direct expansion. Full range of sizes, 1 to 40 tons. All coils are constructed entirely of copper. Fins are both solder-bonded and mechanically-bonded to the tubes for permanent high efficiency. Flowmeters (to visually indicate water flow) are standard on all water units.

General Utility Models

Floor Models

Central Plants

**DOUBLE-KOOL "2-stage" COOLING UNITS**—3 to 56 tons. 2 Tons cooling per compressor hp. Air is first pre-cooled using water up to 70° F, then further cooled and de-humidified by Freon coil. Packaged and remote models. Up to 100 per cent **FRESH AIR** may be used for cooling, regardless of outside conditions. Saves approximately 50 per cent of water and power cost.

**HOME AIR CONDITIONERS**—2 to 5 tons

Easily attached to any furnace.

**Water Coil Models**—for water up to 60° F.

**Double-Kool Models (Combination Water-DX)**—for water up to 70° F.

**GAS UNIT HEATERS**—50,000 to 220,000 Btu capacity

Equipped with **CENTRIFUGAL** or **PROPELLER** type fans.

**DUCT HEATERS** available for use with remote blowers.

A.G.A. approved for all gases.

Aluminized steel heat exchangers for fast heat transfer and extra long life.

Stainless steel ribbon burners for quiet, efficient combustion. Dual directional, adjustable louvers permit complete control of air delivery.

**HEATWELL POWER GAS CONVERSION BURNERS**—

**Inshot**—To replace oil burners. Up to 370,000 Btu.

**Roundhead**—For any round furnace or boiler. Up to 250,000 Btu.

**Adjusto "V"**—Commercial, Multiple-dwelling, and Industrial. Up to 4,000,000 Btu. No combustion chamber required. Adjustable flame placement.

13 Sizes. 300 to 21,600 cfm. Horizontal or Vertical. Catalog No. AC.

**MULTI-ZONE UNITS**  
Sizes up to 36 sq ft. Cooling Coil Face Area. Catalog No. MZ.

**HEATING AND VENTILATING UNITS**  
Air Volumes 300 to 28,800 cfm, and up to 36 sq ft Coil Face Area. Catalog No. HV.

**SPRAYED COIL DEHUMIDIFIERS**  
56 Sizes. Coil Face Areas up to 81 sq ft. Catalog No. SC.

**COOLING TOWERS AND EVAPORATIVE CONDENSERS**  
Sizes from 3 to 15 tons. Centrifugal type fan for quiet Indoor operation-propeller fan water turbine driven for Outdoor operation. EC and CT models for 15 to 75 tons (not shown). Catalogs No. KT and QT.

**FINNED COILS**  
Direct Expansion, Water, Steam Distributing Tube, Standard Steam Coils. Sizes up to 48 in. wide x 132 in. long. Catalogs No. CC and HC.

**LIQUID CHILLERS**  
Direct Expansion, Freon Shell and Tube Liquid Chillers. Internally finned tubing (Pat. Applied For), brass baffles, positive oil return, closed refrigerant circuits without freon gaskets. Catalog No. LC.

## Niagara Blower Company

Executive Offices: 405 Lexington Ave. New York 17, N.Y.

Sales representatives in Principal Cities of U. S. and Canada

Over 35 Years' Experience in Industrial Air Conditioning

### NIAGARA AIR CONDITIONING SYSTEMS

For human comfort and for all industrial applications requiring controlled conditions of temperature, relative humidity, air purity and air movement.

#### NIAGARA AIR CONDITIONER, TYPE A, AND CONTROLLED HUMIDITY METHOD USING HYGROL LIQUID ABSORBENT

High precision apparatus using saturation to obtain control of R. H. to 1 per cent for laboratory work and control of hygroscopic materials. Ask for *Bulletins 112 and 122*

#### NIAGARA AIR CONDITIONER, TYPE C

A year around air conditioning unit providing heating and humidifying or dehumidifying. Ask for *Bulletin 80*.

#### NIAGARA FAN COOLER AND DISK FAN COOLER

For comfort cooling, process cooling, low temperature storage for dairies, fruits, meats, food products, fur storage vaults, etc. *Bulletin 72*.

#### NIAGARA SPRAY COOLER

For all cooling applications requiring high humidity or high capacity in small space. Ask for *Bulletin 110*.

#### NIAGARA "NO FROST" SYSTEM

Using Niagara "No Frost" Liquid in spray coolers prevents frosting of cooling coils, automatically keeps spray solution at proper concentration, gives freedom from brine troubles, corrosion. Constant, efficient operation. Temperature to -100F. Ask for *Bulletin 105 (Food)* or *Bulletin 95 (Industrial)*.

#### NIAGARA AEROPASS CONDENSER

Saves power and water cost utilizing atmospheric air to remove heat of condensation. Patented Duo-Pass prevents scaling, saves power. "OILOUT" positively removes oil and dirt from refrigerant lines, assuring always full capacity. Balanced Wet Bulb Control assures operation of refrigeration plant at minimum head pressure regardless of weather or load conditions. Capacities up to 400 tons refrigeration. Ask for *Bulletins 103, 111 and 123*.

#### NIAGARA "DUAL" COOLERS

Simultaneously cools a room and furnishes chilled water as a refrigerant. Saves equipment cost, operating expense. Patented. Ask for *Bulletin 70*.

#### NIAGARA AERO HEAT EXCHANGER

For cooling industrial liquids, water, oils, solutions, chemicals, compressed air and gases, with Niagara "Balanced Wet-Bulb" temperature control to improve efficiency and obtain precise results. Capacities up to 30,000,000 Btu. Patented (U. S. Nos. 2,296,946 and R. I. 22,553). Ask for *Bulletins 120 and 124*.

#### NIAGARA INDUSTRIAL LIQUID COOLER

Furnishes refrigerated water or aqueous solution in any quantity up to 220 gpm. Positive control of temperature regardless of load variation. Delivers "sweet" water at 33F without danger of freezing damage. Ask for *Bulletin 104*.

#### NIAGARA FAN HEATERS AND HIGH PRESSURE STEAM FAN HEATERS

For heating and ventilating large areas. Units of the highest quality in engineering, material and workmanship. Ask for *Bulletins 73 and 109*.

#### NIAGARA MOTOR BLOWERS

One, two and three-fan units. High and low static pressure models. Ask for *Bulletin 89*.

## Parks-Cramer Company

Fitchburg, Mass.

Charlotte, N. C.

Atlanta, Ga.

### CERTIFIED CLIMATE

Industrial air conditioning systems, including humidifying or dehumidifying, cooling by evaporation or refrigeration, ventilating, filtering, air washing; with automatic control of humidity, temperature and air change. Engineered, manufactured, installed and serviced by Parks-Cramer.

### CENTRAL STATION AIR CONDITIONING

A complete system for conditioning the factory atmosphere, with positive circulation and controlled ventilation. One or more air washer units. High humidifying and evaporative cooling capacity. Heating, filtering, and refrigerated cooling where needed. Ducts with adjustable outlets distribute conditioned air uniformly. Slight air pressure also improves uniformity. Centralized maintenance. Used with or without booster humidification. Under gradual acting automatic control. Exclusive multi-speed control of fan improves economy.

Central Station Air Washer Units. Nozzles and Self-Cleaning Tank Screens for Central Station Air Washers.

### LABORATORY AIR CONDITIONING

An essential of a good testing laboratory is adequate and dependable air conditioning. Accuracy in testing is maintained only when samples and testing equipment are free from fluctuations in both temperature and humidity. A vertical or horizontal unit is located within or adjacent to the laboratory. Includes equipment for heating, humidifying, dehumidifying, refrigeration, circulation, and adjustable recorder-controller. Heat by steam or electricity.

## Parks-Cramer Company

Fitchburg, Mass.

Charlotte, N. C.

Atlanta, Ga.

Industrial Humidifying and Air Conditioning Since 1904

### AUTOMATIC AIRCHANGER

An improved system of forced air change and distribution used with direct humidification. Insures fixed uniform humidity and maximum evaporative cooling. Amount of air change and operation of humidifiers controlled by humidity and temperature Psychrostat. Designed for either complete new installations or for supplementing existing direct humidifying equipment, especially Gradumatics. Includes heating, refrigeration, filtering, where needed.

### GRADUMATIC HUMIDIFYING SYSTEM

Vastly improved direct humidifying system for use alone, with Airchangers, or as booster for Central Station system. Air and water under pressure, water pressure always less than air. Safe. Economical. Humidifier is self-cleaning.

Has few component parts, easy to take apart and reassemble. Proper operation assured without testing. No adjustment required. When humidification is needed, heads operate continuously, evaporative output being varied gradually and automatically by Certified Climate Psychrostat to suit requirements for constant humidity at all times.

### CERTIFIED CLIMATE PSYCHROSTAT

For gradual control of humidity and temperature. Improved model more sensitive than ever before. Rugged and reliable. Use of the wet and dry bulb principle permits Psychrostat to perform the many and varied tasks in the field of humidity and temperature control which contribute to the success of Certified Climate systems.

### THE PETTIFOGGER (not illustrated)

A compact centrifugal humidifier, with fan, for offices, storerooms, experimental rooms, hospitals, or other isolated departments. Self-contained in lacquered copper casing. Easily connected to water and electrical supplies. Automatic control. Adjustable capacity.

## Pittsburgh LECTRODRYER Corporation

Foot of 32nd Street

Pittsburgh, 30, Pa.

*This machine protects equipment in storage by maintaining a relative humidity of 35 per cent or lower.*

*Small automatic air conditioning type LECTRODRYER used for providing lowered relative humidities.*

### FOR INDEPENDENT CONTROL OF DEHUMIDIFICATION IN COMFORT AND INDUSTRIAL AIR CONDITIONING

The results of years of experience in the independent control of industrial dehumidification are now available for comfort air conditioning in the form of sturdy, dependable, thoroughly tested machines for controlled adsorption dehumidification.

**LECTRODRYER** equipment using Activated Alumina, a solid adsorbent, is widely used in maintaining lower than normal relative humidities in the chemical, pharmaceutical and other industries.

In comfort air conditioning these machines handle the latent heat load with only the sensible heat load left for refrigeration or water cooling. With this type

system, only the air needed for the sensible heat load is cooled and no reheat is required.

Machines are available for steam, gas or electric operation, whichever the purchaser specifies. Standard machines are available in several sizes ranging from 350 cfm upward.

**LECTRODRYERS** are shipped complete as self-contained automatic units in that they require no regular manual attention except for starting. They are built for continuous operation with reactivation being carried on simultaneously with the drying operation.

Write for full details.

## Walton Laboratories, Inc.

Irvington 11, New Jersey

MANUFACTURERS OF

*Walton*

HUMIDIFIERS  
and AQUA-SORBER  
DEHUMIDIFIERS

**WALTON PATENTED CENTRIFUGAL ATOMIZER** principle has been embodied in all of the Walton humidifiers for over 25 years. Positive humidification is available continuously without the need for pressure devices, nozzles and other auxiliary equipment.

**PORTABLE ROOM HUMIDIFIERS** are available in table and automatically controlled console models, attractive design; uses no heating coils, nozzles or filters.

**INDUSTRIAL HUMIDIFIERS** self contained, easy to install. Water and electrical connections are the only requirements. No costly ducts, compressors or drain piping are used. Sizes and types to accommodate small and large installations requiring humidification up to 100 per cent.

**DUCT OR WARM AIR SYSTEMS** can utilize Walton Model WF which can supply positive humidification without plates, drip pans, or jets, unaffected by mineral content in water.

Available to engineers, architects, and industrial designers is the complete new Walton Catalog file including—

- "Industrial Humidification"
- "Humidification for Textiles"
- "Humidification for Knitting"
- "Humidification for Graphic Arts"
- "Humidification for Hospitals"
- "Humidification for Home and Office"
- "Humidification for Warm Air Systems"
- "Dehumidification for all Applications"

## Westinghouse Electric Corporation Air Conditioning Division

Self-contained Air Conditioners—2 to 25 tons;  
Heat Pumps; Field-assembled  
Air Conditioning Equipment

Staunton

Offices in all principal cities

Virginia

### AIR CONDITIONING UNITS

Type HP Heat Pumps are flameless, water-less, all-electric units which will heat the home in the winter and cool it in the summer, automatically. Recommended for areas where extremes of temperature are not of long duration. Available in nominal 3 and 5 hp ratings.

Type RG/RO Year-Round Air Conditioners heat in summer and cool in winter. Features ingenious slip-in cooling package, economical gas or oil burner operation, year-round thermostat control. (A.G.A. approved.) Available in 2 or 3-ton cooling capacities.

Type RU Unitaire Conditioners for residential and commercial cooling requiring duct work. Installed with new or existing forced-air heating system, or independently with own duct work. Features compact design, sturdy welded-frame construction. In 3 and 5-ton capacities.

Type ACU Air-Cooled Condensing Units for residential cooling applications with new or existing forced air furnaces. May be installed indoor or outdoor with cooling coil in furnace discharge duct or plenum. Full nominal capacity at high ambient. Features durable bonderized cabinet, waterproof electrical panel, versatile vertical discharge arrangement. In 2, 3 and 5-ton capacities.

Type SU and MU Unitaire Conditioners are designed for commercial and industrial use. They cool, dehumidify, filter and circulate air. Accessory heating coil available. Dual refrigeration cycles on MU Unitaire provide 50 and 100 per cent capacity operation. Available in 3, 5, 7½, 10 and 15-ton capacities.

Type LU Central Plant Unitaire Conditioners for installation with supply and return air ducts. In capacities of 20 to 28 ton.

**REFRIGERATION COMPRESSORS**  
Type CLS Refrigeration Compressors are hermetically sealed, direct connected units with refrigerant cooled motors made in 12 sizes from 2 to 125 ton.

### WATER COOLED CONDENSERS

They are constructed with integrally finned copper tubing, steel sheels and silver soldered tube sheets. Manufactured in accordance with the recommendations of the ASME Boiler Construction Code, Section VIII. Available in 16 sizes within 2 to 125 ton range.

### Packaged Air Conditioners

Provide cooling (and heating, if desired), dehumidification, ventilation, and air cleaning for commercial and industrial applications. 3, 5, 7½, 10, 15, 20, and 25 ton capacities.

### Centrifugal Refrigeration Water Cooling Systems

150 to 1,200 tons, 56 unit sizes. Freon centrifugal compressor, water cooler and water-cooled condenser in compact unit assembly. Electric motor or steam turbine drive.

### Reciprocating Compressors Freon

V and W type, to 150 tons with Freon-12 and to 170 tons with Freon-22. Full force feed lubrication above 10 hp. Capacity reduction and unloaded starting by gas unloaders. Mounted on steel base, with water cooled condenser or for use with separate evaporative condenser.

### Evaporative Condensers

Series ECZ, 10 to 150 tons. Sectionalized construction, all parts easily accessible. Bare copper coils for Freon-12.

### Packaged Liquid Chillers

Series LCP Freon-22 Packaged Liquid Chillers for process cooling, refrigeration, or air conditioning. 14 sizes, 7½ to 150 hp; 4 to 303 tons. Incorporate a complete refrigeration cycle with all necessary components. Factory assembled, 7½ to 80 hp; field connected, 100 to 150 hp.

## York Corporation

York, Pennsylvania

Factory Branches and Distributor Engineering and Sales Offices throughout the World.

Air Conditioning and Refrigeration for maintaining proper atmospheric conditions for industrial processes or comfort requirements. Installations of unit and central systems in a wide range of capacities and types for every design need.

**Turbomatic Compressor**—a completely assembled "packaged" compressor with a capacity range from 115 ton to 350 ton. Factory assembly speeds installation of complete system jobs. Single stage aluminum alloy impeller, reduced shaft diameter, simplified shaft seal, permit higher rpm, less friction than in multi-stage equipment, assure longer service life. Model L-95, York's largest Turbomatic, weighs only 1600 lb.

Other turbos available over wide range of capacities—up to 2500 ton refrigeration for Freon water cooling duty—suitable for steam turbine or motor drive. Self-contained dynamically balanced, non-vibrating V/W type reciprocating compressors available in capacities up to 350 ton refrigeration in a single unit, with water cooled or economizer type condensers. Efficient automatic capacity reduction available for economical operation at reduced load.

**Yorkaire Complete Systems**—Three basic types available for big building applications. Designed for maximum flexibility in each case.

**York CI System** utilizes York Turbo or V/W Compressor as cooling source, with one air intake, usually at top of building. Air brought in by fan, filtered, dehumidified. Sound trap eliminates fan noise. Units in individual rooms also provide heat in winter by hooking into existing hot water system.

**York CF System** cools in summer, heats in winter, uses Turbo or V/W compressor for cooling, building's hot water system for heating. Air intake located in unit in each room. Economical for buildings where space is at a premium. No large fan room required; units individually operated.

**York CSA System**—Individual room units cool in summer, heat in winter, require no fan room for cooling equipment, hook easily into existing hot water system. Units can be added one room at a time; no extensive alterations required.

## ADDISON PRODUCTS COMPANY

Addison, Michigan

Specialists in Air Conditioning Systems  
Contract Manufacturers

Addison Units are built to Customer Specifications

WATER COOLED

AIR COOLED

Addison air conditioning systems are available in vertical or horizontal types for water cooled operation.

The vertical system is available in 2 hp, 3 hp and 5 hp sizes. 2 hp and 3 hp sizes mounted within a 24 in. x 20 in. x 40 in. frame. 5 hp unit available with single compressor or two compressor, two stage cooling operation. Both 5 hp models mounted within a 38 in. x 24 in. x 40 in. frame. Vertical units are designed to install easily in companion cabinet for hi-boy type furnace installations or, if desired, in hi-boy type cabinet for space cooling.

The horizontal type is available in 2 hp or 3 hp sizes. The entire assembly is mounted within a 21½ in. x 21½ in. x 42¾ in. frame. Louvered or solid drain pans are optional. The horizontal system is ideal for a companion cabinet installed with hi-boy furnace installation. It may also be used in limited spaces such as crawl space or attic type of installations.

The horizontal attic air conditioning system is available in Economy 2 hp size. This system was designed primarily for small home operation where economy is especially important. Dampened air flow in evaporator plenum provides zone cooling.

Air cooled systems are also available in 2, 3 and 5 hp sizes. Condensing assembly is designed for outdoor operation with vertical or horizontal evaporators designed to fit in plenum of existing air ducts of heating system. These units are ideal for areas where water supply is critical.

All systems are designed and engineered to customer specifications and requirements, subject to Addison high quality standards. All sheet metal parts have a corrosion resistant finish. All service connections are of standard size in construction and easily accessible. Equipment is Underwriters' Laboratories approved.

## AMERICAN-Standard AIR CONDITIONING DIVISION ELYRIA, OHIO

Executive Offices: 40 West 40th St., New York 18, N. Y.  
A Division of American Radiator & Standard Sanitary Corporation

Distributors are listed under "Air Conditioning Equipment & Supplies"  
or "Furnaces" in the yellow pages of your telephone directory.

### AMERICAN-STANDARD SUMMER AIR CONDITIONERS

HCA-2H

HCA-2

AC-2A

RC-2V

RC-2HA

HCA-3F

CCA-5

**RESIDENTIAL UNITS—WATER COOLED.** All are compactly designed and have 100 per cent hermetically sealed refrigerant circuits covered by American-Standard Air Conditioning Division 5 Year Protection Plan. Models HCA-2H and HCA-3H, 2 hp and 3 hp horizontal units, less blower, utilize the blower of new or existing furnace, as do Models HCA-2, -3, -5, offering choice of 2, 3 or 5 hp cooling. Models HCA-2F, -3F, -5F, equipped with blower, can be used either with forced air furnace, or independently with their own ducts, for 2, 3 or 5 hp cooling.

**RESIDENTIAL UNITS—AIR COOLED.** New, outdoor air-cooled condensing units AC-2A (2 hp) and AC-3A (3 hp) have 100 per cent hermetically sealed refrigerant circuits covered by 5 Year Protection Plan. Easily connected to evaporator unit installed in discharge air duct of new or existing forced air furnace. Evaporator units RC-2HA and RC-3HA (2 hp and 3 hp respectively) are for horizontal air flow; RC-2V and RC-3V (2 hp and 3 hp respectively) are for vertical air flow.

**COMMERCIAL UNITS.** These are self-contained, water-cooled package units for 2, 3 or 5 hp cooling of shops, offices, restaurants and other business establishments. All have 100 per cent hermetically sealed refrigerant circuits covered by 5 Year Protection Plan and are finished in Coltan—a neutral shade that blends with any color scheme.

### AMERICAN-STANDARD YEAR 'ROUND AIR CONDITIONERS

C-G-W

C-OB-W

**GAS-FIRED HEATING WITH 2 hp OR 3 hp COOLING.** A complete winter-summer unit under a single jacket. Choice of 7 size combinations ranging up to 150,000 Btuh input winter heating with 3 hp cooling for summer air conditioning. The 100 per cent hermetically sealed refrigerant circuit is covered by 5 Year Protection Plan; slides in or out as a complete unit for easier installation or servicing. The air conditioner is available less cooling circuit for owners who need immediate winter air conditioning but prefer to add summer air conditioning at a later date.

**OIL FIRED HEATING WITH 2 hp OR 3 hp COOLING.** This unit, complete under single jacket, has the same easy slide-out refrigerant circuit as the gas-fired model listed above; may be obtained less cooling circuit. Choice of 2 hp or 3 hp cooling and either 85,000 or 112,000 Btuh winter heating output at bonnet. Features include heavy gauge steel heating element specifically designed for oil firing to insure efficient, economical combustion of fuel.

### AMERICAN-STANDARD GAS-FIRED FURNACES

GLA

SG

GUA

GCA

SHC

**GAS BASEMENT.** Model GLA low-boy completely assembled and wired, blower-equipped, in 8 sizes, from 75,000 to 300,000 Btuh input, all Installation Tested\* at the factory. Model SG gravity furnace, equipped with automatic controls, in 4 sizes, from 85,000 to 150,000 Btuh input.

**GAS UTILITY.** Compact, narrow-width Model GUA (smallest size is only 13 1/2 inches wide), completely assembled, wired and Installation Tested\* at the factory. Seven sizes, from 50,000 to 200,000 Btuh input. A.G.A. approved models for 1-inch or zero clearance installations. Models with belt-driven or direct-drive blowers available.

**GAS COUNTERFLOW.** New, more compact Model GCA for perimeter heating installations in modern, slab type homes. Permits 1-inch clearance at sides, zero clearance at rear; can be installed on combustible flooring if optional sub-base is used. Three sizes—75,000, 100,000 and 125,000 Btuh input—completely assembled, wired and Installation Tested\* at the factory.

**GAS HORIZONTAL.** Unit can be suspended from ceiling, in crawl space or placed on attic joists. Five sizes, from 60,000 to 140,000 Btuh input, all completely assembled, wired and Installation Tested\* at the factory. Models available with vertical or horizontal flue outlet.

\* Installation Testing of completely assembled unit at factory includes actual gas firing and operation of blower and controls.

### AMERICAN-STANDARD OIL-FIRED FURNACES

1307-OB

1310-OB

1200-OB

1400-OB

HS

**OIL BASEMENT.** Models 1307-OB and 1310-OB for small and medium size homes are approved for installation on combustible flooring. Convertible to gas with American-Standard GP package. Six sizes, from 67,000 to 167,000 Btu capacity at register.

**OIL UTILITY.** Model 1200-OB units are designed for small homes and individual apartments. Standard and zero clearance models available. Three sizes—79,000, 96,000 and 102,000 Btu output at bonnet. Convertible to gas.

**OIL COUNTERFLOW.** Model 1400-OB units for basementless and slab construction houses, are approved for zero clearance installations; convertible to gas. Three sizes—79,000, 96,000 and 102,000 Btu output at bonnet.

**OIL HORIZONTAL.** Model HS units can be placed on attic joists, suspended from ceiling or installed in crawl space; are applicable either to perimeter or conventional heating systems. Three sizes—93,900 and 102,000 Btu output at bonnet.

### AMERICAN-STANDARD ELECTROSTATIC AIR CLEANER

EF

**MAGNE-FILTER.** Model EF is a dry type electronic air filter, easily installed in the return air duct of warm air furnace or summer air conditioner. Traps even smallest particles; remove pollen, bacteria, dust and smoke from the air. Made in 7 sizes; to meet the requirements of any installation. No water connection required.

# Armstrong Furnace Company

Columbus, Ohio

## WARM AIR HEATING EQUIPMENT

Domestic Winter Air Conditioning Furnaces

**Basement Models**—Gas, oil, or coal; 17 basic sizes; ideal for all types of new homes; widely used to replace obsolete furnaces. Gas-fired: 7 sizes, 85,000 to 250,000 Btu/hr input. Oil-fired: 6 sizes, 80,000 to 200,000 Btu/hr output. Coal-fired: 4 sizes, 20 to 27 inch.

**Counterflow Models**—Warm air delivered at bottom to ducts in slab floor or crawl space. Fits into closet or utility room corner. Gas-fired: 3 sizes, 65,000 to 105,000 Btu/hr input. Oil-fired: 2 sizes, 80,000 and 110,000 Btu/hr output.

**Hi-Boy Models**—Designed for modern basementless homes and homes with basements. Approved for operation in close quarters. Quiet, compact, attractive. Gas-fired: 6 sizes, 65,000 to 125,000 Btu/hr input. Oil-fired: 2 sizes, 80,000 to 110,000 Btu/hr output.

**Horizontal Models**—Lies flat in crawl space or attic, or suspended from ceiling anywhere. Occupies no floor space. Gas-fired: 4 sizes, 70,000 to 135,000 Btu/hr input. Oil-fired: 4 sizes, 80,000 to 165,000 Btu/hr output.

## DOMESTIC GRAVITY FURNACES

All furnaces listed above are forced air furnaces. For homes suited to gravity heating, Armstrong has models for basement installations, to burn oil, coal or gas. 10 sizes.

## HEAVY DUTY INDUSTRIAL FURNACES

Seven sizes, either gas or oil-fired.

Standard models, 350,000 and 450,000 Btu/hr gas or oil-fired. Stainless steel heat exchanger. Two blowers. Induced draft. Units may be installed vertically (as illustrated) for air delivery upward or suspended for air delivery downward or horizontal. Factory assembled, wired and fire-tested.

Suspended units, oil-fired only, 225,000, 275,000, and 350,000 Btu/hr. Stainless steel combustion chamber, aluminized steel secondary tubes. Factory assembled, wired, and fire-tested.

Columbus, Ohio

## COOLING EQUIPMENT

### Air Cooled

Air-cooled summer air conditioners designed for convenient installation. Evaporator unit, including only those elements which must be located close to the cooling coil is installed inside. Other parts are incorporated in the condensing unit, which is usually installed outside. Evaporator unit is connected to the condensing unit by two copper lines—a liquid refrigerant line and a suction line. Motor-compressor unit guaranteed in writing 5 years. Up-flow, down-flow, horizontal-flow, and independent unit cooling coils, 2, 3, 5-ton capacities.

Up-Flow Coil

Down-Flow Coil

Vertical Companion Model

Motor-Compressor Unit

Horizontal Independent Coil

Horizontal-Flow Coil

Vertical Companion Model

### Water Cooled Residential Models

Vertical or horizontal companion units to harmonize with Armstrong winter air conditioners. Entire refrigeration unit hermetically sealed. Five year written guaranty. Water-cooled. Vertical units: 2, 3, 5-ton capacities. Horizontal units; 2 and 3 ton capacity.

Duct Cooler

Write for the Armstrong consolidated catalog, a useful reference book on heating and cooling. Includes detailed specifications, dimensions, illustrations and descriptions of all Armstrong furnaces and air conditioners. Please address Department G-5 at the plant nearest you.

Dayton 1, Ohio

AIR CONDITIONING • HEATING FOR HOMES, BUSINESS, INDUSTRY

**WATER-COOLED "PACKAGED" AIR CONDITIONING** ... 2, 3, 5, 7½, 10, 15 hp Complete—assembly and tested at the factory. Cools, dehumidifies, filters and circulates air. Free air discharge or duct distribution. Heating coil for year 'round service optional. Compact—entire unit is enclosed in "Bond-erized" steel cabinet of modern, FUNCTIONAL design. Occupies very little floor space. Easily Installed—Needs only electric, water and drain connections. Flexible—can be installed singly or in multiple to meet virtually every requirement. 5-year warranty on entire refrigeration cycle.

**WATERLESS COMMERCIAL AIR CONDITIONING** ... 2, 3, 5, 7½ hp. Uses no water, needs no plumbing, all-electric operation. Flexibility of installation. Low cost of operation. 5-year warranty on entire refrigeration cycle.

**"SPACESAVER"—GAS OR OIL-FIRED FURNACES** ... 67,000 to 240,000 Btu output. Hi-Boy and Lo-Boy models heat, humidify, filter and circulate the air. "Bond-erized" and insulated cabinets. Burners start, stop and operate quietly, have many features for high-efficiency heating. Gas models approved by A.G.A.; oil models approved by Underwriters' Laboratories.

**"HORIZONTAL"—GAS OR OIL-FIRED FURNACES** ... gas—48,000 to 120,000 Btu output, oil—84,000 to 168,000 Btu output. May be installed in attic, under floor, or hung from ceiling. Gas models have dual flue outlets and draft diverter mounts on either side. Completely automatic controls fully enclosed.

**COUNTERFLOW—GAS OR OIL-FIRED FURNACES** ... 65,000 to 100,000 Btu output. May be installed in closet. Fully automatic. Quiet rubber-mounted blower. Front flue outlet. Factory-assembled, easy to install.

**RADIAL COMPRESSOR UNITS** ... 10 to 125 hp. These heavy-duty units, for use with Freon, are especially designed for air conditioning or refrigeration. Radial compressors are direct connected and have force-feed lubrication. Automatic capacity-reduction. Light weight, economical to operate.

Dayton 1, Ohio

AIR CONDITIONING • HEATING FOR HOMES, BUSINESS, INDUSTRY

**"PACKAGED" LIQUID COOLERS** ... 3 to 250 hp for use with Freon refrigerants. A completely assembled unit that is piped, pressure tested, dehydrated and supplied with a refrigerant holding charge. Starters and control panels optional.

**CENTRAL DUCT "PACKAGED" AIR CONDITIONING** ... 20, 25, 30, 40, 60, 75, and 100 hp. Self-Contained Central Type "Packaged" Air Conditioners. Utilizes the Airtemp Radial Compressor with its exclusive features. Units available with evaporative condenser or for use with cooling tower. 5-year compressor warranty on 20, 25, 30 hp sizes.

**INDIVIDUAL—ROOM AIR CONDITIONING UNIT** ... For year 'round cooling and heating when used with central cold and hot water systems. Ideal for hotels, motels, offices. Three types—floor, wall and ceiling. Built-in controls make each unit independently operated. Two centrifugal fans provide circulation.

**CONVENTIONAL—ROOM AIR CONDITIONING** ... new window models available in ½, ¾, 1, 1½ hp. Flush mounts up to 3½ in. from sash line or can be installed half in and half out. Full directional control of discharge air. Cools, filters, dehumidifies, exhausts, and ventilates. Thermostatic control of temperature.

**CASEMENT—ROOM AIR CONDITIONING** ... Window models in ½ and ¾ hp. Easy inside installation without cutting or removing glass—nothing projects outside or interferes with opening, closing or locking of window.

**IMPERIAL—ROOM AIR CONDITIONING** ... In-The-Wall Installation for individual Room Air Conditioning—in ½, ¾ and 1 hp. Ideal for homes, offices, motels and hotels. Filters, dehumidifies, cools, and gently circulates the air. Only 18½ in. deep, fits flush on outside of building with minimum projection on inside. Thermostatic control of temperature. **IMPERIAL—WINDOW MOUNT**—in ½, ¾ and 1 hp. Fits all windows 28 in. and larger.

## Combustion Engineering, Inc.

Home Equipment Division

911 West Main Street, Chattanooga, Tennessee

Heatmaster  
Home Heating  
and Cooling

The simple way  
to heat and cool  
a home

Heatmaster Home Heating and Cooling System is pre-engineered and factory assembled

This "wet" system is assembled at the factory, ready to install on the job. The C-E units are approved by A.G.A., built and inspected in accordance with ASME code and backed by the C-E warranty. Designed to meet FHA Minimum Property Requirements for financing.

Take just 4 sq ft of floor space

The C-E Heatmaster Home Heating and Cooling System uses only standard piping and wiring practices. Compact room conditioners are recessed between standard studding.

### C-E HOME HEATING UNIT

Model 110GHB-88 LM

Height—36" Inlet—1" I.P.S.  
Width—24" Outlet—1" I.P.S.  
Depth—24 3/4" Gas Supply—3/4" I.P.S.  
Flue Dia.—6" Drain—1/2" I.P.S.

Weight of Complete unit—Approx. 250 lbs (including controls and circulator)

FURNISHED AS STANDARD WITH: Circulator, Gas Regulator, Gas Automatic Pilot and Safety Valve, Gas Flue Diverter (Draft Hood), Control Relay, Complete wiring and piping for simple hook-up, Three Way Control Valve, Fan Control Switch, Drain Valve, Gas Control Valve (Solenoid) Temperature, Pressure and Altitude Gauge.

## Hydraline Products

Division Borg-Warner Corporation

General Sales Office: 18538 Mack Avenue • Detroit 36, Michigan

District Engineers in Principal Cities of the United States

**Hydraline** YEAR 'ROUND  
RECESSED ROOM AIR CONDITIONERS

Hydraline combines in one central forced-water heating and cooling system the desirable features of two separate systems—gentle forced-water heating or cooling to the room, filtered air circulation in the room.

The basic Hydraline units measure only 17 3/4 in. x 14 in. x 4 3/4 in. and may be fully recessed between standard studs or under floor between joists.

A manual blower speed control with each unit provides individual room control. Automatic Control Kits also provide thermostatic control of individual room temperatures.

Balanced heating or cooling is no problem even in the most rambling type of structure because Hydraline units are controlled independently of the central system.

As many thermostatically controlled zones can be specified as are needed without the need of a separate circulator for each zone.

With modulating controls, Hydraline units can be economically combined with Radiant Panel Heating, such as snow melting, where such combinations are specified.

Mechanical specifications, system designs and technical data available upon request.

Model HAC-155  
Basic unit in wall (before plaster). Up to 155 cfm  
9M-Btu, heating—4M-Btu, cooling.

Model HAC-155  
Completed in-wall installation with grille attached.

### DUCT FURNACES

Constructed of Type 321 Stabilized Stainless Steel. Non-corrosive property of heat exchanger permits installation downstream of cooling coils or washer. Heat exchanger will not corrode when subjected to continuous ventilation during the summer season. Designed for continuous blower operation for offices, theaters, schools, churches, factories. Air throughput in either direction. Draft Hood and Vent Manifold reversible, adjustable for both horizontal and vertical connection. 14 sizes, 80,000 to 600,000 Btu per hr input in 40,000 Btu increments. A.G.A. certified for all gases.

### MODEL SED-E

Non-corrosives type 321 stainless steel heat exchanger. Permits installation downstream of cooling equipment, for continuous blower operation. Air throughput in either direction. 80,000 to 600,000 Btu input.

### MODEL SED-S

Same as SED-E except controls are at the side, instead of at the end where accessibility requires. SED-S is available in sizes from 80,000 to 600,000 Btu input in increments of 40,000 Btu.

Both SED-E and SED-S can be used for industrial applications for drying.

### FORCED AIR FURNACE MODEL SEC

Heat exchanger constructed of identical die formed sections of type 321 stabilized stainless steel. Sections are seam and arc welded. One piece cast iron burners with drilled ports. Oversize double inlet blower. Long hour motor. Equipped with glass filters. Can furnish permanent filters at extra cost. Finished in baked silver grey. 6 sizes 70,000 to 245,000 Btu per hr input in 35,000 Btu increments. For natural, manufactured and L.P. gases. Can be used for 0 clearance

ALL HAYES FURNACES ARE A.G.A. APPROVED

1252

### DUCT FURNACE MODEL SED-VF

Tested and approved as a DUCT FURNACE—Constructed of type 321 stabilized stainless steel. Re-circulated or fresh air is introduced through bottom, sides or back of furnace. Equipped with air bypass. Handles large cfm per Btu input. Vent in front of furnace. Made in 6 sizes from 70,000 to 245,000 Btu per hr input in increments of 35,000 Btu. For natural, manufactured and L.P. gases.

### FORCED AIR SUSPENDED FURNACE, MODEL SES

Equipped to install in a suspended duct system. Inlet and outlet designed for sheet metal duct connection.

### UNIT HEATER MODEL SEU

Used where room air is to be recirculated. Diffuser outlet with adjustable vertical and horizontal vanes. Both types of Suspended units are designed for factories, commercial and other large Btu requirements — equipped with brackets for suspension, save floor space. Double inlet forward curve blower. Continuous duty variable pitch drives; cast iron, raised port, precision machined burners. Made in sizes 80,000 to 600,000 Btu per hr input in 40,000 Btu increments. For natural, manufactured and L.P. Gas.

### EJECTAIR Power Roof Ventilator by HAYES

Centrifugal backwardly curved blower type . . . the blower wheel cannot be overloaded regardless of length or curves in the duct or variation in design. It is belt driven to provide flexibility. The ventilator is mounted on a built up curb on the roof. Special features include low profile with streamlined design and a corrosion resistant housing. The motor and fan bearings are grease packed ball bearings and are out of the air stream. A manually operated safety cutoff switch is provided.

HEATING

# Mueller Climatrol

COOLING

Division of Worthington Corporation  
Milwaukee 15, Wisconsin

Type 101 (Gas)—201 (Oil) Gas or oil, steel, gravity furnace, convertible. Modular design. Available in three sizes: 135-, 160-, 180,000 Btu. (Type 120-220 also available in 90,000 Btu inputs.)

Type 105 (Gas) 202 (Oil) Gas or oil, steel, winter air conditioners. Convertible. Available in eight sizes with input ratings of 150,000 to 675,000 per hour.

Type 116 (Gas) 216 (Oil) Gas or oil, lowboy winter air conditioners. Four sizes—90,000 to 150,000 Btu input. Convertible. Types 119 (Gas) 219 (Oil) also available.

Type 117 (Gas) 217 (Oil) Versatile unit that meets the requirements of either a low-boy or highboy. Available in four sizes—80,000, 100,000 and 125,000 and 150,000 Btu input. Shipped assembled, pre-wired. Enclosed burner.

Type 118 (Gas) 218 (Oil) Counterflow winter air conditioners. For perimeter heating, slab or crawl-space homes. One size only—100,000 Btu input. Types 115 (Gas) and 215 (Oil) available in 150,000 Btu input.

Type 124 (Gas) 224 (Oil) 906 Highboy winter air conditioners. Four sizes; 80-, 100-, 125-, 150,000 Btu input. Compact. Shipped assembled and pre-wired. Type 906 companion cooling unit available.

Type 123 (Gas) 223 (Oil) 928 Versatile combination heating and cooling unit. Casing has integral compartment for cooling cycle. One size only, 100,000 Btu.

Type 165 Gas-fired horizontal winter air conditioners. Available in two sizes with A.G.A. rating of 100,000 and 120,000 Btu. Shipped assembled and pre-wired. Large size centrifugal blower.

Type 253 Oil-fired horizontal winter air conditioner, or blower heater. Up-draft design. All welded steel heat exchanger. Convertible to gas firing. Available in five sizes, 110,000 to 350,000 Btu input.

## Mueller Climatrol

Type 160 Gas, direct fired, steel, suspended unit heater. Horizontal air tube design; propeller type fan. Available in nine sizes, with A.G.A. ratings of 25,000 to 225,000 Btu input.

Type 10 Gas-fired, cast iron boiler for residential heating, and hot water supply. A.G.A. approved for all types of gas. Sizes range from a 3-section, 54,000 Btu input to a 15-section, 378,000 Btu input. Controls enclosed. (Also with controls exposed, Type 11).

Type 21 Gas-fired, cast-iron boiler for larger installations. Sectional construction, (sizes increase in increments of 70,000 Btu). A.G.A. rated in sizes from 6-section, 350,000 to a twin 31-section, 4,200,000 Btu unit.

Type 900- 912- 914 Summer air conditioning coil units; for operation with remote air- or water-cooled condensing units. Type 900- installs vertically with any forced air unit. Available in 2, 3, 5 and 7½ ton sizes. Type 912- installs horizontally. Available in 2 and 3 ton sizes. Type 914- Counter-flow. Available in 2-3 ton sizes.

Type 903 Self-contained cooling unit for installation with any warm air system, new or existing. Refrigeration cycle is factory-assembled, charged. 2, 3 and 5 hp sizes. Water cooled.

Condensing Units Remote Type 908, air-cooled, (illustrated). Water-cooled Type 902 also available. Both in 2, 3, 5 and 7½ hp sizes. Type 907 remote condenser, for converting water cooled units. Available in 2, 3, and 5 hp sizes.

Type 904 Self-contained cooling unit for stores, restaurants; or used with duct systems in homes with steam or hot water heat. Built-in blowers and filters. 2, 3, 5, 7½, 10 and 15 hp sizes.

Type 920 For heating and cooling in hotels and commercial buildings. Cooling is self-contained—air cooled. Heating through central system with steam or hot water coil. Operates with 370 cfm. Cooling is 1 hp.

Type 911 Self-contained, air-cooled summer air conditioner. May be installed singly or as multiple units in conjunction with existing duct system, or with its own duct system. Available in 1 hp size.

## Lamneck Division

Clayton & Lambert Mfg. Co.

1026 Lamneck Street,  
Middletown, Ohio

Phone 2-6304.

DISTRIBUTORS IN PRINCIPAL CITIES

Fittings and duct work illustrated are selected to indicate range of design and construction of the Lamneck line of air distribution pipe and fittings for heating and cooling. This line is designed with full-throated elbows and angles for full efficiency to simplify later air cooling demands. Line includes complete range of perimeter heating fittings. *New catalog 5529 available.*

No. 700-P standard L-shaped corner seam duct. Manufactured in 8 in. depth, 16 in. and 32 in. length, in widths from 4 in. to 26 in. Also available as No. 700-T, standard U-shaped center-seam duct. Duct sections furnished complete with No. 737-T Snap-lock connector.

No. 700-P

No. 794

No. 794 combination top and side takeoff (adjustable collar). Available in 4 in., 5 in., 6 in., 7 in. and 8 in. sizes.

No. 753 45 degree angle boot available in register sizes  $2\frac{1}{4}$  in. x 12 in. and  $2\frac{1}{4}$  in. x 14 in. for 6 in. systems and  $2\frac{1}{4}$  in. x 10 in. for 4 in. systems.

No. 753

No. 700

No. 754

No. 754 center end register boot available for register sizes from  $2\frac{1}{4}$  in. x 12 in. to 6 in. x 10 in.

5 ft Snap-lock pipe

5 ft Snap-lock pipe available 4 in through 8 in.

No. 700 wall stack. Complete with No. 737 connector attached to each half. Available in  $3\frac{1}{4}$  in. depth, 10 in. to 14 in. width, and 15 in. to 60 in. length.

## Norman Products Company

1150 Chesapeake Avenue,  
Columbus 12, Ohio

MANUFACTURERS OF A COMPLETE LINE OF GAS HEATING AND AIR CONDITIONING EQUIPMENT. FOR INFORMATION CONTACT FACTORY REPRESENTATIVE AT COLUMBUS HEADQUARTERS SALES OFFICE.

Norman Southerner—Horizontal forced air gas furnace for compact home installation. Factory assembled and tested. Right or left-hand unit. Newly designed heat exchanger provides more efficient heat transfer. Five sizes: 70-85-100-120-140 thousand Btu input.

Norman Duct Furnace—for Commercial and Industrial Heating—in combination with air conditioning. Installed in ducts of warm air and air conditioning system where air is circulated by remote blower. 70-85-100-120-140 thousand Btu input.

Norman '360'—Gas fired overhead forced convection heater. "Circular" heat distribution eliminates hot blasts and cold corners. Streamlined design. UL listed. 100,000 Btu input.

Norman Blower-Filter Unit... a compact blower, motor, and filter package for handling air requirements of heating and cooling systems up to 5 tons capacity. Entire unit is housed in a heavy gauge steel cabinet. Doors on either side for easy access to filters and blower.

Norman Gas Conversion Burners—Commercial-Industrial in 4 sizes with ratings from 300,000 to 2,000,000 Btu. Converts apartment, commercial and industrial heating plants. Residential burners, ratings 50,000 to 300,000 Btu.

Norman Direct Gas-Fired Unit Ventilator for schoolrooms, offices, stores. Low-cost, self-contained central heating and ventilation system. No piping, or expensive outside ventilating system needed. Easy to install... saves space. 85,000 Btu input.

Norman Winter-Summer Air Conditioner—Horizontal year round air conditioner combining Norman Duct Furnace with independent cooling and blower assembly in one package. Damper compartment operated by single thermostat control. Cooling only in Separate Package for Existing Furnace. Cooling available in 2 or 3 ton unit, heating in capacity of 70-85-100-120-140 Btu input.

DESCRIPTIVE LITERATURE on all items listed above is available from manufacturer. Write for detailed specifications.

## Pennsylvania Furnace & Iron Company

316 North Pine St., Warren, Pennsylvania

Representatives are in principal gas using centers. Pennsylvania Gas Furnaces, Floor Furnaces, Conversion Burners, Pennco Gas Fired Boilers for steam, vapor and water, for residences, schools, hospitals, hotels, stores, and any other type of building that requires a heating plant. A full and complete line of sizes.

### SERIES 6 PENNCO BOILER

The Series 6 Pennco boiler is a large capacity type boiler. It is a cast iron sectional type with all sections having hollow projections which add to the heating surface. The sections are assembled on a specially designed steel base. The design of this base greatly reduces assembling time and reduces installation costs.

The Series 6 boiler sections are hydro-statically tested to 150 psi. All boilers are constructed in accordance with the ASME code. They are also approved by the A.G.A. Testing Laboratory. Twenty-seven different sizes are available from 400,000 Btu per hr input to 4,400,000 Btu per hr input. All Series 6 Pennco boilers are furnished with completely automatic controls.

### SERIES 2 & 3 PENNCO BOILERS

Series 2 & 3 Pennco boilers are the cast iron sectional type with all sections having hollow projections to add to the heating surface and efficiency. Both the Series 2 & 3 are made in either Standard or Deluxe type. The Series 2 is made for water only in four sizes from 175 sq ft EDR to 350 sq ft EDR.

The Series 3 is made for steam, vapor or water and is made in eight sizes from 96,000 Btu per hr input to 400,000 Btu per hr input.

### SERIES 10A PENNSYLVANIA FURNACES

The Series 10A Pennsylvania Forced Air Furnace is constructed with an all steel combustion chamber and corrugated steel radiator. All joints and seams are continuous welded assuring gas tightness. A two-tone blue baked enamel casing contributes to the beauty of the Series 10A Pennsylvania furnace. This Series furnace is made in seven sizes, ranging from 75,000 Btu per hr input to 225,000 Btu per hr input.

### SERIES 10-V VERTICAL TYPE PENNSYLVANIA FURNACE

The Series 10-V vertical type furnace is constructed with the same type combustion chamber and radiator as the Series 10 horizontal. This unit is compact and made in three sizes; 60,000, 90,000 and 120,000 Btu per hr input.

### SERIES 11 AND SERIES 11 ULTRA

The Series 11 and Series 11 Ultra are newly designed forced air furnaces. The Series 11 Ultra is constructed of 12 gauge steel to comply with SUR and for burning fuel oil and gas. Both series are available in three sizes—75,000, 100,000 and 125,000 Btu per hr input.

### SERIES 55 PENNSYLVANIA GRAVITY FURNACES

This new line of Pennsylvania Gravity Furnaces is made in six sizes—75,000 to 250,000 Btu per hr input. A two-tone blue enamel finish casing and special designed lining which forms a dead air space contribute to the high efficiency of this unit.

### PENNSYLVANIA CONVERSION GAS BURNERS

The Pennsylvania Conversion Gas Burner is made in three sizes and ranges in size from 75,000 Btu per hr input to 350,000 Btu per hr input.

1258

## Refrigeration Appliances, Inc.

909 West Lake Street, Chicago 7, Illinois

MAKERS OF

AIR CONDITIONING AND REFRIGERATION EQUIPMENT  
SINCE 1931

### A—New Krack Komfort Masters

Quiet remote type air conditioners. Models adaptable to practically all remote comfort cooling and heating uses. Designed for ceiling or floor mounting, use with or without ducts. Can be supplied without cabinets for furred-in installation. Volume control dampers and 3-speed control on fan motors give wide range of air velocity modulation. Wide choice of coil arrangements for direct expansion, water, steam, or combinations. Sizes: 2, 3, and 5 ton. Removable filters.

### B—New Krack Furnace Bonnet Koils

Convert new or existing forced air furnace duct systems to summer cooling service with minimum installation problems. Compact V-bank arrangement of air-conditioning coils. Three models have 24,000, 36,000, and 60,000 Btu per hour nominal capacities.

### C—New Krack Transom Komfort Conditioners

Quiet remote type cooler and heater for multi-room offices and commercial, institutional, and private housing. Direct expansion, chilled water, hot water. Optional 3-speed fan control. Two models handle 410 and 480 cfm.

### D—Krack Air Kooled Kondensers

Eliminate all water problems. Easy, inexpensive installation and maintenance. Five models, 1 to 7.5 ton certified nominal capacities based on 110 F condensing temperature and 90 F ambient.

### E—Krack Koils

Air-E-Fex series air conditioning coils . . .  $\frac{3}{8}$  in.,  $\frac{1}{2}$  in.,  $\frac{3}{4}$  in. tube surfaces, for all sizes of installations, old or new. Patented construction features give increased strength, reduce static resistance.

### Evaporative Condensers & Cooling Towers

Floor types for indoor and outdoor applications. Nine sizes 5 to 50 ton.

## Rheem Manufacturing Company

Chicago, 29, Illinois

### REGIONAL OFFICES

SPARROWS POINT 19, MD. 4361 FIRESTONE BLVD., SOUTH GATE, CALIF.  
7600 S. KEDZIE AVE., CHICAGO 29, ILL. 3693 E. MARGINAL WAY, SEATTLE, WASH.  
1025 LOCKWOOD DRIVE, HOUSTON 20, TEX.  
EXPORT SALES OFFICE: 477 MADISON AVE., NEW YORK 22, N. Y.

Every Rheem Furnace is "Fire-Tested" with pilot and burners ignited, Automatic controls, safety checks, operational and construction details must pass rigid tests.

### WARM-AIR HEATING EQUIPMENT GAS-FIRED

Fully automatic, factory-assembled, forced-air furnaces of all-steel, electrically welded construction. "Flame-shaped" combustion chambers (in all but horizontal models) and multiple channel heat exchanger prevent expansion-contraction noise, and provide high heat transfer in limited space. All models feature built-in draft diverters, except for 3302 gravity model and 1603 B floor furnace, and enclosed controls. A.G.A.-approved for natural, mixed, manufactured and LP gases.

**Imperial Highboy—Model 3202**—for first-floor utility room or small basement installation. Top rear flue outlet. Side or bottom filter frames. Knockout plates on casing sides for optional cold-air return. Eight sizes—from 85,000 through 300,000 Btu/hr input—assure a tailored-heat-loss installation for small to largest residences, commercial buildings, churches and stores. 2-tone grey and green baked enamel finish.

**Imperial Lowboy—Model 3402**—for basement installation. Top rear flue outlet with built-in draft diverter. Four sizes from 85,000 through 150,000 Btu/hr input. Completely insulated jacket, finished in attractive grey and green baked enamel for safe, exposed recreation room placement.

**Standard Highboy—Model 3203S**—"File cabinet" styled for compact utility room, hall, closet or small basement installation. Top front flue outlet. Six sizes from 60,000 through 150,000 Btu/hr input finished in pearl-grey baked enamel. All models approved for zero clearance.

**Standard Lowboy—Model 3402S**—designed for even limited overhead clearance basement installation. Top rear flue outlet with built-in draft diverter. Four sizes from 85,000 through 150,000 Btu/hr input. Poly-chromatic, baked-on grey enamel finish. Oversized glass fibre filters assure high dust removal efficiency.

**Horizontal Furnace—Model 2400**—for "perimeter" heating or conventional duct systems. Suitable for attic, attached garage or basementless home crawl space installation. May be suspended from roof rafters or ceiling joists, or rigid support brackets can be placed on bottom of unit for base setting. Five sizes from 60,000 through 140,000 Btu/hr input.

**Counterflow Furnace—Model 3205**—for "perimeter" heating applications. 80,000 and 100,000 Btu/hr input sizes, both A.G.A.-approved for zero clearance installation. Readily accessible blower-filter assembly in top of unit. Ample space in bottom for dehumidifier placement.

**Gravity Furnace—Model 3302**—designed for low cost installation in basements of smaller, compact houses. Four sizes from 77,000 through 150,000 Btu/hr input. Piping and controls fully enclosed in insulated, grey baked enamel-finished jacket. Optional side gas connection.

### RHEEM OIL-FIRED HEATING EQUIPMENT

Highboy—Model 2448, Lowboy—Model 2446, and Counterflow—Model 2444, are pressure atomizing oil-fired. 90,000 and 112,000 Btu/hr bonnet output sizes in all three models. Additional 140,000 Btu/hr bonnet output size available in Lowboy. "Air-foil" design in convoluted heat exchanger assures rapid heat transfer, and expansion and contraction without noise. Factory-assembled burner and support for easy, accurate positioning during installation. All models readily convert to gas-fired furnaces.

### RHEEM SPACE HEATING EQUIPMENT

Four types of space heaters for small homes, "hard-to-heat" rooms and small commercial applications. All are A.G.A.-approved for natural, manufactured, mixed or LP gases.

Flat floor and dual wall (series 1603B) registers in 25,000, 35,000 and 50,000 Btu/hr input sizes. Only 25½ in. overall depth. 2-way adjustable head on dual wall model for easy installation in walls of varying thickness. Console heaters (model 1703) in similar input sizes with minimum space requirements. Tailored design in golden tone finish. Available with automatic or manual controls.

Recessed wall heaters (model 1801) in 28,000 Btu/hr input single wall unit and 50,000 Btu/hr input dual wall units. Both models 60 in. high, 17 in. wide, in neutral ivory casing. Thermostat or manual controls.

### RHEEM AIR CONDITIONING EQUIPMENT

**Year 'Rounder—Model 3103**—offers forced warm-air heating and summer air conditioning controlled by a single thermostat. Summer-winter changeover damper leaves control circuits energized during transfer. Burner operates quietly, efficiently on all gases. Models available with water or air cooled refrigeration condensers. Water cooled refrigeration circuits hermetically sealed for life. Remote air cooled condenser field installation work involves only two refrigeration lines. Wide selection of furnace and cooling capacities.

**Add-on Conditioner—Model 3150**—provides year 'round air conditioning when installed beside any Rheem warm-air heating furnace. For economical summer air conditioning, unit may be combined with existing warm air, or wet heat systems, or used in houses without heating systems. 2 and 3 ton water or air cooled models. Thermostat available, including "off-on" switch. Completely automatic controls. Water cooled refrigeration circuits hermetically sealed for life. Only work required for field-installed air cooled units involves two refrigeration lines.

# Servel

**Air Conditioning Division**  
Servel, Inc.  
Evansville 20, Indiana

## SERVEL All-Year® GAS AIR CONDITIONERS

Model DE

Model TG-15

Model DC

Model TE-10

### 5.4-TON MODEL AND COOLING TOWER

Complete year-round air conditioning. Delivers 5.4 tons of refrigeration, and 96,000 or 144,000 Btuh of heating output depending on model. Fully automatic. Induced draft type tower with capacity to match model DE unit.

### 3.3-TON MODEL AND COOLING TOWER

Deluxe unit for medium-size homes. Supplies 3.3 tons of refrigeration, and 96,000 Btuh of heating output. Fully automatic. Induced draft type tower with capacity to match model DC unit.

Model DYCS

### SERVEL 25-TON WATER CHILLER (Steam Operated)

Completely "packaged." Requires only simple plumbing connections plus 115-volt line to operate controls. Steam controls built in. Provides chilled water at minimum temperature of 40 F for wide range of applications—from industrial processing to comfort air conditioning. Chilled water circuit operates under normal pump pressure—is not a part of absorption vacuum system.

## SERVEL ABSORPTION REFRIGERATION CYCLE

In these Servel Air Conditioners an absorption refrigeration unit takes the place of the usual electric compressor refrigeration system. It is a compact factory-sealed unit that is actuated by heat. Gas-operated, self-contained steam generators supply the heat in DE and DC models.

The 25-ton Water Chiller does not incorporate its own steam generator.

In all models, water is the refrigerant and lithium bromide the absorbent.

Five-Year Factory Warranty is provided for all models—one year on the complete unit and four additional years on the absorption refrigeration unit. In DE and DC models, the steam generator and heating coil are also covered for five years.

## Utility Fan Corporation

A Division of Utility Appliance Corp.  
911 East 59th Street, Los Angeles 1, Calif.

Cable Address: UTILIFAN, Los Angeles

Manufacturers of heavy and standard duty blowers for heating, air conditioning and ventilating installations. Producers of blowers and blower parts for original equipment manufacturers.

Built, tested and rated in accordance with ASHVE and NAFM codes.

Sizes 6 inches to 60 inches.

Write for catalog data.

Heavy duty blower, Type "B" backward curved DWDI.

Enclosed Drive Blower

Four-Way Blower

Silent Direct Drive Blower

**HEAVY DUTY BLOWERS**, Double Inlet Double Width and Single Inlet Single Width, Forward and Backward Curved Wheels. Wheel diameters range in size from 12 inches to 60 inches. These blowers are of Class I construction, in any of ten drive arrangements and eight discharge positions.

**NEW ENCLOSED DRIVE BLOWERS**, sizes 10 inches to 36 inches, with fully enclosed drive compartment. Ideal for roof installation. The ED blowers are of the forward curved slow speed type, built for ease of installation and a minimum of maintenance.

**UTILITY'S FAMOUS "FOUR WAY" BLOWERS**, designed by Utility, available in single width single inlet as well as double width double inlet. A simple change in bearing position makes it possible to obtain discharges in any of four directions. An economy unit for medium duty use, rigidly constructed and factory guaranteed.

**NEW SILENT DIRECT DRIVE BLOWER**. By using vibration-absorbing Neoprene in the basic hub design, the blower wheel is isolated from the motor shaft. This unique development produces a very quiet blower. The direct drive blower is available in three wheel sizes providing a varied range of capacities, depending on motor horsepower selected.

## Union Asbestos & Rubber Company

332 S. Michigan Ave., Chicago 4, Illinois  
HEATING AND COOLING PRODUCTS

The UNARCO  **ROYAL-AIRE** (CU series) provides full comfort cooling range. Refrigerant flow through vertical coil is thermostatically controlled, utilizing UNARCO "pump-down" control system. Oversize vari-flow blower and oversize condenser, plus large "fin area" cooling coil, insure full-rated capacity.

The UNARCO  **CEILING SUSPENDED UNIT** (CS series) is a completely self-contained unit available in 2-, 3-, 5- and 7½-ton capacities.

The UNARCO  **COMPLETE AIR CONDITIONING PACKAGE** for stores and industrial plants (series AEC) is available in capacities from 5 to 60 tons. It is of single cabinet construction, with packaged condensing unit, blower coil section and evaporative condenser.

UNARCO  **HORIZONTAL AND DOWNBLOW UNIT HEATERS** (down-blow shown) include die-formed cabinets of not less than 20 gauge steel. Casings are phosphatized and finished in hammer enamel, baked on for permanence.

UNARCO  **WALL RADIATION**. Covers are of 14, 16 and 18 gauge steel in sloping top, flat top and expanded metal styles. Available in 2 ft to 10 ft lengths in 6 in. increments. Elements range from 2 ft to 12 ft in 6 in. increments. Accessories available.

UNARCO  **CONVECTOR RADIATORS**. Cabinets are phosphatized, finished in prime gray paint, and constructed of furniture quality steel. Also available in other models. Elements consist of cast brass headers, aluminum fins, copper tubes and 20 gauge side plates.

### HEAVY DUTY FORCED WARM AIR HEATERS

Heavy Cast Iron Construction—Integrally Cast Fins.  
Shipped Knocked Down—Assemble Inside Building.  
Tight Bolted Joints.  
Long Fire Travel—Ample Heating Surface.  
Design Relieves Internal Stresses When Expanding.  
Horizontal Flues With Access Doors Facilitate Cleaning.

#### CENTRAL TYPE

"June-Aire" conditioning for schools, public and commercial buildings. Heats and ventilates with same system. Outside air and recirculated air used in any desired proportion. Air filters—Germ killing means. Atomist humidifier—Humidistat control. Individual room temperature control with constant ventilation. Time clock program control of plant. Oil, Gas, Coal (hand or stoker fired) and convertible models. Capacity for buildings of any size. Warm floors (air tubes in slab) combined with window sill air supply, optional application method. Summer cooling by adding compressor and coil.

#### UNIT HEATER TYPE

"Superfin" (Cast Iron\*) and "Dyne-Aire" (Stainless Steel) for factories, industrial buildings, warehouses, etc. Complete heating plant in one package. Use for heating and ventilating or tempering outside air supply. Main blower, burner, and induced draft fan driven by separate motors. \*Cast iron units with built-in refractories recommended for heavy oil.

RESIDENTIAL UNITS: "June-Aire" cast iron—oil and gas fired. Complete information available at nearest sales office or factory.

### "AFFCO" VENTILATING SPECIALTIES

"Affco" Specialties Comprise A Full Line Of Fresh Air Intakes, Outside Wall Adjustable Louvers, Dampers (Single and Multiple Blade—Parallel and Opposed Blade), Automatic Fire Dampers, Fan Outlet Louvers, Fan Pent Houses, Low Profile Roof Ventilators, Et Cetera. Used in Public, Commercial, Factory, and Industrial Buildings Including Power Plants. Inquiries Invited On Standard Or Special Constructions In Any Size, Any Metal, Any Quantity.

#### S-454-F COMBINATION STORMPROOF LOUVER AND DAMPER

Frame: 20 gauge galvanized steel. Stationary Stormproof Louvers: 26 gauge galvanized riveted to frame—apron extends over sill.  
Insect Screen: 16 mesh, rust-proofed, in removable "U" type frame, back of stationary louvers.  
Louver Control Damper: 16 gauge galvanized steel multiple blades in 2 x 1/2 x 1/2 galvanized steel channel frame. Manual or motor operation means available.  
Wall Thickness: 8 in. minimum.

#### F-12 LOUVER DAMPER

Frame: 2 x 1/2 x 1/2 steel channel, 2 x 1/2 bar iron optional, heavier frames for large sizes.  
Blades: 16 gauge steel.  
Bearings: Oilite, ball, or brass trunnions.  
Position Installed: Vertical or horizontal.  
Maximum Blade Length: 48 in. Longer dampers are made in sections with all blades arranged to operate in unison.  
Motor Mounting Brackets: Internal or external—at extra charge.  
Motors and Connecting Linkage: By others, or from us at extra charge.  
Finish: Prime coat—galvanized steel optional.

#### "LO-VENT" ROOF VENTILATOR

Designed to hug roof and be inconspicuous. For buildings with pressurizing ventilating systems—propeller fans may be added.  
Body: galvanized steel—cover hinged.  
Back Pressure Dampers: aluminum blade.  
Bird Screen: over exhaust openings on four sides.  
Louver Control Damper: optional for inside curb.  
Vent Grille: By others if desired—may be placed under curb.  
Sizes: 8 to 42 in. square standard—special sizes optional.

## Campbell Heating Co.

\* Type A units include Special Oil or Gas Heater, Casing, Blower, Motor, Drive, Filters, Humidifier, and Blower Control but less Burner, Controls and Built-in Combustion Chamber.  
Type B units include same as Type A plus Oil or Gas Burner and built-in Combustion Chamber and Standard Controls.

† Based on 80% thermal efficiency for oil and gas and 70% for coal. Add 10% to 35% over calculated heat loss for pick-up load and 10% to 15% for duct radiation losses. The higher figure is preferable for best operating economy and life of the equipment.

‡ For other air volumes and static pressures consult our Engineering Department.

§ An induced draft blower can be furnished if a stack or chimney is not available. The gas passages of the heaters are adequate so an induced draft blower is not ordinarily needed.

For Complete Specifications, See Sweet's Catalog Service

## E. K. Campbell Company

Manchester at 18th Street, Kansas City 26, Missouri

Since 1910 Manufacturers of Heavy Duty Furnaces

Unit capacities up to 8,000,000 Btu per hour

District Offices: NEW YORK CITY, ST. LOUIS, MO., DENVER, COLO., KANSAS CITY, MO.  
Representatives: MINNEAPOLIS, MINN., SALT LAKE CITY, UTAH, MEMPHIS, TENN.

### "THERMIDAIRE" DESIGN 20 TYPE H-D FURNACE

Standard equipment for engineered application—available for installation in any position in capacities from 400,000 to 3,000,000 Btu per hour output—requires separate blower equipment—highly compact heavy duty furnace of high operating efficiency up to 84 per cent—available in any fuel except coal—normally shipped assembled. Available for special air volumes if required.

"Thermidaire" Design 20

### "THERMIDAIRE" DESIGN 30 TYPE H-D FURNACE

Standard equipment, industrial type direct fired heater—available from 400,000 to 2,000,000 Btu per hour output—available in vertical, horizontal and inverted models—provides maximum compactness—available for single or multiple unit installations—equipped with burner, induced draft fan, and controls mounted and wired at the factory.

"Thermidaire" Design 30

### "THERMIDAIRE" DESIGN 10 TYPE H-D FURNACE

Custom equipment for engineered applications—units from 400,000 to 8,000,000 Btu per hour output—any required duct-outlet arrangement—equipment component arrangements extremely flexible—balanced job design, blower and furnace sized separately—available in any fuel, oil fired model illustrated—large air volumes at low temp. rises up to 84 per cent operating efficiencies—normally shipped K-D.

"Thermidaire" Design 10

"THERMIDAIRE" TYPE H-D FURNACES are all heavy-duty high-quality equipment—extra heavy, welded steel construction—induced draft fan on all models—baked enamel exterior finish—low internal resistance of flue gases—low static pressure-drop across equipment—permanently smoke and gas tight—true counterflow heat transfer—operating efficiencies up to 84 per cent. Outstanding for schools, churches, auditoriums, factories, hangars, warehouses, etc.

Designed to provide uniform heat at low cost, eliminating the need for boiler rooms, costly chimneys or extensive duct work. All CSF equipment is constructed for durability, utilizing heavy gauge steel heat exchangers, high temperature refractories, and heavy duty fans. All models supplied with approved firing equipment. All heat exchangers are warranted for ten years.

There is a CSF model designed to meet any application, requiring either light oil, heavy oil, or gas.

### Dravo Counterflo SPACE HEATERS

400,000 to 2,000,000 Btu/hr output

- **ECONOMICAL**—Low initial cost—30-70 percent less than standard wet-type equipment to install. 80-85 percent efficient at bonnet . . . burns gas or oil, readily convertible from one to the other.
- **EASY INSTALLATION**—Just hook up fuel, electric and exhaust connections—no ductwork required.
- **STAINLESS STEEL COMBUSTION CHAMBER**—Rugged mill-type construction . . . top quality engineering. Exhaust whirl-cooled through two sets of economizer tubes.
- **SAFETY-TESTED**—Approved by A.G.A. and listed by Underwriter's Laboratories, Inc. Dravo Safety Control Circuit is accepted by Factory Mutual Engineering Division and Factory Insurance Association.
- **10-YEAR GUARANTEE**—All standard model Counterflo heaters carry a fully bonded 10-year guarantee on all parts in direct contact with flame or flue gases.

Dravo Counterflo Space Heaters in addition to comfort heating are easily adapted to heat curing and process drying, tempering of replacement air and

summertime ventilation. Dravo Counterflo Space Heaters can also be tied in with air conditioning systems.

### Dravo Paraflo SPACE HEATERS

200,000 to 250,000 Btu/hr output

- **POWER AND FUEL**—Heater operates on 220 volt 60 cycle current. 220 or low voltage operation can be supplied if desired. Unit can be equipped with a self-contained gun-type oil or gas burner depending upon the fuel available.
- **FAST TRANSFER OF HEAT**—Stainless steel combustion chamber allows faster heat transfer from fuel to air and guarantees longer heater life and sustained efficiency. Equipped with UL approved gun-type oil burner or A.G.A. approved gas burner.
- **FLOATING COMBUSTION CHAMBER**—Supporting straps hold stainless steel chamber in place for inverted or horizontal mounting. One end floats freely relieving stresses and strains due to normal expansion of chamber.
- **HEAT ANY DIRECTION**—Warms areas up to 3600 sq ft. Directional nozzle can be rotated 360 deg heating any desired location, high velocity discharge assures good distribution up to 90 ft from the unit without the use of ductwork.

This new Dravo heater is ideal for garages, service stations, construction offices, recreation centers, agriculture buildings, warehouses, stores, offices and

showrooms. The heater fan can be used for summer ventilation. Heaters can be adapted to air conditioning systems.

#### PARAFLO

| Htr. No. | Output Btu/hr | CFM at 70°F | Temp. Rise | Efficiency | Fan Mtr. hp | Nozzles | Approx. Shpg. Wt. | Dimensions |      |       |
|----------|---------------|-------------|------------|------------|-------------|---------|-------------------|------------|------|-------|
|          |               |             |            |            |             |         |                   | L          | W    | H     |

| 25       | 250,000       | 2700        | 84°        | 80%        | ¾           | 2       | 795               | 4'2"       | 2'5" | 7'10" |

### Dravo Gas Fired SUSPENDED TYPE UNIT HEATERS

68,000 to 180,000 Btu/hr output

- **COMPLETE RANGE OF SIZES**—Heaters are available in a wide range of capacities in various model sizes with outputs from 68,000 to 180,000 Btu/hr.

- **FLEXIBILITY OF GAS FUELS**—Heaters can operate on natural, manufactured, mixed, butane, sewer, or propane gas and liquefied petroleum.

- **LOW COST HEATING**—These heaters are ideal for economically heating small unit areas in commercial or industrial buildings such as garages, stores, machine shops, warehouses, amusement centers and other similar type buildings.

## Johnson Heater Corp.

1 Winnisimmet St. Chelsea, Mass.  
DESIGNERS MANUFACTURERS

15 Models, single heater capacities to 5,000,000 Btu fired by light or heavy oil, gas or combination gas and oil burner.

Multiple criss-cross air tube heating surfaces over the combustion chamber.

**DIRECT FIRED "AIR ROTATION" HEATING UNITS (PATENTS PENDING)  
FOR INDUSTRIAL AND COMMERCIAL APPLICATIONS  
LOW INITIAL INSTALLATION—FUEL AND MAINTENANCE COST**

Simplified heating for large open buildings such as Warehouses—Machine Shops—Garages—Airplane Hangars—Fabricating plants, etc.

Our exclusive method of "air rotation" heating (Patents Pending) uniformly blankets with warm air all areas of an open building. All duct work, piping spotting, and throwing of the heated air is eliminated. One Johnson Heater can successfully heat in excess of 1,500,000 cubic feet of building space.

- TUBULAR DESIGN
- FULLY AUTOMATIC
- HIGH EFFICIENCY
- CONSERVATIVELY RATED
- PRACTICALLY SELF CLEANING

### SMALLER JOHNSON FLOOR MODEL HEATERS

Five models of horizontal extended casing units: 110,000-138,000-165,000-210,000-275,000 Btu.

Five models of vertical Hi-Boy units: 110,000-138,000-165,000-210,000-275,000 Btu.

## Jackson & Church

Furnace Division

Saginaw, Michigan

**J-C**

"Work well done since '81"

The school building heating system shown incorporates all the advantages of perimeter heating... plus seven complete air changes per hour; constant blower operation, and individual room temperature control. A J-C furnace provides both heat and ventilation. A blending of desired proportions of fresh outside air and room air is heated to proper temperature and delivered through floor ducts in tunnels used for wiring and piping. Air may be introduced through floor registers, elevated registers or book-shelf-register combinations. High inside wall returns are used.

**SUSPENSION FURNACES**—the line of horizontal units. Available in wide range, 80,000 to 1,000,000 Btu output. Oil and gas fired... with UL and A.G.A. approval.

**POWERAIRE FURNACES**—for most commercial and large residential jobs. Air conditioning units can be added to system. Outputs from 152,000 to 320,000 Btu. Oil and gas fired.

**POWERATED FURNACES**—for industrial heating and industrial ventilating where outside air is introduced. Outputs from 380,000 to 3,800,000 Btu. Oil, gas and coal fired.

J-C Direct-fired units now available with outputs from 400,000 to 2,000,000 Btu/hr.

### LEE HEAVY DUTY HEATERS

LEE HEATERS have been in continuous operation since 1918. Lee Heater installations have been made in most of the States of the United States, in Canada, Alaska, Yukon Territory, Northwest Territory, Labrador, Iceland, Norway, Mexico and South America.

Firing Equipment manufactured specially for us by leading Companies with International service organization. There is a Service man near you if and when you require assistance. In addition Lee maintains a competent field serving staff.

Replacement and Spare Parts Service is maintained. Most items are carried in stock.

### VERSATILE

#### Types of Fuel

- Light Oil (#3 or Lighter)
- Medium Oil (#5 or Lighter)
- Heavy Oil (#6 or Lighter)
- Gas (Natural, Manufactured Propane Coke Oven.)
- Combination Light Oil & Gas
- Combination Heavy Oil & Gas

#### Mount in any Position

- Floor Mounted
- Horizontally Mounted (& Suspended)
- Vertically Mounted (& Suspended)
- Use with Ducts for Central Heating System
- Use without Ducts as Self Contained Heating System

\* Based on Standard Air at 70 F Free Delivery

\*\* Requires large Air Fan Motor

\*\*\* Fuel consumption based on 1000 Btu per cu. ft of Gas, 145,000 Btu per gal of Oil and on 80 per cent efficiency for the heater.

## Mammoth Furnace Company

509 Vandalia Street St. Paul, Minnesota

Commercial-Aire

Strong—built for rugged service and safe shipment.

Quiet Fan Operation—a rigid tubular fan shaft supported by two self aligning bearings eliminates shaft and bearing problems.

Retractable Burner Tray—allows complete service to burner. Permits removal from unit with no disassembly and minimum handling.

Central Control Cabinet—provides controls, fusing and wiring in an accessible dust-tight enclosure.

Direct Driven Induced Draft—trouble-free, vortex cooled motor shaft connection to blower wheel. No belts and additional bearings to service.

Variety Of Controls And Power Supplies—units may be "off-on" thermostat controlled, hi-low fire or modulated control.

Wiring and controls can be provided for all power supplies.

Integrated Burner Applications—burners by reputable manufacturers are tailored to produce the most effective flame configuration for the heater design.

Combustion Safety And Draft Controls—MH-Electronic flame control system, pre-ignition draft purge timing and draft sensing give a high degree of operation safety.

Series "F" Floor mount with discharge heads for industrial plants, foundries, etc.

Series "H" Horizontally suspended unit for use where floor space is unavailable.

Series "FD" For duct distribution. For churches, schools, auditoriums, etc.

Series "U" Suspended inverted unit for make-up air applications in plants, foundries, etc.

## Arthur A. Olson & Company

Canfield, Ohio

Manufacturers of Direct Fired Heaters

Olson

A completely automatic direct-fired unit heater. Olson heaters operate on gas, oil, dual gas-oil or coal. These units may be hung, suspended horizontally or inverted. All heaters can be adapted to filtering, humidifying and air conditioning. Use of standard accessories and easy access to bearings and other vital parts simplify maintenance. Also special adaptations for make-up air, drying, high-temperature and process work.

- Austinitic Stabilized Stainless Steel Combustion Chamber with floating design and a multiple battery of 10 gauge boiler tube economizer section.
- Heavy Duty Fans and Shaft.
- Inlet Screens or Frame for Filter Box.
- Adjustable, Deflecting Outlets.
- Separate Induced Draft Fan.
- Bearings Outside Heater at End of Shaft.

Four Pass Gas Travel-Counter Current.

### Engineering Data—Gas, Oil, or Dual Gas-Oil Heaters

## National Heater Company

**NATIONAL**  
*Champion*  
DIRECT FIRED

2180 Cleora Avenue St. Paul 4, Minnesota

### NATIONAL CHAMPION HEATERS

200,000 to 2,000,000 Btu

Direct fired for oil, gas, or combination units

Engineered for industry—space heating, tempering make up air, and drying

MODEL H Available in ceiling suspended, inverted and portable units

- **GUARANTEED 80 PER CENT OPERATING EFFICIENCY** — in factories, foundries, warehouses, garages, hangars, terminals and many other installations.
- **SAVE ON OPERATION** — National Champion Heaters circulate warm air at working levels, keep roof heat loss at a minimum. Low initial cost—no boiler house or power piping required. Low operating cost—standby losses eliminated, no licensed attendant needed!
- **SAVE ON FUEL**—National Champion Heaters burn fuel only when zone thermostats call for heat. Burner shuts off when temperature is attained. No fuel wasted to overcome transmission losses. No wasteful recycling to maintain steam pressure or water temperature.
- **SAVE ON MAINTENANCE**—National Champion Heaters feature simplified burner and controls and easily accessible clean-out plates—no problem to maintenance personnel. Spare parts are readily available.

**TESTED CONSTRUCTION** — Features high chrome nickel stainless steel combustion chamber, in efficient teardrop design. Structure welded into rugged, one-piece steel unit with baked enamel exterior finish. Engineered for dependable, enduring service. Underwriter's laboratories listed.

- **SAVE ON INSTALLATION**—National Champion Heaters save 30 per cent to 70 per cent over systems requiring expensive ductwork, piping, condensate lines, traps, pumps, etc. Units are shipped completely wired, assembled and flame-tested at the factory to guarantee peak performance.

1280

## National Heater Company

2180 Cleora Avenue

St. Paul 4, Minnesota

Efficient heat exchange, high velocity discharge develop truly economical space heating.

1. When thermostat calls for heat, induced draft blower starts first to purge combustion chamber and establish draft before burner is fired.
2. Main blowers—separate from induced draft blowers—start only when proper bonnet temperature is attained.
3. Cool air is drawn through louvered panels at floor level.
4. Air passes over National's stainless steel teardrop combustion chamber and then around multiple banks of economizer tubes.
5. After this full uniform heating, air discharges at high velocity from adjustable heads atop the heater.
6. Separate blower integral with burner, and separate induced draft blower, are independently adjustable for maximum combustion efficiency.

Cutaway view of the National Champion Model H shows air flow from floor intake to adjustable discharge heads.

**RESULT:** No "cold blasts" on start-up; proper, uniform heating of air; high velocity discharge keeps warmed air at working levels; minimum temperature differential between floor and roof.

## Reznor Manufacturing Company

66 Union Street, Mercer, Pa.

Gas Unit Heaters—nine sizes: 25,000 to 250,000 Btu; Console-Type Room Heaters—25, 50, 65 and 75,000 Btu; Duct Furnaces—50,000 to several million Btu; Gas Horizontal Furnaces—75,000, 100,000 and 125,000 Btu.

### Reznor Series DS Sectional Duct Furnaces 150,000 to Several Million Btu

Sectional assembly simplifies installation. Capacities totaling 2,000,000 Btu and above can be installed in custom engineered heating systems from sections weighing no more than 315 pounds. Unlimited number of sizes in steps of 50,000 Btu from 150,000 to several million Btu. All assembled from four basic sections—150, 200, 250 and 300,000 Btu.

Units are compact, highly efficient, lightweight heat exchangers, each with a full complement of combustion controls. For assembly with components for air-moving, cooling, cleaning and humidification selected to meet the exact requirements of each job. May also be used as booster units to supplement other warm air heating equipment.

Designed for installation as an integral part of the ductwork, all sections are equipped for either suspended or base mounting. Because air flow through the heater may be in either direction, sections can always be turned to provide easy access to controls and burners. To provide for seasonal operation of less than the total capacity, each section is complete with controls and built-in draft diverter.

The unit shown above is a 450,000 Btu duct furnace (one 150,000 and one 300,000 Btu section mounted side-by-side). Because sections can be mounted in a single bank or in a double bank, overall dimensions

sions depend on the manner of installation. All sections are 37 in. high and 24 in. deep. Width varies according to capacity.

Gas and electrical controls are normally installed on the front of the heater, but can be relocated to the side if preferred. Controls include main and pilot shut-off valves, electric valve, pressure regulator, safety pilot and adjustable limit control. All controls supplied by leading manufacturers. All electrical components Underwriters' Laboratory approved.

Aluminized steel is the standard heat exchanger material; stainless steel heat exchangers are also available.

Built-in draft diverter is reversible so that flue connection may face in either direction. Flue collar on snap-out plate for easy adaption to vertical or horizontal discharge.

#### Specifications—DS Duct Furnace Sections

| Section | Btu Input | Btu Output | EDR  | Thruput-cfm |       | High | Deep* | Wide**  | Weight  |
|---------|-----------|------------|------|-------------|-------|------|-------|---------|---------|
|         |           |            |      | Mini-       | Maxi- |      |       |         |         |
| DS-150  | 150,000   | 120,000    | 519  | 1200        | 1900  | 37"  | 24"   | 21 1/2" | 190 lbs |
| DS-200  | 200,000   | 160,000    | 692  | 1600        | 2400  | 37"  | 24"   | 27 1/4" | 235 lbs |
| DS-250  | 250,000   | 200,000    | 884  | 2000        | 3000  | 37"  | 24"   | 35 3/8" | 275 lbs |
| DS-300  | 300,000   | 240,000    | 1033 | 2400        | 3600  | 37"  | 24"   | 40 7/8" | 315 lbs |

\* 90° rise || 60° rise.  
\* For total depth of multiple banks, add depths of sections, then add 12" if sections will be installed back-to-back, or add enough space to allow for removal of burners if units are to be installed front-to-front or front-to-back.  
\*\* For total width of multiple sections, add widths of sections. For total width of duct on multiple sections subtract 2 1/4" from total overall width.

### Methods of Installation—DS Series Duct Furnaces

This schematic diagram shows how Reznor Series DS Duct Furnaces may be combined in the duct system with other components. All components shown (except the blower or other air-impelling equipment) are optional, to be used only as required by the specific job to be done. It is recommended that cooling and humidifying equipment be installed downstream.

Multiple-section single bank installation with common air supply and distribution ducts.

Multiple-section, double-bank installation with common air supply and distribution ducts.

### Reznor Gas Unit Heaters

Completely automatic heating for all commercial and industrial buildings... as the basic system or to supplement other types of equipment. Eight sizes—25,000 to 200,000 Btu with choice of propeller fan or centrifugal blower plus 250,000 Btu twin-fan model. Aluminized steel heat exchangers. Cast iron universal burners. Built-in draft diverter. For complete details, dimensions and specifications write for Bulletin B-55-UH.

### Reznor Series D Duct Furnaces

For residential and small commercial applications requiring a heat exchanger for use in a custom engineered system. Four sizes: 50, 75, 100 and 125,000 Btu. For installation with any combination of equipment for air moving, cooling, cleaning and humidification. Burner access and controls completely enclosed on same side of handsomely-styled cabinet. All models 22 in. wide by 23 in. high; depth varies with capacity. Complete with combustion controls and built-in draft diverter. For suspended or base mounting. Bulletin B-55-D.

# THERMOBLOC

Division of PRAT-DANIEL CORPORATION

Meadow Street

South Norwalk, Conn.

**THERMOBLOC DIRECT-FIRED INDUSTRIAL HEATERS**  
The Thermobloc heater is a direct-fired, self-contained heating unit designed to provide high efficiencies for all commercial and industrial heating applications.

The Thermobloc Heater is a product of a firm with over 30 years of experience in the industrial heating field. It represents up-to-date proven design and engineering principles to assure a minimum of installation and operating costs and dependable comfort conditions.

Thermobloc Heaters are sold in 28 countries. They are available in a complete range of sizes from 100,000 Btu/hr to 2,250,000 Btu/hr output to cover any industrial or commercial application.

All heaters are factory assembled, tested, and shipped complete—requiring only connection of fuel, power and vent for immediate operation in the field. Range of sizes available offers a versatile unit or a combination of units for any industrial or commercial job regardless of size. They may be located directly in the area to be heated or may be full ducted and placed where desirable.

Units are available for all commercial fuels; oil—number two or four; gas; combination gas and oil; combination gas and LP gas.

**PORTABLE THERMOBLOC HEATERS.** Designed for temporary or emergency heating in industrial construction, agriculture or personnel applications. The Industrial Model P 420 is oil-fired, has a capacity of 4,500 cfm and may be used in open areas or ducted, as required. Maximum output is 420,000 Btu/hr vented and 560,000 Btu/hr unvented. Unit may be easily moved to location.

The personnel heater Model P 190 provides radiant heat with an output 175,000 Btu/hr. It is oil-fired and completely self-contained including fuel tank, and may be easily moved by one man.

**PANELBLOC GAS-FIRED INFRA RADIANT INDUSTRIAL HEATERS.** The overhead Panelbloc (formerly the Overhead Panelray) offers an entirely new design for industrial heating. Proven for the past seven years in over 15,000 installations, the Panelbloc has demonstrated its advantages as a heater for personnel or equipment. The Overhead Panelbloc is available in two sizes, 62,500 and 125,000 Btu/hr input and it is available for all commercial gas fuels. All models are A.G.A. approved.

Operating on the radiant heat principal, the Overhead Panelbloc requires no fans, blowers or electrical energy for operation. The absence of moving parts make maintenance negligible.

The sun-like radiant heat output from the Overhead Panelbloc is not affected by drafts from open doors or windows, assuring a deposit of heat on the objects and floor in the area being heated. The Overhead Panelbloc, makes it possible to properly heat spots or areas within large unheated buildings,

# Tjernlund Manufacturing Co.

2140 Kasota Avenue • St. Paul 14, Minnesota

TJERNLUND  
"Quick Heat"

Manufacturers of DOMESTIC, INDUSTRIAL, and COMMERCIAL WARM AIR HEATING EQUIPMENT, OIL and GAS BURNERS, BLOWERS and DRAFT INDUCERS

7 MODELS

134,000-896,000 BTU OUTPUT

Style "A" Suspended or Lo-Boy

Style "E" Counterflow

Style "D" Suspended Units

## HEAT EXCHANGER

Features well known Tjernlund Counterflow flue system coupled with direct firing into high heat resistant stainless steel combustion area. No internal baffles or restrictions.

## FIRING EQUIPMENT

Oil fired units utilize Tjernlund high pressure integral draft inducing oil unit for #2 or #3 oil. Single motor operation of inducer and oil burner. Two stage fuel units—standard equipment.

## GAS FIRED UNITS

Feature Tjernlund jet fire power type gas units. Models 150, 200, 280 incorporate integral draft inducing equipment identical to that shown on oil units with electric ignition, prepurge timing electronic safety control.

## DUCT HEATERS

All Tjernlund units available less blower equipment for use in conjunction with air conditioning units or as replacement heaters where existing blower equipment can be utilized.

## BLOWER EQUIPMENT

Properly sized DWDI blower wheels with correctly designed scrolls. Blowers made by Tjernlund for correct application to each piece of equipment. Extra capacities available for higher air delivery and external static pressure.

## Engineering Data

For cfm and s.p. other than stated request additional information from factory.

## Fedders-Quigan Corporation

Heating Division

Lalor & Hancock Sts., Trenton 7, N. J.

### FEDDERS

Manufacturers of Convactor-Radiators, Wall Radiation, Baseboard Radiation, Unit Air Conditioners, Unit Heaters, Railroad Car Convectors, Unit Coolers, Refrigeration Coils, Air-Cooled Fin and Tube Condensers, Clip-on Thermometers, Room Air Conditioners, Automotive Radiators, Car Heater Cores, Dehumidifiers.

Fedders Series 17 Horizontal Unit Heaters made in capacities from 83-1225 EDR.

Fedders Series 16 Down-blow Unit Heaters for high or low ceilings and spot locations. Capacities from 165-2050 EDR.

Fedders Series 18 Gas-Fired Unit Heaters in eight sizes—185-667 EDR.

#### FEDDERS UNIT HEATERS

Made in horizontal and down-blow types. Well graduated range of capacities to fit requirements. Quick response to manual and thermostatic controls assures comfort and fuel economy. Complete data given in catalogs.

#### FEDDERS BASEBOARD RADIATION

Provides uniform around-the-room comfort. Delivers radiant and convected heat at floor level. No interference with furniture arrangement, draperies or wall-to-wall carpeting. Packaged units factory assembled in 4, 6 and 8 ft lengths. Aluminum-finned, copper tube heating elements. Also steel-finned steel tube. Full length, built-in deflectors serve as adjustable dampers for individual control. I-B-R Approved. Write for catalog.

#### FEDDERS CONVECTOR-RADIATORS

Cabinets are attractively designed for free standing, semi-recessed and flush installations. Heating elements have copper tubes and aluminum fins. Types F, FE and FB available with Fedders slide-in front panels. Code-approved in accordance with Commercial Standard CS140-47. Write for catalog.

#### FEDDERS WALL RADIATION

For industrial, commercial and institutional uses. Available with aluminum-finned copper tube elements or steel-finned steel tubes. Flat or sloping top covers. Also expanded metal covers. Write for catalog.

#### FEDAIR AIR CONDITIONERS

Remote Type

For multiple room installations using circulating hot and cold water supplied from a remote source. Individual room control, quiet operation, no duct work. 3 sizes. Free standing, semi-recessed, concealed and overhead models. Write for catalog.

## ILG Electric Ventilating Co.

2880 North Crawford Ave., Chicago 41, Ill.

Offices in more than 40 Principal Cities

ILG UNIT HEATERS—STEAM, HOT WATER, ELECTRIC OR GAS

Tested and rated by IUHA and ASHVE codes. "One-name-plate" guarantee.

**HORIZONTAL TYPE UNIT HEATERS**—New design. Four side pipe connections for simplified piping. Copper tubes hydraulically expanded for permanent mechanical union with aluminum fins, brazed to one-piece cast iron headers. Suitable for hot water and steam to 150 lbs pressure . . . tubes hydrostatically tested to 500 lbs. Motor totally enclosed, continuous duty type with oil lubricated bearings. 16 capacity sizes.

**VERTICAL TYPE UNIT HEATERS**—New design. Ball bearing motors shielded from radiant heat. Heating surface features similar to Horizontal Type above. Type V for standard outlet temperatures, Type VL for low outlet temperatures. 12 capacity sizes.

**ILGDUALGAS UNIT HEATERS**—Use natural, manufactured, mixed, Butane-air mixtures, Propane, or Butane gas. Safety pilot, automatic control valve, electric limit switch. Motor has thermal overload protection.

**TEXTILE TYPE UNIT HEATERS**—More tubes, no fins—for applications where lint, etc. normally adheres to fin surfaces. Other features same as Horizontal Type above.

**HEAVY DUTY ELECTRIC UNIT HEATERS**—Non-glow heating coil. Ideal for heating isolated buildings and for completely automatic heating, periodic, temporary, and auxiliary heating. Capacities 1½ to 15 kw . . . all sizes available for 110, 230, 440 and 550 volts.

**McQuay Inc.**

• Heating • Air Conditioning • Refrigeration

1602 Broadway, N. E., Minneapolis 13, Minn.

SALES OFFICES IN PRINCIPAL CITIES

3/8" Tube Evaporator

3/8" Tube Condenser

#### McQUAY RIPPLE-FIN COILS

McQuay now makes the famous Ripple Fin coils in three tube diameters, 3/8 in., 1/2 in. and 3/4 in.; in a wide variety of styles and sizes; for steam, hot water, cold water, direct expansion and refrigerant condensing.

"Custom Engineered" coils are readily obtained as McQuay's manufacturing methods provide a wide variety of fin spacings, fin heights, finned lengths, rows deep, and circuiting; thereby both space and capacity requirements can be met.

Ripple-Fin coils have all tubes mechanically pressure bonded into the wide smooth fin collars providing a permanent bond and high heat transfer

efficiency. McQuay coils are pneumatically tested under water at 300 psig.

Ripple-Fin coils have a staggered tube pattern which combined with the ripple fin produces a turbulent air flow and reduces air "by-pass."

In addition to the ripples across the air flow the fins of McQuay coils have rippled edges to give strength and a pleasing appearance.

McQuay Evaporators and Condensers are dried to minus 40°F. dew point to assure moisture free coils.

McQuay Ripple Fin coils have been approved by *Underwriters' Laboratories* for use as evaporators or condensers with either Freon 12 or Freon 22.

Direct Expansion Coil

Water Coil

Steam Coil

Horizontal Unit Heater

Heating and Ventilating Unit

Seasonmaker (Ceiling Type)

Seasonmaker (Floor Type)

#### HORIZONTAL UNIT HEATERS

Two basic types available—Standard and High cfm. 13 Standard models ranging in size from 21,600 to 360,000 Btu; 11 High cfm models 20,300 to 248,000 Btu. Write for *Catalog 322*.

#### DOWN FLOW UNIT HEATERS

Two basic types available—Standard and High cfm. 11 Standard models ranging in size from 39,300 to 500,000 Btu; 11 High cfm models 25,400 to 289,000 Btu. Write for *Catalog 762*.

#### "RH" AIR CONDITIONER

(For Small Commercial Jobs)

Deluxe units with attractive appearance. Four basic sizes: 1000, 1500, 2000, and 3000 cfm. Nominal capacities range from 2 to 10 tons. Freon and water cooling coils—steam and water heating coils—condenser reheat coils. Write for *Bulletin 88*.

#### HEATING AND VENTILATING UNIT

Horizontal, vertical, wall and inverted types. Covers the entire range from 1280 cfm and 26,000 Btu to 32,000 cfm and 2,227,000 Btu. Filters, face and by-pass dampers, mixing boxes, humidifiers, discharge plenums, and nozzles are available. Write for *Catalog 344*.

#### SEASONMASTER

(Central Station Air Conditioner)

Horizontal and Vertical types. Cools, dehumidifies, filters, and circulates air in summer; heats, humidifies, filters, and circulates air in winter. Freon and water cooling coils—steam and water heating coils. Cooling capacities from 1 to 100 tons, cfm from 640 to 21,000 in both suspended and floor type. Write for *Catalog 505*.

#### SEASONMAKERS

(For Multi-Room Buildings)

Room air conditioner, four types: floor, hideaway, basic, and ceiling. Cooling and heating medium supplied from central plant. Cools, dehumidifies, and filters in summer; heats and filters in winter. Three basic sizes: 200, 400, and 600 cfm (up to 25 per cent of cfm may be fresh air). The Seasonmaker's compactness, attractiveness, quiet operation, and ease of installation make it ideal for hotels, apartment buildings, hospitals, motels, etc. Write for *Bulletin 704*.

#### ICY-FLO ACCUMULATORS

The practical "Storage-Battery" for refrigeration effect is now available for handling heavy loads of short duration. Ideal for churches, lodges, mortuaries, noon cafeterias, and many industrial applications. Write for *Bulletin 109*.

## Modine Manufacturing Company

Heating and Air Conditioning Division

General Offices: 1515 Dekoven Ave., Racine, Wis.

Factories at Racine, Wis., LaPorte, Ind., Paducah, Ky., and Whittier, Calif.

Sales Representatives in all Principal Cities

### NEW MODINE AIRditioner\*

Console Type AIRditioner

Four types available: The Console (illustrated) for exposed and partially recessed installation . . . the Concealed . . . the Ceiling . . . and the Overhead Models, with or without casings. Each is available in three sizes rated at  $\frac{3}{4}$ ,  $1\frac{1}{2}$  and 2 tons of refrigeration (220, 440 and 640 cfm respectively).

All Modine AIRditioners are designed and engineered for fast, easy installation and quick access to all connections and parts. Casings are Parker-Bonderized and finished in a semi-gloss Marine Green primer.

### MODINE UNIT HEATERS FOR WATER AND STEAM

A fully coordinated line of Modine Unit Heaters offers greatly expanded opportunities for correct unit heater application. Individually or in combination, they meet the exacting engineering demands of any space heating application.

For steam, Modine builds 26 sizes of vertical (includes 13 low outlet temperature models), 19 sizes of horizontal (includes 9 low outlet temperature models), and 10 sizes of power throw units. For hot water, Modine builds 13 sizes of vertical and 15 sizes of horizontal units.

\* Trademark

The modern room unit for cooling and heating hotels, apartments, motels, offices, hospitals, schools and homes. Ideal for new construction and modernization. Provides cooling with chilled water and heating with hot water—from a central source. Filters and dehumidifies while introducing and circulating fresh air. Four-speed motor control for maximum adaptability to conditions.

**Rugged Condenser**—Tubes and headers are cylindrical and brazed at the joints for greater pressure-resisting strength. Individual expansion bends of horizontal models absorb differential stresses.

**One-Piece Construction**—Tubes, header, inlet and outlet connections are brazed into a rugged, pressure-resisting unit.

**Safety Fan Guard**—On all Horizontal models, a built-in fan guard offers constant protection from exposed fan.

**Bonderite-Treated Casings**—All unit heater casings are Bonderite-treated to prevent rust and bond paint to steel.

**Efficient Motors**—Nationally known makes of continuous-duty, totally enclosed fan type. Rubber mounted to prevent vibration noise.

**Easy Installation**—Direct-from-pipe line suspension for low cost, fast installation of all Horizontal types. Accurately rated in strict accordance with the Standard Test Code for Unit Heaters.

### MODINE GAS-FIRED UNIT HEATERS

Half the weight . . . half the size . . . of the average of 7 other leading gas units of comparable capacity.

Gas-fired unit heater

Modine Gas-Fired Units are made with both stainless steel burners and a choice of stainless or aluminized steel heat exchangers. Lighter weight means easier, less expensive installation plus faster heat delivery . . . within five seconds after thermostat calls for it. Individually fired tubes provide higher heat transfer. Elongated ports—four times free area of conventional drilled ports—minimize clogging and simplify cleaning.

Seven sizes—from 25,000 to 220,000 Btu. A.G.A. and CGA approved for natural, mixed, manufactured LP and LP-air gases.

### MODINE CONVECTOR RADIATION

Modine Convectors combine exceptional beauty with outstanding performance. Available in Deluxe and Standard enclosure styles, they are also obtainable in heavy-duty Institutional models. Floor, wall, sloping wall, concealed, fully recessed and partially recessed styles offer a wide selection to meet any requirement.

Deluxe Floor Convector—for recessed or free-standing installation.

**MODINE HEATING COILS** The extensive line of Modine Heating Coils is engineered to meet the diversified requirements of modern air-handling systems. In addition to more than 1200 cataloged heating coils for use with steam and hot water, Modine produces many custom built coils for installation in air-handling equipment produced by other firms. Types include standard and non-freeze heating and booster coils, and hot water heating coils.

Standard Heating Coil

**MODINE CABINET UNITS** The Modine Cabinet Unit line provides economical heating, cooling and ventilating where the expense of air conditioners or unit ventilators is not warranted. A single Cabinet Unit can provide quick, positive, quiet distribution of heated or cooled air—with or without ducts. Addition of inexpensive accessories permits introduction, filtering, heating and distribution of fresh outside air for ventilating.

Type BT Cabinet Unit

Five different models provide (1) heating with steam or hot water and (2) cooling with chilled water in addition to heating. Various combinations, with or without optional equipment, permit free-standing, recessed and concealed installations—floor, wall or ceiling mounting.

## D. J. Murray Manufacturing Co.

Wausau, Wisconsin  
Offices in Principal Cities

MANUFACTURERS OF GRID UNIT HEATERS  
AND GRID BLAST COILS

One piece construction "fin" heating sections of high test cast iron—no soldered, brazed, welded or expanded connections. Patented.

Designed and tested to operate with steam or hot water systems—for steam pressures from 2 lbs to 250 lbs. GRID Unit Heaters are "Put up to stay up" without repairs or other maintenance... service records from all types of industry prove it.

Overall dimensions for installation of Cast Iron  
GRID Unit Heater

### NO ELECTROLYSIS TO CAUSE CORROSION

Low maintenance expense.  
More air changes per hour.  
Positive "directed" heat.  
No leaks—no breakdowns.

Lower outlet temperature.  
Larger air volume.  
No soldered, brazed or expanded joints.  
Open design that keeps units clean.

## JOHN J. NESBITT, INC.

Philadelphia 36, Pa.

Manufacturers of  
NESBITT SCHOOLHOUSE HEATING AND VENTILATING  
EQUIPMENT AND AUXILIARY STORAGE CABINETS

Ensemble of  
the Nesbitt  
Syncretizer and  
metal shelving.

### THE NESBITT PACKAGE

Modern classroom ensemble of storage cabinets and the Nesbitt Syncretizer heating and ventilating unit. Provides quick, economic heat without overheating; draft-free ventilation and cooling when needed; room-by-room balance. A fully automatic, quiet-operating unit adaptable to four cycles of control. Sturdy, attractive 28 in. and 32 in. high ensembles with laminated plastic hardtop, choice of 6 baked enamel finishes. Capacities from 750 to 1560 cfm anemometer rating. Publication 101.

### SERIES-WIND-O-LINE SYSTEM

A new hot water heating and ventilating system (Syncretizers and Wind o-line piped in series circuits) that reduces mechanical system costs by eliminating pipe trenches, coverings and individual runouts. Variable water temperature provides better control, ideal cold surface protection. Pub. 104.

Wall-hung casing

Recessed fin  
Storage Units

### WIND-O-LINE RADIATION

For integration with the Syncretizer under large glass areas with cold exposures. Consists of fin and tube radiation in a gridded wall-hung casing or recessed in components of the Nesbitt Package. Controlled in cycle with the Syncretizer to meet the heat demands of low temperature surfaces. Capacities 450, 550 and 700 Btu/lineal ft. Pub. 261, Section W.

### SERIES T THERMOVENTS

New higher capacity heating and ventilating units for large auditoriums, gyms, shop rooms, cafeterias and similar gathering places. Available for both low-pressure and high-pressure, relatively high-resistance applications. Unique acoustically treated discharge plenum assures quiet operation. Available in capacities from 1250 to 15,000 cfm. Publication 270.

Horizontal mounted  
Series T Thermovent

### SILL-LINE RADIATION WITH STORAGE CABINETS

For modern school and office installations which require practical storage space combined with a need for heating, this low-cost combination of high-capacity Sill-line perimeter heating with Nesbitt open and closed storage shelving is ideal. Cabinets are made in 28 in. and 32 in. heights, 2 ft, 3 ft and 4 ft lengths to form continuous ensembles. Piping Compartment and Fill-in Section conceal control valves, piping, etc. Available in choice of 6 attractive baked enamel finishes with laminated plastic hardtop for extreme durability. Steam heating capacities from 1435 to 2520 Btu per hr per lineal ft, true condensation. Publication 261, Section S.

## JOHN J. NESBITT, INC.

Philadelphia 36, Pa.

Nesbitt Sill-line

### NESBITT SILL-LINE RADIATION

High-capacity perimeter heating in an attractive 16-gauge wall-hung enclosure for use in schools, hospitals, offices, showrooms, etc. Made in five casing styles with one-piece back panel for true, rigid alignment; seven lengths from 2 ft to 8 ft; choice of finishes. Full range of accessories and sleeves eliminate on-the-job cutting. Eight heating elements with CODE approved ratings from 2.9 to 12.1 sq ft EDR. *Publication 102.*

### NESBITT HEATING AND COOLING SURFACE

**SERIES W.** Water surface for air-cooling, dehumidifying or heating. Copper tubes, aluminum or copper fins. Wide range of sizes in three types: Type WD (continuous tube with exclusive freeze-proof drainability feature, and surface pitched in the casing). Pub. 246. Type WB (continuous tube sections for booster-heating or air-cooling relatively small air volumes but without drainability feature) and Type WC (standard Series W cores pitched in the casing; cast iron headers removable cover plates to permit cleaning, single or double serpentine circuits.) Pub. 255.

**SERIES T.** With Trombone-shaped steam-distributing tubes that eliminate stratification and all danger of freezing under modulated valve control. Gives uniform temperatures over the entire capacity range. Ideal for heating and ventilating and for preheating outdoor air. Copper tubes and headers, aluminum or copper fins. Type TO with steam and condensate connections at opposite ends, Type TS with connections at same end. Fin lengths from 12 in. to 120 in. *Publication 305.*

**SERIES H.** General blast coil surface for heating, ventilating, air-conditioning and drying in both high and low-pressure systems. Copper tubes, aluminum or copper fins. Seven types, full range of sizes. Pub. 248.

### NESBITT GAS-FIRED UNIT HEATERS

Modern, attractive direct-fired unit heaters in seven basic models ranging in capacity from 25,000 to 200,000 Btu heat input. Made of die-formed furniture steel finished in heat-resistant, baked-on enamel. Low-speed motor equipped with thermal overload protection. Quiet-operating fans; die-formed adjustable louvers. Equipped with automatic controls and safety pilot. Units are A.G.A. approved and listed by Underwriter's Laboratories. *Publication 280.*

### NESBITT BASEBOARD RADIATION

A new approach in baseboard design. Combines an enclosure of unusual beauty with a heating capacity ample to achieve true perimeter heating (4.1 sq ft EDR per lineal ft). CODE approved steam and hot water ratings. Copper tube, aluminum fin element. Furniture steel cabinet in 4, 5, 6, 8 ft lengths. Pub. 272.

Nesbitt Baseboard Radiation

## JOHN J. NESBITT, INC.

Philadelphia 36, Pa.

NESBITT UNIT HEATERS are designed to circulate large volumes of air at comparatively low temperatures, assuring quick heating.

Ratings of Nesbitt Unit Heaters are based on tests made in accordance with standard test code of Industrial Unit Heater Association and ASHVE.

### PROPELLER FAN UNIT HEATERS

Featuring universal heating elements of continuous tube design, each size unit gives a comparable range of capacities with either steam or hot water. Made for high temperature drops, low water rates for installation economy. Small physical size for comparable Btu output *saves space*. Sturdy steel casings with baked-on gray-green hammertone finish for lifetime beauty. Flush-to-ceiling mounting permitted by male pipe connections extending through casing rear. Sealed-for-life motors in most models. Balanced aluminum fans with large blade areas assure gradual, quiet, efficient air delivery. Eight basic sizes, 24 models, capacities from 15,000 to 335,000 Btu per hour. Sound rated within lowest classifications of new Bulletin 13, I.U.H.A. Sound Test Code. Pub. 401.

Standard Propeller-Fan Type

### GIANT BLOWER-FAN UNIT HEATERS

Large capacity units for: heating and/or ventilating, free delivery or static pressure, steam or water systems. Twelve basic sizes, each with one of three standard steam coils, three distributing-tube coils, or with a single, two, three, or four-row hot water coil. Air deliveries from 2000 to 28,000 cfm. Basic steam ratings, 83,000 to 1,735,000 Btu/hr. Hot water capacities from 50,000 to 2,460,000 Btu/hr, 1800 to 3400 fpm. Control may be STANDARD—periodic fan operation; THERMADJUST—continuous fan operation with thermostat-controlled dampers; or VALVE-CONTROLLED—with thermostat controlling steam supply. Horizontal-suspended, wall, inverted or floor-mounted with wide choice of cowls, fans, dampers, filters and other accessories. Pub. 404.

Giant Blower-Fan Type

### LITTLE GIANT UNIT HEATERS

Adaptable to a wide variety of applications and field conditions. Eight basic sizes, each with a choice of two (some units three) heating elements. The three smaller sizes are of the blow-through type, having lower outlet velocities generally intended for the lower mounting heights of commercial installations. These sizes in down-blow type only. The five larger models are of the draw-through type; produce the high discharge velocities necessary to blow long distances. These five available for either horizontal or vertical down-blow.

Durable lightweight Heating Elements. Extended fin-and-tube type, copper condensing tubes and plate-type aluminum fins. Steam capacities from 28,500 to 510,000 Btu. Pub. 402.

Little Giant Down-Blow Type

### SERIES "C" UNIT HEATERS

The new Series "C" permits complete flexibility of design and operation. Units are available for floor mounting, horizontal, wall or inverted applications and can be installed fully recessed, semi-recessed or free standing. The discharge or intake can be face, top or bottom—direct or with ducts. Available in five basic sizes—46 basic capacities ranging from 25,000 to 148,000 Btu per hour. For steam or hot water. Pub. 403.

Series "C" Cabinet Heater

## HERMAN NELSON

American Air Filter Company, Inc.

Office — Louisville, Ky. Factories — Louisville, Ky., and  
Moline, Ill.

Branch Offices and Product Application Engineers in Principal Cities

Horizontal Shaft Heater

Gas Fired Heater

◀ **HORIZONTAL SHAFT PROPELLER-FAN TYPE UNIT HEATERS.** For ceiling or wall mounting. Use with steam or hot water. Copper heating element with patented stay tube prolongs unit life. Many models and sizes. *Bulletin 700.*

▶ **VERTICAL SHAFT PROPELLER-FAN TYPE UNIT HEATERS.** Designed for high ceiling installations. Long life copper heating element for use with either steam or hot water. Units available in range of capacities with high or low velocity discharge. *Bulletin 700.*

Vertical Shaft Heater

◀ **GAS FIRED UNIT HEATER.** Operates on all types of gas. Compact in design—easy to install—readily moved. Available in 7 sizes with heat output ranging from 20,000 to 160,000 Btu's per hour. *Bulletin 715.*

Centrifugal Fan Unit Heaters

▶ **CENTRIFUGAL FAN UNIT HEATERS.** Use has supplied solution to many heating and ventilating problems. Wide variety of models, sizes and speeds assure right unit for every commercial and industrial building need. *Bulletin 750.*

**CONSOLE HEATER.** Compact, quiet, economical and attractively styled. Ideal for offices, showrooms, corridors, stores, etc. May be placed on floor, wall or suspended from ceiling. 18 models and sizes. *Bulletin 727.*

Unit Ventilator

Console Heater

### DRAFT/STOP UNIT VENTILATORS.

A Unit Ventilation System that traps cold drafts before they reach classroom occupants—automatically heats, ventilates and cools. System is quiet and economical—requires little maintenance. *Bulletin 600.*

Herman Nelson Unit Heaters and Unit Ventilators are tested and rated in accordance with the Standard Test Codes adopted by the *Industrial Unit Heater Association* and *ASHVE*.

## HERMAN NELSON

American Air Filter Company, Inc.

Louisville, Ky. • Moline, Ill.

▶ **PROPELLER FANS.** A complete line of belt or direct drive ventilating fans. Twenty-nine sizes with wheel diameters from 10 to 54-in. Unit capacities ranging from 655 to 36,150 cfm. *Bulletin 800.*

Propeller Fan

Unit Blowers

◀ **UNIT BLOWERS.** Direct or belt drive with forwardly curved or backwardly inclined wheels. Wheel diameters from 4½-in. to 30-in. and capacities from 160 to 18,303 cfm. *Bulletin 825.*

**HEATING AND VENTILATING UNIT.** Features sectionalized construction, low outlet velocities, slow fan speeds, wide selection of heating coils. Available with humidifier. Ideal for institutional or commercial use. *Bulletin 775.*

Heating and Ventilating Unit

Centrifugal fans

▶ **CENTRIFUGAL FANS.** Designed for systems requiring a Class I or II centrifugal fan. Slow speed or non-overloading type. Wheel diameters from 12¼ to 73-in., single or double width. Direct or belt drive. Any rotation or discharge. *Bulletin 850.*

### RADIATION PRODUCTS

**BASEBOARD RADIATION.** Recess and flush types for steam or hot water feature aluminum fin on copper tube and are designed to prevent "wall streaking." *Bulletin 792.*

**CONVECTOR RADIATORS.** Range of sizes for steam or hot water. Heating elements made of non-ferrous materials. Cabinets designed for free standing or semi-recessed installation. Also sloping top models. *Bulletin 791.*

**FINNED RADIATION AND COVERS.** Adaptable to any system as a primary or supplementary heating source. Range of sizes with choice of expanded metal, flat top or slant top covers. *Bulletin 790.*

Herman Nelson Propeller and Centrifugal Fans are tested and rated in accordance with the Standard Test Code adopted jointly by the *National Association of Fan Manufacturers* and *ASHVE*.

## TRANE REFRIGERATION

### 1. CENTRAVACS

A self-contained hermetic centrifugal refrigeration unit in 19 sizes. Capacities 45 to over 800 tons.

### 2. RECIPROCATING COMPRESSORS

Two cylinder sizes in 4, 6, and 8 cylinder units. Single or duplex direct drive arrangements with capacities from 10 to 150 tons.

### 3. COLD GENERATORS

Complete refrigeration machine meets all normal requirements of chilled water systems. Models from 10 to 150 tons.

### 4. CONDENSING UNITS

Trane Reciprocating Compressor complete with water cooled condensers. Capacities 10 to 150 tons.

### 5. EVAPORATIVE CONDENSERS

Condenses Freon-12 and Freon-22 refrigerants. Uses minimum amount of water. Sizes 3 to 100 tons.

## TRANE AIR CONDITIONING

### 6-7-8. SELF-CONTAINED AIR CONDITIONERS

Packaged air conditioning units for offices, shops or home air conditioning. Available in 6 sizes—9 models ranging from 3 to 20 tons. Smaller 3, 5, and 7½-ton sizes have de luxe cabinet design to be installed in the conditioned space and blend with any surrounding. Larger 10, 15, and 20-ton sizes constitute the commercial line and are usually installed in a remote location, outside the conditioned area. De luxe units available with water cooled condenser. Commercial units may be had with either water cooled condenser or built in evaporative condenser.

### 9-10. ROOM AIR CONDITIONERS

UniTrane air conditioners heat, ventilate, filter and circulate air in the winter. In summer, they cool, ventilate, filter, control moisture content and circulate air. Two vertical and two horizontal models. Each available for 200, 300, 400 and 600 cfm delivery.

### 11-12-13. CLIMATE CHANGERS

Any or all phases of air conditioning available in one unit. Two models, horizontal and vertical, each in 12 different sizes. Capacities range from 600 cfm to 29,000 cfm for any application, comfort or process.

Multi-Zone Climate Changers provide a number of zones with different air conditions at the same time.

### EDUCATIONAL MATERIAL

"Trane Air Conditioning Manual" (\$6.50), an unbiased 380-page textbook for the engineering profession. New revised edition now available. Many tables and charts included for making computations. In general, text covers heat gains, psychrometry, calculations for the conditioned air supply, refrigeration for air conditioning, water for air conditioning, and ducts and fans.

"Trane Refrigeration Manual," a reference for servicing and installing all types of refrigeration systems. Also available from The Trane Company, La Crosse, Wis. Price \$1.50.

**TRANE****HEATING AND  
VENTILATING****14-15. CONVECTORS**

For all steam and hot water systems. Type C—immediately available in many standard sizes. Other units for specific application problems.

**16. BASEBOARD CONVECTORS**

Non-ferrous fin-and-tube heating element. Attractive steel cabinets, 8¼ in. or 12 in. height. Damper or valve controls, optional.

**17. WALL LINE CONVECTORS**

High capacity radiation designed to run continuously below window expanses. Cabinet depths 4 in. and 6 in., heights—14 in., 16 in., and 26 in.

**18-19-20. WALL-FIN**

Ferrous or non-ferrous finned radiation. Lengths 2 ft to 12 ft in 6 in. increments. Cabinets and expanded metal grilles available.

**21. PROJECTION UNIT HEATERS**

Model "P" taps the reservoir of ceiling heat, solves multitude of heating problems. Louver Cone diffuser, optional.

**22. HORIZONTAL UNIT HEATERS**

Combines Trane broad blade propeller fan and extended surface coil. In 24 sizes, 22,000 to 352,000 Btu. Louver Fin diffuser, optional.

**23. STEAM SPECIALTIES**

Complete line including thermostatic traps, valves, float traps, bucket traps, strainers, vents and temperature control valves.

**24. TORRIDORS**

Blower type unit heaters combining Trane Centrifugal Fans and extended surface coils for heating and ventilating large spaces and for process applications.

**25. ROOF VENTILATORS**

Complete line of supply and exhaust ventilators and ventilating heaters. 355 to 25,000 cfm.

**26. FORCE-FLO HEATERS**

De luxe cabinet-type unit heater with centrifugal fan. Capacities: 17,700 to 105,000 Btu.

**27. UNIT VENTILATORS**

Kinetic Barrier System with lateral extensions the length of the outside wall provides constant protection against window downdrafts. Conventional discharge type units with all air being delivered from the unit itself, also available.

**28. SHELIVING**

Available for Kinetic Barrier and conventional units in open or closed type. Have plain tops, or may be linoleum covered. Three sizes.

**29-30-31. FANS**

Centrifugal fans in non-overloading backwardly inclined or slow speed forward curved types. All standard arrangements in sizes from 12 in. to 108 in. Capacities 668 to 491,000 cfm.

Utility fans, both belt-driven and direct connected, in non-overloading backwardly inclined or slow speed forward curved types. All standard arrangements in sizes 4½ in. to 30 in. Capacities 110 to 15,450 cfm.

Propeller fans with direct or belt drive. Sizes 10 in. through 72 in. Capacities 475 to 58,560 cfm.

**32-33-34. EXTENDED SURFACE COILS**

Heating coils include a complete range of same and opposite end connection steam distributing tube coils, standard coils, heavy duty, high pressure steam coils, and equipment coils. Cooling coils are manufactured for direct expansion or water cooling in thousands of sizes and types. All extended surface coils have exclusive Delta-Flo Fin for greater heat transfer efficiency.

### WING REVOLVING UNIT HEATERS

An outstanding and unique feature of WING Revolving Unit Heaters is the revolving air distributor, which slowly turns, delivering air obliquely downward, in ever changing direction, to the working floor. Warm air spreads across the floor and around obstacles creating a pleasant atmosphere. In warm weather with heat off, WING Revolving Units furnish refreshing zephyrs of cooling air. Write for *Bulletin HR-6A*.

### WING FRESH AIR SUPPLY HEATERS

Ventilating and fume exhaust systems require free admission of air into the building to balance the air exhausted. WING Fresh Air Supply Heaters provide an adequate supply of properly warmed, evenly distributed fresh air without chilling drafts. They cannot freeze, regardless of outdoor temperature, as the steam is on at full pressure all the time. Write for *Bulletin HS-4*.

### OTHER WING HEATERS (Left to Right)

WING Stationary Discharge Unit Heater. WING Door Heater. WING Utility (Horizontal Discharge) Unit Heater. WING Electric (Horizontal Discharge) Unit Heater. WING Gas-Fired Unit Heater (Horizontal). WING Gas-Fired (Vertical Discharge) Unit Heater.

### WING FANS

The Elbow Type WINGFOIL Duct Fan replaces an elbow in a run of duct. The WINGFOIL Straight Line Duct Fan is inserted in a straight run of duct. In both of these types the motor, outside the casing remains cool and clean. The WINGFOIL Vaneaxial Fan has a sealed motor within the casing. All deliver large volumes of air for size of fan, quietly, without vibration. Capacities to 95,000 cfm. Write for *Bulletin F-10A*.

### WING DRAFT INDUCERS

WING Draft Inducers for heating boilers assure positive draft regardless of weather conditions and eliminate the need for high chimneys. New design has interchangeable inlets, automatic belt tension, sealed bearings. Fan assembly may be withdrawn from housing for inspection or servicing. Available in a wide range of capacities. WING Packaged Power Plant Draft Inducers for power

plants up to 120,000 lbs of steam per hour. Send for *Bulletin I-56*.

### WING BLOWERS

WING Motor Driven Forced Draft Blowers for statics up to 10 in.; volumes up to 50,000 cfm. Manual or automatic capacity regulation. Vertical or horizontal mounting. Voltrol vanes permit regulation to 10 per cent of maximum. *Bulletin FD-4*.

WING Turbine Driven Blowers are easily installed on burner fronts or boiler settings, providing precise draft control manually or automatically. Oil-free exhaust steam permits utilization in processes or heating. *Bulletin FD-4*.

WING STEAM TURBINES for driving pumps, fans, compressors, etc. are sturdy, dependable sources of auxiliary power. Capacities to 150 bhp. Temp. to 750F. Speeds to 4000 rpm. *Bulletin T-54*.

# YOUNG Radiator Company

Sales & Engineering Representatives in all Principal Cities

Heating, Cooling, Air Conditioning Products for Home and Industry, Heat Transfer Products for Automotive, Agricultural, Industrial, Gas and Diesel Engine Applications

## CONVECTORS & UNIT HEATERS

Convectors are available from stock in six standard cabinet styles; also Institutional and bathroom models; for steam or hot water systems.

"Vertiflow" Unit Heaters are built in nine sizes; capacities from 52,600 to 552,000 Btu per hr; adjustable louvers, nozzles, diffusers, Anemostats.

Type "SH" Unit Heaters are built in 14 sizes; capacities from 19,000 to 325,000 Btu per hr; for steam and hot water systems.

Cabinet Type Unit Heaters are available in number of arrangements, wall hung, horizontally suspended, etc.; from 26,200 to 115,000 Btu per hr.

"Perimaheat" Baseboard Convector for hot water service; available in 6 and 8 ft lengths; capacity with 190 deg average water 822 Btu per lineal foot; available with either adjustable damper or splitter.

Gas-Fired Unit Heaters are available in seven sizes ranging in capacities from 50,000 to 230,000 Btu/hr output. Have welded corrosion-resistant aluminized steel combustion chamber and heat exchanger; other important design features.

## HEATING & COOLING COILS

Young manufactures a complete line of heating and cooling coils for central heating or cooling systems.

## AIR CONDITIONING UNITS

Young "YAC" Air Conditioning Units provide year around service for cooling, heating, filtering, circulating, humidifying and dehumidifying in any combination. Units are available in nine sizes; capacities from 400 to 22,000 cfm; vertical (right) or horizontal types;

Young "Roomaire" Cabinet Air Conditioner cools, heats, filters, circulates and dehumidifies—for use with chilled water systems. Available in 3 sizes and 4 models.

## ELECTROMODE CORPORATION

45 Crouch St., Rochester 3, N. Y.

Complete line of Electric Heating Systems

For HOME, INDUSTRY, FARM

Division of Commercial Controls Corporation

The advantages of electric heat are well known. However, there is a great difference in the safety of electric heaters. Electromode has a completely sealed-in, cast-aluminum heating element which

provides absolute protection against fire, shock, burn or explosion. This element acts as a superior heat diffuser, resulting in greater heating efficiency and economy.

For Big Rooms

For HOME and OFFICE

Bathroom  
Small Room

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Electromode Wall-type Heaters are made in models and capacities suitable for all size rooms, ranging from 1320 to 4000 watts, with built-in thermostat or manual control. Heat is fan-circulated at floor level. All have automatic thermal safety switch. The big room heaters have silver grey hammertone finish; small room or bathroom heaters are available in gleaming chrome or white enamel. See figs. 1 and 4.

**ELECTROMODE RADIANT HEATING PANEL** combines radiant and convection heating. Modern design with silver grey hammertone finish. With or without built-in thermostat. Capacity 1100 watts. See fig. 2.

**ELECTROMODE BASEBOARD HEATERS** provide low level perimeter heat. Blank sections, endpieces, corners, for making up system to room dimensions. 600, 900, 1200 watts; 120 or 240 volts. See fig. 3.

Fig. 5.

**ELECTROMODE RADIANT CABLE HEAT.** Coils of cable hidden in ceiling radiate clean, healthful heat downward. Each room temperature controlled by separate thermostat. Cables are a measured length of specially constructed and insulated electric wires; waterproof; non-corrosive. Used in plaster or drywall ceilings, or concrete floors. Magic Seal coating prevents streaks on ceiling. See fig. 5.

## For INDUSTRY

Fig. 6—  
Suspension

**UNIT HEATERS** available in Suspension-type and Combination Portable and Suspension models. Capacities from 1500 to 45,000 watts. Ideal for auxiliary warmth in hard-to-heat areas and for complete heating in outlying buildings. Adjustable louvers for directing fan-circulated heat into working zone. Thermostat control available on all models. See fig. 6 and 7.

Fig. 7—  
Portable &  
Suspension

**EXPLOSION-PROOF HEATERS** for areas charged with inflammable vapors. Listed by Underwriters' Laboratories for Class 1-Group D Hazardous Industries. Convection type. Three models range from 2000 to 6000 watts. See Fig. 8.

**ELECTROMODE BLAST COILS** consist of a bank of Electromode cast-aluminum heating elements mounted in a 16 gauge formed steel frame having a 1 1/2 in. wide

Fig. 8

Fig. 9

flange with 5/16 in. holes on approx. 6 in. centers for mounting to air ducts. Complete wiring diagrams for special applications furnished on request. See Fig. 9. All Electromode Heating Systems are approved by Underwriters' Laboratories and are fully guaranteed.

Engineering help gladly given. For more information, see your supplier or write Dept. HVG-16, Electromode Corporation.

## Industrial Engineering and Equipment Co.

711 South Theresa Ave., St. Louis 3, Mo.

ELECTRIC BLAST COIL HEATERS FOR  
PACKAGE AND DUCT AIR CONDITIONERS  
AND SUPPLEMENTARY HEAT

3,487 INSTALLATIONS—150 to 15,000,000 Watts  
More than 100 Installations at Rockefeller Center

INDEECO Electric Blast Coil Heater for  
Package Air conditioners as shipped and  
ready for installation

Leading commercial, industrial and governmental properties are heated by these units. They offer the following advantages:

1. COMPLETE UNIT, ready for installation, eliminating design and layout work
2. SIZED TO FIT
3. THERMAL CUT-OUTS, furnished with each unit
4. WIDE SIZE RANGE

INDEECO UNITS FOR PACKAGE AIR CONDITIONERS, are furnished in 280 sizes to fit 11 manufacturers' package units—write for *Bulletin E97P*.

INDEECO UNITS FOR DUCT-INSTALLATION are furnished in 422 sizes—write for *Bulletin E97U*.

SPECIAL UNITS in both categories furnished at no extra cost. INDEECO Blast Coil Heaters are made to suit your specifications. You are not compelled to change your plans to meet our specifications.

INDEECO Electric Blast Coil Heater for  
duct installation. Listed by Underwriters'  
Laboratories. 200,000-watt capacity. Above  
is part of installation totaling 1,880,000  
watts.

## Wesix Electric Heater Co.

390 First Street

San Francisco 5, California

CHICAGO DALLAS DENVER DETROIT HUNTSVILLE  
LOS ANGELES NEW YORK PORTLAND SEATTLE  
Complete line of Electrical Air and Liquid Heating Equipment for  
Residential, Commercial & Industrial Applications

BASEBOARD PERIMETER PANELS available in standard lengths for simple, inexpensive installation without special tools or metal cutting. Heating lengths: 32 in. and 48 in., 157 watts (536 Btu) per lineal foot. Control Section (thermostat and switch) 6 in. long. Approved by UL.

AUTOMATIC ELECTRIC BRACKET TYPE HEATER for commercial, institutional or industrial applications, these units are available in a large range of sizes and types including explosion-proof models for use in Class I, Group C and D locations. Approved by UL.

AUTOMATIC ELECTRIC WALL FURNACE sizes range from one to eight kilowatts for use in domestic and commercial installations. Available in radiant-convection (model illustrated), convector or blower type (5000 watt maximum). Approved by UL.

DUCT HEATERS utilizing either Wesix "dust free" or conventional transverse fin elements, these units may be ordered from a wide variety of self contained, standard units, or built to order. Units available complete with sensitive integral overtemperature control.

LOAD REGULATORS control electric heating capacity automatically by switching voltage supply from 240 volts to 120 volts by means of outdoor thermostat control. Controls heating loads up to 24 kw. Approved by UL.

INDUSTRIAL UNIT HEATERS—BLOWER TYPE for horizontal or vertical mounting either as suspended unit heaters or duct system use in standard sizes to 60 kw. Larger sizes or models for special applications on order. Approved by UL.

QUIET AUTOMATIC SWITCH, a motor operated contactor for resistance loads to 24 kw, 1 $\phi$  or 40 kw 3 $\phi$ , 240 volts and 33 kw 1 $\phi$  or 55 kw 3 $\phi$ , 480 volts. Actuated by SPDT switch or thermostat. Available with sequence action for control from single switch of two or more contactors. Approved by UL.

COMMERCIAL UNIT HEATERS—AXIAL FLOW sizes from 3 to 40 kw for ceiling or pedestal mount. Feature Wesix longitudinal fin, "dust free" inclosed heating elements. Approved by UL.

HEAVY DUTY WALL THERMOSTAT AND SWITCH for control of electric heating apparatus directly up to 30 amp, this unit includes a lockout switch double-pole in the "off" position. Thermostat action is bi-metallic, sensitive to  $\pm 2^{\circ}\text{F}$ . Fits standard wall box mounted horizontally. Approved by UL.

## Edwin L. Wiegand Company

7672 Thomas Boulevard Pittsburgh 8, Pa.

Representatives in all Principal Cities

**PRODUCTS:** Over 15,000 types, sizes and ratings of Chromalox electric heaters for Industry and Home. All heating elements are metal or alloy sheathed in metal for strength and corrosion resistance, fully insulated for safety.

### CHROMALOX RADIANT WALL PANEL

Heavy gauge, all-metal construction including breakproof, moistureproof, shockproof, radiant heating plate. Quickly supplies gentle radiant heat controlled by optional on-off switch or built-in thermostat. For flush or recessed mounting in homes, motels, playrooms, doctors' offices, cottages, first aid rooms. Easy installation. Available in 1000 watts for 120 or 240 volts a-c, and 1500 watts for 240 volts a-c.

### CHROMALOX HI-FLOW PORTABLE

Fully-enclosed metal sheathed elements quickly heat the high volume of air forced through the unit by the smooth running fan and motor. Heavy-gauge case in metallic blue finish. Controlled by manual on-off switch with protective device and reset button. UL listed cord 5½ ft long with polarized plug. For bedrooms, dens, kitchens, drugstores, etc. In wattages from 2000 to 4000 for 115-120 to 230-240 volts a-c.

### CHROMALOX BASEBOARD RADIATORS

Clean, balanced radiant and convected heat supplied by rugged baseboard measuring only 8¾ in. high and 2¾ in. deep. Lengths in standards of 1 ft with 100 watts, 2 ft with 300 watts, 5 ft with 800 watts, 8 ft with 1250 watts. Extremely easy to install. Heating element is all-metal fully enclosed, flat strip type which is breakproof, moisture-proof and shockproof. Designed for maintenance-free heating in homes, offices and public buildings.

### CHROMALOX FORCED-AIR WALL HEATERS

Smooth molded contours of heavy-gauge steel form the front grill of this forced-air recessed wall heater. Recessed section contains a quiet, fully-enclosed motor and smooth-running dustproof fan. Metal sheathed fin-tube element and fan are controlled by manual on-off switch. Variable temperature control knob for setting automatic built-in thermostat. Available in wattages from 1500 to 4000 for 240 a-c supply for gamerooms, living rooms, motels, reception rooms, cottages, etc.

## Edwin L. Wiegand Company

7672 Thomas Boulevard Pittsburgh 8, Pa.

Representatives in all Principal Cities

### CHROMALOX AIR DUCT HEATERS

For use in square or rectangular forced air ducts. Construction of heater allows free-flow of existing forced air circulation. Finned radiator design presents maximum surface contact for fast heating and minimum air friction. For room heating and process work requiring heated air blasts. Ratings from 6 kw to 100 kw.

### CHROMALOX FINSTRIP HEATERS

Finstrip heaters are used in air ducts having forced circulation, in ovens, dryers and for process work requiring heated air blasts. Temperatures to 750 F can be maintained accurately with thermostatic controls.

### CHROMALOX CIRCULATION HEATERS

Circulation Heaters heat fluids in convection or forced heating systems; for washrooms, laundries, dishwashers, central heating systems, superheating and drying steam, preheating fuel oils and heat transfer fluids, heating nitrogen and other gases. Temperatures to 750 F.

### CHROMALOX PORTABLE UNIT HEATERS

High volume comfort heater for industrial offices, shipping depots, stockrooms and isolated small buildings. Sturdy construction of motor fan gives long, dependable service and a reliable supply of heated air. Available with manual or automatic controls in 1.5 to 4.0 kw capacities.

### CHROMALOX FAR-INFRARED UNITS

Far-Infrared Radiant Heat for mass heating, drying, baking, dehydrating and similar uses. Compact pre-engineered panels, heaters and lamps can be made into banks, tunnels, and ovens. All-metal construction gives protection against breakage, splash of liquids plus high safety against shock hazards.

### CHROMALOX HIGH VOLUME HEATERS

For heating of larger areas or as central heating system for distribution of heat through ducts to desired locations. Ratings from 15 to 40 kw.

## The American Brass Company Waterbury 20, Conn.

District Offices in Principal Cities  
IN CANADA: ANACONDA AMERICAN BRASS LIMITED, NEW TORONTO, ONTARIO

**PRODUCTS**—Anaconda Phosphorized Copper Tubes and Fittings; Anaconda "85" Red Brass Pipe; Everdur Metal for storage heaters, storage tanks, ducts and air-conditioning equipment

### ANACONDA COPPER TUBES AND FITTINGS

For Heating, Plumbing and Air Conditioning

Anaconda Types K and L Phosphorized Copper Tubes, assembled with solder joint Fittings, offer an unusual combination of advantages for hot water and low pressure steam heating systems, including radiant panels. These advantages may be summarized briefly as follows:

**Low Friction Loss**—Because the inside surfaces of copper tubes are inherently smoother than those of pipe and tubes made of ferrous materials and also because they do not become roughened by the formation of rust, these tubes offer a lower resistance to flow. In addition, the long-radius turns of elbows and the smooth inside surface of wrought copper fittings further reduce friction losses.

These factors naturally increase the efficiency of the system, particularly when it includes a forced-pressure circulator.

**Ease of Installation**—In many places the flexibility of copper tubes simplifies connections that ordinarily would be awkward and expensive to make with rigid pipe and threaded fittings. Solder joint fittings are compact. They can be installed in restricted space where the use of a wrench would be impossible.

They meet the requirements for these types of tubes in Federal Specification WW-T-799a and ASTM Specification B88. Type K, the heavier, is recommended for heating lines and general piping.

Anaconda Copper Tubes, in standard sizes are furnished soft in 60- and 100-ft coils; also hard and soft in 20-ft straight lengths.

### CUSTOM-MADE CAPILLARY TUBES

Anaconda Custom-Made Capillary Tubes, for restriction purposes, are made to specific mutually-agreed-upon airflow limits. These limits alone are the base for production.

Initial shipments contain Master Reference Sample Tubes with labels giving maximum and minimum flow capacities agreed upon. Duplicate Master Samples are kept in the mill files. Every subsequent shipment of tubes will be made to the limits of the Master Samples.

### REFRIGERATION TUBING

Anaconda Dehydrated Copper Refrigeration Tubes are manufactured in accordance with the ASTM Specification for this product in all standard sizes up to and including 3/4 in. O.D., in 50-foot coils. The tubes are sealed immediately after annealing and dehydrating.

### VIBRATION ELIMINATORS

American Vibration Eliminators—Compressor vibration and noise are muffled in a line equipped with an American Vibration Eliminator. The corrugated bronze tubing is *seamless*. Copper ferrules and tube ends are *brake welded*. Each unit is pressure-tested under water, is spotlessly clean and dry, with ends firmly sealed.

## The American Brass Company

### ANACONDA "85" RED BRASS PIPE

Anaconda "85" Red Brass Pipe, in standard pipe sizes, is considered the highest quality corrosion-resistant pipe commercially obtainable at a moderate price and is recommended for steam return lines.

Anaconda "85" Red Brass Pipe contains 85 per cent copper and conforms to Government specifications for Grade "A" water pipe. The mark "Anaconda 85" is stamped in the metal at one-foot intervals throughout each length.

### EVERDUR\*

Everdur Metal is the original copper-silicon alloy group. It is manufactured by The American Brass Company in five standard compositions and in practically all commercial forms.

These high-strength engineering alloys are resistant to a wide range of corroding agents. Because of a versatile combination of useful properties, Everdur has become standard as a material for equipment in many fields of engineering and industry.

In addition to their non-rusting properties and high strength, Everdur alloys possess many qualities not usually found in metals of this character. They are unusually resistant to general atmospheric conditions and other normally corrosive factors. Everdur alloys have excellent machining and working characteristics and can be fabricated into a variety of forms and shapes. Everdur

alloys are available for oxyacetylene, carbon-arc and inert-gas arc welding.

**Everdur Tanks**—Everdur copper-silicon alloy is an ideal material for durable, non-rusting water tanks of every description—from domestic range boilers to large storage heaters for hotels, laundries, hospitals, textile plants, schools or breweries.

Everdur is made in all commercial shapes, including annealed tank plates which have physical properties as given in ASTM Specification B96.

Minimum specification requirements for hot-rolled-and-annealed tank plates are: Tensile Strength, 50,000 psi.; Yield Strength (at 0.5 per cent elongation under load) 18,000 psi.; Elongation, 40 per cent in 2 inches.

Welds made with annealed Everdur tank plates meet the requirements for construction in the A.S.M.E. Boiler and Pressure Vessel Code.

For additional data and names of fabricators address our nearest District Sales Office.

### EVERDUR FOR AIR-CONDITIONING EQUIPMENT

Because of its strength and welding properties, Everdur may be substituted for steel and fabricated by substantially the same methods, with much the same equipment as steel.

Everdur metal has been used with marked success for fans, blowers, ducts, humidifiers, cast and wrought parts of other equipment items subject to corrosive influences.

### EVERDUR LITERATURE

Descriptive literature containing much pertinent tabular data will be sent on request.

\*"Everdur" is a trademark of The American Brass Company registered at the U. S. Patent Office.

Aeroquip Corporation, Jackson, Michigan

# AEROQUIP SELF-SEALING COUPLING FOR "FREON 12" AND "FREON 22"

This new coupling for "Freon 12" and "Freon 22" applications is finding wide use for all refrigeration and air-conditioning applications. Convenient connection and disconnection without loss of refrigerant or inclusion of air and moisture. Simplifies production and charging

and testing of equipment and permits shipping of factory charged units for easy field installation. Rapid assembly in equipment by means of sweat-type adapters and mounting flanges. Sizes through 1½ in. O.D. tube size.

# AEROQUIP 1540 HOSE FOR "FREON 12" APPLICATIONS

Aeroquip 1540 hose and reusable fittings are designed for refrigerating and air conditioning systems using "Freon 12." Aeroquip flexible hose lines can be installed easily, even in confined areas, withstand compressor vibration and reduce noise. Ease of assembly makes Aeroquip hose and fittings ideal for engineering mockups and production models. Available in sizes from ¼ in. to 3 in. Operating pressures up to 350 psi; temperature range -40 F to +170 F.

Revere Copper Water Tube does not rust. It is smooth inside and out, easy to install and bends and flares readily. There is no thread cutting; it takes solder or compression type fittings.

# Specifications:

Federal: WW-T-799 ASTM: B88

# REVERE DRYSEAL COPPER TUBE

For:

Air conditioning and refrigeration systems  
General service work  
Revere Dryseal Copper Tube is dehydrated and sealed at the factory before packaging. It is soft and flexible and when flared for compression fittings, it does not split on the ends. Its ability to take smooth hand bends virtually eliminates the need for fittings.

50 ft. coils in sizes from ¼ in. to ¾ in. O.D., with wall thicknesses from .030 in. to .035 in., are packed in individual cartons.

# REVERE RED BRASS & COPPER PIPE

For use when threaded pipe is required. Both are manufactured in standard pipe sizes—hence can be used with standard threaded or silver brazed fittings. Because of their extraordinary resistance to corrosion, they function with unimpaired efficiency even after many years of normal service.

# Specifications:

Revere Red Brass Pipe meets the following specifications:

Federal Standard: WW-P-351, Grade "A"

Navy Department: 44P12, Grade "A" ASTM: B43 (Red Brass)

Revere Copper Pipe meets the following specifications:

Federal Standard: WW-P-377

Navy Department: 44P2

ASTM: B42

## Wolverine Tube

1463 Central Avenue • Detroit 9, Michigan  
Manufacturers of Quality-Controlled Tubing and  
Extruded Aluminum Shapes

Plants in Detroit, Michigan and Decatur, Alabama  
Sales Offices in all Principal Cities.

Wolverine Trufin is available in Canada through the Unifin Tube Co.,  
London, Ontario.

### WOLVERINE COPPER WATER TUBE

... a roll of tube that rolls

Wolverine's round cartons for rolls of copper water tube represent a new packaging concept. The carton now becomes even more functional than its primary job of protecting the contents. For example, it can be rolled like a hoop to storage or job site. There's an arm hole in the middle for convenient carrying. And also important to users, it can be used as a reel with the carton protecting the tube right up to its last inch. The package is extra sturdy, designed with a

heavy corrugated core for extra protection. It's easy to open, easy to identify, and color coded.

### WOLVERINE COPPER WATER TUBE

Wolverine copper water tube is available in all three types:

Type K—in straight lengths and coils—is recommended for general plumbing involving severe service conditions and for heating, gas, steam and oil lines and for underground service. It is available in nominal sizes from 1/4 in. through 6 in.  
Type L—in straight lengths and coils—is recommended for general plumbing involving less severe service conditions and for interior applications for heating, gas, steam and oil lines. Available in nominal sizes from 1/4 in. through 6 in.

Type M—in straight lengths only—suitable for use with soldered fittings only; for interior applications, for heating and for waste, vent, soil and other non-pressure applications. Available in nominal sizes from 3/8 in. through 6 in.

Wolverine also manufactures S.P.S. and extra heavy pipe in copper and red brass. Pipe is available in standard lengths of 12 and 20 feet. Sizes range from 1/2 in. through 3 1/2 in.

### WOLVERINE COPPER REFRIGERATION TUBE

Wolverine copper refrigeration tube is well-known in the industry. It, too, is packaged in round cartons. It has mirror-bright inside diameter finish, is dehydrated, is consistent in quality and soft in temper. **CONVENIENT NEW SEAL:** Wolverine has a new refrigeration tube seal that keeps tubing clean and dry. Because the O.D. of the seal is no larger than that of the tube proper, it makes it easier to insert through partitions.

## Wolverine Tube

1463 Central Avenue • Detroit 9, Michigan  
Manufacturers of Quality-Controlled Tubing and  
Extruded Aluminum Shapes

Plants in Detroit, Michigan and Decatur, Alabama  
Sales Offices in Principle Cities

Wolverine Trufin is available in Canada through the Unifin Tube Co.,  
London, Ontario.

### WOLVERINE CAPILATOR\*

Wolverine Capilator\* is designed for precision control in the metering of gases, liquids or air. Capilator is plug drawn—has a smooth, mirror-bright bore held to exceptionally close limits. It can be made of copper or aluminum and is available in sizes from .026 in. to .090 in. inside diameters. Capilator is washed, deburred, flow-tested and its ends are paper wrapped.

### WOLVERINE TRUFIN\*

Wolverine Trufin is an extended surface tube with fins extruded from the tube wall. It increases heat transfer surface—transfers more Btu's per foot of tube. Fins resist vibration, temperature changes and fluctuating pressures. Trufin is available in a wide range of sizes, alloys and fin spacings in copper, copper base alloys, aluminum, electric-welded steel and bi-metal.

### FABRICATED TUBULAR PARTS

Wolverine's fabrication facilities include the Wolverine Spun End Process†. One-piece tubular shaped parts with closed or partially closed ends can be produced in one fast operation. Other fabrication techniques include finning, coiling, bending, expanding, flaring, brazing and soldering and piercing, to name but a few.

### ALUMINUM TUBE AND SHAPES

Wolverine produces strong, lightweight aluminum tube—plain or finned—drawn or extruded—in the following alloys: 1100 (2S); 3003 (3S); and 6063 (63S). Wolverine aluminum extruded shapes, in the same alloys, are rigidly quality controlled, can help you save machining and assembly time and reduce material requirements.

### FIELD ENGINEERING SERVICE

For the convenience of our customers, Wolverine maintains a Field Engineering Service. Highly-trained tubing technicians are ready at all times to help you solve such problems as design, corrosion and fabrication.

### AGITAIR AIR FILTERS

Type FM  
HIGH  
VELOCITY  
•  
ALL  
METAL  
•  
PERMANENT  
•  
CLEANABLE

#### HOW IT WORKS

High turbulence of many finely divided air streams is the keynote of Type FM air filters. The media divides the air into countless fine streams and throws those streams into violent cyclonic turbulence against countless viscous-coated "wiping surfaces" which virtually scrub the air clean by catching and holding the dirt.

#### HIGH VELOCITY

The Agitair FM Filter is designed to perform at highest efficiency at an approach velocity of 432 fpm—or 1200 cfm through a 20 x 20 in. filter panel.

#### 1/3 LESS SPACE REQUIRED

The ability of the FM to filter, with greater efficiency, 50 per cent more air at the high velocity of 432 fpm reduces the number of filter panels required. Now TWO FM's will do the work of THREE ordinary filters . . . 1/3 less space required . . . fewer units to be installed . . . fewer units to be serviced . . . overall installation and maintenance costs reduced to a minimum.

#### HIGH EFFICIENCY

At the recommended velocities, the Agitair FM has a high dust arresting efficiency, which increases as the dust load is applied.

### LOWER RESISTANCE

The sustained low resistance of the Agitair FM means sustained peak volume of air for longer periods of time . . . no loss in air volume . . . no danger of unloading . . . clean filtered air at all times.

### HIGHER DUST HOLDING CAPACITY

Employing a new formula for air filtration the new Agitair FM holds more dirt, from two to six times as much as ordinary 2 in. permanent, cleanable filters. No early clogging of air passages . . . less frequent servicing . . . lower maintenance cost.

### TWO TYPES OF HOLDING FRAMES

**Individual type:** Designed and constructed for easy handling in single unit installations, and to facilitate "on the job" assembly, into a multiple unit bank. **Pre-Fabricated Type.** Made of heavy gauge steel and delivered completely knocked down. They can be quickly and easily bolted together to form a sturdy panel bank.

### GREASE FILTERS

**Strong Expanded Metal Media** recommended for use in kitchens where grease-laden air is a fire hazard and a maintenance problem. Prevent grease from entering exhaust ducts, eliminate frequent duct cleaning, protect fans, greatly reduce fire hazard, and help maintain good ventilation.

### AGITAIR WIND-ACTUATED EXHAUSTERS

Type CNO

Provide proper ventilation regardless of wind direction, and with positive elimination of down-draft. Functions at peak efficiency at average low wind velocities. Will not restrict the exhaust of air or gases when there is no movement of out-door air across the head.

## Air Filter Corporation

108G North Water St. Canadian Representative Milwaukee 2, Wis.  
DOUGLAS ENGINEERING CO., LTD. MONTREAL

(formerly Aircor)

AIR FILTERS

Permanent-Cleanable

GREASE FILTERS

### AIRSAN AIR FILTERS

Industrial Domestic Commercial

Airsan's expanded metal face plate acts as a lint arrestor to provide easier cleaning and servicing. It distributes air evenly over entire filtering area providing high filtering efficiency and dust-holding capacity with low resistance. Media is viscous type, permanent, cleanable, and is constructed of multiple layers of galvanized wire mesh to give maximum air resistance. All Airsan Filters have full bronze welded corners, galvanized steel frames and drain slots for quicker, easier cleaning.

Airsan Air Filters are available in standard 1 in. and 2 in. thickness—*Bulletin L301*. Also HEAVY DUTY filters for industrial and special applications in 2 in. to 4 in. thickness—*Bulletin L401*.

### AIRSAN GREASE FILTER

Permanent cleanable type Airsan Grease Filters specially designed for range canopies, galleys, kitchens.

Removes grease at source, reduces fire hazard in exhaust ducts and prolongs life of fans, motors and other mechanical equipment. Assemblies for mounting on ceiling or wall, single or multiple units—includes holding frames, supporting angles and end seals. *Bulletin L503*.

Initial Resistance: .07 in. w.g. at 216 fpm  
Efficiency Rating: 98.5% Stand.  
Thickness: 2 in.

AIRSAN VIRO-CRIMP FILTER

Pat. No. 2,653,876

The specially designed high velocity Airsan Viro-Crimp filter core is viscous type and constructed of horizontal layers of galvanized wire mesh so arranged as to assure a large filter-area with no appreciable pressure drop.

Its outstanding Viro-Crimp is designed to operate at face velocities of 300-500 fpm at minimum resistance. Viro-Crimp edges are hemmed, an important safety feature that provides a smooth surface, extra rigidity and filtering area.

Airsan Viro-Crimp filters are easily cleanable. Drain slots are provided, hasten drying and aid in cleaning. Airsan Viro-Crimp Air Filters are of all metal construction throughout, the formed galvanized steel frames having full bronze welded corners and joints. *Bulletin W801*.

### ENGINEERING DATA

| Initial Resistance                                         | Rated Efficiency |
|------------------------------------------------------------|------------------|
| Type F <sub>1</sub> (1 in. thick) .060 in. w.g. at 288 fpm | 98.5%            |
| Type F <sub>2</sub> (2 in. thick) .065 in. w.g. at 288 fpm | 98.5%            |
| Type D <sub>1</sub> (2 in. thick) .09 in. w.g. at 288 fpm  | 98.5%            |
| Type D <sub>2</sub> (4 in. thick) .10 in. w.g. at 288 fpm  | 98.5%            |
| Type W (2 in. thick) .07 in. w.g. at 300 fpm               | 95.1%            |
| Type W (2 in. thick) .012 in. w.g. at 500 fpm              | 97.9%            |

### AIRSAN FILTER RETAINER

Meticulous design includes such features as positive snap locks, oil resistant rubber seals to assure no by-pass of air. Particularly flexible to any type of installation of flat or "V" banks. Easily built up to any height or width by progressive addition of Airsan Filter Retainers. Available in 2 or 4 in. sizes. *Bulletin L608*.

Write AIR FILTER Corp. for Complete Bulletins

## AIR-MAZE CORPORATION

25000 Miles Rd. Cleveland 28, Ohio

THE FILTER ENGINEERS

Representatives in all principal cities

Since 1925, Air-Maze engineered air filtration has been successfully applied to every phase of the heating and ventilating industry. A complete line of filters are available for fresh air and re-circulated air intakes, kitchen range canopies, railroad, marine and aircraft applications. Send for catalog sheets on specific products. General catalog also available on request.

AIR FILTER PANELS

Available in metal washable, viscous impingement types, and dry disposable types. Dry filters also available with washable strainer-type filter element.

ELECTROMAZE ELECTRONIC AIR FILTER

Super-cleans air. Has semi or completely automatic vertical spray washing system. Removes particles as small as 0.1

micron diameter, has rated efficiency over 90 per cent, as tested by the *National Bureau of Standards* Discoloration Method. Collects smoke, fumes, pollens, and soot.

AUTOMAZE AUTOMATIC AIR FILTER

Where continuous operation without servicing is required, the Automaze "pulse action" automatic self-cleaning filter should be used. It combines a double filter panel curtain with a positive effective panel cleaning action to provide the best in viscous impingement air filtration with a minimum of maintenance. New self contained drive mechanism and unitized control system simplifies installation. Standard Automaze filter media is satisfactory for most installations, but other media types are available for special applications.

ACCESSORIES

Cleaning tanks, holding frames, complete assemblies for range canopies, viscous adhesive coatings, spray guns, etc. are available for complete installation and service requirements.

## American Air Filter Company, Inc.

673 Central Avenue, Louisville 8, Ky.

AMERICAN AIR FILTER OF CANADA, LTD., MONTREAL, P. Q.

**THE COMPANY:** The American Air Filter Company, Inc., is recognized internationally as an authority on air filtration and dust control. In 30 years, its leadership and scientific "know how" have been responsible for installations of AAF equipment in every industrialized part of the world. Because its continuous research, high engineering standards and exclusive specialization have been consistently maintained, AAF equipment is used by leading companies in nearly every industry and is specified by leading architects and engineers for use in commercial and industrial air conditioning.

The American Air Filter Company, Inc., manufactures a complete line of air filtering and dust control equipment. A few representative types are shown here. AAF's years of experience and the scope of its knowledge dealing with the elimination of air-borne particles in every form insures maximum efficiency in application, design, manufacture and installation... with a minimum of field engineering. Write AAF on all problems of air filtration and dust control, or its Herman Nelson Division (see pages 1296-1297) on heating or ventilating problems.

### AAF AIR CLEANING PRODUCTS

**Electro-Matic Self-Cleaning Electronic Precipitator**—The Electro-Matic Precipitator is an automatic electronic precipitator combining advanced principles of electronic air cleaning with an exclusive self-cleaning principle. It eliminates the necessity of shutting down the filter for manual cleaning, minimizes the need for personal attention and permits continuous high-efficiency operation. It also allows the Electro-Matic filter to be built in standardized self-contained sections, easy to install and with all exposed parts of the filter casing electrically grounded for the protection of operating personnel. Send for *Bulletin No. 250*.

**ROLL-O-MATIC Renewable Media Filter**—An automatic air filter featuring a low cost, renewable media filtering curtain of bonded glass fibers supplied in convenient roll form. The media, mounted at top of filter, moves down the face of the **ROLL-O-MATIC** and is re-rolled on a driven spool at bottom. Introduction of clean material to maintain desired operating resistance is controlled by an automatic time switch. **ROLL-O-MATIC's** maintenance-free operation provides continuous, high efficiency cleaning at less than half the operating cost of a disposable type filter of equal capacity. Send for *Bulletin 248*.

Electro-Cell Electronic Filter

Electro-PL Electro-matic Filter

Multi-Duty Automatic Filter

**Electro-Cell Electronic Filter**—A plate type electronic precipitator offering simplified design, improved performance and maintenance advantages. Built in vertical sections 2-ft and 3-ft wide. Hinged ionizers extend the full height of the sections for easy access. Collector assemblies may be removed for individual cleaning—washed in place manually—or, with the addition of Type "H" Washer, cleaned automatically by traveling water sprays. Write for *Bulletin No. 252*.

**Electro-PL**: An exclusive dry-type electronic air filter with charged Airmat collector element which combines air filtration and electronic precipitation in a single unit. Gives intermediate efficiency at lower cost, when the need for super-clean air is not indicated. However, it has twice the efficiency of uncharged dry-type filters. Available in Straight Bank or "V" arrangement to meet virtually any space or capacity requirement. Send for *Engineering Bulletin No. 257*.

**Multi-Duty Automatic Filter** provides outstanding features of performance and design and will accommodate either armored screen panels or die stamped louvre panels available in three types. Offers advantage of uniformly constant air supply, fixed operating resistance and automatic operation. Ideal for ventilation and air conditioning service. Available in any size or capacity. Send for *Bulletin No. 241-A*.

AMER-glas Disposable Filter

American Type HV-2

Airmat Type PL-24

**AMER-glas Replaceable Unit Filters.** A new viscous impingement type for eliminating atmospheric dust from forced air heating systems. The highly efficient filtering media consists of continuous, curled and interlaced, extremely fine glass filaments, bonded with thermoplastic to form a thick resilient pad. The pad is sprayed with a special Viscosine and odorless and the Viscosine remains in a fluid-jell state for the life of the filter. Available in 15 sizes. Write for *Bulletin No. 211-A*.

**Airmat Type PL-24**—Airmat filters use standard Airmat medium, renewable after collecting dust load. Used both for comfort and industrial air conditioning. Available with unit frames to be set up to meet any capacity requirement or space condition. Send for *Bulletin No. 230*.

**Type HV-2 Filter**: A high capacity, low-resistance unit designed for velocities up to 500 fpm. Exclusive pyramid pocket media design eliminates through-air passages and gives uniformly high efficiency over wide range of air velocities. HV-2 has large dust capacity, long life, and decided advantages where space is limited. Available in three designs. Write for *Engineering Bulletin No. 203*.

## AAF ROTO-CLONE DYNAMIC DUST PRECIPITATORS

**THE ROTO-CLONE** is an exclusive, patented development of AAF combining the functions of exhausting, separating and storing dust in one simple, compact, self-contained unit. Most types of dust collectors or separators are so large that they are usually installed outdoors, which requires long pipe runs, increased power consumption, and higher installation costs. The **ROTO-CLONE**, however, eliminates expensive ductwork

and reduces both installation and operating costs to a minimum. Available in a wide variety of types and sizes for either individual unit or central system installations and with wet or dry type collectors, the **ROTO-CLONE** has a proven record of economy and efficiency covering thousands of production line and individual applications. Write for profusely illustrated 35-page application and *Engineering Bulletin No. 274-A*.

**Type D ROTO-CLONE**—A dynamic precipitator designed for dry collection of granular industrial process dust. Combines functions of exhauster, dust separator and storage facilities in one compact unit. High collection efficiency remains constant over entire pressure volume range. Adapted for individual unit or central system use. Capacities—from 100 to 15,000 cfm. Write for *Bulletin No. 274*.

Type W ROTO-CLONE

AMERjet

**Type W ROTO-CLONE** offers high dust separation efficiency where extreme fines and heavy dust loads are involved. Combines dynamic precipitation with integral water sprays. Delivers a constant air volume and collects dust as a sludge. Compact design makes for easy, low-cost installation. Capacities from 1,000 to 50,000 cfm. Write for *Bulletin No. 274*.

**Type N ROTO-CLONE** is a hydro-static collector, with induced water scrubber. Requires minimum space—easy to install. No moving parts, spray nozzles or pumps. Completely self-contained with dust discharged as a sludge. Capacities—from 1,000 to 50,000 cfm. Write for *Bulletin No. 277*.

**AMERjet**—A reverse jet type fabric arrester offering high collection efficiency, constant pressure drop (constant air volume), compact design and continuous operation. Other features are (1) tension control to compensate for variation in fabric dimensions, (2) rugged mechanism for dislodging collected material with high pressure air jets and (3) venturi-shaped inlet for dust-laden air which extends life of cloth. Available in range of capacities. *Bulletin No. 279*.

**AMERclone**—A dry centrifugal dust collector designed to handle large exhaust volumes containing dust in high concentrations. Unit requires small space due to compact design and high cleaning capacity of the AMERclone tubes. Abrasion resistant construction featured throughout. Collection efficiency remains practically constant over wide range of exhaust volumes. Available in wide range of capacities. Write for *Bulletin No. 291*.

Type D ROTO-CLONE

Type N ROTO-CLONE

AMERclone

Odor Removal  
Solvent Recovery  
Reactivation Service

#### PUR AIR RECOVERY

By purifying and recirculating air which is already heated or cooled, as much as 40 per cent can be saved on operation costs of heating or air conditioning equipment. A Pur Air RECOVERY system can reduce the volume of outside air necessary for ventilation by 90 per cent. "First cost" of new systems can also be reduced 20 to 45 per cent by incorporating activated carbon for Air Recovery.

#### ODOR REMOVAL

Pur Air adsorbers eliminate odors from fresh air intakes, from exhausts, or from enclosed spaces. Pur Air Activated Carbon adsorbs or physically removes odors, staleness or stuffy air, revitalizing it for re-use at low cost.

#### AIR PURIFICATION

Air Purification is sometimes necessary without possibility of recovery, when industrial wastes, processing or combustion odors, vaporous impurities, atmospheric contaminants or other nuisance situations must be handled. Pur Air Activated Carbon does a thorough job of air purifying.

#### SOLVENT RECOVERY

Our Solvent Recovery Division designs, engineers, fabricates and erects complete systems for industries requiring recovery of volatile solvents which are normally lost in "thin air." Such systems readily amortize installation costs in savings of solvent.

#### ACTIVATED CARBON and REACTIVATION SERVICE

We manufacture high-grade Activated Carbon for all heating and ventilating, as well as industrial uses. We also reactivate any carbon of suitable type or hardness to peak adsorptive capacity.

#### PUR AIR ACTIVATED, COCONUT-SHELL CARBON ADSORBERS

Barnebey-Cheney Company manufactures both the Activated Carbon and the equipment to use it. This combined, integrated function permits the Pur Air Division to offer the greater protection of better quality carbon and adsorbers designed to utilize this basic ingredient to the fullest extent. Pur Air adsorbers are compact, easy to handle, and designed specifically for the special jobs they're meant to do.

#### DACOR

DACOR stands for Disposable Activated Carbon Odor Remover. It utilizes high-grade activated carbon in a lightweight framework of porous fiber tubes. DACOR clips easily to either permanent or throw-away dust filters in forced air furnaces or air conditioning units. It is also available with built-in dust filter. DACOR is designed to adsorb all odors after several recirculations, will last from three months to one year—depending on conditions—and can easily be replaced. DACOR "soaks up" odors, allows pure, fresh air to recirculate. Stocked in standard dust filter sizes; other sizes are manufactured to order.

1322

Panel Adsorber

#### PUR AIR PANEL ADSORBER

The Pur Air activated, coconut-shell charcoal Panel Adsorber permits installation of the most carbon in the smallest possible space. For precision results, install one Panel Adsorber per 100 cfm. Air resistance only 0.30 (w.g.). Available in assembly frame components or self-contained units.

Filter Fold, Model M available with built-in dust filter on request

#### PUR AIR FILTER FOLD "FF"

Another Pur Air "package filter" that does a big job for its size. In a small space—24 in. x 24 in. x 8 3/4 in.—it recovers (deodorizes) 1000 cfm of "used" air. Can be used in multiples in duct work. Removes stuffiness, body odors, smoke irritants, etc., in homes, public buildings, restaurants or any type of enclosed spaces. Model M handles 1000 cfm, contains 45 lb carbon, Model D, 500 cfm, with 22 1/2 lb. carbon. Stat. 125 in. mg.

#### M-15 CANISTER

For replacement on existing systems, or new installations where canister-type equipment is indicated.

Canister

#### BREEZE UNIT

Modern design portable unit for home or office. Uses Dacors to adsorb common household odors, reduce amount of outside air needed for ventilation. Three sizes available.

Breeze Unit

#### AIR FRESH'NER

Purifies air, removes odors from small laboratories, offices, hospital rooms, darkrooms, toilets, etc. Capacity is 65 cfm. Serves up to 1500 cubic feet.

Air Fresh'ner Unit

#### PORTABLE UNIT

Suitable for larger areas—offices, recreation rooms, hospital rooms, libraries, vaults, etc. 500 and 1000 cfm models available.

Portable Unit

#### FIXED MOUNT UNIT

A complete line of self-contained units available for warehouses, cold storage areas, industrial space, etc. Made in 12 sizes, from 220 cfm to 2640 cfm. Is particularly adapted to apple storage use, to prolong life of stored fruit.

Fixed Mount Unit

#### STANDARD EQUIPMENT

Efficient air recovery and odor removal requires selection of proper Pur Air adsorbers for each application and problem involved. Standard units available to purify air and remove odors in practically any occupied space.

#### CUSTOM DESIGN

Custom design and fabricating service available for special requirements of abnormal odor problems, industrial solvent recovery, etc. Inquiries invited on any phase of air recovery, odor removal and air purification. Key personnel have security clearance for handling classified military documents.

## Cambridge Filter Corporation

736 East Erie Boulevard—Syracuse 3, N. Y.

Manufacturers of High-Efficiency Air Filters  
Offices in all Principal Cities

### CAMBRIDGE ABSOLUTE FILTERS

A Series

B Series

This type of filter has been used for many years by the Atomic Energy Commission for the removal of radioactive particles and by many leading companies in the industrial field which have critical air cleaning problems. Removes essentially all smoke, dust, bacteria and mold spores. Every filter is individually tested with 0.3 micron smoke particles and has a guaranteed efficiency of 99.95 per cent. Initial  $\Delta p$  1.0 in. w.g. at rated air flow. Long life—6,000 hours and longer when prefiltered—provides economical owning and operating costs. Over 200 sq ft of filtering area in a 1,000 cfm unit (24 in. x 24 in. x 11½ in.). Filters are easily installed—No supporting frames. Provide positive, trouble-free cleaning. No costly shut downs. No product contamination. Filters in standard size units from 25 cfm to 1,250 cfm available for immediate shipment. Special size units upon request. A-Series—For Standard Applications. Asbestos bearing cellulose filter media, rubber base sealer. D-Series—For High Humidity and Fire Resistant Applications. All glass filter media, rubber base sealer. Similar to A-Series in appearance. B-Series—For Fireproof Applications. All glass media, refractory sealer. Will withstand temperatures up to 1,000°F.

### CAMBRIDGE AEROSOLVE FILTERS

Cambridge Aerosolve

A Model of a  
Bank of Filters

A new, widely accepted, high efficiency, low pressure drop system of air filters designed for multi-filter banks in industrial and comfort ventilation and air conditioning supply systems. Also used in filtration of exhaust gases. Filters consist of a permanent cadmium plated steel frame and interchangeable cartridges. Filter media used in the cartridges composed of special glass mats, available in efficiencies from 35 per cent to over 90 per cent, based on the Discoloration Test Method developed by the National Bureau of Standards. All tests employ normal atmospheric dust. This is the same test as used in rating Electrostatic Precipitators. Initial pressure drops range from 0.16 in. to 0.35 in. w.g. The greater area and thickness of these specially designed mats provide long life, which together with a low initial cost guarantee economical owning and operating costs. Installation is easily made. Multi-filter banks quickly erected. Cartridges slide easily into frames and are held tightly in place by quick-acting fasteners. Operation is reliable and trouble-free. Protective screens and prefilters available if desired. 1,000 cfm unit 24 in. x 24 in. x 12 in.

## CAREY Electronic Engineering Company

METAL WOOL DIVISION

**A-Lum-O-Aire**  
FILTERS

**A-Lum-O** ALUMINUM  
AND  
COPPER WOOL

1875 CLIFTON AVENUE

SPRINGFIELD, OHIO

### CONSTRUCTION

The A-LUM-O-AIRE Filter is a permanent-type, all-metal air filter designed for top economy and efficiency in all warm-air heating, air-conditioning and ventilating applications. In 90 per cent of all installations, the A-LUM-O Aluminum Wool media catches and holds dirt—without the aid of oils and adhesives. Rustproof and fireproof, the media can be quickly cleaned with water. Frames, with corners welded for extra support, are aluminized steel which combines the strength of steel with the protection of an aluminum surface.

Mat retainers are heavy-gauge expanded steel, plated after cutting to size. Media is securely locked in position to prevent slipping or moving.

### EFFICIENCY

The Metal Wool Division of Carey Electronic Engineering Co. has devoted many years to the research and development of the uses and methods of producing A-LUM-O Aluminum and Copper Wool. Hundreds of tests, under simulated operating conditions, have proved its unusually high efficiency as a filter media. Millions of tiny barbs provide an extremely rough surface which catches and holds even the most minute particles. Consisting of continuous strands with no short fibers, the wool is processed from special alloys produced to rigid specifications developed by Carey for this particular purpose.

### AVAILABILITY

Furnished in all standard ½, 1 and 2 in. sizes, A-LUM-O-AIRE Filters are also available in special sizes to order. Copper wool media with copper-plated mat retainers available for acid and corrosive conditions. Units can be loaded with proper media for specific operating requirements. Thousands in use in all phases of industry have proven the advantages of greater efficiency and economy in all types of installations.

### ENGINEERING

Carey maintains one of the most modern engineering laboratories in the industry to aid you in solving your air filtration problems. The facilities for research, design and testing—plus the experience and assistance of competent personnel—are entirely at your disposal. You are invited to submit specifications for complete recommendations.

Above is a photomicrograph of aluminum wool showing the countless rows of barbs and ridges which screen out dirt, dust and lint. In a standard 30 x 30 x 1 filter there is an area of more than 69 sq ft of wool media—with literally millions of barbs in each inch of filter surface.

Air Recovery

Air Purification

In Canada: Douglas Engineering Co., Ltd., Montreal, P. Q.

### WHERE TO APPLY AIR RECOVERY

Air Recovery is simply the conversion of foul or stale air to fresh air. It has been used to advantage wherever air is conditioned to enhance comfort, raise production efficiency, extend food preservation or protect product quality. Depending on the source of contamination, Dorex Air Recovery Equipment has been installed to remove

odors and other gaseous impurities from intake air, from recirculated air or from exhaust air.

When applied to recirculated air, Dorex Adsorbers reduce the amount of unconditioned outdoor air needed for ventilation and effect savings in installation and operation costs. For example: Given an air conditioning requirement of an area of 20,000 cfm, of which it is assumed 14,000 cfm would be recirculated and 6,000 would be outdoor ventilation before installation of Air Recovery Equipment, it may be possible to cut the amount of unconditioned outdoor air intake to 2,000 cfm by converting 4,000 cfm of used, already conditioned recirculated air to fresh air. Figured for average temperate zones, this 33 1/4 per cent load reduction would lower the installation and operating cost substantially because each 1,000 cfm of heated or cooled air that is converted saves: (1) 100,000 Btu of installed heating capacity, (2) 2.6 tons of installed refrigeration, (3) 1,800 kw hours of current per cooling season, (4) 1,500 gallons of fuel oil or 9 tons of coal per heating season, and (5) incidental water consumption and maintenance. In existing systems, the application of Dorex Air Recovery Equipment will enable the system to serve a larger space or satisfy a greater conditioning load without increasing cooling or heating equipment and without consuming more fuel or power.

#### Activated Carbon Traps Gases and Odors

Activated carbon removes gases and odors by adsorption—a natural phenomenon which takes place when airborne gases or vapors come in contact with it. An instantaneous condensation occurs and the condensed impurities are held tenaciously until the carbon is forced to give them up in reactivation. For air conditioning purposes, however,

Fig. 1. Dorex Canister

Fig. 2. Typical Canister Arrangement—side view

## Connor Engineering Corp.

the carbon must be especially processed, activated, and impregnated to meet the following specifications: (1) High activity (adsorptive capacity) for a wide range of gases and vapors; (2) High retentivity over an entire range of normal operating conditions; (3) No retentivity for water vapor; (4) Extreme hardness to avoid dusting in handling and in service; (5) High apparent density (in the granular form) of not less than 0.45; (6) Adaptability to repeated reactivation without appreciable loss in activity or retentivity. In actual use, Dorex activated carbon has removed and retained 95 per cent of all gaseous impurities from the air passed through it and maintained that efficiency from six months to two years, depending on the air contamination.

#### Equipment to Suit Individual Requirements

Dorex Air Recovery Equipment is available in a range of types and sizes to suit individual requirements. Each type is designed to hold the correct amount of activated carbon in a manner to provide a maximum area for decontamination, a minimum of air resistance and uniform air flow through the carbon. The average resistance to air flow ranges only from 0.15 to 0.2 in. wg.

#### TYPE H—Adaptable to Most Central Systems for Recovering the Freshness of Intake Air and Recirculated Air and for Eliminating Exhaust Nuisances

Type H Equipment—for complete decontamination of all air passed through it—consists of removable, perforated, carbon-filled canisters which are mounted in multiple on one or more supporting manifold plates. Fig. 1 shows a canister and its function; Fig. 2 shows a typical arrangement of canisters as installed. The flexibility of this arrangement makes Type H Equipment readily adaptable to a wide variety of space limitations. Write for *Bulletin 105-B*.

#### TYPE C—Equipment for Recovering the Freshness of Recirculated Air.

Dorex Type C Air Recovery Cells were developed to meet a need for a large capacity, easily handled and installed air purification unit. Each cell measures only 24 in. x 24 in. x 8 3/4 in. deep and completely purifies 1,000 cfm. They require no more engineering than that required for ordinary dust filters and can be mounted right along with them in either flat or "V" arrangement. (Fig. 3) Write for *Bulletin 117-C*.

TYPE G—for "Package" Conditioners, Unit Heaters, Refrigerated Spaces, Airplane, Bus, Railway Car, and Marine Installations and Other Systems Where Space is at a Premium. Write for *Bulletin 106-C*.

These compact panels consist of sturdy metal frames, each housing a battery of exposed perforated metal tubes which contain the activated carbon. Standard units of one, two or three tube rows in depth are available in a range of stock sizes for arrangement in air ducts. (Fig 4)

Fig. 3. Dorex Type C Air Recovery Cell

Fig. 4. Dorex G Panel

**CONTINENTAL**

**AIR FILTERS, Inc.**

P. O. BOX 1647

LOUISVILLE 1, KY.

**CONTINENTAL AUTOMATIC, SELF-CLEANING** Air Filters, viscous impingement type; 91.3 per cent efficient, 0.28 W.G. resistance at 500 fpm (ASHVE method test). Features: Patented E-Z-Wash media, "Ferris Wheel" action of continuous rotating filter curtain, and positive automatic flush-cleaning of curtain in each rotation cycle.

Ferris Wheel action passes filter sections from front to rear curtain without reversing them to the direction of air-flow... thus eliminating problem of trapped dirt being blown into clean air stream.

Cam action tilts and lowers each filter section while in oil reservoir so as to forcefully flush filter oil through the media counter to air-flow.

**E-Z-WASH PATENTED MEDIA** is a honeycomb of opposed V-corrugated metal strips which provides exceptional efficiency with extremely low resistance and effective self-cleaning... because air passages are relatively large and smooth-walled. Write for *Bulletin No. 801-D*.

**CONTINENTAL E-Z-WASH UNIT FILTERS**, available in all standard dimensions, 2 in. or 4 in. thick, use same advantageous patented media as discussed above. Can be washed easily by brisk cold water hosing, and quickly re-oiled with E-Z-Oil spray bomb. Write for *Bulletin No. 401-A*.

**DYCON CA-24**, dry-type air filters have an excellent dust-holding capacity because the efficient media is a blanket of specially prepared synthetic fibers. Low maintenance cost: quickly and easily restored to like-new efficiency by cold-water rinsing. No oil involved. Write for *Bulletin No. 501-A*.

**DYCON, Type DY**, one-inch dry-type filter for domestic and commercial use, is available in a wide range of standard sizes, and custom sizes as well—for air-conditioners, warm air furnaces, and air-handling units. Write for *Bulletin No. 550*.

**GREASE FILTER, Type GW**, uses same type media as E-Z-Wash filters, thus affords extremely low resistance. Since fatty acids of kitchen exhausts would be highly corrosive upon steel, Continental grease filters are made entirely of corrosion-resistant 3S aluminum. A sturdy permanent filter, type GW is easily washed in a commercial dishwasher. Write for *Bulletin No. 700*.

**Electro-air Cleaner Company**

1285 Reedsdale St., Pittsburgh 33, Pa.

Representatives in Principal Cities

Electro-air Electronic Air Cleaners have been developed for ease of installation, maintenance-free operation, and high efficiency (90 per cent by the *National Bureau of Standards* Dust-Spot Test). New features such as selenium rectifiers and a self-adjusting, ballasted, single circuit are incorporated in the design of all Electro-air equipment. All parts, including selenium rectifiers are unconditionally guaranteed for two years.

"Built-up Line" equipment is manufactured in every capacity to handle all sizes of buildings. All units have aluminum frame-work and top and side panels. Washing systems can be of either the "fixed horizontal manifold" type, or with a "traveling vertical manifold and adhesive applicator" operated by semi-automatic or completely automatic controls. "Built-up Line" units are also furnished with "enclosures" complete with drain pans and 2½ ft. of ducts before and after the Electro-air.

"Built-up Line" Electro-air

"Custom Line" units are furnished as complete "packages" and are designed for use in those cases where space is limited and access doors in ducts are not practical. These units are furnished in capacities from 1,350 to 12,000 cfm and are complete with required number of collecting cells, drain pans, washing systems, and power packs. "Custom Line" Electro-airs are furnished in either horizontal or vertical ("up or down" air flow), and may be floor mounted or suspended.

"Custom Line" Electro-air

"Compact Line" Electro-airs are moderately priced and are designed for easy installation in homes and smaller commercial and industrial buildings which have forced air ventilation. They are available in nine models, both horizontal and vertical (down) flow, in capacities from 800 to 4,800 cfm. Horizontal flow models may be either floor mounted or suspended. "Compact Line" units include most of the features of larger "made-to-order" Electro-air models.

### STAYNEW MODEL A-3 AUTOMATIC FILTER

An endless curtain type oil-bath filter for handling large volumes of heavily dust-laden air at low cost. The efficiency of Staynew Model A-3 is outstanding among mechanical self-cleaning filters.

**Operation and Features:** Double filter curtains (1) carried on heavy roller chains driven by sprockets keyed to the shafts of the curtain rollers (2). These rollers float on ball bearings for quiet, frictionless operation. Curtains consist of removable panels (3) made of a single layer of bronze screen cloth to which are attached layers of woven copper mesh.

The first of the curtains is the denser, having about twice the impingement surface of the second or rear curtain. This first curtain acts as the filter and travels through the oil reservoir. The second curtain does not enter the reservoir, but acts only as a safeguard against oil entrainment. This design permits a direction of certain travel such that cleaned panels (4) are always on the filtered air side. Therefore no dust can be carried across the back or return side of the front curtain to be blown off and carried on by the flow of air.

Patented, exclusive Staynew Compressed Air Curtain Cleaners (5) are available for special conditions.

#### Specifications

Model A-3 Filters are sectional and may be bolted together to obtain any required capacity. Sections come in two widths, 4 ft 3 in. and 2 ft 9 in. Curtain drive and control mechanism (6) arranged either as an integral part of filter unit or for remote mounting, includes a 1/4 hp motor (7) driving through a reduction gear and a momentary contact time switch (8) for testing and checking curtain travel and compressed air control. All are mounted on a common base plate (9) on clean air side of filter. Shear pin (10) is provided for protection of moving parts from accidental damage.

Drive motor operates for a few seconds at 15 minute intervals, and compressed air curtain cleaners can be arranged to operate simultaneously.

1330

Model A-3 Automatic Filter (numbered features are referred to in accompanying description)

### STAYNEW PANEL TYPE FILTERS

Model WKE  
Panel and Frame

**Model WKE:** Dry-type finned panel filter for use in ventilation and air conditioning systems. Extremely large filtering area in relation to overall size. Adaptable to wide variety of filtering media—in fact, almost any medium obtainable in sheet form that can be crimped. Steel mesh on both sides of medium prevents sagging and makes the WKE *fire-resistant* (models available to meet Class I *Fire Underwriters* approval), and cleanable without possible damage from vacuum cleaning tool or cleaning nozzle. It may also be washed or dry cleaned when and if necessary. There are no cross bars, spacer bars, or other obstructions to interfere with the cleaning operation. Unaffected by temperature changes.

Filter cells are held in rigid box-type supporting frames of heavy gauge metal by spring-loaded cam-type locking latches. Two lifting handles are provided on each cell. Filtering medium supplied already crimped and cut to size. It may be inexpensively replaced in 2 to 5 minutes right at the filter bank—no special tools required.

Frames are drilled so that they can be riveted together to form a flat bank, or by the addition of angle uprights into a "V" or staggered arrangement.

Handles and Latches

Viscous Model DPV  
Panel and Frame

**Viscous Panel (Model DPV):** A permanent type panel for air conditioning systems used in heavy duty industrial service. Filtering media consist of a series of layers of crimped galvanized screen cloth and woven mesh. These media when coated with PD-10 Pingene Filter Oil form an unusually efficient filter. Model DPV filters are cleaned easily with live steam or by washing in a suitable solvent. Spring-loaded locking latches and lifting handles are provided as in Model WKE.

Both Model WKE and DPV cells are furnished in 2 in. and 4 in. depths in various standard sizes.

1200 cfm  
Electro-Staynew Precipitator

**Electro-Staynew Electronic Filter:** Ionizer and Collector Cell built into one compact unit. Highly efficient—removes 90 per cent of all air-borne dirt, including smoke, dust, pollen, oil mist. Available in single units of 1200 and 1800 cfm; any capacity in multiple units.

### STAYNEW LIQUID FILTER

**Model ELS:** Widely used for the filtration of cooling water to prevent clogging of spray nozzles. Exclusive, low-cost SLIP-ON INSERT easy to remove, clean, replace. Radial Fin Construction provides all possible filtering area in smallest possible space. Standard models available to handle up to 1000 gpm.

New York

Manufactured under license by Farr Co. Mfg. Ltd., Montreal, Canada

### FAR-AIR® FILTER AND HOLDING FRAME

A high velocity, low resistance, viscous impingement unit for industrial and commercial applications. Available in a wide range of types and sizes for dirt, lint, grease, entrained water, ink, paint, etc. Herringbone-crimp media design assures higher performance, larger dirt holding capacity, lower pressure loss, easier cleanability and reduced maintenance costs. Standard interlocking holding frames are 16 gauge steel. Various protective coatings available.

#### FAR-AIR CAPACITIES

Recommended net face velocity is 519 fpm although velocities up to 700 fpm may be used. The following chart is a

guide in estimating FAR-AIR Filter requirements. 4 in. filter thickness has twice the pressure loss of the 2 in.

#### MEDIA DESIGNATION AND APPLICATION

Type 44: 14 mesh zinc-electroplated steel screen. For ventilation, paint, lint, ink, oil.

Type 44F: Coated with vinyl or other special paint. For fume-resistant applications.

Type 44G: Standard filter, uncoiled. For grease arrestance.

Type 44MZ: Screen painted with zinc

chromate before and after assembly. Frame hot dip galvanized. Marine ventilation application.

Type C4C4H: All copper media and filter frame. Corrosive atmosphere and water elimination applications.

Type A4A4: All aluminum media and filter frame. Stainless steel and monel filters for special applications can be supplied on special order.

\*Trade Mark Reg.

### HOW TO SPECIFY STANDARD TYPE 44 FILTERS & FRAMES

Filter shall be permanent, impingement, washable, all metal, panel type. Media shall be zinc electroplated, 14 mesh steel screen, arranged in alternate layers of flat and herringbone-crimped screens, so that at no point is air flow restricted to flow through the screen, 4 layers of each per inch, 1/8-in. rod reinforced, and enclosed in a frame of 16 gauge steel with flush mitered corners. Resistance to air flow of a clean filter

shall not exceed 0.12 in. w. g. at 3.6 cfm per square inch of net face area.

Holding frames shall be factory built on 16 gauge steel "T" section, with felt air seal, interlocking edges, and filter locking device.

Filters shall be Far-Air Type 44 and frames shall be Far-Air Standard Interlocking as manufactured by Farr Company, Los Angeles 45, California.

#### ROTONAMIC

#### ROTONAMIC

The Rotonamic is a compact, multiple tube, cyclonic type air cleaner with continuous dirt removal by air bleed. Efficiency averages 98 percent on 5 to 10 micron dust of 2.5 specific gravity. Efficiency is even higher on larger particles or on denser material. Rating of 20 x 20 x 4 1/8 in. panel is 1000 to 2000 cfm depending on available pressure. Apparent straight through air flow requires no difficult change in duct direction. Bleed off piping is simple. Deflecting vanes form a high velocity vortex in each tube. Internal reversal of the direction of flow doubles the cyclonic action, producing the high efficiency.

#### SELF WASHING FILTERS

These completely automatic units wash and re-oil themselves on any frequency cycle desired. Each is made up from 4 in. thick corrosion-resistant filters in combination to meet any cfm requirement. Washing water and contaminated oil is immediately flushed away, eliminating messy sludge and oil sumps. There is no oil entrainment. Each unit has a safety deluge valve that automatically prevents fire from passing the unit. Installation is simple and inexpensive.

#### ENDLESS GREASE ELIMINATORS

FAR-AIR Endless Grease Eliminators halt the deposit of highly combustible grease and lint in the air ducts, reduce maintenance, protect blower and fan, provide better ventilation and sanitation. Available in one-sided and two-sided models in sizes to meet any cfm requirement.

Full catalog and technical information on any FAR-AIR product is available on request.

Akron 16, Ohio

## PLIOTRON\*

## AIR CLEANER

## WHAT IT IS

PLIOTRON is a self-charging, electrostatic, washable, permanent-type air cleaner. Revolutionary feature is its new filter medium of shredded polyethylene. Sound engineering and construction insure long life and minimum maintenance.

## HOW IT WORKS

Shredded polyethylene carries inherent positive and negative charges in close proximity to each other. These charges are greatly increased with the passage of air. Since particles of dirt are similarly charged, the meshed plastic does an effective job of attracting and capturing them.

## SPECIAL SHREDDING INCREASES EFFICIENCY

A special method of shredding produces

a feathered edge with thousands of cilia-like serrations. These increase the area exposed and create a heavy turbulence that brings the dirt particles into intimate association with the statically charged polyethylene.

## AVAILABILITY INFORMATION

PLIOTRON is supplied through distributors located in every major marketing center across the country. It is presently available in four standard sizes, all 1 in. in thickness. It is so designed as to stay in the general resistance range of ordinary, 2 in. thick, impingement filter, yet do a superior job of air cleaning. Spacer clips which are also available, or another PLIOTRON, are recommended in instances where a filter greater than 1 in. in thickness is required.

## NU-AIR TYPE "A" AIR RECOVERY UNIT

TYPE "C"—CANISTER, a perforate metal cylinder filled with granular carbon (for 15 to 35 cfm each with recommended maximum of 25 cfm). Made up of one perforate metal cylinder within another, with the side walls of the two forming an open area which is filled with granular activated carbon. The top is completely sealed with a cap that encloses both the inner and outer shell. Air flows through the cylindrical side-wall and carbon bed, into the hollow center of the inner cylinder—then down through the opening punched manifold plate upon which it rests.

The Canisters may be set on the manifold plate in any arrangement that best suits the requirements and available space. Canisters and/or manifold plate can be furnished in stainless steel, brass or aluminum for special installations.

The Type "A" panel Air Recovery unit handles from 700 to a maximum of 1000 cfm. For use in removing odor and gaseous impurities where those concentrations are light to medium. The shape of the carbon bed offers a great exposed area to the air flow for maximum efficiency. The carbon bed is formed by two parallel sheets of perforated metal, fashioned in a series of S-curves, comprising the surface through which the air flows.

PERFORMANCE TABLE

| CFM  | Static Pressure Loss*<br>V-Arrangement | Flat  |
|------|----------------------------------------|-------|
| 500  | 0.105                                  | 0.08  |

\* Resistance is overall.

Both types of equipment can be used in single or multiple units for required capacities. Complete technical data available in new bulletin 15-CX, 15-DX, by writing the manufacturer.

# Owens-Corning Corporation

Toledo 1, Ohio

**DUST STOP**

Available in standard 1/4 in., 1 in., 2 in. and made-to-order sizes.

## AIR FILTERS

### THE ALL-PURPOSE, REPLACEMENT-TYPE AIR FILTER

Air flows freely through a Fiberglas Dust-Stop® Air Filter, yet virtually all dirt is trapped inside. Correctly sized fibers mean peak efficiency . . . minimum resistance. "Depth-loading" extends filter life.

#### THE FILTER

Dust-Stop Air Filters are impingement-type filters constructed of glass fibers which are non-absorptive, fire-proof and will not shrink or swell. Fibers are coated with a non-evaporating odorless adhesive which effectively traps dust, lint and pollen. Dust-Stops are replacement-type filters and should not be laundered.

Uses—Dust-Stop Filters may be used at approach velocities up to 450 fpm without impairment of their high efficiency characteristics but with higher resistances. Maximum permissible resistance of filters is 1 1/2 in. water gage.

#### DUST-STOP FILTER FRAMES

Dust-Stop Filter Frames are designed for the convenience of the engineer in constructing filter banks. Metal frame is of universal style, suited to use in flat or "V" banks. Designed-in, self-locking device permits fast, economical assembly. Made to take 2 in. or 4 in.

#### DUST-STOP RESISTANCE INDICATOR

The Dust-Stop Resistance Indicator acts as a guide to economical bank maintenance. With adjustable filter-change marker set at resistance level specified by engineer as point where filters should

#### Resistances

| Resistance—  | inches, water gage | 300 fpm | 450 fpm |
|--------------|--------------------|---------|---------|
| 1 in. filter | .080               | .170    |         |
| 2 in. filter | .135               | .300    |         |

In cases where velocities approach 450 fpm, care should be taken to see that fan capacity is adequate to overcome increased resistances.

Cfm Capacities—Rated capacities of standard 20 in. x 20 in. Dust-Stop Filters are 800 cfm at 300 fpm velocity and 1250 cfm at maximum permissible velocity of 450 fpm.

depth of standard 20 in. x 20 in. or 20 in. x 25 in. filters. Black painted or galvanized finish. Front, back and side angle uprights for V-bank assembly are also offered in 20 in. increments up to 160 in. length.

be changed, this indicator provides a guide to "when-to-change filters." Insures operation at rated capacity and efficiency.

\* FIBERGLAS and DUST-STOP are trade-marks (Reg. U.S. Pat. Off.) of Owens-Corning Fiberglas Corporation for a variety of products made of or with fibers of glass.

# Pittsburgh Plate Glass Company

FIBER GLASS DIVISION  
One Gateway Center  
Pittsburgh 22, Pennsylvania

Where clean air is a necessity for either residential, commercial or industrial applications specify GLASFLOSS filters. Products of the Pittsburgh Plate Glass Company, these filters are composed of extremely long and exceptionally fine glass fibers. Because of this fineness, they furnish a greater dust-collecting area and provide unusually complete filtering action. GLASFLOSS filters are available in three forms, to suit all filtering requirements:

**GLASFLOSS I-S FILTER**—To the long, fine glass fibers used in the STANDARD Air Filter a special strainer mat has been added. This means that the I-S filter is actually two filters in one. For industry, where clean air is essential, or in the meticulous home equipped with forced air heating, Glasfloss I-S provides new quality air filtering.

#### GLASFLOSS STANDARD AIR FILTER

—Provides millions of fine, glass fibers scientifically bonded and treated with a special fire-resistant, dust-catching adhesive, to trap and hold more dirt. This extends the life of the filter and makes it ideal for normal home heating and air conditioning equipment.

**GLASFLOSS ROLL-PAK**—For bulk users of air filters who are faced with the problem of continuous replacement. The Glasfloss Roll-Pak provides substantial savings . . . as high as 30 per cent. It offers quick replacement of filter media, and is available in rolls of 40 in. wide and 10 in. long and in 1/2 in., 1 in. and 2 in. thicknesses, packed five rolls per carton, to suit every size commercial air filter.

#### ACTUAL DIMENSIONS

Madison 10, Wisconsin

AIR FILTERS FOR  
HEATING AND VENTILATING

Grease Filters for Kitchen Exhaust Systems—Paint Arrestor Pads

### RP AIR FILTERS

Controlled turbulence design is provided in every RP filter. Scientifically staggered baffles cause thousands of sharp reversals of air flow in the filter. Media gradation, insures RP depth loading, an important longevity feature. Air borne particles are centrifuged

### REPLACEMENT

"Snap-In" Grid Air  
Filter Installation  
Showing Self-  
Seal Edge.

### Fiber Self-Seal Air Filter

The highly efficient, soft, resilient, non-fracturing RP replacement media is held in a sturdy, refillable wire grid. Media pad is oversize and no channel is required or used on edge which provides the self-sealing feature. Used in domestic and commercial units and in central system filter banks. Available in  $\frac{1}{2}$  in., 1 in. and 2 in. thicknesses in standard and special sizes.

### Snap-In Grid Air Filter

Designed for central system use of the inexpensive Fiber Self Seal Pad. Paint Arrestors

Specially designed, inexpensive and efficient pad removes overspray from paint spray booth exhaust air. Snap-in grid retains pad in frame.

against the baffles and are held by adhesive in the air filter and by the viscous qualities of the particles, themselves, in the grease filter and paint arrestor applications.

Constructed of slit and expanded material, RP filters are uniform in construction and performance.

### WASHABLE

#### E Z Kleen Air Filter

The RP Alumaloy, E Z Kleen Air Filter is an economical selection for many applications. Like all RP washable air filters, this filter is extremely easy to clean.

#### Industrial Air Filter

RP Alumaloy Industrial air filters are multi-velocity filters, which have extremely low initial resistance and slow build-up resistance. Holding frames for filter banks, combination lift and lock handles, lift handles and water soluble filter coat adhesive are available.

#### Grease Filter

Efficiency in excess of 99 per cent on grease vapors, gleaming appearance, ease of cleaning and light weight have made RP Alumaloy Grease Filters a volume performance leader in its field. A free comprehensive data booklet on kitchen exhaust systems is available.

RP Alumaloy Air Filter and Inset Showing Handle Lock

### ADHESIVE

Two types of adhesives are available. RP Filter Coat for removal of dust and other impurities—RP D-O Kote which has the additional quality of odor removal. Both are for application to RP Alumaloy washable filters.

### APRILAIRE Automatic-Electric HUMIDIFIER

Positive control by humidistat and high capacity are features of Aprilaire Humidifiers. Three models available: Plenum Model (illustrated) for installation in forced air furnaces; Universal Model, for installation in building with steam or hot water heat; Portable Model requiring no installation for any type home or office.

## Somers Corporation

6063 Wabash Ave., Detroit 8, Mich.

Established 1925

REPRESENTATIVES IN PRINCIPAL CITIES

### SOMERS Heavy Duty Industrial Filter

Patented

Somers Hair Glass Filters provide everything required in an efficient air-cleaning system.

### FEATURES

- High rating for dust, soot and bacteria separation.
- Require no adhesive, coating or impregnation.
- Indestructible in normal service.
- Minimum low-pressure drop.
- Odorless and non-absorptive.
- Fireproof.
- No periodic replacement.
- Washable.
- Permanent—Do not rot nor disintegrate.
- All welded zinc-plated 20 gauge steel frame.
- 100 hour salt spray test.
- Metal protection strip on apex.
- Glass cloth between hot-dipped hardware cloth.
- Glass ribbon seal so air cannot short circuit.
- Refills.

Somers Hair Glass Filters consist of a 20 gauge zinc plated frame holding galvanized wire cloth packed with hair-spun glass strands. The glass strands are flexible, do not break up and cannot be drawn into air stream.

Hair Glass being chemically inert, has no facility of absorption; it cannot rust and lasts indefinitely in service. Water either hot or cold may be used to clean it, without impairing its efficiency.

Available in all standard and special sizes. Quotations and further engineering data will be sent on request. Master holding frames available.

## TRION, INC.

1000 Island Avenue, McKees Rocks, Pa.  
In Metropolitan Pittsburgh

Designers and manufacturers of equipment for cleaning and purifying air and other gases.

### TRION ELECTRONIC AIR CLEANERS

Highest efficiency air purification equipment. Electronically removes more than 90 per cent (*National Bureau of Standards Dust-Spot Test* using normal atmospheric air) of dust, dirt, smoke, pollen, germs and virus from air. All airborne particles are electronically charged (positive) as they enter the Trion. They are then attracted to and collected upon plates having an opposite electrical charge (negative). An integral washing system flushes the dirt to a sewer.

**Field Assembled:** Built to specifications for required cfm and assembled on job.

**Custom-Built:** Built to specifications up to 9330 cfm and shipped as a complete unit.

**Standard Packaged:** Residential and small commercial units. Seven sizes up to 4,800 cfm. Shipped from stock.

**Special:** Designed for specific requirements such as by-product recovery, gas purification, nuisance elimination.

### TRION OIL MIST PRECIPITATOR

Electronically recovers coolant oil mist from high speed cutting and machining operations. Unit includes blower.

### TRION MECHANICAL AIR FILTER

Inexpensive, viscous impingement air filtering equipment featuring high velocity, progressive loading, low pressure drop, high dirt holding capacity and non-clogging. Manufactured from wire screen or aluminum strip media with exclusive "air scoop" design.

**Fixed Panel:** Permanent and cleanable panels for filtering larger particles of dirt, pollen and grease. Automatic self cleaning accessories available.

**Traveling Curtain:** Advanced design automatic filters with continuous self cleaning features for large volumes of air where filtering of coarse particles is sufficient.

## Vortex Company

Claremont, California

Panel Air Filters for all Industrial Applications

Vortex Panel Air Filters are of the cleanable, impingement, viscous-coated type with exceptionally low air flow resistance. They are made for use in air conditioning, ventilation, range canopies, engine intakes, and general air filtration.

Vortex Panel  
Filter with Frame

**EFFICIENCY.** Vortex Panel Air Filters are efficient at both high and low air flows. Consequently to reduce costs of the original installation or to save space, fewer Vortex Filters may be used at higher air velocities. To assure a longer service life, more Vortex Filters may be used at lower velocities. In either case Vortex Panel Air Filters provide better cleaning at lower cost.

**OPERATION.** Numerous changes in direction of dust laden air cause the dust particles to impinge on the adhesive viscous-coated surfaces of the filter

Vortex Type VR Panel Air Filter illustrated above is the type used on engine intakes and in car bodies of diesel locomotives. It is constructed to withstand the severe usage of locomotive service. It has the exceptional characteristics as in all types of Vortex Panel Air Filters.

**FILTER ELEMENT.** Fabricated of elastic units of fine steel wire positively interlocked to provide a permanent filter, the element offers many advantages: (1) In a 2 in. x 20 in. panel there are from 9300 to over 15,000 feet of fine steel wire, depending upon the type. (2) Even distribution of filaments exposes innumerable viscous-coated surfaces to the air stream, thus obtaining the most effective cleaning for space occupied. (3) Proper spacing of filaments prevents clogging and assures maximum dust removal efficiency. (4) Structural strength and permanent resilience combine to withstand "packing" effect of vibration and pulsation.

element. Coarser particles collect near the entrance, while finer particles penetrate to a greater depth. As the entrance becomes saturated the cleaning action takes place deeper in the filter and the restriction is increased slightly. Increased restriction in certain sections of the filter diverts the air to cleaner sections, thus distributing the dust load for a higher over all efficiency and a greater total dust-holding capacity. **EASY TO CLEAN.** All dust and lint are easily and completely flushed from the filter by water or steam sprays.

| Nominal<br>Size of Panel<br>Inches* | Actual<br>Outside<br>Dimensions<br>Inches | Capacity<br>Range In<br>CFM** | Outside<br>Dimensions<br>Of Holding<br>Frames Inches |

| 20 x 25 x 2                         | 19 1/4 x 24 5/8 x 1 7/8                   | 1000 to 1550                  | 20 1/4 x 25 1/4 x 2                                  |

\* These filters are also made in 4-in. thickness.

\*\* Some filter manufacturers specify very high velocities which are applied to certain internal dimensions of the filter. The range of capacities stated above are computed on the basis of average to high velocities applied to the total filter area using the actual outside dimensions of Vortex Panel Air Filters.

## Westinghouse Electric Corporation Sturtevant Division

Heating, Ventilating, Dust Control and Fume Removal  
Equipment, Electronic Air Cleaners, Mechanical  
Draft Equipment

Hyde Park

Offices in Principal Cities

Boston 36, Mass.

### ELECTRONIC AIR CLEANING

**PRECIPITRON** high efficiency electronic cleaners save money by removing harmful dust and dirt from ventilating air.

In commercial buildings **PRECIPITRON** catches dirt and grime before it settles on walls, merchandise, light fixtures and equipment. In industrial plants **PRECIPITRON** protects valuable equipment, and improves working conditions.

#### Oil Mist Control Units

Designed to collect oil coolant mists generated by high-speed cutting, grinding operations. Have built-in fan for individual machine ventilation. Available in 600 and 1200 cfm capacities.

#### Horizontal and Vertical Air Flow

Manual wash type for installation in ducts. Sizes range from 1200 to 100,000 cfm for operation at 90 per cent efficiency by Blackness Test. Units easily maintained by manual washing. Uses 115 volts single phase power—only 40 watts per 1000 cfm.

Push-Button washing type; washes and applies adhesive with a built-in motorized moving nozzle washing mechanism operated by remote control. Allows operator to service the unit quickly and economically from outside the duct. Sizes from 5000 to 72,000 cfm.

Automatic Washing type for large, heavy duty applications. Washes and applies adhesive automatically without interrupting the air flow. Mobile washer boxes isolate small section of unit for complete servicing. Capacities from 24,000 cfm up.

Vertical Unit for up or down, air flow—manual washing. Suited to small and medium size installations where space is at a premium. Capacities 1200 to 9600 cfm.

## Air Fan Engineering Company

7401 Telegraph Rd.,  
Los Angeles 22, Calif., U. S. A.  
(Telephone RAYmond 3-3354)

### AIRFAN AIR WASHER EVAPORATOR COOLER

The Airfan Air Washer Evaporator Cooler has high cooling efficiency and is next in line to mechanical refrigeration, yet low in cost. Units available from 2,000 cfm to 100,000 cfm.

### AIRFAN H-D BLOWER

Airfan builds a complete line of forward and backward heavy duty blowers, rotatable discharge housing and extended streamlined air inlets for quiet operation and low horsepower. Capacities range from 600 cfm to 100,000 cfm.

Technical Data Catalogs on all Airfan Products are available upon request to building contractors, engineers and dealers.

### UTILITY SETS

For general ventilation complete with weather-proof covers. Self contained package units for easy installation. 300 cfm to 20,000 cfm. Wheel diameters 10 inch to 36 inch.

### ROUND DIFFUSER

Precise control of air delivery and radius of diffusion with Airfan round ceiling diffusers. Nine sizes, 8 inch to 36 inch. Outlets from 200 cfm to 15,500 cfm.

### SQUARE DIFFUSER

Also 2-way, 3-way and 4-way square and rectangular ceiling outlets. From 400 cfm to 20,000 cfm capacity.

## Binks Manufacturing Company

3130-36 Carroll Ave., Chicago 12, Ill.

Representatives in all principal cities

Water cooling systems and nozzles . . . a size and type for every purpose

### Binks atmospheric spray cooling towers

Small sizes, in a variety of standard units with capacities ranging from 10 to 125 gpm—larger units handle from 600 to 1200 gpm. Special designs furnished in sizes of exceptionally large capacity. Standard tower capacity and temperature performance are based on nozzle pressure of 7 lbs per sq in. Ask for *Bulletin 312*

Atmospheric cooling towers, Type "S"

### Binks blower type induced draft cooling towers

The squirrel cage blower provides extremely quiet operation. Available in single or multiple types, capacity range from 9 to 800 gpm of cooling water. Ask for *Bulletin 477*.

Blower type towers, Type "BB"

### Binks steel cased induced draft cooling towers

Towers of this type are of the spray filled or deck filled type—made in 20 standard sizes of sq ft rated area. Larger models are engineered to specification. Air propulsion assemblies for either type can be arranged for V-belt or reduction gear drive, as required. Ask for *Bulletin 333*

Induced draft towers, Types "K-S", "K-W"

### Binks induced draft masonry cooling towers

Engineered for large scale air conditioning systems in towers that harmonize with the architectural features of the building. Spray or deck filled. Ask for *Bulletin 333*

Induced draft towers with masonry walls

### Binks non-clogging Rotojet spray nozzles

Non-clogging Rotojet nozzles are the heart of every Binks water cooling system. They account largely for the efficiency and satisfactory operation of Binks water cooling installations. In addition to cooling tower applications, Binks Rotojet nozzles have found a wide number of uses in brine-spray and quick-freeze refrigerating systems, air washing equipment, metal cleaning and treating machines, chemical plants, etc. Rotojets produce a uniformly fine fluid breakup in a hollow cone pattern. Standard small and medium Rotojet nozzles are machined from brass bar stock, but can be made on special order from monel, stainless steel, or other machinable metals. Large, heavy-duty Rotojet nozzles for use in large cooling towers and spray pond installations, are cast from high quality brass with precision machined threads and orifices. These nozzles may be cast in other metals for special purposes.

### Binks small and medium capacity Rotojet nozzles

To fit  $\frac{1}{8}$  to  $\frac{3}{4}$  in. pipe connections. Regularly supplied in brass, with male or female threads, as specified. Discharge orifices are available over a considerable range for each size. Rotojet nozzles of this type are designed on the side inlet whirl chamber principle, which produces a fine fluid breakup and a uniform spray pattern.

### Binks heavy-duty Rotojet nozzles

To fit 1 to  $2\frac{1}{2}$  in. pipe connections. Female threads only. Discharge orifices available in various sizes, from  $\frac{3}{16}$  in. to  $1\frac{1}{4}$  in. The totally unobstructed involute type of whirl chamber produces a uniformly fine water breakup at low pressures (5 to 7 lbs).

### Binks Spra-Rite nozzles

Produce a solid mass cone spray pattern. Small sizes for  $\frac{1}{4}$  to  $\frac{3}{4}$  in. connections are widely used for air washing, cooling, brine refrigeration, rapid evaporation processes, filtering systems, chemicals, etc.

### Binks large capacity Spra-Rite nozzles

To fit 1 to 3 in. connections meet a variety of heavy-duty uses in blast furnace gas washers, vibrating and revolving screen coal and gravel washers and water cooling.

### Binks pneumatic atomizing nozzles

Series 50 nozzles are designed for use wherever conditions of controlled humidity must be maintained, as in the storage of perishable products, paper storage and printing plants, textile mills, greenhouses, etc. Nozzles of all brass construction deliver round or flat spray and are designed for use with automatic siphon or pressure feed installations.

### Free technical bulletin and engineering service

Binks 40 page *Bulletin No. 5600* contains a wealth of useful information for anyone specifying spray nozzles for air conditioning, refrigeration, humidifying, heating and ventilating, or similar heat transfer processes. Nozzles shown above and all other nozzles in Binks line are illustrated and described. Data given include nozzle dimensions, capacities and spray angles. Cutaway drawings explain nozzle operation in many cases. "Blue print" drawings show installation details for heating and cooling uses where this information is required. Write for a free copy without obligation.

Binks engineering service in planning and installing cooling systems is available without obligation or cost to architects, heating and ventilating engineers and builders.

## Baltimore Aircoil Company, Inc.

2615 Mathews Street  
Baltimore 18, Maryland

Manufacturers of Evaporative Condensers and Cooling Towers

B. A. C. Evaporative Condensers and Cooling Towers are rigidly built for long, trouble-free service. Casings are of galvanized steel construction throughout. Galvanized steel Cooling Tower surface is designed for long and efficient operation.

The above basic construction is further protected against corrosion by the use of B. A. C. Zinc-Chromatized Aluminum Paint and Special B. A. C. Mastic. These finishes have proven through years of research and field testing to be outstanding in corrosion resisting and long wearing properties.

Model "MC"

Model "MC" Evaporative Condenser: (Pat. Pending) Centrifugal fan type . . . indoor or outdoor installation . . . Freon or Ammonia . . . Capacities: up to 350 TR.

Model "U"

Model "U" Evaporative Condenser: Centrifugal fan type . . . indoor or outdoor installation . . . Freon or Ammonia. Capacities: up to 100 TR.

Model "UL"

Model "UL" Evaporative Condenser: Centrifugal fan type . . . indoor or outdoor installation . . . Freon or Ammonia. Capacities: 105 to 300 TR.

Model "MT"

Model "MT" Cooling Tower: (Pat. Pending) Centrifugal fan type . . . indoor or outdoor installation . . . Capacities: up to 400 TR.

Model "UT"

Model "UT-1" Cooling Tower: Centrifugal fan type . . . indoor or outdoor installation. Capacities: up to 100 TR.

Model "LT-1"

Model "LT-1" Cooling Tower: Centrifugal fan type . . . indoor or outdoor installation. Capacities: 115 to 240 TR.

12000 East Washington Boulevard, Whittier, California

Manufacturers of Counterflow Mechanical Draft Cooling Towers—Aerator Natural Draft Cooling Towers

SALES OFFICES AND REPRESENTATIVES IN: BIRMINGHAM, BOSTON, BUFFALO, CHICAGO, DENVER, DETROIT, HOUSTON, LOS ANGELES, MINNEAPOLIS, NEW YORK, PHILADELPHIA, PITTSBURGH, SAN FRANCISCO, TULSA.

ASSOCIATES: FLUOR CORPORATION OF CANADA, LTD., TORONTO, CALGARY, HEAD-WRIGHTSON PROCESSES, LTD., LONDON, ENGLAND

Thirty-four years of intensive development work in research, design, fabrication and erection of cooling towers enable Fluor to offer both natural draft and mechanical draft cooling towers with guaranteed performance, quality construction, and long-life service.

### COUNTERFLOW MECHANICAL DRAFT COOLING TOWERS

**DESIGN:** Counter-flow principle of design which enables the greatest possible utilization of available driving force for cooling. Available in a variety of distribution systems, tower heights, and arrangements. Exterior appearance designed to complement modern plants and buildings.

**PERFORMANCE:** Efficient counter-flow principle provides economy cooling for all services. Costs studies made on individual design conditions dictate the type of tower to be offered from the many available designs.

**MAINTENANCE:** Decking withstands repeated washing and cleaning and the abuse of removing and replacing. Enclosed distribution system eliminates algae growth. Stainless steel fan blades support a man's weight at their tips. Heavy-duty, precision gear units are designed specifically for the conditions peculiar to cooling tower operation.

**MANUFACTURE:** Completely prefabricated. Tower structure based on 4 in. x 4 in. members with fan and gear supported on structural beams. Two-inch redwood in fan deck and stack. Internal gusset plate and bolt-type structural joints take both tension and compression loads. Over 250 tower sizes and combinations are furnished from only 258 prefabricated parts to enable fast delivery and erection.

### FLUOR COOLING TOWERS FOR AIR-CONDITIONING—

#### REFRIGERATION SERVICE

The new FLUOR SERIES L.H. is a small, compact cooling tower designed expressly for the air-conditioning and refrigeration industries. The height of the top deck above basin is less than eleven feet on all models. This low height is accomplished by the use of extended surface packing, and the advantages of counter-flow cooling are maintained. Construction is normally of Select Heart and Clear All Heart redwood with

sheathing of double-walled redwood or inner redwood with asbestos cement board outer.

Ten different models are available ranging from 150 to 1500 tons of refrigeration. This "package unit" meets the same high standards of performance, quality of construction, prefabrication and long-life service that are embodied in the larger Fluor Counterflow Towers. Write for Details.

Be Sure  
with Fluor

Memphis, Tennessee

### Good-Fellow COOLING TOWERS

**GOOD-FELLOW RS Series:** This series is suitable for residential application. Their compact size and extremely quiet operation make them suitable for this type of application. They are shipped completely assembled with lifetime lubricated, totally enclosed motor. *Bulletin PF56-1.*

RS Series

**GOOD-FELLOW PF Series:** These models are manufactured in tonnage from 8 to 100 TR. All sizes of this series are designed to withstand a wind pressure of 30 lb per sq ft. Large diameter, slow speed fans produce efficiency and quiet operation. *Bulletin PF56-1.*

Select Redwood fill is used in both the RS and P series. Salt and acid resistant mastic coating spray applied to the interior assures complete corrosion resistance. Normally shipped completely assembled, they can be separated for ease of installation and rigging.

The PF series conform to Military Specification MIL-T-16278B for Type 2, Style 2, induced draft cooling towers.

PF Series

**GOOD-FELLOW CF Series:** These models are produced in capacities from 2 to 100 TR. They are available with our standard corrosion resistant finishes or hot-dipped galvanized (after fabrication). Standard units have double air inlet and vertical discharge. Front or rear horizontal discharge and/or front or rear air inlet are available on order. This series is available with pump and motor mounted for uni-drive operation or with fan motor only, or with separate arrangement for close-coupled pump mounting. These models are leakproof. Models 15 tons and larger are constructed in three sections to facilitate erection and installation. They are normally shipped completely assembled.

The CF series conform to Military Specification MIL-T-16278B for Type 2, Style 1, or Style 2, induced draft cooling towers.

We believe the CF series is one of the most versatile types of cooling tower available. *Bulletin CF56-1.*

CF Series

## Havens Structural Steel Company

1713 Crystal Avenue • Kansas City, Missouri

**HAVENS TESTING TOWER . . .** This 80-ft testing laboratory is shown accurately measuring air quantity, water quantity and temperatures of a 50-ton Havens Cooling Tower for exacting tower performance. All Havens Towers are given this same rigid test, and a certified guarantee covers all phases of performances.

### HAVENS 2 TO 10 TON WRAPAROUND

. . . A small, economical tower that is ideal for light industrial and home use. Complete, lightweight and constructed for rugged service, it is furnished with combination motor cover and belt guard as are all Havens Towers. Lined inside and out with new HAVENS-COAT, it is guaranteed to withstand the corrosive effects of weather, salt air, water and chemicals.

### HAVENS 5 TO 60 TON KNOCK-DOWN

. . . Shipped assembled, this tower may be disassembled in a matter of minutes for installation in inaccessible places. Designed for medium size installations, it is constructed of heavy gauge steel sheets and select all heart California redwood and is, of course, lined inside and out with HAVENS-COAT.

**HAVENS 60 TO 200 TON . . .** A heavy duty tower in a completely new design that does a tremendous job for large installations. A unique bearing design cuts maintenance time and costs. The rugged construction of this tower plus HAVENS-COAT means years of lasting service.

**ALL HAVENS COOLING TOWERS** are available with erection yokes at no extra charge for rapid one-piece installation.

**WRITE FOR FREE BOOKLET GIVING COMPLETE DETAILS ON ALL HAVENS COOLING TOWERS**

## Halstead & Mitchell

Bessemer Bldg., Pittsburgh 22, Pa.

Plant: Zelenople, Pa.

One of the world's largest manufacturers of Counter-Flow, Water-Cooled Condensors

### HALSTEAD & MITCHELL COOLING TOWERS

The Halstead & Mitchell cooling tower saves and re-uses over 95 per cent of the cooling water used in an air-conditioning and refrigeration system. It does this by saving the thousands of gallons of water which would normally be wasted to the sewer each month by the conventional condensing system.

This economy of operation is one consideration. Waste of water is a second. With water tables falling throughout the country, many municipalities now prohibit wasting air conditioning cooling water, and Halstead & Mitchell cooling towers meet all local specifications in areas where their use is mandatory.

### H & M COMMERCIAL-INDUSTRIAL COOLING TOWERS

Halstead & Mitchell's WT and CT cooling towers are designed in a range of sizes from 5 to 60 tons specifically for industrial and commercial applications. Halstead & Mitchell makes cabinets of both 10-gauge and 14-gauge steel as a part of its regularly scheduled production, and all of these units are protected by the 20-Year Guarantee on the wetted deck surface against rotting or fungus attack. The *Protected Steel* concept also adds many vital years of life.

### H & M RESIDENTIAL COOLING TOWER

The Halstead & Mitchell Type RE residential cooling tower is for home use. This H & M tower incorporates major features found in larger cooling towers. H & M residential cooling towers are protected by the 20-Year Guarantee on the wetted deck surface against rotting or fungus attack. Deep pitch, 4-bladed fans insure quiet, efficient operation. The steel is specially protected, and fans are made of stainless steel. Capacities are 2 through 7½ tons.

### H & M TAKE-APART COOLING TOWER

This cooling tower can be taken apart for installation in difficult places, and can be moved easily to roof tops without the expense of riggers, or down narrow stair wells for basement installations. The K-Series of Halstead & Mitchell take-apart cooling towers is specifically designed for this feature. All of the important long life advantages have been built into the Take-Aparts. Capacities are 5 through 60 tons.

### H & M CENTRIFUGAL COOLING TOWER

Halstead & Mitchell's centrifugal fan cooling tower for home, hospital and other quiet applications can be relied on to meet the most stringent municipal decibel codes. These Type KB towers feature the 20-Year Guarantee on the wetted deck surface against rotting or fungus attack, as well as the *Protected Steel* concept which adds many years of life. They may be installed both indoors and out and are also of the Take-Apart design. Centrifugal fans are for duct-work installation. Capacities are 5 through 25 tons.

### H & M COOLING TOWER CONSTRUCTION DETAILS

#### 20-YEAR GUARANTEE!

#### ON THE WETTED

#### DECK SURFACE

against rotting or against damage due to fungus attack

#### WETTED DECK SURFACE

Halstead & Mitchell's use of Koppers Pressure-Creosoted wood makes possible a 20-Year Guarantee on the wetted deck surface against rotting or damage due to fungus attack.

Cutaway View, H & M Commercial Cooling Tower

#### MOTOR

Special weather and splash-proof, suitable for operating exposed under all weather conditions. Weather shield for motor pulley and belt on all except residential cooling towers permits operation even under icing conditions.

#### HOUSING

Halstead & Mitchell offers electrically welded sheet-steel cabinets of both 10-gauge and 14-gauge steel. The *Protected Steel* concept controls rusting with hydraulically applied coatings of Vinsynite, Vinyl Zinc and chlorinated rubber.

#### WATER DISTRIBUTION

Efficient gravity-type distributing pan eliminates extra pumping head required on spray type towers, and cuts down windage losses due to atomizing of water. The sump level is continuously and automatically controlled by float. (Note: Pumping head due to tower is represented by height of tower.)

#### DRIVE

Drive shaft is stainless steel. Fan bearings are . . . ball bearing . . . permanently grease sealed and lubricated . . . and protected against water drift. Belt tension is adjustable. RE tower motors are totally enclosed and thoroughly protected against moisture, fans being direct driven.

#### FANS

Deep-pitch, stainless steel, 4-blade fans. Type KB units use centrifugal fans for ultra-quiet operation.

#### COMPLETE ASSEMBLY

For installation in cramped quarters, towers with sectional housings are available. All towers easily accessible for cleaning through inlet in back.

## Heller Laboratories, Inc.

124 Fort Lee Road, Leonia, N. J.

SPECIALISTS IN WATER TREATMENT

Equipment, Chemicals and Service for Control of Scale, Corrosion, Algae and Slime  
Agents in Principal Cities

Heller Laboratories furnishes water treating equipment, analysis service and chemicals for treatment of any cooling water application, large or small. Heller Laboratories' chemicals are tailored to suit individual requirements determined after operating surveys and water analyses are made. Heller Laboratories furnishes treatment control equipment as listed below.

HYDROTROL for accurate concentration control and chemical feeding.

HYDROTROL maintains a desired fixed range of mineral concentration and feeds chemicals in proportion to requirements. HYDROTROL assures good treatment results and saves chemicals and water which are normally wasted when the usual fixed bleed-off method is used to reduce excessive mineral concentration.

Excessive mineral concentration is caused by adding natural minerals, contained in the fresh makeup water, but losing only pure water vapor from the system on evaporation. When mineral concentrations build up too high scale may form. When concentrations are too low corrosion may take place and treatment chemicals are wasted with the bleed-off.

Fixed bleed-off obtained by the usual float valve and overflow arrangement cannot maintain a fixed range of mineral concentration because the evaporation load in a cooling system is not fixed.

HYDROTROL does maintain a fixed range of mineral concentration and controls bleed-off and chemical feed in proportion to evaporation by means of differential level regulation. HYDROTROL works as follows: When a predetermined, fixed, adjustable amount of water is evaporated a fixed adjustable amount of water is bled off, then a fixed adjustable amount of chemical is added while the fresh water is added back to the full operating level.

HYDROTROL is entirely automatic and can maintain accurately a concentration as high as 50 cycles when windage loss is negligible.

HYDROTROL units are available from stock in three sizes: For systems up to 25 ton, 50 ton and 100 ton. Larger sizes are available on order.

HYDROTRON is a patented process and equipment used to apply an electro-physical treatment to control mineral scale formation. It is used for cooling systems working under difficult operating conditions where chemicals or softening are not practical or too costly for control of scale formation.

Water is treated electro-physically in the HYDROTRON unit by subjecting the water to a closely controlled and proper range of voltage while the water is brought into intimate contact with a special electrode. This treatment brings about a change in nucleation and crystal habit so that after treatment, when saturation is reached, hardness minerals are precipitated as a fine soft sludge instead of a cement-like coating on heat exchange surfaces. The sludge formed is removed by normal blowdown or flushing.

Hydrotron for Scale Control

The HYDROTRON Process is applicable for treatment of water for use in cooling systems, boilers, condensers, hot water generators and many other types of heat exchange equipment where scale forms due to concentration of hardness minerals.

HYDROTRON equipment requires very little attention or maintenance, gives life time service and saves the cost of chemicals used for scale control. HYDROTRONS are available from stock in sizes to treat up to 10,000 gph, larger sizes are available on order.

## Lilie-Hoffmann Cooling Towers, Inc.

Exclusive Builders of Cooling Towers Since 1898

1450 So. Vandeventer Ave., St. Louis 10, Mo.

Two Modern Plants—St. Louis, Mo., and Plainview, Texas

### INDUCED DRAFT TOWERS

New type filling reduces static pressure. Filling consists of slats, assembled in grids. Slat arrangement insures maximum wetted surface, minimum pressure drop of air flowing through tower packing, and uniform distribution of water and air over the entire effective area within the tower. Gravity distribution system requires only one riser pipe. Teco timber connectors develop 100 per cent working stress of members. Normally constructed of selected California redwood. All fans furnished by Lilie-Hoffmann are P.F.M.A. tested and certified.

### ATMOSPHERIC SPRAY TYPE

Generally offered in capacities up to 3000 gpm. Distribution by galvanized pipe header with smaller lateral arms, equipped with non-clogging spray nozzles. Water atomized as finely as possible. Sides and ends of towers equipped with narrow louvers, which fit into mast slots—no nails required. Recommended where cost is prime factor; and close approach to wet bulb is unnecessary.

### HORIZONTAL DRAFT (Package Type)

Designed specifically for 4 to 100 ton refrigeration installations. Structure and basin of California Redwood. Sides of corrugated and flat cement asbestos sheets with stainless steel trim; no painting required. Distribution of splash gravity type, non-sag, non-warp removable filling.

## The Marley Company

222 W. Gregory, Kansas City 14, Missouri

Representatives in All Principal Cities (Consult Classified Phone Directory)

Water Cooling Towers of All Types and Capacities.

**MARLEY DOUBLE-FLOW AQUATOWER** . . . Series 8 and 12 of this "low silhouette", low pumping head cooling tower fill every intermediate capacity cooling requirement for air conditioning and refrigeration. They combine the efficiency of Marley Double-Flow design with the simplicity of Marley Aquatowers. Mechanical equipment has been field proved in thousands of Marley industrial installations. Available with either wood or steel structure for easy job erection, for either single or multi-cell installations. Write for *Bulletin DFA-56*.

**MARLEY AQUATOWER** . . . Available in a complete range of 11 sizes, rated for servicing from 3 to 60-tons of air conditioning or refrigeration. Thousands of steel packaged units have proved themselves in years of maintenance-free operation. They are stocked by dealers throughout the country—are shipped completely assembled and require no field construction. Large units may be readily disassembled for easy handling. Write for *Bulletin AQ-56*.

**MARLEY FORCED-DRAFT WOOD AQUATOWER** . . . This new series of cooling towers, specifically designed to combat corrosive atmosphere and water, is produced in 10 models for services of 3 to 50 tons. It utilizes the forced-draft, cross-flow and vertical discharge principles. Because air discharge is vertical, these towers are applicable to many restricted locations. Tower structure is all redwood with heavy asbestos cement board or wood casing; fan and mechanical equipment are located out of hot, humid air stream. Small models are factory assembled; larger models are shipped disassembled. Write for *Bulletin WAQ-56*.

**MARLEY SPRATOWERS** . . . These heart quality redwood cooling towers are available in two series, one designed primarily for air conditioning and refrigeration applications up to 50 tons and a series of larger towers which are built in standardized units for larger capacities and are also available with atmospheric sections for cooling of jacket water, oils and gases. Write for *Bulletin ST-56*.

**MARLEY COUNTER-FLOW SERIES, STEEL AND WOOD** . . . This series of Marley counterflow cooling towers is designed especially for heavy duty air conditioning and refrigeration service wherever appearance is important. The all-steel model (with the exception of corrugated asbestos cement board casing) is designed to meet fire codes in all metropolitan areas. Both the steel and wood models blend well with modern architecture. May be installed with any combination of louvered walls open providing unusual flexibility and maximum utilization of usable space. Write for *Bulletins CS-56 and CW-56*.

**MARLEY CROSS-FLOW** . . . For large capacity industrial cooling, Marley offers 3 towers that utilize the patented Marley Cross-Flow principle—The Double-Flow, Twin-Flow and Single-Flow. Write for *Bulletin CF-56*.

220 Dupont St., Brooklyn 22, N. Y.

Phillips Standard Induced Draft Counterflow cooling towers are designed in Steel and Corrugated Transite, Redwood and Corrugated Transite, or all Redwood in sizes from 150 tons upward. Transite Siding is attached to tower frame by use of Stainless Steel fastenings to prevent staining or deterioration. All steel in Standard Towers is *hot dipped galvanized after fabrication*. All California Redwood is of Select Heart grade. The slip-fit fill construction and box type drift eliminators are extremely efficient and produce maximum cooling with minimum water loss. Fans are of Stainless Steel or Cast Aluminum with low tip speed to reduce sound level to a minimum. Right angle worm gear drives having tapered roller bearings and forced feed lubrication are used to assure long trouble-free life. Weatherproof motors of standard makes are supplied on all models. Bulletins PC-211 or 212.

Phillips Standard Induced Draft Counterflow

Phillips Special Steel &amp; Transite

Phillips Special Steel and Transite

Phillips Spracoolers or Natural Draft Cooling Towers are designed in Steel and Transite, or California Redwood. This type of tower is available in sizes up to 150 tons. It is particularly adaptable where space is not limited and air circulation is not restricted. Bulletin PC-209.

Phillips Spray Ponds and Spray Pond Fences are available in all sizes and arrangements. Bulletin PC-213.

## ACME INDUSTRIES, INC.

JACKSON, MICHIGAN, U. S. A.

Manufacturers of Quality Air Conditioning and Refrigeration Equipment since 1919

37 years experience stands behind these ACME products

Since 1919 Acme has been building units to serve the air conditioning and refrigeration field. They have experimented with thousands of models and installations. Today, Acme has a complete line of commercial refrigeration and air conditioning equipment. Specify Acme on your installations.

### ACME DRY-EX WATER CHILLERS

For cooling water, brines, and other fluids by direct expansion of the refrigerant. Capacities from 5 to 300 ton.

### FREON and AMMONIA CONDENSERS

The standard of the industry. Enough production combinations to assure you of the most efficient operation available. Capacities from  $\frac{1}{2}$  to 700 ton.

### THE FLOW-COLD LINE

A factory assembled and tested packaged liquid chiller designed for industrial process temperature control and air conditioning. Used as a heat pump for both heating and cooling. Capacities—3 through 20 ton.

### FLOW-THERM LIQUID CHILLER

Complete, compact, packaged units of advanced design for air conditioning, heat pump and liquid cooling applications. Proven Acme components pre-piped, tested and ready for operation. With compressor or without. Capacities—20 through 300 ton.

### EVAPORATIVE CONDENSERS and COOLING TOWERS

Solid, sturdy, dependable. All fabricated steel parts are hot-dip galvanized after fabrication assuring long life. Prime surface coils or specially designed Acme Pak for Freon or Ammonia installation. Capacities from 2 to 150 ton.

### HEAT EXCHANGERS, LIQUID RECEIVERS, OIL SEPARATORS

Freon suction and liquid line heat exchangers with capacities from 3 to 200 tons; more than 70 standard sizes of liquid receivers for Freon, Ammonia, or other refrigerants; and a complete line of Freon or Ammonia Oil Separators for  $\frac{1}{4}$  to 100 ton systems.

Write for catalogs and more information on any ACME product.

Standardized Light-weight Heat Exchange Surface

There is a factory-trained Aerofin application and service engineer located near you to give you prompt service. Write, wire or phone the factory.

Aerofin is the modern Standardized Light-Weight Encased Fan System Heating and Cooling Surface originated by Fan Engineers to meet the present and future requirements of this highly specialized field. All Standard AEROFIN Units are furnished as completely encased Units, ready for pipe and duct connections. The patent casings are built of pressed steel and are exceptionally strong and rigid, protecting the Unit from all the strains of pipe connections and expansion or contraction in service. The casings are flanged on both faces, top and bottom, and template punched for bolting together adjacent Units, or for duct connection.

Fig. 1

Aerofin Non-freeze heater (Fig. 1) is non-freeze, non-stratifying spiral fin coil built into casing for air conditioning

units or for installing in ducts. May be installed either horizontally or vertically. Used on any two-pipe steam system for preheating or reheating. Modulating control on preheaters.

Available in 13 lengths and 3 widths, from net face area of 2.76 sq ft to 26.28 sq ft.

Fig. 2

Flexitube Aerofin (Fig. 2) is distinguished from all other developments by its off-set tubes, so arranged as to absorb all expansion and contraction strains.

Headers—Steel.

Tubing— $\frac{5}{8}$  in. O.D. copper, admiralty or aluminum.

Joints—Where admiralty or copper tubes are used together with bronze or steel headers tubes are brazed to headers. Where both aluminum tubes and headers are used tubing is welded to headers.

Casings—Copper, aluminum or galvanized iron.

Design—Constructed with headers on opposite ends making possible installation of units with tubes horizontal or vertical.

Fig. 3

Universal Aerofin (Fig. 3) is distinguished by its "S" bend construction of tubing, units designed with steel headers on opposite ends, the ends of the "S" bends being connected thereto by compression nuts, the bends taking care of the expansion and contraction of the tubing.

Recommended where close control is desired.

Headers—Pressed steel.

Tubing—1 in. O.D. copper or admiralty.

Casings—Copper, aluminum or galvanized iron.

Fig. 4

Aerofin Heavy-Duty Industrial Heating Coil (Fig. 4) for use where extra-rugged coil is needed for close control. Steam pressures from 25 to 450 lb gauge; temperatures to 550 F.

Headers—Pressed steel.

Tubing—1 in. O.D. heavy copper.

Casings—12-gauge galvanized iron.

Fig. 5

Booster Aerofin (Fig. 5)—straight tube type, single pass construction for pressures from 1 to 200 lb gauge.

Headers—steel.

Tubings— $\frac{5}{8}$  in. O.D. copper.

Casings—copper, aluminum or galvanized iron. Recommended where small coils are needed or to raise the air temperatures in branch ducts.

Fig. 6

Narrow Width Aerofin: (Fig. 6) recommended for water cooling or for flooded Freon systems. Made in straight tubes only with headers on opposite ends, joint between headers and tubing being brazed. Construction similar to Flexitube AEROFIN.

Fig. 7

Aerofin Continuous Tube Water Coils (Fig. 7) are designed for air cooling by circulating cold water through the AEROFIN and air over extended fin surface. Made for either horizontal or vertical air flow.

Tubes and fins are copper, completely tinned with permanent metallic bond between fin and tubes. Headers are made of steel and casings of heavy galvanized iron or copper.

Tested to 250 lb air with coil submerged in water.

Fig. 8

Aerofin Cleanable Tube Units (Fig. 8) for cooling only made with headers removable to permit cleaning tubes. Recommended for use where sediment or scale forming chemicals are present in the cooling water.

Headers—Fabricated steel.

Tubing—Copper or admiralty.

Casings—Copper or galvanized iron.

Fig. 9

Aerofin Direct Expansion Units: (Fig. 9) Centrifugal Header Type—For cooling air, using Freon expanded directly into the coil.

#### AEROFIN Sizes

Flexitube: 13 standard lengths, three widths, one and two rows deep.

Narrow: same as Flexitube.

Universal: 17 standard lengths, two widths, one and two rows deep.

Continuous Tube: 13 standard lengths, three widths, 2-3-4-5 and 6 rows deep.

Cleanable Tube: 17 standard lengths, one width, 2 and 4 rows deep.

Direct Expansion: Centrifugal Header—11 standard lengths, three widths, 2-3-4-5-6 rows deep.

Steel Supporting Legs: 18 in. and 24 in. high. Punched same bolt hole centers as standard casings. Quickly attached. No other foundation required.

Sale: AEROFIN is sold only by manufacturers of nationally advertised Fan System Apparatus. List upon request.

Write Syracuse for Heating Bulletin H-45; Direct Expansion Bulletin DE-48-1 on refrigeration type units; Continuous Tube Bulletin C.T. 39-2 for Water Cooling coils; or pamphlet on Cleanable Type Aerofin for cooling.

## The G & O Manufacturing Company

138 Winchester Avenue

New Haven 8, Connecticut

### INDIVIDUAL AND STRIP FIN TUBING

We manufacture a complete line of high efficiency heat transfer surfaces in a wide range of standard sizes with individual square, round and oblong fins.

The use of individual fins permits using fins in groups at intervals along the straight length of any tube for the manufacture of U-bends, continuous return bend, and spirally wound coils. Where space permits, the use of square or oblong fins provides proportionately greater surface than a round fin of a diameter equal to one side of the square or oblong fin.

G&O Individual Fin Tubing is available for heating coils of every description, including unit heaters and blast coils, intercoolers, aftercoolers, baseboard radiation, and convactor elements.

### STRIP FIN TUBING

Continuous strip aluminum fin tubing is particularly suited for cooling and air conditioning coils. The lightweight all aluminum construction is of advantage in installation where weight is an important factor. Various fin spacing is available and sections can be stacked to provide any practical number of rows in direction of air flow within the limits of maximum height and width area dimensions.

G & O continuous strip fin coils are produced in two standard sizes:  $\frac{3}{8}$  in. O.D. tubing with  $\frac{1}{8}$  in. wide continuous strip fins, or  $\frac{5}{8}$  in. O.D. tubing with  $1\frac{1}{4}$  in. wide continuous strip fins.

RADIATING ELEMENTS FOR ALL HEAT TRANSFER PURPOSES ARE AVAILABLE IN A WIDE RANGE OF SIZES

Continuous Strip Fin, All Aluminum Cooling Coil

Standard No. 10

**p-k Balance Loader:** Standard capacities range from  $\frac{1}{2}$  to 50 tons. Shell sizes available from  $4\frac{1}{2}$  in. by  $12\frac{3}{4}$  in. to 14 in. by 90 in. Three types available, depending on application—trombone design, shell and coil, and shell and tube.

**p-k Storage Cooler:** Available in all commercial metals. Sizes range from 24 in. by 48 in. to 60 in. by 192 in. Designed for service where requirements are not constant or where a large volume of fluid must be held in storage for peak load periods.

**p-k Slug Eliminator:** A combination trap and heat exchanger that changes slugs of liquid refrigerant into gas before they reach the compressor. Standard capacities range from  $\frac{1}{2}$  to 60 tons.

**p-k Freon Condensers:** Capacities  $5\frac{1}{2}$  to 410 tons. Shell sizes from 8 in. by 48 in. to 24 in. by 168 in. Two or 4 pass design, built in accordance with ASME code. The integral finned copper tubing is electronically expanded to assure water-tight joints.

**p-k Dry Expansion Freon Cooler:** Catalogued from 2 tons to 232 tons. Shell sizes range from 6 in. by 40 in. to 26 in. by 220 in. Standard units are available in 1 and 2 circuit design arrangements, 3 and 4 circuit arrangements are available on request. Can be constructed of carbon steel, galvanized steel, stainless steel, cupro-nickel, silicon bronze or other alloys.

# Rittling

## The Rittling Corp.

103 Kentucky St.  
Buffalo 4, N. Y.

Representatives in Principal Cities  
Warehouses—Buffalo, Albany, Philadelphia, Chicago  
Factories—Hamburg and Brooklyn, N. Y.

Manufacturers of residential and non-residential Baseboard and Finned Tube Radiation, Convector-Radiators, Finned Tube Surface, Unit Ventilators and Air Conditioners, Unit Heaters, Back Draft Dampers, Air Cooled Condensers, etc.

### RITTLING BASEBOARD RADIATION

### RITTLING HEAVY DUTY RADIATION

### RITTLING UNIT HEATERS

**Rittling Baseboard Radiation.** Complete line of Snap-On and PRE-FAB units for fast installation. Heating element—choice of two tube aluminum finned copper tube or single tube copper tube with steel fins. Write for catalog.

**Rittling Heavy Duty Radiation.** Complete line of heavy duty all-steel or steel finned copper tube units for commercial and industrial use. Flat and sloping top enclosures for wall and baseboard installations. Write for complete catalogs.

**Rittling Unit Heaters.** Horizontal and vertical types. Capacities from 100 to 2000 EDR. Write for catalog.

### RITTLING CABINET CONVECTORS      RITTLING BACK DRAFT DAMPERS

**Rittling Cabinet Conectors (left).** Six standard cabinet styles. Aluminum finned copper tube elements with copper headers for use with steam or forced hot water. Write for catalog giving capacities and dimensions on all sizes.

**Rittling Back Draft Dampers (right).** For high or low velocity. Positive seal. Extremely sensitive, quiet, non-metallic blades. Write for catalog.

### RITTLING UNIT AIR CONDITIONERS

Unit Ventilators for heating and cooling schoolrooms, hotels, hospitals, office buildings, apartment houses and residences. Simplified design and controls give impressive savings on first cost and maintenance. Write for catalog.

## The Rome-Turney Radiator Company

Erie Boulevard, East

Rome, N. Y.

Manufacturers of "Ro-Fin" Extended Surface (continuous helical fin) Tubing for Heat Transfer

### Nearly 100 Sizes of Helical Fin Tubing in Production

Straight lengths up to 30 feet long . . . coils . . . U-bends . . . tube-within-tube coils—sizes suitable for use with standard solder or flare-type fittings. "Ro-Fin" Tubes are adaptable for a wide variety of heat transfer equipment, meet the requirements of the most rigid specifications!

Outside tube diameters from  $\frac{1}{4}$  inch to  $1\frac{1}{2}$  inches, fin widths from  $\frac{1}{8}$  inch to  $\frac{3}{4}$  inch. Number of fins per inch ranges from 3 to 14. "Ro-Fin" tubing is made up in long, continuous lengths to meet customers' specifications. Stainless and other kinds of tubes furnished on special order.

### AIR HEATING AND AIR COOLING CASED COILS

Two foot to ten foot lengths; 3 pace widths, approximately 12 inch, 18 inch, and 27 inch—custom sizes made to your specifications when required.

### ROME CONVECTOR RADIATOR

For heating residential, commercial, or public buildings. Free standing and wall-hung cabinet styles in ten lengths and four depths for steam and forced hot water installations. Non-ferrous fins on copper tube with brass and iron headers.

# SLANT-FIN RADIATOR CORPORATION

87-67 130th Street

Richmond Hill 18, N. Y.

SQUARE-FIN SERIES

SLANT-FIN SERIES

Interlocking Flanges

Increased Surface

## FEATURES OF DESIGN AND CONSTRUCTION

1. **FIN TO PIPE BOND.** Pipe is forced through undersize holes in fins under hydraulic pressure. Pipe is not expanded. Fins do not cut into pipe surface. The result is a strong union of pipe and fin.

2. **THERMAL BONDING.** Standard pipe is rolled to uniform round diameter. Wide flanges of fins press solidly against entire surface of pipe.

3. **SPACING AND STRENGTH OF FINS.** Because of the uniformly wide flanges and their interlocking features, the fins fit tightly one into another.

4. **EFFICIENT AIR CIRCULATION.** Because of the increased surface, fewer of the distinctive "V" shaped slant fins than the traditional square fins can furnish the same radiation per linear foot of pipe. Therefore, fins can be wider apart and a greater volume of air flows more freely.

5. **NO SNAPPING—NO BUCKLING OF FINS.** Because of the patented notched flange, the slant-fin can expand and contract without disturbing the bond to the pipe, even under high steam pressures. The result is a radiator that is trouble-free.

## SPECIFICATIONS

1 1/4 in. IPS and 2 in. IPS steel pipe with steel fins

1 1/4 in. nominal hard copper water tube with copper or aluminum fins.

Square-Fin Spacings: 24, 32, 40 and 48 fins (4 1/4 in.) per foot.

Slant-Fin Sizes: 4 3/4 in. x 3 1/2 in. bent at 45 degrees to 3 1/2 in. x 3 1/2 in. and 5 3/8 in. x 4 1/4 in. bent at 45 degrees to 4 1/4 in. x 4 1/4 in.

Stock lengths in every integral foot from 2 to 12 feet. On specification, lengths up to 12 feet fabricated to nearest inch.

Slope-Top Enclosure

Snap-On Enclosure

Flat-Top Enclosure

Expanded Metal Cover

**RESIDENTIAL BASEBOARD HEATING** for Steam or Hot Water with a choice of 3 heating elements and 2 enclosure styles.

**CATALOG No. 505** for details on "Slant-Fin" and "Square-Fin" radiators and enclosures for commercial and industrial applications. **BULLETIN No. R-602** for residential baseboard heating.

# The Vulcan Radiator Company

26 Francis Avenue

Hartford 6, Conn.

Representatives in Principal Cities

Vulcan Radiation (Linovector) is used in schools, industrial plants, hospitals, office buildings, churches, railroad cars and ships.

Available in steel or copper . . . easy to install . . . light in weight . . . requires few fittings and supports . . . tube ends threaded or chamfered for welding. Heat distribution is uniform. Steel radiation comes in two sizes . . . 2 in. IPS, rated—5 1/4 sq ft per lineal ft at 1 lb steam and 65 deg air . . . for 1 1/4 in. IPS see illustration—this size also available in copper. Illustrated catalog available.

Standard Grille Cover  
Type F  
Type S  
1-B-R Ratings for Vulcan Linovector available in catalog 825 B.

Vulcan Radiation is fabricated by mechanically imbedding offset fins or plates on seamless steel pressure tube or copper water tube. The patented offset fin construction gives complete rigidity to the entire assembly and extends the heating surface of the tube.

Because of its comparatively light weight and compactness, Vulcan Radiation responds quickly to thermostatic control. Full heat output is obtained almost immediately after steam is supplied. Since most of the heat is given off by convection, the result is **EVEN, UNIFORM HEAT** from floor to ceiling.

1 in. IPS TRIMLINE covers in continuous lengths up to 15 ft. Built of .034-gauge galvanized steel  
1-B-R ratings for Vulcan Radi-Vector available in Catalog No. 64.

**Vulcan Baseboard Radiation . . . fin-on-tube construction with TRIMLINE covers** combines radiant and convection heating. High safe working pressure . . . either hot water or two-pipe steam systems. Light in weight . . . easy to install . . . requires few fittings or supports. Comes in two sizes . . . 1 in. IPS . . . steel fins 2 3/4 in. wide by 3 3/4 in. high and 1 in. IPS, 2 in. x 4 1/4 in. . . for 1 in. IPS, see illustration. Also available in copper. Illustrated catalog available.

## Brunner Manufacturing Company

Dept. M-56, Utica, New York, U. S. A.

The Brunner Co., Gainesville, Ga.

In Canada:

Brunner Corp. (Canada) Ltd., Toronto, Ont.

Refrigeration Air Conditioning Air Compressors Industrial Gas Compressors

**PRODUCTS:** Refrigeration compressors and condensing units for commercial and industrial use—motor-compressor units for use with evaporative condensers, 2-stage and sub-zero units, truck units, self-contained and remote air conditioning. Also complete line of single and two-stage air compressors for pneumatic control and industrial applications. Industrial Gas Compressors for transferring Liquefied Petroleum Gas, Anhydrous Ammonia and booster for natural gas in manufacturing plants.

**Refrigeration Compressors**  
Complete line of 2, 4 and 8 cylinder refrigeration compressors, adaptable to any need. Designed for slow-speed operation, less wear, longer life. F-12 and F-22.

**Water-Cooled Condensing Units**  
 $\frac{1}{8}$  hp to 100 hp, for every commercial and industrial use. "Freon-12" or "Freon-22" refrigerants, with cleanable condensers.

**Industrial Refrigeration**  
Sizes up to 100 hp, complete line of water-cooled condensing units and compressor units for use with evaporative condensers, for industrial refrigeration and air conditioning use. Capacity controls available.

**Semi-Hermetic Condensing Units**  
Brunner-Metetics—Commercial and Low Temperature applications. Air-Cooled models, in  $\frac{1}{4}$ ,  $\frac{1}{2}$ ,  $\frac{3}{4}$ , 1, 1 $\frac{1}{2}$ , 2 and 3 hp. Water-Cooled models, in  $\frac{1}{8}$ ,  $\frac{1}{4}$ ,  $\frac{1}{2}$ , 1, 1 $\frac{1}{2}$ , 2 and 3 hp.

**Air and Air-and-Water Cooled Condensing Units**  
 $\frac{1}{4}$  hp to 3 hp, for "Freon-12" refrigerant, finned tube condenser. Also  $\frac{1}{2}$  hp to 3 hp combination air and water-cooled units, with cleanable condensers, to handle fluctuating refrigeration loads.

**Air Compressors**  
Complete line—single stage from  $\frac{1}{4}$  hp to 2 hp, two stage from  $\frac{1}{2}$  hp to 50 hp. Air compressors 5 hp and over available with water-cooled after-cooler.

**Air Conditioning Units**  
2, 3, 5, 7 $\frac{1}{2}$ , 10, 15 and 20 hp sizes, completely self-contained, in various styles for commercial and residential use. Easily installed.

## Copeland Refrigeration Corporation

Sidney, Ohio

COPELAND compressors, motor-compressors and condensing units for all applications

### COPELAMETIC

#### The Accessible Hermetic

Direct-drive Copelametic units are completely accessible, making on-the-spot servicing a plus value. There are no belts or seals. No manual oiling is required. Ninety per cent of service costs removed by these features. Copelametic motor-compressors have rugged, cast-iron bodies; bronze rods, bushings and bearings; Swedish steel valve reeds. Copelametic offers unusual economies: quiet operation, long life and dependability. There are units for all applications... on thermostatic or automatic expansion valves, high- or low-side floats and capillary tubes. Remote, water-cooled from  $\frac{1}{4}$  hp through 7 $\frac{1}{2}$  hp. Air-cooled from  $\frac{1}{8}$  hp through 3 hp. Self-contained models through 2 hp.

Model E-55

Model Z-800W

1 $\frac{1}{2}$  hp Copelaweld

### COPELAWELD MOTOR-COMPRESSORS

Engineered to Copeland's high standards, the welded motor-compressors give maximum economy in package air conditioners, water coolers, refrigerators and other equipment. Cool-running, two-cylinder Copelawelds are free from vibration and chatter. High quality, one-piece body casting for positive alignment of motor and bearings. Solid bronze rods and main bearings assure long wear. Compact size conserves space. Efficient oil pump has no moving parts, will operate in either direction. Heavy-duty, high-power-factor motor delivers high

Model ZR-300H

capacities at low power input. "Freon-12" and "Freon-22" models.

### CONDENSING UNITS WITH SUCTION-COOLED MOTOR-COMPRESSORS

Suction-cooling affords greater flexibility of installation, since no water is required. These larger sizes make possible even wider applications. 2 hp and 3 hp have a centrifugally-forced oiling system. Larger sizes incorporate a gear pump. Both systems allow motor-compressor to operate in either direction. From cast body to solid bronze rod, bearings and bushings, and Swedish steel valve reeds it is quality built. Units have oversize condensers for maximum efficiency in high ambient temperatures. Designed especially for air-conditioning and other high-suction pressure applications. Sizes 2, 3 and 5 hp.

ESTABLISHED 1884

**Products:** Full line of Packaged Air Conditioners from 3 through 20 ton, Condensing Units from 1/4 through 100 hp with Cooling Towers, Air Handling Units to match, Packaged Water Chillers 7 1/2 through 100 hp, Waterless Air Cooled Packaged Condensing Units, 2 through 7 1/2 hp, Residential and Commercial.

15 hp Cleanable Shell and Tube Condensing Unit. Other sizes from 7 1/2 to 100 hp.

### COMMERCIAL REFRIGERATION

Air cooled condensing units from 1/4 to 3 hp, inclusive, combination air and water cooled units from 1/2 to 3 hp, inclusive, and water cooled units from 1/2 to 40 hp, inclusive. All models charged with Freon 12 refrigerant. Mechanical advantages include Timken Bearings, Positive Pressure lubrication. Special models are available for ice cream, frozen food cabinets and for the dairy industry.

Packaged Water Chiller 7 1/2 through 100 ton. For process or solution cooling and various other types of liquid chilling applications.

Waterless Air Cooled Packaged Condensing Unit (right) for residential and commercial application 2 through 7 1/2 hp.

Packaged Air Conditioners (Left) in many combinations of pastel colors 3 through 20 ton.

Manufacturers of Gas and Diesel Engine  
Driven Generators and Air Conditioning  
Units; Gas and Diesel Electric Power  
Units for Industrial Trucks.

Ready-Power Engine Driven Compressor Units are designed and built to meet the need of (1) Low operating cost air conditioning and refrigeration employing NATURAL GAS fuel and (2) Air Conditioning and refrigeration where electric power is not available or high in cost. It is particularly adaptable to portable equipment for cooling airplanes, before take-off, for pre-cooling perishable food shipments by rail or truck, and for installations in refrigerated rail cars and trucks.

### CAPACITY MODULATION

The Ready-Power inherent system of capacity modulation permits operation of the compressor to meet the needs of varying conditions. This assures much better control of temperature and humidity conditions than is possible with the usual "on and off" system generally used with electrically driven equipment.

On units of 15 to 70 ton the capacity modulation is controlled both by varying the engine speed and by unloading the cylinders of the compressor. Since

engine speed can be varied from maximum to less than half of maximum this more than doubles the usual advantages obtained from unloading.

On the smaller units, the capacity modulation is controlled entirely by engine speed variation.

All capacity modulation is automatically controlled.

### UP TO 70 TON RANGE

Unit capacities range up to 70 tons for air conditioning and multiple unit installations of more than 150 ton are in successful operation.

Compressor units are adaptable for use with evaporative condenser, heat exchanger or radiator cooling of the engine. Water cooled manifolds are standard on some models and available on all models. Engine starting is by either storage battery or a-c Motor.

All units are supplied for operation on Natural Gas, Gasoline, Propane or Butane fuels.

Units of 15 ton and larger are also available for operation on Diesel fuel.

Standard Assemblies for Every Air-Moving Requirement

### BELT-DRIVEN AND DIRECT-DRIVEN DUCT

Easily installed in present ducts for hazardous and non-hazardous atmospheres. In sizes 12 to 84 in. with 2, 4, 6 or 7 blades for capacities to 120,000 cfm.

### DIRECT CONNECTED

Heavy-duty units for all industrial applications. Steel ring and panel types. In sizes 9 to 84 in. with 2, 4, 6 or 7 blades for capacities to 120,000 cfm.

### "BI-FLO" DUCT

New divided-duct design for duct or stack installation. Available with new 7-blade Semi-Pressure propeller. Sizes 16 to 48 in. for capacities to 40,000 cfm.

### MANCOOLERS

Four models for any industrial cooling, drying, exhausting or ventilating requirement. Sizes 16 to 48 in. for capacities to 40,000 cfm.

### MATERIALS HANDLING

Reversible rotation and adjustable air discharge for conveying production and waste materials, dust collecting or exhaust. Wheel diameters 19, 26, 33, 40, 51 in.

### VANEAXIAL

Maximum efficiency against resistances to 6½ in. S.P. High-velocity, straight-line air discharge. Sizes 12 to 48 in. for capacities to 77,000 cfm.

### ROOF VENTILATORS

Three types for all industry exhaust and air supply requirements. All-weather construction for use in all climates. Sizes 12 to 72 in. Capacities to 80,000 cfm.

### CERTIFIED RATINGS

All Aerovent Fans are tested and rated in accordance with the Standard Test Code for Centrifugal and Axial Fans and conform with U. S. Department of Commerce Commercial Standard CS178-51.

FC Junior Fans

**EX FAN**—Radial blade fan used chiefly for conveying materials, fume exhaust, etc. Manufactured in 15 sizes, single width only, all arrangements, 5 classes of construction, 3 wheel types. Request *Bulletin 461*.

**UTILITY SETS**—Self contained units for a wide variety of ventilating applications. Manufactured in 14 sizes with forward curved rotors, 12 sizes with backwardly inclined blade rotors, single width only. Request *Bulletins 610-A, 611-A*.

**FC JUNIOR FANS**—Self contained direct connected fans with forward curved rotors. Manufactured in 5 sizes with 13 motor speeds, single width only. Request *Bulletin 422*.

HV Units

Roof Ventilator

Type AR Roof Ventilator

**HV UNITS**—Heating and ventilating unit of universal design. Can be furnished with air filters, face and by-pass dampers or mixing box. Manufactured in 7 sizes with unlimited flexibility as to arrangement. Request *Bulletin 510*.

**ROOF VENTILATOR**—Backwardly inclined blade centrifugal type. Manufactured in 13 belt driven and 12 direct driven sizes with steel, aluminum, copper or stainless steel housings. Request *Bulletin 410-A*.

**TYPE AR ROOF VENTILATORS**—Backward inclined blade centrifugal type. All units fabricated from spun aluminum. Available in both direct connected and belt driven models. Request *Bulletin 411*.

## Bayley Blower Company

1821 S. Sixty-Sixth Street Milwaukee 14, Wis.  
 Branches in Principal Cities  
 Engineers and Manufacturers of Fans, Washers,  
 Heaters and Other Air-Handling Equipment

### CENTRIFUGAL FANS

Bayley offers a complete selection of types, sizes and arrangements of centrifugal fans for ventilating, conditioning, industrial, and mechanical draft service, with slow-speed, power-limiting, or medium speed wheels. Made in single or double widths, with capacities up to 300,000 cfm or more. Smaller sizes have reversible housings for convenience and economy.

Type F  
Ventilating Fan

Vent Set

Type AP  
Ventilating Fan

**VENTILATING FANS AND PACKAGED SETS** Type "F" Fans are equipped with wheels having forward-curved floats, effecting a slow-speed characteristic. The floats of the wheels supplied with Type "AP" Fans are backwardly inclined, producing a non-overloading characteristic. Choice of fans is determined by the design conditions of the individual installation.

Compact, unitary Ventilating Sets are manufactured with drive complete, ready to use, direct-connected and belted styles with capacities to 15,000 cfm. These handy units serve a wide variety of applications in ventilation and exhaust, for kitchens, lavatories, gymnasiums, restaurants, garages, halls, hospitals, laboratories, industrial plants, and many other locations. May be used for supply, exhaust or both. They can be equipped with weather-protection hood for outdoor or penthouse installation. Carefully engineered and sturdily built to give long-lasting, efficient service.

Type EX  
Industrial Fan

**INDUSTRIAL FANS** Bayley Industrial Fans are available in a wide range of sizes and constructions from which to select the unit best fitted for any application in exhausting, conveying, cleaning, drying, blast, draft, or similar duties. Type "EX" is proportioned primarily for medium pressures and capacities usually encountered in materials handling or exhaust. Type "H" is similar, but proportioned for relatively higher pressures and smaller volumes. Designs are adaptable to suit virtually any requirement of temperature, corrosion-resistance or other severe operating conditions.

Turbo Washer

**AIR WASHERS** Because Turbo washers atomize by mechanical means, they cannot clog, hence are admirably suited to handling air contaminated with particulate matter. Standard pressure-nozzle washers also available for use where dust content is light.

Chinook Heater

**BLAST HEATERS** The finless, long lasting iron pipe coils of Chinook Heaters will not clog, therefore maintain full capacity longer. Pipe-within-a-pipe arrangement has single heater for supply and return, cannot short-circuit, and absorbs expansion and contraction without damaging stresses.

## The Bishop & Babcock Mfg. Co.

Massachusetts Blower Division

4901 Hamilton Ave.

Cleveland 14, Ohio

S.C.  
(F.C.)

P.F.  
(B.C.)

### SQUIRREL CAGE AND POWER FIXED FANS

Squirrel Cage (forward curve) and Power Fixed (Backward curve) Fans available in a complete range of sizes—single or double width. For all types of commercial and industrial air conditioning and exhaust systems. *Bulletin 101* (P.F.) *Bulletin 105* (S.C.)

### MASSACHUSETTS UNIT HEATERS AND AIR CONDITIONING UNITS

Both floor and ceiling mounting arrangements available. These units are built in sections to facilitate efficient handling and erection. Offered in a wide range of popular sizes with various heating and cooling coil combinations. *Bulletin 112* (Unit heaters) *No. 120* (A.C. Units)

### POWER ROOF VENTILATORS

Propeller fan type features a steel venturi-type inlet orifice, belt or direct drive. Power fixed type has backward curve wheel, belt or direct drive. Both offered in a wide range of competitive sizes. *Bulletin No. 118* (Power fixed) *No. 124* (Propeller fan).

### BELT OR DIRECT DRIVE UTILITY TYPE VENTILATING SETS

Belt drive wheel diameters 7 in. to 30 in., direct drive 6 in. to 13½ in. Both available in popular competitive sizes. *Bulletin No. 109.*

### PROPELLER FANS

New venturi-type propeller fans. Belt drive 24 in. to 48 in. wheel diameters. Direct drive 12 in. to 30 in. wheel diameters. A complete line of accessory items are available. *Bulletin No. 117.*

**UNIVERSAL BLOWERS** (at left). A stock blower assembly made in single or double width, sizes 7 in. to 27 in. wheel diameter and features universal discharge arrangement. *Bulletin No. 110.* **DESIGN 2 A.C. BLOWERS** (at right). Available in single, double or special width. All housing and wheel parts are die formed and are offered as complete assemblies or parts only. *Bulletin No. 115.*

## Bronson Fan Manufacturing Corp.

4560 Worth Street, Los Angeles 63, Calif.

Representatives in Principal Cities

Manufacturers of Propeller Type Fan Blades for Air Conditioning, Heating and Ventilating Equipment.

Tested and rated according to *NAFM* and *NEMA* codes.

Hi-Static Series

**HI-STATIC SERIES**—Quiet operation against static resistances. Gives high air volumes at reduced fan depth. Diameters 11 in. through 16 in. Neoprene hubs available.

**HI-STATIC SLINGER RING**—Condensate eliminating fan blade for use in air conditioning units where space is a factor. Exceptionally low noise level.

Hi-Static Slinger Ring

Static Pressure Series

**STATIC PRESSURE SERIES**—For efficient air deliveries against static pressures. Diameters 8 in. through 20 in. Pitches 6 deg to 40 deg. Also in **THREE BLADE SERIES**.

**STATIC PRESSURE SLINGER RING**—Designed to eliminate condensate in air conditioning applications. Ring can be positioned anywhere on fan blade. Neoprene hubs available.

S. P. Slinger Ring

Free Air Three Blade

**FREE AIR THREE BLADE SERIES**—Bright finish aluminum blades, steel spider. High efficiency in free air. Diameters 8 in. through 30 in. Pitches 6 deg to 40 deg.

**FREE AIR FOUR BLADE SERIES**—Wide overlapping blades assure quiet operation. Sturdy construction. Diameters 8 in. through 30 in. Pitches 6 deg to 40 deg.

Free Air Four Blade

Hurricane Series

**HURRICANE SERIES**—Semi-pressure type for efficient use against low static resistances. Diameters 12, 14 and 16 in. Neoprene bushed hubs available.

**K-D SERIES ATTIC FAN BLADES**—Heavy duty construction. Shipped knocked down. Diameters 24, 30, 36, 42 and 48 in. 35 deg pitch only.

K-D Series

One-Piece Series

**ONE-PIECE SERIES**—Available with hub or pierced for unit-bearing motors. Diameters 6 in. through 12 in. Many special designs.

**SPACESAVER SERIES**—Off-set design enables the blades to rotate around motor for space reduction. Diameters: 18 in., 20 in. Three blade only. Pitches 15 deg to 35 deg.

Space saver Series

## Brookside Products Company, Inc.

McCordsville, Indiana

Manufacturers of—

**FANS — BLOWERS — VENTILATING EQUIPMENT**

**POWER-FLO 100-SERIES BLOWERS:** Sturdily built with conical shaped inlet ring welded to blades. Built especially for higher pressure ventilating and exhaust systems. Backwardly inclined for non-overloading and low noise characteristics. Both statically and dynamically balanced. 14 in. to 60 in. dia.

100-Series

200-Series

**POWER-FLO 200-SERIES BLOWERS:** Ruggedly and efficiently built as well as lighter in weight for lower pressure applications. Backwardly inclined blades for low noise and non-overloading characteristics, also, statically and dynamically balanced. Fabricated of aluminum or steel. Riveted construction throughout. 11 in. to 60 in. dia.

**POWER-FLO 50-SERIES BLOWERS:** Are general purpose blowers for various air moving applications including air conditioning, heating, oil burners, etc. Available in both single and double inlet types, both rotations. All widths in sizes from 3 in. to 10 in.

50-Series

Slinger Type

**M-PEL-AIR FAN BLADES:** Slinger type for air conditioning or offset spider and conventional propeller type fans for ventilating and other applications. All engineered exactly to your specifications free of charge. Slinger rings are all one piece die drawn.

Off Set Type

**M-PEL-AIR "A" SERIES FANS:** Are of one piece construction of aluminum or steel. Available with hub or unit bearing motor piercing. Designed especially for air conditioning and refrigeration industries.

A-Series

# THE *Brundage* COMPANY

530 N. Park Street

Kalamazoo, Mich.

*Air Conditioning and Furnace Blower Specialists*

**DIRECT DRIVE BLOWERS.** Save space. Cut costs. And maintain full cfm output with top-quality Brundage Direct Drive blowers. Ideal for modern, compact heating and air conditioning equipment. The Brundage Volume Control Damper insures proper air flow at lowest cost . . . requires no electrical components. With full or three-quarter width wheels. Produced in all discharges.

**UX SERIES UNIVERSAL BLOWERS.** Here are all standard and angular discharges your heating or air conditioning equipment may require—in one package. Available with full or three-quarter width wheels, Brundage Universal Blowers are ideally suited to streamlined production facilities where lower inventories are desired.

WRITE FOR DETAILED SPECIFICATIONS AND PERFORMANCE DATA.

1380

**SERIES "X" BLOWER ASSEMBLIES.** A high-performance unit for all heating and air conditioning applications . . . in top and bottom, vertical and horizontal discharges. A full range of standard sizes from 8 in. to 16 in. built to high quality standards. Special discharge models are produced on special order.

**BLOWER-FILTER PACKAGE UNITS.** 7 sizes, from 400 to 3,500 cfm output. Cabinets are heavy-gauge, cold-rolled steel finished in durable baked enamel. Standard replaceable air filters are easily reached.

**SERIES "S" BLOWER-EXHAUSTERS.** 200 to 2,200 cfm output, very compact. Can be fastened directly to wall and easily made weatherproof. Angle of discharge adjustable to any degree. Precision made of heavy-gauge steel.

**SERIES "T" TWIN BLOWERS.** For distribution of large volumes of air over large areas. Consists of two blower wheels on self-aligning, polished shaft. Heavy scroll housings and rugged metal frame for industrial applications.

WRITE FOR DETAILED SPECIFICATIONS AND PERFORMANCE DATA.

1381

## Buffalo Forge Company

450 Broadway, Buffalo, N. Y.

Unit heaters, Ventilating Fans (centrifugal axial flow and propeller), Air Washers, Drying Equipment, Mechanical Draft Fans, Air Preheaters, Blowers, Exhausters, Air Cleaning Equipment, Spray Nozzles. Write for Bulletins mentioned below, or call the "Buffalo" Engineering Representative in your nearest principal city. "Buffalo", publisher of "FAN ENGINEERING", is ready to work with you on any air problem you may have.

**TYPE "BL" VENTILATING FANS.** These non-overloading centrifugal fans are widely used in large ventilating and air conditioning systems where quiet operation and high efficiency are desirable. Performance is completely stable, from free air delivery to shutoff. Smooth bell-shaped inlet and duct collars with "Buffalo" directional inlet vanes, minimize entry turbulence. The rotor has a curved shroud matching the inlet bell, as well as double backward curved blades for smooth, quiet air flow through the streamlined, full-curvature housing. Capacities from 1000 to 500,000 cfm. Wide choice of arrangements. Write for *BULLETIN F-101*.

**INDUSTRIAL EXHAUSTERS:** All-welded steel plate construction in these heavy-duty fans means smooth rivet-free interior surfaces for minimum friction. Available with interchangeable "AW" Air Wheels for airborne dusts, gases, fumes, or with "MW" Material Wheels for grit, sawdust, grain, stringy materials. Available with heat slingers to handle gases up to 1000 F. in induced draft and other high temperature applications. Write for *BULLETIN 3576*.

**AXIAL FLOW VENTILATING FANS.** For light-duty (up to 3 in. s.p.) ventilation, exhausting, system boosting, draft and circulation applications, these lightweight fans fit into straight duct runs, taking up no more room than a section of round duct. Extremely quiet, efficient and non-overloading. Available in tubeaxial (without directional vanes) or vane-axial (with directional vanes) models, with direct connected motor-in-housing or with Vee-belt drive and motor out of air stream. Models for high or low temperatures, non-sparking and/or corrosion resistant construction. Write for *BULLETIN 5533-EF*.

**AIR CLEANING EQUIPMENT.** "Buffalo" builds all types of units from Air Washers like the one shown for cleaning, humidity control, heating and cooling to highly specialized units for abating effluent nuisances in the chemical and process industries. More than a half-century of experience in this field is at your service, as well as our complete manufacturing facilities. Write for Bulletins on the industry-proved "Buffalo" equipment to solve any air cleaning or processing problem you may have.

**PC CABINETS (1).** Heavy-duty units for major air conditioning. Compact,

coils and heavy-gauge paneling and tank. *BULLETIN 5703*.

sectionalized construction permits easy installation and servicing. Vertical floor or flat suspended models for any or all air conditioning functions. Equipped with "Buffalo" Fans and Pumps, Aerofin

**UNIT HEATERS (2).** "Buffalo" breezeo-Fin Heaters operate on as little as 2 lbs steam, have high-radiation one-piece copper-finned tubes and efficient "Buffalo" Breezeo Fan for quick, economical heat where needed. Write for *BULLETIN 3137-E*. Also, a wide selection of heating and ventilating units, with or without filtered intake and by-pass dampers, suspended and floor models for large areas.

## Alan E. Burden Co., Inc.

Manufacturer of Propeller Type Fan Blades

1940-50 Pontius Ave., Los Angeles 25, Calif.

### For Air Conditioning Refrigerating and Heating Applications

All Burden Fan blades are individually inspected after leaving the production line for bore size with "go and no-go" gauges, to a tolerance of plus or minus one  $\frac{1}{1000}$ th of an inch. Each fan blade is individually gauged on a special machine for contour and alignment, then statically and dynamically balanced with Mechanical, Audio Vibration Equipment.

A modern, completely equipped laboratory makes possible exhaustive performance tests. Expert engineering counsel is available for requirements involving unusual applications. A laboratory at the factory is equipped for both routine and special testing when necessary.

**BURDEN 3 BLADE FANS.** Furnished clockwise and counter-clockwise. Diameter range, 10 in. to 24 in. with variations of pitch of from 6 deg to 42 deg in increments of 1 deg. Hubs front or back. Standard spiders cadmium plated. Blades aluminum, commercial bright.

**BURDEN 4 BLADE FANS:** Furnished clockwise and counter-clockwise. Diameter range, 10 in. to 30 in. with variations of pitch of from 6 deg to 42 deg in increments of 1 deg. Hubs front or back. Spiders cadmium plated. Blades aluminum, commercial bright.

**BURDCO REVERSIBLE, INTERCHANGEABLE HUBS:** Designed for special Burden blades produced with uniform size openings. Hubs produced in six bore sizes can be quickly adapted to front or back and keyed firmly into place with a positive locking device. They are adaptable to 3 or 4-blade fans, clockwise or counter-clockwise in all variations of pitches.

**BURFLEX HUBS:** Are similar to the Burdco reversible, interchangeable type with the added feature of a specially designed noise insulating grommet, constructed to fit over the hub in applications where lessened vibration and dampening of sound are desired. Insulated hub absorbs motor noise. Information sent on request.

## CYCLONE ROOF FAN

Compact, symmetrical and low in height for modern buildings. Its high efficiency, large volume capacity, slow operating speed and quiet performance make it ideal for schools and hospital buildings.

Shipped complete with motor, driver, fan, framework and housing. Housing of galvanized steel, aluminum, copper, lead-coated copper and stainless steel to withstand atmospheric conditions. Conforms to code ratings of PFMA, NAFM and ASHVE.

Automatic Draft Inducer

## CENTURY AUTOMATIC DRAFT INDUCER

Installed in boiler breeching. Maintains draft of pre-selected intensity. Eliminates high stacks. Completely automatic and quiet operation. Approved by "Underwriters Laboratory".

## CENTURY MID DRAFT FAN

For low and high pressure heating plants using oil, stoker or gas-fired boilers. Creates perfect uniform draft regardless of weather. Installed in breeching in any position. Rated in conformity with test codes of PFMA, NAFM, and ASHVE.

Mid Draft Fan

Manufacturers of Blowers, Ventilating Fans and Exhaust  
Fans for handling air, material and fumes

Representatives in Principal Cities

CHAMPION TYPE "D" VENT SETS

For general ventilation of all types equipped with backward curved non overloading wheels up to 30 in. diameter, furnished complete with electric motor, adjustable drive and weather proof covers if required.

Champion Cast Iron Housed Fans of various types for fume hood exhaust and for handling corrosive gases. Can be equipped with either plain steel or non ferrous blast wheels, interior of housing and wheel can be covered with special corrosive resisting coating.

Champion Forward and Backward Curve Ventilating Fans and Exhaust Blowers manufactured in sizes up to 60 in. dia. Fans also furnished in all standard arrangements with Ball, Bab-bitted or Water Cooled Bearings as required.

New aerodynamic blade design

**Axial Airfoil Fans** for removing fumes, vapors in dangerous locations. 1100 to 105,000 cfm. *Bulletin AA-101.*

**Axial Mushroom Roof Exhausters** for industrial, commercial ventilation. 870 to 47,800 cfm. *Bulletin CAM-102.*

**Gyra-Flo Roof Exhausters**—Extremely quiet for schools and hospitals. 830 to 29,750 cfm. 61 to 88 db. *Bulletin GPE-103.*

**Centrifugal Fans** for heating, ventilating, air conditioning, all drive styles. 600 to 750,000 cfm. *Bulletin C-102.*

**Propeller Fans** for commercial, industrial, business, home ventilation. 1200 to 24,100 cfm. *Bulletin CEF-103.*

**Steel Plate Fans** for removing dust, materials or high temperature air, gases. 200 to 50,000 cfm. *Bulletin SPE-103.*

**Turbo-Pressure Blowers** for oil or gas burners in industrial furnaces, ovens. 80 to 5500 cfm. *Bulletin CTB-102.*

**MD Fans** for commercial ventilation. Direct or belt drives. 300 to 17,000 cfm. *Bulletin MD-102.*

## NEW AIRFOIL CENTRIFUGAL FANS REDUCE NOISE LEVELS 65 PER CENT

Quieter Operation, Greater Efficiency for industrial, commercial and all other heating, ventilating and air conditioning applications.

- Efficiencies in excess of 90 per cent.
- Steep pressure characteristic curves.
- Noise level ratings lower than other type wheels.

Certified ratings. All drive arrangements; directions of rotation and discharge. 600 to 1,000,000 cfm to 32 in. sp. Class I to V construction. Wheels 12 to 143 in. diameter. *Bulletin A-102.*

# CLARAGE

CLARAGE FAN COMPANY  
Kalamazoo, Mich.

Air Handling and Conditioning Equipment  
Application Engineering Offices in All Principal Cities

For nearly a half century Clarage has been a leading manufacturer of equipment and units for ventilating, exhausting, cooling, air cleaning, humidifying and complete conditioning. Clarage equipment is designed to meet all types of industrial, commercial and public building requirements. For other equipment in the complete Clarage line see "Air Conditioning—Central Systems."

Clarage Fans for ventilating and air conditioning are offered in many different standard types and arrangements. Capacities range from 200 to 725,000 cfm.

Clarage Unit Heaters are available for either floor or suspended installation. 23 sizes range from 24,000 to 1,160,000 Btu. They can be operated on either steam or hot water.

Clarage Industrial Fans (shown above) range up to 130,000 cfm, 18 in. sp, and 60 in. inlet diameter. Can be constructed for special applications.

Clarage Ready Units (left) are furnished complete ready-to-run. V-belt or direct connected. Capacities to 12,000 cfm.

We welcome your inquiry on any air handling or conditioning problem. Contact our nearest branch office, or write us at Kalamazoo, Michigan.

CONSULT YOUR TELEPHONE DIRECTORY UNDER "FANS" OR "VENTILATING EQUIPMENT"

### FOR CONTROLLED VENTILATION

Centrifugal  
Roof Ventilator

Centrifugal Roof Ventilator is ideal for schools and hospitals where whisper-quiet operation is a must. It runs at low speeds and moves large volumes of air efficiently against static pressures. Capacities up to 32,980 cfm.

Vertical Discharge Roof Ventilator exhausts oil or grease-laden air straight up at high velocity. It keeps harmful residue off the roof and thus prolongs roof life. Capacities up to 48,925 cfm.

Vertical Discharge  
Roof Ventilator

Power-Flow Roof Ventilator is most popular of all for general usage. It is a ruggedly built unit in an aerodynamically correct, weatherproof housing. Capacities up to 43,070 cfm.

All three DeBothezat roof ventilators are low in silhouette and distinctively profiled... blend well with modern architecture. Write for separate catalogs, mentioning units by full name.

Power-Flow Roof Ventilator

Certified Capacity Ratings. All performance ratings are the output of the completely assembled unit... obtained from wind tunnel tests as per *Standard Test Code for Power Roof Ventilators*... and conform to U. S. Department of Commerce Standard 178-51.

### FOR FUME REMOVAL

Bifurcator Fan

### BIFURCATOR FAN

Bifurcator Fan exhausts hot, corrosive or flammable fumes. Motor is mounted in a through-ventilated chamber and destructive fumes are by-passed (bifurcated) around it. Bifurcators install directly in the duct, in any position from horizontal through vertical. Fan wheels 12 in. through 48 in. in diameter, with capacities up to 54,200 cfm. Write for Catalog.

Induced Draft Bifurcator

### INDUCED DRAFT BIFURCATOR

Induced Draft Bifurcator provides controlled draft for boilers and furnaces, eliminating the need for tall costly stacks. For high-pressure boilers delivering up to 60,000 pounds of steam per hour and for low-pressure boilers up to 190,000 EDR. Write for Bulletin.

"Hy-V" Air Jet

### "HI-V" AIR JET FOR SPOT COOLING AND GENERAL VENTILATION

"Hy-V" Air Jets blow a directed stream of cooling air as far as 60 feet without ducts. Write for Bulletin. Additional bulletins are also offered on Axial-Flow Vent Sets and Panel Vent Sets.

## Garden City Fan Company

332 South Michigan Avenue

Chicago 4, Illinois

Representatives in principal industrial cities.

Manufacturers of Design "B" Multiblade—Non-Overloading—Hi-Static Cycloidal Standard Steel Plate and Small Exhaust Fans. Wheels designed in forward curved, backward curved and radial bladed types, adaptable to commercial and industrial applications. Suitable for cooling, evaporating, drying, air-conditioning, material conveying and disposal, processing foodstuffs and animal or mineral products and by-products, induced draft, paint spray and fume removal, packaged steam generators, and requirements for fan and blower systems. Standard Steel Plate fans also produced for high temperature operation 300 F to 1600 F, N.O.L. fans to 600 F, and Design "B" Multiblade fans for temperatures to 800 F.

Non-Overloading Fan illustrates an angular up discharge position. Fan interior coated with resistant paint. Backward curved fan blades.

Large Design "B" Multiblade Fan for temperatures to 800 F, showing insulated cup and air-cooled fan shaft. Forward curved fan blades.

Hi-Static Cycloidal Fans—used for systems handling and conveying many materials. Specially designed fan blade reduces power requirement and operates at slow speed.

Small Exhaust Fans—steel plate housing shown. Available with cast iron housing and direct-connected motor. Wheels, 9½ in. thru 16 in. O.D.

High Temperature Fans to 1600 F. Insulated or uninsulated housings. Air-cooled shaft with ball bearings.

Engineering data, information, and catalogs, available upon request.

A

General Centrifugal Fans for complete range of volumes for heating, ventilating and air conditioning. Type SS (seal seam) housing construction.

C

For Industrial applications requiring heavier construction, General offers the type W (Welded) housing construction.

B

General Backward Blade and Forward Curved fan wheels and inlet cones are assembled of spun parts for smooth quiet air movement. Ask for *Bulletins BB102* or *FC-105* for particulars.

E

General Propeller Fans supplied with either cast aluminum or steel blades from 10 in. to 72 in., with direct or belt driven arrangement. *Bulletin PF101*

H

Inlet vane controls of General design are offered for manual or automatic operation.

Material handling Exhausters convey air borne particles caused by grinders, polishing or cutting. General Steel Plate Exhausters are suitable for high temperature air recirculation. *Bulletin MX-104*

General Util-A-Vent sets of FC or BB wheel construction recommended for low cost air handling requirements for ventilating and industrial needs. Direct motor connected units for up to 12 in. fan wheels. Belted units up to 36 in. *Bulletin UVS-103*

For removal of fumes and foul air where no duct system is required, General offers the Automatic Propeller type Roof Ventilator having vertical discharge. *Bulletin PF-101*

General Power Roof Ventilator, of low silhouette design having type BB centrifugal fan wheel meets architectural design requirements. Aerodynamic design provides quiet efficient operation. *Bulletin RV-101*

## Hartzell Propeller Fan Co.

DIV. OF CASTLE HILLS CORP.

Piqua, Ohio

Engineering Offices In Principal Cities

### PROPELLER TYPE FANS

Standard fans (shown) in single-propeller, two-propeller and multi-blade models, diameters from 12 in. to 60 in. Also Low Noise Fans, 24 in. to 60 in., and a special high pressure fan which operates efficiently against pressures as high as 3 in. water gauge. All can be supplied in direct-drive, belt-drive, pulley-drive or extension shaft construction—ring or panel mounted. Cast aluminum-alloy propellers.

### VANEAXIAL BLOWERS

For use in duct systems, against very heavy pressures. Direct-drive in six sizes, 18 in. to 42 in. Belt-drive in 10 sizes, 12 in. to 54 in. Air deliveries to 88,000 cfm. Special high-temperature models move air at elevated temperatures, and air containing mild acids and alkalis, without danger of premature failure of belts and bearings. All-welded construction. Dynamically-balanced cast aluminum alloy impellers.

### DUCT FANS

Standard duct fans are prefabricated duct sections which can easily and quickly be bolted into place in any duct system. Direct or belt-drive, 12 in. to 60 in. Bi-Pass Duct Fan has motor in tunnel out of air stream; for high temperature applications (up to 550 F with special heavy duty construction) and for moving corrosive fumes.

### REVERSIBLE FANS

Move air in either direction with the same high efficiency. Can be reversed manually or automatically. For many cooling and drying processes and for ventilating jobs where intake may be desired under some conditions and exhaust under other conditions. Available in 28 in., 36 in. and 44 in. fans diameters, in duct section or double-ring construction.

### ROOF VENTILATORS

The Vertijet (shown) or the Automatic Airjet attain unusual efficiency and economy through extreme simplicity of design. Lids open automatically when the fan is on, close weather tight when it goes off. Other ventilators include a Rotary Ventilator and a new Reversible Roof Ventilator which also meets all the requirements for a blackout unit.

**OTHER HARTZELL VENTILATING EQUIPMENT:** Centrifugal blowers, man and materials cooling fans, intake air units, unit heaters, aluminum and plastic adjustable-pitch fans for cooling tower and heat exchanger applications and mine ventilation.

## ILG Electric Ventilating Co.

2880 North Crawford Ave., Chicago 41, Ill.

Offices in more than 40 Principal Cities

### ILG PROPELLER FANS, CENTRIFUGAL FANS, ROOF VENTILATORS

Tested and rated by NAFM, PFMA and ASHVE code. Capacities guaranteed.

Type "X" Explosion Proof Fans carry UL certification of suitability for all Class I, Group D hazardous applications.

Type "TA" Tubular Duct Fans for pressures up to 0.8 in. Easily installed duct section for vertical or horizontal use.

**ILG DIRECT-CONNECTED SELF-COOLED MOTOR PROPELLER FANS**—Exclusive self-cooling feature: motor covered for protection against corrosive and contaminating exhaust air, but cooled by a vent, the entrance of which is outside the exhaust area. Motor never "gums up" from contact with foul air . . . saves on power costs . . . practically no maintenance required. Direct drive assures permanent alignment. Exceptionally quiet operation. Wide range of sizes.

Volume Blower Type "B" left—Small volume, low pressure, quiet running. Cast iron base. Universal discharge positions, 7 capacities.

Volume Blower Type "P" left—For exhausting dust, fumes, vapors. Four discharge positions, 7 capacities.

**ILG DIRECT-CONNECTED CENTRIFUGAL FANS, NEW AIRFOIL TYPE BC** above, far left—Motor load is constant for wide range of volume and static pressure changes. Direct drive design with motor partially recessed, 10 sizes. Belt-drives in 12 sizes.

**TYPE LSQ**—Direct-connected propeller fan type featuring low silhouette, low maintenance and high capacity, 5 sizes up to .6 in. static pressure.

**TYPE RVS**—Centrifugal fan type, ideal for low volume requirements. 9 sizes up to .5 in. static pressure. 17 in. high above curb. Optional without damper, Type RAS, 13 in. high above curb.

**ILG PRV POWER ROOF VENTILATORS**—Centrifugal fan type, shown above left, for exhaust from vertical flues or duct systems. Direct drive, self-cooled motor. Non-overloading, backward curved wheel. 10 sizes. Up to 1½ in. Static Pressure.

### SERIES 1000 AXIVANE\* INDUSTRIAL AND COMMERCIAL FANS

Joy Series 1000 adjustable blade AXIVANE\* Industrial fans are available in 136 sizes ranging in volume capacity up to 200,000 cfm with pressures up to 11 in. W. G. Housing diameters range from 18 in. to 84 in. For complete specifications, construction details, and selec-

tor charts giving pressure-volume range for each fan, write for bulletin number J-611.

Joy AXIVANE\* Series 1000 fans are efficient, quiet, compact, flexible, and easy to install.

#### ADJUSTABLE BLADES

Joy AXIVANE\* Industrial Fans have the extra performance flexibility of adjustable blades. Adjustable blades are standard equipment on all Series 1000 fans. The factory blade setting can be quickly changed to provide either a wide pressure range for any particular volume or a change in a volume simply by loosening

Blades are adjustable on the job by loosening one lock nut

Cutout drawing showing location of motor and compact construction

Rear view, showing vanes and motor

Front view, showing simplicity of construction

ing a lock nut with a wrench, setting the blades uniformly with the indicator, and retightening the lock nut. A permanent stop prevents setting blades in a position likely to overload the motor. Minimum blade settings are limited by the fan housing.

Adjustable blades permit on-the-job correction for unpredictable duct resistance or for poorly installed duct work.

#### MORE EFFICIENT

Stationary straightener vanes, located immediately behind the rotor, partially recover the rotative energy imparted to the air by the rotor, and re-establish axial flow to the air leaving the vanes. This eliminates excess turbulence at the point where the air enters the duct system and increases efficiency by decreasing pressure loss.

The Joy AXIVANE\* fan utilizes an aerodynamically efficient blade and stationary vane design.

#### QUIETER OPERATION

For equal weight and space the Joy AXIVANE\* fan is quieter than a centrifugal type fan of equal volume and pressure. The streamlined airflow from an AXIVANE\* fan makes sound insulation a simple and inexpensive operation when required for the ventilation and air conditioning of quiet spaces such as hospitals, auditoriums, radio stations, etc., where insulation against system noise must be used.

#### MORE COMPACT

Joy AXIVANE\* fans are built around the motor, the fan housing becoming an actual part of the duct system. This produces a more compact design than is

possible with a centrifugal fan. An AXIVANE\* fan, installed on an in-line connection with ventilation ducts, parallel to and close by an overhead structure, may require 70 per cent less space than a conventional belt-driven centrifugal fan. The compactness of a Joy AXIVANE\* fan assures a maximum of net operating or rentable area. Fan rooms are virtually eliminated.

#### EASIER TO INSTALL

The Joy AXIVANE\* Series 1000 fan develops a greater volume and pressure per pound of fan and motor because of its compact, in-line construction. This light weight permits a simplicity of installation that minimizes installation costs and total weight by eliminating heavy foundations, complex duct offsets and elbows, drives and guards. AXIVANE\* fans can be installed quickly and easily, even by relatively inexperienced or unskilled labor.

#### MATCHED ACCESSORIES

Inlet bells, screens, and fan supports are accessories designed to fit all AXIVANE\* fan housings. In ordering, it is only necessary to state the model number with or without the accessories as desired. If required with accessories, these will be furnished to fit the fan model ordered without special number.

No matter how carefully a duct system is planned, an incorrectly selected inlet bell will reduce fan efficiency by increasing intake turbulence. This excess turbulence will also increase the noise level of the fan. When a fan takes its air directly from the weather, a plenum, a fan room, or from a duct system larger in circumference than the fan housing, a bell should be used.

## The Lau Blower Company

2004 Home Avenue, Dept. J, Dayton 7, Ohio

In Canada • The Lau Blower Company of Canada, Ltd., Kitchener, Ont., Canada  
Manufacturers of Exhaust and Portable Fans, and Air Conditioning Blowers

LAU all new \*ELECTRO-WHEEL BLOWER: Two unobstructed air inlets on wheel sides plus compact motor design gives more air delivery with less power load. Stationary shaft with rubber mountings reduces vibration to a minimum. Rugged tripod mountings give greatest shipping strength without impeding air flow. Air deliveries from 500 to 1500 cfm, static pressure from .5 to 1.25 in. (water gauge),  $\frac{1}{4}$  hp motor. Available in 115 and 230 volt ac. Housing supports optional. Pre-punched holes in housing unit make any discharge angle possible.

LAU Econo-Pak Blowers cover most applications for residential air-moving equipment; effect savings up to 10 per cent by eliminating special blowers for each application; reduce blower inventories by simplified order procedures, quick handling of model changes, lower handling costs, up to 26 $\frac{1}{2}$  per cent reduction in warehouse space. Three Basic Sizes each in 2 widths, with all features of Standard Series A Blowers. Package Includes blower wheel, housing with cut-off, housing supports, motor mount (not attached), all hardware. Exclusive Lau-Pak Bearings without oil cups require no lubrication. Adjustable Discharge, any one of 5 positions.

Write for LAU Blower Catalog 707. Mention all Blower items of interest.

LAU Standard Blower Assemblies (Series A), heavy-gauge steel housing assemblies, entire unit die-formed. Capacity range 350-22,000 cfm. Motor Mounting adjustable for any motor location. Housing Base heavy 16-gauge steel, rigid. Discharge Outlet improved design, construction. Belt special composition for blower operation. Shafting 2-stage centerless ground, burnished. Bearing Bracket 3-point suspension; same bracket used for all discharge angles. Lausteel Pulleys employed; V.S. motor pulley allows speed variations up to 30 per cent. Center Suspended Wheel. Embossing of Scroll Sides reinforces venturi inlet and discharge. Bearings highest grade self-aligning porous bronze sleeve type. Plastic Thrust Washer absorbs shocks.

LAU Spun Wheels, Center Suspended Riveted Wheels, S.I. and D.I. Weld Wheels, a complete wheel line. Spun Wheels center disc construction; baked enamel, Ruspruf, or hot-dip galvanized

2004 Home Avenue, Dept. J, Dayton 7, Ohio

In Canada • The Lau Blower Company of Canada, Ltd., Kitchener, Ont., Canada  
Manufacturers of Exhaust and Portable Fans, Air Conditioning Blowers

Lau Series A Bearing

Lau-Pak Gold Seal Bearing

Self-Aligning Pillow Block

LAU Series A and Lau-Pak Gold Seal Bearings are noted for their high performance and longer life. Series A is a self-aligning, self-oiling bronze bearing held in housing under uniform spring pressure; bore sizes  $\frac{5}{8}$ ,  $\frac{3}{4}$ , 1 and  $1\frac{1}{16}$  in. Lau-Pak Gold Seal Bearings require no additional lubrication; ample supply of plastic petroleum is sealed in housing; bore sizes  $\frac{5}{8}$ ,  $\frac{3}{4}$ , 1, and  $1\frac{1}{16}$  in.

LAU Self-Aligning Pillow Blocks are low-cost, light-weight, oil-tight steel housings with porous bronze bearings. Hold much more oil than cast iron types. Durex bushing feeds oil to shaft by capillary action. Spring keeps spherical surface of bearing and ring in close contact. Long bolt slots permit interchanging with other makes of pillow blocks. Bore sizes available are  $\frac{5}{8}$ ,  $\frac{3}{4}$ ,  $1\frac{1}{16}$ , 1, and  $1\frac{1}{8}$  in.

con't.

finish; standard steel or Power Lock hubs. Center Suspended Wheels, blades double-riveted to end rings, are welded to center disc, diameters 18 in.-30 in.; standard steel or Power Lock hubs. S.I. and D.I. Weld Wheels, individual blades of correct length, width, pitch; baked enamel, Ruspruf, or plated; diameters  $4\frac{1}{2}$  in.-9 in.; widths  $2\frac{1}{4}$  in.-9 in.

Lausteel Variable and Constant Speed Pulleys are in balance and true-running. Lausteel Variable Speed Pulleys available in three standard bores:  $\frac{1}{2}$ ,  $\frac{5}{8}$ , and  $\frac{3}{4}$  in. Diameter  $3\frac{1}{4}$  in. OD. Allow speed variations up to 30 per cent for many drive combinations. Lausteel Constant Speed Pulleys available in diameters of 6 in. to 10 in., inclusive. Suitable for both "A" and "O" section belts. Lau also offers cast iron pulleys in diameters of 11 in. to 14 in.

LAU Niteair\* Exhaust Fans for residential, commercial, and industrial use. Niteair\* Rancher, for homes with low-pitched roofs, pulls air up through ceiling opening; four sizes: 24-30-36-42 in. Niteair\* Panel Unit in standard and heavy-duty models, with four blades properly pitched for greatest air movement; five sizes: 24-30-36-42-48 in. All Lau Fans carry PFMA Certified Ratings and UL Approval; also regular manufacturer's warranty.

General Purpose Fan

M15—A unit that delivers, warmed, filtered, outside air to industrial spaces to replace exhausted air and balance minus pressure. Corrects drafty conditions and uncontrolled infiltration. Made in 4 sizes from 5,000 cfm to 20,000 cfm. Described in Bulletin 523.

IPL Centrifugal Fans—Capacities up to 101,000 cfm. Slow speed wheels offered from 7½ to 73 in. Capacities up to 123,000 cfm. Quiet operating (IPL) medium speed wheels with non-overloading horsepower characteristics for heating, ventilating and air conditioning or industrial applications. Wheel diameters from 18 in. to 73 in., with any speed or discharge required. Class I, II, III or IV construction. Write for Bulletins 543 and 544.

Steelfin Hot Blast Heating Surface—Extra heavy duty, fin-and-oval tube, all-steel, welded construction. A hot dip metallic coating over all, including headers, affords perfect bonding and conductivity. Suitable for continuous heating service on steam pressures up to 150 lb. Bulletin 492.

nyb Propeller Fans—Deliver large volumes of air at low resistance and low current consumption. All wheels are machine balanced for smooth, vibrationless operation. Made in two types and eight basic sizes. Wheel diameters from 12 in. to 48 in. Direct or belted drive. Capacities from 400 cfm to 23,500 cfm. Ask for Bulletin 541.

nyb Unit Heaters—Heavy duty, welded steel, fin-and-tube heating element. Suitable for continuous heating service on steam pressures up to 150 lb or more. 10 sizes with capacities from 30 Mbh to 490 Mbh. Bulletin 522.

Type GI Industrial and Heat Fans—For dust and gas removal, conveying of materials and handling hot gases. Housings, drives, and discharge arrangements to meet any requirement. Wheel diameters from 10 in. to 66 in. Capacities from 450 cfm to 60,500 cfm. Details and engineering data in Bulletin 521.

General Purpose Fans—Portable, self-contained units for Class I industrial and ventilating applications. Recommended for ease of installation, low maintenance and space saving features. Made in three types and eight basic sizes. Capacities 400 cfm to 18,000 cfm. Bulletin 545.

Walls, Windows, Hoods,  
Roof Ventilators

Propellair  
Direct-  
Connected  
Fans

For Heat, Moisture, Fumes,  
Dust, and Gases

Propellair Extended-Shaft Fans

For use wherever motors may operate within the air stream, from free air to medium and relatively high resistance. A compact, durable design with fan having two to six blades. Sizes: 12 in. to 60 in. Capacities: 1,020 to 85,000 cfm. Type "CD."

This design locates motor outside air stream when fan is installed in duct at right angle turn, elbow, "Y," or offset. Simple installation usually can be supported by duct without auxiliary bracing. Drive shaft is enclosed and sealed within steel tube. Sizes: 12 in. to 60 in. Capacities: 1,020 to 78,800 cfm. Type "CE."

For Heat,  
Acids, Alkalies—Fumes,  
Gases, Dust

Belt-Driven  
Propellair  
Tube-Axial  
Type

A complete fan unit in short duct section ready for installation in lines from 20 in. to 60 in. diameter. Type "CS" may be used for severe acid or alkaline conditions, explosive fumes and gases. Type "CSV," for excessive temperatures, circulates outside air through belt and fan shaft tubes to keep drive and bearings cool. Capacities: 5,075 to 78,000 cfm.

Power Roof Ventilator

Propellair  
Sky-Blast®

Dependable and economical power roof ventilators. Butterfly dampers open wide the instant fan is started, close automatically as fan coasts to a stop, offer virtually zero resistance as heat, fumes, moisture, dust shoot high into air. Rain is prevented from entering by fan when operating. Drainage shed prevents leakage when dampers are closed. Sizes: 16 in. to 60 in. Capacities: 2,800 to 78,000 cfm.

Propellair  
Vaneaxial  
Fans

A compact, highly efficient pressure fan using standard steel drum sections incorporating standard *NEMA* frame motors in direct drive models. Also available in belt-driven ratings with motor outside the air stream. Cast aluminum airfoil propeller and guide vanes for maximum efficiency and durability. Available in 20, 24, 30, 36, 48, and 60 in. diameters in belt and direct driven models. Capacities from 3410 to 85,000 cfm.

Airfoil Principle  
Entrance Ring

Airfoil-Section Blades

Propellair fans have airfoil-section blades with variations of pitch, curvature, and thickness to compensate for different lineal speeds of points at various radii. Air movement is uniform over whole fan area. The Propellair curved entrance ring eliminates eddy currents; helps efficient Propellair blades deliver highest pressure and volume.

# Reed

## Unit-Fans, Inc.

1001 Saint Charles Ave., New Orleans, La.

Manufacturers of Industrial, Direct-Drive Axial Flow Fans, Belt-Drive Exhaust Fans, Window Fans, Attic Fans and Portable Air Circulators

### REED INDUSTRIAL AXIAL-FLOW FANS

The Reed APD Industrial Fan line consists of heavy-duty axial-flow direct-connected fans capable of operating against static pressures up to 3 in. water gage, with air delivery ratings from 1,000 to 100,000 cfm. Cast aluminum air foil blades of unique design make it possible to vary the number of blades and their angle of attack, thus providing the necessary flexibility to custom-build to specific requirements.

The basic line consists of four groups of sizes, namely 9 in. through 18 in., 21 in. through 27 in., 30 in. through 36 in., and 42 in. through 60 in. These groups are further subdivided in 3 in. steps. Totally enclosed ball-bearing motors, either single or three phase are standard, but special motors are furnished on request. Fan frames are of heavy hot-rolled steel, electro-welded throughout.

### REED PACKAGED ATTIC FANS

Seven stock sizes ranging from 24 in. to 48 in. blade dia. Corresponding free air cfm ratings of from 5,000 to 18,600. Simply and quickly installed with hanging brackets on rafters. Completely automatic shutters.

### REED PORTABLE AIR CIRCULATORS

Supplied in 5 stock sizes; 22 in., 26 in., 30 in., 36 in., and 42 in. blade dia. Wire guards front and back, four hard-rubber casters at bottom of fan case. Completely vibrationless, two-speed and reversible. Ideal for commercial and industrial spot-cooling.

## Revcor

249 Edward Street

Carpentersville, Illinois

Phone: HAZEL 6-4819

ENGINEERS AND MANUFACTURERS OF SINGLE AND DOUBLE BLOWER WHEELS AND HOUSINGS

Two single inlet blower wheels welded together back to back and having a common hub make up the REVCOR DOUBLE INLET BLOWER WHEEL. Any two REVCOR single inlet wheels of the same diameter and of the same or varying widths can be assembled to make the double inlet blower wheel.

Heavy gauge backplate and inlet ring assure rigid support for blades and hub.

Individual blades of correct number, curvature, depth, and blade angle to deliver the greatest amount of air both efficiently and quietly.

FULL WIDTH blades with a blade tip diameter substantially the same as the outside diameter of the wheel enable REVCOR BLOWER WHEELS to deliver the MAXIMUM AIR AND PRESSURE FOR THE SPACE DIMENSIONS REQUIRED.

Blade tips projecting through slots in the backplate and ring are bent toward the blade curvature to securely lock the backplate and ring between the bent tip and the shoulder at each end of the blade. Tips may be spot welded for greater strength when required for special severe applications.

Cast hubs are attached to the backplate with 4 or 6 rivets. Hubs can be mounted either inside or outside of the wheel.

SIZES: 1 1/4 in. to 12 3/4 in. Diameter; wheel widths from 5/8 in. Special Sizes of Single and Double Inlet Blower Wheels can be made to your specifications.

Hubs machined from bar stock are attached to the serrated center hole in the backplate by curling the hub material on to the backplate. The hub material is then pressed into the serrations in the backplate to key the hub to the wheel to prevent loosening. Hubs can be mounted either inside or outside of the wheel.

MATERIALS: Steel. Also available in Aluminum, Brass and Stainless Steel.

AVAILABLE: Sheet Metal Housings for all Revcor Wheels

### CABINET VENTILATOR

At left, Model 3501 for kitchen cabinets, shown with optional Stationary Hood.

**SUPER CLIPPER MODEL 3501.** 550 cfm kitchen ventilator installs in cabinet directly over stove. The dual inlets, one directly over the stove, the other at ceiling level are equipped with cleansable metal filters. The unit has twin blowers, isolated and radio shielded 140 watt motor, 4-speed switch control and built-in back draft damper. Three optional hood styles are available. Finished in choice of copper or stainless steel, the Stationary Hood comes in standard sizes from 30 in. to 48 in. The Expansion Hood adjusts from 30 in. to 54 in. The stainless steel Fold-Under Hood comes in 39 in. or 42 in. sizes.

### CEILING VENTILATORS

Trade-Wind ceiling ventilators are designed for small rooms such as kitchen, laundry, den, ticket booths, offices and photographic darkrooms. They come in complete "unit package" assembly, requiring only the application of a discharge duct for installation. Units are Underwriters' approved and listed and carry a (pro-rata) five year guarantee.

**CLIPPER MODEL 2501.** Shown above. 425 cfm for 2000 cu ft room. Dual centrifugal blowers. 130 watt motor. Interchangeable horizontal or vertical discharge, complete with grille and 4-speed switch.

**CLIPPER MODEL 1501.** 300 cfm for 1000 cu ft room. Dual centrifugal blowers. 105 watt motor. Interchangeable horizontal or vertical discharge, complete with grille.

**CLIPPER MODEL 1201.** 100 cfm for bathrooms only. 50 watt motor. Horizontal discharge, complete with grille. Optional time delay switch available.

**AXIAL FLOW MODEL AF-7M.** Compact 300 cfm axial flow ventilator for ceiling or wall in 100 cu ft room. It can be installed between joists in ceiling or between studs in the side wall. No elbows are required for vertical discharge. 50 watt motor. Available with aluminum or ivory grille.

**VENTILATOR/LIGHT MODEL 1701.** 100 cfm for bathrooms. 50 watt motor, horizontal discharge. Features modern Alba-lite glass grille, with two light sockets. Unit is prewired to external switch box. May be connected to single or double switch. Optional time delay switch available.

"Slinger Rings" for Assembled Fans

"P" Series Airstocrat Fan Blades

New "LU" Series One-piece Airstocrat Fan Blades

"Slinger Rings" for Assembled Fans—A rolled ring, L-shaped in cross-section, with riveted construction. Designed to adapt all popular sizes of assembled Airstocrat fan blades for application in eliminating condensate from room air conditioners. Design allows considerable flexibility as to diameter, location of ring on periphery of blade, etc., without expensive tooling.

"P" series AIRISTOCRAT fan blades—This fan blade has outstanding pressure characteristics and is widely used in room air conditioning units—many times with slinger rings. It is available in heavy gauge construction in all diameters and in light gauge construction on certain diameters for special applications.

New "LU" Series One-Piece AIRISTOCRAT Fan Blades—An extremely quiet and very efficient one-piece fan designed especially for refrigeration and air conditioning applications. This quality product is hand-set to assure accurate forming and alignment. Made of aluminum, pierced for all unit-bearing motors. Sizes: 7 $\frac{3}{4}$ , 8 $\frac{3}{4}$ , and 10 in. diameters.

Torrington Airotor Blower Wheels are light, sturdy and inexpensive—incorporate new principles of design and construction, which insure rigidity and concentricity. Single Width—Single Inlet wheel is of simple four-piece construction. No rivets or welds are used; concentric rib serving as backing for blade strip is formed at same time as hub socket, insuring trueness of wheel. Rigid radial ribs prevent deflection by thrust. Three thicknesses of metal in rims make for maximum strength. Excellent for many heating and ventilating uses. Manufactured in both aluminum and steel in 1 $\frac{1}{2}$  in., 2, 3, 3 $\frac{3}{8}$ ,

The Torrington Mfg. Co.

4 $\frac{1}{4}$ , 4 $\frac{3}{4}$ , 4 $\frac{7}{8}$ , 5 $\frac{1}{8}$ , 5 $\frac{1}{4}$ , 5 $\frac{3}{4}$ , 6 $\frac{1}{8}$ , 7 $\frac{1}{8}$ , 7 $\frac{3}{8}$ , 8 $\frac{1}{2}$ , 9 $\frac{1}{8}$  and 11 in. diameters. Clockwise or counterclockwise rotation. Same sizes available in DA type double width, double inlet wheels.

Torrington Airotor Blower Wheel—Double Inlet—Spider End Plates. Has blades punched and formed in a single strip, rigidly held by flanged single piece end rings. Hubs are rigidly mounted by peening. Wheels of 2 $\frac{1}{2}$  in., 3, 3 $\frac{3}{8}$ , 7 $\frac{3}{8}$ , and 11 in. diameter are available at present. Additional sizes now being developed.

"E" Series AIRISTOCRAT Fan Blades—Outstandingly high efficiency is the chief characteristic of this fan blade. It delivers more air for any given horsepower. Size for size it looks bigger, more powerful.

Convincing proof of the superior performance of this fan may be found in the NEMA and NAFM tables prepared as a guide to selection. The catalog containing these tables and specifications will be mailed upon request.

Specifications: Three-blade models in 10 in., 12, 14, 16, 18 and 20 in. diameters; four-blade models 8 in., 10, 12, 14, 16, 18, 20, 22 and 24 in. diameters. Five pitches in most sizes. Aluminum blades, steel spider and hub.

Neoprene Hubs for Shaded Pole motors—designed to minimize the transmission and amplification of motor noises by the fan blade. These hubs are currently available in  $\frac{1}{4}$ ,  $\frac{3}{16}$ ,  $\frac{3}{8}$ ,  $\frac{1}{2}$ ,  $\frac{5}{8}$  in. diameters for Torrington propeller fans up to and including 12 in. diameters.

AIRISTOCRAT "M" Series—Master Ventilating (Attic Fan) Blades—Three outstanding features of this new design are: (1) Extremely high efficiency, which gives maximum cfm per horsepower; (2) knockdown construction which drastically lowers shipping costs; (3) quiet operation—a point of major interest to the consumer.

This all steel four-blade fan is manufactured for domestic application exclusively, in 24, 30, 36, 42 and 48 in. diameters, in 40 deg pitch only.

Heating, Cooling and Ventilating Blowers for Furnace and Air Conditioner Manufacturers

Belt Drive Blowers

Universal Foot Blowers

In addition to standard (Top Horizontal, Bottom Horizontal, Upblast and Downblast) positions, motor can be mounted and outlet located in any specified position.

Both Belt Drive and Direct Drive Blowers are available without foot mounted. Lock-on feet provided which you can mount in any position on your own production lines.

### New Direct Drive Blowers

Equipped with  $\frac{1}{8}$ ,  $\frac{1}{4}$  or  $\frac{1}{2}$  hp motors. New 6-point motor mount test-proven to resist shipping abuse. Mount by feet in standard positions or by outlet in any other position. Brackets available if you choose to buy and mount motors at your plant.

### Universal Duct Blowers

Designed to be mounted in duct work in any position required to boost air movement for heating, cooling and ventilating.

New 16 page "Viking Blower Assembly Work Book"—For use in specifying sample model blower assembly you need for testing with your air conditioner, cooling tower, and evaporative cooler.

### Contents:

1. Air Selector Table for determining cfm
2. Blower Capacity Table
3. Speed Ranges of Variable Pitch Pulleys
4. Dimensions of Blowers in all positions
5. Motor Location Grid for 9 in., 11 in., 13 in. blowers... with acetate template guide
6. Belt size table for all motor positions
7. Effect of side and rear wall clearance on performance
8. Effect of blower outlet and furnace drum clearance on efficiency

### AIR HANDLING PRODUCTS

**Centrifugal Fans**—General purpose and Heavy Duty centrifugal fans are highly effective in both commercial and industrial service. Capacities up to 480,000 cfm and pressures up to 32 in. w.g.

**Axial Flow Fans**—Axiflo fans are designed to operate against resistance, are available for either vertical or horizontal airflow. Widely used in industrial heating, ventilating and fume removal.

**Ventilating Sets**—Series 900: direct connected units for maximum efficiency at popular motor speeds. Manufactured in six sizes up to 3200 cfm. Series 1000: compact V-Belt driven units for large capacity and quiet operation. Twelve sizes up to 14,400 cfm.

**Air Handling Units**—For year-round air conditioning, also available for heating and ventilating or ventilating only. They feature sectional construction, various types of coils, and accessories to give combinations to suit the application and space. Capacities to 23,000 cfm.

### HEAT TRANSFER PRODUCTS

**Heat Transfer Surfaces**—Sturtevant cooling and heating coils are available for Freon, chilled or hot water and steam. Steam coils are of standard, heavy duty steam, and steam-distributing types.

**Air Blenders**—For both winter and summer conditioning of individual rooms, air blenders mix conditioned air from a central system with recirculated air.

**Surface Dehumidifiers**—For central plant air conditioning, these sprayed coil units are available with chilled water or direct expansion coils. Capacities to 115 tons of refrigeration and 45,000 cfm.

### UNIT HEATERS

**Industrial Heaters**—For heating of manufacturing areas, warehouses, garages and general industrial and commercial buildings. Also for continuous duty heating in industrial processes and steel, paper and rubber manufacturing. Capacities to 2,500,000 Btuh and 25,000 cfm. **Propeller Fan Heaters**—Available for steam, hot water and gas-fired applications in horizontal and downblast models. Capacities range from 20,000 to 400,000 Btuh.

## Kewaunee Manufacturing Company

5119 South Center Street, Adrian, Michigan

Representatives in principal cities.

Products: AIRFLOW control fume hoods—CONVENTIONAL fume hoods—SPECIAL purpose hoods—C.B.R. SYSTEM laboratories and components—LABORATORY EQUIPMENT—wood-metal construction—HOSPITAL casework—EDUCATIONAL equipment—LABORATORY SINKS and SERVICE FIXTURES.

Catalog No. 3604 (Stainless steel interior)  
(72 in. long, 38 in. wide, 84 1/4 in. high)

Safe operation for personnel protection and comfort is paramount with Airflow fume hoods. Aerodynamically efficient, modern design enables Airflow hoods to operate at lower face velocities. Gently curved, streamlined entrance shapes at the hood face decrease turbulence—increase efficiency.

Airflow hoods operate at 50 lineal feet per minute minimum face velocity, thereby effecting reductions in cost of operation for heating and cooling systems. Automatic bypass results in constant-volume exhaust regardless of sash position. Hoods are available in various sizes in addition to those listed below. Interior lining materials include stainless steel, Kemstone and Transite. Exterior of hoods is carbon steel with acid resistant painted finish.

| Recommended Min. Face Velocities and Total cfm |                     |                              |           |
|------------------------------------------------|---------------------|------------------------------|-----------|
| Length of Hood                                 | Overall Dimensions  | Min. Face Velocity @ 1/4" sp | Total cfm |
| 4 ft                                           | 49" x 38" x 84 1/4" | 50 fpm                       | 375       |
| 5 ft                                           | 61" x 38" x 84 1/4" | 50 fpm                       | 500       |
| 6 ft                                           | 72" x 38" x 84 1/4" | 50 fpm                       | 625       |
| 8 ft                                           | 96" x 38" x 84 1/4" | 50 fpm                       | 875       |

### Automatic bypass-constant volume hoods especially adaptable for air conditioned laboratories.

The bypass is completely open in the down position of the sash. Air enters through the bypass and purges the interior of the hood. Use of the bypass limits the maximum air velocity such that disturbing air currents cannot be induced within the hood. This bypass is positive and completely automatic—there are no moving parts, controls or linkages to require service and maintenance. Operation of the bypass is controlled solely by positioning of the sash.

Booklets on "Airflow Fume Hoods" and "Airflow Control Fume Hoods Characteristics and Applications" are available without charge or obligation upon written request.

The Kewaunee Manufacturing Company's two modern plants in Adrian, Michigan, are equipped to design, engineer, and manufacture nuclear laboratory equipment, and scientific laboratory furniture. One of our field engineers will gladly visit you, upon request, to discuss the requirements of the job you have in mind and to offer any service possible without cost or obligation.

Sectional view with sash down.

## E. H. Sheldon Equipment Company

Muskegon, Michigan

### SHELDON INDUCTION FUME HOODS

Manufacturers of Laboratory Equipment for Schools, Industry, and Hospitals.

SHELDON'S *induction* hoods are designed for use in air-conditioned laboratories or in any situation where it is necessary to conserve room air.

By injecting regulated volumes of "out-door" air into the working areas of the hood to supplement the primary airflow from the laboratory, the following controlled conditions may be achieved:

1. Sufficient volume of air passes through the working areas of the hood at the face velocity required to insure complete evacuation of fumes from the system. The exhaust system of the Sheldon induction-type hood handles the same *volume* of air that the exhaust system of the conventional hood handles at a face velocity of 70-80 linear feet per minute.

2. At the same time, air movement from the room into the hood has a low enough velocity to minimize turbulence within the hood and assure quiet operation, and to prevent objectionable drafts in the work area, and excessive drain on the heating, cooling, and air-conditioning systems of the room. The difference between the exhaust volume and the volume of intake from the room is provided by adjusting the supplementary-air supply.

3. Sufficient volume of air flows into the hood from the room to carry generated fumes into the fast-moving, high-volume evacuation air currents, and also to insure optimum laboratory air changes.

If air movement from adjacent parts of the building to the laboratory is desired, a condition of negative pressure in the laboratory may be induced by lowering the supply-fan capacity or increasing the exhaust-fan capacity. Also, even if the front sash is closed, the hood will purge of fumes because a definite part of the exhaust capacity is still being supplied

mechanically and passes through the hood.

Except for minimum filter requirements, provided for in the hood design, supplementary air seldom needs to be treated, since it does not enter the room.

The following table gives the velocity, velocity pressure and total entrance loss for both exhaust and supply for various lengths of hoods with duct sizes as shown in diagrams below. These values are for volumes as shown. These values are based on exhaust fan capacity capable of producing a face velocity of 75 lfm with only the exhaust fan operating and with a supply fan capable of introducing  $\frac{3}{4}$  the exhaust capacity and producing a face velocity of 25 lfm with both fans operating.

\* Total negative static developed by the hood.

The conversion factor to obtain entrance loss from velocity pressure is 1.5 for 3 ft, 4 ft and 5 ft hoods, and 1.75 for 6 ft, 7 ft and 8 ft hoods.

\*\* Total positive static developed by the hood.

The conversion factor for all hoods for the supply air static is 1.5. These statics should be added to the duct resistances when computing fan sizes.

5' Hood operating under the above conditions.

The duct stubs are located on the top of the hoods as shown. The supply air can enter from below when building conditions require such arrangement. The values given in the table for various lengths of hood are for average conditions.

Consultation is solicited without obligation on other or unusual conditions. Since the hoods use a definite volume of "conditioned" air, their requirements should be considered very early in the

work of designing and specifying heating and/or conditioning plants.

Sheldon engineers welcome new problems arising out of recent production and development programs. A laboratory at Muskegon is maintained for this purpose. A list of satisfied users of a wide variety of industrial installations is available upon request.

### LOW SILHOUETTE ROOF FAN

Allen "I-Line" Roof Fan is designed to meet the architect's demand for an attractive low silhouette and the engineer's demand for high efficiency. This is accomplished by use of a circular spun steel hood, and venturi, with baffle so arranged in relation to the propeller as to provide maximum efficiency with minimum over-all height. Its appearance and quiet performance recommend it for new or old construction, such as schools and offices as well as industrial plants. It is easy to install (no extra base required) and it is easy to lubricate and clean. Available with *Direct Drive* (450 to 34,000 cfm) or with *Belt Drive* (4,000 to 20,150 cfm).

### VERTICAL DISCHARGE FAN

Allen Type "VD" Roof Fan is designed for use where extremely high discharge velocity prevents the tendency of fumes to short circuit back through building openings. Fabricated of prime zinc-coated iron sheet, welded construction throughout. Automatic wing dampers open with air blast, close weathertight when not operating. Available with *Direct Drive*, with motor readily accessible, or *Remote Drive*, with motor in outside housing and enclosed V-belt drive.

### STAXAUSTER FAN

Allen Staxauster is a simple, compact, sturdy unit that can be used to convert all types of roof ventilators into powerful exhaust or air supply units. It is available in many sizes with either *Direct Drive* or *Remote Drive* for handling corrosives and/or high temperature air.

### TURBINE VENTILATOR

Allen Type "C" Turbine Ventilator is wind driven and economically removes heated air, fumes and dust. It is made of heavy-gage coated iron or of special non-ferrous metals, and is easy to install and maintain. Many thousands of Type "C" Turbines are in use in industry.

### BACKWARD CURVE DIRECT CONNECTED

"BCD" Non-Overloading Roof or Wall Exhauster. Designed for optimum performance at lowest possible velocities, reduces noise level to an absolute minimum. Motor directly connected to dynamically balanced wheel eliminates costly maintenance.

### BELTED ROOF EXHAUSTER

"BCB" Lo-Boy Non-Overloading Centrifugal Wheel. Capacity table offers a selection of 16 wheel sizes—204 constant speed combinations with tip-speeds as low as 2000 fpm. Unit is exceptionally low in height. Standard construction consists of welded structural steel frame, heavy 16 gauge mild steel. Storm band and motor cover is 18 gauge.

Patents No. 2571513-26666378. Others Pending

### POWER ROOF EXHAUSTER

"PB" or "PFAS" Lo-Boy Wall or Roof Units. Efficient and quiet operation for low static pressures up to  $\frac{1}{2}$  inch. Rubber grommets are installed around all points where metal contacts metal. Powered fresh air supply units on "PB" exhausters with reversed pressure blade to bring fresh air in under power.

### DISAPPEARING EXHAUST SYSTEMS

Under the Floor and Overhead exhaust systems for all makes and models of cars and trucks. Will accommodate flexible metal hose up to six inches in diameter. Write for Bulletin No. 650H.

## THE G. C. BREIDERT CO.

P.O. Box 1190, San Fernando, Calif.

Representatives in Principal Cities of the United States

### MANUFACTURERS OF VENTILATORS FOR EVERY NEED!

There is a Breidert Air-X-Hauster for every ventilation problem. Breidert guarantees **POSITIVE VENTILATION UNDER ANY WIND CONDITION**, barring internal negative pressures!

#### FOR ROOF VENTILATING:

Patents applied for

Old Method  
of Testing

Breidert Method  
of Testing

Patent # 2269428

#### THE NEW BREIDERT POWAIR-X-HAUSTER—

The latest addition to the Breidert line of Air-X-Hausters is this low silhouette power unit. Its unusually large capacity against high static resistance is made possible by horizontal discharge. The top-mounted motor is kept cool and trouble free by ingenious use of outside air. Continues to operate by gravity action when power is off!

#### FOR CHIMNEYS

Breidert Air-X-Hauster Chimney Tops overcome sluggishness caused by down drafts... have produced excellent results on Industrial, Commercial and Residential applications.

In every case where Breidert Air-X-Hausters were properly installed they have never failed to function as advertised.

Write for Free Engineering Data Book containing detailed specifications and installation data and certified capacity ratings.

• Pittsburgh Testing Laboratories

#### THE ORIGINAL BREIDERT AIR-X-HAUSTER—

A gravity flow ventilator, stationary with no moving parts. Widely used on all types of factories, commercial buildings and residences. Breidert Air-X-Hausters pioneered with published certified capacity ratings based on tests\* made with wind blowing in all directions as shown. Only such tests can guarantee the capacities a ventilator will deliver under actual operating conditions.

#### FOR GAS APPLIANCES

The Breidert L. S. Vent Flue Cap assures positive ventilation with complete safety. Pilot lights cannot be blown out, barring internal negative pressures!

## The Gallaher Company

4108 Dodge Street, Omaha 3, Nebraska

Representatives in Principal Cities of USA and in Canada by Canada Fans Ltd., Montreal

Manufacturers of AIR-VAN® and AIR-MAX® Power Roof Exhausters

Pat. 2188241 2526290  
Pat. Pending

#### Series 1, 2, 3, 4, AIR-VAN® Direct Drive

Capacities 150-11,700 cfm. Static Pressure to 4 in. Low installed silhouette design with motor out of airstream for protection against fumes. Exclusive Gallaher scroll effect design. Shipped as complete package ready for installation. Series 1, 2, and 3 have forwardly curved wheels with blades at varying angles. Series 4 has backwardly curved non-over-loading wheels. Choice of wheels allows buyer to tailor-make unit and select exact capacity desired. Ratings are certified by an independent laboratory.

#### Series 5 AIR-VAN® Belt Drive

Capacities 1,000 to 65,000 cfm. Static Pressures to 4 in. The one belt driven power roof exhauster with guaranteed high static pressures and air volumes. Motor out of airstream. Patented scroll effect design. Shipped as complete package including base. Does not require extra height for unobstructed discharge. Extremely heavy construction. Certified ratings by an independent laboratory. Weatherproof under extreme conditions.

#### AIR-MAX® Downblast Model C

Capacities 1,000 to 44,000 cfm. Static Pressures to 1/2 in., and more on special order. Designed to handle relatively dry air at minimum horsepower. Low silhouette. Economical direct connection to duct system without field assembly. Fully blackout. Certified Ratings. Can be furnished for summer or winter supply as well as exhaust. Propellers incorporate latest features in air foil design—four or six blades. Can be replaced without buying new wheel.

#### AIR-MAX® Upblast Model CU

Capacities 1,000 to 44,000 cfm. Static Pressures to 1/2 in. and more on special order. Designed for upward discharge. Special clam shell type dampers give weatherproof protection when units are not in operation. Units have low silhouette characteristics of all Gallaher units. Sturdy construction throughout. Damper stops prevent locking in the open position.

Units can be supplied in Aluminum, Copper, Monel, Stainless Steel, and in any resistant finish.

For complete catalog information including certified rating tables, and all pertinent selection and installation data, write The Gallaher Company or contact its representatives.

GENIE-AIRS exhaust, recirculate, supply or mix recirculated and supply air—any 1,2,3 or all 4 functions with the same unit.

MODEL ER exhausts in summer and recirculates in winter. During the recirculating cycle the butterfly dampers, which seal the opening between the roof jack collar and sleeve section, remain in closed position and the heated air trapped at the roof line is recovered through the opening between the venturi and jet and returned to the occupied area; thus improving the efficiency of the heating system and reducing operating costs as well as initial costs. The cycle of operation may be changed at any time through a three-position switch or thermostat. In new design the amount of heat normally required can be greatly reduced when used in conjunction with these units. This model, with slight modifications, can also provide for supply of fresh air.

MODEL ES either exhausts or provides for supply of fresh air merely by reversing fan rotation through a three-position switch.

MODEL PRE is a typical power roof ventilator. This unit is equipped with butterfly dampers, which prevent heat loss in winter. Domes are optional.

MODEL RS recirculates or supplies; also, any proportion of recirculated and supply air may be obtained by varying the opening between the venturi and jet thru a manually, pneumatically, or electrically-operated mechanism. Filters are optional.

DELUXE MODEL ERS provides all four functions listed above. Filters are optional. Raise the sleeve or fan section for recirculated or exhaust air and close it for supply. The sleeve or fan section is raised or lowered by: (1) gear ratio motor and rack assembly, controlled either by a three-position switch or thermostat or (2) manual mechanism. This model available in sizes 31 and 38 only.

NOTE: Cfm delivery of all models has been calculated on the basis of the static pressure through the unit. As the percentage of cfm delivery is reduced when fan blade rotation is reversed, specify on which cycle of operation the greater cfm is required. Units having larger capacities or special combinations of fan blades, motor sizes and speeds are available on special order.

## Dimensional Data

Models ER, RS, ERS

Models ES and PRE

Type 1 and Type 2 roof jacks, as illustrated below, are furnished with all Genie-Airs. Any model may be installed in either type of roof jack; however type 2 is preferred because of its simplicity of installation. In either case, CD dimension plus 2 in. must be held vertically clear downward through the full length of equipment below the underside of roof. Unit sizes 31 and 38 require support in addition to the roof jack. Support is to be furnished by others. See suggested method for framing or support.

Type 1 Roof Jack

Type 2 Roof Jack

The Following Dimensions Are to Be Used With Type 1 Roof Jack:

Minimum Overall Height

(So Desirable for Modern One-Story School Buildings)

|                  |        |     |     |     |        |     |     |     |     |
|------------------|--------|-----|-----|-----|--------|-----|-----|-----|-----|
| Roof opening "A" | 10"    | 12" | 15" | 18" | 20"    | 24" | 30" | 36" | 42" |
| Cowl height "C"  | 5 1/4" | 6"  | 7"  | 8"  | 9 1/4" | 11" | 12" | 14" | 16" |

The Hirschman Type "CAF" Electric ventilator shown has been designed in response to a demand for the absolute minimum in overall height above the roof line, and as standard construction uses our INSULATED DOUBLE SHELL STEEL CURB of any of the several types for any kind of roof deck. Fan and motor assembly available for a wide range of capacities at the lower static pressures. The companion Type "CA" gravity or pressure relief ventilator (not shown) uses the same general construction minus the fan and motor. Either type subject to numerous modifications to meet the needs of any building project.

Our Type "LA" STATICK Power ventilator designed for efficient exhaust at either low or high static pressure, using non-overloading backward curved blade centrifugal fan, available in many sizes for almost any required capacity within reason. Note the damper housing above the top of the curb providing ready access to whatever type of damper is used. The Type "LB" STATICK Power ventilator (not shown) uses a similar construction minus the damper housing.

See Sweet's Architectural, Engineering, or Industrial Construction Files.  
Complete data on any or all types gladly furnished on request.

## Muckle Manufacturing Co.

666 Belford Road

Owatonna, Minn.

Sales Engineering Representatives in Principal Cities

**MUCKLE VENTS**—are ideal for moisture laden applications or corrosive conditions. Motor is located out of the air stream, and housing is hot dipped galvanized after fabrication for maximum protection. Capacities 254 to 10280 cfm. Units very efficient at low static pressures. Constructed from heavy gauge steel, electrically welded.

**MUCKLE LO-SIL**—designed for low silhouette appearance. Largest unit only 25 1/2 in. high. Capacities from 225 to 17,600 cfm. Automatic back draft dampers built in on all models. Vibration separators are provided to eliminate vibration and hum. Totally enclosed, ball bearing motors are directly connected to propeller.

**MUCKLE BC VENT**—Centrifugal backward curved wheel is ideal for operation where static pressures are encountered. Non-overloading, dynamically balanced wheel, directly connected to totally enclosed motor. No maintenance of belts, pulleys, or bearings. Motor is out of air stream for protection. Capacities from 280 to 7650 cfm. Heavy gauge construction.

**MUCKLE BELTED VENT**—offers over 100 different capacities for any specific requirement. High exhaust capacity utilizes low fan tip speed to make unit very quiet in operation. Low in height, compact and symmetrical design, blends well with modern architecture. Heavy duty, ball bearing motors and non-overloading backwardly curved wheels used on all units.

# PENN VENTILATOR COMPANY

Goodman above Allegheny Ave. Philadelphia 40, Penna.  
Representatives and Distributors in Principal Cities.

## Roof Ventilators and Accessory Products for PUBLIC, COMMERCIAL AND INDUSTRIAL BUILDINGS

**DOMEX**—V-belt and direct driven centrifugal fans in a weather-tight spun aluminum housing. Backwardly curved statically and dynamically balanced fan wheels with non-overloading characteristic. Over 40 capacity selections.

**PENN DYNAFAN**—Quiet, steady exhaust against system resistances. Centrifugal fans in sixteen sizes belt-driven at speeds to fill many capacity requirements.

**AIRETTE**—Efficient fans housed in easily installed modern and inconspicuous roof mounted housings. Certified capacities from 9,000 cfm to 40,000 cfm.

**HI-EX**—Straight thru—high velocity—vertical discharge air exhausters—streamlined housings. Certified capacities from 2,400 cfm to 60,000 cfm.

**TURBINE**—Ball bearing turbine ventilators are true rotary, air-driven suction turbines that work automatically and continuously without maintenance or operating expense. Ball bearing action enables the slightest motion of air to move the rotor.

**PULLMAN**—Efficient gravity roof ventilator with large protected outlet area. Large exterior suction band converts passing wind currents into a powerful suction force accelerating the movement of air up through the ventilator.

**RIDGE**—Provides complete ventilation for continuous openings of various lengths. Furnished in many throat sizes and in 10 ft standard lengths. Fabricated to be inconspicuously low and to blend with building.

**RECTANGULAR PUL-AIR**—Modification of standard round unit, intended for use where odd size ducts, masonry flues or shafts extend through the roof or openings of irregular areas must be capped with a weatherproof gravity ventilator. They can be furnished in any desired size.

18511 Euclid Avenue,

Representatives in Principal Cities

Cleveland 12, Ohio

### GRAVITY ROOF VENTILATOR

#### Swartwout-Dexter Heat Valve

Continuous opening natural draft ventilator particularly effective for ridge of peaked roof, saw-tooth construction or skylights; adaptable to flat or slant roofs. Made in throat opening sizes 4, 6, 9, 12, 15, 18, 24, 30, 36 and 42 in. Ten foot units. Adjustable damper. Weatherproof.

### DUCT EXHAUST VENTILATOR

The Airlift is a centrifugal fan unit for duct exhaust against static pressure. Operates at very low noise levels. Fan has backwardly curved blades completely non-overloading; bottom of wheel flared to form throat overlapping inlet increases efficiency, avoids turbulence. 14 sizes, 138 capacity variations.

### GRAVITY ROOF VENTILATOR

#### Swartwout Airmover

Compact multiple opening type featuring very short air travel, built in units 10 ft x 7 ft, 6 in. x 32 in. high; 30 sq ft of opening per unit. Used as single units, or single or multiple width runs. Unusual large scale ventilation results possible by roof coverage such as illustrated. Can be adapted to any type of roof. Insert shows "open roof" effect.

### FIRE VENTILATION

#### Swartwout Fire Valve

Roof unit for release of heat, smoke, gases in event of fire. Two large dampers drop, released by fusible link; provide 46 sq ft free area opening. Only 21 in. high above curb. Weatherproof when closed.

## Western Engineering & Mfg. Co.

ESTABLISHED  
4112 Glencoe Ave.

1921  
Venice, Calif.

Representatives in Principal Cities

### HIGH EFFICIENCY ROOF VENTILATORS

#### Western Rotary Ventilator

High exhaust capacity for relatively small bulk in weight. Remains in continuous motion between gusts, and is stormproof. It cannot backdraft because the throat velocity rises at an increasing rate with the wind speed. Wind tunnel tested. Rigid center support, and vibration absorptive rubber mountings, quiet performance. Enclosed, long-life lubrication, and durable hammertone sea-green finish. Sizes: 6 in. to 48 in. inclusive.

#### Western Continuous Ridge Ventilator

For high volume, low velocity exhaust capitalizing on air movement generated by temperature difference plus induced draft, this ventilator provides a continuous opening of any length desired in 17 throat sizes. The structure is storm and rain proof and is available with or without adjustable dampers and screens. Inherent characteristics qualify this ventilator for use in factories, foundries, mills and similar buildings.

#### Forbes Syphonaire

A highly-engineered stationary type roof ventilator employing a circular wind band that prevents the entrance of outside air. High capacity, rain and storm proof, rugged construction, and low silhouette, obviating the need for guy wires. Wind tunnel tested by aeronautical laboratory. Sizes range from 6 in. to 48 in. inclusive.

#### Westernaire Curb-mounted Fan

For low cost air movement under low static conditions, this unit is designed to meet practically every application involving a roof-mounted exhaust fan. High speed, high velocity for industrial use or slow speed, quiet operation for commercial use. Available in 39 models. 8 in. to 48 in. Can be used in conjunction with any type gravity ventilator.

### U.S.S. GALVANIZED STEEL

for high quality results and ease of fabrication

U.S.S. Galvanized Steel Sheets are especially processed for the jobs they have to handle. They are uniform in flatness and surface. They can be bent, cut, stamped, rolled and formed—all with unusual ease of handling. In the production of U.S.S. Galvanized Steel Sheets careful attention is paid to the adherence of the zinc coating. This is done in order that forming operations may not fracture or flake the coating and thereby expose the base metal to atmospheric corrosion and rust.

Because of all these outstanding qualities, U.S.S. Galvanized Steel Sheets permit true bends, tight joints and neat seams, even in forming difficult angles and shapes when working in close and confining places.

#### Other U.S.S. Steels famous for service

U.S.S. STAINLESS STEEL is ideal for use in chemical plants, laboratories, and other places where highly corrosive atmospheres would spell early destruction for less durable materials. Its high resistance to corrosive attack, great strength, ease of cleaning and high resistance to extremes of temperature are definite money-saving advantages.

U.S.S. COPPER STEEL—coated or uncoated, insures increased resistance to

U.S.S. Galvanized Steel Sheets are produced in a wide variety of sizes and forms. Our engineers are specialists in their use and will gladly assist you in their application.

corrosion, and increases life under all conditions of atmospheric exposure.

U.S.S. GALVANIZED PAINTBOND STEEL—for ductwork requiring immediate painting without preliminary treatment or weathering. Paint will not flake. Bonderized surface prevents deteriorating action between paint and galvanized coating. A similar sheet, U.S.S. DULKOTE, is available in the South and the West.

Kansas City 27, Missouri

### REGISTERS

### GRILLES

### DIFFUSERS

Model 400 VH Grille

A-J No. 44 Series Dampers are the same dampers furnished with No. 440 Series registers, but are also available as separate units for easy installation in the

Model 44 Damper

duct behind a grille. They provide positive metered air flow by means of their opposed blades which are controlled by a patented Phillips screw gear drive. Air is distributed evenly over the entire area of the grille. Damper locks at any degree from fully opened to fully closed, as in the photos above. Maximum depth of the unit in full open position is  $3\frac{1}{4}$  in. Sizes range from 8 in. x 4 in. through 40 in. x 12 in.

Model 440 H Register

A-J No. 400 Series Air Conditioning Grilles and No. 440 Series Air Conditioning Registers are available as either single or double deflection units to fit most standard duct sizes from 8 in. x 4 in. through 60 in. x 24 in. Choice of vertical or horizontal bars only, or combination of both with either vertical or horizontal in front. Both the spring tension mounted bank of extruded aluminum face bars and the bank of back bars are individually adjustable. No. 440 Series registers combine any size No. 400 Series grille with a corresponding size opposed blade damper which can be locked in any desired position.

A-J No. 45 Series Return Air Grilles are the matching counterpart for the No. 400 Series grilles and the No. 440 Series registers. Designed for return air intake, they are available with horizontal face bars—straight deflection,

Model 45-D Grille

vertical face bars—straight deflection, and horizontal face bars—35 deg downward deflection. Face bars are of  $\frac{3}{4}$  in. wide extruded aluminum set on  $\frac{3}{4}$  in. centers. Bar deflection is fixed at the factory. Available in all standard duct sizes from 8 in. x 4 in. through 60 in. x 24 in. For positive volume control, can be used with No. 44 Series dampers.

## A-J Manufacturing Co.

A-J Architectural Grilles are available in square meshes of  $\frac{1}{2}$ ,  $\frac{5}{8}$ ,  $\frac{3}{4}$ , and  $\frac{7}{8}$  inches, and in various slotted designs. Made to your order in any size from steel, aluminum, bronze, monel or stainless.

A-J Double and Single Diffusers are furnished with one-half of the vertical curved louvers facing to the right, one-half to the left. In cases where deflection is required in one direction only, louvers will be assembled to direct all of the air to one side only.

A-J No. 70 Series No-Vision Door or Partition Grilles are ruggedly constructed, yet are light in weight and have a free area of approximately 70 per cent. Completely sight proof. Excellent for door or partition installations. Illustration at right shows grille and cut-away view of auxiliary frame.

A-J No. 77 Series Thin Core Grilles are only  $\frac{1}{2}$  in. thick, yet are completely sight proof. Free area is approximately 80 per cent. They were developed to answer the increasing demand for ventilating grilles for panels or partitions, and can be installed in any panel ranging from  $\frac{1}{4}$  in. to  $\frac{3}{4}$  in. thick. Illustration at left shows grille and cut-away view of auxiliary frame.

A-J No. 55 Diffusing Perimeter Registers are designed specifically for installations with perimeter heating systems. Heavy gauge curved vanes are set at the factory to deliver a fan-shaped pattern

of air to cover window areas and cold outer walls. Excellent for installation in stair risers, under kitchen cabinets, in picture window sills, or as side wall outlets with high velocity systems.

FOR COMPLETE SPECIFICATIONS AND PRICES ON ALL A-J PRODUCTS, WRITE FOR  
ILLUSTRATED CATALOG NO. 55

## Air Control Products, Inc.

Coopersville, Michigan

Air Conditioning Registers, Grilles, Ceiling Diffusers  
and Leigh Building Products.

### No. 20 Series Air Conditioning Registers and Grilles

Superbly styled. Two tone finish. Positive control of air stream assured by adjustable vertical front fins plus adjustable horizontal back fins. Both banks of fins are easily adjusted from the face of the register, making it simple to set for heating or cooling.

The front fins are factory set for a multifold horizontal air pattern, an unique Air Control feature. Back fins are set for 22½ deg deflection but may be easily adjusted for any desired up or down flow. Special fin adjusting tool furnished.

The air flow pattern is not changed by the damper position. Its design provides for perfect volume control, plus ideal air

distribution. The volume control damper is formed for rigidity and strength and opens easily to a full 90 deg. An adjustable spring loaded operator makes this register ideal for upside down installation on systems where duct comes down from the attic, or on shallow depth stackheads. Adjusto-stop makes it easy to balance system at the register face. Does not interfere with closing of the damper.

No. 20 Series Sidewall and Baseboard Registers are available in the following duct sizes: 8 in. x 6 in., 10 in. x 6 in., 12 in. x 6 in., 14 in. x 6 in. Sidewall and Baseboard Grilles are available in the above sizes plus the following: 24 in. x 6 in., 30 in. x 6 in.

### MULTI-TROL REGISTERS AND GRILLES

Air Control's Multi-Trol Register line was developed to solve the problem of installation in standard wall construction. Here is a commercial type, adjustable bar register with an opposed action

valve that is so shallow it can be used with standard fittings and duct work, even in ¾ in. risers.

The shallow depth air control valve is achieved by moving the pivot point as

WRITE FOR AIR CONTROL CATALOG NO. 56-AC—COMPLETE ENGINEERING DATA, SIZES

### MULTI-TROL REGISTERS AND GRILLES (Cont.)

close to the face as possible and closing the louvers practically flat. Louvers are butterfly type and in closed position, air pressure seals the valve and prevents whistling and air leakage. At any degree of opening, air is distributed evenly over the face of the register.

Micro operator gives positive control in any position and opens and closes the largest valve smoothly and easily. On residential installation, the attractive operator key may be left in place if desired.

Face bars are built with an airfoil contour, reducing resistance to a minimum and making units extremely quiet at high velocities. Bars pivot on a round bearing surface. Pivots are rolled over where they extend through the margin—will not pull out. Easily adjusted with deflection key furnished. Bars are full depth, spaced on 0.666 in. centers, the ideal spacing to give positive air deflection and maximum free area.

Beige prime coat finish. A wide range of sizes to 36 in. x 36 in.

### NO. 188 BASEBOARD DIFFUSER WITH BUILT-IN ROTARY DAMPER.

In 2-ft and 4-ft lengths.

With built-in rotary damper the No. 188 assures peak efficiency in air patterns for heating or cooling. Insures uniform velocity at the face, regardless of degree of opening. In 4-ft lengths (29.36 sq in. free area) and 2-ft (14.68 sq in. free area) for single or continuous installation. Sculptured plastic operator.

New Adjusto-Bottom Base Strip cuts

installation time in half. After diffuser is located over the duct, the base strip is withdrawn to duct width, snipped off, and the cut-off inserted into other end of base. No. 186 Return Air Grille in matching design offers 58.72 sq in. free area. Both diffusers and return air grilles may be installed before or after plastering, on sub-floor or finish floor.

WRITE FOR AIR CONTROL CATALOG NO. 56-AC—COMPLETE ENGINEERING DATA, SIZES

**NO. 42 PERIMETER FLOOR DIFFUSER.** One-piece face has no corner seams to mar the beauty of its curved, flowing contours. New, extra wide flanges insure complete coverage of rough cut or irregular floor opening. Smoothly curved vanes and wafer-thin valves reduce resistance, increase free area, and provide more efficient air distribution. Outside walls are blanketed with a layer of warm air—prevents cold drafts from flowing into the room.

Adjusto-Stop screw stops the valve at any desired opening, balances system at diffuser face—eliminates the need for additional duct dampers. Vanes can be set for any desired deflection without shearing off at ends. Outstanding for use with conventional heating systems, perimeter heating and small-pipe perimeter heating. Standard Oak and Metal-escint finishes.

**OPENING SIZES**—14 in. x 6 in., 12 in. x 6 in., 14 in. x 4 in., 12 in. x 4 in., 10 in. x 4 in., 14 in. x 2½ in., and 12 in. x 2¼ in. Latter two are ideal for narrow, hard-to-fit spaces under kitchen cabinets, in sill of large picture window, under stair risers, etc.

**NO. 265 OUT-OF-THE-WALL PERIMETER BASEBOARD REGISTER.** Solves installation problem where duct does not or cannot enter wall. Adjusto-Stop permits the system to be balanced at diffuser face. Horizontal fins can be adjusted to throw air stream at any angle in relation to wall. Matching No. 262 Baseboard Grilles have same construction, without damper.

WRITE FOR AIR CONTROL CATALOG—No. 56AC—COMPLETE ENGINEERING DATA, SIZES

**NO. 333 RETURN AIR GRILLE.** Answers the problem of centralized returns—easily installed in ceilings, walls, doors. Made of heavy gauge steel, one-piece construction, with angle frame for added stiffness. A single return in one of the larger sizes has enough capacity for an entire heating or cooling system. In 15 sizes from 10 in. x 10 in. to 30 in. x 18 in.

**No. 15 SIDEWALL PERIMETER DIFFUSER.** Scientifically engineered to give a draftless blanket of air over the outside wall from a sidewall location. Two sizes—12 in. x 6 in., and 10 in. x 6 in. Provide complete, rapid diffusion of air when used with conventional duct or loop or radial slab installations. Top section is flared away from diffuser face—prevents air from scrubbing wall. Balancing is easily accomplished at face. Flat-spring linkage holds valve rattle-free in any position. Sponge rubber gasket seals against wall. Beige prime coat or Metal-escint finish.

**No. 16 OUT-OF-THE-WALL-DIFFUSER.** Same advantages as the No. 188 or No. 42 series. Ideal for baseboard diffuser, particularly in remodeling. Duct connected through floor; back fits flush with wall. Made in 10 in. x 6 in. and 12 in. x 6 in. opening sizes.

**“E” FRAME FOR NO. 15 DIFFUSER.** Makes conversion of No. 15 Diffusers to baseboard use extremely easy. New style frame blends smoothly with diffuser contours. Made of heavy-gauge steel, finished in beige prime coat or Metal-escint. Sculptured plastic operator.

## CEILING DIFFUSERS

**FLUSH TYPE** for installation where projection from ceiling is not desired. Air Flow Rings discharge air in concentric jets for rapid diffusion. Curved contours of ring directs air slightly downward with minimum resistance.

**STEP-DOWN TYPE**, with approximately 30 per cent more free area than Flush. Delivers air downward more directly. Both types suitable for cooling, since air is delivered at ceiling level for gradual settling. Both in 6 sizes, 8 in. to 22 in., finished in Beige prime coat.

**DOUBLE VALVE DAMPER** gives exact control of air volume, plus even air distribution. Chain operated, permit balancing system at face. For 8-in. to 16-in. Diffusers. Single valve types available for 18-in. and 22-in. Diffusers.

**INSTALLATION RINGS** simplify firm seating of Ceiling Diffusers. Easily screwed or riveted to duct end or blocking. Not used with dampers. In sizes to fit all Air Control Ceiling Diffusers.

**ADJUSTABLE CEILING DIFFUSER**—adjusts to any pattern from straight downward deflection to flat pattern. 6 sizes from 8 in. to 22 in.

No. 40

**NO. 40 FLOOR REGISTERS** feature famous Rigid-Lock type construction. Each fret is locked to each crossing fret and to margin. Dial-operator valves run the short way of face. Medium mesh (¼ in.) between faces. Same construction in No. 41 Floor Return Air Faces.

**NO. 110 SERIES REGISTERS** with vertical adjustable fins. Provide horizontal control of air stream. Single-shutter damper with sculptured plastic operator, equipped with Adjusto-Stop for balancing.

No. 110

No. 50

**NO. 50 SERIES BASEBOARD REGISTERS.** A gravity-type register with removable face for streak-proof installation. Balanced damper with sculptured plastic operator, stays at any open position. No. 80 Sidewall Gravity Register is styled to match; with damper.

### AGITAIR DIFFUSERS

Type RC

AGITAIR square and rectangular air diffusers are available with removable core and three distinct types of mounting frames, attractive in appearance, and practical for all job conditions.

The removable core is a tailor-made diffuser with patented built-in diffusing vanes. The vanes and louvers are assembled in a wide variety of patterns and sizes to suit conditions of each application. Air is discharged in one-two-three or four directions with each side delivering a quantity of air proportional to the area being served. These AGITAIR Diffusers perform efficiently, quietly, draftlessly with rapid temperature equalization.

Square or Rectangular in Shape

New method of installing AGITAIR Type "RC" Air Diffusers saves time and labor costs. Only two steps are required to finish installation: 1) attach mounting frame to duct collar. 2) Insert diffuser core and lock in position.

For installation in acoustical ceilings AGITAIR square and rectangular diffusers are made in sizes to conform to standard tile dimensions.

The AGITAIR Diffuser Data Book, available to architects and engineers, will help you design and install air distribution systems. Consult our engineers.

STRIPLINE

STRIPLINE Diffusers incorporate patented built-in diffusing vanes which produce extremely high turbulence and aspiration. Rapid temperature equalization is achieved with maximum allowable temperature differentials between room and supply air. STRIPLINE insures an unvaried distribution of noiseless, draftless conditioned air over a predetermined area. Hot or cold spots are eliminated in the zone of occupancy. Available in two styles and supplied as a continuous decorative unit or in sections.

### CIRCULAR DIFFUSERS

Type "OA" adjustable units employ a radically new means for controlling air direction at 4 different angles of discharge simultaneously without disturbing the position of the spinings. Not only is it possible to produce any angle of discharge from above horizontal to vertical, but each of four 90 deg segments are independently adjustable. Thus, it is possible to blow horizontal from one segment; vertical from a second; 45 deg downward from a third and 20 deg from a fourth if desired. AGITAIR Type "OA" Diffusers are truly adjustable, with or without ceiling.

Type "O" are non-adjustable. They are identical to the Type "OA" except for omission of deflectors. Air is discharged horizontally or above—with or without a ceiling.

1624 So. Raymond Ave.  
Air Distribution

Monrovia, California  
Air Control

### SERIES LCF SIDEWALL DIFFUSERS:

MODEL LCF-RC (Removable Core)

Factory set outlets distributing air in laminar counterflow layers mix supply with room air reaching design conditions in minimum time and space. LCF outlets can be equipped with secondary flexible horizontal vanes which may be reset on job, giving maximum, vertical control with varying length of blow.

### SERIES B60 CEILING DIFFUSERS:

MODEL 4B60-RC (Removable Core)

Patented construction provides proportionately balanced air distribution with controlled total air motion through laminar counterflow core. Square or rectangular air diffusing outlets. Full range sizes and capacities allows maximum mixing of primary and secondary air with distribution of supply air in direct ratio to floor area.

### SERIES AVP-QO Adjustable Air Proportioning Vanes:

Maximum entry into duct 2½" when full open

Balances air distribution for given supply outlet. Quick opening feature extracts air with a 2½ in. maximum entrance into main duct, reducing velocity evenly over outlet face. Full shutoff. Manufactured separately or attached to sidewall ceiling outlet or diffuser. Key or rod operated.

### SERIES OBD-KO Air Volume Control:

Opposed acting blades; center pivoted. Operate from full open to full closed position. Used directly attached to grille, diffuser or installed as separate unit. Key operated. Friction linkage maintains blades in position when set.

### SERIES ACD DIFFUSER:

For ceiling installation. Patented laminar counterflow core and flexible vanes permit on-the-job adjustments for controlling blow length and ceiling discharge angle.

## Anemostat Corporation of America

10 East 39th Street **ANEMOSTAT**® Representatives in  
New York 16, N. Y. **DRAFTLESS Aspirating AIR DIFFUSERS** Principal Cities

### PRINCIPLE OF ASPIRATION

The Anemostat Air Diffuser splits the supply air into multiple, separate air streams and at the same time creates low pressure areas in certain parts of diverging passageways. This causes room air to be siphoned into the device where it is thoroughly mixed with supply air. The mixture is discharged in a series of expanding turbulent air layers and, therefore, readily entrains a large amount of additional room air.

As a result, temperature and humidity are equalized throughout the room and a continuous air motion in the occupancy zone within low acceptable velocity limits is established. Stagnant air pockets are also avoided.

The quantity of room air drawn into Anemostat Air Diffusers depends on the specific design, size and type of the various units and is equal to as much as 35 per cent of the supply air. This effective aspiration distinguishes Anemostat Air Diffusers from all other air outlets.

### SMALLER DUCTS

Aspiration permits the use of greater temperature differentials and higher supply air velocities than customary, which results in savings in the initial cost of fans and ducts and in the operating cost of the system. Duct layouts may be simplified because Anemostat Air Diffusers distribute air evenly in spite of unusual room plans, columns or other obstructions.

### THE COMPLETE LINE

Anemostat Corporation of America has developed air distribution devices and related equipment for every purpose. Circular, semi-circular, square and straightline Anemostat Air Diffusers of various types and sizes for ceiling and wall distribution are available for comfort conditioning and industrial heating, ventilating and air conditioning installations. These are available for both conventional and high-pressure, high velocity systems.

### QUALITY

Anemostat Air Diffusers are scientifically designed according to modern fluid flow theory and manufactured according to modern production standards.

### ANEMOSTAT PATENTS

The Anemostat Corporation of America holds over fifty patents covering the use and design of diffusers in the field of air distribution. The superior functioning of the Anemostat is protected by these patents which are the result of inventive spirit, diligent research and constructive engineering.

### RESEARCH AND ENGINEERING

Anemostat Corporation of America maintains a large, well equipped laboratory manned by experienced scientific and technical personnel for testing purposes and the development of new products. Engineers from all over the world have visited the Anemostat laboratory to witness demonstrations of Anemostat products and their applications to any conceivable problem pertaining to air diffusion. Anemostat has spent over a million dollars in research and engineering and will continue to make substantial contributions to the progress of the science of air distribution.

### EXPERIENCE

Over a million and a quarter Anemostat Air Diffusers are now doing an excellent job in thousands of comfort conditioning and industrial heating, ventilating and air conditioning installations. In addition to applications in commercial buildings, industrial plants, hotels, stores, hospitals, theatres, restaurants and homes, Anemostat Air Diffusers are used in military and commercial aircraft, railroad cars, buses and ships.

### SPECIAL INSTRUMENTATION

Anemostat engineers have developed various instruments for the accurate and convenient testing of the performance of air outlets. The Anemotherm Air Meter, a self-contained, compact, portable instrument, facilitates the balancing and checking of air distribution systems by engineers and contractors. It is now commercially available and is being used with great success by engineers and contractors throughout the country.

### TYPICAL ANEMOSTAT ALL-AIR HIGH VELOCITY INSTALLATIONS

## The Auer Register Co.

6600 Clement Avenue, Cleveland 5, Ohio

Manufacturers of Registers and Grilles for Gravity and Air Conditioning Systems; Metal Grilles for Radiator Enclosure, Ventilation, Concealment

### AIR CONDITIONING REGISTERS AND GRILLES

Auer has a complete line for warm air or air conditioning, a wide choice of styles for every purpose. For gravity systems, the Heat-Rite is a quality model, adjustable for up-or-down flow. DuraBilt floor registers and intakes provide extra strength with interlocked cross-bar construction. "Streamliner" registers and grilles for high velocity outlets are made in 8 styles, with single bank of adjustable bars, vertical or horizontal, also with double bank, front

vertical and rear horizontal (or the reverse), also all these types with the addition of multi-louvre valves. Auer Register Book showing entire line sent on request.

Auer perforated grilles are made in many designs and sizes, in steel (or stainless), aluminum, brass or bronze. Finished or plated as desired. Grille Catalog, "G" gives full scale details, tables of openings and free areas.

Streamliner Register No. 1005V-HML. Adjustable bars, multi-louvre valve.

Streamliner No. 1205VH. Double deflection grille, adjustable bars.

Airo-Flex No. 4432 Register—Multi-louvres adjustable up, straight or down. Grille bars adjustable for right or left flow. Grille to match.

Airo-Flex No. 7032 Register—Grille bars set to direct air downward at 22½ deg, but adjustable for other angles. Single louvre. Grille to match.

5A—Square Lattice Grille

No. 100 Perforaire

## Barber-Colman Company

**uni-flo®**

Air Distribution Products  
Rockford, Illinois

Engineered Air Distribution Products and Complete Engineering Data to Meet Any Air Distribution Requirement

### GRILLES AND REGISTERS

Uni-Flo Grilles and Registers provide rapid diffusion, a high rate of aspiration with resultant high air entrainment ratio, low pressure drop, low noise level, simple adjustment of the air pattern, and a pleasing appearance. A variety of frame styles is available to meet sidewall, panel, or exposed duct installation requirements. A removable core feature makes it unnecessary to break the paint or plaster seal for cleaning or decorating purposes.

### HIGH VELOCITY

Uni-Flo High Velocity Air Valves reduce high velocity air to conventional velocities. Installed directly behind grilles or at junction of high velocity trunk duct with conventional velocity branch duct. Uni-Flo High Velocity Control Units, for use at individual diffusers, reduce air velocities, providing maximum attenuation of noise in minimum space. Uni-Flo High Velocity Double Duct Units mix hot and cold high velocity air and reduce it to conventional velocities.

### CEILING DIFFUSERS

Uni-Flo Square and Rectangular Ceiling Diffusers blend with acoustic ceiling tiles, providing air pattern modification without altering outward appearance of diffuser. Venturi-Flo Diffusers, for installation on ceilings or exposed ducts, provide simple adjustment of air patterns from vertical to horizontal. They are available in a complete range of sizes. Line-O-Flo Ceiling Diffusers have distinctive linear design and can be installed individually or in a continuous strip.

### ACCESSORIES

Uni-Flo accessories simplify system balancing; assure uniform air distribution across diffusers and duct sections, reducing noise, turbulence, and pressure losses; and effect savings in ductwork installation and system operation. Uni-Flo Airturbs give sweeping radius performance to square duct corners. Uni-Flo Volocitrol is a balancing device designed to provide even distribution across the grille. The Deflectrol is an air turning device designed for installation at diffuser or branch duct runouts.

## BURGESS-MANNING COMPANY

*Architectural Products Division*

5970 Northwest Highway, Chicago 31

3-Way Functional Ceilings

### A Finished Ceiling that Supplies

1. Radiant Panel Heating
2. Radiant Panel Cooling
3. Acoustic Control

The radiant panel principle of this modern ceiling provides heating and cooling independently of air movement. Heat is conducted from the coils through the aluminum ceiling panels, which are secured directly to the coils. Heat energy is then radiated to or from the entire ceiling to or from every surface and object in the room. Every square inch of the Burgess-Manning Functional Ceiling works—every square inch is heated or cooled as the case may be. Nature's way of controlling human comfort.

Uniform air temperatures are maintained, convection drafts and heat shadows are minimized. Concentrated heat sources and overheated air are eliminated.

Burgess-Manning Ceiling can satisfy a wide range of heat requirements including panel demands of 125 Btu/sq ft/hr.

### THE BURGESS-MANNING CEILING CREATES A NEW STANDARD FOR COMFORTABLE WORKING AND LIVING CONDITIONS.

- \* Carries the entire Heating Load
- \* Carries approximately one-half of the entire cooling load. (Air requirements usually limited to latent heat removal and ventilation—reduced air handling equipment and smaller ducts save building cubage.)
- \* Standard controls—instantaneous response to water temperature changes.
- \* Controlled heating and cooling without LAG or OVER-RUN.
- \* Modular system for design flexibility as to layout, lighting, and any system for air distribution.
- \* Unrestricted use of floor area.

### TYPICAL SPECIFICATION

Install Burgess-Manning Ceiling complete with suspension system, heating-cooling coils, acoustic-thermal blanket, perforated aluminum Snap-On Panels standard finish and matching metal edge molding. Each coil is to be provided with threaded nipple ready to accept supply and return piping. Openings to be provided for recessed light troffers, diffusers and sprinkler heads. Supply and return piping, including balancing cocks and air vents to be supplied and installed by others.

For design procedure and performance curves send for Catalog A-129-G.

Standard 1½ in. Carrying Channel

## Charles Demuth & Sons, Inc.

Mineola, N. Y.

### Demuth Draftless Air Distributors

Representatives in Principal Cities

Designed and Patented by Demuth

The DEMUTH DRAFTLESS AIR DISTRIBUTOR consists of a series of curved vanes, mounted on a deflecting cone, to insure 360 deg distribution without the aid of secondary equalizing devices. A second hollow deflecting cone is arranged at a tangent to the primary cone, forming an injection nozzle.

The curved vanes discharge the supply air in turbulent streams, mixing room air with conditioned air, thereby providing constant air motion, uniform temperature and draftless distribution throughout the room.

Secondary air currents, which are created by the turbulence of the discharge air, are drawn into the diffuser by the bottom or secondary cone, mixed with the supply air, resulting in positive aspiration.

Type (SQ) square and rectangular Air Diffusers are made to any size with removable core assembly. Air distribution is from one, two, three or four sides of the diffuser. Made to any air pattern.

### Accessories

Combined lighting is available with the circular type. Volume and Splitter Dampers are available for all types.

# CONNOR ENGINEERING CORP.

Danbury, Conn.

Representatives in  
All Principal Cities

In Canada: Douglas Engineering Co., Ltd., Montreal, P. Q.

## CONTROLLED AIR DIFFUSION

Type KDA for supply air. Aluminum, sizes 4 to 36 in. neck dia. Capacities 50 to 15,000 cfm per unit.

Type SRD for combination supply and return air. Sizes 6 to 24 in. supply neck dia. Capacities 50 to 2,500 cfm per unit, return neck area 75% of supply.

Kno-Draft Diffusers are geometrically proportional, size for size, insuring like resistance at like neck velocity for any size—a considerable advantage when selecting various size diffusers for a common system.

## Anti-Smudge Cone

Where exceptionally sooty or dusty air conditions are expected or where rough-textured ceilings are employed, the use of this accessory cone is recommended. It furnishes the additional control needed to provide the precise air separation which inhibits smudging.

Diffuser with anti-smudge Cone assembled

Diffuser and Cone separated

## Square Diffusers

Kno-Draft Square and Panel-type Air Diffusers with built-in volume control and precision circular air patterns are engineered to give the utmost in air distribution efficiency.

Designed for installation in modern acoustical ceilings their simple geometrical lines complement the inherent beauty of the ceiling pattern, creating a uniform effect that is pleasing to the eye.

Utmost flexibility of installation is an outstanding feature of the Panel-type diffuser. By use of special patented flexible tubing the diffuser need not be lined up with duct and may even be installed in adjacent bays. Entire offices, partitions and floor areas may be relocated without moving ductwork.

Integrally stamped Panel Type diffusers shown installed in Acousti-Line ceiling. Sizes available, 4 in. to 6 in. neck dia. with capacities from 75 to 175 cfm.

Type KP for installation in acoustical ceilings, 4 in. to 14 in. neck dia. sizes. Capacities from 50 to 1850 cfm.

Kno-Draft Diffusers are covered by U.S. Patents Nos. 2,365,867; 2,369,119; 2,452,259 and others pending; Canadian Patents Nos. 429,208; 443,235.

## HIGH PRESSURE AIR DIFFUSION

In 1949 Connor Engineering Corp. was among the first to supply units for large high pressure diffuser installations. Since that time, the company has been continuously active in the development and use of high pressure systems. High pressure techniques are now applicable to almost every type of proposed or existing structure. High pressure air transmission systems using Kno-Draft high pressure air diffusers are installed and operating satisfactorily in office buildings, hotels, hospitals and schools.

The air outlets are of utmost importance to the successful operation of a high pressure system. Located directly above the occupied areas, they must perform in a completely satisfactory manner if the system is to be a success and its potentialities fully realized. Various high pressure diffusers are required to satisfy all job requirements. Different outlets are necessary for different systems; also, different installations require different methods of air distribution. The illustrations show two of the many types of Kno-Draft high pressure diffusers.

HPC-J High Pressure Diffuser for exposed duct in installation.

Cutaway view of HPR-KA showing internal construction.

The HPC-J was the first high pressure diffuser made by Connor Engineering Corp. The one shown is the result of improvements that have been made over the years. This diffuser was specifically designed for use on exposed ducts in existing department stores and office buildings with particular emphasis on achieving a neat, unobtrusive appearance.

The HPR-KA is one of the most silent high pressure diffusers made. The cutaway illustration shows internal construction including the damper mechanism and sound trap. The damper is a perforated cylindrical type patented by Connor Engineering Corp. It is used in all Kno-Draft high pressure diffusers. The inlet tube and perforated cylinder are fabricated from one piece of corrosion resistant, stainless steel. An adjustable felt-edge piston seals the cylinder. Changes of position increase or decrease the number of perforations exposed and thus vary the air delivery of the unit.

This cylindrical perforated damper has many advantages: it is quiet, simple in construction, self-cleaning, and permits both a complete and positive shut-off together with a wide open position where unavoidable construction dirt can pass through the damper mechanism. The sinuous sound trap is another patented development. It absorbs both low and high frequency noises and the carefully designed contours prevent turbulence and noise generation.

Kno-Draft high pressure units are also available in dual-duct models which feature the same unique construction. Provision is made for operation of the dampering mechanism by pneumatic motors.

## Free Handbooks on Air Diffusers

Complete information on Kno-Draft high pressure diffusers is contained in the newly published Bulletin K-33. This manual also answers many of the questions about high pressure air transmission and contains complete detailed information for designing these systems.

Bulletin K-20A contains complete information on the standard line of Kno-Draft low pressure diffusers. The unique characteristics of these single-jet, high velocity diffusers makes them ideally applicable to low pressure installations. Either of these bulletins may be obtained by writing on your company letterhead to: Connor Engineering Corp., Dept. Y29, Danbury, Connecticut.

Kno-Draft High Pressure Bulletin K-33 gives complete technical data on high pressure systems and diffusers.

Kno-Draft Adjustable Air Diffusers and their operating characteristics are fully described in Bulletin K-20-A.

See pages 1326 and 1327 for data on Dorex Air Recovery and Air Purification Equipment.

## General Register Corporation

14 Factory St., Cedar Grove, N. J.

General Register manufactures a complete, quality line of adjustable and fixed supply and return registers and grilles for cooling systems.

Double-deflection register illustrated consists of double-deflection grille with Silentite opposed-blade damper. Front fins may be either horizontal or vertical. Single-deflection type also available.

Double-deflection adjustable grilles offer quiet, efficient diffusion. Face fins are hollow, streamlined, sturdy, staked on close-fitting pins to prevent movement after setting. Heavy frames have solid corners and pleasing radius edges. All registers and grilles available with fins on either  $\frac{1}{2}$  in. or  $\frac{3}{4}$  in. centers; supply units furnished with rubber gasket.

Fixed return registers and grilles are of same quality construction as supply outlets, with fins set straight or at 40 deg angle. Registers are furnished with key-operated Silentite damper.

G-R's standard baked prime coat paint is a handsome finish suitable for permanent installation unchanged, or may be readily repainted later.

Simple, inexpensive dampers of the multi-shutter type are available for all General products. Supply registers, with very shallow depth, contain the entire blade structure within the damper housing, whether damper is in open or closed position. Curled edges of rolled blades interlock when closed, providing positive shut-off.

## General Register Corp.

Silentite Volume Damper, outstanding feature of the General line, is supplied with all commercial registers; also furnished as a separate unit. Diagram shows hollow blade construction, made by an automatic precision fabrication process. The streamlined contour eliminates turbulence, allows greatest free air passage. Hollow formation provides for positive gripping of bearings, assuring firm, free action without rattling. Reinforcing rib and double-thick edges produce great durability, also rigidity in longer blades.

The General line includes a long list of air handling and control devices for ventilating and cooling systems.

The Ductrol consists of a series of individually adjustable deflecting blades staked on close-fitting pins, to divert air from a supply duct into a collar.

Mounting frames are provided where it is desirable to remove registers or grilles periodically.

Also available is a full line of ventilating grilles for doors and partitions, fusible links for Silentite dampers, angle-iron frames, pulley and chain operators, adjusting keys, and a variety of plated, polished, and lacquer finishes.

Plain lattice stamped grilles can be furnished as exhaust registers with key-operated dampers. Other grilles include Pencil-Proof for schools, and Sanitary, readily suitable for cleaning. Various metals can be supplied, as well as a variety of finishes.

## Hart & Cooley Manufacturing Co., Holland, Mich.

Air Conditioning Registers, Grilles & Diffusers—Warm Air Registers—Damper Regulators—Furnace Regulators—Pulleys—Chain

**No. 74 DESIGN—Economy Type Air Conditioning Register.** Flexible-fin face

permits any up or down deflection of airflow. Positive valve with volume control for accurately balancing system. Gasket prevents streaking. Side-wall and Baseboard Registers in sizes 8x4 through 14x8. Grilles 8x4 through 30x8.

**No. 75 DESIGN—Multi-deflection.** Flexible-fin face provides for any deflection

of airflow sidewise. Turning-Blade Valve, an H & C exclusive, turns airflow up, straight or down with 30 per cent less resistance. Instantly adjustable. Gasket prevents streaking. Side-wall and Baseboard Registers in sizes 6x4 through 14x8. Grilles 6x4 through 30x8.

**TRIPL-AIRE Sidewall Registers.** Excellent for commercial type installa-

tions. Provide any deflection or combination of deflections desired. Opposed louvers afford absolute volume control. 26 standard sizes up to 36x12... each available in 10 combinations of horizontal and vertical front and secondary face bars and louvers. All key adjusted from front. Maximum size: 36x36.

**No. 76 DESIGN—Ideal Register for Shallow or Horizontal Ducts.** Multi-

shutter valve (depth  $1\frac{1}{16}$  in. from wall) and flexible-fin face provide for all deflections desired. Any up or down deflection can be maintained with adjusting screw. Sealed to prevent streaking. Sidewall and Baseboard type Registers in sizes 6x4 through 30x8.

**No. 88 DESIGN—Shallow Ducts, Large Installations.** Similar to No. 76 except

that face bars are adjustable in  $2\frac{1}{2}$  in. sections (one moves all in section). Exceptionally good for large installations. Removable handle available to avoid tampering. Sidewall Registers or Grilles 6x4 through 30x24.

**FIXT-AIRE Return Air Grilles and Registers.** Similar in construction and

perfect complement to TRIPL-AIRE line. Same louver, but face bars (single bank) are fixed in either horizontal or vertical position. Grilles may be had with horizontal face bars set at 22 degree angle for up or down deflection. Maximum one-piece size: 36x30.

**No. 401 DIFFUSAIRE—For Perimeter Heating or Cooling.** Installed above the baseboard on outside walls, provides an excellent means of blanketing outside wall and window areas with a curtain of warm or cool air. This diffuser disperses air in full 180 degrees spread upward in addition to directing a small portion downward over floor. Adjustable stop on handle permits balancing system at the face. Sizes: 10x6, 12x6, 14x6.

No. 401

**No. 405 DIFFUSAIRE—For Perimeter Installations.** Particularly good for use in established homes. Out-of-wall Baseboard type. No stackhead required. Provides same air pattern as our No. 401 Sidewall DIFFUSAIRE.

No. 405

**No. 411 DIFFUSAIRE—For Perimeter Heating or Cooling.** Floor type. Counteracts downdrafts from windows and cold walls. Opposed louver valves and set-screw adjustment permits accurate volume control for easy balancing of system. Design of louver blades provides even spread of air in fan shaped pattern with minimum resistance. Sizes:  $2\frac{1}{4}$ x10, 12, 14; 4x10, 12, 14; 6x10, 12, 14.

No. 411

**No. 44 Series DIFFUSAIRE—For Perimeter Systems.** Continuous Baseboard type for installations of 8 ft or more. Furnished in 2 ft or 4 ft units, KD. No disassembly or lining up of screw holes necessary. Precision parts snap together without need of tools. Easy to install, easy to clean. Damper available with balancing adjustment.

No. 44 series

**No. 452 DIFFUSAIRE—2 Foot Perimeter Unit.** Same construction as No. 44 with additional top perforations for greater volume. Equal to 8 ft continuous type. No cutting of bottom section required. Balancing damper available. Its high throw makes it ideal for cooling as well as heating.

No. 452

**CEILING DIFFUSAIRE—Low resistance eliminates necessity of changing blower in "residential package heating."** Does excellent job on any residential or small commercial heating or cooling installation. 5 popular sizes. Gasket prevents streaking. Damper available.

## Hendrick Manufacturing Company

Hendrick Bulators; Hendrick Perforated Metal Grilles; Hendrick Mitco  
Open Steel Flooring, Armorgrids, Shur-Site Treads

### HENDRICK BULATOR

*the dual-unit combination  
of a deflecting vane grille  
and an ornamental grille*

Now you can secure in a single installation all the advantages of an adjustable vane grille—to direct air flow—and an ornamental grille—to harmonize with the decorative scheme—by specifying the new dual-unit Hendrick BULATOR\*. It is a practicable combination that meets both the engineer's specifications for air throw and spread, and the decorative requirements of the architect.

In this dual-unit, the deflecting vanes are not noticeable, although they are mounted just behind the ornamental grille. The vanes are adjustable so that the air flow can be deflected to right or

Photograph taken with deflecting vanes less than an inch behind grille, shows that vanes are not noticeable.

Vertical deflecting vanes, showing how the vanes may be set to produce any desired air stream pattern.

left, up or down, or in a combination of both directions.

For the imposed ornamental grille section of the dual-unit Bulator, Hendrick offers a wide selection of attractive designs, with the essential open area.

#### Tested at Case Institute

To determine the efficiency of the dual-unit, tests were made at the Case Institute of Technology, Cleveland, under the direction of Professor G. L. Tuve, as a result of which, "it was found that at a given air volume, the presence or absence of the 'Mosaic' (design) grille made very little difference on either the air stream pattern or the throw."

A copy of the detailed report on these tests will be mailed on request.

#### How to specify or order Hendrick Bulators

In specifying or requesting quotations on the Hendrick dual-unit Bulator, the following information is required:

1. The name or description of the desired ornamental grille, as given in the Hendrick Grilles catalog.
2. The metal, gauge and finish of the ornamental grille, that is required.
3. The dimensions of the air duct opening.
4. The type of deflection desired in the deflecting vane section; whether right and left, up and down, or a combination of both.

\* Beauty + Ventilator

### HENDRICK PERFORATED METAL GRILLES

Hendrick decorative grilles are furnished in over a hundred patterns, and in a wide variety of overall dimensions, bar sizes, and number and size of perforations.

Many exclusive Hendrick designs, originally produced to meet an architect's specifications for some particular project, are now available as standard numbers, and facilities for making special designs to specifications make the Hendrick service even more complete. The wide range of patterns permits the choice of a grille that will harmonize with any style of architectural design or period construction.

Arglin—63 per cent Open Area

Grilles are fabricated in heavy-gauge aluminum, bronze, copper, Monel, steel, stainless steel, and other commercially rolled metals. With ample open areas and accurate sizes, Hendrick grilles are characterized by clean-cut perforations, fine finish, and freedom from burrs and other imperfections.

M-No. 2—67 per cent Open Area

M-No. 3—67 per cent Open Area

They are easy to install, and always lie flat because of a special flattening operation in their manufacture.

Argive—60 per cent Open Area

La Crosse—55 per cent Open Area

### AIR CONDITIONING GRILLES AND REGISTERS

Hendrick air conditioning grilles and registers for directed air flow are made in various meshes, the standard having  $\frac{3}{8}$  in. opening between face bars. All types are furnished with either horizontal or vertical directional bars.

The standard mesh can either be furnished with grille bars permanently set at the factory for straight or directional air flow, or furnished so that the grille bars may be individually adjusted on the job to direct air flow to any desired degree.

Front View

Rear View

## The Independent Register Co.

ESTABLISHED 1898

3747 East 93rd Street, Cleveland 5, Ohio

AIR CONDITIONING REGISTERS AND GRILLES

No. 321A-HMV Tandem

With these grilles, compound deflections of air flows can be obtained with accuracy and certainty. The directional adjustment can be made at the time of installing or after the grille is in position. Each vertical bar on the front may be individually adjusted for air flow right

or left. The HMV valves on the back may be adjusted by the levers in front so as to direct the air flow up or down, or they may be fully closed. If width exceeds 24 in. the valves are made tandem as illustrated above.

No. 27

Adjustable Vertical Front Bars. Adjustable Horizontal Rear Bars. Key Control opposed blades for volume control attached.

No. 311D-WG Bars Fixed Down

These grilles are designed for commercial installations. Style No. 311-D-WG illustrated has grille bars set permanently at approximately 35 deg. down. Other models available have grille bars set for straight flow.

No. 27 Rear View

Opposed blades for volume control.

No. 60A

For floor installations. Bars are set to diffuse the air up and out to both sides. Famous "Fabrikated" construction, excelling in rigidity, open area and fine appearance. Size shown 24 x 14. Other sizes are made and comply with code requirements of NWAH and ACA.

## Knowles Mushroom Ventilator Co.

Established 1906 All Patents Protected

Main Office and Factory

Upper Montclair, New Jersey

*Nu-Notch*

### NU-NOTCH Specifications

Furnish and install where indicated on drawings or as hereinafter specified (5 in.) (6 in.) (7 in.) (8 in.) (10 in.) (Dome Top) (Flat Top) Nu-Notch Cast Iron Mushroom Air Diffusers with recessed notches for the permanent adjustment of mushroom caps at any desired opening, together with center locking screw feature.

Cast iron mushroom, successfully serving in over 5,000 buildings in U. S. and abroad. Provides correct draft-free distribution of air to each individual in any size auditorium, orchestra or balcony. Close regulation of air—10 different adjustments for all possible conditions. Easily regulated by part turn of cap, and locked in position by tightening head screw with special key—new feature to prevent tampering. Supplied with dome or flat tops, 5 diameter sizes. Easy, permanent anchorage to wood, concrete or monolithic floors.

PROPER auditorium ventilation is now recognized to be a combination of temperature, air motion and distribution, humidity, dust, bacteria, odors, and carbon dioxide. Air motion and distribution is second only to temperature in importance. The Synthetic Air Chart adopted by the ASHVE takes into account all of these factors and makes it possible to arrive at an average which will show the percentage of ventilation obtained in any given installation.

For nearly a half century KNOWLES has devoted itself to one specialized field—the manufacture of air diffusers for auditoriums.

Write for free Guide to Distribution of Air in Auditoriums.

Adaptability of the KNOWLES Mushroom Air Diffuser. In an auditorium seating 2000, requiring 40,000 cfm, it is desired to use 6 in. dia. NU-NOTCH Mushrooms with air velocity of 600 fpm. By referring to the table below, it will be seen that a 6 in. mushroom will exhaust 120 cfm. Dividing 40,000 cfm by 120 indicates 333 units are required.

| Size | Dimensions in Inches |       |       |       |       |       | Net Wgt. Lbs. | Area Sq. Ft. | Cfm at Velocity of |       |       |       |       |       |       |       |       |  |

\* The 10" dia. Nu-Notch is the most economically priced Mushroom to use also affording the greatest exhaust area and least duct connections.

### KNOWLES NU-NOTCH MUSHROOM AIR DIFFUSER

For Auditoriums

MODERN practice shows that 8 cu ft of fresh air per minute per person is ample to keep the air in an auditorium free of odors; and to maintain body heat and to balance the outdoor heat of a warm summer's day, about 20 cu ft per minute per person must be introduced. The accurate amount becomes an engineering problem too extended for this outline.

Of the 20 cu ft per minute per person introduced, 12 cu ft may be recirculated, economizing heat in winter and cooling in summer. If too much air is recirculated, odors will result; and when smoking is to be allowed, much more new air must be introduced.

**Lima**

## Register Company, Lima, Ohio

Complete line of floor, baseboard, wall and ceiling diffusers, registers and grilles for heating and cooling.

SOLD EXCLUSIVELY THROUGH HEATING WHOLESALERS AND MANUFACTURERS.

### Proper Diffusion of Air

There is a Lima diffuser designed to assure efficient air distribution over a wide area from any location in the room—floor, baseboard, sidewall or ceiling. Lima's standard sizes of heating diffusers have extra sturdy construction and are equally efficient for cooling as well as heating. Unretouched photo shows front view diffusion pattern of Lima Series 70 Extended Baseboard Diffuser.

### Series 70, Perimeter Extended Baseboard Diffuser with Automatic Pushbutton Damper

Factory set louvers assure uniform diffusion over a wide area. Correct vertical angle eliminates wall scrubbing and allows aspiration of room air down between

wall and air stream. Equally efficient for cooling. Full length spring operated automatic pushbutton damper. Finger tip balancing adjustment. Available in 4-ft and 2-ft sizes. Can be installed in any multiples using joining connector. Permanent medium beige finish.

### Series 75 without damper

This unit is identical in sturdy construction and permanent medium beige finish as the Series 70 but without the automatic pushbutton damper feature, for economy installations where a damper is not required. Available in 4 ft and 2 ft sizes.

### Series 77 Matching Return Air Grille

For use as a return air grille in perimeter extended baseboard installations. This attractive matching unit has the same modern styling, sturdy construction and permanent medium beige finish as Lima Series 70 and 75 diffusers.

### Aspiration of Room Air

All Lima diffusers are engineered to induce imperceptible aspiration of room air for satisfactory indoor comfort without drafts, in heating and cooling. Photo shows Lima Series 70 side view diffusion pattern with arrows indicating how air within the room is drawn into air stream, setting up induced recirculation of room air. This air pattern holds constant even at low cfm delivery and the velocity remains uniform without whistling, regardless of damper setting.

## Lima Register Company

## Air System Equipment • Registers, Grilles And Diffusers

### Series 65 Round Step-Down Ceiling Diffuser

Step-down rings have curved contour without straight edge for proper air diffusion and greater free area. Air stream is deflected outward and slightly downward in all directions without ceiling smudges or drafts. Angle permits aspirating effect with continuous recirculation of room air. Equally efficient for cooling. Spring-loaded butterfly damper, with exclusive balancing control feature. Available in seven sizes.

### Series 60 Square Step-Down Ceiling Diffuser

Square design harmonizes with modern tile or block ceilings. Tiers of step-down vanes assure maximum free area with a minimum of resistance and provide effective air diffusion in heating and cooling. Also recommended for return air outlets, especially in perimeter systems, eliminating large, unsightly grilles. Spring-loaded butterfly damper. Exclusive balancing control feature. Six sizes available. Permanent light beige finish.

### Series 45 Wall Diffuser

Offers perimeter heating and cooling advantages from side wall. Adaptable for replacing wall or baseboard registers when cooling is being added.

Diffuses air upward and outward so air stream does not strike room occupants. Vertical angle induces aspirating effect of room air.

### Series 40 Floor Diffuser

Spreads a full fan-shaped blanket of air upward and outward to both sides at reasonably high velocity. Pulls air from within the room toward outer wall, setting up induced recirculation of air. This constant aspiration of room air is comfortable and complete without being noticed. Equally efficient for cooling. Five popular sizes are available in a choice of permanent finishes.

See Sweet's Architectural File 29f-Li. For complete catalog contact your local heating contractor or write direct to The Lima Register Company, Lima, Ohio.

## Louvra Manufacturing and Sales Company

Union, New Jersey

Products of Satisfaction

RESIDENTIAL • INDUSTRIAL • SCHOOL • INSTITUTIONAL REGISTERS & GRILLES

Louvra Manufacturing and Sales Company manufactures one of the most complete lines offered. Carefully designed and built to highest specifications. Solid vanes. Resistant to inward corrosion and rust. Maximum free area in all designs. Manufactured of prime steel, aluminum and brass, electro-plated finishes of all types.

1. The Flow Trol, volume controller of air, easily adjusted, complete range in setting. Adjustable tension.

Vision Proof Door louvers available in three types. Core type A, core and flange type B, core flange and reverse frame type C. Maximum free area. (Not shown.)

2. 111-Series. Maximum range four way deflection supply grille. Adjustable face bars.

3. 115-Series. Maximum range single deflection register with protector vanes and adjustable face bars.

4. 116-Series. Maximum range. Four way deflection plus complete volume control and shut off. Adjustable face bars.

5. 111-S-Series. Four way deflection with adjustable range. Back vanes have screw adjustment in and out of air stream without removing face. Available on all series. Face bars adjustable on all types.

6. The 25-75 Lattice Register and Grille in 10 to 14 gauge steel.

7. 103-Series. Conversion-Aire air wall heating or cooling.

8. 110-Series. Maximum range, single deflection grille. Adjustable face bars.

Positive tamper proof volume control available on all series registers. (Not shown.) Patent Pending.

9. Vane-O-Line. One of the original strip grilles with adjustable vanes.

### ADVANTAGES OF MULTI-VENT TYPE AIR DIFFUSER

1. Conditioned air is delivered straight down into the room at a comfortable low velocity.
2. Complete concealment when used with standard perforated metal pan ceilings.
3. Complete freedom of partition movement with no mechanical adjustment or relocation required because air gently drops straight down.
4. Eliminates dirt smudge on ceiling, usually found adjacent to conventional diffusers having horizontal high velocity distribution.
5. Exceptional performance with no drafts even when used on applications requiring 60 air changes per hour.

#### RECOMMENDED MODULAR LAYOUT

#### TYPE-MVAR UNITARY MULTI-VENT PANEL

1. The Control Plate and Frame are installed in the bottom of the air supply duct of plenum or in a collar extending down through the ceiling.
2. The Pressure Displacement Air Valve is located in the center of the control plate. Its function is to control the volume of air admitted to the unit and to reduce both velocity and pressure of the incoming air.
3. The Perforated Plate spreads the delivery of the incoming air over a large area and further reduces the velocity which, in a typical installation, is only 30 to 50 ft per minute at 6 in. below the perforated plate.

cleaning equipment, perforations will not clog.

## Standard Stamping & Perforating Co.

3111 W. 49th Place, Chicago 32, Illinois

Air Conditioning Registers and Grilles—Cold Air Faces  
Perforated Metals for all Purposes

No. 551 Perimeter Wall Register

Gives four way air diffusion. Equipped with Fractionator Volume Control and Damper Tension Screws. Also available with a base extension as Model No. 451 perimeter base board register.

No. 331 Sidewall Register

Horizontal multiple valve louvers attached to vertical "bend-ezy" faces, adjustable for four way deflection.

B-24 Perimeter Baseboard Diffuser

Maintains heating and cooling comfort at a high level. New Adjustamatic fingertip control regulates built-in damper. No damper installation required. Provides uniform temperature along outer walls, keeping floors warm and avoiding condensation on windows. Replaces lost heat immediately, where it's lost, without creating blasts, hot spots, or cold corners.

2 ft sections, 4½ in. high.

Open area 28 inches.

Heavy gauge steel construction, baked-on metallic finish.

No. 100-LO Multiple Louvre, Lever operated register.

Also available as: 100-KL, a Key Operated register; 100-RK, a register with a Removable Key; 100-PO, a Pulley Operated register (especially suited for inaccessible installations). Register faces are attached to louver boxes with screws so that the boxes are detachable.

### Single System Ceiling Air Diffusers

For Air Conditioning And Warm Air Heating

Supply full dimension distribution of warm air in the winter and cool air in the summer. FLUSH or EXTENDED models available with dampers and installation rings. Both models are finished in Standard's baked-on metallic finish. Packed one to a box and 10 to a carton.

Complete specifications will be furnished upon request

## Stewart Manufacturing Co., Inc.

Cedar Grove, Essex County, New Jersey

Technical and price information available through representatives in all principal cities, or at factory headquarters.

A complete line of Registers, Grilles and Scoops for all types of Industrial and Residential air conditioning applications.

DDV A double deflection grille affording four way diffusion—individually adjustable streamlined fins ¾ in. C.-C. heavy gauge metal and sturdy construction.

DVL A directional-type register employing 1 in. wide, parallel-acting valves. Face fins are individually adjustable right and left.

The 1 in. wide, parallel-acting valve mechanism is available with any/all STEWART face patterns.

DDVO A double deflection grille with opposed action valves. The valve consists of a series of hollow, internally reinforced air-foil sections. Through a unique actuating mechanism each air-foil section turns in a 90 deg arc toward a similarly turning section.

SCOOPTROL A device designed to deflect and control the air from a supply duct into a collar, and installed at the junction of the duct and collar. Scooptrol is a double-blade functional product, easily adjusted, positioned and then fastened by sheet metal screws; it cannot move or fall.

DG An exhaust grille with non-adjustable fins. Fins are normally factory set at 45 deg down angle to restrict vision. Also available with fins set at 0 deg vertical or horizontal.

PLASTER FRAME Permits the removal of grille when desired without damage to surrounding painted areas.

FINISH DIRECTIONAL TYPE OUTLETS ARE PROTECTED BY A PRIME COAT FINISH AND A FINISHING COAT OF SILVAIR ENAMEL, BAKED ON. SILVAIR FINISH IS A MODERN, ATTRACTIVE COATING CONTAINING ALUMINUM PIGMENT, AND IS SILVER-BLUE IN TONE. NO ADDITIONAL PAINTING IS REQUIRED.

# Airfoil

AIR CONDITIONING OUTLETS

Titus Mfg. Corp.  
WATERLOO, IOWA

Titus Mfg. Corp. are designers and manufacturers of Airfoil Grilles featuring the Airfoil Louver—patterned after the airfoil section of an airplane. The following distinctive features identify Titus Airfoil Louvers. (1) Smooth as glass streamlined surface (2) Solid construction (3) Noiseless performance (4) Minimum turbulence.

270 Airfoil Grille Gives 4-way directional control. Louvers set on  $\frac{3}{4}$  in. centers. Individually adjustable to create any air pattern desired.

274 Multi-Shutter Register Airfoil Louvers are featured in front. Individually adjustable. Rear multi-shutter damper blades.

275—Double deflection register with opposed blade damper, key operated.

276 4-Way Multi-Shutter Register Consists of the #270 4-way directional grille combined with a multi-shutter damper. Damper blades inter-locked when closed to provide complete shutoff.

277 4-Way Registers with opposed blade dampers. Two front sets Airfoil louvers individually adjustable,  $\frac{3}{4}$  in. spacing. Opposed blade damper key operated in rear.

230 Return Air Grille—blades on  $\frac{3}{4}$  in. centers. Parallel to long dimension. Deep fins. Standard  $1\frac{1}{4}$  in. beveled border. Any size grille can be furnished. R-240 (not illustrated) combines #230 return air grille with multishutter damper blades. R-241 (not illustrated) combines #230 with opposed blade damper.

AG-25 Volume Controllers provide positive control of air volume. Blades individually adjustable. Sponge rubber gasket holds unit firmly in duct.

AG-35—Opposed acting volume controller. Provides complete control of air volume to the outlet with minimum disturbances of air pattern. Louvers move simultaneously in opposite directions and can be set at any degree from full open to full closed.

AG-45—Air volume extractor and controller. Will control air volume and also produce balanced air distribution. Replaces extra volume controller. Fifty percent savings on cost and installation.

Perimeter Baseboard Diffusers—Made in 17 in., 30 in. or 60 in. lengths complete with built-in damper. Easily installed. Outstanding performance.

WRITE FOR NEW ILLUSTRATED CATALOG.

Door Grilles—No vision door and partition grilles. Made with flange frame or channel frame. All steel—V shaped louvers. T-700 standard thickness. T-800 thin core.

200 Series—New hi-efficiency sidewall or ceiling diffuser. Adjustable curved design louvers. 1, 2, 3, or 4 way deflection.

CONVECTOR GRILLES—Louvers closely spaced. Heavy-duty support bars on 6 in. centers. Over 70 per cent free area. Can be installed in any special surface, such as marble or tile.

FRAME 115 FOR ALL AIRFOIL GRILLES AND REGISTERS (not illustrated) Allows quick easy removal for cleaning or adjusting. Can be installed either before or after plastering has been completed.

mercial and Institu-  
tional Air Condition-  
ing, Heating, Venti-  
lating

NEW BRITAIN, CONNECTICUT

### HIGH PRESSURE AIR DISTRIBUTION UNITS

Type MPW

A complete line of equipment designed to meet the growing demand for high pressure installations in multi-story office buildings, schools, hospitals, hotels and institutions.

#### TYPE MPW

Medium Pressure Periphery Wall Mixing Plenum Unit for individual room control on heating or cooling cycle, or zone control. Handles static pressure in system up to 3.5 in. w.g.

#### TYPE MP

Medium Pressure Sub-Central Station Unit for distribution of air to one or more diffusers by means of rigid or flexible ductwork. Handles static pressure in system up to 3.5 in. w.g.

#### TYPE MPD

Medium Pressure Ceiling Diffuser Double Duct Mixing Plenum Unit for individual unit or zone control. Single duct units also available. Handles static pressure in system up to 3.5 in. w.g.

#### TYPE HPD

High Pressure Ceiling Diffuser Unit for individual unit or zone control. Handles static pressure in system up to 6.0 in. w.g.

### Aerofuse CEILING DIFFUSERS

A wide selection of diffuser types and sizes, styled and engineered to meet the most rigid requirements of appearance and performance at the point of air delivery.

### TRI-FLEX SUPPLY AIR GRILLES AND REGISTERS

Available as single and double deflection grilles; single and double deflection registers with opposed blade dampers. Blades are regulated by means of a key operator and may be set in any position from fully open to fully closed. Face bars are individually adjustable. Stocked in 26 standard sizes.

#### 26 STANDARD SIZES

|        |        |         |         |
|--------|--------|---------|---------|
| 8 x 4  | 14 x 4 | 20 x 6  | 30 x 6  |
| 10 x 4 | 14 x 5 | 20 x 8  | 30 x 8  |

## United States Register Company

General Offices: Battle Creek, Mich., U.S.A.

Branches: MINNEAPOLIS, MINN., KANSAS CITY, MO., ALBANY, N. Y.

Air Conditioning Registers, Vents and Grilles

No. 249—Multiple-Valve Air Conditioning Register. Gives complete Air Control. Vertical Front Bars—Key-pin adjusted to provide 45 deg Right and Left or Two-way Side Flow. Lever operated Horizontal Back Valves Give from Full Closed to any degree of Upflow and to 45 deg Downflow. FULL FACE COVERAGE. Can be supplied with any style of Setting Frame. Fits all Stack Heads of Standard Size Dimensions.

No. 153—Single-Valve Air Conditioning Register—Bars  $\frac{1}{4}$  in. deep—Spaced 4 openings to the inch affords Non-Vision. Can be supplied in Directional Flow in either Horizontal or Vertical Bar Styles. Can be furnished with all styles of Setting Frames.

No. 256—Multiple-Valve Flex-bar Air Conditioning Register. Vertical Front Bars set 22 deg Right and Left. Side Flow Deflection attained by setting of Grille Bars with bending wrench to accommodate room condition. Back-valves give same Up and Down control of air flow as No. 249 above. FULL FACE COVERAGE. Can be supplied with any style of Setting Frame. Fits all Stack Heads of Standard Size Dimensions.

No. 153-VVL Horizontal Bar Non-Vision Design Vertical lever operated rear valves. No. 145-VVL—Specially adapted to Combination Heating and Cooling Systems. Horizontal Bar Adjustment to 60 deg Up and Down Flow.

All of above Styles can be supplied with either Lever or Individually adjusted Multiple Valves or Louvers. i.e. 177VVI—Vertical Valves Individually adjusted. 145VVL—Lever operated Vertical Valves. Specially adapted to Combination Heating and Cooling Systems.

Grilles and Vents in Matching designs are available.

For Complete Information Write for Catalog No. 55-6.

Multiple Valve A. C. Registers available with Key Operation.

1462

## United States Register Co.

No. 500 U.S. Round Ceiling Diffuser  
Step-Down Style

No. 500 U. S. Round Ceiling Diffuser. Made in 6 in., 8 in., 10 in., 12 in. and 14 in. sizes. Furnished with or without No. 900 frames. However, frames are recommended. No. 500 diffusers will be furnished with Dampers when required.

No. 410 U. S. Perimeter Floor Register.

No. 191 U. S. Multi-Flex Register Streamlined Double-Edged Grille bars. Front bank of bars—Horizontal Adjustable. Second bank of bars—Vertical Adjustable. Opposed Rear Valves—Key operated.

No. 191 U. S. Multi-Flex Register

No. 192 U. S. Multi-Flex Register—same as No. 190—but with Vertical Front Bars.

No. 193 U. S. Multi-Flex Grille—same as No. 190—but less Rear Valves.

No. 194 U. S. Multi-Flex Grille—same as No. 191—but less Rear Valves.

No. 195 U. S. Multi-Flex Grille—same as No. 193—but Vertical Bars only.

No. 196 U. S. Multi-Flex Grille—same as No. 194—but Horizontal Bars only.

See our Catalog No. 55-6 for the additional Non-Flex Register and Grille Line.

1463

No. 1000 U.S. Super Base Diffuser is equipped with Balancing Set-Lock and Adjustable Slide-Plate bottom opening. Furnished in 2 ft and 4 ft sections with which any continuous lengths may be assembled.

No. 1000 U.S. Super Base Diffuser

No. 105 U.S. Diffuser Sidewall Register furnishes a complete 180 deg Sunburst Diffusion at an even fpm at every degree of air diffusion.

No. 105 Diffuser Sidewall

No. 190 U.S. Multi-Flex Register

No. 190 U. S. Multi-Flex Register Streamlined, Double-edged Grille bars. Front bank of bars—Vertical, Adjustable. Second bank of bars—Horizontal, Adjustable. Opposed Rear Valves—Key operated.

## Universal Diffuser Corp.

1360 Garrison Ave., New York 59, N. Y.

Manufacturers of FLEXIFLO Adjustable Diffusers

*Flexiflo-Type R and V*

*Flexiflo-Type S*

*Flexiflo-Series MP*

*Flexiflo-Adjustable Series HAR*

### VARIABLE EFFECTIVE AREA

The FLEXIFLO diffuser is unique in that it has an infinitely variable effective area. All blades move simultaneously when the control knob is moved up or down. This provides a simple, effective means of controlling the volume of air. The pattern of diffusion for cooling purposes remains constant on the Type "R" FLEXIFLO. For cooling and heating purposes the Type "V" FLEXIFLO provides a variable pattern of diffusion from horizontal to downflow.

#### Type R—For Cooling

Provides a diffusion pattern and radius of diffusion that are not altered by change in air volume. Air leaving the Type R diffuser always travels parallel to the ceiling, assuring satisfactory performance under all operating conditions.

#### Type V—For Cooling, Ventilating and Heating

Has a special blade configuration that gives a variable air distribution cone from horizontal to downward flow. Air can be delivered at practically any angle.

#### Type S—For Side Wall or Ceiling Installations

Model SC is for ceiling installations in cooling work. Model SW is for wall installations. Every Type S diffuser has one set of equalizing deflectors.

#### Series MP—Multi-Pattern Diffusers

FLEXIFLO Series MP diffusers are made to order in all rectangular shapes for one, two, three and four way blows to accommodate rooms of irregular shape. The diffusion pattern is parallel to the ceiling in all cases. Standard finish is metallic gray baked enamel. Other colors are available at no extra cost.

#### Series HAR

The FLEXIFLO HAR Series of adjustable square diffusers is built for either ceiling or acoustical tile installation. The blades move simultaneously when the control knob is moved up and down. Air volume can thus be controlled with great precision and can be varied between near zero and full output at constant horizontal pattern.

## Waterloo Register Co. Inc.

"Since 1902"

P.O. Box 72

Waterloo, Iowa

Complete Line of Air Diffusion Equipment for All Air Conditioning and Heating Installations. Offers: Performance. Appearance. Selection. Prompt Delivery. Features Silent Flow "Tear Drop" Louvre Design which provides unobtrusive diffusion with SUFFICIENT SURFACE to turn high velocity air WITHOUT TURBULENCE.

#### 2V SUPPLY GRILLE

Two sets of extruded aluminum louvers, each individually adjustable for four-way deflection at degree desired. Designed for long or short throw.

#### 3H RETURN AIR GRILLE

Fixed fins at 45 degree or 0 degree deflection, in heavy gauge frame, strengthened with adequately spaced support bars.

#### IVMH SUPPLY REGISTER

One set of adjustable louvers for easy control of air, right or left, with multi-shutter damper, horizontal blades. Ideally suited for home installations because of narrow stack depth.

#### DV DOOR VENTILATORS

V-Shaped fixed fins, permanently spot welded in channel frame for rigidity. Offers more than 57 per cent free area, yet completely sight proof. Available flange both sides, one side, or no flange.

#### 2VO SUPPLY REGISTER

Two sets of adjustable louvers, vertical and horizontal, with opposed blade damper, vertical blades, for even volume control. Fins spaced on 3/4 inch centers. Provides positive air control.

#### DUCTROL Air Volume Extractor

Volume controller and extractor adjusts from full open to full closed, to provide even distribution to entire grille surface. Completely assembled at the factory—ready to install on job.

Waterloo 6-page "Size Selection Table" available in folder form to use in making SIZE SELECTIONS of outlets on commercial jobs.

## Duro-Dyne Corporation

800 Third Avenue, New Hyde Park, N. Y.  
Manufacturers of Accessories for the Sheet Metal,  
Heating, Air-Conditioning and Ventilating Fields

### NEVA BIND DURO-BLADE KIT

#### Multi-blade Louver Damper Hardware

The Neva Bind Duro-Blade Kit—multi-blade louver damper hardware permits smoothly operating, *absolutely non-binding* dampers to be assembled with little care and no alignment afterward. The Kit's unique 4-way adjustability automatically compensates for slight errors in blade dimensions or formation, minor misplacements of bearing holes or other inaccuracies which cause stress or bending of the connecting rod—the main cause of binding. The Neva Bind feature allows the rod to remain absolutely straight regardless of inaccuracies in damper construction. Besides operating smoothly and never binding, dampers made with the Neva Bind Duro-Blade Kit can be fully closed without the bracket hitting the duct. The damper can be fully opened without interference of the connecting rod.

### JIFFY DAMPERS

#### Complete, Prefabricated Dampers for Round Pipe

Jiffy Dampers are complete, prefabricated dampers ready for immediate installation in ductwork. A comparable damper fabricated in the shop costs considerably more. The P-K Jiffy Regulator (now manufactured by Duro-Dyne) is pre-attached to a galvanized damper blade. The steel threaded bearing will never break. There are no loose parts to rattle.

JD Series—Consists of damper plate with a 1/4 in. square end bearing, washer, handle and wing nut.

JDS Series—Same as JD Series plus patented P-K Spring-Loc Bearing. For high air velocities or when necessary to keep damper in perfect position.

JD and JDS Series Jiffy Dampers are regularly available in 4 in., 5 in., 6 in., 7 in., 8 in. and 9 in. pipe sizes. Other sizes, and rectangular dampers on quotation.

JDS Series—With Spring-Loc

JD Series—No Spring-Loc

### DAMPER REGULATORS AND CONTROLS

(formerly Manufactured by Parker-Kalon)

UNXLD Damper Quadrant Heavy Duty Quadrant Jiffy Regulator Dial Damper Regulator

### FLEXIBLE DUCT CONNECTOR PRODUCTS

#### Rolls of Preassembled Metal-to-Fabric-to-Metal

### LAI D OUT AND PUNCHED SIDE RAILS FOR MAKING AIR TURNING VANES

Air turning vanes made with Duro-Vane-Rail side rails save 50 per cent to 70 per cent in installed costs. Vanes are merely sheared from scrap. No tab cutting on vanes is necessary. Insert vanes in notches provided in Duro-Vane-Rail.

Place chisel (supplied with each bundle of Duro-Vane-Rail) on protruding portion of vane in slot. One blow securely locks vane to rail. Duro-Vane-Rail allows maximum free area; eliminates noise and "whistle." Completed air turning vane assembly meets most engineering specifications.

Duro-Metal-Fab and Econ-O-Fab are preassembled metal-to-fabric-to-metal for making flexible duct connectors (for eliminating vibration travel). They eliminate the annoying time-consuming job of attaching metal to fabric in the shop. The exclusive Double-Loc Seam cannot pull apart and prevents the metal from cutting the fabric when the finished connector vibrates. Duro-Metal-Fab for industrial or heavier gauge ductwork consists of 24-gauge galvanized iron attached to U.L.-Approved Canvas, Asbestos or Neoprene Fiberglass. Econ-O-Fab, for residential and lighter gauge ductwork, is identical to Duro-Metal-Fab, except lighter. Both Duro-Metal-Fab and Econ-O-Fab are packed 50 ft or 100 ft to the handy Dispens-O-Flat carton.

DUCT FABRIC is available for special cases where fabrics without metal are desired. Packed in 100 ft rolls, available 6 in. or 10 in. wide canvas and 6 in. wide asbestos or neoprene.

## Elgen Manufacturing Corporation

41-34 39th St., Long Island City 4, N. Y.

**ELGEN SILENT DUCT**—Pre-assembled metal and material for flexible duct connectors.

**ELGEN ALL-TITE VANE RUNNERS**—for making turning vanes for square elbows.

**ELGEN DAMPERSET**—for damper control in blower and exhaust systems.

### ELGEN SILENT DUCT

Factory-assembled metal and material. Delivered in dispenser carton . . . pulls out flat, ready to use. Union made.

- Available in 24 or 26-gauge galvanized steel . . .
- Fastened to fire, water and mildew-resistant *UL* approved canvas (*Govt. Spec. MIL-D-10860*) or to Johns-Manville asbestos (wire-filled, if

- desired) or to U.S. Rubber Co. Neoprene-coated fiber glass.
- Delivered in 100-ft (approx.) coils; 50-ft coils with asbestos available.

### ELGEN ALL-TITE COILED VANE RUNNER

Button Type for single and double blades

- Quick, inexpensive method of making turning vanes.
- 24-gauge galvanized steel.
- Eliminates notching, punching, etc. No special tools needed.
- Is screwed into elbow . . . absolutely rigid and rattleproof.

- Delivered in the 100 ft coils (approx.) Unrolls absolutely flat. Union made.

### ELGEN DAMPERSET

for multi-blade dampers—parallel or opposed

- Licensed by Minneapolis-Honeywell.
- Quick and easy to assemble.
- Precision-machined—cadmium plated.
- Bronze self-oiling bearings.
- Packed in single boxes or bulk 100's.

All Elgen products engineer-approved; available at leading jobbers in U. S., Canada, Hawaiian Islands. Descriptive literature on request.

## The WIREMOLD Company

Hartford 10, Connecticut

Manufacturers of Wiremold Air Duct for  
Commercial Air Conditioning Systems.

### Wiremold Air Duct has REMARKABLE FLEXIBILITY

. . . proved on every type of Commercial  
Air Conditioning System!

Designed for connecting air-distribution  
units to branch ducts, strong, durable,  
and extremely flexible Wiremold Air  
Duct conducts air at temperatures of 0  
to 250F at high or low velocities.

Wiremold Flexible Air Duct Type 57-1A connecting  
four diffusers to sound box and sound box to main duct  
in modular ceiling construction.

Takes all bends without kinking. Flexi-  
bility of duct allows for expansion and  
contraction of system and prevents  
transmission of mechanical vibration.

Wiremold Engineering Data Sheets give  
details of Wiremold Air Duct installa-  
tions. Send for your copies.

Type 57-1A, 6-in. and 7-in. I.D. flexible connectors  
high velocity system, City County Building, Detroit.

Unique construction—vinyl coated fiber-  
glass fabric mechanically locked into the  
steel spiral—gives Wiremold Air Duct  
extraordinary longevity and strength.  
No glue or other adhesive to dry out and  
crack.

Saves time, effort, and money in in-  
stallation—easily bends 90 deg to 180  
deg. Can be easily run around structural  
members. Solves misalignment problems.

Finished modular ceiling installation—Wiremold Air  
Duct permits relocating of diffusers.

There are WIREMOLD AIR DUCT  
SALES ENGINEERS to give you on-  
the-job service throughout the United  
States and Canada.

## Young Regulator Company

5209 Euclid Avenue, Cleveland 3, Ohio

### YOUNG SURFACE - CONCEALED - SPLITTER - SQUEEZE - REMOTE CONTROL DAMPER REGULATORS

No. 1

No. 315

No. 700-CP

A complete line of manually controlled damper regulators for every type of heating, ventilating and air conditioning installation in office buildings, factories, hospitals, ships, schools, churches and residences. Young Regulators are used by many leading companies in nearly every industry and are specified by leading architects and engineers.

**Model No. 1, FOR SURFACE MOUNTING.** The original Young Damper Regulator, of which thousands have given satisfactory service for years, has been modernized and streamlined. It is used to regulate a damper, controlling the air flow through a duct. It is readily set and locked into position by a key.

**Model No. 315, ADJUSTABLE COVER CONCEALED REGULATOR.** For use in acoustical ceilings. Similar to No. 301 Concealed Type, except the cover plate is adjustable for height to meet the various thicknesses of acoustical or plastered ceilings by screwing down the cover plate. The adjustment or locking the regulator is by a socket wrench.

**Model No. 700, CP REMOTE CONTROL.** For manual operation of dampers and registers to give individual room temperature by remote control. With No. 704 Corner Pulleys, Remote Control operates Young Dampers at a distance of 250 ft or more. Two registers or dampers can be operated by a single unit.

**Model No. 900, AIR-SPLIT REGULATORS.** For operating a splitter or squeeze damper. Operating head may be placed in any accessible location. Operation is by a crank.

**Model No. 914, CONCEALED AIR-SPLIT REGULATOR,** with beveled gears. It is used when regulator is operating a vertical damper from suspended ceiling. No. 301 Operator is used.

**Model No. 912, CONCEALED AIR-SPLIT REGULATOR.** It is used when regulator is operating a horizontal damper from suspended ceiling. No. 301 Operator is used.

No. 900

1470

### OPPOSED BLADE DAMPERS— REGISTERS—GRILLES—CEILING DIFFUSERS

**Model No. 830, OPPOSED BLADE DAMPER** distributes the air evenly over the entire face of the grille. It is easy to install in the duct behind the grille. It is operated by a Young Remote Control placed in any convenient location. Tubing to Remote Control is attached to duct by Young Compression Fitting. Furnished as part of No. 840 Series Air Conditioning Register, No. 855 Ceiling Diffuser, or separately.

**Model No. 831.** Same as No. 830, but without the Remote Control attachment. It can be locked in any position. A Phillips head screw driver is the tool required to operate it.

**No. 840 SERIES REGISTERS** is a combination of the various No. 800 Grilles and a vertically Opposed Blade Damper. All specifications as to register construction are identical to the No. 800 Series details. These registers give individual room control when operated by Model No. 700 Remote Control.

**No. 800 SERIES AIR CONDITIONING GRILLES.** Grille bars are made of extruded aluminum secured in a frame and dividing mullions. They must be adjusted with a hand tool, lessening the possibility of tampering. Gasket is furnished with all supply grilles. No. 800-VH has double banks of blades, one vertical, the other horizontal, both banks adjustable.

**SERIES No. 845 RETURN AIR GRILLES** for intake has been designed to match the No. 800 Series for supply.

**No. 855, CEILING DIFFUSER** is designed to distribute the air without drafts. The unit has two banks of bars; each bank is 4-way adjustable to 45 deg angle to direct the air flow. The Opposed Blade Damper that is attached to the Diffuser is controlled by Young No. 700 Remote Control.

## Alco Valve Company

ENGINEERED REFRIGERANT CONTROLS

851 Kingsland Avenue, St. Louis 5, Mo.

New York Office: 55 West 42nd Street

Chicago Office: 4554 North Broadway

### THE COMPLETE LINE OF REFRIGERANT CONTROLS

**ALCO THERMO EXPANSION VALVES:** for automatic control of liquid refrigerant on all types of refrigeration and air conditioning systems. Capacities—from fractional tonnage to 220 tons "Freon-12," 350 tons "Freon-22," selective charges. Low temperature valves for  $-40^{\circ}\text{F}$  to  $-100^{\circ}\text{F}$ .

Type 40S with pressure limiting feature

Type TK  
"3 valves in 1"Type TCL  
Angle type or straight-through connectionsType TR—  
Multi-Outlet

**ALCO SOLENOID VALVES:** for all types of service. For Liquid: "Freon-12" up to 75 tons; 110 tons "Freon-22." For Suction: "Freon-12" up to 10 tons; 15 tons "Freon-22." For brine, water, steam, hot gas discharge, air and oil.

Type S1

Type M3

Type R2

**ALCO AMMONIA CONTROLS:** Solenoid Liquid Valves—up to 172 tons. Solenoid Suction Valves—up to 28 tons. Thermo Expansion Valves—from fractional tonnage to 125 tons. Automatic Expansion Valves—from fractional tonnage to 60 tons.

Type M91P

Type UG

Type TX

Type E with Strainer

### ALCO SUCTION LINE CONTROLS:

Type EPR EVAPORATOR PRESSURE REGULATORS—for all refrigerants, with connection sizes up to 6 in.

Types 771-772 SUCTION PRESSURE REGULATORS—HOLD-BACK VALVES—prevent motor overload. Freon-12, Freon-22.

Type 760 "EVAPOTROL"—Pressure Regulator— $\frac{1}{2}$  ton, "Freon-12"— $\frac{3}{4}$  ton, Methyl Chloride.

**ALCO ALSO MAKES:** Constant Pressure (Automatic) Expansion Valves—Liquid and Suction Line Strainers—High Pressure Float Valves—Electric Float Switches—Reversing Valves.

## Barber-Colman Company

Automatic Temperature Controls

Rockford, Illinois

### THERMOSTATS

Single and two-stage room and remote bulb thermostats for on-off control; room and remote bulb thermostats for proportioning control.

### OUTDOOR RESET CONTROLS

Both fixed and adjustable ratio outdoor reset hot water controls applicable to any size building.

### MOTOR-OPERATED VALVES

A complete line of factory-assembled motor-operated valves for two-position and proportioning control.

### ELECTRONIC CONTROLS

On-off or fully proportioning. Extremely sensitive and flexible control of air or liquid temperature. Large, legible, easily understood dials. Mounted in metal "Control Center."

### ECONOSTAT ZONE CONTROL

Outdoor-indoor zone control for multi-occupancy buildings. Night depression with automatic morning warm-up. Optional week end cutout.

### CONTROL MOTORS—PROGRAM SWITCHES

Spring return, unidirectional, reversible, multi-position, and proportioning types. Adjustable speed optional. Program switches for multiple step control of compressors, pumps, etc.

## Cam-Stat, Incorporated

Division of The Paul Henry Company

11831 W. Olympic Blvd.

District Offices in All Principal Cities

### AUTOMATIC TEMPERATURE CONTROLS

These compact warm air furnace controls are available, as shown below, for integral mounting on the furnace, and also in conduit housings to meet U.L. requirements for plenum or duct mounting. Any one of the controls below is available in combination with any one of the other controls, complete in a conduit housing. Extreme sensitivity is obtained through the use of a low mass bimetal actuator. This insures uniformly accurate control results even with high rates of temperature change.

#### FAN CONTROL

Model No. F14-11A

Specification: Range—80 to 120 F. Differential—25 F. (Fixed). Rating— $\frac{1}{2}$  hp at 120 or 240 volts A.C. Other differentials available on request.

#### FAN CONTROL

Model No. F14-12A

Specification: Range—80 to 120 F. Differential—20 to 35 F. (Adjustable). Rating— $\frac{1}{2}$  hp at 120 or 240 volts A.C.

#### FIXED LIMIT CONTROL

Model L22-7A

Specifications: Fixed cut-out and differential to manufacturer's requirements. Rating—90 volt-amperes at 30 volts A.C.

#### ADJUSTABLE LIMIT CONTROL

Model L22-8A

Specifications: Range—170 to 200 F. or to manufacturer's requirements. Differential—Fixed anywhere between 15 and 50 F. Rating—90 volt-amperes at 30 volts A.C.

#### RESET LIMIT CONTROL

Model No. L22-9A

Specifications: Fixed cut-out to manufacturer's requirements. Equipped with push button to reset after cut-out. Rating—90 volt-amperes at 30 volts A.C.

## COMBUSTION CONTROL DIVISION ELECTRONICS CORPORATION OF AMERICA

718 Beacon Street, Boston 15, Mass.

### FIREYE PANEL CONTROL SYSTEMS FOR AUTOMATIC OIL, GAS BURNERS.

Fireye flame failure protection plus complete automatic programming in a single integrated unit, assembled and tested by factory experts. Includes System FP-2 primary controls, short circuit protection, motor starters, fuel selector switches, signal lights, any needed optional equipment such as sequence draft controls, draft and temperature indicators.

### FIREYE SAFETY INTERLOCK SYSTEMS FOR SEMIAUTOMATICALLY AND MANUALLY-LIGHTED BURNERS.

Complete safeguard systems for up to four burners per boiler—oil, gas, or combination oil-gas. Assures safe light-off and firing. Includes System FP-4 primary control in pre-wired cabinet assembly, plus all external valves, switches, and alarms.

### FIREYE ELECTRONIC SAFEGUARDS AND PRIMARY CONTROLS.

System FP-2. Flame failure protection and programming for automatic industrial oil, gas, and combination oil-gas burners.

System FJ-2. Flame failure protection and programming for automatic commercial light oil, gas, and combination light oil-gas burners.

System FP-4. Flame failure protection for semiautomatically and manually-lighted oil, gas, and combination oil-gas burners.

### FIREYE FLAME FAILURE INDICATION AND ALARM SYSTEMS.

System FP-3. Electronically senses presence or absence of oil, gas or pulverized coal flames, and actuates a visible or audible signal.

Type F18T-3. A sensitive photoelectric switch in a rugged industrial housing. Used with industrial oil burners to shut off fuel on loss of flame.

### FIREYE PHOTOELECTRIC SMOKE DENSITY INDICATOR.

System FE-3. Provides low cost, easy-to-install smoke density indication with assured accurate readings. Helps keep smoke within legal limits. Saves fuel dollars. Chart recorders also available.

## TEMPERATURE INDICATING AND RECORDING THERMOMETERS

### MODEL 1000 RECORDING ← THERMOMETER

Temperature cycles are permanently charted by this latest addition to the Auto-Lite line of temperature recorders. Has evenly calibrated, 6-in. chart; attractive die-cast case. Various standard chart ranges from minus 40°F to plus 550°F. The style shown is wall mounting type, with capillary tubing for remote, eye-level reading. Also available with portable case with capillary and portable self-contained. Obtainable with cycle indicator for refrigeration. Choice of 24-hour or 7-day mechanical chart rotation.

### MODEL F-1 INDICATING THERMOMETER →

Designed to facilitate systematic temperature observation for air conditioning, refrigeration or heating applications. Large, easily read dial, evenly calibrated and fully compensated for temperature changes at the indicating head. Adjustable to 3 positions. Choice of temperature ranges from minus 40°F to plus 750°F. Available with electric alarm contact at small added cost.

### MODEL "G" INDICATING ← THERMOMETER

These thermometers have the same efficient one-to-one ratio, solid liquid-filled movement as Model "F" with evenly calibrated scales. Capillary tubing for remote reading or rigid stem.

Send for Catalog describing styles and types of Auto-Lite Thermometers.

# Field Control Division

of H. D. Conkey & Company, Mendota, Ill.

Manufacturers of FIELD DRAFT CONTROLS

## FIELD BAROMETRIC DRAFT CONTROLS

**FIELD "MG" DOUBLE ACTING:** For commercial gas fired heating plants. Double acting gate opens inward to regulate up-drafts, and outward to relieve down drafts. Highly sensitive. Optional safety switch closes main gas valve in case of prolonged down draft, thus providing full protection. Available in 10 in., 12 in., 16 in., 20 in., 24 in., 28 in. and 32 in. sizes. Illustration shows up-draft view.

**FIELD TYPE M:** For automatic heating equipment, designed to assure finer performance, greater fuel economy, through highly accurate control of drafts. Available in sizes from 6 in. through 24 in. for pipe diameters of 6 in. through 25 in. Features "Rocking Chair" gate action, off-center gate mounting, sidewings, extended housing. Widely used in the heating industry.

**FIELD TYPE RC:** Calibrated draft control in sizes 7 in. and 9 in. for 6 in. through 10 in. flues. Features extreme capacity, and reversible wing flap on gate for more precise adaption to either vertical, horizontal or sloping flues. Friction-free gate mounting, single strap attaching, easily leveled on a sloping flue.

**FIELD TYPE M Heavy duty commercial** model for oil and coal fired equipment, in sizes 28 in. and 32 in. Features stainless steel knife edge bearing, and very heavy construction to eliminate vibration (14 gauge steel throughout, weights up to 140 lbs net). Includes all the outstanding patented type "M" features for accuracy and dependability.

Principal Cities

Manufacturers of

Sylphon Automatic Temperature  
Controlling Instruments and  
Packless Expansion JointsSeries 800  
ROOM  
THERMOSTATS

Heavy duty, super sensitive wall thermostats for accurate, direct control of electric heating units, air conditioning units, etc. Sensitive thermostat responds to both radiant heat and air temperature changes to  $\pm 1/2^\circ$  differential under actual load conditions. Other features include: positive snap-action switch; mounts on standard outlet box with only two screws and without removing cover; electrically rated for both non-inductive load ratings and motor ratings; instrument type construction; accurately calibrated dial; calibrated thermometer eliminates guesswork as to room temperatures; shock-proof plastic cover; compact, attractive design; UL approved, and guaranteed for 18 months against defective workmanship or materials.

801 Series: Temperature Range: 64°-80°F. Operating Differential:  $\pm 1/2^\circ$  20 amps (non-inductive load) at 125-250 volts ac, 3/4 hp at 115 volts ac, 1 1/2 hp at 230 volts ac.

802 Series: Temperature Range: 55°-85°F. Operating Differential:  $\pm 1^\circ$  20 amps (non-inductive load) at 125-250 volts ac, 3/4 hp at 115 volts ac, 1 1/2 hp at 230 volts ac.

Type 801-A3: Combination thermostat for heating-cooling use. Temperature Range: 64°-80°F. Operating Differential:  $\pm 1/2^\circ$ . Requires only a simple connection with a manually operated summer-winter switch to provide change from heating to cooling.

HOT WATER SUPPLY  
No. 999

Temperature Regulator controls temperature of liquids. Particularly suited for storage water heaters and for all industrial processes requiring accurate temperature control. Stainless steel frame for minimum heat conduction. Large size Sylphon Bellows provides added power. Self-operating. Valve sizes from 1/2 in. to 4 in. Temperature ranges start at 40° F, up to 420°F. *Bulletin HVG-E.*

## SPACE HEATING CONTROL

No. 885

## Automatic Radiator Valve—

For exposed radiation. Small, neat, attractively finished, adjustable to room temperature desired. Simply replace ordinary radiator valves with these Sylphon Automatic Valves—no wiring, piping or auxiliary equipment is required. These valves answer the demand for an inexpensive means of providing accurate, dependable space temperature control in rooms, sections or throughout large buildings, new or old. Similar type valves for concealed radiation—get *Bulletin HVG-E.*

Sylphon No. 890  
Radiator Control Valve

For either exposed or concealed radiation. Similar in appearance and action to other Sylphon Automatic Valves, but operated by an electric wall thermostat. The closing of the thermostat circuit energizes a low voltage electric heater coil surrounding a bulb containing a volatile liquid. This liquid expansion causes pressure on a bellows in the valve head operating the valve. This provides radiator valve control from a remote location, permits regulation of several radiators from a single thermostat, enables a time switch to be installed, if desired, offers effective zone control of large areas at a fraction of the cost of conventional motor-operated valve systems. *Bulletin HVG-E.*

REFRIGERATION  
CONTROLS  
No. 945-Z Regulator

Adaptable wherever brine is used as the refrigerant. Latest development is a "freeze-proof" valve (illustrated) on the popular Sylphon No. 945-Z Regulator. *Bulletin HVG-D.*

PACKLESS  
EXPANSION JOINTS

## No. 110-M Sylphon Expansion Joint

The Sylphon Packless Expansion Joint eliminates expensive construction, non-revenue producing space. No leaks or repairs, no repacking. Use No. 110-M for steam lines; No. 111-M for water lines. Sizes 3/4 in. to 3 in., inclusive. *Bulletin HVG-65.*

NO. 96066 SYLPHON EXPANSION  
JOINT

Used on hot water lines, a simple, compact means for absorbing expansion of "baseboard" radiation, finned convectors, horizontal supply lines, etc. A two-ply Sylphon bellows absorbs expansion, prevents noise, pipe strains, leakage. Complete factory assembled unit. Easily installed or removed. Sizes 3/4 in. to 2 in., inclusive. *Bulletin HVG-E.*

HEATING AND AIR  
CONDITIONING CONTROL

Almost any type of heating, ventilating or air conditioning system can be advantageously controlled wholly or in part by Sylphon Regulators. Basic advantages of Sylphon Controls are:

**Modulating**—Maintain ideal conditions—not continually correcting too hot, too cold, too humid or too dry conditions.

**Compensating**—Many Sylphon Regulators offer compensating control, automatically raising their low limit setting at a predetermined rate as outside temperatures fall.

**Sensitive**—Close operating temperature differentials. Quick response.

**Simple**—in design.

**Rugged Construction**—Give years of satisfactory service.

**Adaptable**—Any one of many combinations of Sylphon Instruments can be ar-

anged to control any air conditioning system and to provide exactly the conditions desired. Write for *Bulletin SAC-850.*

## The No. 928-H Regulator

Simple, compact yet highly sensitive. Suitable for modulating control of air temperatures in ducts. Bulb is constructed of numerous coils of copper tubing giving sensitivity to the slightest temperature variation. Packless valve eliminates service problem and makes this regulator ideal for installation in inaccessible locations. Suitable for steam pressures up to 15 lbs; other types available for pressures up to 75 lbs.

## The Sylphon No. 889-C Regulator

A modulating, dual-function regulator for control of duct heating and ventilating systems—two independent valves in a single body.

Adjustable Thermostat "A" governing Valve "D" functions to maintain room temperature from temperature of recirculated air. Adjustable Thermostat "B" acts as a low-limit ductstat controlling Valve "E" to maintain minimum discharge air temperature. Bulb "C" compensates Bulb "B" to maintain even discharge air temperature irrespective of demand. Compensated Thermostat "B" can also be furnished to raise its setting at a predetermined rate with falling fresh air temperatures if desired. Suitable for steam pressures up to 15 lbs.

## The Sylphon No. 889-C7 Regulator

The No. 889-C7 regulator has a wall type adjustable thermostat that is placed in the room or space to be controlled. This thermostat "A" operates upper half of the regulating valve. Otherwise, same as No. 889-C regulator described above.

## GENERAL CONTROLS

MANUFACTURERS OF AUTOMATIC CONTROLS FOR HOME, INDUSTRY AND THE MILITARY

40 FACTORY BRANCH OFFICES SERVING THE UNITED STATES AND CANADA

FIVE PLANTS: IRON MOUNTAIN, MICHIGAN •  
GLENDALE, CALIFORNIA • BURBANK, CALIFORNIA •  
SKOKIE, ILLINOIS • GUELPH, CANADA

(A) Type T-70

(B) Type K-10

### (A) THERMOSTATS

Compact, snap action, Line or Voltage Thermostats. Functional beauty for accurate, remote control of desired temperature. Extends only  $\frac{3}{8}$  in. from wall. Streamlined stainless cover, sensitive to slightest temperature change, ivory plastic base.

### (B) K-10 MAGNETIC LEVER VALVES

Provides six times more power than ordinary solenoid valves. Controls air, gas, water, light, heavy oils, steam. Positive opening, complete shutoff, packless, hum-free. Available for any voltage, a.c. or d.c., in sizes up to  $1\frac{1}{4}$  in. I.P.S., port sizes up to  $\frac{3}{8}$  in.

### (C) BX-69 GAS ACTUATED PACKAGE SETS

No outside current required. Operates on all types of gases. Safe, quiet, dependable. For all gas-heating appliances. Set consists of a PG-9 700 millivolt pilot generator, a B-60 gas control valve, a T-70 snap action thermostat, thermostatic cable and vent tubing. Everything needed in convenient package for remote gas control.

(D) Type B-55G

### (D) SLOW OPENING GAS VALVES

New combustion control afforded by these diaphragm-controlled gas valves. Governor model regulates fuel supply to burner in direct ratio to steam pressure, eliminating hunting aspect. Available 1 in. to 6 in. I.P.S.

### (E) MAGNETIC GAS VALVES

Versatile, two-wire, straight magnetic current-failure valve. Packless. Insures tight shutoff indefinitely. Humless. Size range  $\frac{3}{8}$  in. to 6 in. I.P.S. Operating pressures up to 10 lb. Voltages and frequencies a.c. or d.c. Quiet, positive, trouble-free. Available in explosion-proof housing.

(F) Type V-110

### (F) MANUAL RESET VALVES

Equipped with manually-reset electromagnetically-held valve operator. Current flowing to operator permits manual opening by turning valve wheel at side. Current failure releases operator allowing valve to close. Trip-free mechanism won't open under unsafe conditions. Closed, valve must be reopened manually.

(E) Type K-3A

(G) Type G-2-1

(H) Type K-16

(I) Type PV

(L) Type V-200

(M) Type MR-5 PG/SC

### (G) HYDROMOTOR VALVES

Simplify valve control installations. Two-wire, current failure, electric-hydraulic operation. Ample motor-driven power, slow opening and closing movement. G-1 Series, designed for low pressure steam, hot and chilled water circulating systems. G-2 and G-3 Series for high pressure applications.

### (H) REFRIGERANT CONTROLS

Magnetic Stop Valves. Piloted, two-wire current failure, high pressure, packless. Handle large capacities with minimum pressure drop and loss. Tight shutoff. Operates on air, steam, water, and refrigerants.

### (I) "hi-g" MAGNETIC VALVES

Designed for positive operation on aircraft, trucks, tractors, tanks, graders, ships, and other moving equipment. Handle all fluids, vapors and gases on anything that rolls, floats or flies at pressures up to 3000 lbs or more. Packless, two-wire, current-failure type, available normally open, normally closed for intermittent or continuous duty.

(K) Type A-100

(J) Type RS-100 Relay

### (J) RELAYS AND TRANSFORMERS

Type RS-100 handles single phase motor loads up to 1 hp or heating loads up to 1.1 kw. Combines double break relay and integral transformer. Normally open; large double-break contacts. Two-wire control circuit; maximum holding current 0.4 amps. Furnished with  $\frac{1}{2}$  in. conduit connections and low voltage outlet. a.c. only.

\* Trade mark—"hi-g" indicates positive ability to function in any position, regardless of vibration, change of motion or acceleration.

### (K) A-100 THERMOPILLOT RELAY

Gas safety control—thermocouple in pilot flame closes control circuit automatically through relay to hold gas valve open. Gas valve shuts off when pilot is extinguished, prevents gas escape. Thermocouple adapts to pilot burners. Pilot generator models for long couple lengths or operating multiple controls.

### (L) THERMAL EXPANSION VALVES

Type V-200 with new selective capacity cartridge provides instant sizing adjustment. Only one valve required for full capacity range in each body size at all back pressure or suction temperature ranges. For Freon, Methyl Chloride or Sulphur Dioxide.

### (M) THERMOPILLOT VALVE AND GAS COCK SAFETY VALVE

Manually reset, electromagnetically holds valve open with current generated by thermocouple, subject to heat of pilot flame. Automatically shuts off gas if pilot goes out. Type MR-5 combines manual gas cock with thermopilot safety valve. Available in  $\frac{3}{8}$  in. to  $1\frac{1}{2}$  in. I.P.S.

(N) SA & SY Strainers

### (N) STRAINERS

Protects automatic regulators or valves from pipe scale, other foreign matter. Assures proper seating, closing of valve. Prevents leakage. Convenient cleaning or blowoff without breaking line. Monel screen.

### OTHER GENERAL CONTROLS ITEMS

- IMMERSION THERMOSTATS
- COMBINATION FAN AND LIMIT CONTROLS
- STEAM PRESSURE, VAPOR AND VACUUM CONTROLS
- TEMPERATURE CONTROLS
- LOW WATER CUTOFFS

## Henry Valve Company

MELROSE PARK, ILLINOIS  
(A Chicago Suburb)

HENRY PRODUCTS FOR REFRIGERATION, AIR CONDITIONING, AND INDUSTRIAL APPLICATIONS: CONTROL DEVICES, VALVES, STRAINERS DRIERS, FITTINGS, AND ACCESSORIES.

Balanced-Action Diaphragm Packless Valves

**STANDARD TYPE**—Valves cannot stick shut regardless of pressure above or below Valve seat. Forged brass body and bonnet, ports-in-line and non-directional. Back seat and ball check permit diaphragm inspection and replacement under pressure. Sizes:  $\frac{1}{4}$ " thru  $\frac{3}{8}$ " Flare;  $\frac{1}{4}$ " thru  $1\frac{1}{2}$ " O.D.S.;  $\frac{1}{4}$ " thru  $\frac{1}{2}$ " F.P.T. Line, angle and branch types.

**BLUE BANTAM TYPE**—Two-way line shut off valves, flare or solder connections. Contain same field proven features as STANDARD line except that diaphragms cannot be inspected or replaced while valves are under pressure. Stock sizes  $\frac{1}{4}$ " thru  $\frac{3}{8}$ " flare and solder.

**WING CAP PACKED VALVES**—Bronze with solder connections, sizes  $\frac{1}{8}$ " thru  $4\frac{1}{2}$ " O.D. Semi-steel with F.P.T. connections in valve body, sizes  $\frac{1}{2}$ " thru  $2\frac{1}{2}$ ". Semi-steel flanged type, with separate brass O.D.S. adapters, sizes  $1\frac{3}{8}$ " thru  $5\frac{1}{8}$ "; with separate steel butt weld adapters, sizes  $1\frac{1}{4}$ " thru  $5$ "; with one piece F.P.T. flanges, or with one piece slip-on weld flanges, sizes  $1\frac{1}{4}$ " thru  $6$ ".

### RELIEF VALVES

Straight-Through Type and Ferrous Type

Most sizes meet ASME Standards—National Board Certification.

**STRAIGHT-THRU TYPE**—Large capacity—Brass Construction.  $\frac{1}{4}$ " thru  $1$ ".

**ANGLE TYPE**—for ammonia,  $\frac{3}{8}$ " thru  $2$ ".

### DRIERS

Filled with PA400 silica gel.

**TYPE 705**—Brass shell, forged brass end caps with integral fittings—silver brazed joints. Dehydrant capacity 10 to 32 cu in. Sizes,  $\frac{1}{4}$ " thru  $\frac{1}{2}$ " flare.

**TYPES 77, 78 and 79** cartridge driers with side outlet, safety disc, cartridge retaining spring and distortion-proof access flange. Dehydrant capacity 12 to 500 cu in. Sizes  $\frac{3}{8}$ " thru  $2\frac{3}{8}$ " O.D. solder. Can be converted to strainer by use of strainer screen cartridges.

### STRAINERS

**TYPES 891 and 892**. Brass shell, forged brass end caps. Screen area 11 and 25.5 sq in. respectively. Sizes  $\frac{1}{4}$ " thru  $\frac{3}{8}$ " flare and  $\frac{3}{8}$ " and  $\frac{1}{2}$ " O.D. solder.

**TYPE 895**—Brass plated steel "Y" strainer, welded construction, forged brass end caps. Distortion-proof access flange. Screen area 12 to 150 sq in. Sizes  $\frac{3}{8}$ " thru  $4\frac{1}{8}$ " O.D.S.; and  $2\frac{1}{2}$ " thru  $4$ " butt weld.

Stocked by Wholesalers. Ask for Catalogs

MASON EMMANUELS CO.  
91 Dearborn St., Seattle 4, Wash.

Designers and Manufacturers of Automatic Control Valves for All Refrigerants

Type SA-5, SF-5

Type SA-6, SF-6

Type SA-7, SF-7

Back Pressure Regulating Valves are of the conventional type used to maintain a constant evaporator pressure.

Combination Back Pressure Regulator and Stop Valves. This regulator is of the conventional type used to maintain a constant evaporator pressure and the addition of a small solenoid pilot valve built into the head, makes it a suction stop valve.

Type "T"

Type DSA-9, DSF-9

Type SAC-6, SFC-6

1. The Type "T" suction stop valve is used where automatic suction line control is required. It is operated by high pressure gas and its construction makes a tight closing valve and its dependability surpasses the conventional magnetic stop valve.

2. The DSA-9-DSF-9 is a dual regulator which will control evaporators with two load conditions requiring different refrigerant temperatures. The diaphragms in the dual head may be set for

any two evaporator pressures and will automatically change from one to the other by the opening or closing of the solenoid pilot valve.

3. The SAC-6 and SFC-6 valves are of the compensating type and are used where a constant temperature is desired in the medium being cooled. These valves will increase or decrease the evaporator pressure to compensate for the increase or decrease of the cooling load. Operated with air, electricity, or thermal type.

Solenoid Valves from  $\frac{3}{8}$  in. to 2 in. inclusive for liquids and gases with composition seat discs readily renewable, coils for any electrical characteristics, built-in lifting stem standard, with either screwed, welding flanges or copper tube connections.

Strainers in all sizes for liquids and gas with very large screen areas and arranged to bolt directly to valve or with screwed, welding flange or copper tube connections for installation wherever strainer is necessary.

HUBBELL-ize your plant with "Service Free" controls.

## Johnson Service Company

**AUTOMATIC TEMPERATURE AND AIR CONDITIONING CONTROL**  
General Office and Factory 507 E. Michigan St. Milwaukee 1, Wis.

Direct Branch Offices in Principal Cities

JOHNSON TEMPERATURE REGULATING COMPANY OF CANADA, LTD., 120 BERMONDSEY RD., TORONTO 16, ONT.

**MANUFACTURERS, ENGINEERS and CONTRACTORS.** A complete line of automatic temperature and humidity controls for heating, cooling, ventilating, air conditioning, industrial processing, military installations and special temperature and humidity control applications.

**SPACE CONTROL**—Automatic room temperature and humidity control for convectors, radiators, radiant heating, unit ventilators, unit heaters, and heating and cooling air delivery equipment.

**INDUSTRIAL PROCESSING**—Automatic temperature and humidity control for every requirement in manufacturing and industrial processing.

Thermostats, valves, dampers for tanks, dryers, vats, kettles, curing rooms, coolers, kilns, and other special equipment in textile, rubber, paper, petroleum, meat, dairy, baking, sugar, brewing, distilling, tanning, candy, foods, pharmaceutical, and other industries.

**SERVICE ORGANIZATION**—Johnson sales engineers, and trained installation experts at all branches in United States and Canada. No agents, jobbers, or part-time representative! All Johnson salaried personnel for exclusive service of Johnson Service Company customers.

**JOHNSON LITERATURE:** Available at your nearest JOHNSON branch office or write to address above.

### JOHNSON THERMOSTATS

**Room Thermostats**—single and dual temperature (Day-Night, Heating and Cooling). Proportional or two-position action. Maintain temperatures within one degree above or below setting. Wide selection of adjusting features, guards, and mounting. Furnished with or without thermometers.

**Insertion and Immersion Thermostats**—Liquid-filled temperature measuring elements. Stem type for direct measurement. Remote bulb types for applications requiring location of thermostat at a distance from the point of temperature measurement. Various bulb styles available. Standard capillary length is 8 ft. Lengths of 15, 25, 35 and 50 ft available on special order.

**Submaster Thermostats**—The set point of these Johnson controllers is changed from a remote location by the action of another (master) controller. Available with liquid-filled stem and remote bulb measuring elements.

Johnson "Duo-Stats," weather compensated primary controllers, control heating system temperatures in accordance with the outdoor temperature. Duo-Stats are available for any heating system, all types of buildings, and furnished in pneumatic, electric or electronic models.

### PRESSURE CONTROLLERS

**Pressure Regulators** with ranges of 30 inches of water to 300 psi. Static pressure regulators measure variations in pressure from .009 inches to 3 inches of water. Used also as differential regulators measuring difference in pressure between two chambers. Pressure switches and governors also available.

### JOHNSON HUMIDITY CONTROL

**Humidistats**—Room and insertion types with humidity measuring elements of wood or animal membrane, the most sensitive of which controls within 1 per cent at relative humidities as high as 95 per cent, at temperatures of 200 F. Submaster models also available which are adjustable from a remote point by another controller (master) or may be manually readjusted from a remote point by means of a Johnson Gradual Switch.

**Humidifiers**—Steam grid (perforated pipe supplied with low pressure steam) or pan type with copper evaporating pan, brass or copper heating coils and float control.

T-901 Liquid-filled Remote Bulb Submaster Thermostat

Series T-400 Room Thermostat

T-804 Liquid-filled Immersion Thermostat

## Johnson Service Company

## Controls and Instruments

### SPECIAL CONTROLLERS

**Aspirating Cabinets**—Several models with many combinations of controlling and auxiliary devices required to provide control of temperature and humidity. Cabinets equipped with blowers for positive air circulation and air gages for checking function of controllers at all times.

**Pneumatic Step Controllers**—for capacity control of reciprocating refrigeration equipment or any application where sequence of pressure switches is used.

**Record-O-Stat**—Combination capillary temperature controller and recorder. Available in single pen, two-pen, and submaster models. Indicating controllers and recorder-controllers also available.

**Liquid Level Regulators**—(Float Type) control within extremely close limits. Mounted through wall of containing vessel by stem with 1 inch pipe thread. Floats of copper, stainless steel or special alloys.

**Thermometers**—Insertion and immersion types for air and liquids. Stem and remote bulb temperature measuring models with vapor tension or liquid filled elements. Variety of styles, mountings and finishes.

T-1000 Single Pen Record-O-Stat

18 Point Model Pneumatic Step Controller

### JOHNSON VALVES

**Johnson Diaphragm Valves**—Simple, rugged. Diaphragms of special molded rubber, resistant to age and oxidation, operate valve stems against spring pressure. Available also with "Sylphon" seamless metal bellows. In standard sizes and patterns including compact valves for convectors and unit conditioners. Normally open or normally closed. Three-way mixing and bypass valves, for water, brine and other liquids.

**Johnson "Streamline" Diaphragm Valves**—With modulating discs and special internal construction. Smooth proportional control. Where maximum power is required for repositioning at slightest demand of controlling instruments, the larger molded rubber diaphragm valves are fitted with pilot positioners.

V-108 3-way Mixing Valve—Rubber Diaphragm

V-165 "Sylphon" Convector Valve

D-225 Proportioning Lower Damper

### JOHNSON DAMPERS AND SWITCHES

**Standard Johnson Dampers**—Galvanized 16-gauge steel blades in flat steel frames with adequate bracing to form rigid assembly. Black lacquer or special corrosion-resisting finishes. Angle iron frames optional.

**Special Dampers**—Galvanized iron frames and monel metal, aluminum, copper or rust-resisting steel blades on special order. Frames of same material as blades, if desired. Brass pins in steel bearings or ball bearings.

**Johnson Damper Operators**—Similar in operating principle to valves. Specially molded rubber diaphragm or seamless metal bellows operates damper through suitable linkage. Johnson "piston" damper operators afford long travel at full power. With or without pilot mechanism, as described for "Valves."

**Johnson Pneumatic Switches**—For direct operation of dampers and to switch controllers in and out of service from remote locations. Standard switchboard panels are Masonite. Ebony, asbestos, steel, polished oak and genuine or imitation marble panels on special order. Special switchboards including all types of control equipment available on special order.

D-251 Piston Damper Operator

Room 516, 420 N. La Salle St., Chicago 10, Ill.

*Alnor*

Precision Instruments for Every Industry

The direct-reading ALNOR  
VELOMETER

TYPE 4-F Standard minimum set for heating and air conditioning air velocity measurements.

The Alnor Velometer is an instantaneous, direct-reading air velocity meter designed for convenient, rapid determination of air velocities in air conditioning, heating and ventilating, and exhaust systems. It gives instantaneous direct readings in feet per minute, without timing, calculations, or reference to tables or charts. Accurate information on performance of equipment, duct systems, etc., can be obtained with a few moments inspection with the VELOMETER. It can be effectively used to locate drafts and leaks around windows and doors, or in duct systems.

The Alnor Velometer is built in several standard ranges from 20 fpm to 6000 fpm, and up to 3 in. static or total pressure. Special ranges available as low as 10 fpm and up to 25,000 fpm velocity and 20 in. pressure.

Alnor Velometer, Jr. A miniature, direct reading Velometer—4 in. high, 3 in. wide, 1-1/4 in. deep. Weight, 8 oz. Accurate, strong. Available in single and double scale ranges: 0-200 to 0-2500 fpm. Bulletin 725.

Alnor Thermo-Anemometer. For accurate measurement of low air velocity. Compact, direct-reading, battery operated, self-contained, portable. Scale 6 in. Meter ranges: 0-600 fpm and double range 0-300/100-2000 fpm. Accurate readings as low as 5 fpm. Temporary Bulletin 913-A.

## Leslie Co.

MARK

Temperature Regulator  
Class TPump Pressure Regulator  
Class PRFloatless Level Control for  
Boilers, Tanks, Evaporators,  
Heaters, Standpipes, etc.

**LESLIE COAST-TO-COAST SERVICE**  
In all principal industrial centers LESLIE factory-trained engineers are available to help with any control problem involving steam, liquid, air or gas. Look for LESLIE REGULATORS under "Valves" or "Regulators" in your classified telephone directory.

**INTERCHANGEABILITY** — Internal parts of LESLIE Regulators are dimensionally interchangeable. Maximum interchangeability in all sizes and classes.

**LESLIE EXCLUSIVE FEATURES**—at no extra cost!

- Stellite Seat Rings
  - Hardened Stainless Steel Main Valves, 500 Brinell
  - Corrosion Resistant Springs
  - Hardened Stainless Steel Cylinder Liners, 500 Brinell.
- Supplied as standard equipment.

**LESLIE PRESSURE REDUCING VALVES, PUMP PRESSURE REGULATORS and TEMPERATURE REGULATORS**

Self-contained, spring loaded, internal pilot piston or diaphragm operated with stellite seat rings, hardened stainless steel trim, bronze, iron, or steel construction. All LESLIE Regulators feature:

- Accuracy of regulation comparable to instrument control
- Single-seated construction for positive dead-end shutoff
- Valve acts fast for sudden load changes
- Maximum resistance to corrosion and wear
- Maximum spring range—from minimum to maximum controlled pressure range without change of spring or diaphragm

## Maxitrol Company

12200 Beech Road

Detroit 39, Michigan

*Maxitrol*

LOW PRESSURE GAS REGULATORS

Pacific Coast Distributor; PACIFIC SCIENTIFIC CO.  
San Francisco, Los Angeles, Seattle, Portland

Maxitrol gas regulators feature the patented "Straight-Thru-Flow" design principle. This construction sharply reduces pressure loss commonly encountered in conventional type gas pressure regulators. The new feature permits greater flexibility in design of manifolds for domestic equipment, and frequently allows a reduction in pipe size of gas manifolds. Capacity charts at greater differential pressures for industrial use at inlet pressures up to 5 psi available on request.

CAPACITY RATING (A. G. A. Listed)

| Model No. | Pipe Size | Cu Ft./Hr at 0.3 Pressure Drop 0.6 Sp. Gr. Gas | Btu/Hr Gases 800 Btu/Cu Ft. or More (Natural Gas) | Btu/Hr Gases Less Than 800 Btu/Cu Ft. (Mfd. Gas) |
|-----------|-----------|------------------------------------------------|---------------------------------------------------|--------------------------------------------------|

## The Mercoid Corporation

Main Office and Factory, 4201 BELMONT AVENUE, Chicago 41, Illinois  
 New York Office, 205 EAST 42ND ST. PHILADELPHIA OFFICE, 3137 N. BROAD ST.  
 AUTOMATIC CONTROLS FOR HEATING, AIR CONDITIONING,  
 REFRIGERATION AND VARIOUS INDUSTRIAL APPLICATIONS

## 100% MERCURY SWITCH EQUIPPED CONTROLS

## STEAM PRESSURE CONTROLS

Type DA-31 Circuit opens on pressure rise. For application where pressures change slowly. Equipped with outside double adjustments for setting cut-in or cut-out points. Elec. Cap.—A-C or D-C 10 Amp. 115V; 5 Amp. 230V. 1/4 in. I.P.S. connection. Ranges 0-14 lbs, 0-30 in. vac., 10 in. vac.—12 lbs, 0-20 lbs, 0-35 lbs, 0-60 lbs, 0-100 lbs, higher ranges available.

Type DA-21 Circuit opens on pressure rise. For applications where pressures fluctuate rapidly. Similar to Type DA-31. Electrical Capacity same as DA-31 above. Ranges available to 2,500 lbs.

## HOT WATER TEMPERATURE CONTROLS

Type 437 Circuit opens on temperature rise. Bimetal-operated (back angle immersion well type) used as a high limit for hot water boilers. Equipped with outside double adjustment for setting cut-in or cut-out operating points. Electrical Capacity—A-C or D-C 10 Amp. 115V; 5 Amp. 230V. Connection 1/4 in. I.P.S. Ranges 80-240 F and 40-200 F.

Type DA-36 (straight stem) Circuit opens on temperature rise. For immersion applications where bulb is directly installed into boiler water. Equipped with outside double adjustments. Electrical Capacity same as 437 above. Connection 1/2 in. I.P.S. Immersion bulb 3 in. long. Ranges 100-200 F and 135-235 F.

## WARM AIR TEMPERATURE CONTROLS

Type M-41 Limit Control. Equipped with outside adjustments for setting cut-in and cut-out operating points. Range 70-310 F.

Type M-43 Fan or Blower Control has outside adjustments together with summer switch used for ventilating purposes during summer. Range 50-300 F. Electrical Capacity all types A-C or D-C 115V, 10 Amp; 230V, 5 Amp.

## ROOM THERMOSTATS

Type H, opens circuit on temperature rise (low voltage). Regulates heating equipment from True Room Temperature without the aid of artificial stimulation. The Mercoid switch is unaffected by dust, dirt or lint. The cover has a jewel hard alumilite finish that will last a lifetime. Electrical Capacity 3/40 Amp, at 24V, or less. Ranges 55-85 F and 65-95 F.

Type R same as above except circuit closes on temperature rise.

## OIL BURNER PRIMARY CONTROLS

Type JMI (intermittent ignition) stack mounted safety ignition control provides complete protection against flame or ignition failure—low line or power failure protection.

Type JM (constant ignition) same as above except that no ignition switch is employed. Electrical Capacity A-C 10 Amp. 115V; 5 Amp, 230V.

Write for Catalog No. 800ASHV.

## A COMPLETE LINE OF MATCHED CONTROLS

## TO FACILITATE THE EARLY DESIGN OF EVERY CONTROL SYSTEM

Minneapolis-Honeywell manufactures a complete line of automatic controls for heating, ventilating and air conditioning. They are used singly or in combination in any type of control system. Therefore, at the time the building is designed you can specify Honeywell for all controls. You can be sure all the controls you need will be available from one manufacturer.

## FOR ALL TYPES OF BUILDINGS

Honeywell control systems may be adapted to your own individual plans to give custom-tailored performance in such various structures, as apartments, hospitals, hotels, schools, motels and commercial, industrial and residential buildings. And, there are Honeywell controls for all three principal types of control systems—electric, electronic and pneumatic.

## FOR ELECTRIC CONTROL SYSTEMS

Honeywell offers a complete line of such precision-tested equipment as thermostats, humidity controls, temperature controls, pressure controls, valves, relays, motors and accessories, all of which may be interlocked and co-ordinated to obtain a high degree of operating economy and efficiency in every heating, ventilating or air conditioning system.

Motorized Valve Assembly

## FOR ELECTRONIC CONTROL SYSTEMS

Electronic Thermostat

The flexibility of electronic controls makes them adaptable to control applications from the simplest to the most complex. From small buildings where completely automatic control of heating, ventilating and air conditioning requires only one thermostat, to large buildings where the entire control system can be supervised at one control-supervision center. All electronic thermostats, from the round room model to the 27 foot duct model, are co-ordinated at a convenient central panel where complex sequences can be set up; adjusted, and inspected in minimum time.

Pneumatic Round Thermostat

## FOR PNEUMATIC CONTROL SYSTEMS

Honeywell offers a complete line of pneumatic controls for applications from simple domestic temperature regulation to precision control of industrial processes. New Pneumatic Round thermostats provide faster response and more accurate control plus a "decorator" cover which can be painted to match surroundings. Honeywell pneumatic operators have a positive positioning feature which provides full power for even a relatively small adjustment.

Pneumatic Radiator Valve

## FOR COMBINATION SYSTEMS

Honeywell combination systems make it possible for you to take advantage of the most salient features of electric, electronic and pneumatic controls. These systems also allow you maximum flexibility, low-cost installation and permanent dependable control results.

## INSTRUMENTATION

Recording Thermometer

Honeywell indicating and recording instruments provide quality control of air conditioning systems. Used to measure temperature, humidity, pressure, or flow, they offer many advantages. These remote reading instruments also facilitate central panel supervision of control systems.

## AT YOUR SERVICE

There is a Honeywell sales and service office near you. This office maintains a staff of experienced control engineers who are highly qualified to give you advice on a broad range of applications and to install and service all types of control equipment. Honeywell engineers are equally well prepared to assist you in the writing of specifications and to furnish control layouts and cost estimates without charge.

## WRITE FOR FREE HONEYWELL LITERATURE

Listed below are but a few of the many pieces of literature Honeywell has prepared to help you select controls and control systems for your own specific requirements. In addition, instruction sheets on design systems and reference manuals for both electric and pneumatic controls are available to you. You may obtain literature and answers to your problems by contacting your nearest Honeywell office or writing to the Merchandising Division, Minneapolis-Honeywell Regulator Co., Minneapolis 8, Minnesota.

## Milwaukee Gas Specialty Company

730 North Jackson St., Milwaukee 2, Wisconsin

### SERIES EA SOLENOID VALVE

Internal parts in contact with gas are aluminum or stainless steel to prevent corrosion; aluminum bodies. Straight through models in  $\frac{1}{2}$  in. and  $\frac{3}{4}$  in. pipe sizes with or without pilot tapings and pressure tapping. Voltage types: 20v, 60 c, a-c; 115 v, 60 c, a-c; 230 v, 60 c, a-c; and 440 v, 60 c, a-c. Low voltage transformers in three-terminal and two-terminal types, DA1 and DA2, respectively.

### ACTROL® VALVE

Automatic main gas control valve. Maximum force exerted at beginning of stroke. Valve has built-in, current limiting transformer for 24-volt control circuits. Straight through body tapped with  $\frac{3}{4}$  in., 1 in., or  $1\frac{1}{4}$  in. F.P.T. inlet and outlet. Valve can be mounted in a 360 deg circle around horizontal centerline of body. Other models with manual set, safety switch, or Baso® valve.

MA8G1

Type AK Basoid Valve

### BASOID® VALVES

Basoid valves Series AE, AH, and AK are 1 in.,  $\frac{3}{4}$  in., and  $\frac{1}{2}$  in. sizes, respectively. They combine solenoid valve for automatic main gas control and Baso automatic safety pilot in one aluminum body. One or two pilot tapings optional. Current types: 20 v, 60 c, a-c; 115 v, 60 c, a-c; 230 v, 60 c, a-c; and 440 v, 60 c, a-c. Low voltage transformers in three-terminal and two terminal types, DA1 and DA2, respectively.

Switches No. 860 and 861 are wired in series with other controls. Opens circuit to main valve in case of pilot failure. Circuit closes automatically when pilot is relighted. MODEL No. 860 is a two-wire switch and No. 861 is a three-wire switch.

Electrical Rating:  
8 Amp at 115 v, a-c.  
4 Amp at 230 v, a-c.  
 $\frac{3}{4}$  hp 115/230 v, a-c.

860 Switch

ANNULAIR® PILOT BURNERS are available in a variety of tips and dual orifice inlet fittings for all kinds of fuel gas and pilot line connections. They are made in four types, "B" for low consumption appliances, "C" for medium consumption, and "D" and "F" for larger capacity appliances.

Thermocouple leads of the 88D and 58D types are available in standard lengths from 12 in. to 72 in. and in special lengths to 240 in.

Write for complete catalog SV-300-3.

## Moeller Instrument Company

132nd St. and 89th Ave., Richmond Hill 18, New York

Representatives in Principal Cities

### INSTRUMENTS FOR HEATING AND VENTILATING

MOELLER INDUSTRIAL THERMOMETERS made in all forms, in scale ranges from minus 120 to plus 1125 F or its equivalent in centigrade. Available in 5 in., 7 in., 9 in. and 12 in. scale sizes.

DIAL INDICATING THERMOMETERS, Mercury Actuated, made in 4 $\frac{1}{2}$  in., 6 in. and 8 $\frac{1}{2}$  in. sizes with flexible extension tubing. Scale ranges from minus 40 to plus 1000 F or its equivalent in centigrade.

THERMOMETER TEST WELLS, THERMOCOUPLE PROTECTING TUBES and WELLS, made up in all sizes and alloys.

ENGRAVED STEM and PORCELAIN and PAPER SCALE THERMOMETERS made in ranges from minus 150 to plus 1125 F or its equivalent in centigrade.

RECORDING THERMOMETERS, Mercury Actuated, made in the round or rectangular cases. Charts 10 in. or 12 in., 1 hr, 12 hr, 24 hr or 7 day. Ranges from minus 40 to plus 1000 F or its equivalent in centigrade.

MOELLER BI-METAL THERMOMETERS are actuated by a powerful, specially processed bi-metal helix. Made in 3 in. and 5 in. diameter cases. Scale ranges from minus 150 to 1000 F. or its equivalent in Centigrade.

RECORDING PSYCHROMETERS, Mercury Actuated. Round and Rectangular Case, 12 hr, 24 hr or 7 day charts, self contained or remote reading, with or without motor driven fan.

HYDROMETERS PLAIN FORM or COMBINED with THERMOMETER. Made in all scales. Standard and commercial grades.

Automatic Controls for Heating, Refrigeration, Air Conditioning, Engines, Pumps, Air Compressors and Gas Appliances

Oil Burner Stack Switches

Heating Thermostats

Series 926 Gas Valves

Warm Air Fan and Limit Controls

### HEATING CONTROLS

A wide selection of controls is available for automatic heating service on steam, vapor, hot water, or warm air systems . . . gas, oil or coal-fired. Typical controls in Penn's complete line are: Low and Line Voltage Room Thermostats—Stoker Timers—Oil Burner Stack Switches—Magnetic and Motorized Gas Valves—Hot Water and Warm Air Temperature Controls (including a complete line of Liquid Expansion Fan and Limit Controls)—Vapor and Steam Pressure Controls—Relays and Relay-Transformers—Humidistats—Day-Nite Temperature Controls—Pilot Burners and Pilot Generators—Thermopilot Relays—Low Pressure Gas Regulators—Damper Motor Controls—and Solenoid Valves.

Heating-Cooling Thermostats

Series 271 Dual Pressure Control

Series 275 Oil Protection Control

### COOLING CONTROLS

A complete line of automatic commercial refrigeration controls . . . in a wide choice of pressure and temperature models to fit every need. Series 270 single pole, standard duty or two pole, heavy duty controls feature direct reading, calibrated scales. Other controls in the refrigeration line include: Cooling Room Thermostats—Humidistats—Relays—Solenoid Valves—Line Starters and Motor Contactors in Size 0, 1, and 1½—Water Regulating Valves in sizes up to 2½ in. N.P.T.—and Oil Protection Controls for pressure lubricated refrigeration compressors.

### SERIES MS RELAYS

MS series motor starting relays are voltage controlled to insure cut of starting windings when the motor reaches running speed, regardless of the load on the motor. This design permits an exceptionally wide differential between pull-in and dropout voltages. Relays can be either factory or field adjusted to meet exact requirements. MS2A for use with ¾ hp motor 115 or 230 volt 60 cycle, MS4A motors up to 3 hp either 115, 230 or 440 volt, 60 cycles. All relays are mounted on molded phenolic bases. Contact arrangement MS2A, SPST-NC, MS4A, SPST-NC double break.

### SERIES PR RELAYS

SERIES PR are heavy duty, fast acting relays designed for high current or high voltage switching requirements. The full floating movable contact carrier assures ample wipe and contact pressure.

Standard contacts are 5/16 in. diameter, fine silver, rated 15 amperes, 115 volt, 60 cycle non-inductive or 20 amperes double break contacts. By the use of equivalent size cadmium oxide contacts higher ratings are possible. A wide variety of standard and auxiliary contact arms are available for multiple current handling requirements.

Terminals for printed circuits, plug or screw type, are available.

The PR series are Underwriter Laboratory approved.

Some of the many controls employed in a Powers pneumatic control system for heating, ventilating, air conditioning and industrial processes are shown here. Controls for water heaters, fuel oil pre-heaters and heat exchangers appear on third page.

Powers Thermostats have true gradual action with no constant bleed of compressed air. They give many years of dependable control with practically no maintenance. Various types for specific applications are available. Some are shown at left.

A) Type D Single temperature range room thermostat has durable stamped brass cover and plastic insulating base. Because of its small size  $5\frac{5}{8}$  H x  $2\frac{1}{4}$  W x  $2\frac{1}{4}$  in. deep, it fits into narrow vertical spaces. B) Type D Two-temperature range Day-Night thermostat. C) Type 190 Room Hygrostat for humidity control, duct type also available. D) Type D Summer-Winter remote bulb thermostat for air conditioning units. E) Limitem thermostat for unit ventilators and ducts. F) Type K remote bulb thermostat. G) Type K remote bulb Submaster thermostat. H) Accritem Temperature Regulator has adjustable sensitivity and calibrated dial adjustment with ranges 50-250F and 150-350F. J) Static Pressure Regulator for air ducts.

Powers Series 100 Recording and Indicating Controllers also control switches, gages, etc., are available in a variety of models; some are shown on control panels on next page.

Powers Packless Control Valves (K and L) are made in various types and sizes for convectors, unit ventilators, unit air conditioners or coils in ducts. With their durable construction, ample power and Duo-Seal packless feature they eliminate normal packing gland friction and give better control. They eliminate steam or water leakage, loss of vacuum and packing maintenance.

Modern Control Panel employing various types of Powers pneumatic controlling, indicating and recording instruments which regulate four complete year round air conditioning systems.

**UNIT VENTILATOR CONTROL** Powers latest advancement the **LIMITEM Thermostat** (E on previous page) is a precision instrument engineered to provide accurate low limit control of unit ventilator discharge temperatures... a critical requirement for classroom comfort. It has sturdy construction, accurate response, Powers famous **NON-WASTE** double air-valve with adjustable sensitivity and graduated temperature dial for changing the control point. It is fully described in *Bulletin 308*.

Powers **MASTROL** Systems for controlling forced hot water heating, radiant panel heating, etc., are available in various combinations of Master and Sub-Master controls. Control panel below shows **MASTROL** system using Powers Series 100 Recording Master Controller readjusting Sub-Master Indicating Controllers.

Left: Powers Wet and Dry Bulb Recording Controller with motor driven fan.

Powers FLOWRITE diaphragm valves. See other models next page.

POWERSTROKE Piston Operators for Dampers, etc. Available in 3 in., 4 in. and 6 in. size.

Powers modern line of diaphragm control valves, and damper operators meet all heating and air conditioning requirements.

Simplicity and good design features in Powers **FLOWRITE** Valves give close control and they last longer. They are available with single seat, double seat, 3 way mixing and V-Port characterized valve which gives straight line control. Accurate control results from smooth rolling diaphragm and minimum of valve stem friction. Diaphragm has formed bead which provides increased sealing action with increasing control pressure. It has no bolt holes. Diaphragm lasts longer without replacement.

Piston plate assembly has a free floating thrust plate which absorbs side thrust. Closely guided piston plate maintains valve stem in accurate alignment. Series 344 Bulletins give more facts about these valves.

Above: Powers FLOWRITE  
Diaphragm Control Valve.

## POWERS

Temperature Control for Water Heaters, Heat Exchangers, Fuel Oil Preheaters, and many other uses.

No. 11 Regulator below, is self-operating, especially adapted for hot water storage heaters. Available with 60F, ranges, various types of valve bodies and trim, also 3 way valves for water mixing.

Accritem Regulator at right, is compressed air or water operated, used to control Powers Three-way Flowrite valves. Is especially adapted for control of instantaneous water heaters, submerged and indirect heaters, 2-Temp. domestic water heating systems—applications requiring accurate control and having frequent load changes and for large size valves. Has adjustable sensitivity, calibrated dial temp. adjustment, ranges 50-250F and 150-350F. Sensitive bulb 12 in. long, 1/2 in. IPS connection.

No. 11 Regulator

Thermostatic Water Mixing Valves—complete line for individual shower baths, gang showers, hydrotherapy, hot water line control, and processes. Contact nearest Powers office for bulletins.

## Scully Signal Company

Main Offices and Factory: 174 Green Street, Melrose 76, Mass.

Representatives in Principal Cities  
Canadian Branch: Scully Signal Ltd., 286 King St., W., Toronto, Ontario

SCULLY PRODUCTS include VENTALARM Whistling Tank Fill Signal, VENTALARM GAUGE, combination audible fill signal and tank gauge, and the separate SCULLY GAUGE.

**VENTALARM Signal**—An audible whistling tank fill signal installed directly on the fuel oil tank as an integral part of the vent pipe. Displaced air forced from the tank by intruding oil motivates a sensitive but sturdy whistle within the body of VENTALARM Signal. The sound travels up and out the vent pipe where it is audible to the man filling. He simply fills until the whistle stops which is when the oil reaches the bottom of the whistle stem (at a predetermined safe level within the tank allowing for expansion zone). Permits householder to come and go regardless of oil delivery time. Eliminates need for delivery man to enter home. Stops damaging spills and while the whistle sounds there is positive proof that all parts of the tank fill system are in good working order.

Models LA and L for New Tanks

These models thread into tank vent flange opening. The lower end of vent pipe threads into top of VENTALARM Signal.

Model LA (Listed as Standard by Underwriters Laboratory)

|                                      |               |          |
|--------------------------------------|---------------|----------|
| Bottom                               | Top           | Part No. |
| 1 1/4" male                          | 1 1/4" female | 201      |
| Model L (same as LA except for size) |               |          |
| Bottom                               | Top           | Part No. |
| 2" male                              | 1 1/4" female | 521      |
| 1 1/4" male                          | 1 1/4" female | 240      |

Special models for special situations including Model LC for Old Tanks—furnished complete with quick-fit compression lock device eliminating need for threading or special fittings.

**SCULLY TANK GAUGE**—Easily read even 10 feet away. Gauge face adjustable for convenient reading. Pure white button indicator within oil and odor-proof plastic housing in a gasketed seat. Jam-proof lever arm. Oil resistant cork float. Button-Lift allows installation with or without oil in tank. Model GA for 2 in. tank opening. Model GB for 1 1/2 in. tank opening. Model GC for 1 1/4 in. tank opening. Specify tank depth—24 in., 26 in., 27 in., 28 in., 37 in., 42 in., 44 in., 47 in. Underwriters' approved.

Scully Tank Gauge

Combination Ventalarm Gauge

**Combination VENTALARM-GAUGE**—Both an audible fill signal and gauge in one unit. No reducing bushing needed. Only one item to install instead of three. Sizes VG-A, 2 in. x 1 1/4 in.; VG-B, 1 1/2 in. x 1 1/4 in. For 275 gal cellar tanks with depth of 24 in., 26 in., 27 in., 28 in., 37 in., 42 in., 44 in., 47 in. Scully products are manufactured under U.S. and Foreign Patents or Patents Pending.

Prices subject to change.  
Over 4,000,000 Scully VENTALARM Signals in use—UL approved.

SIM-TROL Barometric Draft Controls—SIMPLEX Roof Vent Flashings

Type "A"

Breechings and stacks must provide sufficient draft under adverse atmospheric conditions. During normal and high barometric periods, cold months and windy days they generate excessive intensities with resulting inefficiency and fuel waste.

### ADVANTAGES

SIM-TROLS automatically maintain a minimum draft required for good combustion, fuel economy, increased heat transfer by reduction of gas velocity through the boiler, and minimize cold air infiltration and inrush causing sudden shrinkage of boiler parts. They eliminate local hot spots, floating and pulsating flame and sucking out of pilots. They improve feed water regulation, super-heater results, boiler life and boiler room ventilation.

SIM-TROLS aid materially in smoke abatement and boiler cleanliness by reduction of unburned combustibles and air dilution of stack gases. Lowered stack temperatures prolong liner life and reduce fire hazards.

### CONSTRUCTION

Properly sized SIM-TROLS adjust easily to any desired draft intensity. The races adjust laterally, the race assembly vertically, and the arm angle may be varied in relation to the plane of the gate.

Gates of Type A and Type C SIM-TROLS rotate on cold rolled arbors and dust proof ball bearings. Curved tubular counterbalances contain metal balls which constantly change position to compensate for varying rotation angles of the gate, maintaining over-fire draft within 0.01 in. water, plus or minus.

SIM-TROLS are protected by hard, heat resisting boiler room enamels. All counterbalance members are outside, free from encrustment and corrosion by products of combustion.

### DESIGN FACTORS

Sizing is important. The input opening should equal the stack area, plus 10 per cent for each 35 ft of stack height over 65 ft thereof. Preference should be given to control width, rather than height for ease of adjustment and smooth operation.

Horizontal clearance from installation point approximates gate height plus 30 in. Over-all height approximates gate height plus 37 in. Over-all width approximates gate width plus 8 in. Designs for limited space may be made if plans are submitted.

Types A, C and F are individually designed to plant specifications presented, including breeching and stack dimensions, clearances, fuel, method of firing and number of boilers. Detailed sketches are submitted for approval without obligation.

### GAS MODEL SIM-TROLS

Types A, F and H are available to provide full back pressure relief and draft control. If specified, Types A and F are designed for use with coal, gas or oil by minor adjustment by the operator.

## Spence Engineering Company, Inc.

28 Grant Street, Walden, N. Y.

Regulators for the accurate control of Pressure, Temperature, Differential, Back Pressure and Liquid Level; also Pump Governors, Electrically Controlled Regulators, Desuperheaters and Strainers.

The SPENCE Type ED-W27 Two-Stage Pressure Reducing Station is designed to serve a heating system dependably, at low cost and with utmost safety. The primary is a pilot operated, Type ED Pressure Regulator. SECO Metal trim affords guaranteed resistance to wire-drawing. The secondary is a direct operated, Type W27 Valve, simply constructed, yet engineered for long trouble-free, heating duty.

Note that the Diaphragm of the SPENCE Safety Pilot is connected to the low side. Should the secondary valve fail, this Pilot will assume control of the primary; thereby effecting a one-stage reduction from primary to final delivery pressure.

A Spence Type E2T100 Temperature Regulator reduces the steam pressure in addition to accurately modulating the flow as required to control the temperature. No separate reducing valve is necessary.

By adding a SPENCE Solenoid Pilot any SPENCE Regulator may be cut on and off electrically.

The Spence design provides a self-operated, pilot controlled regulator entirely packless in construction and guaranteed to shut tight. SECO Metal seats and discs will not be cut by the wire-drawing action of steam. Spence thermal elements are not injured by overheating.

Pilot Type T100 is weight-loaded for heaters requiring not more than 10 psi pressure. Pilot Type T150 is spring-set for pressures up to 50 psi. Either may be used on a storage or instantaneous heater in combination with a main valve selected to suit the initial steam conditions.

## CONDENSATION and VACUUM PUMPS

4100 and 4200 Series (illustrated): neat, convenient unit with either steel or cast iron tank. Dual voltage capacitor type motor and carbon type rotary seal—for all jobs up to 15,000 sq ft EDR, 20 psi. 3500 Series: heavy duty units with pedestal mounted steel tank for a wide range of jobs—2000 to 65,000 sq ft, up to 150 psi. 3700 Series: with heavy cast iron tank for installation underground or in wet locations. 2000 to 20,000 sq ft, 20 or 30 psi. Vacuum Pumps: Type V, 2500 and 5000 sq ft, 20 psi. Type S, 10,000 to 40,000 sq ft, 20 to 40 psi.

Popular 69B illustrated

## FLOAT and THERMOSTATIC TRAPS

Used wherever it is desired to prevent flow of steam, but to permit passage of air and water... on unit heaters, large radiators and convectors, water heaters, steam main drips and other types of equipment where steam is used. Compact, rugged, easy to service. Bellows thermostat vents air, float valve has plenty of capacity for large amounts of condensate. Sizes:  $\frac{3}{4}$  in., 1 in.,  $1\frac{1}{4}$  in.,  $1\frac{1}{2}$  in., 2 in. Max. pressures: 15, 100 psi.

Also Strainers, Radiator Valves, Boiler Return Traps.

## Series 150-E TEMPERATURE CONTROL VALVES

Self-powered, modulating control valves—applicable to any process involving heating and cooling by means of water, oil, steam or other fluids. Sturdy bellows—sealed valve with stainless steel trim and monel bellows. Armored capillary tube. Extremely compact—MOUNTS and OPERATES in ANY POSITION. Sizes:  $\frac{1}{2}$  in.,  $\frac{3}{4}$  in., 1 in. Max. pressure: 125 psi. Direct or reverse acting. Series 117-A: Dependable action for larger capacities. Sensitive thermostat bellows operates a pilot valve—steam supply pressure is used for smooth positive operation. Sizes:  $1\frac{1}{4}$  in.,  $1\frac{1}{2}$  in., 2 in. Max. pressure: 125 psi. Direct acting only.

## SERIES 120-A THERMOTROLS

Self-contained individual radiator temperature controls for steam or hot water. Simple to install! Eliminate overheating, save fuel. Maintain even temperature for comfort and health. Sizes:  $\frac{1}{2}$  in.,  $\frac{3}{4}$  in., 1 in. Body styles: Angle, Straightway, Corner.

**THERMOSTATIC TRAPS:** Keep radiators clear of condensate without wasting steam. Dependable bellows thermostat, sturdy bronze bodies and covers, replaceable seats. Sizes:  $\frac{1}{2}$  in.,  $\frac{3}{4}$  in., 1 in. Max. pressures: 15, 65, 100, 125 psi. Body styles: Angle, Straightway, Corner, Vertical.

Taylor Instruments for Indicating, Recording and Controlling Temperature, Pressure, Humidity, Flow and Liquid Level

(A) Taylor Industrial Thermometers—with BINOC\* Tubing. Includes many styles and scale ranges with bulbs for every application. These thermometers use the well known Taylor BINOC Tubing—a designed and optically correct glass tubing which assures ease of reading generally lacking in industrial thermometers. BINOC tubing more than doubles the angle of vision within which readings can be made. Because of the patented triple-lens construction, its broad mercury column can be read easily and accurately with both eyes. Bore reflection is absent.

(B) Taylor Biram's Anemometer. For measuring air velocities with fan revolutions indicated on dial. Various models for a wide range of air speeds and registration limits.

(C) Mason's Form Hygrometer. Provides temperature and humidity measurements. Magnifying thermometer tubes are mercury-filled, approximate range 30 to 120 F. Thermometer scales and siphon reservoir are mounted on a mahogany finished wood panel,  $8\frac{1}{2}$  in x  $4\frac{1}{2}$  in.

(D) FULSCOPE\* Recording Controller. An air-operated controller that gives practically any character of process control.

\*Trade Mark

trol regardless of time lag in apparatus. Available for controlling temperature, pressure, humidity, rate of flow, liquid level. Where extreme load changes or badly balanced operating conditions exist, precision control can be maintained by the automatic reset feature. For applications where a record is not essential, Taylor supplies an Indicating FULSCOPE Controller.

(E) Sling Psychrometer. Two accurate etched-stem thermometers mounted on die-cast frame, with the bulb of one covered with a wick to be moistened. Whirling bulbs subject this hygrometer to complete air contact to produce extreme accuracy of temperature and humidity measurement.

(F) Recording Hygrometer. Records both wet and dry bulb temperatures on the same chart in different colored inks, making comparison very easy. Type shown has motor-driven fan for conditioned rooms or passages where circulation is poor. Furnished without fan for installations where circulation across bulb is good.

Taylor also offers a complete line of the famous Taylor Recording and Dial Thermometers; Ratio, Pneumatic Set, Self-Acting and Type "P" Controllers; Indicating Hygrometers and many types of Humidifiers.

### HYDRAULIC-ACTION CONTROLS

The complete line of White-Rodgers controls includes:

|                              |                                             |
|------------------------------|---------------------------------------------|
| Warm Air Controls            | Relays                                      |
| Low Voltage Thermostats      | Gas Valves                                  |
| Line Voltage Thermostats     | Oil Burner Controls                         |
| Hot Water and Steam Controls | Refrigeration and Air-Conditioning Controls |

Hydraulic-Action temperature controls operate on the principle of expansion and contraction of a solid liquid charge against a diaphragm.

This system, developed and perfected by White-Rodgers provides accuracy comparable to that of a fine thermometer... and other outstanding features guaranteeing excellent performance.

### ADVANTAGES OF HYDRAULIC-ACTION

Hydraulic-Action controls provide maximum sensitivity—positive dial settings—full range accuracy—consistent differential—eliminates temperature drift—simplified installation—extra sturdy switch mechanism—and other qualities that assure long satisfactory operation.

### PRIMARY CONTROLS

In addition to Hydraulic-Action Controls, White-Rodgers manufactures Oil Burner primary controls, Gas Valves (both diaphragm and solenoid types) and automatic safety pilots for gas installations.

Dual Hot Water Controls. Limit and Circulator, High and Low Limit combinations. Also made in single controls.

Low voltage room thermostat. Ivory and chrome finish.

Line voltage thermostat for unit heaters or air conditioning installations.

Remote bulb heavy-duty thermostat, also available with self-contained bulbs.

Fan & Limit controls in single case. Note the flexible elements. Also in single units.

"Cushioned Power" Solenoid Gas Valves. Quiet, soft seat, spring loaded. For ALL gases.

Oil Burner primary control (stack switch). Intermittent or Constant Ignition types.

Contact your nearest White-Rodgers office for complete information. Catalog and engineering data furnished quickly.

## AMERICAN DISTRICT STEAM DIVISION

AdSCO INDUSTRIES, INC.

20 MILBURN ST. BUFFALO 12, N. Y.  
PLANTS, BUFFALO, N. Y.—RICHMOND, CALIF.

### PACKLESS EXPANSION JOINTS

AdSCO's Corruflex packless expansion joints absorb pipe expansion and are adaptable to any piping condition. They are made in two basic types. The self-equalizing joint is used for various types of motion and is suitable for pressures to 300 psi and higher. The non-equalizing type is generally used to absorb vibration and a small amount of expansion under vacuum or pressures to 30 psi.

Depending on the type of metal used in the expansion element, these joints are suitable for temperatures from sub-zero to 1600 F. With variations in design, these joints will absorb axial, lateral, or angular motion, or any combinations of these motions. Some types handling these conditions are the universal, hinge, swing, gimbal, tie-rod, balanced, and anti-compression joints.

They are made in nominal pipe sizes ranging from 3 in. to 54 in., with single or multiple corrugations. Most types can be supplied with covers to permit joints to be fully insulated and to prevent foreign matter from being lodged between the corrugations. When used for axial movement, joints can be equipped with internal guide sleeves to provide a guiding feature and rigidity. For other purposes they can be equipped with telescoping inner sleeves to reduce turbulence in the fluid being handled.

### SLIP-TYPE JOINTS

Slip-type expansion joints, designed for axial motion, offer long traverse, low initial cost, and produce minimum stresses and strains on pipe anchors. With proper maintenance, they will last as long as the pipeline.

The piston-ring joint, illustrated above, with external-internal guiding, can be unpacked and repacked under full line pressure because of its piston-ring feature. The polished, chrome-plated slip is in contact with packing only. Hence, it cannot be scored by metal-to-metal contact. Packing can be quickly lubricated to prolong its life. The slip in the externally-internally guided joint is fully supported at both ends throughout its entire length of travel. The gland is not used as a guiding feature.

The internally-guided joint (not illustrated), being more compact, is especially recommended for use where space is limited.

AdSCO slip joints are furnished in both single and double units, with flanged ends or welding ends. Sizes range from 1 1/4 in. to 48 in. and traverse per slip is 4 in., 8 in., and 12 in. Semi-steel joints can be used for working pressures to 250 lbs and temperatures to 450 F. Steel joints can be used for working pressures to 400 lbs and temperatures to 800 F.

### PIPE ALIGNMENT GUIDES

AdSCO pipe alignment guides insure straight movement of pipe line for efficient operation of expansion joints, permit line to be completely insulated. In all nominal pipe sizes for various thicknesses of insulation; 12 in. of pipe movement permitted.

## Badger Manufacturing Company

230 Bent St., Cambridge 41, Mass. • 60 East 42nd St., New York 17, N. Y.

Representatives in principal cities  
Also in Canada and Mexico

### "BADGER PACKLESS CORRUGATED EXPANSION JOINTS"

To compensate for thermal expansion and contraction in pipe lines carrying hot gases or fluids; also used to absorb vibrations. Hinged, Tandem, and Balanced Expansion Joints are available for complex piping problems where forces are critical.

Badger Non-Equalizing Expansion Joint, Multiple Corrugation. Single corrugation type available. Wide range of sizes.

Badger Self-Equalizing Expansion Joint, Directed Flexing Type. Wide range of sizes and traverses available.

### INSTALLATION, OPERATING, MAINTENANCE FEATURES

**Packless**—Each Badger Packless Expansion Joint is formed from a single tube hence, no packing is needed etc.

**Engineered Relationship**—Between diameter of joint, depth of corrugation and allowable traverse.

**Heat Treatment**—Successive heat treating operations during manufacture removes forming stresses and increases life.

**Wide Pressure Range**—Standard joints for pressures up to 300 psig.

**Wide Temperature Range**—Standard joints for temperatures up to 900 F.

**Wide Traverse Range**—In standard in-

crements up to 7½ in. for single joints; up to 15¼ in. for double joints.

**Connections**—Flanged or welding ends available.

**Materials**—Standard joints fabricated from stainless steel or copper.

**Compact, Easy to Install**—Outside diameters of all Badger Expansion Joints are approximately the same as standard pipe flanges; joints are as easily installed in the line as any fitting.

**Special Designs**—Our Engineering Department will be pleased to consult with you regarding applications involving large sizes, special alloys, or abnormal operating conditions.

### FLEXON EXPANSION COMPENSATORS FOR STEAM AND HOT WATER HEATING SYSTEMS

#### Model L for pressures to 40 psig

The Flexon Model L Expansion Compensator consists of a two ply phosphor bronze bellows with copper tube end connections enclosed in a floating protective shroud of brass. It is especially designed for control of expansion in finned type convectors, baseboard, radiator or heating supply and return lines.

Sizes from ¾ in. through 1½ in. Suitable for temperatures from -60 F to 250 F and for pressures up to 40 psig. A single unit will handle motion up to ½ in. (¾ in. compression, ½ in. extension). Available with all commonly used fittings.

#### Sizes and Dimensions

| Pipe Size (in.) | Overall Length, in. |                      | Max. O.D., in. |                      |
|-----------------|---------------------|----------------------|----------------|----------------------|
|                 | Sweat Ends          | Female Threaded Ends | Sweat Ends     | Female Threaded Ends |
| ¾               | 5⅞                  | 7⅞                   | 1½             | 1½                   |

| 1¼              | 7¾                  | 9⅞                   | 2¼             | 2¼                   |
| 2               |                     | 10⅞                  |                | 3⅞                   |

#### Model H for pressures to 150 psig

The Flexon Model H Expansion Compensator is used primarily on vertical risers for high pressure steam and hot water lines. However it may also be used on horizontal runs. The Model H consists of a corrosion resistant Flexon bellows enclosed in an all-welded steel housing. The unit is provided with a positive anti-torque device to prevent possible bellows damage during installation.

Sizes from ¾ in. through 3 in. Suitable for temperatures from -60 F to 750 F. A single unit will handle motion up to 1¼ in. (1½ in. compression, ¼ in. extension). Mild steel male NPT pipe nipples on both ends are standard. Ground joint unions or weld ends are optional.

#### Sizes and Dimensions

| Pipe Size (in.) | O/A Length (in.) | Max. O.D. (in.) | Working Press (psi) | Unit Wt. (lb.) |

| 3               | 14⅞              | 5½              | 100                 | 17.4           |

### FLEXION EXPANSION JOINTS FOR POWER AND PROCESS PIPING

For medium and high pressure piping, Flexonics offers a complete line of corrugated expansion joints in free-flexing and controlled flexing types. Free-flexing units are available in standard sizes from 3 in. to 48 in., I.D. for pressures to 30 psi, temperatures to 850 F. Designed for expansion travel up to 3¼ in. per unit.

Controlled-flexing units are available in standard sizes from 3 in. to 48 in., I.D. for pressures to 300 psi, temperatures to 850 F. Designed for expansion travel up to 7½ in. per unit. Both free-flexing and controlled flexing types are available with flanged or welding ends.

TO MARK PROGRESS

## LADISH CO.

Cudahy,  
Wisconsin

Complete service in Controlled Quality pipe fittings regardless of size, type, wall thickness, pressure rating or material specifications.

DISTRICT OFFICES: Atlanta, Buffalo, Chicago, Cleveland, Havana, Houston, Los Angeles, Mexico City, New York, Odessa, Philadelphia, Pittsburgh, St. Louis, St. Paul, San Francisco, Seattle, Tulsa.

BRANCH PLANTS: Los Angeles, California—Brantford, Ontario, Canada—Kenosha, Wisconsin

Standardizing on Ladish assures unrestricted selection in meeting your entire fittings requirements . . . for the Ladish fittings line is complete in types, sizes, pressure ratings and materials, including carbon, alloy and stainless steels, aluminum, brass and other non-ferrous alloys. All Ladish fittings are produced under rigid metallurgical and manufacturing controls.

### BUTT WELDING FITTINGS

½ in. through 42 in. Schedule 5 through Double Extra Strong and special heavy wall thickness up to 4 inches. All fittings carry permanent heat code identification.

### ASA AND MSS FLANGES

ASA Flanges ½ in. through 24 in. 150 lb through 2500 lb ratings. MSS 150 lb Flanges ½ in. through 12 in. Large O.D. Flanges in sizes up to 20' ft diameter. Forged under exacting metallurgical controls, accurately machined to full dimensions.

### SCREWED AND SOCKET WELDING FITTINGS

Forged Steel Fittings ½ in. through 4 in. 2000 lbs through 6000 lbs. Wide reinforcing bands provide ample wrench grip surface and extra strength at stress points. Sharp, clean threads of Ladish Screwed Fittings assure tight, leak-proof joints. Socket Welding Fittings have deep, true welding sockets to assure proper alignment and slip fit. 150 LB STANDARD SCREWED FITTINGS are also available in a complete range of sizes.

## The Robvon Backing Ring Co.

675 Garden Street

Elizabeth 2, New Jersey

Robvon Backing Rings for Welding Pipe, Valve and Fitting Joints

ROBVON Type "CCC"

**ROBVON BACKING RING TYPE "CCC."** This RING is designed for application where variation inside diameters is relatively great. Extra-long chamfered NUBS maintain the established root opening under the most adverse fit-up. The easy "STRIKE OFF" feature of the "CCC NUBS" permits each to be removed with a light tap of a hammer. Normal welding currents may be used when the NUBS have been removed.

ROBVON Type "CC"

**ROBVON TYPE "CC"** is inserted into beveled end of pipe with the split end of the ring placed at the bottom of the pipe and the spacer NUBS flush against the land of the pipe.

The beveled end of adjoining pipe is slipped onto the backing ring until the edge of pipe bevel is firmly abutted against the spacer NUB. Diameter of NUB automatically sets the root opening for the electrode.

The welder has the choice of "STRIKING OFF" the NUBS or leaving them intact. If the NUBS are not chipped off, a higher welding current will insure full penetration and fusion of the spacer NUB.

ROBVON Type "C"

**ROBVON TYPE "C."** The fit-up procedure is the same as outlined above. The non-removable NUB is readily and completely fused during welding by using a slightly higher than normal welding current.

**MACHINED** rings are manufactured to specification in either the solid or split type design.

All ROBVON Rings are available in carbon steel, wrought iron, alloys, stainless steel, aluminum, etc.

Machined Ring

### SPECIFICATIONS

| Nom. Pipe Size | I.D. of Pipe |               | No. of Root Opening Spacers |               | Dia. of Spcr. | Ring Thickness | Ring Width | Width of Land |

## Floats

### Arthur Harris & Co.

210-218 N. Aberdeen Street

Chicago 7, Ill.

Engineers—Metal Float Manufacturers

Floats Fabricated of Aluminum, Brass, Copper, Admiralty, Everdur, Monel, Nickel, Inconel, Stainless Steel, Type 304, Type 316, etc., Steel and other Workable Metals

Floats can be plated with copper, nickel, chrome, zinc, tinned, or lead coated. Special connections can be furnished where required. B-262 ball floats are provided with standard female pipe spuds—unless special connections are ordered. Stainless steel, steel, nickel and monel floats, are suitable for high pressure and high temperature. Where corrosion is a factor, our catalog should be consulted so that floats of suitable material can be furnished. Open tank floats can be loaded with sand, lead or steel to bring them to a desired weight. Aluminum floats are vulnerable to corrosion by many solutions, but also give satisfactory results when properly used.

#### Various Types of Harris Floats

#### Metal Floats

Seamless copper ball floats carried in stock in diameters of 3 in., 4 in., 5 in., 6 in., 7 in., 8 in., 10 in., and 12 in. for open tank. . . . 25 lb, 50 lb, 100 lb, and 150 lb working pressure. Copper floats of special sizes and for special pressures made to order.

Stainless steel ball floats 2½ in. to 12 in. diameter for high pressure and corrosion carried in stock. Special stainless steel floats made to order.—Copper Ball floats of 12 in. and to 18 in. diameter, and stainless steel floats over 12 in. to 14 in. diameter made to order. Consult our Engineering Department when you have float problems. Catalog on request.

Copper plated—brazed joint—steel ball and special floats for high and low pressure. Ask for Special Bulletin on these steel base floats.

## Heating Systems • Baseboard Radiation Boiler Burner Units

### General Automatic Products Corporation

2300 Sinclair Lane Baltimore 13, Md.

Manufacturers of a Complete Line of Gas and Oil Heating Equipment and Summer Air Conditioning FLOORLEVEL BASEBOARD RADIATION

#### "FLOORLEVEL®" Hot Water

#### TWO TYPES FOR EASY INSTALLATION

| Specifications I-B-R Ratings Water Temp. | Capacity (per lin. ft) STANDARD | HI-CAP  |
|------------------------------------------|---------------------------------|---------|
| 200°                                     | 610 Btu                         | 750 Btu |
| 190°                                     | 550 Btu                         | 680 Btu |
| 180°                                     | 490 Btu                         | 600 Btu |

Each package consists of enough material to do the average installation for the amount of square footage required. The packages are sized to fit any installation. Carton No. 1 contains the fin type heating element, assembled with front panel, back panel, etc., in 10-ft lengths, Carton No. 2 contains the front paneling, top moulding and fittings, and Carton No. 3 contains the panel and moulding. Elements are interchangeable, without adjustment to enclosure or other parts.

Note: Rating at water flow rate of 3,000 lb/hr. The above hot water ratings were based on an active length of 8 ft 9 in. with total length of 10 ft.

#### DUAL DE-AIRATOR TANK

A complete unit with feed and relief valve, for positive elimination of air in hot water heating systems; also acts as an expansion tank. Three sizes to 1500 sq ft.

#### SERIES "L" GAS FIRED BOILER BURNER UNITS

Available for natural, manufactured, mixed or LP gas. All units only 30" high, completely assembled. Controls available to meet all local code requirements. SPECIFICATIONS:

| Model       | Btu Input         | Btu Output        | A.G.A. Ratings Sq Ft Output |
|-------------|-------------------|-------------------|-----------------------------|
| L-4 to L-10 | 72,000 to 180,000 | 57,600 to 144,000 | 384 to 960                  |

#### OIL FIRED BOILER BURNER UNITS

"WA" is pre-wired and pre-assembled, complete with Burner, 3 controls and circulator. Available in 2 sizes:

| Model No. | Boiler Ratings Capacity EDR Hot Water Sq Ft |
|-----------|---------------------------------------------|
| WA-85     | 500                                         |
| WA-100    | 650                                         |

Series "T" Steel water-tube Boiler-Burner unit, constructed to ASME Code. Available in following sizes and ratings:

| Model No.    | Boiler Ratings EDR Hot Water Sq Ft | Steam Sq Ft |
|--------------|------------------------------------|-------------|
| T-16 to T-30 | 580 to 1980                        | 326 to 1100 |

Also manufacturers of a complete line of summer and winter air conditioning equipment.

# KRITZER RADIANT COILS, INC.

## KRITZER Radiant Panel Heating

**SEE YOUR  
JOBBER FOR  
KRITZER  
PRODUCTS**

Simple, efficient, and economical method of Radiant Panel Heating. KRITZER coils are positioned between joists slightly back of plaster line. They touch no part of the building, are not imbedded in any building material. Heating Contractor can install complete job without special cooperation from other contractors. Air between joists is heated which in turn heats floor and/or ceiling surfaces. For complete information on installation and advantages, send for *Bulletin 155*.

## Shaw-Perkins Manufacturing Company

manufacturers of convector radiators  
 delivering

201 East Carson St.

## AIR-e-ATED RADIANT HEAT

Pittsburgh 19, Pa.

## Shaw Panel Radiators

### Shaw Panel Radiators

**WIDTH:** 3 in. thin. **6 HEIGHTS:** 11 in., 14 in., 17 in., 20 in., 23 in., 26 in. **51 LENGTHS:** 11 in. to 111 in. incl. in 2 in. increments. **TAPPING:**  $\frac{1}{2}$  in.,  $\frac{3}{4}$  in., or 1 in.—same end or opposite end. **RATING:** 3.9 to 480.7 sq ft EDR. **GRILLE:** front or top air outlet. **INSTALLATION:** wall hung, free standing, open or closed recess. **APPLICATION:** hot water, steam to 150 psi or mixed systems. End panels, air chambers, wall brackets available for any application.

All Shaw Radiators convert the heat furnished by the steam or hot-water into an exact engineered ratio of warm circulating air and mild radiant heat rays which creates an "ideal heat environment" in each room. It is known as **AIR-e-ATED RADIANT HEAT.**

## Shaw Panel Baseboard Radiators

**WIDTH:** 3 in. thin. **HEIGHT:** 8 in. **LENGTHS:** 2 ft 5 in. to 72 ft 7 in. with opposite end tapping; 2 ft 3 in. to 36 ft 7 in. with same end tapping. **TAPPING:** Supply and return on same end or opposite end. **RATING:** 6.0 sq ft EDR per lineal foot. **GRILLE:** Front air outlet. **INSTALLATIONS:** Wall hung and corner radiators; end panels available. **AIR CHAMBERS:** Factory installed for hot water systems. **APPLICATION:** Hot water or steam systems, up to 15 psi.

### Shaw Baseboard Radiators

Shaw Panel Baseboard Radiators are factory assembled one-piece-bonded units, each unit individually packaged complete with fittings to assure simplified, quick installation.

## PERKINS AIRadiators

**WIDTH:** 5 in. thin. **3 HEIGHTS:** 14½ in., 23½ in., 45 in. **LENGTHS:** 15 in. to 125 in. inclusive in 2½ in. increments. **PIPING:** 1 in. tapping, can be bushed to ½ in. or ¾ in. as specified. **RATINGS:** 14 to 474 sq ft EDR. **TAPPINGS:** supply and return on opposite ends—radiator reversible. **AIR CHAMBERS:** factory installed for hot water systems. **INSTALLATION:** wall hung, free standing, ceiling mounted. **APPLICATION:** hot water, low or high pressure steam systems to 150 psi.

Factory assembled, sturdy, heavy duty, industrial heating unit ready to connect to new or existing piping. Used on low or high pressure steam or forced circulation hot water systems. Constructed of 1 in. copper tubing and full-height steel plates.

Perkins AIRadiators

**Represented in principal cities. Send for catalog.**

### CLAY PIPE HEATING, VENTILATING, AND AIR CONDITIONING DUCTS

Information contained here includes the basic data needed by engineers, architects, builders, and heating contractors to evaluate and install low-cost Vitrified Clay Heating Ducts in basementless slab-floor homes and other structures. This new development has become so popular that many requests for authoritative information have followed the publication of articles about the new system in the trade press. There are three major reasons for its popularity:

**ECONOMY**—The complete Clay Pipe installation is economical and efficient. It combines the advantages of radiant heat and controlled warm-air circulation at greatly reduced costs.

**SERVICE**—Clay Pipe actually outlasts the foundation slab. It is chemically inert and cannot be eaten away by lime in the concrete. It does not rust, corrode, or disintegrate from moisture and furnace gases. It will not crush or deform as concrete is poured over it.

**INSTALLATION**—Clay Pipe's handy lengths and easy-to-make joints permit fast installation and lower labor costs. A wide variety of fittings is available to solve construction problems with no on-the-job delay, and Clay Pipe cannot "float" as the concrete is poured.

**PERIMETER LOOP SYSTEM**—The data and instructions contained here apply to the Perimeter Loop System, since it is more highly recommended by heating authorities. Its pattern eliminates the "waterfall" of cold air at the outer walls and effectively combats "radiant cold" at the outside edges of the slab. It combines the advantages of forced warm-air heating with heat by radiation through the concrete slab. Heat is concentrated where people are sitting—not at the ceiling. In test installations, the new heating method has cut operating costs from 20 to 30 per cent

by eliminating high heat-loss at ceilings or attics. Successful research conducted by the *National Warm Air Heating and Air Conditioning Association* has been followed with great interest by the building and heating industries. According to the *Association*, "Warm Air Perimeter Heating is a highly successful method of heating a basementless building. . . . It produces the ultimate of occupancy comfort. It is economical to install; can be designed to use a minimum amount of scarce materials; and requires no unusual skill in its design and installation that the heating contractor cannot supply."

**THIS PERIMETER LOOP DESIGN** is used in structures built upon a concrete slab directly on the ground. Its air distribution system includes a warm air duct that extends completely around the perimeter of the building in a continuous loop. The ducts are buried in the slab 2 to 18 inches from its outside edge, and the tops of the bells will be 1½ inches below the slab surface. Heat is delivered into the rooms by warm air discharged from registers placed in the floor beneath the windows, and by radiant heat from the warm floor surfaces over the embedded ducts. The loop is supplied by feeders extending from a plenum chamber in the slab.

## National Clay Pipe Manufacturers, Inc.

Washington 6, D. C.

Typical Installation of Clay Pipe Heating Ducts

### Heating Ducts

**Advantages**  
It is well known that the greatest heat loss in a well constructed and insulated building—commercial or residential—will be found at the outside walls and glass areas. This loss will usually average 65 per cent of the total structural heat loss. Concrete slab floors will account for approximately 18 per cent of the total heat loss. The rest of the heat will be lost through the ceiling or attic. Perimeter heating introduces the heat along the outside walls and along the glass area. The heat rises and the resulting blanket effect reduces the radiant heat loss from all outer walls and windows. Furthermore, this blanket effect also eliminates air drafts which are caused by the cooling influence of the walls. The heating ducts, embedded in the concrete slab floors, help to maintain the floor surface temperature at desired comfortable levels. It can be seen that perimeter heating accomplishes three important basic functions: first, it replaces the heat that is lost; second, it replaces the heat at the same point where it is lost; and third, it replaces the heat as fast as it is lost.

**Test Results**  
Tests conducted by the *National Warm Air Heating and Air Conditioning Association* at its *University of Illinois Research Center* and in actual installations throughout the country indicate that temperatures in residential structures can be maintained well within the limits established for comfort conditioning. Perimeter heating systems can be designed so that the following temperature coefficients may be maintained:  
(a) Floor surface temperatures can be maintained at 70F plus 2 deg in all usable areas.

- (b) Temperature gradients from floor to sitting level—30 inches above the floor—can be maintained at less than 2 deg.
- (c) Temperature gradients from floor to ceiling level can be maintained at less than 8 deg.
- (d) Temperature variations from outside wall areas to the center of rooms can be maintained at less than 2 deg.
- (e) Temperature variations between rooms can be maintained at less than 3 deg.

### Versatility

Clay pipe heating ducts can also be adapted for ventilation purposes. This is another advantage of the under-slab duct design—the required amount of ventilation air can be circulated through the same distribution ducts used for heating.

### Furnaces

Although a down-flow type of furnace is generally associated with the perimeter warm air heating system when installed in basementless structures, all types of winter air conditioning units can be used. Successful installations have been made using up-flow types of equipment as well as horizontal units. When up-flow furnaces or horizontal suspended units are used, down-comer ducts are used to connect the warm air plenum of the furnace unit with the distribution plenum in the floor. Also, two or more furnaces can be installed—each unit having separate control for its own distribution system so that various sections of the structure can have individual temperature control. However, one unit sized for the entire heat loss can be also installed, using two or more bonnet outlets with automatically controlled dampers in each.

# National Clay Pipe Manufacturers, Inc.

Washington 6, D. C.

### Storage

There are no storage problems, because vitrified clay pipe heating ducts can be exposed to weather in any season.

### Performance in Use

Clay pipe ducts have such advantages as permanence, resistance to shock loads, and resistance to corrosion from lime in the concrete. They create no odor as warm air flows through them during furnace operation. The smooth inner surface eliminates turbulence and minimizes register noise. The clean smooth surface of the Vitrified Clay Duct is free from dust.

### Design Data

Detailed design recommendations have been prepared by the National Warm Air Heating and Air Conditioning Association and are contained in the new revised edition of *Manual 4* (\$1.50) and *Manual 9* (\$.75), which are available from the association's offices, 145 Public Square, Cleveland 14, Ohio. Manual No. 4 describes warm air perimeter heating systems as applied to structures without basements. Manual No. 9 contains detailed information on design and installation of warm air winter air conditioning systems and all necessary engineering data, tables, and recommendations for selection of the proper heating equipment.

### Case Histories

For data on actual case histories of Clay Pipe heating, ventilating, and air conditioning duct installations in homes, schools, churches, hospitals, factories, gasoline stations, garages, stores, and theaters, write the National Clay Pipe Manufacturers, Inc., 1820 "N" St., N.W., Washington 6, D. C.

Large diameter clay pipe heating duct and plenum connection used in commercial structure. This type of duct, when installed in garages and maintenance or repair shops, can be used for heating, ventilating, air conditioning, and removal of exhaust gases. When the registers are located under the windows, the warm air will blanket the glass area and eliminate frosted and wet windows, sills, and walls.

Clay Pipe Heating Ducts ready for the concrete pouring. Wire mesh may be installed at the contractor's discretion to reinforce the floor slab.

## National Clay Pipe Manufacturers, Inc.

Washington 6, D. C.

### Construction Data

The building site must be well-drained. If the natural ground-slope is not sufficient for good drainage, a simple network of Perforated Clay Pipe should be installed underground. The site should then be levelled and graded. All ground beneath the building should be cleared of organic material. A four to six inch layer of coarse fill is then laid—washed gravel, crushed rock, or stone that has been passed over a coarse screen. Cinders or fine sand should never be used for the fill.

Figure 1

The fill must be covered with a moisture barrier before the slab is poured. This membrane should be the equivalent of a good grade of roll roofing at least 55 lb per 108 sq ft. Strips should be overlapped at least four inches and tarred. The barrier must completely cover the area within the foundation walls and extend up the walls to the top of the slab. See Figure 1.

Edge insulation must be placed completely around the concrete slab. Two-inch thick insulation is recommended, but one-inch is acceptable.

It is not necessary to anchor the Clay Pipe ducts to stakes, or to surround them completely with concrete (as with lighter materials). The Clay Pipe is laid directly upon the membrane, and gravel or sand is used to level it. Small depressions should be made in the sand or gravel so the pipe bells "hang free." This facilitates proper pipe alignment and prevents buckling at the joints. See Figure 2.

Registers must be located before the slab is poured. Wooden forms like those shown in Figure 3 are secured to the pipe by a wire wrapped around the duct.

Figure 3

After the slab has hardened, the form can be removed and an opening cut into the pipe with a heavy hammer or bar. Some contractors prefer to retain the wooden register forms in the slab for register mounting frames.

Figure 4

The Clay Pipe bell at the plenum should be butted firmly against the wooden forms of the plenum pit and the concrete poured around it. See Figure 4. The pit floor is poured after the wooden form is removed. The moisture membrane must extend under the pit floor. Recommended distance from the slab floor to the top of the pipe bell is five inches.

Figure 5

## National Clay Pipe Manufacturers, Inc.

Washington 6, D. C.

Figure 6

Clay Pipe in the Perimeter Loop should be installed so that the top of the bell closest to the perimeter will be 1½ inches below the slab surface. Feeder ducts should slope downward toward the plenum, so that the top of the bell next to the plenum will be five inches below the floor slab surface. See Figure 5. All Clay Pipe joints must be waterproof.

Care must be taken when the slab is poured not to puncture the moisture barrier or dislodge the ducts. Wheelbarrows should not be moved over the ducts without suitable planking. A strip of mesh should be placed over the top of the ducts to give added strength to the slab. Mesh may be extended over the entire slab at the contractor's discretion.

For Heating Satisfaction—Think first of AIRTHERM

**AIRTHERM Cabinet Unit Heater**  
Combines 22 industry approved, performance proved features that guarantee maximum efficiency.

**AIRTHERM Gas or Oil Fired Space Heaters**

A complete heating, and heating and ventilating unit. Equipped with motors, burner and all safety and operating controls. Easy to install and operate. Heavy duty stainless steel combustion chamber. Capacities from 400,000 to 2,000,000 Btu per hour. Write for *Catalog 804*.

**AIRTHERM Convectors**

Airtherm Convectors are designed for easy installation and outstanding per-

formance. Copper coil for all hot water and two pipe steam systems. Produced in full range of types and sizes. Write for *Catalog 703*.

Vertical

Horizontal

### AIRTHERM Steam Unit Heaters, Horizontal and Vertical Discharge

Horizontal models are produced in capacities from 18,000 to 270,000 Btu. Vertical models 32,000 to 350,000 Btu per hour. Write for *Catalog 1209 A*.

**AIRTHERM Gas Fired Unit Heaters**  
Efficient answer to heating needs where there is no steam supply. Compact, suspended, propeller fan units available from 25,000 Btu to 200,000 Btu. Write for *Catalog 500*.

**AIRTHERM Centrifugal Fan Unit Heaters**

For all types of heating, and heating and ventilating installations, in industrial and commercial buildings, auditoriums, gymnasiums, schools. Available with dampers, filters and non-freeze coils. Capacities up to 1,440,000 Btu per hour. Write for *Catalog 403*.

## AMERICAN-Standard

Plumbing & Heating Division

American Radiator & Standard Sanitary Corporation,

New York 18, N. Y.

**1. EMPIRE BOILER** For all types of gas. Made in a complete range of sizes for smaller homes and buildings with or without basements. Approved by *American Gas Association*. *I-B-R Ratings*: Steam—165 to 275 sq ft, Water—160 to 1,055 sq ft net installed radiation.

**2. G-4 BOILER** For all types of gas. For larger homes and small commercial establishments. Approved by *American Gas Association*. *I-B-R Ratings*: Steam—395 to 1390 sq ft, Water—725 to 2400 sq ft installed radiation.

**3. G-6 BOILER** For all types of gas. Designed for medium to very large buildings. Approved by *American Gas Association*. *I-B-R Ratings*: Steam—1520 to 13450 sq ft, Water—2615 to 21520 sq ft installed radiation.

**4. ARCOLINER PACKAGED OIL-FIRED HEATING UNIT.** Compact unit for small to medium sized homes. Wet base construction ideal for homes with or without basements. *I-B-R Ratings*: Steam—260 to 520 sq ft, Water—485 to 940 sq ft installed radiation.

**5. OAKMONT BOILER** Exclusively for oil firing. Also available as complete oil heating unit with Arcoflame Burner. *I-B-R Ratings*: Steam—390 to 810 sq ft, Water—715 to 1440 sq ft installed radiation.

**6. EXBROOK BOILER** For oil or stoker. Sized for larger homes and buildings. Available with Arcoflame Burner as oil heating unit. *I-B-R Ratings*: Steam—775 to 1830 sq ft, Water—1380 to 3100 sq ft installed radiation.

**7. SEVERN BOILER** For all fuels. Efficient boiler with advanced features for convenience and economy. Available with Arcoflame Burner as oil heating unit. *Ratings*: Steam—400 to 780 sq ft, Water—730 to 1390 sq ft installed radiation.

**8. REDFLASH BOILER** For all fuels. Economical heat for any size or type of building. Attractive jacket, fully insulated. *Ratings*: Steam—770 to 9900 sq ft, Water—1230 to 15,840 sq ft installed radiation.

**9. WATER TUBE BOILERS** For oil or stoker. For medium to large buildings. *Ratings*: Steam—930 to 4600 sq ft, Water 1640 to 7360 sq ft installed radiation.

1. **RADIANTRIM PANELS** Replace ordinary baseboards. Cast iron panels provide all the advantages of both convected and radiant heat. For forced hot water or two pipe steam. Sheet metal accessories also available for complete installation.

2. **HEATRIM PANELS** Non-ferrous panels provide convected heat with forced circulation hot water systems only. Adaptable to mainless or series loop installations. Available in 4, 6 and 8-ft lengths. Two models: Model 75-A Standard, Model 75-B High Capacity.

3. **ARCO RADIATORS**—Highly efficient, slim tube radiators. Available in four widths—3, 4, 5 and 6 tubes—and four heights—19, 22, 25 and 32 in.

4. **CONVECTORS** With cast iron (Arco) or non-ferrous (Multifin) heating elements. Styles and sizes for every need. Special designs for hospitals, institutions, etc. Multifin Type K (shown) available in 63 packaged stock sizes.

5. **SUNRAD RADIATORS** Recessed or free-standing. Need no enclosure. Two sizes: 5 in. deep x 20 in. high and 7½ in. x 23 in. Inlet grilles if desired.

6. **AMERICAN STANDARD WATER HEATER**—Approved by A.G.A. Heats water automatically, stores it for instant use. White enameled jacket, gray trim. Thrifty and dependable. Three sizes—20, 30 and 40 gal.

7. **NEW STANFLAME CONVERSION BURNER** Gas fired. Vertical, upshot-type burner for boiler, furnace, or winter air conditioner. Fits round or square combustion chamber. Runner pilot igniter. Burns all gases. A.G.A. inputs of 60,000 to 325,000 Btu per hour.

8. **ARCOFLAME OIL BURNER**—Listed by Underwriters' Laboratories, Inc. Complies with Commercial Standard CS-75. Special flange types for oil heating units. Pedestal types for conversion. Capacities from 0.70 to 7 gal per hour.

9. **TEMTRIM**—Finned tube radiation for schools, hospitals, factories, offices, churches, theaters and similar buildings. For forced hot water and two-pipe steam installations. Available in two sizes: 1½ in. tube with 3¼ in. x 3¼ in. fins or 4¼ in. x 4¼ in. fins, and 2 in. tube with 4¼ in. x 4¼ in. fins; 3¼ in. size fins are spaced 24 and 34 fins per lineal foot; 4¼ in. fins are spaced 28 and 36 fins per foot. Three attractive covers in three tier heights—expanded metal grille, flat top cover, and sloping top enclosure. Heating element fabricated in lengths of 2 to 12 ft in 1-ft increments. Covers and enclosures are available in lengths of 1- to 6-ft in 1-ft increments. I-B-R approved.

**DETROIT HEATING CONTROLS AND ACCESSORIES**—A complete line of heating controls and accessories for all types of systems.

1. **VERTICAL REMOTAIRE ROOM CONDITIONER**—A remote type unit providing year-round air conditioning for central-plant, multi-room installations such as office buildings, apartments, hotels, schools, hospitals, motels and residences. Features individual room control. Available in 200, 300, 400, and 600 cfm sizes for free standing, partially recessed and fully recessed applications. Uses hot water for heating, chilled water for cooling, both supplied by remotely located water chiller and boiler and using the same piping system. Units are listed by Underwriters' Laboratories, Inc.

2. **HORIZONTAL REMOTAIRE ROOM CONDITIONER**—Similar in operation to Vertical Remotaire. Installed overhead either exposed or concealed in a closet, drop ceiling or furred space. Available in four sizes—200, 300, 400 and 600 cfm—and three models to meet every architectural requirement.

3. **PACKAGED WATER CHILLER—MODEL ACS**—Central chilled water source for medium and large air conditioning systems. Complete, packaged units; sizes 7.5, 10, 15, 20, 25, 30, 40, 50, 60 and 75 hp. Assembly consists of refrigerant compressor, compressor motor, evaporator, condenser, heat exchangers, controls, piping and framework. Units tested and given a holding charge of refrigerant prior to shipment.

4. **PACKAGED WATER CHILLER—WATER COOLED—MODEL PAS**—Central chilled water source for residential and small commercial air conditioning systems. Hermetically sealed. Available in 2 and 3 hp sizes. Assembly consists of steel framework enclosing a motor-compressor assembly, condenser and evaporator with connecting tubing, complete with operating charge of Freon-22 and all auxiliary components.

5. **PACKAGED WATER CHILLER—AIR COOLED—MODEL PAS-AC**—Completely factory-assembled 2 and 3 hp water chillers with air-cooled condenser. For residential and small commercial systems in areas where water is scarce. Has a permanently lubricated and hermetically sealed motor-compressor unit containing a 5-year warranty.

BOILERS and RADIATORS

Irvington-on-Hudson, N. Y.

There's a Burnham for Every Purpose—Write for Descriptive Catalogs

**Burnham BASE-RAY®**  
Radiant Baseboard  
— Two Sizes, No. 7  
and No. 9 (Cast Iron)

*I-B-R* Rating per lineal foot for No. 7 is 2.35 and for No. 9 it is 3.45 per sq ft. Tappings  $\frac{3}{4}$  in. top and bottom. Sections come in 12, 18, and 24 in. lengths. New matching sheet metal baseboard extensions and accessories available.

**PACEMAKER®** Boiler for oil firing. *I-B-R* Ratings 270 to 710 sq ft for Steam and 490 to 1270 for Water. A cast-iron vertical flue boiler. Can be equipped with tankless or storage type domestic hot water coils.

**New HOLIDAY** Cast-Iron Gas Boiler A.G.A. approved for manufactured, natural, mixed or LP Gases and *I-B-R* approved and rated for water from 300 to 1100 sq ft; for steam 160 to 610 sq ft supplied with or without domestic hot water.

**PACE-PAK®** Boilers—*I-B-R* Net 565 sq ft and 810 sq ft for Water. Design same as PACEMAKER. Delivered in one crate ready for installation with all controls and wiring factory installed for assured performance.

Radiant

**YELLOW-JACKET** Boiler (shown with extended Jacket). All fuel, convertible. *I-B-R* Ratings 305 to 935 sq ft for Steam and 490 to 1600 sq ft for Water.

Slenderized

**BURNHAM RADIANT RADIATORS**—Two heights 20 and 23 in. Ratings 2.25 sq ft per section and 3.40 sq ft per section respectively.

**BURNHAM SLENDERIZED RADIATORS**—Three to six tubes in four heights 19 in. to 32 in. Ratings are from 1.6 sq ft per section to 3.7 sq ft per section.

BOILERS and RADIATORS

Irvington-on-Hudson, N. Y.

There's a Burnham for Every Purpose—Write for Descriptive Catalogs

## PACE-KING® BOILER

A new Burnham Series, exclusively oil fired, for apartment houses, schools, hospitals, commercial installations, etc. Its vertical flue design is engineered similar to PACEMAKER and PACE-PAK... low internal draft loss... lower stack temperatures... lower chimney design... no baffles used. Provided with tankless hot water heaters with capacities from 6 to 10 gpm. Available in 14 models with *I-B-R* ratings from 1100 to 4500 for Steam and 1925 to 7200 for Water. Built for safety and dependability according to the ASME Construction Code and the *I-B-R* Rating and Testing Code.

**PACE-KING SECTIONS** are designed with hundreds of efficient fins for fast heat exchange and fuel economy. Can easily be passed through existing doorways. Sections are reversible... this feature also allows wider choice of location since outlet connections and clean out panels can be placed on either side. Boiler can be fired from front or rear. Long water legs provide plenty of room for combustion.

No. 1, 2, 3 and 36 in. Series and 50 in. Twin Series—Famous Burnham 3-times-back-and-forth fire travel; for all fuels. 230 to 14,600 sq ft for Steam; 370 to 23,360 sq ft for Water.

**Welded Steel Boiler**—Compact type—Capacities from 2500 to 35,000 sq ft for Steam and 4800 to 56,000 sq ft for Water. Furnished for coal, oil or stoker firing. SBI Rated.

Line Steel Boiler

**CRANE SUNNYDAY 15**—All-new packaged cast iron boiler saves up to 15 percent on fuel. Nine firetube flues give greater heating surface in 20 per cent less space. Water, oil-fired, net  $I=B=R$  rating from 67,000 to 156,000 Btu.

**CRANE SUNNYDAY 16 "SENIOR"**—A packaged cast iron boiler for steam or hot water, designed for maximum efficiency with oil. Patented Sustained Heat Principle assures fuel economy. Water, net  $I=B=R$  rating from 126,000 to 239,000 Btu.

**CRANE SUNNYDAY 20 "ALL PURPOSE"**—Cast iron, completely packaged, all-fuel boiler for home or small commercial systems. Design improvements increase boiler efficiency. Water, oil fired, net  $I=B=R$  rating from 101,000 to 245,000 Btu.

**CRANE-LINE STEEL BOILER**—A complete line of new, assembled and wired, low-cost boilers. Accessory equipment and rectangular steel jacket available. Oil or gas. Four sizes. Oil fired, net  $SB$  rating 66,000 to 168,000 Btu per hour.

Crane 30 Boiler

Fired Boiler

**CRANE 30**—Ideal medium-size cast iron boiler for larger homes, small commercial buildings. Easy-to-handle sections speed assembly. Water, oil fired, net  $I=B=R$  rating 201,000 to 736,000 Btu.

**CRANE 41**—New all-fuel boiler for institutions and other large buildings. Precision ground cast iron sections easy to assemble. Water, oil fired, net  $I=B=R$  rating 622,000 to 1,440,000 Btu.

**CRANE 2WG**—A completely assembled cast iron gas boiler only 33 inches high. Patented "staggered heat travel" fins set up unusual scrubbing action. Water, A.G.A. input 70,000 to 210,000 Btu per hr.

**CRANE 60**—Big new 6-inch gas boiler. Patented "staggered heat" travel surfaces capture all liberated heat. Steam, hot water, or large volume indirect water heating. Net A.G.A. ratings from 625,000 to 5,000,000 Btu input.

**VALVES—FITTINGS**—The complete Crane line of valves and fittings offers all necessary piping items for any heating system.

## Crane Co.

Type P (fabricated)

Type RC (cast iron)

Type R (cast iron)

Compac  
Radiators

**CRANE RADIANT BASEBOARD** introduces an even distribution of radiant warmth at floor level, leaving entire floor area free from obstruction. If baseboard area is limited, Type R panels may be installed vertically or at ceiling level. Type RC provides radiant and convected heat. Type R provides radiant heat only.

**CRANE COMPAC RADIATORS**—Slender lines give pleasing modern appearance, require minimum space without sacrificing heat output. For free-standing or recessed installation, steam or hot water. Sizes up to 111 sq ft output  $I=B=R$  rated.

**WATER SPECIALTIES**—available to suit every installation—including water heaters, circulators and flow control valves.

**CRANE OIL BURNERS** are newly engineered to provide automatic heating comfort at low fuel cost with a minimum of maintenance.

**GAS BURNERS** feature "Spreader Flame" principle of construction and operation that eliminates losses due to incomplete combustion or excess air.

## NATIONAL-U. S. ALL-FUELS BOILERS (CAST IRON)

Designed especially to meet the special requirements of automatic firing... rugged cast iron construction. Provided with many features to insure high operating efficiency and maximum fuel economy. Convertible to any fuel or method of firing. Wide range of both storage and tankless water heaters available.

"27" Series... for medium to large size residential installations available in six sizes: Net Steam Ratings from 350 to 880 sq ft, and Net Water Ratings from 560 to 1560 sq ft.

"37" Series... for large residential and small commercial installations... available in nine sizes: Net Steam Ratings from 700 to 2300 sq ft, and Net Water Ratings from 1120 to 3835 sq ft.

"47" Series... for commercial, industrial and institutional installations... available in eight sizes: Net Steam Ratings from 2500 to 6000 sq ft, and Net Water Ratings from 4000 to 9600 sq ft.

## NATIONAL-U. S. OIL HEATING BOILERS AND UNITS (CAST IRON)

Developed specifically for oil firing... the Oil Heating Units comprise a cast iron boiler, dependable oil burner, pre-cast combustion chamber and high quality controls. Oil Heating Boilers are designed for top performance with any oil burner. A wide range of both storage and tankless water heaters is available with all Units and Boilers.

"10" Series... an economical wet base Boiler and Unit for installation in small and medium size residences... available in five sizes: Net Steam Ratings from 230 to 500 sq ft, and Net Water Ratings from 430 to 910 sq ft.

"12W" Series... priced low and styled right for installation in the small to medium size home... wet base design... available in four sizes: Net Water Ratings from 430 to 855 sq ft.

"12" Series... a popular wet base Boiler and Unit for the small to medium size home. Available in four sizes: Net Steam Ratings from 230 to 470 sq ft, and Net Water Ratings from 430 to 855 sq ft.

"25" Series... a high capacity Oil Heating Boiler... wet base construction for residential, commercial and industrial installations... available in five sizes: Net Steam Ratings from 545 to 1985 sq ft, and Net Water Ratings from 985 to 3355 sq ft.

"37" Series... for large residential and small commercial installations... available in nine sizes: Net Steam Ratings from 700 to 2300 sq ft, and Net Water Ratings from 1255 to 3835 sq ft.

"46" Series... Boiler and Unit of special design for medium to large size residential installations... available in four sizes: Net Steam Ratings from 310 to 700 sq ft, and Net Water Ratings from 570 to 1255 sq ft.

## NATIONAL-U. S. GAS BOILERS

National-U. S. Gas Boilers are modernly styled, compact and designed exclusively for gas firing. Cast iron sections for long life, effective gas travel, dependable controls and many other feature-advantages contribute to efficient and economical operation... A.G.A. approved for all gases.

"11B" Series... a factory-assembled packaged boiler, economically priced... for small to medium size homes... available in seven sizes: Net Water Ratings from 185 to 725 sq ft.

"16B" Series... dependable, efficient gas heating for residential and small commercial installations... can be equipped with water heater... available in twelve sizes: Net Steam Ratings from 295 to 2090 sq ft, and Net Water Ratings from 545 to 3510 sq ft.

"22", "33" and "44" Series... tapering zig-zag flue passages extract maximum heat-save fuel... to meet heating requirements of small residences up to commercial and industrial structures... available in twenty-one sizes: Net Steam Ratings from 110 to 1920 sq ft, and Net Water Ratings from 205 to 3245 sq ft.

"66" Series... National-U. S. gas heating comfort for larger apartments, stores, hotels, hospitals, schools and other large installations... available in eighteen sizes: Net Steam Ratings from 1770 to 12950 sq ft, and Net Water Ratings from 3005 to 20720 sq ft.

### NATIONAL-U. S. STEEL BOILERS

National-U. S. Steel Boilers meet all the requirements of the SBI Testing and Rating Code and the ASME Boiler Construction Code. All are inspected and approved at the factory by a representative of a boiler insurance company.

17 and 24 in. Series . . . available as a Boiler or as a complete Oil Heating Unit—suited for small and medium size residential installations . . . available in four sizes: Net Steam Ratings from 320 to 700 sq ft, and Net Water Ratings from 580 to 1260 sq ft.

26, 29 and 39 in. Series . . . can be furnished as a Boiler or as a complete Oil Heating Unit for installation in medium residential to small commercial buildings . . . available in nine sizes: Net Steam Ratings from 700 to 3000 sq ft, and Net Water Ratings from 1260 to 5400 sq ft.

41 in. Series . . . a modern automatic heating boiler . . . for firing with oil burner, gas burner or stoker in commercial, institutional and commercial installations . . . available in four sizes: Net Steam Ratings from 3500 to 5000 sq ft, and Net Water Ratings from 6300 to 9000 sq ft.

Commercial Series . . . adaptable to either automatic or hand firing for the very largest installations . . . available in sixteen sizes: Net Steam Ratings from 2500 to 35000 sq ft, and Net Water Ratings from 4000 to 56000 sq ft.

### NATIONAL-U. S. PACKETS

Compact, all-in-one, factory-assembled automatic oil or gas fired home heating Units for small installations. An integral tankless or storage heater provides domestic hot water. Furnished with either flush or enclosing jacket. Net Water Ratings: for gas—460 to 520 sq ft, for oil—495 to 580 sq ft.

The Packet, combined with National-U. S. Baseboard, provides a modern, low-cost, easy-to-install forced hot water heating system for homes, motels, diners and stores.

### NATIONAL-U. S. CONVERTORS

Art Convertor . . . a non-ferrous convertor for flush and semi or full-recessed installations. Aluminum fins bonded to copper tubing comprise the heating element. Enclosures are made in a variety of types for residential or commercial installations.

Aero Convertor . . . heating element is made of cast iron with fins cast integral with tubes. Adaptable to any type of hot water or steam heating system. Numerous types of enclosures can be furnished for residential or commercial installations.

17 and 24 in. Series

41 in. Series

Model U Packet (with Flush Jacket)

Aero Convertor

26, 29 and 39 in. Series

Commercial Series

Model K Packet (with Enclosing Jacket)

### NATIONAL-U. S. BASEBOARD HEAT DISTRIBUTING UNITS

Art Baseboard (Non-ferrous)

Sunray Radiator

Unit Heater

Conversion Oil Burner

Radiant Baseboard (Cast Iron)

Thin Tube Radiator

Pintube Radiation

Conversion Gas Burner

Three types of baseboard can be furnished: Art (non-ferrous), Radiant (cast iron), and steel . . . all combine the best features of radiant and convected heating—radiant heat at floor level and convected heat to banish drafts. For new or old buildings—residential or commercial. Ideal for remodeling old homes, and for basementless homes.

### NATIONAL-U. S. RADIATORS

Sunray Radiators . . . modern cast iron radiation for recessed or free-standing installations . . . available in 19, 20, 21 and 22½ in. heights . . . piping can be completely concealed by grilles.

Thin Tube Radiators. Compact, slender tube cast iron construction. Blend inconspicuously with most decorative schemes. Efficient and quick heating.

National-U. S. Unit Heaters for hot water and steam, also for gas firing—both types in a wide range of sizes.

National-U. S. Fintube Radiation . . . ideal where heating requirements are heavy and space limited. Available in two types: steel tubing with steel fins and copper tubing with aluminum fins. Sloping top, flat top and expanded metal grille covers can be furnished.

National-U. S. Oil Burners and Gas Burners are available in a number of sizes for conversion of either boilers or warm air furnaces to automatic firing.

### CAPITOLAIRE AIR CONDITIONING AND WARM AIR FURNACES

1. Hi-Boy Series available for all fuels.

Output: from 65,000 to 100,000 Btu/hr.

2. Lo-Boy Series available for all fuels.

Output: from 68,000 to 160,000 Btu/hr.

3. Horizontal Series available for gas and oil firing. Output: from 48,000 to 180,000 Btu/hr.

4. Hi-Cap Series available for all fuels.

Output: from 330,000 to 1,000,000 Btu/hr.

5. Suspended Air Conditioner, Model HRZ recessed with deluxe cabinet. Can be furnished with cabinet for duct mounting. Range from 300 cfm to 1750 cfm.

Floor Model, Fan Coil Unit, freestanding and concealed, Model VER, ¾, 1, and 1½ ton.

Packaged Chillers, water and air cooled condensers, 2 and 3 ton units (not shown).

6. Self-contained Hi-Boy, model COM . . . range from 2 to 15 ton.

7. Residential Packaged Air Conditioner, air cooled (remote) and water cooled condenser. Range from 2 to 6 ton. Self-contained Hi-Boy, model US-AEC with built-in evaporative condenser . . . range from 3 to 60 ton. (Not shown).

Sales Offices in Principal Cities

Pacific Standard Firebox Boilers

Pacific Scotch Marine Boilers

Pacific Front Smoke Outlet Boilers

Pacific Split-Firebox Boilers

#### SBI TABLE 1 BOILERS

A Complete Line of Low-Pressure  
Steel Heating Boilers For  
Commercial Application

All Pacific Commercial Boilers are built  
using the ASME Boiler Code Stand-  
ards as minimums, and rated in ac-  
cordance with Steel Boiler Institute code.

#### PACIFIC STANDARD FIREBOX BOILERS

Pacific Standard Firebox Boilers for  
mechanical firing, stoker, oil or gas are  
built in capacities of 2680 to 56830 sq ft  
for steam and in corresponding capacities  
for water. Design is of two types: Low  
Water Line and High Firebox.

Pacific Direct Draft and Smokeless  
Boilers for coal firing are built in cap-  
acities of 2200 to 35000 sq ft for steam and  
in corresponding capacities for water.

#### PACIFIC SCOTCH MARINE BOILERS

Pacific Scotch Marine Boilers for oil or  
gas firing. Capacities of 5470 to 42500  
sq ft SBI rating steam and in cor-  
responding capacities for water. Fully  
Wet Back.

#### PACIFIC FRONT SMOKE OUTLET BOILERS

Pacific Front Smoke Outlet Boilers for  
hand, stoker, oil or gas firing are built  
in capacities of 4000 to 42500 sq ft for  
steam and in corresponding capacities  
for water.

#### PACIFIC SPLIT-FIREBOX BOILERS

Low Water Line and High Firebox of  
Pacific Boilers are built in three sections  
—shell, firebox and base—and require  
minimum building opening. Where neces-  
sary, Pacific fireboxes can be split (as  
illustrated) to allow the boiler to be  
taken into the building in four sections,  
through any ordinary door or window.  
No cutting, no welding is required in  
assembling any Pacific Boiler.

Descriptive bulletins on  
Pacific Commercial  
Boilers will be mailed on request

#### SBI TABLE 2 BOILERS

A Complete Line of Residential Steel  
Boilers for Coal, Stoker, Oil or  
Gas Firing

All Pacific Residential Boilers are built  
using the ASME Code Standards as  
minimums, and are rated in accordance  
with Steel Boiler Institute code.

#### PACIFIC "PLATE FLUE" BOILERS

Pacific "Plate Flue" Boilers are designed  
for oil or gas firing and are built in 4  
sizes. Capacities range from 9600 to  
216,000 Btu/Hr steam and from 108,000  
to 243,000 Btu/Hr water. They are avail-  
able with either flush or extended  
jackets:

#### PACIFIC "O" SERIES BOILERS

Pacific "O" Series Boilers for residential  
application are designed for steam or  
water and for either automatic oil or  
gas firing. They are built in 7 sizes with  
capacities from 264,000 to 720,000 Btu/  
hr steam and from 297,000 to 810,000  
Btu/hr water. Available with flush  
jacket.

#### PACIFIC SERIES 700 BOILERS

Pacific Series 700 Boilers are designed  
for steam or water and for either stoker  
or hand firing. Capacities range from  
194,000 to 595,000 Btu/hr steam and  
from 219,000 to 670,000 Btu/hr water  
for hand fired models. Stoker fired  
models have capacities from 264,000 to  
720,000 Btu/hr steam and from 297,000  
to 810,000 Btu/hr water. All series 700  
Boilers available with flush jacket.

#### PACIFIC SERIES 33 BOILERS

Pacific Series 33 Boilers are designed for  
oil, gas, and stoker firing. Capacities  
range from 840,000 to 1,200,000 Btu/hr  
steam and from 945,000 to 1,350,000 Btu/  
hr water. Available with flush jacket.

### PROX BOILERS

For Large Installations in Schools, Theatres, Apartments, Churches, Hospitals, Hotels, Etc. Write for complete catalog.

The 40 Series—50-inch Water Line.

The fire travel is in three successive layers—full length of the boiler three times. Rotating action of hot gases in evenly shaped flues greatly increases effective heat absorbing capacity of the large heating surfaces.

Independent connections to each individual section. Each section is a separate boiler with outside, accessible connections. No shut-downs. Guarantees service since any section can be plugged off and firing continued.

### The 40 Series DUPLEX ECONOMIC BOILERS FOR STOKER, OIL, OR GAS

Swinging connections! No vibration! No pulsation!

Plenty of room for stoker, oil burner, or gas conversion burner!

No iron to iron joints! Expansion and contraction troubles eliminated!

22 in. Cast Iron Base

## The H. B. Smith Company, Inc.

Westfield, Mass.

Branch Offices and Sales Representatives in Principal Cities

A complete line of modern cast iron sectional boilers for residential, commercial and industrial heating and for domestic hot water supply.

SMITH "CENTURY" GAS BOILER, A.G.A. approved, for steam or hot water heating. Input ratings from 138,000 to 745,500 Btu. Combines latest features of gas boiler design. Available with five sizes of built-in tank domestic hot water heaters, capacities to 168 gal, and eight sizes of tankless heaters, capacities to 8 gpm. Entire burner assembly mounted on wrought iron frame with casters for easy removal.

"100" and "2000" OIL BOILER-BURNER steam or water units for homes and small commercial installations. Furnished with line of tankless heaters with capacities up to 8 gal of hot water per minute. Net radiation to 1275 sq ft, steam; 2210 sq ft, water.

SMITH-MILLS BOILERS, Series 15-20-25; capacities 200 to 2275 sq ft steam radiation. This complete line of modern push nipple boilers is available in models for gas, oil, stoker or hand firing. Have provisions for built-in domestic hot water heaters and controls.

MILLS WATER TUBE BOILERS, Series 24-34-44; capacities 900 to 13,380 sq ft steam radiation. Independent header type construction. Tens of thousands are installed in schools, hospitals, apartment houses, stores and other commercial and public buildings. Models for hand and all types of automatic firing.

SMITH HY-TEST BOILERS for hot water supply are furnished in several models, and many sizes for tank capacities to 20,000 gal. Constructed of the finest quality grey iron castings, these Hy-Test units are carefully tested at extremely high pressures before shipment.

42 and 60 SMITH BOILERS, may be used in batteries for heating loads up to and over 100,000 sq ft steam radiation. Many of these large units installed in industrial plants furnish steam for processing requirements as well as for heating and domestic hot water.

STERLING FIN-TYPE RADIATORS for low-cost heat in public and commercial buildings, and baseboard convectors for homes, are distributed nationally by The H. B. SMITH COMPANY, Westfield, Mass.

Complete catalog information describing Smith boilers is filed in current issues of Sweet's "Architectural" and Domestic Engineering Catalog Directory.

## STEEL AND CAST IRON HEATING BOILERS

FOR EVERY BUILDING . . . FOR EVERY FUEL

"LW," "A," "C," and "R" Series fully approved by Steel Boiler Institute

All products manufactured in strict accordance with the ASME code and carry the code seal. Every Spencer meets rated specifications, is easy to install, and assures economical operation.

"A" Series

3,500 TO 42,500 SQUARE FEET, STEAM  
Steel Commercial Heating Boilers.—Exclusive peaked firebox design aids in making the "A" Boiler quick steaming and efficient. Space for either storage tank or instantaneous type service water coils. Larger sizes can be cut in half to move through narrow openings.

### 1,300 to 5,000 NET SBI STEAM

Steel Commercial and Residential Heating Boilers—For oil burner, stoker, or hand firing. With heavy-duty doors and frame precision-ground for airtight fit. Adaptable to front, rear, or side installation of oil burner or stoker. Available with domestic hot water coils and attractive insulated jacket.

"C" Series

1538

"LW" Series

"R" Series

"LW" SERIES—3,500 to 42,500 SQUARE FEET, STEAM. New Divided Low-Waterline Commercial Boiler  
Flattened out to beat low headroom and excavation problems. Divided for easier entrance through narrow basement openings, yet 2 watertight sections require no welding.

Easier to install because of specially designed smokebox. Low stack designs possible because boilers designed to be installed with induced draft fans.

Both instantaneous or tank type service waterheating coils. Quickly convertible from mechanical to hand-firing.

"R" SERIES—320 to 1,100 SQUARE FEET, STEAM, NET LOAD  
Steel Residential Heating Boilers—Excellent for small homes requiring economical heat and instantaneous hot water. Available with attractive beauty jacket.

Suburban

### SUBURBAN

87,000 BTU NET SBI WATER RATING .  
Oil Fired Boiler Burner

Kitchen appliance beauty fits in anywhere. Quickly installed in minimum floor space, no special base required. Extra-high combustion chamber assures quiet, trouble-free operation. Easily cleaned and serviced.

### RANCHER

1G SERIES: 40,000 TO 128,000 BTU

2G SERIES: 80,000 TO 232,000 BTU

Gas-Fired Boiler Burner

Extremely compact and efficient. A.G.A.-approved for manufactured, mixed or natural gases. Ease of installation, cleaning and service saves time and money. Gleaming white kitchen appliance beauty.

Rancher

1539

## WEIL-McLAIN COMPANY

General Sales Office: Michigan City, Indiana  
Distributors in all principal cities

### WEIL-McLAIN CAST IRON OIL-FIRED BOILERS

HR Series Heavy Duty boilers for horizontal rotary burners. Special steel front plate and section simplify rotary burner installation. Large fire box volume develops better combustion conditions—high base eliminates high brick foundation. These boilers are also available as all-fuel units.

Load range: steam 2,700-12,270 sq ft; water 4,450-19,630 sq ft.

### BOILER FOR OIL AND OIL HEATING UNITS

Designed specifically for efficient oil burning. Long flue travel extracts maximum heat. I-B-R. rated, ASME constructed. Available in residential sizes as complete package units for forced hot water systems.

Load range: Steam 285-3,400 sq ft; water 525-5,505 sq ft.

### WEIL-McLAIN CAST IRON GAS-FIRED BOILERS

A complete line of jacketed gas-fired boilers for residential, commercial and industrial applications. Cast iron construction for long life. Special design features assure efficient fuel combustion—longer fire travel through finned flues permits maximum heat absorption. A.G.A. approved for natural, mixed, manufactured or liquefied petroleum gases—ASME constructed.

Load range: steam 260-12,950 sq ft; water 300-20,720 sq ft.

Snug Baseboard Panel

### Weil-McLain Snug Cast Iron Baseboards and Radiation

Snug Cast Iron Baseboard Panels provide a balanced combination of radiant convected heat which assures uniform temperature from floor to ceiling. Available in two heights—7½ in. x 2½ in. and 9¾ in. x 2½ in. Complete line of metal finishing accessories.

Solray Cabinet Radiators have attractive, easily cleaned cabinet top. Large waterways store heat for release when burner shuts off.

Raydiant Recessed Radiators are designed exclusively for recessing virtually flush in the wall—completely unobtrusive.

Junior Radiators offer modern slender-tube design—can be installed in open recess if desired.

"HR" Series Heavy  
Duty Boiler

Series "OB"  
Oil-fired Boiler

Type J Gas Boiler

## Aldrich Company

121 E. Williams St., Wyoming, Illinois

Series "B"  
Boiler-Burner

### Boiler-Burner Units, Domestic and Commercial Oil Burners

Aldrich Boiler-Burners are available in sizes for hot water heating, steam heating and hot water supply. Heavy duty double spiral hot water coils factory installed and tested in SC and WC models. Matched Aldrich Oil Burner with each unit, or choice of gas fired models.

Welded steel fire box lined with refractory of high deterioration resistance. Extra thick wool insulation minimizes heat loss. Easy access to fire box.

**ALDRICH GULF STREAM BOILER-BURNER PACKAGE**—Five sizes of compact, economical units designed for the small home, fully erected, wired, equipped. From 495 to 1260 sq ft of water radiation. Quick heating load pick-up means fuel saving. Efficient and economical in operation. Tankless hot water coil optional.

Water-tube Boilers for Stationary Power Plants, and Marine Services... Superheaters... Economizers... Air Heaters... Pulverized-Coal Equipment... Chain Grate Stokers... Oil, Gas, and Multifuel Burners... Seamless and Welded Tubing and Pipe... Refractories... Process Equipment.

**B&W INTEGRAL-FURNACE BOILER, TYPE FM**

Shop-Assembled Steam Generator

B&W Type FM Boiler combines the benefits of package steam with cost-saving big-boiler advantages. This compact self-contained unit has been widely applied to heating services in hospitals, schools, colleges, and other buildings. It has also gained wide acceptance throughout a broad range of industries—supplying steam for combination services.

The Type FM Boiler is particularly suitable for small- and medium-sized plants where excessive fuel consumption and costly maintenance are often serious problems. And, even for some larger steam requirements, multiple-unit Type FM installations have proved more flexible in operation and more economical than one or more large boilers requiring costly field erection and close operating

supervision. A large part of the total FM capacity now in service or on order consists of multiple-unit installations.

The Type FM Boiler is fast steaming and features automatic operation with special safety provisions. It quickly responds to load changes and operates at high efficiency over the load range. This versatile unit burns gas and/or oil, separately or in combination, with quick and easy changeover accomplished at the control panel.

The Type FM Boiler is available in standard sizes for steam requirements to 40,000 lb per hr and for operating pressures to 235 psi. Many have been installed for higher pressures and with a moderate degree of superheat. *Details are given in Bulletin G-76—copies sent on request.*

## Bryan Steam Corporation

Chili Pike, Peru, Indiana

Hot Water and Steam Boilers designed exclusively for oil or gas firing. Products include domestic hot water or vapor steam boilers, commercial low pressure heating boilers for hot water or steam, and high pressure boilers up to 50 hp

Bryan Copper Tube Boilers are engineered expressly for oil or gas firing, where the flame is either on at full intensity or entirely off. Such combustion characteristics call for a boiler that is able to capture heat units with utmost rapidity—and able to withstand sudden expansion and contraction. Average stack temperature of the Bryan is 412 degrees.

### BRYAN COPPER TUBES

The Bryan starts with copper tubes. Copper has a coefficient of heat transfer approximately 6 times that of iron or steel. Heat applied to a Bryan tube is therefore transferred to the water inside 6 times as fast.

The design of the Bryan tube is such that water circulates rapidly through all parts of the boiler. There is a veritable

nest of tubes directly over the flame where heat is most intense. These tubes break up the path of heat travel, reducing "surface film" to a minimum. Of the many advantages of Bryan Boilers, none is more important than the use of Copper Tubes for the heating surface. All gas fired heating boilers A.G.A. approved.

Domestic Boilers

Commercial Heating Boilers

High Pressure Boilers

### DOMESTIC BOILERS

The Bryan Domestic Boiler is available in 7 sizes for hot water radiation. 70,000 Btu's to 560,000 Btu's.

For steam radiation 5 sizes are available, 390 to 1560 sq ft of radiation.

All models come complete with built-in combustion chamber and flange mounted oil burners. In gas fired models the burner is built in.

### COMMERCIAL HEATING BOILERS

Any of the domestic Bryans may be used for small offices or buildings; but they are supplemented with three additional larger capacity boilers. These boilers are rated 2600 to 5000 sq ft of steam radiation or 4150 to 8000 sq ft of hot water radiation. They are used also for supplying hot water or low pressure steam in industrial applications.

### HIGH PRESSURE BOILERS

Bryan High Pressure Boilers are made 5-10-20-35- and 50 hp ratings. Every one carries the ASME stamp. They are made for high efficiency on long, hard pulls but are exceptionally useful in operations requiring fast, safe steam on short notice. Hospitals, dry cleaning plants, laundries, milk plants, tire repair shops and many others find them ideal for their operations.

### CLEAVER-BROOKS BOILERS OPERATE AT A GUARANTEED MINIMUM 80 PER CENT EFFICIENCY

Cleaver-Brooks boilers are guaranteed to operate at fuel-to-steam efficiency of not less than 80 per cent, at ratings from 30 to 100 per cent and at the designated working pressure. Economical operation is assured by establishing an efficient flame, and utilizing forced draft to send the hot gases through four successive passes, thus absorbing maximum usable heat before combustion gases leave the boiler. Boilers are fully automatic in operation... meet ASME code requirements. Factory finished and tested under load conditions.

Available with "10-Second" Oil and Gas Fuel Interchange Feature

80 PER CENT EFFICIENCY RATINGS are established at the factory and can be maintained with relative ease after installation.

Write for complete Specifications, dimensions data, firing rates, etc. Catalog AD-157 sent on request.

### CLEAVER-BROOKS HELPS YOU SELECT THE EXACT STEAM BOILER YOU WANT TO MEET YOUR SPECIFIC NEEDS

**JOB RATED**—Each Cleaver-Brooks steam boiler is job rated to meet the steam requirements of your plant. A competent sales engineer helps analyze your load demands and takes into account these conditions:

- Pop valve settings • Per cent of total feed water returned as condensate • Temperature of condensate • Pressure of make-up water • Type of fuel available • Electric current characteristics • Space and machinery arrangement. Suggested boiler room layouts • Plant altitude above sea level • Maximum steam requirements in pounds per hour or boiler horsepower • Whether your steam load is constant or fluctuating, and the degree of fluctuation • The heating load requirements • Standby requirements • Steam pressure required at point of use • Future growth or expansion of plant facilities •

Look for the "CLEAVER-BROOKS" listing in the Boiler Section of your classified Telephone Directory for name of nearest distributor.

Factory Distributors throughout the United States

### CYCLOTHERM STEAM AND HOT WATER GENERATORS

... operate on Cyclonic Combustion principle. Completely automatic with full safety controls. Oil, gas or interchangeable gas and oil firing. Only four connections required.

The Cyclonic Combustion operating principle causes the fuel to be burned while spiraling at high velocity around the inside wall of the combustion chamber, forming virtually a tube of flame. This provides uniform and highly efficient heat transfer over the entire furnace wall without hot spots. Complete utilization of heat transfer areas provides quick heat as well as greater than 80 per cent efficiency with the reduced maintenance of a two-pass design.

18 to 80 hp models are equipped with "on-off" control; 100 to 500 hp models have modulated control. 80 hp units with modulating controls furnished at customers request. Automatic combustion safeguard, low water and other safety controls are included.

Sizes from 18 to 500 hp

### Pressure Range

Available in standard low pressure units or high pressures up to 200 psi. Hot water generators are also available in all sizes.

### Standard Burner Arrangements

| Fuel                         | Cyclotherm Model No. |

# COLUMBIA Boiler Company of Pottstown

Pottstown, Pa.

Makers of steel power and heating boilers

## COLUMBIA'S H.R.T.\* OIL OR GAS FIRED BOILER

**ASME CODE CONSTRUCTED—**  
Available for pressures of 15 to 150 psi.

A complete, automatic power plant wherever steam is used for processing

**Horizontal Design for longer life:** The complete submersion of tubes protects them from water line corrosion.

**Dry Steam Assured:** Large steam space and greater liberation area virtually eliminate waste producing water carryover.

**Over-All Efficiency:** Factory installed, specially designed combustion chamber provides rapid heating refractory surfaces for peak combustion efficiency. Insulation, 7 inches thick in the combustion chamber proper, and 4 inches thick in the gas passage, keeps heat loss at a minimum. Special refractory brick heats up to great intensity to complete the combustion of previously unignited fuel particles. This complete combustion not only increases efficiency but makes for clean combustion. Soot accumulation on heating surfaces is minimized. Boiler tubes require less cleaning.

**Safety Assured:** Two pass updraft design lowers direct loss and reduces possibility of furnace pressure, pulsation or excessive combustion noises.

**Accessibility and easy Maintenance:** Simplified construction provides easy front and back access to the single bank of tubes. Entire unit can be gotten to for inspection of boiler and chamber by removing the covers.

Columbia h.r.t. boilers are fully automatic, compact, complete steam generators. Available in sizes ranging from two to sixty horsepower. Designed for firing with gas, light or heavy oils. A special Columbia unit makes possible the inter-changeable use of gas or oil.

**Overfiring Permitted:** Conservative ratings plus large combustion volume permit overfiring. This frequently eliminates the need for additional boiler capacity, allows for plant expansion.

**High Steam Output:** Columbia's h.r.t. boilers have an unusually large heating surface to produce more steam at higher efficiencies. More heat is converted into steam since it is proportioned to make maximum use of hot gases of combustion for the production of steam.

\* Horizontal return tubular type boiler

# COLUMBIA Boiler Company of Pottstown

Pottstown, Pa.

Makers of steel power and heating boilers

## STEEL, TUBELESS OIL-FIRED, WATER TUBE GAS-FIRED AND COAL-FIRED HEATING UNITS

**ASME CODE  
CONSTRUCTED**

Available with highly efficient, custom engineered gas or oil burners. Columbia steel boilers, gas or oil fired, have self contained large copper instantaneous tankless coils, supplying a continuous flow of year 'round domestic hot water.

**Maximum operating efficiencies assured** by the balanced design of the boiler and burner; by the arrangement of the baffles which force the hot gases to travel four of five times the full length of the boiler.

**One piece electric welded construction:** Columbia offers a heating unit with full electric welded construction of heavy copper bearing steel, to assure lower heating cost and longer operating life. **Quiet operation:** Ample combustion space, the insulation and heavy steel jacket completely eliminate objectional noise.

**Dual Firing:** Columbia gas heating units may be easily converted for efficient oil firing.

\* Constructed Water Tube Only  
\* Gas Fired Units A.G.A. and S.U.R. Approved for outputs from 72,000 to 172,000 Btu's per hour.  
\* Coal Hand Fired Conversion Units available in sizes L-18, L-22 and L-30

### COLUMBIA BASEBOARD RADIATION

- Suspended Element—no noise!
- Tension Fastening—no rattling!
- Low Angle Heat—no drafts!
- Pre-Punched Holes—fast installation!

## Combustion Engineering, Inc.

All Types of Fire Tube and  
Water Tube Boilers  
Mechanical Stokers

Complete Steam Generating Units  
Pulverized Fuel Systems

200 Madison Avenue, New York 16, N. Y.

Offices in all principal cities of the world

More than 20,700 C-E Stokers purchased to date

C-E Skelly Stoker

C-E Spreader Stoker—Dumping Grate Type

C-E Spreader Stoker—Continuous Discharge Type

C-E Traveling Grate Stoker

**C-E SKELLY STOKER**—A compact, self-contained unit with integral forced-draft fan, designed to burn either bituminous coal or anthracite. Alternate fixed and moving grate bars assure lateral distribution of fuel. Automatic control is standard equipment. Approximate capacity range—20 to 300 rated boiler horsepower.

**C-E SPREADER STOKER**—A simple, rugged overfeed stoker designed to burn a wide variety of coals. Revolving spreader blades feed fuel into the furnace in criss-crossing streams which assure uniform distribution. Fines are burned in suspension and the coarser coal on a grate which may be of either continuous discharge or dumping type. Rate of coal feed and air supply may be regulated over a wide range and are adaptable to automatic control. Applicable to boilers from about 100 boiler hp up.

**C-E TRAVELING GRATE STOKERS**—Available in either bar or chain grate designs. These stokers are used for anthracite, coke breeze or free-burning bituminous coals. Available in either forced draft or natural draft designs. Application range from 150 boiler hp to units producing 275,000 lb steam per hr.

**OTHER TYPES**—The C-E line includes the Type E Underfeed Stoker available for use with boilers from 150 to 600 boiler hp. A single retort underfeed stoker, it is one of the best known and most widely used in the world. It burns a variety of bituminous coals and it is particularly adapted to coals having caking and coking characteristics.

### C-E PACKAGE BOILER, TYPE VP

For medium size and smaller plants . . . completely shop assembled . . . pressures to 500 psi . . . capacities from 4,000 to 40,000 lb per hr . . . oil or gas firing.

The VP is a completely packaged two drum vertical bent tube boiler with integral water-cooled furnace. Automatic controls provide protection from flame failure, high steam pressure and low water level; also adjust the air supply to the needs of fluctuating loads. Pressure fired, the unit requires no induced draft fan. Being self contained, it needs no special foundation and may be placed on a concrete slab or on a level floor. Only connections required are water, fuel, steam, electric and flue vent.

C-E Package Boiler, Type VP

### C-E LA MONT CONTROLLED CIRCULATION HOT WATER BOILER

For commercial or industrial heating or processing . . . capacities to 200 million Btu per hr . . . pressures to 300 psi . . . temperatures to 425 F . . . for coal, oil or gas firing.

Using high pressure, high temperature water in a closed system, this unit is ideally suited for those applications where high temperature water is preferred over steam. The C-E La Mont HT Boiler offers many advantages over other water systems—complete control, low pressure loss, single pass design with low draft loss, efficient heating surfaces and pressurized operation. It needs no induced draft fan or separate boiler pump.

C-E LaMont Controlled Circulation Hot Water Boiler

### C-E VERTICAL-UNIT BOILER, TYPE VU-10

For medium-sized and smaller plants . . . pressure to 475 psi . . . capacity to 60,000 lb per hr, or more . . . suitable for any type of fuel.

A standard unit, the VU-10 is especially designed for industrial load conditions and plants having a limited number of operating personnel. It is of symmetrical design, and steam is released evenly across the full width of the unit. Gas flow is uniform, heat absorption is efficient and draft loss is low; it is essentially a "quick steamer." The boiler is bottom supported with no outside supporting steel. Type VU-10 boilers are adaptable to stoker firing or may be fired with oil or gas.

C-E Vertical Unit Boiler, Type VU-10

## The Dewey-Shepard Boiler Co.

Sales Office: 1311 N. Capitol Avenue, Indianapolis, Ind.  
STEEL FIRE TUBE BOILERS & HEATERS  
GAS & OIL FIRED

VERTICAL FIRE TUBE UNITS capacities 95,000 to 1,000,000 Btu  
ASME CODE CONSTRUCTED  
NATIONAL BOARD REGISTRATION AVAILABLE

All Dewey-Shepard boilers and water heaters (oil and gas fired) are built on the patented "Tube within a Tube" principle. All units are jacketed with fiber-glass insulation ready for instant hook-up.

- Oil Burners Underwriters Approved.
- Gas Burners A.G.A. Listed.
- Boilers Automatically Welded.
- Built-in Coils Optional.

### NET RATING

| K     | 3000          | 1895         |
| L     | 4480          | 2800         |
| M     | 5960          | 3730         |

Boiler ratings do not include allowance for Built-in Coils.

\* If piping and pick-up loss exceeds 20 percent of installed radiation, allow for such added loss.

### OIL and GAS BOILERS and WATER HEATERS

Dewey-Shepard's patented "Tube within a Tube" principle gives you 80 per cent or more heat absorption, resulting in pre-heating the incoming cold water before it comes in contact with the metal surfaces to which radiant heat is being applied. There is one square foot of heating surface for every gallon of water, transferring every possible unit of heat to the water, resulting in EFFICIENT, ECONOMICAL OPERATION . . . plus many other advantages for your customers, such as:

● LESS FUEL USED ● LOWER INSTALLATION COST ● NO LIME—NO SCALE ● 20 PER CENT LESS HEAT LOSS THROUGH THE STACK ● NO EXPANSION, CONTRACTION OR CONDENSATION ● CLEANEST HEAT POSSIBLE ● SUFFICIENT HOT WATER AT ALL TIMES

DEWEY-SHEPARD'S NEW OIL and GAS FIRED "COUNTER FLOW" BOILER Designed for use with Baseboard Radiation, Copper Convectors, and Radiant Panel with forced circulation and small pipe sizes.

### SPECIFICATIONS COUNTER-FLOW

| Output Net Btu      | Size                     | Weight |
|---------------------|--------------------------|--------|
| Model A Oil 90,000  | 19 in. x 19 in. x 31 in. | 400 lb |
| Model A Gas 80,000  | 20 in. x 20 in. x 34 in. | 275 lb |
| Model B Oil 135,000 | 19 in. x 19 in. x 38 in. | 450 lb |

## Dutton Boilers

Division Hapman-Dutton Co.

639 Gibson Street, Kalamazoo, Michigan

Four types, many sizes . . . From 5 hp up . . . Firing with gas, light or heavy oil, stoker coal or by hand . . . For processing, power, high and low pressure steam and hot water heating . . . For Industrial Plants, Dairies, Laundry and Dry-Cleaning Plants, Chemical and Food Processing, Hotels, Schools, Institutions, etc.

Off-Center Firing With EconoTherm "Packaged" Models—Gas or Oil or Combination Gas-Oil.

Multiple Convertible Firing With The EconoMist "Packaged" Models.

EconoTherm Models are automatic, self-contained, "packaged" units with full safety controls. Of 3-pass fire-tube design, they feature a modified Scotch Internal Furnace located off-center. This firing creates rotary water circulation, resulting in more uniform water temperature, fast steaming, steady water line at all times, and high quality dry steam. Higher water column above furnace adds extra safety, efficiency.

Rotary combustion, large steam storage space, and five or more square feet of heating surface per rated hp combine to deliver guaranteed 80 per cent efficiency with dryness rating of 99 plus 0/0 dry steam under proper operating conditions.

Induced draft or forced draft fan available for positive, fast firing. Only a vent pipe is needed—no chimney or stack. Boiler shell is welded in one piece, X-ray inspected; complies with all ASME requirements. Every unit gets full running test. Certified ASME Data Report furnished.

EconoMist Models are automatic, "packaged" boilers featuring multiple convertible firing. They can be equipped for firing by hand, stoker, light oil, heavy oil, or gas, singly or in combinations. Can also be fired with by-products such as wood chips, sugar cane, corn husks, waste gas, etc.

EconoMist Models give you the dependability and simplicity of operation of H.R.T. design, plus greater combustion space, less heat loss. Installation, operation and maintenance costs are low. Welded boiler shell is X-ray inspected; complies with all ASME requirements.

Sizes from 15 to 105 hp are available as "packaged" units ready to connect or as basic units less refractory lining and accessories. Can be equipped with induced draft fan to eliminate need for stack or chimney. Conversion from one type of fuel to another is simple and inexpensive. Each unit is fully tested and certified ASME Data Report furnished when shipped as a packaged unit.

## Fitzgibbons Boiler Company, Inc.

101 Park Avenue, New York 17, N. Y.

Sales Branches in Principal Cities

Member

Manufactured at Oswego, N. Y.

Steel Boilers since 1886

Reg. U. S. Pat. Off.

**PRODUCTS—STEEL HEATING BOILERS AND BOILER UNITS** for all fuels and all heating systems. Capacities to meet requirements of any building. Built and rated according to ASME and SBI Codes and "Hartford" inspected.

### 770 SERIES UNITS

A completely pre-assembled and wired **OIL FIRED** unit for forced hot water heating systems in small homes. Combines the Fitzgibbons boiler, oil burner and **TANKSAVER®** with all the necessary controls and specialties into a coordinated unit that provides abundant heat and tankless hot water at low cost. 580 (87,000 Btu) and 720 (108,000 Btu) sq ft water—**SBI** Net Rating.

**GAS FIRED:** Available pre-assembled and wired, or as unassembled units. A.G.A. approved units, 96,000 and 124,000 Btu output.

### R-Z-U JUNIOR® BOILER

The popular choice for a wide range of intermediate installations ranging from large residences to medium sized schools and commercial buildings. Large combustion area and two passes through 3 in. tubes account for efficient firing with oil, gas or coal. No rear or left side clearance necessary as all servicing can be done from the front. In eleven sizes from 264 to 1200 Mbh—**SBI** net. **FITZGIBBONS TANKSAVER®** available for service hot water.

### "400" SERIES BOILER

The aristocrat of steel boilers for residences. Quick heating, low fuel consumption. Abundant hot water, winter and summer, without the need of a storage tank with the Fitzgibbons **TANKSAVER®**. In sizes from 400 to 900 sq ft steam, 720 to 1620 sq ft water—**SBI** Net Rating.

1552

### "D" TYPE FIREBOX BOILER

For mechanical firing with oil, gas or stoker in ratings from 3650 to 60,700 sq ft steam, 876 to 14,570 Mbh EDR. 15 lbs Steam—30 lbs Water.

For hand fired coal in ratings from 3000 to 35,000 sq ft steam, 4800 to 56,000 sq ft water, 720 to 8400 Mbh EDR.

The steel boiler for heating apartments, office buildings, theatres, schools, hospitals and other large commercial buildings. Provides year 'round service hot water, without the need of a separate storage tank, with the Fitzgibbons **TANKSAVER®**, a copper coil submerged in the boiler water.

### "SCOTCH TYPE" BOILER

A Full Wet Back—Low Pressure Heating Boiler for oil and gas firing in sizes from 5470 to 60,700 sq ft steam, 1313 to 14,570 Mbh EDR. 15 lbs Steam—30 lbs Water. This compact, efficient Fitzgibbons

Boiler has the design advantage of complete water jacketing of all heating surfaces, including the rear furnace wall, thus eliminating usual rear dry-wall refractory lining and corresponding upkeep and repair expense.

### PACKAGED BOILER UNIT

Fully assembled and wired integrated unit for low pressure commercial applications. Fire tested and shipped as a unit ready for firing on the job. Boiler has full wet back construction that eliminates recurring expense for maintaining rear refractory. **SBI** ratings based on 8.2 sq ft heating surface per boiler hp with guaranteed gross outputs based on 5.0 sq ft of heating surface. Induced draft for quieter, cleaner operation. Thirteen sizes from 39 to 464 hp.

**SCOTCH WET BACK HEATING BOILERS**

Series 3000, for packaged heating units. These boilers can be used with any manufacturer's burner equipment. Two-pass design gives good distribution of heat transfer with low stack temperatures and permits easy access to tubes. Large water and steam space assures smooth operation, steady pressure, and constant heat. Among the features are:

Wet front furnace—Front end of furnace, with water all around, is flush with front of boiler. Burner can be connected to fire directly at water heating surface without heat loss.

Complete wet back—Entire combustion chamber is surrounded by water, for efficient and quick conversion of water to steam. There is no heat waste in rear; boiler room is cooler.

Sizes from 4200 to 70,000 sq ft of steam radiation.

**SCOTCH WET BACK HEATING BOILERS**  
Series 2600

Where economy of installation and operation are paramount and the space is small, F & T Series 2600 Boilers are ideal. No expensive foundations, pits, or external brick work are needed. Piping to boiler is easily installed, especially where headroom is at a minimum.

Steam space extends the entire length of the boiler, since the surface above the rear combustion chamber is covered with water. This provides large steam space and disengaging area.

Series 2600 boilers are self-contained and can be moved easily and installed on two saddles. All parts are readily accessible for inspection and cleaning. Boilers can be furnished with special front furnace extension to suit burner requirements.

Sizes from 3160 to 42,500 sq ft of steam radiation.

**BISON COMPACT HEATING BOILERS**

Bison Compact Heating Boilers are designed to have a large furnace volume, ample water and steam storage, proper steam liberating surface and a balanced circulation. The result is a remarkably steady waterline.

Original cost of Bison Compact Heating Boilers is low and they are easily installed. They come complete, ready for piping. Minimum brick work is required. These boilers are designed for mechanical firing with oil, gas or stoker, but can be made for hand firing with anthracite or bituminous coal. Sizes from 2680 to 42,500 sq ft of steam radiation.

**HYDROTHERM**

Northvale, New Jersey

**HYDROTHERM**

The "Packaged" Automatic Gas Heating Plant. For residential, commercial and industrial hot water systems.

Model R150 without jacket  
600 sq ft installed radiation.

HYDROTHERM is designed to deliver maximum hot-water heat with minimum fuel consumption. Fully A.G.A. approved for use on manufactured, natural and LP Gas ... from 45,000 to 500,000 Btu.

**Outstanding for:**

- Baseboard, convector and radiant panel heating systems
- Individual apartment heat
- Natural companion for central cooling system
- Booster service for 180 degree sterilizing water
- Volume hot water heating

Model R150 with jacket 425  
lbs, 16 in. x 31 in. x 27 in.

**CONSTRUCTION:** all cast iron Hydrotherm's unique absorption unit has deep ribbed horizontal sections, which are connected in zig-zag. This design affords maximum heat transfer surface for minimum water volume, resulting in greater efficiency and faster pick up. Hydrotherms are factory tested at 250 lb hydrostatic pressure and are ASME approved for 100 lb working pressure. Unit is fully wired and assembled for speedy installation. All controls including automatic gas control valve, Baco safety pilot, pressure regulator, aquastat and tridicator are enclosed in De Luxe jacket of Hammeroid finish.

BOILER BUILDERS SINCE 1856

## THE INTERNATIONAL BOILER WORKS CO.

500 Birch St., East Stroudsburg, Pa.

Sales Offices in Principal Cities

### WATER TUBE BOILER DESIGN ASSURES...

- **QUICK STEAMING** ... due to rapid and directed water circulation.
- **MORE HEAT ABSORPTION** ... due to extra long three pass gas travel, across the entire bank of water tubes.
- **EASY CLEANING** ... free access to heating surfaces makes cleaning easy.

### INTERNATIONAL WATER TUBE BOILERS...

- Standard sizes: Heating Boilers 400-70,000 sq ft steam, Power Boilers 10-600 bhp.
- Steel Boiler Institute ratings.
- Heating Boilers 15 lbs steam-30 lbs water.
- All Boilers ASME standard
- For Oil, Gas, Stoker or hand fired Coal.

### INTERNATIONAL "COMPAK" PACKAGE BOILERS...

- Completely assembled factory fire-tested water tube package boilers.
- For low pressure and high pressure requirements.
- Oil, gas, or combination oil-gas fired.

### INTERNATIONAL-LA MONT\* FORCED RECIRCULATION BOILERS

Specifically designed for ...

- High Temperature Water distribution systems.
- Hi-Temperature process systems employing Dowtherm, Aroclor, Socony Vacuum Heat Transfer Oil and other Thermal Liquids.

Write for complete catalog.

- Licensed under LaMont patents.

### "PACKAGED" STEAM BOILER UNIT FULLY AUTOMATIC HEAVY OIL AND/OR GAS

Standard Scotch Boiler  
Water-back Type,  
Natural Draft.

### WATER-BACK TYPE, FORCED DRAFT, THREE-PASS, TROUBLE-FREE, EFFICIENT.

Catalog-Rating guaranteed and at least 25 per cent overloads readily obtained.

**HIGH PRESSURE TYPE** from 60 to 800 hp and pressures of 125, 150 and 200 lb psi (250 lb available as a special)

**LOW PRESSURE TYPE** for heating; 15 lb pressure, and EDR rating from 2190 sq ft to 42,500 sq ft steam.

ASME Code construction. Underwriters' Laboratory and Factory Mutual Approved. Specification Forms in detail to exactly cover the requirements of any particular job will be furnished upon request and without any obligation whatever. Ask for *Bulletin 509 A*

Firebox Heating Boiler, Compact Type. Oil, Gas, Stoker or Hand Firing. Three-Pass, 15 lb pressure, ASME Code. Capacities 2190 to 42,500 sq ft, SBI rating. Ask for *Bulletin 1500*.

Also built for High Pressure (125 psi.) Ask for *Bulletin 702*.

### POWER, PROCESS, HEATING

25 to 300 hp and pressures 15 lb to 200 lb psi. For mechanical firing with Coal, Gas or Oil. Overloads up to 200 per cent of rating readily developed. Oil or Gas firing equipment and controls can be installed for completely automatic operation and in emergency or fuel scarcity, can be readily converted to Coal firing.

Ask for *Bulletin 4000 and 9000 and 9200*.

# KEWANEE BOILER DIVISION

of American-Standard

101 FRANKLIN STREET, KEWANEE, ILLINOIS

KEWANEE OFFERS A COMPLETE LINE of boilers for every type and size of building. All fuels can be used. The policy of Kewanee for more than eighty-five years has been to build boilers that can be depended on to deliver more than rated capacity. The Kewanee Reserve Plus rating certifies up to 50 per cent more power is built into every Kewanee boiler. This assures efficiency, low cost operation and low maintenance cost.

All Kewanee boilers meet or exceed the ASME Code for construction, and comply with the SBI Code for ratings.

1558

Hi-Test Boiler

Heating Systems • Boilers, Steel

Mechanically Fired—oil, gas or stoker

Heavy Duty Two-Pass Tubular Boilers for High Pressure.

To cover a wide range of usage there are 8 sizes of Hi-Test 2-Pass Tubular Boilers for power or industrial Process Steam—61 to 304 hp—Streamline construction, quick steaming—compact. Joints are fusion welded. X-Ray checked. Designed for refractory lined fire-box, making it entirely self-contained.

## KEWANEE SCOTCH TYPE BOILERS

For Commercial and Industrial Use

High and Low Pressure

THERE ARE SIX SIZES of the Welded Scottie Jr., all capable of carrying large overloads without loss of efficiency—Under-slung design means more headroom—comes ready to hook up—easy to clean—rear combustion chamber has refractory lining installed at the factory. Can be ordered as packaged boiler burner unit.

LOW IN OPERATING COST YET HIGH IN EFFICIENCY—that's the M-800 Scotch type boiler for high and low pressure steam or hot water heating—burns oil or gas. There are 13 sizes from 5,470 to 42,500 sq ft high pressure steam, 125-150 lbs working pressure. Low pressure sizes from 1,313,000 to 10,200,000 Btu, 15 lbs steam or 30 lbs water.

Scottie Jr. 18 to 44 hp 185-160 lbs W.P.

Heating Systems • Boilers, Steel

**KEWANEE TYPE "C" BOILER**  
With Corrugated Crown Sheet

Here is a compact boiler requiring a minimum of floor space yet produces steam in great amounts, at low cost, especially adaptable for heating large buildings at low cost without sacrificing efficiency, uses oil, gas, or stoker. Available in 13 sizes.

Type "C" Boiler

The Corrugated Crown Sheet, exclusive with Kewanee, has many advantages over conventional designs. Corrugations add strength and provide additional heating surface next to the fire. Being right-side-up eliminates pockets to collect sediment. Water circulating over the crown sheet makes it self-cleaning.

Corrugated Crown Sheet

**KEWANEE "5000" SERIES**

"5000" Welded Boiler

Features large heating surface, steam space, disengaging area, furnace volume and water content. All seams are welded. Fifteen sizes ranging from 4,250 to 42,500 sq ft steam.

Square "R"

Round "R"

W Series

KEWANEE STORAGE WATER HEATERS

For installations where there are sudden demands for plenty of hot water and where exhaust or live steam is available. Capacities 95 to 2,240 gph. Equipped with supporting cradles.

**KEWANEE TYPE "R" RESIDENCE BOILERS**

Kewanee builds these smaller boilers with the same skill and engineering excellence as found in larger units. Ideally suited for medium and small size buildings and larger homes . . . and designed for oil, gas or stoker firing. Noted for dependability, economy, and ability to withstand many years of rugged service.

**SQUARE-HEAT TYPE "R"** comes in twelve sizes from 900 to 5,000 sq ft steam. Can be furnished with attractive jacket.

**ROUND TYPE "R"** available in 4 sizes from 400 to 900 sq ft steam. With Square or insulated round jacket. The W Series boilers are designed for forced hot water heating in small homes. 74,000 to 189,000 Btu. Occupy small space . . . sturdy steel jacket in two-tone green. Also available as oil or gas fired OW, GW Series boiler-burner units.

**DIRECT FIRED WATER HEATERS**

Ideal for any building requiring large quantities of hot water. 150 lbs hydro-static test for 100 lbs water working pressure. Easy to clean. The Tabasco Heater comes in five sizes to heat 165 to 700 gal of water 50 deg per hour. Burns any fuel.

Morgantown Road, Reading, Pa.

## Powermaster® PACKAGED AUTOMATIC BOILERS

Powermaster boilers are modern, compact, self-contained, automatic units with an outstanding record for highly dependable and efficient performance in public buildings, hospitals, schools, apartments, industrial plants and other installations. Two models are available in standard sizes of 15 hp to 500 hp for steam generation to 250 psi, and for hot water to 30 psi. As delivered, Powermasters are completely factory-assembled on a structural steel base for simple installation. Both models are designed and built to ASME Boiler Code requirements, approved by Underwriters' Lab-

oratories, Inc., and fully guaranteed by Orr & Sembower, Inc. All units are thoroughly factory-tested under fire.

**Advantages**—Cost-saving installation... space-saving compactness... fuel-saving efficiency at all loads... fast steaming... instant response to load swings... clean, dry steam... hospital-clean operation... maintenance-saving accessibility... fully automatic operating and safety controls... one-source responsibility for complete unit... nation-wide factory trained service.

**Model 3 Powermaster (40-500 hp)** provides... Complete fuel flexibility: Light or heavy oil, any gas or combination oil and gas... Choice of: Air atomizing oil burner—pre-mix gas burner—combination oil and gas burner—all designed and built by O & S... full-range modulation... selection of automatic operating and safety controls... instant change from fuel to fuel.

**Model 4 Powermaster (15-100 hp)** provides... Choice of fuels: Light distillate—natural gas—manufactured gas—combination oil and gas... Choice of: Mechanical pressure atomizing oil burner—pre-mix gas burner—combination oil and gas burner—all designed and built by O & S... dependable on-off and low-fire start burners... selection of automatic operating and safety controls... quick change from fuel to fuel.

## SPECIFICATIONS

|           | Btu<br>input | Btu<br>output | EDR        | 60° rise | 100° rise | Weight  |
|-----------|--------------|---------------|------------|----------|-----------|---------|
| Model 75  | 75,000       | 60,000        | 400 sq ft  | 120 gph  | 72 gph    | 125 lbs |
| Model 110 | 110,000      | 88,000        | 586 sq ft  | 176 gph  | 106 gph   | 160 lbs |
| Model 160 | 160,000      | 128,000       | 853 sq ft  | 257 gph  | 154 gph   | 195 lbs |
| Model 225 | 225,000      | 180,000       | 1200 sq ft | 360 gph  | 216 gph   | 225 lbs |

All models listed also available as packaged "plug-in" boilers for central heating, including expansion tank, transformer DPST relay, air vent, automatic fill, thermometer, pressure gauge, relief valve and high head circulator; all piped, wired and jacketed. Special packaging for swimming pool direct heating with self-contained independent electrical system, thermometer and low-water cut-off.

## COMPACTNESS FEATURED

All three Raypak models are similar in exterior appearance to those illustrated with controls concealed and protected and are available in every Btu size. Raypak is quiet-engineered, a packaged boiler of single-shell construction with heavy 18-gauge baked enamel jacket.

Model 75 is designed primarily for central heating. All models are adaptable to radiant heating, swim pools, (included sensitive pressure detector for low-water cut-off), air conditioning, volume supply and baseboard radiation.

## EXTRA ADVANTAGES

Quiet efficient modulating gas valve operates at any temperature, sizes the boiler for the job. Heavy wall monolithic cast insulated refractory keeps outside cool to touch. Integral copper fin tube heat exchanger in grid form, extra heavy headers, concealed and

protected controls, electric diaphragm main gas valve are features of all models. Raypaks are condensate protected with clean air foil transfer surfaces. Minimum pressure drop is assured, plus equal tube flow.

## RADIANT HEATING, BASEBOARD RADIATION AND AIR CONDITIONING COIL UNITS

Model-T and -TP, designed primarily for residential and small commercial heating, combine on-off firing with gas modulation... turns off and on at lowest flame for quietness and to minimize excessive firing. Model-75 preferred in group construction installations for lightness (125 pounds) and easy one-man installation. Occupies only 1½ sq ft of floor space or can install elevated. Controls concealed—no installation clutter. All models have 100 per cent copper waterways, preventing electrolysis, rust, ferric corrosion or water discoloration.

## PACKAGE BOILERS

Type Designation Ticosteam

The Ticosteam Generator is a packaged steam power plant, completely equipped at the factory, tested and certified. Essentially the unit is a three-pass, constant furnace pressure, forced draft, fire tube, horizontal boiler, with burners of special design using any desired type of gas, fuel oil, or combination of the two. Built in sizes from 20 hp to 350 hp, this unit provides outstanding economy in operation, with thermal efficiencies of not less than 80 per cent.

Type Designation WTP

The Titusville Type WTP Water Tube Steam Generator is completely shop-assembled, ready for operation as soon as service connections are made. The Type WTP features forced draft, pressurized furnace operation, and requires no high stack or induced draft fan. It is adapted for firing with heavy oil, light oil, natural gas, coke oven gas or manufactured gas, and combinations of these fuels. Capacities are from 7,500 to 40,000 lbs of steam per hour.

## TYPE CM SPLIT FIREBOX BOILER

Designed for replacement installations where entrance conditions are not sufficient to accommodate standard boilers, the Titusville Type CM Split Firebox Boiler offers maximum utility and convenience. Separating into four basic sections (see cut), the Split Firebox CM Boiler can be taken easily through narrow doors and passageways impossible to negotiate by standard models, without damage or alterations to building. Wide range of sizes and capacities.

Titusville, Pennsylvania

## LOW PRESSURE HEATING BOILERS

Type Designation CM

Titusville Compact Steel Heating Boilers built in 22 sizes ranging from 129 square feet to 3571 square feet heating surface, and maximum steam working pressure 15 psig.

Type Designation SOH

Titusville Scotch Marine Heating Boilers built in 22 sizes from 129 square feet to 3571 square feet heating surface, and maximum steam working pressure 15 psig.

## HIGH PRESSURE FIRETUBE BOILERS

Type Designation WP

Titusville All-Welded Portable High Pressure Firebox Boilers built in 12 sizes ranging from 250 square feet to 2500 square feet heating surface, steam pressure 100 psig, 125 psig and 150 psig.

Type Designation Wee Scot to 50 HP, SP above 50 HP

Titusville Scotch Marine Power Boilers built in 13 sizes ranging from 97 square feet to 3000 square feet heating surface. Pressures 125 psig and 150 psig.

## WATER TUBE BOILERS

Type Designation Ticotherm

Titusville Ticotherm Steam Generators built in 13 standard sizes ranging from 1000 square feet to 5000 square feet heating surface. Pressures 160 psig, 200 psig, 250 psig and higher.

Type Designation TDL

Titusville Three Drum Low Head Water Tube Boilers built in numerous sizes ranging from 729 square feet to 6109 square feet heating surface. Pressures 150 psig, 200 psig, 250 psig and higher.

Descriptive technical literature is available on request.

Unit Steam Generators • Oil, Gas and Combination Burners  
Draft-A-Justors • Fuel Oil Heaters • Heating Accessories

### PREFERRED UNIT STEAM GENERATOR

The fully automatic "package" boiler of outstanding reputation for producing steam or hot water at a low overall operating cost. Burns oil, gas or both fuels in combination with equally high efficiency.

Factory fire-tested before shipment, every Preferred Unit is certified to operate at a guaranteed thermal efficiency of 80 per cent or more. Its fast steaming means faster response to fluctuating boiler loads.

The unit, fully piped and wired, is mounted on a heavy H-beam base so that no excavation or special foundation, frequently a major item of installation cost, is necessary. It occupies about half the space needed by ordinary boilers of equivalent output. No ugly, costly stack is needed.

Capacity—20 to 600 bhp, 15 to 250 psig (see table).

#### Preferred's 25 Year Features

- 1—5 sq ft of Heating Surface per boiler horsepower for reliable, economical, continuous steam production.
- 2—Four-Pass Gas Travel for uniform heat distribution, quick steaming; clean heat transfer surfaces minimize tube cleaning; lower stack temperature.
- 3—Down Draft Design for guaranteed high operating efficiency and low off-period losses.
- 4—Induced Draft for smoother starting, higher combustion efficiency, less refractory maintenance.
- 5—Intermediate Furnace Position protects tube areas and safeguards shell from unequal heating.
- 6—Expansile Precipitator, installed in flue gas offtake, prevents rapid build-up of non-combustible deposits.
- 7—Staggered Tubes insure thorough heat wiping of the entire tube circumference at all times; makes possible faster heat pick-up rate.
- 8—Anti-Stress Deck keeps the sections of the rear tube sheet, above and below water line, in close balance, preventing unequal stress action within the area.

19 Standard Sizes

9—Dual Purging Action removes gas vapors from the entire vessel before and after firing.

10—Horizontal Rotary Burner for oil, gas or combination—starts, ignites, follows the load, shuts off, cleans and purges itself automatically.

For detailed information write for Bulletin 2000.

#### Other Preferred Products

Horizontal Rotary Burners for oil (7½ to 175 gph); for gas and oil (15 to 90 gph-oil) and (2050 to 12,300 cfm of 1050 Btu gas).

"Thermopak" completely integrated oil or gas combustion system for existing boilers of 20 to 525 bhp.

Pump and Heater Sets for preheating oil, 110 to 1200 gph.

Draft-A-Justors, barometric type for controlling stack draft.

Fuel Oil Heaters, Combustion controls, Oil Valves, Gauges, Boiler Accessories.

#### Industrial Type

A compact steam generator—a safe, dependable, push-button "boiler plant" you merely set and forget!

It's the answer to your plant expansion—to steam for any use. Moving a desk makes room, or any corner will do. Needs no enclosure, special foundation, expensive stack. Operation is clean, quiet, automatic. Two-minute steam from cold-starts ends early reporting and standby.

Saves time, saves fuel

Modulatic tracks fluctuating steam demand, up or down, with speed and accuracy. Fuel consumption is exactly proportional to volume of steam used. Shipped complete, passes through plant-type doorways.

Sizes, 10 to 160 hp. Pressures to 1000 psi. Multiple installations can have a single automatic control that cuts whole units "in" or "out" according to steam demand. Oil, gas, or flip-switch combination burner. Vapor Modulatic Steam Generators are built to conform to both the ASME Power Boiler Code and ASME Heating Boiler Code.

Drum-Type for heating, low pressures. Full Modulatic advantages of compactness, quick steaming, and high efficiency incorporated into a heating boiler with controls materially simplified. Reduced cost, reliable performance, minimum maintenance. Especially designed for operating pressures below 15 psi.

Industrial Type

Drum Type

### VAPOR WAIKIKI HEATER

Gives a flood of hot air at the touch-of-a-button for every conceivable use. Sets on floor, shelf; hangs from ceiling; burns kerosene, fuel oil, gas. Plugs into 110-volt, a-c outlets.

Versatile, simple to service

Permits simple connection to exhaust vent or stack, or including combustion products in forced air circulation. Burner and blower are outside-mounted—no moving parts inside the unit.

Shipped fully assembled and wired. Output: 2400 cfm. Compactly quality-built for efficient performance with extra large heat transfer area.

Two sizes: 145,000 and 200,000 Btu per hour.

**DETROIT**

**STOKERS**

## DETROIT STOKER COMPANY

General Motors Building - Detroit, Michigan

### Detroit LoStoker (Underfeed type)

Compact firing unit—single retort—mechanically driven—plunger feed—side cleaning stoker. Sizes and capacity for all heating boilers, from 50 to 150 horsepower rated capacity. Now available with Detroit Adjustable Feed—provides automatic control of coal and air. Efficient and dependable operation assured.

*Detroit LoStoker—a great coal saver. Easily installed. Thousands in operation. Write for catalog.*

### Detroit UniStoker (Underfeed type)

Plunger feed, side cleaning, compact unit type. For boilers of 125 to 250 hp rated capacity. Detroit Adjustable Feed keeps air supply in ratio to coal feed. May be motor or steam turbine driven automatically controlled. Readily installed with existing boilers to provide automatic heat at low cost.

*Detroit UniStoker with Adjustable Feed provides a wide range of coal feed control.*

### Detroit RotoStoker (Spreader type)

Built with stationary, hand or power dumping grates or continuous cleaning grates. Wide range of sizes. Burns all bituminous coals without special preparation, but with high thermal efficiency. Responsive to fluctuating loads.

*Detroit RotoStoker (CC) is a new type with continuous ash discharge at the front. For steaming capacities approximately 5,000 to 75,000 lbs. Smoke-free operation at light loads.*

### Detroit RotoGrate (Large spreader type)

For medium and large heating and power boilers up to 400,000 lbs steam per hour. Forward moving grates continuously and automatically discharge ash at the front. Combustion loss in ash usually less than two per cent.

*Detroit RotoGrate Stoker burns all grades of coal. Permits higher burning rates. Responds quickly to changes in load. Burns wood and other refuse separately or in conjunction with coal.*

## The Will-Burt Company

Orrville, Ohio

COMMERCIAL • INDUSTRIAL • RESIDENTIAL  
AIR-CONTROLLED BITUMINOUS STOKERS

### HOPPER MODELS

Patented automatic air control insures delivery of correct quantities of air to meet constantly changing fire-bed conditions, eliminates need for banked firing methods and prevents back-smoking. If overload occurs, shear pin and auto-

matic switch protect stoker against damage. Strong, cast iron hopper base with heavy gage rust-resisting steel hopper.

Will-Burt hopper type stokers are available in 20 to 750 lbs per hr capacities.

### BIN FEED MODELS

Like the hopper models, Will-Burt bin-feed stokers offer all the advantages of

automatic air control and the patented protective shear pin and switch. Patented flange and set screw locking device prevent coal screw from disengaging from drive shaft. Precision machined power unit. Capacities from 20 to 750 lbs per hr.

### PANEL BOARDS

Prewired, pretested control panel boards provide an interconnected control system for stokers to be operated by either a common operating and/or individual holdfire control, depending on the setting of the safety switch, off-on switch and timeswitch cycle. Mounting wall brackets are provided. Not illustrated, but available are control cabinets with controls mounted and wired on a sub-panel and completely enclosed in a heavy steel cabinet.

Write for your free copy of the Will-Burt Engineers and Architects Manual.

# McDonnell & Miller, Inc.

Safety Devices for Steam and Hot Water Heating Boilers and Hot Water Tanks

3500 N. Spaulding Ave., Chicago 18, Illinois

The McDonnell line consists of the following safety devices: (1) For Low Pressure Steam Boilers . . . Boiler water feeders, low water fuel cut-offs and combined feeders and cut-offs; (2) For Higher Pressure Steam Boilers . . . Pump controls, low water fuel cut-offs and low water alarms for pressures to 150 lbs, and receiver make-up water feeders; (3) For Hot Water Space Heat-

ing Boilers . . . ASME pressure relief valves, boiler water feeders, low water fuel cut-offs and combined feeders and cut-offs; (4) For Domestic Hot Water Tanks and Heaters . . . ASME pressure relief valves, temperature relief valves and combination T & P relief valves. McDonnell also manufactures liquid level controls for humidifying pans and many other applications.

### McDONNELL Boiler Water Feeders and Feeder Cut-off Combinations

McDonnell No. 47-2

McDonnell No. 51-2

McDonnell No. 53-2

McDonnell No. 47-2 Feeds water when necessary to maintain safe water level in boiler. If water level for any reason falls into emergency zone, cut-off switch cuts burner circuit until emergency has passed. Has "Quick-Hook-Up" for installation in gage glass tapplings; "cool" feed valve; extra-deep sediment chamber; stainless steel valve and seat; ASME approved blow-off valve. Also available for hand fired jobs without No. 2 Switch, as No. 47 Feeder.

McDonnell No. 51-2 is same as No. 47-2, except it has greater feeding capacity for larger boilers, and is installed with 1 in. equalizing pipes instead of "Quick-Hook-Up." Also available for hand fired boilers without No. 2 Switch, as No. 51 Feeder.

For boilers operating at higher pressures, from 35 to 75 lbs, use McDonnell No. 53-2 (or No. 53, without switch).

No. 67

**McDonnell Low Water Cut-offs**  
For automatically fired steam boilers of any size  
Maximum steam pressure, 20 lbs.

No. 67 has McDonnell "Quick-Hook-Up" for installation in gage glass tapplings; deep sediment chamber with large opening blow-off valve; packless non-binding construction; adjustable terminal box; snap-action twin switches. One switch can sound low water alarm, or control McDonnell No. 101 Electric Water Feeder; second switch cuts burner current if water level drops into emergency zone.

No. 61 has same mechanism as No. 67 but has larger body for installation with 1 in. equalizing pipes.

69 Series "Built-ins" meet same operating conditions, fit 2 1/4 in. tapplings provided by many boiler manufacturers. Order by boiler make, model.

**McDonnell No. 101 Electric Boiler Water Feeder**  
For boilers up to 5000 sq ft capacity.

No. 101

For use with No. 67 Low Water Cut-off, No. 61 or "Built-ins" which are standard equipment on many modern heating boilers. Its use converts cut-off into feeder cut-off combination.

## (2) HIGHER PRESSURE STEAM BOILERS

**McDonnell Pump Control, Low Water Fuel Cut-Off and Alarm Switch**

No. 150

No. 192

**Maximum boiler pressure, 150 lbs.**  
The McDonnell No. 150 has two switches; one controls electric feed pump or electric valve in line to steam pump; second stops burner on greater float drop and completes alarm circuit. Underwriters' Laboratories approved. No. 150 has automatic reset; for manual reset order no. 150-M.

**Maximum boiler pressure, 250 lbs.**  
The No. 192 is a totally new kind of control. Introduces a new principle of repulsion magnetic switching. Has junction box totally sealed from float chamber; remarkable heat dissipation meets new Underwriters' Laboratories standards for use of 75 deg C. wire. Water column body has all tapplings for steam trim. For manual reset order No. 192-M.

No. 157

No. 157 is the same as No. 150 but has integral water column which simplifies installation and has all tapplings for steam trim. No. 157 has automatic reset; for manual reset order No. 157-M (Tri-cocks and gage glass not included.)

No. 92

No. 92 is same as No. 192 but without water column body; is installed with 1 1/4 in. equalizing tapplings. For manual reset order 92-M.

## McDONNELL No. 27 Make-up Water Feeder for Receivers

No. 27

Teams up with McDonnell No. 150 or No. 157—assures an adequate minimum supply of water in receiver at all times. Features large feeding capacity, well-guided valve action, all-brass construction of valve assembly. Models also available without float bowl for mounting right inside of receiver. Maximum receiver pressure, 35 lbs; maximum supply pressure, 100 lbs.

(3) HOT WATER SPACE HEATING BOILERS  
Service Recommendations

## Boiler Water Feeders and Feeder Cut-off Combinations

| Boiler Size (Btu/hr Output)   |                               |                               | Maximum Boiler Pressure | McDonnell Product to Use     |                     |
|-------------------------------|-------------------------------|-------------------------------|-------------------------|------------------------------|---------------------|

\* Differential Pressure equals water supply pressure less boiler pressure.

## Low Water Fuel Cut-off (only) (for Automatically Fired Jobs)

McDonnell No. 63. For boilers of any size. Maximum Boiler Pressure, 50 lbs.

## ASME Safety Pressure Relief Valves

| Boiler Size (Btu/hr Output) | Opening Pressure | McDonnell Product to Use |
|-----------------------------|------------------|--------------------------|
| 303,000                     | 30 lbs           | No. 230 3/4 In.          |
| 743,400                     | 30 lbs           | No. 230 1 In.            |
| 1,025,100                   | 30 lbs           | No. 230 1 1/2 In.        |
| 1,488,000                   | 30 lbs           | No. 230-M1               |
| 1,928,400                   | 30 lbs           | No. 230-M2               |

## McDONNELL Boiler Water Feeders and Feeder Cut-off Combinations

Experience has shown that hot water heating boilers, just like steam boilers, can run into low water trouble—as a result of leakage in the system, prolonged discharge from pressure relief valves, or simple negligence. Best answer is a McDonnell feeder cut-off combination for automatically fired boilers, and a boiler water feeder for hand fired jobs. No. 247-2 is a modification of the dependable 47-2, but without "Quick-Hook-Up." No. 51-2 and No. 53-2 are larger capacity and higher pressure feeder cut-off combinations. (No. 47-2, 51-2 and 53-2 are described under "Low Pressure Steam Boilers.")

## McDONNELL No. 63 Low Water Fuel Cut-off

Suitable for boiler pressures to 50 lbs, the No. 63 is ideal for cut-off service on hot water boilers. Has time-tested No. 2 low water cut-off switch, center pivoted bellows construction. Underwriter's Laboratories approved. Can also be used on steam boilers.

No. 247-2

No. 63

## McDONNELL 230 Series ASME Pressure Relief Valves for Hot Water Space Heating Boilers

No. 230 3/4 Inch

Manifold Type 230 Series

The 230 Series was developed to provide dependable protection against over pressure at a moderate price. Each valve in the series conforms to ASME Boiler Code in every respect, and has been certified, and Btu-rated by the National Board of Boiler and Pressure Vessel Inspectors. All operating parts are of noncorrosive materials. Valve seat is brass, valve disc of silicone. Testing lever is independent of valve action, cannot interfere even if tied down. All connections are internal tappings.

Five sizes are available, three individual valves and two manifold valves. These manifold valves offer two units, set to open at progressively higher pressures, on a common manifold; they have the advantage of keeping discharge from larger boilers in step with the actual need, avoiding water waste when only a small discharge to take care of thermal expansion is required.

(4) DOMESTIC HOT WATER TANKS AND HEATERS  
Service Recommendations

## ASME Safety Pressure Relief Valves

| Opening Pressure | Capacity Btu/hr | McDonnell Product to Use |
|------------------|-----------------|--------------------------|
| 75 lbs           | 502,000         | No. 230-75               |
| 100 lbs          | 640,000         | No. 230-100              |
| 125 lbs          | 783,000         | No. 230-125              |

## McDONNELL 230 Series Pressure Relief Valves

## For Hot Water Tanks and Heaters

Used to guard against dangerous over-pressure, the McDonnell 230 Series valves conform to the ASME Boiler Code and have been tested and Btu-rated by the National Board of Boiler & Pressure Vessel Inspectors. Available with four standard opening pressures. Construction features non-corrosive materials for all operating parts, independent action test lever, internal tappings for connections. For larger hot water tanks, two and three valve assemblies are available, up to 125 lbs maximum pressure.

No. 230-75

## McDONNELL No. 201 Temperature Relief Valve

Safeguards hot water tanks and heaters against excessive temperature. A.G.A. listed for heat input to 1,200,000 Btu/hr. Vernatherm element provides positive operation, drip tight reseating. Extra connection for fixture flow simplifies pipe hook-up, improves operation. In regular or dip tube models.

## McDonnell No. 202 Combination P-T Relief Valve

Combines working mechanisms of 230 Series and No. 201; safeguards hot water tanks against both pressure and temperature. Bears the ASME symbol. Pressure side is steam-rated by the National Board of Boiler & Pressure Vessel Inspectors—650,000 Btu/hr at standard 125 lbs opening pressure. Temperature side is listed by A.G.A. for heat input to 750,000 Btu/hr. Opening pressures of 75 and 100 lbs also available.

No. 201

No. 202

## Pennsylvania Separator Co.

Box 348H, Brookville, Pa.

Mfgs. of Boiler Blow-down SEPARATORS

Pennsylvania's Separators utilize the velocity of the boiler blow-down injected tangentially into the tapered cylinder to separate heavier water-suspensions from flash which is forced to center vent. Thus excess pressure and temperature are removed by venting, leaving remaining water and suspensions acceptable to most drains. Water suspensions are directed by Spiral Baffle

to drain. When requested, units will bear ASME Code Stamps at extra cost. The unit meets national and most state and local requirements. Stainless Steel "Striking Plate" reinforces Separator at blow down entry to greatly extend life of unit. State boiler operating pressure and blow down valve size when making inquiry.

Consult the table for size. Prices and additional information on request.

### SEPARATOR INLET SIZE TO EQUAL BOILER BLOW-DOWN VALVE SIZE

| AVAILABLE SIZES |       |      |
|-----------------|-------|------|
| Inlet           | Drain | Vent |
| 1"              | 2"    | 2½"  |
| 1¼"             | 2½"   | 3"   |
| 1½"             | 3"    | 4"   |
| 2"              | 4"    | 6"   |
| 2½"             | 4"    | 6"   |

DIMENSIONS  
TOP—12"  
BOTTOM—14"  
HEIGHT—(20") (34")

### SUGGESTED HOOK-UPS

A popular and simple installation with the Separator installed below the blow-down valve. It provides ready drainage and blow-downs at all pressures or from a dead boiler.

Elevated Separator installation when boiler room floor space is not available. May be installed indoors or outdoors for Separator is self draining—no freezing.

Where Receivers are required, they may be open tanks, or vented closed tanks 4"-6" vent. Manual or siphon drainage may be provided.

## Packard Water Conditioner Division, Inc.

Packard Manufacturing Company

Post Office Box 719

Jacksonville 1, Florida

The Packard Water Conditioner eliminates and prevents corrosion and scale formation in boilers and water systems. It is an important commercial application of nuclear physics principles to the effective treatment of boiler feed waters—without the use of chemicals. The Packard Water Conditioner prevents scale and corrosion by imparting added energy to the atoms of the water solution.

The unit is easily installed. It has no moving parts and requires no expensive maintenance or servicing either in the form of labor or added chemicals.

Use of the Packard Water Conditioner reduces operating costs and increases plant efficiency, minimizes shutdowns for maintenance and repair.

Laboratory and field tests substantiate the theoretical and practical value of the device.

Complete boiler protection is assured by installing Packard Water Conditioners to treat both the raw water and condensate return lines. Flow rates should be carefully determined and provision made for variations in pumping capacity caused by changes in back pressure. All feed water will be conditioned when a single Packard Water Conditioner is installed between the feed pump and the boiler. Capacity of the Conditioner should be great enough to handle the maximum output of the pump.

The Packard Water Conditioner is manufactured in sizes handling from 6.5 to 1760 gpm for connection with corresponding standard iron pipe ranging from ¾ in. to 12 in., as shown in chart below.

Conditioners are guaranteed for a period of ten years.

\*NOTE: All sizes 200 PSI WP on all screwed. All others 150 PSI WP. For all sizes up to 40 inches write factory. For heavy duty units to withstand pressure up to 1,000 lbs, add 25 per cent to cost.

## Gordon-Piatt Inc.

P. O. Box 914 Winfield, Kansas

Combustion Engineering

GPH Inshot Burner

GPV Upshot Conversion Burner

Glow Top Burner

Type H Inshot Burner

**GORDON & PIATT** are combustion engineers, specializing in the design and manufacture of a complete line of Domestic, Commercial and Industrial Burners. Engineering Service available for customer convenience.

**GPH-INSHOT GAS CONVERSION BURNER**, designed to replace Gun-Type Oil Burners without alteration of combustion chamber. Four inch tube; 75,000 to 150,000 Btu hr input; A.G.A. Listed. See Cat. GPH-1

**GPV-UPSHOT GAS CONVERSION BURNER**, for Domestic Heating Plants. Annular Slot Head. No Burner parts in flame, adjustable length, 75,000 to 350,000 Btu hr A.G.A. Listed. See Cat. GPV-1.

**GLOW TOP BURNER** to convert large Commercial Heating Plants and Power Boilers. Standard firebrick completely covers cast ports. Shape and capacity flexible. 45 sizes listed in Cat. GT 55-1. Other sizes on application.

**TYPE H INSHOT ATMOSPHERIC BURNER**, for Marine Boilers and other applications where horizontal flame is indicated. 30 sizes listed in Cat. H-1, others on application.

**TURBO-FIRE POWER TYPE GAS BURNER**. Refractory nozzles and distinctive air distribution giving desired flame characteristics. Factory assembled with prewired control panel. Sizes listed to 18,000,000 Btu hr in Cat. FG-1.

Also available dual fuel, gas-oil and gas-gas combination units. Write for details.

Turbo-Fire Power-Type Burner

GAS HEATING

EQUIPMENT

Buffalo 6, N. Y.

**NEW! MULTURI (Multiple Venturi) GAS BURNER**

Especially designed for **HARD-TO-FIRE**

• **SCOTCH MARINE BOILERS • STEEL FIRE BOX BOILERS AT HIGH FIRING RATES AT HIGH EFFICIENCY**

A Premix Type Gas Burner, ideal for commercial and industrial size boilers and warm air furnaces. Gives maximum performance from hard-to-fire Scotch Marine and steel fire box boilers. Flame characteristics make the burner appropriate for units with extensive refractory surface. Suitable for any gas at 4 in. gas pressure or more. Permits high firing rates at high efficiency. Simple to install, adjust, and operate. Completely Factory Wired and Assembled . . .

Ready for Immediate Installation!

**MULTURI BURNERS** are available in standard modular units of 6 to 54 mixers. Capacities from 1,200,000 to 10,800,000 Btu/hr. Special units of higher capacities can be furnished. Write or phone us for detailed information.

**NEW! COMBINATION GAS-OIL BURNERS**

362,000 to 4,300,000 Btu/hr.

25 1/10 to 30 Gallons of Oil

Completely Automatic Switch-over from 1 Fuel to Another. Write or phone for details.

**ROBERTS-GORDON APPLIANCE CORP., DEPARTMENT HVG • BUFFALO 6, N. Y.**

## The Sonner Burner Company

Designers and Manufacturers of Gas Conversion Burners and Unit Heaters

Offices and Factories: Winfield, Kansas

Type L-52 Heat Machine

Type LV SONNER Burner

Type D SONNER Burner

Type X-54 Burner

Sonner Gas Conversion Burners are a product of a quarter century of specialization in design and manufacture. A wide range of designs provides a Sonner Burner for domestic, commercial or industrial use. Consult Sonner Engineering for advice.

**TYPE L-52 HEAT MACHINE** is designed specifically for the conversion of residential heating plants to gas. Completely automatic burner is A.G.A. listed. Available in two sizes with capacities ranging from 75,000 to 400,000 Btu/hr. See Cat. 52-L-2.

**TYPE LV SONNER BURNER** for large heating and power boilers, handles a wide range of fuels. Standard assemblies from 320,000 to 7,200,000 Btu/hr are described in Cat. 52-LV-1. Step fired assemblies are described in Cat. 50-LVS-1.

**TYPE D SONNER BURNER** offers complete flexibility for all types and sizes of boilers and plants. Type "D" Burner Units can be readily manifolded into exactly the correct size and shape of burner for any kind of firebox. See Cat. 49-D-1.

**TYPE X-54 SONNER BURNER** specifically designed for replacing gun type oil burners in domestic furnaces or oil boilers. A.G.A. listed with inputs ranging from 75,000 to 175,000 Btu/hr. See Cat. 54-X-1.

**GAS OIL UNIT FOR COMMERCIAL AND INDUSTRIAL BOILERS**, two fuel burning units each designed for one fuel—natural gas, light fuel oils. Standard assemblies 280,000 to 2,800,000 Btu/hr input. See Cat. 52-CU-1.

Sonner Gas Oil Unit

## The Webster Engineering Company

115 South Frisco St., P.O. Box 2168

Tulsa, Oklahoma

Division of

SURFACE COMBUSTION CORPORATION, TOLEDO, OHIO

WEBSTER  
KINETIC\*

Low Pressure Atmospheric Gas Burner with full venturi mixers and Meehanite alloy flame retention nozzles. Compact and easy to install, the assemblies are available in any desired size and shape.

WEBSTER ROTONETIC\*

Dual Fuel Burner utilizing low pressure gas and any grade of commercial fuel oil under forced draft. Completely assembled, wired and tested at the factory; the units are available to 400 horsepower.

**WEBSTER ALSO MANUFACTURES:** Series F600 and Series 650 Vertical Gas Burners for Heating and Power Boilers. Series 340 Gas Burners for Vertical Boilers. Series VI and Webster Rectilinear High Pressure Inspirators for Boilers, Kilns, Stills, Dryers, Etc. Series 200 and Series R Combination Gas and Oil Burners for Power Boilers.

SALES and SERVICE IN ALL PRINCIPAL CITIES

\* Trade Mark

WEBSTER CYCLONETIC\*

The Webster Cyclonetic\* Dual Fuel Burner is designed to operate on either gas or light oil with only the flick of a switch necessary to change from one fuel to another. Employing 100 per cent forced draft, the Cyclonetic\* provides fully automatic operation on both fuels with complete programming and safety built in. Capacities from 675,000 to 4,000,000 Btu/hr.

WEBSTER DYNETIC\*

Forced Draft Gas Burner. A completely packaged unit available from 800,000 to 14,000,000 Btu/hr with low pressure gas.

## Cleaver-Brooks Company

498 E. Keefe Ave., Milwaukee 12, Wisconsin

Cleaver-Brooks oil, gas and combination oil and gas burners for commercial, industrial and institutional applications.

Use the most available and most economical fuel in your area. Burn oil, gas or combination oil or gas with equal efficiency.

Cleaver-Brooks conversion burners can be installed as easily as domestic burners to fire any acceptable boiler. Recommended for buildings containing over 1500 sq ft of radiation—or if 45 tons of coal or more than 6000 gallons of oil are burned per year.

GAS

Uses natural, mixed or manufactured gas. 9 models available.

### COMBINATION LIGHT OIL OR GAS

Combination burners have same Btu output, burning gas or oil as regular HEV-E-OIL burners.

OIL

15 models available. Burners equipped with automatic electric ignition. Motor starter delayed until oil at nozzle is heated. No expensive pilots needed.

ALC Burners use Honeywell RA 817A stack-mounted relay.

AMCH Burners use Honeywell R890C electronic relay—delayed start with thermostat, post purge and high-low air solenoid valve.

AMCF Burners use combustion controls Fireye FJ-2 electronic relay with immediate shut-down on flame failure, and non-return of ignition to meet Factory Mutual requirements.

All maximum capacities are necessarily approximate. Burners installed with adequate draft provisions and correct furnace volume, properly designed, will develop capacities indicated, at sea level.

#### APPLICATION

Enterprise Horizontal Rotary Burners are specifically designed for Commercial and Industrial use. Commercial heating includes heating plants in all types of buildings larger than private homes, including apartment houses, hotels, hospitals, schools, greenhouses, public buildings, offices, manufacturing plants. Industrial applications include furnaces, kilns, driers, etc.

#### MULTIPLE TYPES

**Manual**—To be started, regulated and stopped by operator.

**Semi-Automatic**—Started and stopped by operator, but automatically regulated by temperature or pressure control.

**Full-Automatic**—Burner automatically starts, stops, and is regulated to provide desired temperatures or steam pressure. Fixed fire start available on smaller sizes. Low fire start for high-low or full modulating control on all sizes.

All burners available with either **Standard gear pump** or **P. D. Metering Pump** or **Non-pump** (for use with separate pump set).

Any grade of fuel oil is burned efficiently—No. 6 (Bunker C) fuel is burned by burners equipped with oil heating system.

#### COMBINATION OIL-GAS BURNERS

All of the above types of burners are incorporated in combination type burner

to burn either fuel oil or gas. Gas may be natural, manufactured, or L. P. gas.

#### STANDARD EQUIPMENT

All full-automatic burners are furnished with: V-Belt drive, with known advantages of standard electric motors. Gas-electric ignition—dual ignition on sizes G to M.

Interconnected linkage to provide proportionate mixing of oil and air or gas and air at all firing rates.

Optional open type or angular vane air nozzles for flame control.

Copper tubing—provides free flow of oil with minimum connections.

Operating and combustion safety controls—oil burners, temperature or electronic type—Combination Oil-Gas burners, electronic controls exclusively.

#### SPECIAL FEATURES

The **Enterprise P. D. Metering Pump** provides exact delivery of oil to the burner by positive displacement, rather than through a metering valve. This definitely insures correct oil supply and air proportioning regardless of the viscosity of the oil, resulting in high efficiency.

**Burner hinges** are provided with leak-proof "O" rings rather than conventional packing glands.

#### FULLY APPROVED

All Enterprise Burners have been tested, approved, and listed as standard by **Underwriters' Laboratories, Inc.** and by other recognized boards and bureaus of safety, measures, and controls.

**ENGINEERS** will be provided with complete engineering information, either by manufacturers or qualified distributors, upon request.

**MODEL 53 fully AUTOMATIC  
METERING PUMP BURNER**

This revolutionary new heavy-duty Johnson Burner will automatically maintain a fixed Air-Fuel Ratio regardless of variations in oil temperature and viscosity. This fact explains why the Model 53 Burner is so remarkably successful at starting up and operating automatically even when the oil in tank and lines is cold and difficult to pump.

Model 53 Metering Pump Oil Burner

The Model 53 Burner is built with a positive-displacement Metering Pump, a 3-Way Magnetic Oil Valve and a high efficiency Suction Pump. Because it keeps fuel and maintenance costs down to a minimum, the Model 53 is exceptionally economical to own and operate. And already it has achieved an enviable reputation for dependability and faithful performance.

Model 53 Burners are available in 8 sizes as listed below, with either Direct Drive or Belt Drive. Dual-Fuel Oil-and-Gas models are also available as shown at the bottom of this page.

| SIZE AND BHP | MOTOR HP | GPH OIL | SQ FT STEAM RADIATION |
|--------------|----------|---------|-----------------------|
| 25           | ¼        | 7½      | 3500                  |
| 50           | ¼        | 15      | 7000                  |
| 75           | ¼        | 22½     | 10500                 |
| 100          | ¾        | 30      | 14000                 |
| 150          | 1½       | 45      | 21000                 |
| 200          | 2        | 60      | 28000                 |

San Francisco 12, Cal.

Atlantic Seaboard Division  
629 Grove Street  
Jersey City 2, N. J.

There is a RAY Burner for every Heating Purpose.

### RAY FORCED DRAFT PACKAGED BURNER

FD-ARC Size #6 fully automatic, combination gas-oil, Forced Draft Packaged Burner.

A factory assembled unit readily applied to any type of boiler designed for forced draft operation. Fully automatic operation on oil, gas or combination gas-oil.

The combination gas-oil unit includes a rotary oil burner, integrated ring type gas burner, secondary air control with a forced draft fan, windbox, refractory support ring, completely wired control panel and pre-piping completely factory assembled for quick and easy installation to the boiler.

Oil components may be selected to burn any grade of oil with the secondary air control providing increased efficiency even with the difficult-to-burn catalytic residual #6 fuel oils. From 83 to 540 equivalent boiler horsepower.

### RAY COMBINATION OIL-GAS BURNERS

ARC-144 Model 50 for heavy oil and low pressure gas.

Type PC for oil and low pressure gas.

Type AR-HN Combination Oil and High Pressure Gas.

**ARC-MODEL 50.** Consists of a rotary type oil burner of Ray conventional design coupled with a gas housing for low pressure gas, from 2 in. WC to 10 in. WC. The gas burner parts provide for the introduction of gas in a manner which fully utilizes the energy in the high pressure air supplied by the rotary burner fan. Gas and primary air are intimately combined, in two stages, before mixing with the secondary air which is introduced through a vaned annular opening concentric with the nozzle. Change-over requires less than one minute. Available to burn any grade of oil in 9 sizes with capacities to 31,500,000 Btu/hr.

**TYPE HN** for gas pressures above 1 lb/sq in. may be used alone or in combination with a Ray Oil Burner. Built in ten sizes; in capacities to 48,000,000 Btu/hr.

**TYPE PC.** Combination gas-oil burner of the pressure atomizing type. Available in three sizes with capacities from 560,000 to 2,500,000 Btu/hr.

### RAY DOMESTIC AND MARINE BURNERS

Fully Automatic, Type JP, #2 or lighter oil.

Steam Turbine Drive, Type TG, all grades oil. Tested and approved for U. S. Navy Service.

Ray Warm Air Oil Furnace

**RAY PRESSURE ATOMIZING OIL BURNERS** Fully automatic for No. 2 oil, or lighter. AC or DC; capacities 1 to 18 gallons per hour.

**WARM AIR FURNACES** Built in five sizes, with input capacities of 105,000; 140,000; 230,000; 350,000; 450,000 Btu.

**RAY OIL WATER HEATERS** Five sizes. Capacities: 35, 45, 60, 75 and 100 gal. Maximum recovery rates: 100 to 240 gph.

**Products:** A complete line of Horizontal Rotary and Pressure Atomizing Oil Burners; Combination Oil-or-Gas Burners; Industrial Gas Burners; Forced Draft, packaged Burners; Oil Burning Water Heaters; Warm Air Furnaces.

Type AR-144 Size 10 for No. 6 oil. Available in 10 sizes from 2 to 110 gph. Fully automatic.

Fully Automatic Type AR-134, for No. 5 oil.

1 to 1000 Boiler hp Type AG. Manual, Semi-automatic control.

Type ARJP, Fully Automatic for heavy oil where gas for ignition not available.

### RAY HORIZONTAL ROTARY OIL BURNERS

Built in fully automatic, semi-automatic and manual types; in sizes from 1 to 1000 Boiler hp; to burn all grades of fuel oil.

Standard models include both direct and belt drives—the latter being recommended for use where other than 50 or 60 Cycles AC, or only DC is available. Types for straight electric or straight gas ignition; pump or gravity feeds. Direct drive types include a steam turbine driven model.

All fully automatic types for heavy oil incorporate the Ray Dual Pump and Reservoir, with the Ray VISCOSITY Valve, a patented, exclusive feature which automatically meters the correct amount of fuel at all times, regardless of changes in viscosity of the oil due to temperature variations. All larger sizes employ dual ignition system, consisting of dual high-voltage transformers, dual electric ignitors and dual gas valves. Fully automatic sizes 9 and 10 include as standard equipment electronic pilot and flame failure control.

Type BR-144, Belt Drive, Fully Automatic, Available in 8 sizes. Capacities from 2 to 110 gph.

NOTE: These ratings are predicated upon specific conditions of draft and furnace volume. It may be permissible, under desirable conditions, to operate at higher rates, or advisable under restricted conditions, to operate at reduced rates. Heating capacities are based upon 150,000 Btu per gal of oil for rotary burners and 140,000 Btu per gal of oil for pressure atomizing burners and upon an overall boiler efficiency of 75 per cent.

\* Steam capacity based on steam F and A 212 F.

## Rayfield-Staffco Burner Co.

2066 S. Canalport Ave. • Chicago 8, Ill.

DOMESTIC, COMMERCIAL AND INDUSTRIAL OIL BURNERS FOR ALL GRADES OF FUEL OILS, FOR SMALLEST TO LARGEST BUILDINGS.  
DOMESTIC AND SMALL COMMERCIAL AND INDUSTRIAL GAS BURNERS

### RAYFIELD-STAFFCO BURNERS for No. 4 or No. 5 HEAVY OILS

Model JR.—1.00 to 5.00 gph.  
Model D4—3.00 to 12.00 gph.  
Model D5—10.00 to 22.00 gph.  
Maximum 8,800 EDR

For No. 4 or No. 5 Heavy Oils

These fully automatic burners are designed to provide efficient heating with the cheaper grades of oil. Both models are all-electric operating, self-lubricating and have self-cleaning nozzles for long, trouble-free service. By utilizing the low-priced fuels, these units keep heating costs to a minimum. Ideal for smaller commercial and industrial application.

### RAYFIELD-STAFFCO ROTARY BURNERS FOR No. 5 and No. 6 HEAVIEST FUEL OILS

9 sizes ranging from 10 to 165  
gph firing rates  
Maximum 66,000 EDR

For No. 5 or No. 6 Heaviest Oils

These sturdy burners, known and used all over the world, give excellent results and are built for long life with minimum service. Available with many types of controls including mechanical, electrical and electronic types. All equipped with Regulating valves to maintain constant oil flow regardless of oil viscosity or temperature. Adjustable air vanes to produce any flame shape or size desired.

### SHELL COMBUSTION HEAD OIL BURNERS for No. 2 or No. 3 CATALYTIC OILS

### "POWER-FLAME" Gas Burners

The "POWER FLAME" forced draft burners offer **EXTREME FLEXIBILITY**. "FG" series Gun Type units are ideal where limited space is a factor such as Scotch Marine type boilers, narrow fire-box heaters and the like.

FG Series—Gun Type

Series "BFG" units—Block Type—designed for use where high capacities are required and minimum base heights for installation are available. Both types employ standard items of control equipment, are shipped as a package, factory wired and tested before shipment. Ask for Cat. Nos. FG-1055 and BFG-655 for complete specifications.

BFG Series—  
Spread-block type

### "COMBI-MATIC" Forced Draft GAS-OIL Burners

Listed as standard by Underwriters' Laboratories. The "FGO" Series units employ a "tube within a tube" principle to fire both fuels (gas and light oils) efficiently. Installation costs are reduced to a minimum since all units are packaged and factory wired and "FIRE TESTED BEFORE SHIPMENT." All units are pressure atomizing type, **SIMPLE TO INSTALL, SERVICE AND MAINTAIN.** Ask for Cat. No. FGO-9154 for complete specifications.

See other page for additional offices

STV

### SERIES STV GAS BURNER

Ideal for heating boiler installations. From one head to fifty heads. Quiet, efficient and economical operation. Write for literature.

VR

### SERIES VR VERTICAL GAS BURNER

This burner is of the "upshot" or vertical radiant type with multiple burner heads so designed as to entrain a certain amount of primary air from the total air entering through the louvre. The "VR" burners are especially designed to operate in boilers having low draft and small combustion space. Write for literature.

YC

### SERIES YC COMBINATION GAS AND OIL BURNER

The John Zink Series YC Combination Gas and Oil Burner is recommended for boilers and process furnaces where maximum heat release at low excess air and high heat density is required. Features of the Series YC are Rugged Weather-Proof Construction; Easy to Remove Fuel Guns; Lightweight Fuel Guns; Burn Any Commercial Fuel Oil; Burn Any Gas at Reasonable Pressure; Draft—Natural, Forced or Induced; Center Firing of Both Fuels; Will Operate with Either Fuel as well as in Combination; Can Be Equipped With Any Standard Type Controls.

Also: SMOKELESS FIELD FLARE BURNERS

## John Zink Company

### FLOOR FURNACES

A size for every home heating requirement. Small grille—fool proof—simple to operate—A.G.A. approved—sturdy construction.  
Sizes—35,000; 50,000 and 65,000 Btu input. Write for literature.

### NEW SUSPENDED UNIT HEATER (Series U H S Fan Type)

A.G.A. approved for Natural, Mixed, Manufactured or LP Gas. For clean, safe trouble-free heating of industrial and commercial establishments. A complete packaged unit that is fully automatic. Conserves valuable floor space. Designed for an attractive addition to any store or shop. Write for literature.

### CENTRAL GAS HEATERS (Horizontal-Vertical)

A truly universal, efficient, simple and compact central heating unit. Fully automatic, it is a complete packaged unit ready for installation. May be installed in the basement, attic, service closet or utility room. It is designed as a winter air conditioner with a summer switch to provide air circulation during warm weather. Two models available. Write for literature.

Also: EVAPORATIVE COOLERS, CONVERSION BURNERS,  
ATTIC FANS

## York-Shipley, Inc.

Main Office and Plants—York 16, Pennsylvania  
OIL AND/OR GAS-FIRED EQUIPMENT FOR INDUSTRY

York-Power provides a complete line of economical automatic heating and processing equipment, gas or oil-fired, for every industrial and commercial need.

York-Power Steam-Pak (illustrated) and Steam-Pakette Generators are designed for either low-pressure heating loads or high-pressure processing loads, from 15 to 500 hp using Nos. 3, 5, or 6 fuel oil, or gas.

York-Power Horizontal Rotary Burners come in a wide range of sizes, from 45 to 400 boiler hp; oil or combination oil or gas fired. Burners take Nos. 3, 5, or 6 oil.

York-Power Econol Burner, our latest oil-gas combination burner with improved low-cost operating features. Burns Nos. 1, 2, 3, 4 and 5 fuel oil. Available in two sizes: 36 and 75 max boiler rating hp at boiler outlet.

York-Power Scotch Marine (Illustrated) or Firebox Boiler Burners for efficient, low-cost heating. Oil and/or gas fired.

York-Power F/C (Factory Coordinated) Industrial Fuel Burning Systems now provide factory-packaged, industrial fuel burning systems, with all basic components pre-wired and mounted in position. Photo shows details of wiring of main control panel.

For further information write York-Shipley, Inc., or call the York-Shipley Distributor nearest you.

## Eddington Metal Specialty Company

Eddington, Pennsylvania

Filters, Nozzles, Valves, Stabilizers & Air Cones, Strainers, Adaptors, Inspection Mirrors, Servicemens' Nozzle Kits, Combustion Heads

### HIGH PRESSURE COMBUSTION HEAD (HP-53)

Developed especially to provide Air-Oil Mixture of Catalytic Fuel Oils at high CO<sub>2</sub> ratings. Excellent results in field tests with both steel and cast iron furnaces. Ready adaptation to conventional burners in field and by Oil Burner Manufacturers. Also available is a low pressure combustion head (LP-53) which converts high pressure oil burners to low pressure without change in housing design.

### FUEL OIL FILTER

For heating oils in pressure and gravity type oil burners, space heaters, water heaters, stoves and ranges. Light weight, sturdy aluminum construction. Staggered surface of cartridge provides maximum filtering area. Easily replaced by loosening a single bolt and without interrupting pipe connections. Completely interchangeable with other makes.

### DIMENSIONAL SPECIFICATIONS OF FILTERS

| MODEL NO. | HEIGHT                        | DIAMETER         | WEIGHT      | INLET                                         | OUTLET                                        | SURFACE AREA | UNDERWRITERS APPROVED |
|-----------|-------------------------------|------------------|-------------|-----------------------------------------------|-----------------------------------------------|--------------|-----------------------|
| S-252     | 6 $\frac{5}{16}$              | 4 $\frac{1}{16}$ | 1 lb 10 oz. | $\frac{1}{4}$ - $\frac{3}{8}$ - $\frac{1}{2}$ | $\frac{1}{4}$ - $\frac{3}{8}$ - $\frac{1}{2}$ | 98 sq in.    | 25 gph                |
| S-254     | 5 $\frac{1}{2}$ $\frac{1}{2}$ | 3 $\frac{1}{16}$ | 1 lb 5 oz.  | $\frac{3}{8}$                                 | $\frac{3}{8}$                                 | 72 sq in.    | 25 gph                |

### OIL BURNER NOZZLE

Stainless steel throughout with particularly high quality steel and finish of Tip, Disc, and Locknut for maximum wear and heat resistance. Supplied standard with Hollow (H), Semi Hollow (SH), and Solid (S) spray patterns. Custom made if so required for specific Combustion Heads, Boiler Burner Units, or Burners. Factory tested for spray angle, atomization, and actual rated capacity.

**METALBESTOS** DIVISION  
WILLIAM WALLACE COMPANY • BELMONT, CALIF.

## Be Sure of Safe Gas Venting

Use  
**METALBESTOS—**  
the insulated vent

### Right for you . . .

because Metalbestos is easily and quickly installed. Precision made couplers slip together without forcing . . . are tightly and permanently sealed without using mastic or cement. Adjustable lengths, adjustable elbows and other versatile fittings speed assembly and eliminate wasteful cutting and fitting. Your costs are lower, profits higher, because with Metalbestos you can make more installations per man per day.

### Right for your customers . . .

because Metalbestos assures safe, trouble-free venting for the lifetime of the house itself. Double-wall design provides an inner "hot stack" to create a strong venting draft and prevent condensation . . . and an air insulated outer pipe to protect adjacent wall surfaces from dangerous overheating. Joints that stay permanently tight and sturdy damage-resistant construction are further reasons why you can install Metalbestos and then forget it.

### Send for free copy of VENT INSTALLATION HANDBOOK

Based on the latest gas venting research, this pocket-size booklet contains complete, up-to-date information on venting practices plus many helpful installation tips. Write today for your copy. No obligation.

**METALBESTOS** DIVISION  
WILLIAM WALLACE COMPANY • BELMONT, CALIF.

## specify METALBESTOS for all Type B venting needs

RV Metalbestos Round Vent  
—for standard applications.

WV Metalbestos Oval Vent  
—for in-the-wall venting

Approved by *Underwriters' Laboratories*  
for use with approved gas appliances.

**DOUBLE-WALL DESIGN . . .** an inner "hot stack" for strong draft, minimum condensation . . . a cooler outer pipe for maximum protection of surrounding wall areas.

**QUICK COUPLERS . . .** and adjustable fittings for fast, low-cost installation.

**DURABLE CONSTRUCTION . . .** all metal, will never crack or break . . . makes a sturdy, tightly sealed venting system that will last the lifetime of the house itself.

Typical Metalbestos gas vent installation for two-story structure. Refer to adjacent list for identification of various fittings.

### SAFE, CORRECT VENTING FOR RECESSED WALL HEATERS

Metalbestos Type B-W Gas Vent is listed by *Underwriters' Laboratories, Inc.* for use with recessed wall heaters. Installation in 2 x 4 stud walls is simple with no furring out or extra insulation required. The narrow double-wall gas vent measuring only 2½ in. x 7¼ in. overall in cross section, when centered in standard stud walls provides a full ½ in. clearance from adjacent material. Furnished in 4 in. size in 3, 4 and 5-ft lengths.

1. Draft Hood Connector
2. RV Round Pipe
3. RV 90° Adjustable Round Elbow
4. RV Round to WV Oval Tee
5. WV Oval Pipe
6. WV Oval to RV Round Adapter
7. RV Round Increaser
8. RV Round Tee
9. Type B-W Wall Heater Vent
10. RV 45° Adjustable Round Elbow
11. RV Round Adjustable Length
12. RV Adjustable Roof Flashing
13. RV Storm Collar
14. RV Belmont Top

NOTE: RV Round pipe and fittings are furnished in sizes of 3 in. to 8 in. diameter. WV Oval Metalbestos and Type B-W Wall Heater Vent are available in standard 4 in. size only.

## AMERICAN DISTRICT STEAM DIVISION

AdSCO INDUSTRIES, INC.

20 MILBURN ST. BUFFALO 12, N. Y.  
PLANTS, BUFFALO, N. Y.—RICHMOND, CALIF.

EXPANSION JOINTS—HEATERS  
HEAT EXCHANGERS—STRAINERS  
SEPARATORS

### INSTANTANEOUS HEATERS

AdSCO instantaneous heaters are made in a large variety of types, including the simple U-bend instantaneous shown above, which is used to heat water for showers, dishwashers, laundries, and other purposes. These heaters are also used as Convertors for furnishing hot water to space heating systems.

Many straight-tube, float-head units are used as closed feed-water heaters; boiler blow-down heaters, and for various uses in the process industries.

### TANK SUCTION HEATERS

AdSCO tank suction heaters reduce viscosity of heavy oil or other fluids so they can be pumped economically. Instead of employing pipe coils on the bottom of the tank to raise the temperature of all the liquid, only the liquid to be pumped is heated. Steam waste is eliminated. These heaters are furnished with nozzle for welding into storage tanks or with flange for bolting to existing flanged nozzle.

### OIL PRE-HEATERS

AdSCO oil pre-heaters help obtain the highest performance from fuel oil by heating it properly for complete combustion in the burner. In many cases, the work done by oil pre-heaters permits the use of heavier grade, less costly fuel oil. These heaters frequently are used with AdSCO tank suction heaters, the two units making an efficient team.

### STORAGE HEATERS

AdSCO storage heaters are built in accordance with the ASME code for working pressures desired. Tanks are made of flange-quality steel, nickel-clad, or stainless-clad steel, or copper silicon alloy. Where alloy tanks are used, tube sheets are of non-corrosive metal, so that service water does not come in contact with any ferrous parts. Steel tanks can be lined with AdSCO Phenolic 6-2 or Adscote bitumastic to prevent corrosion. All units are equipped with cold-water spreaders. Manholes are heavily reinforced. Copper U-bend heating element is easily removed for cleaning.

### STRAINERS

AdSCO strainers remove dirt, scale and other foreign matter from steam, gas, air, water and oil lines. Their installation ahead of every regulator, pump, valve or trap protects this delicate equipment, reduces maintenance and prevents expensive shut-downs.

Type Y strainers with flanged ends, left, have large screen surfaces and are easily cleaned. Sizes 1½ in. to 14 in., pressures to 600 psig.

Type S strainers, right, are usually installed on suction side of pump. Five cover designs are available: lever and toggle, toggle and bolt, clamp, through bolt, and stud-bolt.

AdSCO separators (not shown here) remove moisture, oil and small solid matter from steam, air and gas lines. Available in vertical up-flow and down-flow as well as horizontal types. Sizes to 10 in. and pressures to 300 psig.

## Aerco Corporation

Paris Avenue, P.O. Box 248  
Northvale, N. J.

AERCO's Controlled "HTR" (Heat Transfer Rate) Heat Exchanger is a Compact Storage Water Heater featuring an Internal Compensator which:

Figure 1—Sectional drawing of Aerco Compact Storage Water Heater.

- Anticipates changes in required steam flow before the actual heat transfer takes place.
- Meters the steam flow accurately in direct proportion with load.
- Prevents surges in steam flow, eliminating need for large storage.
- Maintains ACCURATE control of outlet water temperature.
- Prevents OVERRIDE of outlet temperature on sudden interruption of water flow.

For UNIFORMLY VARYING LOADS (i.e. Hospital General Water Supply), the ability of the above heater to prevent steam flow surges ELIMINATES the need for large STORAGE.

For NON-UNIFORMLY VARYING LOADS or periodic high peak flows and low average demands (i.e. Small Commercial Laundry), the AERCO COMPACT STORAGE WATER HEATER with an Accumulator and Recirculating Pump (as shown in Figure 2) gives a low cost combination which also permits:

- Minimum storage volume for peak demands.
- Minimum steam input for required load.
- Accurate controlled outlet water temperature under all load conditions.

Figure 2—Aerco Compact Storage Water Heater in combination with Accumulator and Recirculating Pump.

### CONSTRUCTION

Shell fabricated to ASME Code Standards, of Flange Quality Steel with plastic or copper lining. Shell ends Cast-iron or Bronze. Internal parts of Copper or Brass. Tested for 125 psig operating pressure. Capacities, 300 to 25,000 gph.

### OPERATION

Cold water enters top, flows down through the Compensator, then up across steam coils to discharge at top. Steam feeds into coils through Steam Riser and leaves through Condensate Return.

Compensator anticipates and controls heat transfer rate by sensing changes in flow or incoming temperature before water passes over the heating coils. It accomplishes this by causing variations of temperature to occur at the Regulator bulb which are definitely related to changes in flow and incoming temperature as well as the final temperature.

Send for booklet: "THE NEW APPROACH To the Design of Hot Water Supply Systems" and Bulletin #22 for capacity data and sizes.

## General Fittings Company

Box 151K, East Greenwich, R.I., U.S.A.

HOT WATER HEATING AND HEAT TRANSFER

### GENERAL Instantaneous Water Heaters

For continuous supply of hot water for industrial service or processes, apartments, hotels, etc. No storage tank. Two types: steam or boiler water through shell instantly heats water drawn through copper coils as needed. Capacities to 300 gpm.

### GENERAL Fuel Oil Heaters

Baffle-type heaters for use with live steam, exhaust steam or boiler water through tubing; fuel oil through heater shell. U-type heaters for water-through shell, oil-through tubing. Capacities to 2,000 gph.

### GENERAL Converters

Compact, efficient heaters for supplying forced hot water heating systems. Two types available: for use with constant steam supply, or for mounting below boiler water level. Capacities to 9,000,000 Btu per hr.

### GENERAL Indirect U-Type Water Heaters

Horizontal heaters for use with large-size storage tanks. For use with steam source or below water-line installation on heating boilers.

### GENERAL Coil-Heated Tanks

Black Iron or Galvanized. Boiler water or steam through coils. Heater easily removable for cleaning.

Engineering

Corporation

8640 Pardee Lane, Saint Louis 23, Mo.

### ASME FABRICATION

### FRE-FLO INSTANTANEOUS WATER HEATER

Easily cleaned, straight tube with removable cover plate and floating head. Designed for heavy loads and fouling fluids. Standard sizes from 50 gph up.

### FRE-FLO RADIATION CONVERTER

Complete range of sizes. Used with steam or boiler water. Cast iron head, steel shell, copper U tubes and bronze tube supports or baffles.

### FRE-FLO STORAGE WATER HEATER

Steel (rust resistant lining optional) or alloys. Copper tubes on square pitch or flat bundles to set low in tank for use as condensate cooler or used where heavy fouling requires complete access for cleaning.

### FRE-FLO LOAD LEVELER

A simple, rugged, packaged water heater designed specifically for handling extreme surge loads, yet levels the steam load on your boiler. Will deliver one or two temperatures of your selection, individually controlled. The Fre-Flo Load Leveler is completely assembled, ready to connect to utilities. Sizes from 450 gph and up.

## Bell and Gossett Company

Morton Grove, Illinois

### HYDRO-FLO HOT WATER SYSTEMS AND SPECIALTIES

#### B & G Booster Pumps

The B & G Booster is the basic unit of a B & G *Hydro-Flo* Forced Hot Water Heating System. It is built as a horizontally driven unit for sound engineering reasons which have demonstrated their practical value in thousands of installations. This construction makes possible many desirable, exclusive features. For example, the patented water-tight Seal eliminates need for a stuffing box.

This Seal positively prevents entry of water into bearings. Shaft is of highly polished, hardened machine steel. The close-fitted Impeller makes every revolution count by holding water slippage to a minimum.

Oil Lubricated Bearings

B & G Boosters have a genuine oil-circulating lubrication system—one of the greatest reasons for quiet, dependable, economical operation. Oil is drawn up from the oil well by wool fibre wicking and dropped on the horizontal bearing surfaces. Medium grade motor oil is used and only a few drops at infrequent intervals are required.

SEE THE B & G HANDBOOK FOR COMPLETE DESIGNING DATA

1598

#### B & G Flo-Control Valves

This valve, installed in the main, shuts off circulation to radiators when heat is not needed, permitting summer operation of a B & G Indirect Water Heater. It also helps maintain a uniform room temperature during the heating season.

#### B & G Monoflo Fittings

B & G Monoflo Fittings permit the use of a *single* pipe main instead of the conventional flow and return lines. They are installed at the junction of the radiator risers to the single main and assure the diversion of the proper amount of heated water into each radiator. Savings in space, labor and materials are obviously effected. Available in cast-iron and copper.

#### B & G Motorized Valves

Thermostatically operated valves used to control boiler water flow through individual circuits of zoned heating systems.

#### B & G Universal Pumps

Designed for forced hot water heating systems in apartment and office buildings, factories, schools, etc. The Universal is not an ordinary centrifugal pump, but is specially designed to assure quiet operation, so essential in heating system applications.

### HOT WATER SYSTEMS AND SPECIALTIES

#### B & G Relief Valves

Designed and built to ASME requirements. Tested by National Board—labelled with ASME symbol.

For relieving excess boiler pressures in hot water heating systems, and in the lines of service water systems. B & G Relief Valves have the design features which assure dependable service.

#### B & G Reducing Valves

All working parts brass, with built-in strainer. Easily adjusted to meet varying building heights. Also high pressure reducing valves for protection of plumbing fixtures.

#### B & G Comfort Control System

Outdoor type, *wind-compensating* temperature control. The Regulator projects through the building wall, with the indoor end warmed by water in the radiation circuit. A small amount of this heat is conducted to the outside end, where it is dissipated at a rate dependent upon temperature and wind velocity. This heat dissipation governs the Control Valve, which permits hot boiler water to enter the system in required amounts.

#### B & G Type "WU" Heat Exchangers

A shell and tube heat exchanger with hot boiler water pumped through the shell by a B & G Booster, making possible big capacity in a small unit.

Pumping boiler water through the heater also affords excellent temperature control and permits use of much smaller pipe and fittings.

#### B & G Type "SU" Heat Exchangers

For heating water with steam. Ideal for industrial plants or wherever large volumes of hot water are required continuously for service water supply or process work. No storage tank required—the large heat transfer surface in these units heats water instantly as needed. Available in a wide range of capacities.

#### B & G Centrifugal Pumps

Design and construction based on years of experience in the industrial field. Rugged, compact units—built to withstand strain of continuous operation. Semi-open or enclosed impellers—motors flexible coupled or integral with pump. Series 1522 illustrated.

#### B & G Refrigeration Components

A very complete line of direct expansion evaporators, condensers, liquid receivers, combination liquid receivers and subcoolers for refrigeration and air conditioning. Special alloys may be incorporated in the units for those critical heat transfer applications.

## FORCED CIRCULATING THRUSH FLOW CONTROL SYSTEM OF HOT WATER HEATING AND HEATING SPECIALTIES

Horizontal Water Circulator

Thrush Flow Control System of Hot Water Heat assures continuous radiant heat whether used with radiant panels, convectors, radiant baseboards or radiators. Circulation is forced and operation is entirely automatic. It automatically compensates for outdoor weather changes. Hot water for kitchen, laundry and bath, both summer and winter is provided by the heating plant boiler. Piping plans and engineering assistance are available to the trade.

### THRUSH WATER CIRCULATORS

Forced circulating pumps for Hot Water Heating and Domestic Water Systems. Insure uniform heating. Quiet and efficient, long lived and vibration-free. Sealed-in lubrication. Made in 7 sizes,  $\frac{3}{4}$  in., 1 in.,  $1\frac{1}{4}$  in.,  $1\frac{1}{2}$  in., 2 in.,  $2\frac{1}{2}$  in., and 3 in. Hi-Head Horizontal Thrush Water Circulators, designed for use with radiant baseboards, convectors, radiant panels, etc., which require higher heads, are also available in 1 in.,  $1\frac{1}{4}$  in., and  $1\frac{1}{2}$  in. sizes.

Vertical with Air Tube

### THRUSH FLOW CONTROL VALVES

Special check valves for use on automatically fired boilers, automatically control circulation when installed with a Thrush Circulator. Close tight when circulator is not running, prevent gravity circulation when heat is not needed in the radiators. Available with Air Tube which vents air from boiler into pressure tank, greatly improving heating efficiency by eliminating air from the system. 1 in. through  $1\frac{1}{2}$  in. valves also available with solder type outlet unions. Also made in angle type with or without air tube and in horizontal type for zoning. Made in six sizes, 1 in.,  $1\frac{1}{4}$  in.,  $1\frac{1}{2}$  in., 2 in.,  $2\frac{1}{2}$  in. and 3 in.

Thrush Pressure Tank With Vacuum Breaker

### THRUSH PRESSURE TANKS NOW HAVE VACUUM BREAKER

Genuine Thrush Pressure Tanks are air tight... tested under pressure... and equipped with the convenient Thrush Vacuum Breaker at no extra cost. Easy to drain if waterlogged.

No. 18— $\frac{3}{4}$  in. Automatic Filling Valve

No. 4 Bronze or Iron  $\frac{1}{2}$  in.  $\frac{3}{4}$  in. and 1 in.

### THRUSH AUTOMATIC FILLING VALVES AND LOW PRESSURE RELIEF VALVES

Whenever system pressure drops below 12 lbs. city water pressure will automatically open the Thrush Automatic Filling Valve and admit water until the system is filled.

Thrush Relief Valves protect heating boilers from excess pressures. Large metal diaphragm assures positive closing and opening.

### ASME APPROVED NO. 46 THRUSH SAFETY RELIEF VALVE FOR HOT WATER HEATING SYSTEMS

Rated output of 283,500 Btu based on steam capacity discharge. Primarily a water relief valve designed to serve double duty of relieving water, as well as steam should critically high temperatures occur. Testing lever. 30 lbs pressure.  $\frac{3}{4}$  in. inlet, 1 in. outlet.

No. 75

No. 76

### NO. 75 THRUSH HIGH PRESSURE WATER RELIEF VALVES

To protect hot water heaters, range boilers and automatic water heaters from excess pressure. Factory setting 85 lb. Adjustable at factory to 150 lb maximum.

### NO. 76 HIGH PRESSURE AND TEMPERATURE RELIEF VALVES

The valve illustrated above at right has an added safety feature. It not only guards against excessive pressures, but also relieves if excessive temperatures develop. A fusible element melts at 210 F. Both types are designed for use in the hot water outlet line.

C. I. Patent No. 2,404,998 —Bronze Patent No. 2598148

### ADJUSTABLE THRUSH SUPPLY TEES FOR ONE PIPE SYSTEMS

Provide exact balancing of forced circulating one-pipe hot water heating systems. Easily adjusted. When branch flow is cut down main flow is increased, not retarded. Available in bronze with solder connections for use with copper pipe and in threaded cast iron for steel pipe. Non-adjustable tees also available.

### NO. 5 HOT WATER AIR VALVE

An inexpensive, dependable, automatic air vent for Hot Water coils, convectors, radiators, unit heaters, and high points of mains. Tapping  $\frac{1}{8}$  in., I.P.T.

### THRUSH TANK DRAIN

Combines Drain Valve and Vacuum Breaker in one handy, inexpensive fitting. Removing plug admits air to permit quick draining of waterlogged tank.

### WRITE FOR NEW CONDENSED CATALOG

Patent No. 2,180,620

### THRUSH WATER HEATERS

Highly efficient heat exchangers or converters. Fifteen sizes, for Hot Water or Steam. Pressure up to 150 lb water, 50 lb steam. Straight tubes readily cleanable. Provide Domestic Hot Water at low cost. Also used industrially for heating or cooling liquids.

1 in. and  $1\frac{1}{4}$  in., 2, 3 and 4 outlets

$\frac{3}{8}$  in. or  $\frac{1}{2}$  in.

### THRUSH MANIFOLDS AND BALANCING VALVES

Thrush Manifolds save time, space and labor installing Radiant Heating. Available in 1 in. and  $1\frac{1}{4}$  in. sizes, each with two, three or four  $\frac{3}{8}$  in. or  $\frac{1}{2}$  in. threaded branch outlets. Also available in  $1\frac{1}{4}$  in. and  $1\frac{1}{2}$  in. sizes with three or five  $\frac{3}{4}$  in. solder branch connections. Ends have solder connections. Manifold with Balancing Valves as shown above is used in return lines only. Used in supply lines without valves. Balancing Valves permit individual filling of each coil, eliminate air quickly and save time. Two types, three sizes,  $\frac{3}{8}$  in.,  $\frac{1}{2}$  in. or  $\frac{3}{4}$  in. Flared fittings for  $\frac{3}{8}$  in. and  $\frac{1}{2}$  in. tubing.

No. 5 Thrush Air Valve (2 in Box)

Thrush Tank Drain

## Taco Heaters, Incorporated

1160 Cranston Street, Cranston 9, R. I.  
TACO HEATERS OF CANADA, LTD., 4 Gilead Place, Toronto

### TACO CIRCULATORS

Easy to service in the field. Available in a full line— $\frac{3}{4}$  in. to 3 in. Motors are especially selected for quiet performance and low cost operation.

### TACO UNIVERSAL FLOW CHECK

An accurately weighted automatic valve. Opens when circulator is running. Closes when thermostat stops circulator to prevent hot boiler water entering system. For angle or horizontal application.

### TACO PANELTROL

Adjustable to deliver water to radiant heating panels for any temperature between 110 F and 150 F even though boiler water is kept at higher temperature for summer-winter hot water.

### TACO AUTOMATIC AIR VALVES

Taco-Vent is leak-proofed. A porous bronze plug limits the flow of water through valve. The Steam Vent eliminates pinging, clicking or hissing.

### TACO RELIEF AND REDUCING VALVES

Automatically maintains sufficient water and pressure in system. The new Taco ASME Relief Valve ( $\frac{3}{4}$  in.) handles 80 per cent of all hot water heating jobs, and is set to relieve at 29 lbs. Reducing Valve is factory set at 12 lbs.

Send for Catalog I-99 for complete information and engineering data.

### TACO VENTURI FITTINGS

Only one required per radiator on return ... use ordinary tee for supply. Powerful suction action draws water through radiator for positive circulation. May be used for above or below main radiation.

### TACO-MATIC VALVE

Designed primarily to protect the performance of a tankless hot water heater on a forced circulation hot water heating system. Also performs function of a reverse acting control, eliminating added cost.

### TACO AIR-SCOOP

Scoops air from hot water system by a series of baffles. Air is then vented to either atmosphere or expansion tank. When system is first filled ... vent radiators and high points once ... no return to job.

### TACO TEMPERING VALVE

Guards against excessively hot domestic hot water. Mixes cold water with hot water from Taco Tankless or storage heater to provide tempered water at fixtures.

### TACO WATER HEATERS, CONVERTORS AND CHILLERS

Taco Convertors and Water Heaters provide hot water and radiation for commercial and institutional heating purposes. Chillers are designed for chilling water in the air conditioning and refrigeration fields.

## AURORA® PUMP DIVISION

THE NEW YORK AIR BRAKE COMPANY  
40 LOUCKS STREET • AURORA • ILLINOIS

Manufacturers of  
Turbine-Type, Vertical and Horizontal Centrifugal and Special Design Pumps  
Distributors in Principal Cities

APCO Single Stage Turbine-Type Pumps. Also available in Two Stage.

Barring Unusual Conditions We MAINTAIN A COMPLETE STOCK FOR IMMEDIATE SHIPMENT

Packaged Duplex Apco-Matic Condensation Return Unit designed for smaller jobs. LARGER UNITS up to 150 gpm capacity, horizontal and vertical also available.

APCO PUMPS are IDEALLY SUITED to MANY HEATING and AIR CONDITIONING DUTIES—CAPACITIES UP TO 150 GPM—HEADS TO 600 FT.

FEATURES—APCO pumps are distinguished for their ability to deliver small capacities against high heads; their ability to deliver with but slight change in capacity or efficiency against drastic head variations. They possess these advanced features — SIMPLE — WEAR-FREE — COMPACT — HIGH EFFICIENCY — WILL NOT VAPOR BIND — HYDRAULICALLY BALANCED — ACCESSIBILITY — HIGH SUCTION LIFT

LOW HEAD

SMALL CAPACITY—SIDE SUCTION PUMPS

MEDIUM HEAD

At Left  
TYPE—SAC—Close Coupled, Caps 5 to 85 gpm. Heads to 45 ft. Sizes Available  $\frac{3}{4}$ ", 1 $\frac{1}{4}$ ", 2"

At Right  
TYPE—JMC—Close Coupled Caps, 5 to 150 gpm. Heads to 100 ft. Sizes Available 1", 1 $\frac{1}{4}$ ", 1 $\frac{3}{4}$ ", 2"

The SAC and JMC Close-Coupled Pumps are available in a PACKAGED Arrangement for IMMEDIATE DELIVERY. APPLICATIONS

Well suited as integral part of manufacturer's product such as air conditioning units, cooling towers, evaporator coolers, hot water circulators etc., also for general service.

CONSTRUCTION SPECIFICATIONS Made in bronze fitted, all iron or all bronze construction.

CASINGS, vertically split—end suction. High grade material as specified. Casting wearing ring is standard on Type JMC.

MECHANICAL SEAL is standard on all sizes and is located in packing cover—easily replaceable.

IMPELLER is balanced, enclosed type of high grade bronze material.

SHAFTS—Stainless steel on Types JMC, SAC and JA. Can be furnished on Type SA at additional cost.

MOTOR Built to NEMA specifications and equipped with STAINLESS STEEL shaft.

BALL BEARINGS—Permanently sealed against dust and moisture—No lubrication required.

AURORA CENTRIFUGAL PUMPS are available in many types and sizes—all noted for their streamline co-ordination between impellers and shells.

CONDENSED CATALOG "V"

## Buffalo Pumps

Division of Buffalo Forge Co.  
450 Broadway, Buffalo, N. Y.

A complete line of Centrifugal Pumps, Single and Double Suction, Single and Multi-stage, for all types of heating and air conditioning installations. Write for Engineering Bulletins mentioned below, or consult the Buffalo Engineering Representative in any principal City.

### DOUBLE SUCTION SINGLE STAGE PUMPS

Extensively used for handling chilled water and other air conditioning and clear water applications including air washers, these pumps are available in capacities from 10 to 14,000 U.S. gallons per minute, against heads up to 350 ft. Highly efficient operation is provided by their simply formed water passages and their hydraulically balanced impellers (water enters each side of impeller, with equal pressure and volume). All parts are

ample for durability under hard service. Top half of the casing is readily removable for servicing without disturbing piping. Write for *BULLETIN 965-Q*.

### CLOSE-COUPLED SINGLE SUCTION PUMPS

These pumps offer the advantages of compactness, high performance and simple installation without need for shaft alignment. (A 4 in. pump, delivering 600 gpm at 60-ft head, requires less than 2 cu ft of space). Available in 1 in. to 6 in. discharge sizes. Design permits vertical or horizontal installation, with discharge adjustable to desired angle. These pumps are suited to handling hot water with low submergence. Write for *BULLETIN 975-D*.

### SINGLE SUCTION MULTISTAGE PUMPS

Used for boiler-feed and other clear water service, these heavy-duty pumps are especially suited to delivering at high pressures and temperatures. Available in two and four stage models for capacities from 20 to 900 gpm at heads up to 1500 ft. Shaft is extra-heavy and oversize bearings support the shaft on

each end. Top-half of pump casing is removable for servicing without disturbing piping. Write for *BULLETIN 980-D*.

### AUTOMATIC SUMP PUMPS

These are shipped as preassembled units ready to put into the sump pit, wire and start pumping. No priming is necessary, since there is no suction lift. Thrust load is carried by ball bearings, and the shaft is fully enclosed to prevent fouling with waste or stringy matter from the sump. All parts are readily accessible. Write for *BULLETIN 963-H*.

DOMESTIC PUMP & MANUFACTURING CORP.  
SHIPPENSBURG • PENNSYLVANIA

INDUSTRIAL  
PUMPS

**"DOMESTIC"**  
FOUNDED 1903

COMMERCIAL  
PUMPS

Products: Return Line Vacuum Heating Pumps; Condensate Return Pumps; Vertical, Horizontal and Flange Mounted Centrifugal Circulating Pumps.

### THREE COMPLETE LINES OF VACUUM HEATING PUMPS

Type VLR Single and Duplex Units for Standard and Special capacities up to 20,000 sq ft EDR. *Bulletin S110*. Type VLS Single and VLD Duplex for Standard and Special capacities from 25,000 to 150,000 sq ft EDR. *Bulletin S130*. Type VCA with individually sized and separately controlled vacuum and condensate pumps. Air capacities up to 95 cfm at 20 in. Hg and condensate capacities up to 300 gpm at 75 psi. *Bulletin S150*.

Vacuum Pump Type VLR1

The heart of all Domestic-Ames Vacuum Pumps is the multi-orifice vacuum producer. Average air evacuating rate is twice its rating, reducing operating time and power cost. Removes up to 300 per cent of rated air capacity at start of heating cycle to shorten warm-up period. It is simple, efficient and capable of producing a near perfect vacuum. It will retain its original effectiveness year after year.

All types vacuum-tight accumulators (condensate receivers) available.

Vacuum Pump Type VCA4

### CONDENSATION AND BOILER FEED PUMPS

Single and Duplex Units for systems up to 150,000 sq ft EDR and 60 psi. Each motor of the Type CC Unit is controlled by its own float switch. *Bulletin S200*.

The BOILER FEED type CM Unit provides automatic water make-up to replace water lost from the system and to maintain the most efficient boiler steaming level. *Bulletin S200*.

UNDERGROUND CONDENSATE PUMPS are available for use where returns are either too low for a standard pump or below floor level. *Bulletin S240*

Condensation Pump Type CC2

All Domestic-Ames Vacuum Heating and Condensation Pumps have life-time cast iron receivers with low inlets. Vertical pump mountings put motors above dirt and water and contribute to unit's compact design. Pumps are close coupled for precision alignment and smooth, quiet operation.

### GENERAL PURPOSE CENTRIFUGAL PUMPS

New Domestic "Centriflo" for hot and cold liquids. Quiet, efficient and compact. Head to 200 ft capacities to 400 gpm. Bronze fitted, all iron or bronze. Mechanical seal or packing. Motors 1750 or 3500 rpm, 1 or 3 phase, open, totally closed or explosion proof. Flange mounted, vertical or horizontal close coupled. *Bulletin S680*

## Chicago Pump Company

622 W. Diversey Parkway Eastgate 7-1020

Chicago 14

**PRODUCTS**—Return Line Vacuum Heating and Boiler Feed Pumps, Condensation, House, Booster, Fire Pumps, Circulating, Brine, Sewage, Bilge, Sludge, Pneumatic and Tankless Water Supply Systems and Automatic Alternator for Duplex Sets of Pumps.

Fig. D-9900—Duplex "Condo-Vacs" with Duplex Double Automatic Control

### "CONDO-VAC"

Return Line Vacuum and Boiler Feed Pump for Heating Systems

No vacuum on stuffing boxes, ample clearance in rotating member. It costs less to operate a "Condo-Vac." "Condo-Vac" reduces corrosion in piping and boiler to minimum—because pump does not take in air from atmosphere and entirely eliminates all air coming back from system. "Condo-Vac" is quiet, has a low inlet, entirely automatic, fool-proof, easy to maintain. Ask for Bulletin 270.

For every heating system get the pump that is specifically designed for the particular job. For below floor returns, for low vacuum systems, for small capacity

high pressure requirements, for any standard heating system, or any unusual condition, there is a CHICAGO Heating Pump that will do the job better.

Fig. D-9800

### "SURE-RETURN" CONDENSATION PUMPS

for Low and Medium Pressure, and Systems up to 75,000 Sq Ft Radiation

"Sure-Return" Condensation Pumps and Receivers are built for systems up to 75,000 sq ft of direct radiation and for low and medium pressures. Built in either single or duplex units. Duplex units are alternated in their operation by the Automatic Alternator. Complete data in Bulletin 250.

### VERTICAL CONDENSATION PUMPS

for Low and Medium Pressure for Systems from 500 to 100,000 Sq Ft Radiation

The vertical condensation pump is designed to receive returns from lowest radiation. The receiver is placed underground—an ordinary hole sufficing if necessary—and requires very little floor space. Unit is shipped complete, easy to install, assembled so as to prevent steam leaks. Special bearings will stand up under hot water for several years. A special float mechanism is guaranteed not to leak or stick in stuffing box. Complete data and description in Bulletins 245, 253 and 255.

Fig. V-9800 Vertical Condensation Pump

## Chicago Pump Company

622 W. Diversey Parkway

Eastgate 7-1020

Chicago 14

**PRODUCTS**—Return Line Vacuum Heating and Boiler Feed Pumps, Condensation, House, Booster, Fire Pumps, Circulating, Brine, Sewage, Bilge, Sludge, Pneumatic and Tankless Water Supply Systems and Automatic Alternator for Duplex Sets of Pumps.

### TYPE D, DOUBLE SUCTION, HORIZONTALLY SPLIT CASE PUMP

For house pump, fire and booster service. A ruggedly built, heavy duty pump for long trouble-free service. The rotating assembly may be inspected without disconnecting the piping. Capacities up to 1900 gpm—heads to 530 ft. Described in Bulletin 101.

Type D, Double Suction, Horizontally Split Case Pump

For circulating service, heating, bilge, or sewage pumping, CHICAGO equipment is among the best available. Each pump is specifically designed to do the particular job and do it right. Over 40 years ex-

perience with pumps for every application is built into every unit.

For "worry proof" pumping at all times—specify CHICAGO Industrial Pumps.

### TYPE C-C, CLOSE COUPLED BOOSTER PUMP

Designed to handle the toughest pumping jobs efficiently and in the least possible space. May be mounted in any position as long as the motor is not lower than the pump. Provided with leak-proof mechanical seal. Capacities up to 500 gpm—heads to 215 ft. Described in Bulletin 108.

Type C-C, Close Coupled Booster Pump

### TYPE F-C, PEDESTAL MOUNTED, SIDE SUCTION PUMP

Built to the same exacting engineering standards as the Type C-C Pump and with the same capacity and head. The flexible coupling drive permits easy field servicing and the use of customer's choice of motor manufacture. Described in Bulletin 107.

Type F-C, Pedestal Mounted, Side Suction Pump

## The Nash Engineering Company

234 Wilson Road

South Norwalk, Conn., U. S. A.

Sales and Service Offices in all Principal Cities

**NASH HOSPITAL PUMPS**

For vacuum and pressure systems in hospitals to provide vacuum or pressure to operating rooms, laboratories and wards. Nash pumps possess particular characteristics adapting them to this exacting service. Silent service is assured, because the pumps and equipment are installed in a mechanical equipment room. Automatic control assures constant maintenance of the correct vacuum or pressure. No pulsation is present in either vacuum or pressure produced by Nash Pumps. Air delivered by Nash Compressors is entirely free from dust, heat or oil. Even dust entering the pump inlet is effectively removed. No oil or dust filters are required. No expert attendance is required. *Bulletin on request.*

**CONDENSATION PUMP TYPE CS**

Following the advanced design of our CSM Heating Pumps, the CS Condensation Pump has features representing long life, dependable operation and low maintenance and installation cost.

Pump is single suction centrifugal in bronze fitted construction with renewable bronze sealing rings. Balanced impeller is designed for high efficiency handling hot condensate. Pump and motor form a compact unit. Simple mechanical seal replaces conventional stuffing box, eliminating maintenance. Strainer area nearly three times that in previous pumps. Easily removed for cleaning. Inlet connection is only 12, 14 or 15 inches, depending upon size of unit, permitting easy and low cost installation. *Bulletin on request.*

## The Nash Engineering Company

234 Wilson Road

South Norwalk, Conn., U. S. A.

Sales and Service Offices in all Principal Cities

**RETURN LINE VACUUM HEATING PUMP  
TYPE CSM**

The new CSM Heating Pump achieves a high level of performance and efficiency. Complete flexibility is secured in this design, since each pumping element is driven by its own motor, actuated by its own control.

This makes possible a wide range of air and water capacities that can be selected to meet the exact requirements of each particular job.

These pumps are now available in a full range of air and water capacity combinations, for operation up to 20 inches Hg vacuum, and for pressures from 10 lbs to 70 lbs. *Bulletin on request.*

**RETURN LINE VACUUM HEATING PUMP  
UNIT TYPE**

Removes air and condensation from return lines of vacuum heating systems. Separation of liquid and gas is made under vacuum. Independent air and water units, combined in single casing and rotating on single shaft, handle returns with high efficiency. Air unit delivers to atmosphere without back pressure. Water unit delivers directly to boiler. Bronze fitted throughout. No internal wearing parts. No internal lubrication. Supplied direct connected to electric motor, or for belt drive, for continuous operation or with automatic control. Standard capacities up to 40,000 sq ft equivalent direct radiation. Larger units special. *Bulletin on request.*

**KRAISSL** CO.  
INC.

297 Williams Ave. Hackensack, N.J.

Sales representatives in principal cities.

Pumps and separators for fuel oil burner and heating service; circulators for water service; filters and strainers for oil, water, liquids, air and steam applications.

### Class 50 Light Oil Pumps

Direct drive for No. 1 to No. 4 oils inclusive. High suction lift; pressures up to 100 psi. Ask for *bulletin A-1330*. Particularly adapted to dirty oil conditions where extraneous matter would cause seizure in more closely fitted mechanisms. Capacity 1 to 10 gpm. Class 60 M Pumps provide capacities from 2 to 212 gpm; special bearings available for solvent service.

### Class 60 Heavy Oil Pumps

Reduction drive for heavy oils including No. 6 and blended No. 5—for direct burner operation or booster pump application. Internal gear type, machined to close tolerances for max. vacuum characteristics. Ball bearing, V-belt reduction drive—connected to pump by loose coupling—eliminate side deflection from pump shaft. Suction and discharge  $\frac{1}{2}$  in. to 2 in.; capacities 75 to 2100 gph; pressures to 100 psi. Write for *bulletin A-1193*

### Class 72 Separators

Strainers or filters for both suction and discharge service on every burner installation. Single and duplex units for both standard and high pressure service. Design features ease of cleaning and interchangeability of separator baskets. Available with *Underwriters Labels* from  $\frac{1}{4}$  in. to 4 in.; larger sizes up to 6 in. Ask for *bulletin A-1430*

UL listed single strainers for installation as integral part of pump type burners. Any practical degree of separation; sizes  $\frac{1}{4}$  in. to 4 in. inclusive. Ask for *bulletin A-1214*

### Class 34 Water Circulators

Enclosed-impeller type centrifugal pump for both vertical and horizontal mountings—particularly suitable for high head applications. Ball bearing construction, replaceable wear plate, simplified dismounting and remounting without complete disassembly. Capacities up to 140 gpm. Ask for *bulletin A-1531*

## Skidmore Corporation

St. Joseph, Michigan

Quality Heating Pumps for over a quarter of a century

Write for  
*Bulletin No. 19-A*  
on Type UV Pump  
*Bulletin No. 21-B*  
on Type CV Pump

### SKIDMORE TYPE UV PUMP

The Skidmore Type UV Condensation Pump, single or duplex unit, is designed for use where returns are too low to permit the operation of horizontal type pumps. Type UV Pump operates very satisfactorily where condensate is to be returned to the boiler or other points, from all types of steam heating systems or process equipment. Type UV Pump consists of vertical pump and motor unit with float and float switch mechanism mounted on cover plate which is bolted to sump type receiver. Capacities 2000 to 40,000 sq ft EDR and discharge pressures from 10 to 75 lbs.

### SKIDMORE TYPE CVS PUMP

The Skidmore Type CVS Condensate Pump is built for maximum efficiency, requires a minimum of space. Designed in both single and duplex units. Shown above is the duplex pump with two float switches. This model also furnished with automatic alternator on all sizes. Integral pump casing and motor stand of cast iron construction, bolted to top of receiver. Pump bronze fitted throughout, with enclosed centrifugal impeller of special design for hot water. Capacities 500 to 10,000 sq ft EDR, pressures from 10 to 40 lbs.

Write for  
*Bulletin No. 14-A*  
on Type HS Pump  
*Bulletin No. 17*  
on Type TM Pump

### SKIDMORE TYPE HS PUMP

The model HS Condensation pump is economically designed to offer maximum efficiency with lower operating cost. The Type HS will operate at high temperature encountered in condensation pump service. The pump can be disassembled without disturbing piping connections. Furnished in either single or duplex type. Pump casing is constructed of heavy close grain cast iron, vertically split, bronze fitted throughout. Capacities 1,000 to 65,000 sq ft EDR, pressures 10 to 75 lbs.

### SKIDMORE TYPE TM PUMP

Type TM pump consists of motor, steel receiver, automatic make-up valve mounted on receiver, water level gage glass mounted on receiver, self-cleaning strainer between pump and receiver, assembled and mounted on steel base. Cast iron base furnished if required. Electric boiler water level controller furnished for mounting on boiler. The Type TM Condensate and makeup water pump is of turbine type designed for boilers up to 250 hp and pressures up to 150 lbs.

## SUPER-SILVERTOP STEAM TRAPS

Inverted bucket steam traps of an improved, thoroughly tested design. For use on steam-using equipment where it is desired to remove condensate and air automatically in order to produce maximum heating efficiency.

### FEATURES

**Simplified Piping**—Hooks up as an elbow or straight-in-line—only one nipple needed since the U-tube is inside the trap. Saves 3 elbows, 3 nipples and 60 minutes of time, compared to conventional inverted bucket steam traps.

**Precision Parts Alignment**—The bucket does not swing free. It is controlled in true engineering fashion, guided on a hexagonal tube. This makes a knife-edge contact, eliminating almost all friction. The unusual guide arrangement keeps all parts in proper alignment and prevents the bucket from hitting the sidewalls of the case. Positive closing of the valve is insured.

**Self-Cleaning**—The reversing of the condensate flow on entering the trap produces a scrubbing action. This stirs up any sediment and dirt which is carried away in the discharging condensate.

**No Restricting Passages**—Even in the smallest sizes there are no narrow cored passages to become clogged with scale.

**Cannot Air-Bind**—As the air is automatically discharged ahead of the condensate in each cycle of operation.

**Vacuum or Pressure**—These traps do not leak steam. No danger of vacuum being destroyed—trap is recommended for vacuum operation.

Standard

Heat-Kwik

## THREE TYPES OF STEAM TRAPS

**Standard Inverted Bucket**—Use where normal heat-up periods are satisfactory.

**Thermal Air Eliminator**—This trap should always be used where instant heat is necessary.

**Heat-Kwik Traps**—Designed for extremely fast air elimination at pressures up to 150 psi. Recommended for all production units such as steam jacketed kettles, autoclaves, dryers, sterilizers, etc.

### SIZES, LIST PRICES, AND CAPACITIES (Standard Steam Traps)

| Size No. Trap     | 110     | 118     | 119     | 120       | 121       | 122     | 23        | 24      | 25        |

Anderson Air Release Valve No 171

## Anderson Air Release Valves

Anderson air release valves are automatic air vents used for venting air from hot water service and heating systems. Eliminates the annoying venting of air through faucets when water is first turned on. The air release valve consists of an extremely durable valve and seat, a fool-proof lever and ball float which opens or closes the valve, depending upon the presence of water or air. Write for Bulletin No. 454.

Anderson Hi-eF Purifiers are used on steam lines and in boilers to produce clean, dry steam. Type L shown here should always be used ahead of steam engines and turbines to protect this valuable equipment against slugs, line scale, moisture, salts and dirt. Internal type Hi-eF Purifiers should be installed in boilers to assure the delivery of clean, dry steam devoid of carryover, entrainment and condensate. Also for use in cleaning and drying air and other gases. Write for Bulletin No. 700.

## Hi-eF Purifiers

Anderson Hi-eF Purifier Type L

## Anderson Strainers

Anderson Self-Cleaning Strainers remove scale, grit, and sediment from the line ahead of steam traps, reducing valves, air tools, pumps, temperature regulators, etc. Stainless steel strainer screens (brass available on 2 1/2 in. and 3 in.) are standard equipment and have an extremely large free area. Standard screen for steam and other gases has 1/4 in. openings for liquids 1/2 in. openings. Other sizes of openings furnished when specified, prices on application.

### ARMSTRONG INVERTED BUCKET STEAM TRAPS

**FOR LOW PRESSURE HEATING**—for draining mains, risers, coils, convectors, radiators and unit heaters at pressure differentials from 1 lb up—vacuum, gravity or closed return systems. For EDR ratings and selection data, ask for Catalog J.

**FOR UNIT HEATERS.** Bulletin No. 2312 gives complete trap selection and installation data and lists Btu ratings for all sizes of 30 makes of heaters—free on request.

**FOR STEAM HEATED EQUIPMENT**—for draining all types of institutional and industrial units including hot water heaters and kitchen, hospital and laundry equipment. Ask for selection data.

**FEATURES.** High Quality Mechanisms in Armstrong traps for low and medium pressures are identical in design, workmanship and materials to those used in traps for 900 psig. 900F—see illustration.

Open float (inverted bucket) cannot collapse. Nothing to stick, bind or clog. Only two moving parts, heavily reinforced for wear. Corrosion-resistant materials. Non air-binding. Quick-acting. High capacity for size. No cooling legs required.

No. 800-814

No. 880-883

No. 801

No. 21

**OPEN FLOAT AND THERMOSTATIC**—for fast heat-up when steam is turned on to pipe coils, small on-and-off unit heaters. When trap is cold, large thermic vent discharges 500 to 1500 cu ft free air/hr. Thermic closes at 210 F and regular bucket vent handles normal air load. Specify "blast trap"—see table.

**INTEGRAL STRAINER TRAPS.** No. 880, 881, 882 and 883 have strainers in trap body, otherwise identical to 800, 811, 812 and 813 listed in table. No. 880 lists at \$11.50, 881 at \$16.00, 882 at \$25.50, 883 at \$34.00. Each costs less to buy and install than standard trap plus separate strainer.

**RIGHT ANGLE TRAP NO. 801.** Capacity and price same as No. 800 listed in table. For replacing old radiator traps or wherever angle connections are simplest.

**BOTTOM INLET TRAPS**—No. 211 through 214 have same mechanisms and capacities as No. 811 through 814 side inlet traps. No. 215 and 216 are larger. See table.

**AIR RELIEF TRAPS** (ball float) for venting air from high points in hot water systems and similar applications. Stainless steel mechanisms. No. 21 is 6 1/4 in. diameter, lists at \$16.00. No. 21-G fits in wall having 2 x 4 studs, lists at \$18.00. Ask for Bulletins 2062 and 450.

**Y-TYPE STRAINERS**—250 psig semi-steel bodies, stainless perforated or wire mesh screens. Blowout-proof stainless-clad asbestos gasket locked in place by bushing. Square bushing threads assure easy removal. List prices: 1/4 in., 3/8 in., 1/2 in.—\$2.75; 3/4 in.—\$3.25; 1 in.—\$4.00; 1 1/4 in.—\$5.00; 1 1/2 in.—\$6.50; 2 in.—\$10.00. Details in Bulletin 602.

**STEAM HUMIDIFIERS** for Stores, Offices, Hospitals, Factories, Churches, Laboratories, etc. Automatic, closely controlled humidification is provided by introduction of steam directly into the room. Installation is comparable to that of steam unit heaters. A room humidistat controls the solenoid steam admission valve and fan. The smallest unit, for up to 40,000 cu ft, lists at \$170.00. Large models available for installation in central air ducts. Air-operated models available for explosive atmospheres. Capacities range from 31 to 630 lbs/hr steam. Bulletin No. 500 gives complete information.

# Barnes & Jones

New York Office: 101 Park Avenue

34 Crafts Street

Newtonville 60, Mass.

Barnes & Jones Vapor and Vacuum Systems of Steam Heating; Modulation Valves; Adjustable-Orifice Radiator Valves; Packless Quick-Opening Radiator Valves; Thermostatic Radiator Traps; Thermostatic Trap Replacement Units; Condensators (Boiler Return Traps); Float and Thermostatic Traps; Strainers; Gages; Systems of Zone Control for Steam Heating. Complete Catalog on Request

## Vapor and Vacuum

Series K—The Series K Valve is of the modulating type equipped with dial and pointer to indicate whether the valve is open or shut or in an intermediate position. Lever or wheel handle.

Series F—The Series F Valve has no dial or pointer and is therefore furnished only with wheel handle or lock shield. Of same quality as Series K, but lower priced. Both Series K and Series F Valves are quick opening, have non-rising stems, renewable disc seats, of packless design. Made angle pattern in  $\frac{1}{2}$ ,  $\frac{3}{4}$ , 1, and  $1\frac{1}{4}$  in. sizes; straightway (globe) pattern in  $\frac{3}{4}$  and 1 in. sizes. For use in vapor or vacuum systems.

Type H—The Type H Valve is of the adjustable orifice type so arranged that the dial indicates at all times the size of the radiator for which the valve is adjusted. May be adjusted with steam on the system. Noiseless in operation. Lever or wheel handle, unauthorized tampering virtually impossible. Made for pressure differentials of 1, 2, 3, 4 and 5 pounds,  $\frac{3}{4}$  in. valve up to 100 sq ft. 1 in. valve over 100 sq ft.

Thermostatic Radiator Traps—The B & J precision made thermostatic trap contains the unique, patented cage unit which is a complete operating unit in itself. The cage assembly contains the double thermostatic element calibrated in the factory, and locked in correct adjustment with the trap seat, which is also an integral part of the cage unit. Suitable for pressures up to 15 lb  $\frac{1}{2}$  to 1 in. Medium and high pressure traps suitable for pressures between 15 lb and 100 lb can be furnished.

Float and Thermostatic Traps—Barnes & Jones F&T traps respond instantly to sudden loads and pass condensate, regardless of temperature, through water sealed float operated valve. Thermostatic element gives rapid air venting. Made in Low and Medium pressure ratings. All working parts are readily accessible. No special wrenches needed. No disconnecting of pipe lines.  $\frac{3}{4}$  to 2 in.

Cage Units—Most maintenance engineers believe in a regular check-up of their heating systems. Barnes and Jones make this check-up easy by providing a means for testing all steam traps, and for replacing the actuating units of any make trap. The B & J cage unit replaces all working parts. The double diaphragm unit is correctly and permanently adjusted before leaving the factory. Made for all sizes, pressures and makes of vapor and vacuum traps up to 65 lbs. It's a complete one-piece replacement containing thermostatic element, valve piece and seat locked in unalterable adjustment. No field calibration is necessary. Ask for *Bulletins C-34 and R-44*.

**PUMPS—CONDENSATE & VACUUM HEATING.** Condensate Pumps up to 65,000 sq ft EDR. Vacuum Pumps up to 100,000 sq ft EDR. 10 psi to 150 Psi Discharge Pressure. Steel or Cast Iron Receivers. Single & Duplex Units. 1750 rpm & 3500 rpm Units. Ask for *pump catalog*.

# A. W. CASH COMPANY

P. O. Box 551 • Decatur, Illinois

**CASH  
STANDARD**

## AUTOMATIC

PRESSURE, HYDRAULIC, TEMPERATURE,  
PROCESS AND COMBUSTION CONTROLS

The A. W. CASH COMPANY under trade mark CASH STANDARD manufactures a complete line of automatic valves, regulators, controllers, governors, hydraulic valves, refrigeration back pressure valves and complete process and combustion control systems. Typical examples.

**PRESSURE REDUCING AND REGULATING VALVES**  
Streamlined Reducing Valve, Type 1000. Three principles assure high capacity and close pressure control: streamlined inner valve eliminates turbulence; straight-line flow through valve housing; aspirating effect controls valve opening, amplifies slight pressure changes into large valve operating forces. High and low pressure models in eight sizes,  $\frac{1}{4}$  in. to 2 in. x  $2\frac{1}{2}$  in. (expanded outlet if desired).

Self Contained Pressure Reducing Valve, Type 1260. For steam, air, oils, water, gases, other fluids. Spherical self-cleaning inner valve rotates freely, seats in different positions at each closure. Built-in strainer protects seat. Screwed ends,  $\frac{1}{2}$  in.,  $\frac{3}{4}$  in. and 1 in.

Single Seat, Diaphragm Type Reducing Valve, Type D. For steam, hot or cold water, air, oils, many chemicals and gases. Free circulation around moving parts assures even expansion and contraction, prevents seizing. A simple, inexpensive valve. Screwed ends,  $\frac{1}{4}$  in. to 2 in.

## PILOT OPERATED VALVE

Pilot Operated Pressure Reducing Valve. Type 30-AP. For steam, air, most fluids. Pilot normally operated by independent fluid. Manner of connecting control lines to pilot and installing reversible inner valve makes it a pressure reducing and regulating valve or a relief or back pressure valve; determines whether main valve opens or closes with failure of operating fluid delivered to pilot. Screwed ends,  $\frac{1}{2}$  in. to 3 in.; flanged ends, 1 in. to 12 in.

## AUTOMATIC COMBUSTION CONTROL SYSTEMS

Cash Standard Systems are for use on all kinds of boilers (forced or natural draft), stokers and burners, and for coal, powdered coal, gas, oil, other fuels. All elements of efficient combustion controlled automatically; combustion rate regulated to keep pace with changes in steam demand.

Furnace Draft Controller, Type 90. Operates remotely installed hydraulic cylinder, normally regulating damper on forced draft jobs; either alone or as part of a system. Extremely sensitive; fully automatic; no packing or gasometer.

Air-Flow Controller, Type 95. Works with Type 100 to maintain proper flow of air to combustion chamber with respect to rate of combustion, automatically compensating for variables: fuel bed resistance, fan speed variation, number of boilers or fans in service.

Super Sensitive Automatic Controller, Type 100. Double-acting, with four-way valves. Operates balanced valves, chronometer valves, butterfly valves all sizes; controls fans and other motor driven apparatus. For vacuum and pressures to 600 lb gauge. Reduces and regulates pressure, relieves pressure, controls back pressure, maintains constant differential pressure or liquid level, controls rate of flow. For steam, water, air, salt brine, various gases, chemicals. Six sizes of power cylinder employed in many different models for wide variety of uses.

**CONVECTORS**—Attractive, easy-to-install. Use with hot water or steam. Eight models, capacities with steam 1 lb entering air 65F: 9 to 139 EDR. Dimensions: 4, 6, 8 and 10 in. wide; 18 to 112 in. long; 12 in. window convactor, 20, 24, 26, 32, and 38 in. high. Picture window, extra long, plaster front and institutional types also available.

**BASEBOARD**—Snap-on front baseboard for forced hot water, steam or vapor heating. Fits flush with floor. 10 in. high. Shipped in 10-ft lengths for easy, on-the-job cutting. Steel or copper elements shipped in 1- to 6-ft lengths. Semi-recessed and flush-back enclosures. 12 in. baseboard also available for commercial applications.

**FIN-VECTOR®**—Can be installed at any level above 4 in. from floor. Three style covers: sloping top, flat top, expanded metal. Adjustable hook-and-link hanger or new ball bearing bracket supports elements. One, two, or three tiers high. Two tube sizes, 1½ and 2 in. steel or copper tube. Self-spacing fins.

**THERMO VECTOR® RADIATION**  
For along-the-wall heating of educational, commercial or institutional buildings with steam or hot water. Flush-type model, one, two or three tiers high. Two tube sizes: 1½ in. and 2 in. Lever-operated damper.

Type F Convactor

Baseboard Radiation

FIN-VECTOR Radiation

THERMO VECTOR Radiation

VARI-TEMP® Heating-Cooling Unit

Horizontal Unit Heater

Vertical Unit Heater

Blower Type Unit Heater

Model C2 Vacuum Pump

**HEATING-COOLING UNITS**—For individual room heating with steam or forced hot water; cooling with chilled water; ventilating; heating and ventilating; or cooling and ventilating. Three different sizes can be floor, wall, ceiling or inverted mounted. Can be recessed or completely concealed. Capacities at 2 lb steam, 60 F ent. air: 21,000 to 84,000 Btu.

**UNIT HEATERS**—Type M, Model H and HM, not shown. Cabinet type. Seven styles, 3 sizes. Blower fans directly mounted on double end shaft motor. Capacities at 2 lb steam, 60 F ent. air: 18,000 to 108,000 Btu.

**UNIT HEATERS**—Type V. Horizontal discharge. 11 sizes, 2 models. Capacities at 2 lb steam, 60 F ent. air: 15,600 to 360,000 Btu per hour.

**UNIT HEATERS**—Type C. Vertical discharge. Four types of diffusers available. Ten sizes, 2 models. Capacities at 2 lb steam, 60 F ent. air: 42,000 to 576,000 Btu.

**UNIT HEATERS**—Blower, Type R. New, redesigned line. 5 types of mountings for floor, wall, ceiling, inverted or platform. Mixing dampers, by-pass dampers, filter sections available. Capacities at 2 lb steam, 60 F ent. air: 86,000 to 1,500,000 Btu per hour.

**VACUUM PUMPS**—Pull and maintain, at low amperage, up to 26 in. vacuum without dependence on close clearances. Only ONE principal moving part. Single motor easily handles BOTH air and condensate removal. Low 9¼-in. return line connections. Capacities: 2,500 to 65,000 EDR. Single or duplex units.

**CONDENSATION PUMPS**—Pumps feature mechanical seal that eliminates stuffing box worries. Capacities: 2,000 to 50,000 EDR. Single and duplex units.

Panel

**RADIATOR TRAPS**—For all types of low pressure steam heating systems. Body and cover of cast bronze, disc of Monel metal. Available in 6 patterns. Capacities from 200 to 700 EDR.

**THERMOSTATIC TRAPS**—Trap has cast brass body and cover; replaceable stainless steel valve and seat; disc of Monel metal. For 5 to 100 lb working pressures. Capacities from 125 to 4,500 lb of condensate per hour.

**FLOAT AND THERMOSTATIC TRAPS**—Use as drip trap for steam mains, unit heaters, heat exchangers. Float, copper; float valve and seat, Monel metal. Up to 15 psi gauge working pressure. Sizes:  $\frac{3}{4}$ , 1,  $1\frac{1}{4}$ ,  $1\frac{1}{2}$  and 2 in. with capacities from 100 to 5,750 lb of condensate per hour.

**INVERTED BUCKET TRAP**—Body and cover of high tensile iron castings. Valve and seat (renewable and interchangeable) are specially hardened, corrosion-resistant steel. Operating pressures 20 to 150 lb gauge. Sizes  $\frac{1}{2}$ ,  $\frac{3}{4}$ , 1 and  $1\frac{1}{4}$  in. Capacities from 220 to 5,600 lb of condensate per hour.

**SPRING PACKED VALVES**—For low-pressure systems up to 15 lb. Heavy coil spring keeps packing tight around valve stem. Body and bonnet, cast brass. Sizes:  $\frac{1}{2}$  to 2 in. in 4 body patterns.

**PACKLESS VALVES**—Packless construction (no packing spring or stuffing box) provides tight permanent seal. Sizes:  $\frac{1}{2}$  to  $1\frac{1}{2}$  in. in 4 body patterns.

**HOT WATER VALVES**—For hot water heating systems with pressure to 60 lb. Cast brass body. Packing nut, one-piece asbestos ring provides tight stem seal. Sizes:  $\frac{1}{2}$  to 2 in.

**PACKED STEM VALVES**—For low-pressure steam systems and hot water systems up to 60 lb. Cast brass body and bonnet. Sizes:  $\frac{1}{2}$  to 2 in.

## DUNHAM HEATING SYSTEMS

**VARI-VAC® DIFFERENTIAL VARI-VAC HEATING** saves up to 40 per cent on fuel because VARI-VAC automatically provides the exact amount of heat needed by using a continuous flow of sub-atmospheric steam at temperatures that vary with the weather.

**METRO®** single-riser method of piping, costs less to install and maintain. Provides continuous path for flow of steam from top to bottom of building. Continuous pipe runs down through overlying rooms and is offset into each room into convectors or baseboard radiation.

## DUNHAM CIRCULATORS

Standard and high head capacity models for all water heating or cooling systems. Single spring motor coupling. Special brand name motor with built-in overload protection. Extra-large oil reservoir. Field replaceable seals.

## FLOW CONTROL VALVES

Completely automatic. No adjustment for winter-summer operation. Easy to clean without breaking pipe connections or removing valve mechanism. Angle pattern: 1 to  $2\frac{1}{2}$  in. incl. Horizontal pattern: 1 to 3 in. incl.

## AIR SEPARATORS

Automatically remove air from forced hot water heating system. One-piece construction. Positively prevents re-entry of air into system. 30 psi working pressure. Sizes:  $\frac{3}{4}$  to  $2\frac{1}{2}$  in. incl.

## FLOW DIVERTOR FITTINGS

Assure proper water flow through all radiation. Only one fitting normally needed (on return) for each unit of radiation. Size (thread to thread): 1 in. x  $\frac{1}{2}$  in. to 2 in. x 1 in. incl.; (sweat to sweat):  $\frac{3}{4}$  in. x  $\frac{1}{2}$  in. to 1 in. x  $\frac{3}{4}$  in. incl.

## RELIEF AND REDUCING VALVES

Pressure Relief Valves have extra-large diaphragm area, non-stick design. Factory set at 30 lb. Pressure Reducing Valves have built-in strainer. Factory set 12 lb. Adjustable. Combination Relief and Reducing Valves available.

## CIRCULATOR VALVES

Extra-large flow area reduces water resistance and circulator load. T-type handle operates in only  $\frac{1}{4}$  turn. Straightway and angle patterns; thread or sweat; full range of sizes; 60 psi working pressure.

## BALANCING ELBOWS AND FITTINGS

Extra-large flow area. Unique sloping seat provides V-shaped opening for accurate balancing from full open to any degree of closure. Thread or sweat. Complete line includes vent tees, union elbows, connectors.

## AUTOMATIC AIR VENTS

Expansion Type Vents need no adjustment. Manual venting for rapid air removal when system is first filled. 50 lb. working pressure. Float Type Vent has built-in siphon to prevent water-logging. 35 lb. working pressure.

## VARI-FLOW® CONTROLS

Fully automatic indoor-outdoor temperature controls for all types of hot water heating systems. No seasonal adjustment needed. Immersion bulb and capillary "wrap-around" types.

## DISTRIBUTOR HEADS

For radiant panel and "spaghetti" type hot water heating. Same  $1\frac{1}{4}$  in. copper head usable for supply or return, both  $\frac{1}{2}$  and  $\frac{3}{8}$  in. tube connections. Each length has 14 pairs of connections.

C. A. Dunham Company manufactures a complete line of quality heating equipment. For catalogs and literature write: Dept. HVAC-56 C. A. Dunham Company, 400 W. Madison Street, Chicago 6, Ill., or see your local Dunham Sales Engineer.

## ENGINEERED VENT VALVES for STEAM and HOT WATER SYSTEMS

### UNIT HEATER STEAM VENT

No. 74 For steam unit heaters with working pressure up to 35 lbs. Vents air at any time with rising, dropping or steady pressure. Effectively eliminates air from the unit heater to keep it "Piping Hot" at all times. Capacity 300 C.I.M. at 1 lb press., and 800 C.I.M. at 10 lbs and over. Max. oper. press: 35 psi.

### MAIN VENTS FOR WATER SYSTEMS

No. 79 Valve tapped at top for 1/4 in. waste pipe conn. Gives continuous venting under all conditions. Size conn: 3/4 in. male, 1/2 in. female. Max. oper. press: 75 psi.

No. 791 Can be easily taken apart for cleaning. Tapped at top for 1/8 in. drain conn. Size conn: 1/4 in. Max. oper. press: 35 psi.

No. 79 and No. 791

### CONVECTOR VENTS—Steam

No. 1-B Adjustable port. Non-vacuum. Size conn: 1/4 in. Max. oper. press: 10 psi.

No. 71-A Single port, non-vacuum. Size conn: 1/8 in. Max. oper. press: 15 psi.

No. 71-B Single port, non-vacuum. Size conn: 1/4 in. Max. oper. press: 15 psi.

No. 71-C Single port, non-vacuum. Size conn: 3/4 in. male, 1/2 in. female. Max. oper. press: 15 psi.

No. 41 & 43 No. 41 single port, non-vacuum. Size conn: 1/8 in. Max. oper. press: 10 psi. No. 43 same as No. 41 except size conn: 1/4 in.

No. 45 Single port, non-vacuum. Size conn: 3/4 in. male, 1/2 in. female. Max. oper. press: 10 psi.

### MAIN VENTS—Steam

No. 4 Small non-vacuum steam mains. Size conn: 3/4 in. male, 1/2 in. female. Max. oper. press: 25 psi.

No. 4-A For one-pipe or two-pipe non-vacuum systems. Size conn: 3/4 in. male, 1/2 in. female. Max. oper. press: 10 psi.

No. 16-A Small one-pipe vacuum systems. Non-adjustable port. Size conn: 3/4 in. male, 1/2 in. female. Max. oper. press: 10 psi.

No. 75 Medium size non-vacuum systems. Single port. Float. Size conn: 3/4 in. male, 1/2 in. female. Max. oper. press: 10 psi.

No. 75-A Similar to No. 75 except for larger systems. Size conn: 3/4 in. male, 1/2 in. female. Max. oper. press: 10 psi.

No. 76 For one-pipe medium size vacuum systems. Single port. Size conn: 3/4 in. male, 1/2 in. female. Max. oper. press: 10 psi.

No. 76-A Similar to No. 76, except larger venting capacity. Size conn: 3/4 in. male, 1/2 in. female. Max. oper. press: 10 psi.

### RADIATOR VENTS

No. 1-A Adjustable vent ports, non-vacuum. Size conn: 1/8 in. Max. oper. press: 10 psi.

No. 2-A Adjustable port vacuum valve. Size conn: 1/8 in. Max. oper. press: 10 psi.

No. 70-A Single port, non-vacuum. Meets Federal spec. W W—V-151 for Type 1 valves. Size conn: 1/8 in. Max. oper. press: 15 psi.

No. 1000 Large single port, non-vacuum. Size conn: 1/8 in. Max. oper. press: 10 psi.

No. 40 Single port, non-vacuum. Size conn: 1/8 in. Max. oper. press: 10 psi.

No. 500 Vents all systems automatically. Size conn: 1/8 in. Max. water press: 50 lbs Max. steam press: 15 psi.

No. 71-A, B and C

No. 75, 75A

No. 1A, 2A

No. 500

## LOW, MEDIUM AND HIGH PRESSURE THERMOSTATIC TRAPS

Low Pressure Thermostatic Trap

Medium Pressure

High Pressure

Low pressure traps have brass bodies, caps and union nut and tailpiece. 17C is made in Angle, Swivel and Vertical patterns. 8C is made in Angle and Straightway patterns. 9C is made in Angle pattern only. Thermostat and seat both renewable.

No. 17C Capacity 200 sq ft EDR 25 lb pressure 1/2 in. connection

No. 8C Capacity 400 sq ft EDR 25 lb pressure 3/4 in. connection

No. 9C Capacity 700 sq ft EDR 25 lb pressure 1 in. connection

Medium Pressure Nos. 8 & 9 and High Pressure Nos. 8H & 9H have all bronze bodies and caps with union nut and tailpiece. Thermostats are 6 diaphragms of special non-corrosive metal. Thermostats and seats are renewable. 1/2 in. sizes are furnished in Angle, R.H., L.H. and Straightway patterns, others in Angle only. Medium Press. 50 lb limit. High Press. 125 lb.

Capacities—Lb Condensate per Hour—Working Pressure—Lb per Sq In. Gage

| Traps | 5   | 15  | 25  | 50  | Traps | 25  | 50  | 100  | 125  |
|-------|-----|-----|-----|-----|-------|-----|-----|------|------|
| 8     | 100 | 180 | 235 | 400 | 8H    | 235 | 400 | 550  | 590  |
| 8     | 125 | 225 | 300 | 490 | 8H    | 300 | 490 | 650  | 720  |
| 9     | 225 | 350 | 450 | 650 | 9H    | 450 | 650 | 875  | 950  |
| 9     | 325 | 500 | 625 | 850 | 9H    | 625 | 850 | 1125 | 1250 |

## F & T TRAPS, DIRT STRAINERS AND SUPPLY VALVES

F & T Trap

Dirt Strainer

Supply Valve

50 Series Float and Therm. Traps are available in pressure ranges to 125 lbs. Used for venting and draining risers, steam mains, unit heaters, blast coils, etc. 50 Series Traps are made for easy servicing with all working parts mounted on cover. Remove four bolts to expose all parts. Pipe sizes are from 3/4 in. to 2 in. cap. from 70 to 12,000 lbs. condensate per hour.

Radiator Supply Valves are made in sizes from 1/2 to 2 in. in Angle, R.H., L.H., and Straightway patterns. Brass bodies, union nut and tailpiece. Nos. 180 and 185 have non-rising handles. Both are packless. No. 186 is especially suited to vacuum systems.

Hoffman Dirt Strainers are self-cleaning Y type. Brass strainer cylinders and cast iron body. Sizes 1/2 to 2 in. for 125 lb pressure. Should be used in line ahead of all float and thermostatic traps. Also available with monel metal strainers.

## CONDENSATION AND VACUUM PUMPS

Hoffman pumps are available in varying capacities, a-c and d-c current, single, two, or three phase, and in pressures up to 60 lbs.

Vacuum Pumps  
Single and Duplex  
Units Capacities  
from 8,500 to 100,000  
sq ft EDR

Condensation Pump  
Single and Duplex  
Units Capacities  
from 1,000 to 160,000  
sq ft EDR

## HOFFMAN INVERTED BUCKET TRAPS

### Working Pressures to 250 lbs

Simple mechanism assures high operating efficiency. Features include—straight-through pipe connection; simple seat adjustment; all working parts connected to bonnet and easily removed with it; stainless steel seat and pin.

## HOFFMAN PRESS. REDUCING VALVES

Series 700 Max. Press. 200 psi., Low  
Press. 1 to 25 psi.  
Series 710 Max. Press. 250 psi., Low  
Press. 5 to 80 psi.  
Series 715 Max. Press. 250 psi., Low  
Press. 2½ to 125 psi.  
Series 720-S & 720-W Max. Press. 250 psi.,  
Low Press. 2 to 125 psi.  
Series 750 Max. Press. 250 psi., Low  
Press. 2½ to 25 psi.

Choice of types specifically engineered for your needs—continuous service, or, for tight sealing against low pressure side when there is no demand—and with typical Hoffman features of design.

## HOFFMAN TEMPERATURE REGULATORS

**Series 1100**—for steam pressure to 150 lb per sq in. Standard temperature range—80 F to 250 F. Other ranges available on special order. Self-motivated. Hydraulically formed bellows of selected material. Rugged construction. For water heaters, convectors, fuel oil preheaters and other similar applications.

## HOFFMAN "ZONET" ZONE CONTROL

**Series 1200**—Zonet systems or packages for Steam and Hot Water consist of heat anticipating Room Thermostat, motor operated Globe Type Valve, Transformer, Fuse Block and fuse, and in the case of steam zoning, a Vacuum Breaker. The motor operated, two position, single seated, packed globe type Valve (illustrated) is available in sizes from ½ in. to 6 in. Maximum service pressure: steam 100 lbs per sq in., water 150 lbs per sq in.

## WALL AND BASEBOARD RADIATION

Series "S" Wall Radiation made of 18 gauge steel in 1, 2 and 3 tier heights for either 3¼ in. or 4¼ in. steel or aluminum fin element.

Series "F" Wall Radiation made of 20 gauge steel in 1, 2 and 3 tier heights for  $3\frac{1}{4}$  in. or  $4\frac{1}{4}$  in. steel or aluminum fin element.

Series "A" Baseboard. Copper and aluminum heating elements. Furnished in 1 in. nominal size only with 48—2 in. x 4 in. aluminum fins per ft.

Series "B" Baseboard. Pre-assembled unit, ready to install. 10 ft lengths only. Can be cut on job to suit.

## HOFFMAN "PANELMATIC" HOT WATER SYSTEM CONTROLS

**Designed for all Types of Radiant Heating**  
The Hoffman method vastly improves the ordinary forced hot water system by the application of *Continuous Circulation*. This method permits a smoothly modulated regulation of the heat supply. The Control Valve closes and the circulating stream by-passes the boiler as long as the heat requirements are satisfied.  
When the circulating water begins to cool, the Control Valve opens and the water

When the circulating water begins to lose heat, the Control Valve is slowly opened by the Controller, permitting hot boiler water to enter the system. Thus, the delicate precision of the Hoffman Controller smoothly varies the temperature of the *continuously circulating* water so that the heat supply is always equalized with the heat loss and room temperature remains constant throughout all changes in the weather. There is no type of building to which Hoffman Hot Water Control is not applicable.

There is no type of building to which Hoffman Hot Water Controlled Heat cannot be applied. The system permits zoning of apartments, institutions, large residences and factories, thereby assuring a distribution of heat in direct relation to either personal temperature preference or to the functional activities of the building.

HEATING COMFORT IS ACHIEVED BY  
THESE SIX HOFFMAN SPECIALTIES

**The Panelmatic Controller**  
The brain of the Hoffman system. It automatically maintains a constant comfort condition regardless of the outdoor temperature. Its accurate balancing mechanism electrically opens or closes the Hoffman Hot Water Control Valve as required.

**Outdoor Temperature Anticipating Bulb**  
This Bulb transmits changes in the outdoor temperature to the balancing mechanism of the Panelmatic Controller.

**Hot Water Temperature Bulb**  
Accurately relays temperature changes of the supply main water to the balancing mechanism of the Hoffman Comfort Controller.

**Circulating Pipe Orifice**  
A calibrated orifice used to balance the circuits through the boiler and through the Hoffman circulating pipe.

**Hot Water Control Valve**  
Opens only sufficiently to supply the correct amount of water to maintain the proper water temperature being circulated through the system.

**Thermometer.** Should be installed about 6 in. from submerged Water Temp. Bulb.

**Hoffman Hot Water Circulator**  
A centrifugal pump of prescribed capacity and low in power consumption. Usually installed in the return main and continuously circulates the water through the system. Can be installed in horizontal or vertical position.

## ILLINOIS ENGINEERING COMPANY

2059 SOUTH RACINE AVENUE • CHICAGO 8, ILLINOIS

DIVISION OF AMERICAN AIR FILTER COMPANY, INC.

STEAM HEATING SYSTEMS • CONTROLS • STEAM AND POWER SPECIALTIES

**ILLINOIS HEATING SYSTEMS**, with or without control, are offered in five types and cover the complete range of vacuum and vapor heating requirements.

**ILLINOIS SELECTOTHERM CONTROL SYSTEM**—A high vacuum steam heating system with single dial control that provides comfort, economy and convenience. For buildings of any size where boilers are mechanically fired and used for low pressure steam heating only.

**CONTINUOUS FLOW CONTROL SYSTEMS**—Type A—For zoned installations or where steam is used for other than heating and domestic hot water service, or where steam is supplied by Central Station Service. Furnished for pneumatic or manual operation.

**CYCLING FLOW CONTROL SYSTEMS**—Type R—For automatic or manual control of steam flow and pressures in vacuum systems and one-pipe or two-pipe gravity installations.

**VACUUM SYSTEMS**—A two-pipe steam circulating system in which a standard vacuum pump is used. For any type of building, industrial plants, or for groups of buildings heated from a central plant.

**VAPOR SYSTEMS**—A two-pipe system circulating steam at low positive pressures without pump or mechanical vacuum producer. Recommended for Residence, Small Apartment, and similar service.

### ILLINOIS STEAM SPECIALTIES

Heaters, Hot Water Generators, Drips of Mains and Risers. Series G operating ranges from 25 inches vacuum to 15 lbs pressure.

**Illinois Radiator Supply Valves** Quick Opening, Spring Loaded, Packless. For any two-pipe steam, vapor or vacuum heating system. Extremely smooth and easy to operate with a cool, break-proof plastic handle for finger tip control.

**Illinois Thermostatic Trap Series G**

For Vacuum and Vapor Heating Systems—  
For Working Pressures Up to 15 Pounds Positive acting and responsive to the slightest temperature changes, it discharges condensate quickly and freely without loss of live steam.

Series G

**Float and Thermostatic Traps Series G** For Low Pressure Service. Compact, simple, accessible, durable, dirt-proof. Positive valve action. Wire drawing impossible. Low discharge temperatures. Efficient air venting. Trap not damaged by freezing.

#### Recommended Applications

For draining Low Pressure Heating Systems, Ventilating Units, Unit Heaters, Pre-Heaters, Re-Heaters, and other Fan System Heat Surface, Process

## ILLINOIS ENGINEERING COMPANY

2059 SOUTH RACINE AVENUE • CHICAGO 8, ILLINOIS

DIVISION OF AMERICAN AIR FILTER COMPANY, INC.

STEAM HEATING SYSTEMS • CONTROLS • STEAM AND POWER SPECIALTIES

**STEAM TRAPS**—A special feature is the impact operated valve with snap action. The valve is either open or shut. It cannot remain in an intermediate position. Wire drawing, scoring or cutting of valve and valve seat are positively eliminated. The valve cannot chatter on the seat under any operating condition. Sizes from  $\frac{1}{2}$  in. to 2 in. Pressures from 5 psi to 250 psi and heavy duty to 600 psi.

**ILLINOIS MOTORIZED VALVES** (on and off)—Type R5—For automatic control of steam temperatures and pressures to prevent overheating and conserve steam. May be operated by any automatic contact device or by manual switches.

**ILLINOIS THERMOSTATIC TRAPS FOR HIGH PRESSURES**—Series HG—Maximum working pressure 150 pounds. Used where neat appearance and compactness are desirable, as for trapping sterilizers or water stills in hospitals; steam jacketed kettles, coffee urns, warming tables and for process work.

These traps are also furnished for medium pressures.

**ILLINOIS CONDENSATION PUMPS**—The complete line includes both horizontal and vertical, Single and Duplex Units. *Illinois Type "ECR" Pump*. Capacities, 2,000 to 65,000 sq ft edr. Discharge pressures to 50 psi. Bronze fitted throughout. Dependable mechanical seal eliminates leakage around shaft. Heavy duty float control with seamless copper float. Float switch adjustable for various levels. No sub-base required. Cast iron receiver.

**ILLINOIS ASU HEAT EXCHANGERS**—For heating water with steam. Complete range of sizes and capacities.

## Jas. P. Marsh Corporation

Dept. 5, Skokie, Illinois

Branches in Principal Cities

Marsh products include: Pressure, Vacuum and Compound Gauges; Dial Thermometers; Steam Traps; Vents; Packless Radiator Valves and other heating specialties; Tri-trol Regulators; Electrimatic Refrigeration Water Regulators and Solenoid Valves.

**Radiator Traps**—These highly efficient radiator traps are equipped with a phosphor bronze diaphragm charged with a

Thermostatic Diaphragm Radiator Trap

volatile fluid making them equally efficient for use on pressures below atmospheric up to 15 lbs pressure. Also other traps available up to 125 lbs pressure.

**Packless Radiator Valves**—The metal-to-metal seal of Marsh Radiator valves makes them truly packless. They contain no packing of any kind to wear, crack and deteriorate. Proved by many years of service. Easy to operate. Close on less than one turn. Individually tested. Adaptable for hot water as well as steam heating systems.

Packless Radiator Valve

**Marsh Float and Thermostatic Traps**—One of the many types of Marsh Heavy Duty Float and Thermostatic Traps is illustrated. These traps are designed for removal of air and condensate from steam mains, branches, or risers, unit heaters, steam coils, etc. The size and weight of the trap permits installation in the piping without any other means of

support. Condensation is discharged through a float-operated valve located at the lowest point inside the trap body. Air vent is located in a by-pass in the cap or cover of the trap. Air passes through a passageway and out through the trap outlet. Construction permits removal of mechanism without disturbing the piping.

Float and Thermostatic Trap

**Marsh Inverted Bucket Traps** are ideal for all types of hospital and kitchen equipment or similar service where a

Inverted Bucket Trap

considerable volume of condensate is handled. Traps are self-venting and have large water capacity thus assuring unusually high efficiency in removing condensate, air and gases.

## Jas. P. Marsh Corporation

**Marsh Pressure Gauges**—The Marsh standard, low pressure gauge will contribute to the economy and improve the operation of any type of steam boiler. It is finely built throughout and is available with the Marsh "Recalibrator" for quickly and easily resetting the hand to zero when the gauge is knocked out of adjustment.

Marsh Gauges include vacuum and compound types in a wide range of designs covering all services and pressures. Over 90 years of gauge manufacturing has reached its highest achievement in the Marsh "Mastergauge" for use where high pressures and temperatures are present and where maximum stamina and accuracy are essential.

**Marsh Dial Thermometers**—The same basic refinements found in Marsh Gauges are found in Marsh Dial Thermometers. Bourdon tube types are available in self-

contained and distant reading instruments, vapor-tension or gas filled. All ranges up to 400 F are covered. "Recalibrator" is standard in all bourdon tube types. Ask for catalog information.

**Marsh Electrimatic Refrigeration Valves**—The Marsh Electrimatic line of refrigeration valves includes condenser water regulators for ammonia, Freon or methyl chloride service; temperature actuated valves, packless solenoid valves, and other related products.

Type HT  
Water  
Regulator

The Electrimatic Type HT Temperature Actuated Regulating Valve is illustrated. It is used to control the flow of hot water or low pressure steam in heating or other industrial processes. The valve opens with rise in temperature and closes with fall in temperature. Main application is in heating, but may also be used as a by-pass control in cooling and process service. Regulator is quick opening and tight closing on either high or low pressures. Five standard temperature ranges cover most conditions. Cartridge construction of working parts eliminates need for removal of valve from line for cleaning or servicing.

**Marsh Electrimatic Solenoid Valves** are made in both direct-acting and pilot-operated types in  $\frac{3}{16}$ ,  $\frac{3}{8}$  in. and  $\frac{1}{2}$  in. or-

Packless  
Solenoid  
Stop  
Valve

ifice sizes respectively. They are of packless, tight seating construction with impregnated coils to withstand frost and moisture.

## Maid-O'-Mist, Inc.

3217 No. Pulaski Road  
Chicago 41, Ill.

Manufacturers of  
Heating and Air  
Conditioning Specialties

**Products:** Automatic air valves for hot water heating and cooling systems; automatic humidifiers for steam or hot water; automatic humidifiers for warm air furnaces; steam boiler water line controls; water line float control valves; liquid gas and air strainers.

### AUTO-VENT

#### Air Eliminators

No. 7 Auto-Vent

Maid-O'-Mist Auto-Vents permit automatic venting of the air which causes circulation trouble in heating and cooling systems. More and more, contractors who value satisfied customers are installing these trouble stoppers.

**No. 7 Auto-Vent.** For mains, pipe lines, unit heaters, chillers, convectors, coils, etc. Designed for vertical mounting only. Size 4 3/8 in. x 2 1/4 in. with 1/2 in. I.P. female connection. Made of brass and equipped with a self-closing, float operated valve. All working parts, including

valve and copper float, mounted on a removable bonnet for quick servicing or replacement. Valve is equipped with a Monel metal spring and a Neoprene valve seat which is unaffected by high temperatures, oil, anti-freeze, etc. For pressure not exceeding 75 lbs.

**No. 77 Auto-Vent.** Identical to No. 7 Auto-Vent, except for an additional 1/8 in., I.P. side opening to permit its use on overhead pipe lines, coils, etc., where head room is factor. Ideally suited for Diesel engine and cooling manifold use, where vibration demands secure mounting. No air chamber required.

**Auxiliary Equipment:** No. 7X—bonnet assembly for No. 7 and 77; No. 777—self-closing valve core; No. 7A—connector for safe waste.

Venting trapped mains and circulating lines

No. 27 Auto-Vent For Horizontal Mounting Only with 3/8 in. I.P. female side connection—Size 3 in. x 2 1/2 in.

No. 27 and 37  
Auto-Vents

No. 37 Auto-Vent For Horizontal Mounting Only with 3/8 in. I.P. vertical male bottom connection—Size 3 in. x 2 1/2 in.

For convectors and free standing radiation. Construction and internal working parts are same as in No. 7 Auto-Vent. Made of non-ferrous metals and designed for pressure not over 50 lbs. No air chamber required. **Auxiliary Equipment:** No. 27X—bonnet assembly for Nos. 27 and 37; No. 7A—connector for safe waste. No. 666 valve core.

Write for price sheet and descriptive literature.

## Maid-O'-Mist, Inc.

### No. 67 Auto-Vent

No. 67 Auto-Vent

For convectors and baseboard radiators. Designed for vertical mounting only. Size 3 3/8 in. x 1 1/2 in. with a 1/2 I.P. male connection. Designed for limited space, small, self-closing, float operated valve may be installed in trouble spots previously neglected or improperly vented. Valve is equipped with a Monel metal spring and Neoprene valve seat, which is unaffected by high temperature, oil, etc. No air chamber required. For pressures up to 30 lbs. Where a Safe Waste is needed, specify No. 7A connector fitting.

For venting convector radiators

### No. 72 Auto-Vent

No. 72 Auto-Vent

For convectors, baseboard and free-standing radiation. Designed for both vertical and horizontal mounting. Size 1 1/2 in. x 1/2 in. with 1/2 in. I.P. male connection. No. 72 Auto-Vent is a fast venting self flushing valve of the expansion type. All expansion and contraction of the single, non-porous, composition disk is confined to four port vents. Internal siphon tube prevents water logging when installed in either vertical or horizontal position. Immediate drainage means fast disk drying, quick venting cycle which is continuous and no air chamber is needed.

Manual venting features plus tight shut off are all controlled by valve cap adjustment. Valve cap is tamper-proof and can be removed and replaced without damage or special tools for cleaning or flushing, if needed.

For convector radiators

For baseboard radiation

### No. 14, No. 15 and No. 16 Balancing Valve Adapter Units

for Hot Water  
Heating and Cooling Systems

No. 14  
No. 14 for copper and bronze tees. Nominal pipe sizes 3/8 in., 1/2 in., 3/4 in., 1 in.  
No. 15 for tees. Sizes 1/2 in., 3/4 in., 1 in., 1 1/4 in., 1 1/2 in.

Maid-O'-Mist Valve Adapter Units make any copper, bronze, or cast brass or iron tee a balancing valve. These units, quickly soldered or sweat fitted into copper, brass, and bronze tees or threaded into cast iron tees, regulate hot water flow through radiators, convectors, baseboard panels, radiant coils, return mains, and branches. Can be inserted in side outlet or run of tee of same pipe-size to complete either a straightway or angle balancing valve. Full, free flow of water through the tee is possible. Since there is no inside reduction of pipe diameter, there is no water restriction except for the balancing required. This permits the use of additional balancing in a heating or cooling system without preliminary planning. Precision made of non-ferrous metals. Simple balancing requires only a screw driver.

No. 16 unit for 3/4 in. and 1 in. cast brass tees to complete angle balancing valves.

## CONVECTOR HUMIDIFIER

Maid-O'-Mist Convector Humidifier has no flat bottom to block the flow of warm air. Their individual  $\frac{3}{8}$  in. copper water troughs are spaced 1 in. apart to allow unrestricted air flow between the evaporator pads. Maid-O'-Mist Convector Humidifiers are designed for use with radiators and cabinet convectors in hot water heating systems and for all types of warm air furnaces.

2 Trough Convector Humidifier, also available in 1 and 4 trough sizes

## NO. 50 SERIES FLOAT CONTROL VALVES

The No. 50 Series Float Control Valves are precision designed to fill requirements for humidifying units, pan fillers, air conditioning equipment, evaporative coolers, air washers and other applications where dependable water level control is essential in limited space to meet various operating conditions.

(No. 51 float control valve)

(No. 52 float control valve)

\*No. 51 Float Control Valve. Only  $5\frac{1}{4}$  in. long overall, including copper float which is  $2\frac{1}{8}$  in. diameter by  $1\frac{1}{4}$  in. deep. Valve body is made of hex-brass rod with removable, raised, hard nylon valve seat. Valve stem is brass with an incased heat and oil resistant, special Neoprene washer. Valve seat is protected with a 100 mesh Monel Metal screen. Valve body is fitted with two  $\frac{1}{4}$  in. I.P. locknuts for horizontal mounting securely in  $\frac{3}{16}$  in. hole—or valve may be screwed directly into tapped opening. Supply is equipped with union coupling for  $\frac{1}{4}$  in. O.D. copper tubing. Working pressures up to 85 lbs. with capacity of  $\frac{1}{2}$  gal per minute at 50 lbs pressure.

\*No. 52 High Duty Float Control Valve. Same general construction as No. 51 but designed for use where a larger volume of water is required. Capacity 1 gal per minute at 50 lbs pressure, with working pressures to 125 lbs. Overall length 8 in. with oversized float  $1\frac{1}{2}$  in. diameter by  $4\frac{1}{8}$  in. long.

\*No. 53 High Duty Float Control Valve. Same general construction as No. 52 except valve is vertically mounted with special bracket as integral part for mounting on reservoir or pan, well above water line. Only  $6\frac{1}{2}$  in. long. Non-back-siphoning when installed according to instructions.

\*No. 59 Float Control Valve. Same general construction as No. 51 valve, except valve is vertically mounted with special bracket as integral part for mounting on reservoir or pan, well above water line. Non-back-siphoning when installed according to instructions. Only 5 in. long.

\*NOTE: Nos. 51, 52, 53 and 59 can be furnished with a  $\frac{3}{8}$  in. I.P. male connection at additional cost, when specified on order.

Series 6900—Water Line Float Control Diaphragm Valves. The No. 6900 Series float control valves are heavy duty large capacity water level controls. Rugged, strong and precision made, the cast brass body is fitted with a removable chromium valve seat. Controlled water level is accomplished through the action of the oversized copper float, linkage and special Neoprene diaphragm. Valve can be furnished to discharge water in an upward or downward position as specified. Inlet and outlet tapping  $\frac{3}{8}$  in. I.P. Capacities from  $1\frac{1}{4}$  gal to 6 gal per min. The No. 6927 Brass Mounting Plate (3 in. diameter) with gasket and screws is used where special mounting of the No. 6900 Series Valves is necessary. Write for prices and descriptive literature.

## Sarcotherm Controls Inc.

Empire State Bldg., New York 1, N. Y.

REPRESENTATIVES IN PRINCIPAL CITIES, FACTORY AT BETHLEHEM, PA.

Type STA-1 for Hot Water and Radiant Heating Systems

Type W for Steam Heating Systems

Automatic Control Panel

Fully automatic weather modulated control systems for all types of heating, and all necessary accessories.

## Hot Water and Radiant Heating

Sarcotherm provides a carefully engineered control system for radiant or panel heating which is fully modulating, and allows continuous circulation. The customary lag of conventional room thermostats is eliminated with the comfort control "Thermoray" sensitive to both convection and radiation.

For forced hot water heating system for garden apartments, housing developments, hospitals, and institutional buildings, Sarcotherm provides a completely zoned control system, including automatic night set-back and automatic morning pick-up.

## Steam Heating Systems

The Type "W" Sarcotherm Control system automatically proportions the amount of heat supplied to the actual need for any given weather condition. The control is fully modulating, and complete program control panels are provided to meet any control cycle required.

## Control Panels

Adjustments can be made through a manual control panel or through a completely automatic program panel that provides round-the-clock control of heating systems. For special applications control panels with indicating gages can be provided. All panels are electrically operated and can be remotely positioned in any desired location.

## Engineering Service

Consulting Engineers and Contractors are invited to consult with our Engineering Staff on any proposed control system. There is no obligation.

## Sarco Company, Inc.

Empire State Bldg., New York 1, N. Y.

Branches in Principal Cities

Affiliate Company: SARCO THERM CONTROLS, INC.

PRODUCTS in addition to those listed below:

Room thermostats, lift traps, balancing fittings, dial thermometers, motor valves, cooling controls. Also Sarcotherm weather-compensated control systems for hot water and radiant heating. (See page 1633)

### SARCO RADIATOR TRAPS

Radiator Trap, Type H

Type H for VACUUM, vapor or gravity steam systems: Self-adjusting bronze bellows for highest vacuum to 25 psi. Discharges condensate, air and air-steam mixture. Body and cap of brass. Self-aligning head and removable seat of hard bronze or stainless steel. Angle, straightway, offset, vertical.  $\frac{1}{2}$  to 1 in. Cat. N 150.

### SARCO RADIATOR VALVES

Type 40

Type 40—Packless—for VACUUM and all other steam systems. Valve stem sealed by packless bronze bellows, balanced pressure type. Angle or globe,  $\frac{1}{2}$  to  $1\frac{1}{4}$  in.

Details: Brass body, reversible discs, bakelite handle. Available with modulating devices. Lever, wheel or extension handles; lockshield tops. Cat. N150 & N221.

Type SM—Spring-packless or gland packed for all steam and hot water systems. Angle, globe, offset,  $\frac{1}{2}$  to 2 in. Same details as for above type 40. Cat. N150 & N221.

Type SM

### SARCO N-100 TRAPS

N-100 Medium Pressure Trap

Similar in style to above Sarco Radiator Trap, the N-100 Thermostatic Trap is suitable for operation at pressures up to 125 psi. Shield protects bronze bellows from condensate thrust, prevents over-expansion if removed while hot. Stainless steel renewable valve head and seat. Angle, straightway and vertical. Sizes  $\frac{3}{8}$  in. to 1 in. Bulletin 190.

### SARCO FLOAT-THERMOSTATIC STEAM TRAPS

Float-Thermostatic Trap

Discharge condensate at steam temperature, continuously and without shock. Automatically vent air and gases by built-in thermostatic by-pass. Immediately responsive to varying loads and pressures. Sizes  $\frac{3}{4}$  in. to  $2\frac{1}{2}$  in. for pressures to 200 psi. Catalog No. N-450.

### SARCO INVERTED BUCKET TRAPS

Sarco Camlift valve mechanism provides rapid and free discharge of the condensate. Special design to prevent prime loss on light loads. Sizes  $\frac{1}{2}$  in. to 2 in., for pressures to 900 psi. Catalog N-360.

Inverted Bucket Trap

### SARCO THERMODYNAMIC STEAM TRAPS

These new type traps virtually eliminate maintenance. Stainless steel throughout . . . immune to both internal and external corrosion. Safe in fire-hazard locations. Not affected by corrosive condensate, superheat, water-hammer. Only moving part is solid stainless steel disc. No valve-closing mechanism to wear or stick. No critical clearances to choke. No gaskets to leak. Same trap for pressures 10-600 psi. Sizes  $\frac{1}{2}$  in.,  $\frac{3}{4}$  in., 1 in. Bulletin No. N-257.

Thermodynamic Trap

### SARCO PIPE LINE STRAINERS

(Also Scraper Strainers)

Furnished in brass, semi-steel or cast steel for all commercial pressures. They are also furnished with hand or motor operated rotary scrapers, which clean the screen without flow interruption. Catalogs No. N-1200 and N-1225.

### SARCO SELF-CONTAINED TEMPERATURE REGULATORS

Sarco Temperature Regulators are simple, self-operated valves—the self-contained units that use the uniform force of liquid expansion. No stuffing boxes to leak, no auxiliary “power” required. All moving parts are inside the regulator. For steam, gas, oil, water or brine for temperatures to 300 F. Bulletin N-600.

Type TR-21. Standard for hot water storage tanks, fan units, etc.

### SARCO WATER BLENDERS AND TEMPERING VALVES

For mixing hot and cold water to deliver automatically water at any desired temperatures. Type MB for showers, wash basins, etc. Type DB, a tempering valve for use with submerged heating coils or tankless heaters. Bulletin N-800.

Water Blender Type DB

### SARCO AIR ELIMINATORS

For convector and radiant hot water heating systems. Also for chilled water lines in air conditioning systems. Semi-steel or cast brass body. Copper floats, stainless steel valve parts.  $\frac{3}{4}$  in. and 1 in. Bulletin N-190.

Type 6 Air Eliminator

### SARCOFIN FINNED-TUBE AND BASEBOARD RADIATION

A complete line with approved ratings as established by Institute of Boiler and Radiator Manufacturers. Guaranteed for 1-year against defects in materials and workmanship. Heating elements guaranteed for maximum working pressures. Bulletins No. N-1650 and No. N-1625.

Fined Tube Radiation

### SARCO CONDENSATE AND VACUUM PUMPS

Complete line of condensate and vacuum pumps for all capacity ranges. New Sarco Type S Condensate Pump shown combines all these advantages and others:

1. Low inlet height— $7\frac{1}{2}$  in. above floor;
2. Enclosed bronze impellers with replaceable bronze wearing rings;
3. Quick, easy disassembly for inspection and maintenance, without disturbing any piping;
4. Single unit converted to duplex by simply removing a flange and adding a pump and motor assembly with mechanical alternator. Bulletin on request.

Type S Duplex Condensate Pump

# International Heating & Air-Conditioning Exposition

Permanent Address—480 Lexington Ave., New York 17, N. Y.

## EXPOSITIONS HELD

Philadelphia, 1955; Chicago, 1953; Philadelphia, 1951; Chicago, 1949; New York, 1948; Cleveland, 1947-1940; New York, 1938; Chicago, 1936; New York, 1934; Cleveland, 1932; Philadelphia, 1930.

## FUTURE SCHEDULE

No exposition scheduled for 1956. In 1957, the Exposition will return to Chicago at International Amphitheatre, February 25 to March 1.

## UNDER AUSPICES OF A.S.H.A.E.

These Expositions have been and will be held co-incident with the annual meetings of American Society of Heating and Air-Conditioning Engineers, Inc., and under their auspices. Management is by International Exposition Company with permanent headquarters at 480 Lexington Ave., New York 17, N. Y.

## EXHIBITORS

Comprise leading firms in each phase of the industry; number has varied from 150 to more than 400 exhibitors.

## EXHIBITS

These range from and comprise all the types of articles discussed or advertised in this copy of THE ASHAE GUIDE.

1. **The COMBUSTION Group:** Furnaces, burners (coal, oil and gas), grates, stokers, boilers, radiators (various types), refractories and auxiliaries.

2. **The OIL BURNER Group:**

3. **The HYDRAULIC Group:** Water feeders, water heaters, pumps, traps, valves, piping, fittings, expansion joints, pipe hangers, etc.

4. **The STEAM HEATING Group:** Vapor heating, steam specialties.

5. **The HOT WATER HEATING Group:**

6. **The AIR Group:** Warm Air furnaces and stoves, registers and grilles, cooling towers, air filters, motors, fans, blowers, conditioning equipment, ventilators (room and industrial types), unit heaters, etc.

7. **The AIR CONDITIONING Group:** Equipment which circulates and filters the air, in summer dehumidifies and cools; in winter heats and humidifies, and does all these in proper season for complete, all year-round air conditioning.

## 8. The CONTROL Group:

Instruments of precision for indicating, controlling or recording temperature, pressure, volume, time, flow, draft or any other function to be measured.

## 9. The REFRIGERATING Group:

Compressors, condensers, cooling apparatus, contingent apparatus and refrigerants.

## 10. The CENTRAL HEATING Group:

Apparatus and materials especially designed or adapted to the uses of central heating and central heating station supplies.

## 11. The INSULATING Group:

Structural insulators (refractory and cellulose materials), asbestos, magnesia clays and combinations thereof, pipe and conduit covering, etc., weather-strip-ping, etc.

## 12. The MISCELLANEOUS Group:

Electric Heaters, boiler and pipe repair alloys, liquids and compounds, tools of all kinds, and equipment not specifically included in the above groups, but related thereto.

## 13. The MACHINERY AND GENERAL EQUIPMENT Group.

## 14. BOOKS AND PUBLICATIONS.

## VISITOR ATTENDANCE

Attendance is by invitation and registration only, thereby presenting a selected audience. Included are contractors, dealers, jobbers, supply houses, home owners, industrial users, professional and service organizations, public utilities, real estate management concerns, etc. A detailed analysis of registered attendance is available on request.

Industrial Expositions in America lead the expositions of the world in style, business effectiveness, industrial influence and educational value. This Exposition stands among the leaders in Industrial Expositions in America. It is an educational institution which brings together the research developments and improvements in equipment and materials for use in heating, ventilating and air conditioning all types of buildings.

# Strong, Carlisle & Hammond Company

1392 West 3rd St., Cleveland 13, Ohio

"STRONG" The Complete Steam Specialties Line

1. **Standard In-Line Traps (Semi-Steel).** Inverted bucket type. Hi-Cap design. Parts on cover for easy removal without breaking pipe connections. All stainless parts.

| Trap No. | Pipe Size (inches) | Continuous Capacity at psi | Weight lbs | List Price   |
|----------|--------------------|----------------------------|------------|--------------|
| 070      | 1/4, 3/4           | 125                        | 490        | 3 3/4 \$7.00 |
| 170      | 1/4, 3/4           | 125                        | 955        | 7 9.00       |
| 271      | 3/4, 1             | 125                        | 1230       | 7 1/2 13.50  |

2. **"Y" Type Strainers (Semi-Steel).** Features perforated Monel screen and new V-shaped gripping lugs. 250 psi 450 deg steam. 400 psi cold, non-shock.

| Pipe Size (inches) | Weight lbs | List Price |
|--------------------|------------|------------|
| 1/4, 3/4           | 1          | \$1.90     |
| 1/2                | 2 1/4      | 2.25       |
| 3/4                | 3 3/4      | 2.70       |
| 1                  | 5 1/4      | 3.25       |
| 1 1/4              | 8 1/4      | 4.10       |
| 1 1/2              | 11 1/2     | 5.25       |
| 2                  | 17         | 7.75       |
| 2 1/2              | 22         | 18.00      |
| 3                  | 32         | 21.00      |

3. **In-Line Blast Traps (Semi-Steel).** Inverted bucket (open-float) and thermostatic type. Hi-Cap design. Integral bi-metal thermal operated vent. For rapid heating on unit heaters, cookers, etc. Anum-Metl seat, stainless bucket and working parts.

| Trap No. | Pipe Size (inches) | Continuous Capacity at psi | Weight lbs | List Price   |
|----------|--------------------|----------------------------|------------|--------------|
| 070-T    | 1/4, 3/4           | 30                         | 660        | 3 3/4 \$8.50 |
| 170-T    | 1/4, 3/4           | 30                         | 1290       | 8 12.00      |
| 271-T    | 3/4, 1             | 30                         | 1760       | 9 17.50      |

4. **Bottom Inlet Traps (Semi-Steel).** Rugged, heavy duty inverted bucket type. "Lever-lift" action and dual fulcrum give high discharge capacity, dependable operation on light loads. All stainless working parts. Anum-Metl valve and seat. Lowest maintenance.

| Trap No. | Pipe Size (inches) | Continuous Capacity at 125 psi-lbs/hr | Weight lbs | List Price |
|----------|--------------------|---------------------------------------|------------|------------|
| 43       | 1/4                | 3,700                                 | 1334       | \$22.00    |
| 44       | 3/4                | 7,180                                 | 26         | 31.00      |
| 45       | 1 1/4              | 15,000                                | 45         | 48.00      |
| 46       | 1 1/2              | 35,280                                | 84         | 80.00      |

5. **F & T Traps (Gray Iron).** For rapid air and condensate removal in low pressure steam systems. Ball-float mechanism controls condensate flow; expanding thermal element controls removal of air. Stainless steel valve and seat, copped hided float. For pressures to 15 psi.

| Trap No. | Pipe Size (inches) | Continuous Capacity at psi | Weight lbs | List Price |
|----------|--------------------|----------------------------|------------|------------|
| 11-T     | 3/4                | 15                         | 230        | 7 \$17.45  |
| 12-T     | 1                  | 15                         | 575        | 7 21.40    |
| 13-T     | 1 1/4              | 15                         | 1,380      | 12 28.80   |
| 14-T     | 1 1/2              | 15                         | 2,760      | 19 55.55   |
| 15-T     | 2                  | 15                         | 5,750      | 33 80.65   |

6. **Type O & K Pressure Regulators (Semi-Steel).** For steam, air and gas. Direct operated. Rugged construction. Fitted with special laminated, phosphor-bronze diaphragms and stainless valve and seat.

| No.                  | Pipe Size (inches)                                                        | Weight lbs | List Price |
|----------------------|---------------------------------------------------------------------------|------------|------------|
| Type O               | 3/4, 1, Initial pressure to 225 psi, 400 F, reduced ranges 0-200.         | 8          | \$15.00    |
| Type K (illustrated) | 1/4, Initial pressure to 225 psi, 400 F, reduced ranges from 0 to 85 psi. | 15         | 19.00      |
| 1                    | 3/4, Type K has an integral strainer.                                     | 15         | 20.00      |
| 1 1/4                |                                                                           | 18         | 27.00      |
| 1 1/2                |                                                                           | 40         | 38.00      |
| 2                    |                                                                           | 40         | 42.00      |

7. **Type C Pressure Regulators (Semi-Steel).** For installations requiring accurate and dependable regulation. Stainless trim, single-seated, piston-operated, pilot controlled spring-loaded.

| No.    | Pipe Size (inches)                                                                          | Weight lbs | List Price |
|--------|---------------------------------------------------------------------------------------------|------------|------------|
| Type C | 1/4, From initial pressure to 2:0 psi, 450 F. For reduced pressure from 0 to 200 psi        | 17         | \$36.00    |
| 1      |                                                                                             | 17         | 39.00      |

## Warren Webster & Company

The Vacuum System of Steam Heating : Since 1888

Main Office and Factory: 1731 Federal St., Camden 5, New Jersey

### WEBSTER HEATING AND AIR CONDITIONING EQUIPMENT

#### Webster Radiation:

Webster Walvector for Steam and Hot Water  
Convectors for Steam and Hot Water  
Tru-Perimeter Webster Baseboard Heating, for Forced Hot Water  
Webster Unit Heaters for Gas, Steam or Hot Water; Series 45 Unit Heater Controls.

#### Webster Hydro-Heat Hot Water Heating Specialties:

Continuous Flow Controls  
Hydro-Heat Water Accumulators  
Tru-Perimeter Expansion Joints  
Pressure Regulating Valves  
Pressure Reducing Valves  
Flow Control Valves  
Purge Headers  
Balance Valves  
Webster Blendor Controls

#### Webster Steam Heating Equipment: Radiator Valves

Thermostatic Traps  
Float-and-Thermostatic Traps  
Dirt Strainers  
Double Service Valves  
Boiler Return Traps and Vent Traps  
Boiler Protectors  
Lift Fittings  
Expansion Joints  
Vacuum Breakers  
Hylo Vacuum Controllers

#### Webster Process Steam Traps:

Thermostatic Traps  
Float-and-Thermostatic Traps

#### Webster Steam Heating Controls:

Webster Moderator Systems  
Main Steam Control Valves  
Motorized Shut-Off Valves  
Metering Orifices  
Pressure Difference Controllers  
Time Switches

#### Air Conditioning

Webster Heating-Cooling Conditioner  
Warren Webster Cool Air System

### WEBSTER TRU-PERIMETER HEATING

Webster Tru-Perimeter Heating uses Webster Baseboard, Webster Walvector, or a combination of both, to replace the heat at the perimeter where heat loss occurs. Heating elements are mounted close to the floor along outside walls, spreading the heat the entire length of the exposed walls.

Webster Tru-Perimeter Heating warms the air within a room, warms the floors,

and warms the inside surface of outside walls where a normal coolness occurs during the winter months. Gently moving warmed air is drawn to floor level and across the floor into the inlet opening of the radiation. Radiant heat rays strike the floor along the full length of the exposed walls. Floors are warm and comfortable even with slab floor construction.

Wall-to-wall application of Webster Walvector.

#### Webster Walvector

Webster Walvector for steam or forced hot water heating is an elongated convector designed for mounting along the wall, close to the floor line and under windows. For new buildings or modernization. Combines an attractive steel enclosure, newly styled and improved, and a highly efficient heating element of copper tubing and aluminum fins in 3 in. and 4 in. fin sizes.

Custom Webster Walvector employs 3 in. or 4 in. fin size heating elements, single or double row. Front or top outlet enclosures for wall mounting or with integral sill.

For details on standard Walvector, send for *Bulletin B-1551*; for Custom Walvector, get *Bulletin B-1553*.

Isometric view of Tru-Perimeter Forced Hot Water Webster Baseboard Heating with new Hydro-Heat features, installed in typical modern ranch house. Note simplicity. Kitchen can be heated by Webster Walvector or Webster Convector (not shown). Hydro-Heat Water Accumulator replaces expansion tank, eliminates contact between air and system water.

#### Webster Baseboard Heating

Webster Baseboard Heating is a forced hot water system in which a convector heating element is concealed within a specially built metal baseboard. It is run in a continuous loop around the exposed walls of the house, with a separate loop for each floor or zone. Heating element is copper tubing with aluminum fins. Send for *Bulletin B-1602*.

Cut-away view showing design simplicity of Webster Tru-Perimeter Forced Hot Water Baseboard Heating.

#### Webster Moderator System

The new Type IB Electronic Webster Moderator System provides continuous but automatically graduated or throttled steam flow to orificed radiators—without use of mercury. An outdoor thermostat automatically varies the rate of steam delivery to radiators with changes in outdoor temperature. A Variator, manually operated, modifies the action of the outdoor thermostat for such requirements as quick heating-up, changes in occupancy. For details, ask for *Bulletin B-900-4B*.

Diagram of Type IB Electronic Webster Moderator System using a single Main Steam Control Valve.

## The Dole Valve Company

Plumbing and Heating Division 1933 Carroll Avenue, Chicago 12, Ill.

Control with

WATER MIXERS

AUTOMATIC REGISTERS

**Dole**

THE ALL STAR LINE

AIR AND VACUUM  
VALVES

Dole 20 Sr. Vent

This high-quality hot water air valve is designed to provide an automatic air eliminator, a manual shutoff and a manual air vent. A Dole design developed on the hygroscopic principle by The Dole Valve Company. A selector dial permits various settings and provides for faster venting. One of a complete line of Dole Hot Water Air Valves.

Dole No. 100 Water Mixer

Here is a new water mixing valve utilizing the famous Dole element which gives extra power. It is noncorrosive and trouble-free. The No. 100 is made of a brass forging and yet despite its high quality is low in cost, making it a top value. Nonadjustable. 140 deg setting.

Designed for installation at the water heater or storage tank.

Dole Air Valves

The complete Dole line includes air valves for every type of heating system. Below are six typical valves from the line.

**DOLE NO. 1 A VARI-VENT**—adjustable valve that provides an infinite number of venting speeds.

**DOLE NO. 1 D**—a very fast venting, fixed-orifice, nonadjustable air valve. Factory-set to vent two or three times as fast as regular type air valves.

**DOLE NO. 1 B VARI-VENT**—provides better control of heat on convector type

radiation where faster venting is essential.

**DOLE NO. 3**—designed to assure utmost heating performance on hand-fired steam heating systems. Complete venting is assured at any pressure up to 10 lbs.

**DOLE NO. 4 QUICK VENT VALVE**—for quick venting steam mains and returns up to 25 lbs pressure.

**DOLE 2 B VARI-VENT VACUUM VALVE**—for use on hand-fired gravity one-pipe steam heating systems. Has the Dole patented bellows that locks air out once it has been expelled.

Dole Water Mixers

Dole Water Mixers provide safer tempered domestic hot water on all tankless heaters and storage tank installations. Available in three sizes:  $\frac{1}{2}$  in.,  $\frac{3}{4}$  in. and 1 in.; adjustable range—125 to 175 deg F.

Dole Automatic Register

Provides individual room temperature control. Operates thermostatically from room air temperature. Completely self-contained. Dial permits setting for the heat desired. Made in sizes to fit practically any stack-head opening.

## The Fairbanks Company

393 Lafayette Street

New York 3, N. Y.

Pressures—125 through 300 lbs S.W.P.

Ends—Screwed, Flanged, Solder, Brazed and Hose.

Stem Action—Rising with Solid or Split Wedges, Non-Rising with Solid Wedges.

Bonnets—Screwed, Union, Bolted and O. S. & Y.

Radiator Valves

LP—Gas Valves

### BRONZE CHECK VALVES

Horizontal, Angle and Vertical

Types—Swing and Lift

Pressures—125 through 300 lbs S.W.P.

Ends—Screwed, Flanged, Solder and Brazed.

Discs—Bronze, Renewable Composition, Rubber Faced.

LP—Gas Valves

### IRON BODY GLOBE & ANGLE VALVES

Bronze Mounted

Pressures—125 through 250 lbs S.W.P.

Ends—Screwed and Flanged

Discs—Bronze, Renewable Composition, Nickel Alloy Semi-Plug Disc and Seat

Bonnets—O. S. & Y. and Union

Automatic Stop and Check Valves

### IRON BODY GATE VALVES

Bronze Mounted and All Iron

Pressures—125 through 250 lbs S.W.P.

Ends—Screwed, Flanged and Hub

Stem Action—Rising, Non-Rising and Quick Opening

Bonnets—Screwed, U-Bolt, Bolted & O. S. & Y.

Underwriters' and AWWA Approved Valves

### IRON BODY SWING CHECK VALVES

Horizontal—Bronze Mounted

Pressures—125 through 250 lbs S.W.P.

Ends—Screwed, Flanged and Hub

Discs—Bronze, Bronze Faced and Rubber or Leather Faced

Underwriters' Approved Valves.

## HAMMOND BRASS WORKS HAMMOND, INDIANA

Complete line of packed type radiator valves, circulator valves, balancing elbows, convactor valves and gate valves for iron pipe and copper tubing, for use in steam, gravity and forced hot water heating systems; including baseboard, convectors, floor, ceiling, and wall radiant panel heating.

Circulator valves, balancing elbows, and fittings for forced hot water systems.

Service recommendations: These circulator valves provide a "nearly tight" shut off when closed and full flow when open. A quarter turn of the handle gives a smooth, easy, full opening.

Valves can be furnished in any combination of copper to iron, copper to copper, iron to copper, etc. Construction of balancing elbows same as circulator valves.

The external adjustment allows for adjusting and re-adjusting while system is in operation and eliminates necessity of draining. Caps can be furnished to prevent tampering.

These valves are engineered and designed to fit into small enclosures of the concealed or convactor type radiators.

Tapered ball seat gives positive flow control. No chance for rust flakes to collect.

Hammond Radiator Valves and Elbows for Steam and Gravity Hot Water Heating Systems. For Iron Pipe and Copper Tubing.

No. 101—Steam Corner. Same as No. 100. Specify whether right or left hand wanted. Valve illustrated is left hand.  
No. 102—Gate Union. For hot water installations and steam or vapor heating systems. Especially suitable for use with unit heaters; ideal for general shut-off valve service at other points throughout heating systems including boilers and hot water heaters. Specify when ordering for hot water system, as such valves are furnished with a small hole drilled through the disc to provide for slow circulation when valve is closed.  
No. 105—Convactor Single Union Gate. Same as No. 102, but single union does

not permit removal of radiator while system is in operation.  
No. 108—Convactor Female Union Steam Angle. Same as No. 100, but should only be used for convactor radiators equipped with inside leg tapplings. The female union eliminates the necessity for exact roughing in measurements to tapping. Variation of the nipple inside leg will allow for adjustment. Shipped with bonnet loose to facilitate installation.  
No. 300—Union Elbow—For gravity hot water heating installations.  
No. 104—Double union gate for convactor radiators only.

See Hammond Catalog for complete line of valves.

Stocked by all leading wholesalers, also 29 factory warehouse stocks located in 29 cities throughout the United States.

## Jenkins Bros.

100 Park Avenue, New York 17, N. Y.

### JENKINS VALVES for LASTING ECONOMY

### PATTERNS AND PRESSURES FOR ANY SERVICE IN JENKINS COMPLETE LINE

Consult Jenkins Catalog for complete details on more than 500 different valves that cover practically all industrial plumbing and heating, and engineering requirements. Below is a brief list.

All-Iron Valves,—globe, angle, gate; Angle Valves,—bronze, steel, and iron body with bronze mounting or trimming.

Blow-Off or Y Valves,—bronze and iron.

Electrically Operated Valves, Gates, Globes, Angles, Fire Line Valves; Floor Stands; Foot Valves for gasoline service.

Gate Valves,—bronze, iron, steel; with solid wedge or double disc parallel seats; with removable bonnet and renewable bushing.

Globe Valves,—bronze, iron and steel; one piece and union bonnets; renewable and integral seats; rubber composition or metal discs and plugs.

Horizontal Check Valves,—bronze, iron and steel; Hose Valves; Indicator Posts; Lock Shield Valves.

Needle Valves; Non-Return Valves; Quick-Opening; Self-Closing Valves.

Radiator Valves; Rapid Action Valves; Regrinding Valves; bronze and iron body with bronze trimming; renewable plug seats and bevel seats of a special nickel alloy in globe, angle, check and swing check patterns.

Stop and Check Valves,—non-return; Swing Check Valves,—bronze, iron and steel.

Stainless Steel Valves,—globe, angle, gate and check.

Underwriters' Pattern Valves,—check and gate; Whistle Valves; Waterworks Valves.

**April Showers Company, Inc.**

**AUTOMATIC EVAPORATIVE ROOF COOLING**

Distributors and Dealers in Principal Cities

Automatic  
ROOF  
COOLING

*Spray Method*

The logical **FIRST** step in  
any large or medium sized  
Air Conditioning program

Over 19,500,000 Square Feet of Roofs  
Cooled by **APRIL SHOWERS**. Excellent  
results recorded whether in conjunction  
with a true air conditioning system or  
alone as an "under-roof" Cooling  
System.

(Partial List of Users) E. I. duPont de  
Nemours & Co., Inc. (Stores: 19,549 sq  
ft Shipping Dept: 43,902 sq ft. Shops:  
17,772 sq ft) Martinsville, Virginia.  
• Calhoun Garment Co., (44,660 sq ft)  
Calhoun City, Mississippi.  
• American Viscose Corp., (139,120 sq ft)  
Marcus Hook, Penna.  
• Stahl-Urban Company, (64,000 sq ft)  
Brookhaven, Miss.  
• Hamilton Standard, Div. United Air-  
craft (538,500 sq ft) Windsor Locks,  
Conn.  
• Livingston Shirt Corp. (24,544 sq ft)  
Livingston, Tenn.  
• Lockport Felt Company, (180,859 sq  
ft) Starkville, Miss.  
• Write-Right Mfg. Co., (44,352 sq ft)  
Chamblee, Ga.  
And such others as: Lilly Tulip Co.,  
General Electric Co., Westinghouse  
Electric Co., Eastman Kodak Co.,  
Bulova Watch Co. and many others.

In addition, the Federal Government has  
used millions of square feet of **APRIL  
SHOWERS** installations. Among them  
is the 500,000 sq ft roof of the U. S.  
Naval Ordnance Building in Indi-  
anapolis, Ind.

Consider these important Facts when  
planning your next Air Conditioning or  
Cooling installation

• Reduces loads of True air conditioning  
systems as much as 25 percent • Lowers  
temperatures of upper floors 8 deg to 15  
deg • Used on all types and shapes of  
roofs on Industrial, Commercial and  
Residential buildings • Increases em-  
ployee efficiency • Thermostatically con-  
trolled; no pool, no run off • Installation  
is simple, inexpensive, fool-proof • Op-  
eration and maintenance costs are negli-  
gible

The **APRIL SHOWERS** System is fully  
automatic. The Sun operates it. Re-  
quires very little water and City water,  
under normal city pressure, is usually  
adequate. No runoff. Installation and  
Maintenance Costs are low. Only finest  
materials are used. Precision workman-  
ship.

Besides cooling "under-roof" areas,  
**APRIL SHOWERS** adds longer life to  
roofs (preventing the sun from speedily  
evaporating the protective roof-coating  
oils), gives added protection in case of  
fire and acts as a lightning arrestor.

*April Showers is protected by U. S. Pat.*

**WRITE** for complete information or  
Free Estimates. No obligations.

**Muellermist Irrigation Company, Inc.**

2612-22 South Ninth Ave., Maywood, Illinois.

**FANJET EVAPORATIVE ROOF COOLING SYSTEM**

Adapted to Practically Any Kind of Roof Surface

Tests of a sprayed roof\* show that it is  
more effective in excluding solar heat  
than a dry roof; more effective than a  
pool of water one inch deep; and more  
efficient than a pool six inches deep. For  
this reason engineers and plant managers  
are turning more and more to the sprayed  
roof as a relatively inexpensive means for  
improving working conditions in the  
absence of air conditioning, or of sub-  
stantially reducing the load where there  
is air conditioning.

**FANJET** is a low priced roof cooling  
system with unusual features. No spray  
heads are required. By an exclusive pro-  
cess (Patents pending), copper pipe of  
special size and temper is pierced in such  
a way as to produce a fan shaped spray  
of peculiar character in that there are  
both fine and large drops. The fine drops  
wet the near areas while the large drops  
reach the outer areas with intersecting  
streams. Laterals are placed eighteen  
feet apart, with the pipe pierced on both  
sides except around the outside perime-  
ters. The effect is a more evenly wetted

surface than is possible by other  
methods.

The sprays are regulated by adjustable  
automatic controls, so that the quantity  
of water applied approximately balances  
evaporation, with little if any waste.

To absorb all solar energy on a hot day  
may call for up to 36 gal of water per  
1000 sq ft per hr. This would mean an  
excessive demand rate on a large roof, so  
the roof is divided into sections to fit the  
available water supply, each being  
wetted in consecutive order. For design  
purposes allow 200 sq ft to one gallon of  
water. Evaporation from a properly  
wetted surface will go on with full effi-  
ciency for five or more minutes during  
the "off" period. The daily water re-  
quirements would be around 200 gal per  
1000 sq ft.

Water pressure at roof level should be  
enough to allow 20 psi at the valve for  
each section.

Full information and estimates on re-  
quest, without obligation.

Inquiry from Dealers invited.

### TRIPLE-ZONE INSULATION

Gilsulate is a unique solidified hydro-carbon of high resin content which in granular form is poured directly around hot underground pipes for insulation and corrosion-protection.

#### GENERAL DATA

1. Low cost per installed linear foot
2. Easy-to-use: pour . . . tamp . . . normal pipe heat does the rest
3. Fuses itself in hours into 3 zones of permanent protection for the pipe against all commonly-encountered buried-line conditions such as acids, alkalis, roots, water, and corrosion
4. Tested and proved in actual use in hundreds of new construction and replacement installations
5. Can be used under all multiple-pipe and cramped space conditions (see illus. below)
6. Needs no housing or mechanical sheaths to protect it

7. Requires no mixing or special handling
8. Can't be punctured, obviating need to remove rocks from backfill
9. Only normal pipe spacing required; steam and condensate lines can run side by side
10. Pipe expands and contracts within Gilsulate structure
11. Makes repairs to the pipe quick, easy and economical

#### GRADES AND TEMPERATURE RANGES

|                  |              |
|------------------|--------------|
| Type A . . . . . | 220F to 300F |
| Type B . . . . . | 300F to 385F |
| Type C . . . . . | 385F to 520F |

#### TRENCH SIZE

4 in. to 22 in. wider than pipe diameter,  
6 in. minimum backfill over the Gilsulate bed.

#### EFFICIENCY

Heat loss 8-12 per cent of bare pipe  
Inert to ordinary acids and alkalis  
found in soil, excellent dielectric

St., Elizabeth 4, N. J.

## Durant Insulated Pipe Company

Palo Alto, California

Durant International Corporation

Williamstown, New Jersey

REPRESENTATIVES IN PRINCIPAL CITIES AND CANADA

### DURANT Pre-Sealed INSULATED PIPE

Cutaway shows DURANT construction—Insulation and support sections are applied next to pipe—heavy gage galvanized steel casing is slipped over load bearing and spacer sections leaving a minimum 1 in. space which is filled with a special high melting point, non-porous asphalt. The result is a solid, compact unit, permanently waterproofed.

DURANT INSULATED PIPE is pre-fabricated into complete, insulated and water-proofed systems for use in underground or exposed locations. DIP is used for the conveyance of steam, hot water, refrigerants and process fluids, and for tracer type systems.

DIP is fabricated in all standard sizes—Pipe and Insulation supplied as specified—and is equally adaptable to single or multiple pipe units.

#### SPECIAL FEATURES

The DURANT patented insulated anchor eliminates contact between pipe and anchor plate—provides electrical and thermostatic insulation against heat loss and electrolytic action.

Assembly and installation of DIP units consists of joining pipe—applying insulation around pipe joint—securing connector to conduit ends—filling 1 in. space between insulation and connector with DIP special asphalt. Units may be assembled before placing in trench as shown here. No slabs, drains or supports are necessary.

The DURANT engineering staff and representatives are at your service—write or call for information estimates, or new Durant catalog No. 35.

E. B. Kaiser Co.

SINCE 1890

P. O. Box 276, 2114 West Lake Avenue, Glenview, Illinois

**EBKO**

**PIPING SYSTEMS**

REPRESENTATIVES IN PRINCIPAL CITIES

Fig. 1

EBKO underground or overhead prefabricated insulated piping systems are designed for efficient and economical distribution of steam, condensate return, refrigerants, hot and chilled water in single or multiple units (Fig. 1). Made in standard lengths—18 ft for cast iron casings; 20 ft for steel—with all fittings and accessories to complete the system. The spirally-welded, lock-seam steel casing, ranging from 8 to 14-gauge provides substantial support for the inner assembly and resists crushing loads, as does the cast iron; therefore, expensive reinforcements are unnecessary under railways and roadways. These heavy-duty casings may be assembled on the ground and lowered into the trench or hoisted into position overhead, where they can be suspended on 24 ft centers by means of clevis hangers. EBKO casings are designed for 150 psi operating pressures. These casings are protected from weather by an anti-corrosive paint. The anti-corrosive compound used on the underground systems has also proved its effective

resistance to chemical and corrosive attack under all subsoil conditions.

The inner pipe is concentrically aligned within the casing by heavy supports fastened to the inner pipe on 10 ft centers (Fig. 1). This method permits free movement of the inner assembly longitudinally yet controls any tendency for it to deflect or sag during expansion and contraction. Movement is also controlled by the EBKO anchor, an integral part of the system requiring no costly external reinforcing.

Any portion of the inner assembly can be removed after installation without major disturbance to the system. This design permits the rotation of the inner assembly, eliminating many position welds. Another important feature is the continuous, uniform, annular air space throughout the system, designed to afford maximum insulating efficiency. The insulation retains its normal efficiency and form even after being thoroughly saturated and then dried. This process may be accomplished after the system is installed. The sectional fittings permit accurate casing alignment and allow visual inspection of all inner pipe joints during tests. Standard devices for expansion relief are adaptable to an EBKO system. The steel-loop type is prefabricated and tested at the EBKO plant and permits ample unrestricted expansion without crushing the insulation. Installation costs are reduced considerably by the relatively low cost of field erection, which can be mainly performed at ground level.

All EBKO systems are completely guaranteed.

E. B. Kaiser Co.

SINCE 1890

P. O. Box 276, 2114 West Lake Avenue, Glenview, Illinois  
REPRESENTATIVES IN PRINCIPAL CITIES

A, D, EBKO outside and inside viscous liquid systems (Fig. 2)

EBKO Piping Systems for handling viscous materials merit close investigation by those faced with this problem. Here is the system (Fig. 2-3) that handles any degree of viscosity requiring either high or low temperatures to liquefy.

EBKO provides a continuous Heating or Cooling chamber—through valves, fittings, expansion devices, and level controls. Constant temperatures are maintained thermostatically.

The initial investment is rapidly recovered through increased productive capacities. Many industries have found EBKO indispensable to their operations because of EBKO's high efficiencies and low maintenance costs. It is used to convey everything from petroleum by-products to process foods—from chem-

EBKO heavy oil system (Fig. 3)

icals to paints and varnishes—waxes—fats. Anything that liquefies under temperature is conveniently and economically moved in an EBKO Piping System. EBKO systems can be used over any distance, anywhere—indoors, outdoors—underground, overhead—they can be totally submerged without peril to their efficiency or long life. All EBKO systems are guaranteed.

EBKO Heat Exchangers with the counter-flow feature are designed for high efficiencies. They are designed for various liquids and gases, pressure and capacities. All EBKO Heat Exchangers are in accordance with ASME codes. Single and Multiple Stack Type Heat Exchangers (Fig. 5)

This type of Heat Exchanger assures maximum extraction. Each pass can be provided with rod-outs, eliminating disassembly in the event of stoppage. Combination Tank and Suction Heater (Fig. 4)

These horizontal or vertical heaters are designed for large and small storage for various capacities. They heat the liquid in the tank and pre-heat the liquid as it is withdrawn.

EBKO also designs in the line type heaters—single and multiple tube, tank storage heaters, pre-heaters, economizers, reclaiming heat exchangers, and heat exchangers for continuous blow-down.

(Fig. 6) EBKO flanged, single stack, counter flow heat exchanger.

(Fig. 4) EBKO heavy oil section tank heater for 500,000 gal field storage.

**Therm-O-Tile**  
REGISTERED

**H. W. Porter & Co., Inc.**  
817-G Frelinghuysen Ave., Newark 5, New Jersey

Permanent Protection and  
Insulation for Underground  
Pipe Lines.

**REID HAYDEN, INC.**

Baltimore, Md. Richmond, Va. Charlotte, N.C.

Advantages offered by Therm-O-Tile  
Conduit are:

- 1—Higher efficiency PERMANENTLY because insulation and conduit are always DRY.
- 2—Positive sealing throughout. Internal drainage assures dry, efficient insulation.
- 3—Arched construction that is stronger than required by ASTM. Ask for STRENGTH AFFIDAVITS by Pittsburgh Testing Laboratory.
- 4—"Spread-Footing" foundation. The "sidewalk" makes installation easier.
- 5—Surrounded by sealed air.
- 6—All loads are taken directly by an unyielding base.
- 7—The correct slope is PERMANENT hence no condensation pockets.
- 8—PERMANENCE assures maximum economy. Lowest ultimate cost.

PATENTED

THERM-O-TILE

STEAM

CONDUIT

SYSTEMS

Expansion Loops. Expansion Loops may be constructed from over-sized Therm-O-Tile designed to allow proper expansion movement of the piping within the loop.

Therm-O-Tile Expansion Loop

and sagging. The original surveyor's slope is PERMANENTLY held hence condensate pockets cannot form. When installed over filled or boggy ground PERMANENCY is insured by steel reinforcement or supporting piles.

Wide Size Range. Top and base sections of the envelope are made in numerous sizes. Result: any desired section is usually made available. For complete data ask for Therm-O-Tile Bulletin.

Reasonable in First Cost. Despite the many excellent features obtained in Therm-O-Tile, it is nevertheless competitive in total first cost.

Engineers — Contractors — Manufacturers. Write, phone, or wire the nearest Porter-Hayden office for estimates, recommendations, and complete specifications for the conduit and insulation on any underground pipe line project.

**Ric-wiL Incorporated**

Prefabricated Insulated Piping Systems  
UNDERGROUND or OVERHEAD

Barberton, Ohio

Representatives in Principal Cities

Ric-wiL Systems for central heating and process piping are engineered and insulated to specific project requirements for efficient distribution of steam, hot or refrigerated liquids and gases.

**Hel-Cor Insulated Pipe Units... Single or Multiple Pipes**

Prefabricated in 21 ft lengths with any specified combination of pipes and insulation. 16 gage helically-corrugated, hot-dip galvanized metal housing, protected with asphalt coating.

**Hel-Cor Uniline—For Oil or Process Liquids**

Similar to standard units except pipes are nested inside a laminated asbestos insulation liner—insulated from the exterior but not from each other. Designed for oil and process liquids.

**Ric-wiL Cast Iron Insulated Pipe Units**

Factory prefabricated 18 ft 6 in. lengths. Pipe and insulation housed in heavy-duty cast iron conduit. Insulation any type or thickness to meet job requirements.

**Hel-Cor Underground Systems**

Standard 21 ft prefabricated sections for efficient field installation. Single or multiple pipe Hel-Cor Units or Hel-Cor Uniline Insulated Pipe Units can be used underground or overhead.

**Hel-Cor Overhead Systems**

Prefabricated 21 ft pipe units for straight runs. Elbows, tees, anchor units and expansion loops finished at factory and delivered to job site with joint materials for simple assembly.

**Cast Iron Underground Systems**

For underground insulated piping systems where permanency and thoroughly tight joints are required. Prefabricated for easy field assembly, complete with accessories—expansion loops or joints, etc.

For full descriptive literature and technical information on Ric-wiL products and services, call or write the Ric-wiL office nearest you, or Ric-wiL Incorporated in Barberton, Ohio.

## The Stillwater Clay Products Company

Conduit Division

Plants  
Uhrichsville, Dennison,  
and Junction City, Ohio

General Offices  
3334 Prospect Avenue  
Cleveland 15, Ohio

Factory Agents in Principal Cities

### Stillwater Tunnel and Round Conduit Systems

**TUNNEL SYSTEM** The most versatile of the Stillwater Conduit Systems. With Tunnel Arch in ten different sizes, and in conjunction with one of the three different sizes of Side Blocks, any combination of service piping can be accommodated.

#### ROUND SYSTEM

The Stillwater Conduit System supplied complete with Combination Underdrain and Support Structure. The complete system can be quickly installed without a concrete pad. With twelve Round sizes, each with proper size of Underdrain Support, the proper design size is available to fit any job.

Stillwater Conduit is an engineered, proven system. Its major component is Vitrified Clay—the ageless material which has withstood the test of underground use for centuries. Stillwater Conduit Systems are not affected by extremes of temperature or moisture, or the attack of corrosive soils. Vitrified Clay, being dielectric, protects the enclosed metal service piping from electrolytic disintegration.

We offer, without obligation, our Engineering Services for your proposed new project or replacement job. Complete warehouse stock assures prompt shipment of any size order with Stillwater Support Assemblies, Alignment Guides, Anchors and other accessories.

Write for the Stillwater Conduit Manual—your guide to the best in Underground Conduit Installation.

**STILLWATER Conduit Systems assure permanent protection for your underground metal piping investment.**

1652

## Z-Crete Division

Zonolite Company  
135 S. LaSalle St.  
Chicago 3, Ill.

### UNDERGROUND PIPE INSULATION

**Z-CRETE\*** is a Lightweight Insulating Concrete which is poured directly and monolithically around heated underground piping.

**GENERAL DATA** The Z-CRETE system of underground insulation is a field fabrication adaptable to any size, number or arrangement of pipes. Six inches of insulation is ordinarily used on the outside of all pipes. A minimum of four inches is economical spacing between piping.

Z-CRETE insulation serves as a monolithic, jointless insulating filler around pipes. A curing and waterproofing membrane completes the installation.

Z-CRETE installations have no joints to leak heat or collect water—they are as permanent as the earth itself. Anchors, guides and expansion devices (except loops) are the same as used in any other system. The curing membrane provides external water protection and imparts a tensile strength to the conduit.

#### TYPICAL Z-CRETE CONDUITS

Commonly used designs of Z-CRETE are shown above. The single pipe and double pipe conduit consist of a structural concrete pad, pre-cast Z-CRETE support blocks on which the pipes rest, a pour of Z-CRETE insulating concrete and a curing and waterproofing membrane. The multiple pipe conduit at the right has a second pre-cast support for the upper group of pipes.

#### REINSULATION OF EXISTING CONDUITS

The ruinous effect of water on steel pipe and insulation is well known. Z-CRETE insulation restricts moisture, keeps the conduit dry. Inorganic Z-CRETE concrete naturally resists deterioration. Many existing hollow or Box Type Conduits may be reinsulated by *pumping* them full of Z-CRETE. The mass of water resistant Z-CRETE restricts the

movement of moisture, so special drainage provisions are not ordinarily required. Z-CRETE is sold and installed by licensed applicators of Zonolite Company under U. S. Patent No. 2355966—Canadian Patent No. 439356. There is an applicator near you. For further data or information, write Dept. HV-6.

\* Z-Crete is a registered trade mark of Zonolite Company.

## Miracle Adhesives Corporation

Devices, Inc. Division  
 Manufacturer of Miracle Surface Anchors  
 214 East 53 St., New York 22, N. Y.  
 Representatives in all Principal Cities and in Canada

Miracle Surface Anchor method cuts costs • No wiring—No metal corner beads • Ideal for cumbersome installations.

Miracle Surface Anchors consist of perforated metal plates 2 in. x 2 in. or 2 3/4 in. x 2 3/4 in., to the center of each is welded a nail, bolt, spindle, prong or threaded stud. These Anchors are zinc and dichromate finish to resist corrosion. (Figs. 2, 3, and 5) bonded to rigid surfaces with Miracle Adhesive which is manufactured in many formulations to meet various job requirements.

Fig. 1: Attaching Corkboard with Miracle Spindle Anchors to Ducts  
 Fig. 2: Miracle Spindle Anchor and Washer  
 Fig. 3: Curved Plate for Convex Surfaces

**Miracle Spindle Anchors**—When attached to ducts, walls, ceilings, ship hulls, deck heads, etc., will firmly support various types of insulation, such as cork, batt and fiber glass, by impaling the insulation (and wire mesh, if any) on the spindle (Fig. 1). Self clinching washers to fit over the spindles are available, (Fig. 2). Spindle Anchors are also made on a curved plate for attaching to convex surfaces (Fig. 3).

**Miracle Pronged Anchors**—For bonding thermal cellular glass and other types of block insulation to ducts, walls and ceilings. Pronged Anchors are set between rows of block insulation and prongs bent in reverse direction over blocks. For wire mesh with plaster finish, 1 prong of each Anchor is bent over block insulation, the other prong penetrating mesh, then bent over before applying plaster finish (Figs. 4 and 6).

Fig. 4: Wall construction with Miracle Pronged Anchors. Fig. 5: Miracle Pronged Anchor.

Fig. 6: Ceiling construction with Miracle Pronged Anchors.

### MIRACLE TC CLIPS

Miracle TC Clips provide an economical, fast and permanent method of fastening light pneumatic air control lines, telephone cables, and wiring, etc., without drilling to any masonry or metal surface. Each clip will support 1 lb.

For twin lines use Miracle PA-1 Pronged Anchors. For fixing lines to steel work, use Miracle Hanger Supports.

Fig. 7: Miracle PA-1 Pronged Anchors. Fig. 8: Miracle TC Clips. Fig. 9: Miracle Hanger Supports Designed for supporting small cables, tubing, air lines, etc.

### MIRACLE "Z" CLIPS

Miracle "Z" Clips consist of 2 in. x 2 in. or 2 in. x 4 in. perforated 20 gauge steel. Provides an effective and economical means of attaching wallboard, insulation board, etc. to walls when an air space is required. The hinged construction take up irregularities in surface to which they are bonded. (Figs. 10, 11 and 12).

Fig. 10: Cat No. Z-22, 2 in. x 2 in. Fig. 11: Cat. No. Z-24, 2 in. x 4 in. Fig. 12: Vertical wall section illustrating Miracle "Z" Clips in position.

**Adhesives:** For Anchor installations use Miracle Anchor Adhesive for temperatures minus 40F to plus 200F or Miracle RT 1000 for minus 40F to plus 450F or when asphalt primers or compounds are involved.

## L.O.F. GLASS FIBERS COMPANY

Dept. 81-56, 1810 Madison Ave.,  
 Toledo 1, Ohio  
 Sales Offices and Distributors in Principal Cities

Microlite and Super-Fine are low-density, resilient glass fiber insulating materials, which have high thermal efficiency and sound-absorption characteristics. The high insulating efficiency found in both these materials results from the countless dead air cells formed by millions of fine glass fibers, which effectively reduce heat loss or gain.

**Application:** The light weight, flexibility and resilience of Microlite and Super-Fine make them easy to handle in large sections, easy to place properly, and easy to fasten securely by standard methods. Either material can be cut with knife or shears, and can be bent around curved surfaces and easily fitted in irregular areas. In addition, these springy, airy insulating materials are compressed and packaged in convenient rolls which save storage space in factory warehouses and in busy cutting-fabricating rooms.

Microlite and Super-Fine can be fitted quickly around the duct and supporting hangers. Light-pauge wire ties complete the job. Men like to work with L.O.F. Glass Fibers' insulation because it is so soft and flexible—so pleasant to handle.

**Properties:** Composed of minute glass fibers of consistent uniformity, bonded together in blanket form, Microlite and Super-Fine insulating materials resist fire, corrosion, vibration, settling and effects of humidity. Glass fibers are inorganic; they provide no sustenance for fungi or bacteria, and no food for rodents or insects. Inch for inch, Microlite and Super-Fine are two of the most effective of all insulating materials.

**Densities:** 1/2 lb, 3/4 lb, 1 lb, 1 1/2 lb, and 2 lb per cu ft.

**Widths:** 18, 24, 36, 48 and 72 in.

**Thicknesses:** 1/2, 3/4, 1, 1 1/2, 2, 3, 4 and 5 in.

**Lengths:** Comes in rolls from 50 to 200 ft, depending on density and thickness.

**Facings:** Microlite and Super-Fine are available with facings already applied in standard widths of 18 in., 24 in., 36 in. and 48 in. 1 in. flange available on one side or both edges for easier joint sealing. Types of facings include: Plain Vapor Barrier Paper; Reinforced Reflective Vapor Barrier Paper; Aluminum Foil (0.0025 in., 0.001 in., and 0.0007 in. thick); Vinyl Film (0.004 in. aluminum pigmented); Reinforced Duplex Paper Vapor Barrier. Also available are Vinyl and Neoprene Coatings.

Microlite and L.O.F. Super-Fine are efficient thermal and acoustical insulating linings for air supply ducts. Linings are easily applied by fastening the insulation to flat metal sheets with adhesive, and forming the duct in a brake.

**Coated Microlite or Super-Fine Duct Liner:** Either is available for all velocities up to the highest normally required. If desired, uncoated liner may be used for velocities under 3000 ft per minute.

**Noise Reduction Coefficient:** 1/2-in. liner has a noise absorption efficiency of 0.64; 1 in. of 0.80. Type No. 6 mounting used.

District Offices In All Principal Cities

### FIREFOIL BOARD

Firefoil Board consists of successive plies of corrugated asbestos paper sheets bonded with a special fire-resistant adhesive, treated with a chemical and hardened to make it a strong, fire-resisting and water resisting panel. There are approximately 8 layers of corrugation per inch of thickness. This results in a sheet having structurally strong, fire and moisture resisting and insulating qualities.

Standard sheet size 48 in. x 96 in. Cut sizes, available from the standard size sheets, can be cut at factory to customer's requirements.

Materials are available in thickness of  $\frac{1}{2}$  in. to and including 3 in. in  $\frac{1}{4}$  in. multiples.

The use of Firefoil Board with metal corners produces an insulated and acoustical duct construction. Other uses are for bulkheads in ships, partitions, coil housings, ovens, etc.

Firefoil Board can be easily nailed, screwed or bolted into place. It can be cut and installed with ordinary tools. Sheets are self-supporting when installed in metal channels or fastened to structural iron with bolts.

Firefoil can be used at temperatures up to 950 to 1000 F.

The "K" factor at 100 F. mean temperature is .725.

The "U" factor at 100 F. mean temperature as follows:

| Thickness         | Thermal transmittance<br>B.T.U./hr/sq ft/F. |
|-------------------|---------------------------------------------|
| $\frac{1}{2}$ "   | .68                                         |
| $\frac{3}{4}$ "   | .55                                         |
| 1"                | .46                                         |
| 1 $\frac{1}{4}$ " | .40                                         |
| 1 $\frac{1}{2}$ " | .34                                         |
| 1 $\frac{3}{4}$ " | .31                                         |
| 2"                | .28                                         |
| 2 $\frac{1}{4}$ " | .23                                         |
| 3"                | .20                                         |

Firefoil Board is recommended for interior use only and under dry conditions.

### MARINE PANEL

Marine Panel consists of corrugated asbestos sheets laminated together forming a material similar to Firefoil Board to which, on each surface a ply of  $\frac{1}{8}$  in. asbestos-cement board is bonded. It therefore has similar characteristics of Firefoil with the exception that it has added strength and durability resulting from the asbestos-cement facings.

Standard sheet size 48 in. x 96 in. Cut sizes, available from the standard size sheets, can be cut at factory to customer's requirements.

Materials are available in overall thickness of  $\frac{1}{2}$  in. to and including 3 in. in  $\frac{1}{4}$  in. multiples.

Marine Panel is recommended for partitions, coil housings, ovens, plenum chambers, interior elevator enclosures, fire resisting chambers, etc.

Its asbestos-cement facings give the material a rigid surface and an attractive gray-white appearance.

Marine Panel can be sawed and drilled as required in the field. Panels are self-supporting when installed in metal channels, or sheets can be secured to structural iron with bolts. Asbestos-cement or steel battens are used over butt joints, and corner angles of steel or galvanized iron are used at corners. Materials must be drilled prior to nailing or bolting in place. All holes should be slightly oversized.

The "U" factors at 100 F. mean temperature are:

| Thickness         | Thermal transmittance<br>B.T.U./hr/sq ft/F. |
|-------------------|---------------------------------------------|
| $\frac{1}{2}$ "   | .79                                         |
| $\frac{3}{4}$ "   | .62                                         |
| 1"                | .51                                         |
| 1 $\frac{1}{4}$ " | .43                                         |
| 1 $\frac{1}{2}$ " | .37                                         |
| 1 $\frac{3}{4}$ " | .33                                         |
| 2"                | .30                                         |
| 2 $\frac{1}{4}$ " | .24                                         |
| 3"                | .21                                         |

Marine Panel is recommended for interior use only and under dry conditions.

## The Philip Carey Mfg. Company

Lockland, Cincinnati 15, Ohio

District Offices In All Principal Cities

**Carey**  
PRODUCTS

### CAREYCEL FOR AIR DUCTS

Uses: A fireproof, low cost, high efficiency asbestos board for insulating ducts and all types of air conditioning equipment. Use 1 inch thickness up to 25 F difference in temperature and 80 per cent relative humidity. Recommendations for more severe conditions on request.

Description: Composed of 12 to 14 laminations of indented (not corrugated) asbestos felt per inch of thickness. Weight: approximately 1 $\frac{1}{2}$  lb per board foot. Sheet Size: 36 in. x 36 in., or cut to order. Blocks: 6 in. x 36 in. Thickness:  $\frac{1}{2}$  in. up.

### CAREYCEL FOR HEATING SYSTEMS

Uses: Pipe coverings and blocks for pipes, boilers, ovens and other apparatus where the temperature doesn't exceed 300 F. Use 1 inch thickness for temperatures up to 300 F.

Description: Pipe covering sections 36 in. long by 1 in., 1 $\frac{1}{2}$  and 2 in. thick, finished with cotton duck jacket and bands. Blocks: 6 in. x 36 in. Sheets: 36 in. x 36 in., or cut to order. Thickness:  $\frac{1}{2}$  in. up.

### CAREY IMPERVO FOR COLD PIPES

Uses: A high efficiency insulation for cold or ice water pipes—keeps the water cold and prevents sweating. Double  $\frac{3}{4}$  inch thickness recommended for ice water pipes.

Description: Laminated insulating felt with waterproof liner and jacket. 36 in. long in  $\frac{1}{2}$  in.,  $\frac{3}{4}$  in., double  $\frac{1}{2}$  in. and double  $\frac{3}{4}$  in. thick sections, finished with cotton duck jackets and bands.

### CAREY PROTECTO TO PREVENT FREEZING

Uses: Designed especially to reduce the danger of freezing of exposed water pipes.

Description: Consists of two inner layers of hair felt, a waterproof felt liner and an outer layer of insulating felt (wool felt). For severe conditions—exposure down to 0 F—use two-inch thickness. 36 in. long sections with cotton duck jacket and bands. Standard thickness—approximately 1 $\frac{1}{4}$  in.

## Owens-Corning Fiberglas Corporation

General Offices—Toledo 1, Ohio.

Pacific Coast Division, P.O. Box 89, Santa Clara, Cal.

OWENS-CORNING  
**FIBERGLAS**

### A COMPLETE LINE OF INDUSTRIAL INSULATIONS

#### Fiberglas Duct Insulations

Fiberglas Duct Insulations come in both rigid and flexible forms in six basic types. All deliver top insulating performance against heat and cold *plus* the additional advantage of sound control.

**Fiberglas Vapor-Seal Duct Insulation** is ideal for use on air conditioning ducts in warm and humid areas. Built-in vapor barrier of asphalt and kraft paper. Full range of thicknesses for specific temperatures.

**Fiberglas Flexible Duct Liner** is used as a sound absorber and thermal insula-

tion inside ducts. Available in two thicknesses with high NRC.

**Fiberglas Flexible Duct Insulation** can be used to provide thermal insulation on exterior of ducts of any shape.

**Faced Flexible Duct Insulation**, with facings of foils, duplex papers and reinforced laminate for vapor barrier or appearance purposes.

**Fiberglas Coated Duct Insulation** is a versatile product used for both inside and outside duct insulation.

**Fiberglas PF Duct Insulation** for covering rectangular ducts at minimum cost for efficient performance.

#### Fiberglas\* Pipe and Block Insulation

**Fiberglas PF (pre-formed) Pipe Insulation** available in all standard sizes for both low temperature and heated piping.

**Dual-Temperature Pipe Insulation** for use on cold piping or dual-temperature piping.

**Fiberglas Block Insulation and PF Insulating Boards** for small and large heated or cooled equipment.

**Aerowrap\* Pipe Insulation** for heated piping, cooled piping, steam traced lines, valves and fittings.

**Blanket-Type Pipe Insulation** for hot pipes up to 1000F, welded pipe and large pipe sizes.

**Low Pressure Pipe Insulation** for hot water and low pressure steam lines and for cold water pipe.

**Fiberglas PF Insulation**, a general-purpose insulation for heated or cooled equipment.

**Fiberglas TW-F Insulating Wool**, general-purpose insulation used for high-temperature equipment and industrial ovens.

**Metal Mesh Blankets** for breechings, tanks, ovens, and other high-temperature equipment for temperatures to 1000F.

#### Kaylo Pipe and Block Insulation

The low coefficient of conductivity, or "k," of Kaylo Heat Insulation, together with its long life at temperatures up to 1200F makes it ideal for high temperature insulation. Available in all standard sizes. Easily cut or fitted on the job. Made of hydrous calcium silicate by Owens-Illinois Glass Co. and distributed by Owens-Corning Fiberglas Corp.

For detailed information on Fiberglas Insulations look in the yellow pages for your local Fiberglas Distributor-Contractor or write Dept. 44, Owens-Corning Fiberglas Corporation, Toledo 1, Ohio.

\* FIBERGLAS (Reg. U.S. Pat. Off.) and AEROWRAP are trade-marks of Owens-Corning Fiberglas Corporation.

## SONOCO PRODUCTS COMPANY

Construction Products Division

LOS ANGELES, CALIF. PHILLIPSBURG, N. J. AKRON, IND.  
LONGVIEW, TEXAS BRANTFORD, ONTARIO SONOCO DE MEXICO, MEXICO, D.F.

### SONOAIRDUCT® FIBRE DUCT

for slab-floor, warm air perimeter heating systems

Made especially for gas and oil fired warm air, slab-floor perimeter heating systems where the duct is to be encased in dense aggregate concrete. Widely used and approved by engineers, architects and contractors. Saves time, labor and money without lowering the quality of construction.

Designed to comply with *FHA* minimum property requirements. It is lightweight and easy to handle. Available in lengths up to 50 ft long which can be sawed to exact lengths on the job. Fits all standard metal elbows, T's, registers, etc. Aluminum foil lined and wrapped with asphalt duplex kraft.

Also available is **SONOAIRDUCT-XP** fibre duct for crawl, basement and attic space, gas or oil fired warm air systems. Lined with aluminum foil and outer wrapped with 16-lb asbestos. Same sizes as regular SONOAIRDUCT.

#### SONOAIRDUCT SIZES AND WEIGHTS

| Inside Diameter | Wall Thickness | Approx. Wt. Per M Feet | Approx. No. Ft in 40-ft Carload |

## American 3 Way-Luxfer Prism Co.

431 So. Dearborn St., Chicago 5, Ill.

Over 50 years' experience in all types of rooflighting and ventilation

**AMERICAN 3-WAY TOP-LIGHTS AND TOP-BRITES**  
Bring Free Daylight into Interiors... the Scientific Way to  
Transform Daylight into Pleasant, Uniform, Room Light

American 3 Way TOP-LIGHTS consist of uniquely designed glass blocks of prism structure which are assembled into special insulated grids to make up standard panel units of various sizes. These panel units are installed on the roof according to carefully developed specifications whereby one end of the panel is oriented northward within a rotation of 30 deg.

Daylight is automatically transformed as it passes through the specially designed glass prisms. The TOP-LIGHT serves as a sort of traffic director for the various types of daylight that fall on it. The extremely bright rays of sunlight are rejected\*... softer, more comfortable light is given unrestricted passage... and all light is diffused and directed downward in a wide flood of comfortable roomlight.

The diffusion and rejection eliminates traveling "bright spots" such as may appear under ordinary daylighting mediums when the sun travels from east to west.

The hollow semi-vacuum glass blocks substantially reduce solar heat transfer during the hot summer months assuring cooler and more comfortable conditions below than can be expected with ordinary skylighting methods. The blocks also greatly reduce any tendency for condensation on the room side.

The glass blocks are set in aluminum grids surrounded by an insulation fill properly treated, covered and sealed with Tee-Ess compound for protection and weatherproofing. The factory-assembled and sealed panel is designed to carry customary roof loads, yet is comparatively light in weight.

Cross section of joint between blocks viewed from east-west ends

Cross section of grid perimeter showing the flashing

### MADE IN STANDARD SIZES

Whenever possible standard sizes should be ordered because they cost less and can be delivered quicker. Special sizes can be made to order at higher costs up to 22 square feet or up to 6 ft 2 in. in any one direction. Special size orders should specify direction of north and structural members.

### On the Job Directions

Each TOP-LIGHT has a large label on its upper surface which clearly shows: (1) direction of north, (2) direction of structural members, (3) code number. It also has directions for the general contractor and step by step instructions for the roofing contractor.

\* For areas such as stairwells, corridors, etc., where maximum light transmission is most important, TOP-BRITE glass blocks can be specified instead of TOP-LIGHT blocks.

**IT'S THE MODERN TREND** to flood interiors with the cheerful environment of natural, uniform daylight... automatically controlled by American 3 Way TOP-LIGHTS and TOP-BRITES.

## OWENS-ILLINOIS

GENERAL OFFICES • TOLEDO 1, OHIO

GLASS BLOCK AND TOPLITE PANELS

TWO ① PRODUCTS

**GLASS BLOCK PANELS.** Owens-Illinois Glass Block are hollow, hermetically sealed glass units containing a  $\frac{3}{4}$  vacuum. They are laid in mortar to form light-transmitting panels in vertical walls. Owens-Illinois Glass Block provide quality-controlled daylighting by glass areas which reduce heat loss, surface condensation and infiltration in cold weather and heat gain in warm weather.

**TOPLITE PANELS.** Owens-Illinois Toplite Panels are made of hollow, partially evacuated and hermetically sealed glass units, prefabricated at the factory into panels of insulated aluminum-grid construction. Used horizontally in roofs, Toplite Panels offer controlled daylighting with reduced heat loss, surface condensation and solar heat gain.

**THERMAL INSULATION.** The coefficients of heat transmission 'U' for panels of O-I Glass Block and Toplite are as follows:

| Size of Block                                 | U* (Btu/sq Ft/Hr/F Temp. Difference) |
|-----------------------------------------------|--------------------------------------|
| 5 $\frac{3}{4}$ " Sq                          | .60                                  |
| 7 $\frac{3}{4}$ " Sq                          | .56                                  |
| 11 $\frac{3}{4}$ " Sq                         | .48                                  |
| 11 $\frac{3}{4}$ " Sq with Glass Fiber Insert | .52                                  |
| 11 $\frac{3}{4}$ " Sq with Glass Fiber Insert | .44                                  |
| Toplite Panels                                | .58                                  |

**SURFACE CONDENSATION.** Because of the low over-all, air-to-air heat transfer, the exterior air temperatures which will produce condensation on panels of O-I Glass Block and Toplites are much lower than that for ordinary single glass. This permits higher humidities to be maintained where needed for winter air conditioning for comfort or for industrial processes.

**INFILTRATION.** Panels of glass block which are laid in mortar provide a barrier against infiltration. Dusts, drafts, and

air and vapor leakage are minimized. Natural ventilation requirements can be met by installing windows in glass block panels.

**SOLAR HEAT GAIN.** Complete instantaneous solar heat gain data for Owens-Illinois Glass Block designs for all exposures are given on Pages 305 through 307 of this GUIDE. The O-I design numbers which compare with the ASHAE type numbers are as follows:—

| ASHAE Type No. | O-I Block Design Nos.      |
|----------------|----------------------------|
| I              | 307, 316, 330, 331, 370    |
| II             | 340                        |
| III            | 340 with Fiberglass Insert |
| IVA            | 365                        |
| V              | 363                        |

A new O-I Block design, No. 80-F, is now available which has a much lower maximum solar heat gain than any of those shown in THE GUIDE. This reduction is due to the fact that this block reflects a high percentage of the solar energy which is incident on the exterior at the time of year when it reaches a maximum. Calculations of the solar heat gain through this block are now available. Confirming tests are being run. Solar heat gain through Toplite Panels is much less than that through single-glass or plastic skylights, due to the fact that Toplite Panels reflect a high percentage of the solar energy when the sun is at high altitude angles as in the spring and summer months.

**DESIGN AND SIZES.** Owens-Illinois Glass Block are made in a variety of face designs and in three standard sizes (5 $\frac{3}{4}$  in. sq, 7 $\frac{3}{4}$  in. sq, and 11 $\frac{3}{4}$  in. sq—all three are 3 $\frac{3}{4}$  in. thick). Mortar joints of  $\frac{1}{4}$  in. thickness are recommended.

Prefabricated Toplite Panels are available in four standard sizes (3 ft x 3 ft, 4 ft x 4 ft, 3 ft x 6 ft and 4 ft x 5 ft—all four are 3 $\frac{1}{2}$  in. thick). Complete technical data, description and details will be gladly sent. Write: Kimble Glass Company, subsidiary of Owens-Illinois, Department HV, P. O. Box 1035, Toledo 1, Ohio.

# PITTSBURGH CORNING CORPORATION

Dept. AW6, One Gateway Center, Pittsburgh 22, Pennsylvania

# PC GLASS BLOCKS

## THERMAL INSULATION

PC Glass Blocks allow economical use of large glass daylighting areas, reduce heat loss in cold weather and heat gain in warm weather because each PC Block contains a sealed-in dead-air space that is an effective retardant to heat transfer. See Section C, Table 20, Page 200 of this Guide.

## SURFACE CONDENSATION

Because of their high insulating value, condensation will not start forming on the room side of PC Glass Block panels until outside air has reached a temperature much lower than that necessary to produce condensation on single-glazed windows. The accompanying chart shows at what temperatures condensation will form. Note that LX, Suntrol and Skytrol blocks—in which a fibrous glass screen creates a double cavity—provide maximum insulation value.

Outdoor temperature required to produce condensation on the room side surface of PC Glass Block panels.

## SOLAR HEAT GAIN

The use of glass blocks for light-transmitting areas results in a marked reduction in solar heat gain as compared with ordinary windows. This factor is of considerable advantage in buildings that

are properly air-conditioned, but does not eliminate the need for adequate ventilation or shading in non-air-conditioned rooms. PC Suntrol blocks, with green diffusing screen, cut heat gain an additional 25 per cent.

For data on solar heat gain through PC Glass Blocks, see Tables 19 through 23 in Chapter 13. Types listed are the following PC patterns:

Type I—Argus, Argus Parallel Flutes, Decora, Vue  
Type II—Bristol  
Type III—Bristol LX  
Type IV—Esses  
Type V—Prism A, Prism B

## PC GLASS BLOCKS AID AIR-CONDITIONING

The chief aims of air-conditioning—temperature control, humidity control and cleansing of air—are aided by the use of PC Glass Blocks. Heat loss is less in winter—heat gain is less in summer. Solar heat transmission and radiation are significantly reduced. Dirt, drafts and moisture cannot filter in, for each panel is a tightly sealed unit.

## PATTERNS SIZES INSTALLATION

PC Glass Blocks are made in three sizes: 6 in., 8 in., and 12 in. square. All are 3 3/4 in. thick. They are available in decorative and functional patterns—the latter designed for control of transmitted daylight and solar radiation. Usually they are laid up in panels with 1/4 in. mortar joints. Any mason can install PC Glass Blocks; no special tools are required. Insulated skylights that eliminate many of the problems of ordinary skylights can be constructed using PC Skytrol blocks. For complete details, write the above address. In Canada: 57 Bloor St. W., Toronto, Ontario.

# FOAMGLAS®

the cellular, stay-dry insulation

## What FOAMGLAS is

FOAMGLAS is an entirely unique thermal insulation. Its light-weight, strong, rigid structure provides the combination of the two essentials for efficient, long-lasting insulating performance. FOAMGLAS is completely inorganic and has a closed cellular structure. It is made of glass, expanded about fifteen times into minute, non-connecting, hermetically sealed cells.

This sealed cellular structure makes FOAMGLAS water-proof and vapor-proof, preventing moisture absorption which impairs greatly the effectiveness of many insulations. Being inorganic, FOAMGLAS is fireproof, rot-proof and vermin-proof.

These inherent characteristics have enabled FOAMGLAS users to benefit from its long-lasting, constantly-high insulating performance. That is why FOAMGLAS is very rapidly gaining recognition as the ideal insulation for roofs, ceilings, walls, and floors of all kinds of buildings, as well as hot and cold piping, tanks and other equipment.

## How FOAMGLAS can benefit you:

| Properties               | Benefits                                                          |
|--------------------------|-------------------------------------------------------------------|
| Absorption               | 0                                                                 |
| Acid Resistance          | Impervious to common acids and acid fumes                         |
| Combustibility           | Incombustible                                                     |
| Compressive Strength     | 100 lbs/sq in.                                                    |
| Hygroscopicity           | No increase in weight in 240 days in air at 90% relative humidity |
| Density                  | 9 lbs/cu ft (ave.)                                                |
| Thermal Conductivity (k) | 0.38 Btu/hr/sq ft/°F/in.                                          |
| At 50° F                 |                                                                   |
|                          |                                                                   |

For Building Roofs, Ceilings, Walls and Floors. At Winston-Salem, FOAMGLAS' high strength permitted insulating parking deck-roof of Sears Roebuck's air conditioned store. In your building, moisture-proof FOAMGLAS insulation can help maintain air conditioning system efficiency.

For Ducts. Light-weight blocks of FOAMGLAS were easily applied to these metal air conditioning ducts at the Moses H. Cone Memorial Hospital, Greensboro, North Carolina.

For Piping. FOAMGLAS pipe insulation (available for up to 36 in. pipe size) was applied on this welded pipe carrying cold water for the system air conditioning Pittsburgh's new Gateway Center skyscrapers.

For full technical information, please write for our new catalogs indicating which of the above uses of FOAMGLAS you are most interested in. Address Dept. S-6, Pittsburgh Corning Corporation, One Gateway Center, Pittsburgh 22, Pa.

# Pittsburgh Plate Glass Company

FIBER GLASS DIVISION

One Gateway Center

Pittsburgh 22, Pennsylvania

Pittsburgh Superfine insulation is composed of extremely fine glass fibers, ranging upward in diameter from only 3/100,000 of an inch. It's an exceptionally lightweight, efficient thermal and acoustical insulating material. When specifications call for controlled heat or cold—or you need sound absorbed or vibration deadened—here are some of the advantages Pittsburgh Superfine Fiber Glass insulation provide:

**High Thermal Efficiency**—Thermal conductivity,  $k$ , at a mean temperature of 75 F is 0.22 to 0.27 Btu/sq ft/hr/deg F/in. thickness, depending on density. Effective for both high and low temperatures ranging up to 500 F.

**Fine Acoustical Properties** Noise reduction coefficient of a 1 in. thickness is as high as 0.80 with the sound absorption curve showing high efficiencies in the ranges of the most irritating noise.

**Light Weight, Easy to Handle**—Added load in any application is virtually negligible. Density as low as 0.6 pound per cubic foot. Readily cut with knife, shears, or die. Can easily be sewed and quilted, glued, tacked or taped into position.

**Flexible, Resilient, Tough, and Soft** Can be used on round or irregularly shaped objects and spaces as easily as in conventional layers. Fits closely into corners and tight spots quickly and easily, without damage to its structure.

**Saves Vital Space**—In use: Higher insulating efficiency means less thickness of Superfine required, as compared to ordinary insulation. In shipment: Packaged compressed to reduce shipping and storage space.

**STANDARD SPECIFICATIONS**—Pittsburgh Superfine is available in standard roll widths of 18 in., 24 in., 36 in., 48 in., 54 in. and 72 in. It can be supplied in any desired slit down to 2 in. Rolls are wound on 2 in. tubes and wrapped in heavy kraft paper. Superfine is also available in special lengths on request. It can be furnished vinyl coated, or with various paper, cloth or foil facings.

| Type              | Density (lbs per cu ft) | Thickness (inches) | Approx sq ft per lb | Typical Roll Lengths (feet) | Approx OD of Rolls (inches) |
|-------------------|-------------------------|--------------------|---------------------|-----------------------------|-----------------------------|
| S-314             | 0.6                     | 1/4                | 40                  | 100                         | 18                          |

## Low Temperature Insulations

**Corkboard**—Moisture resistant, strong, durable, lightweight, easy to handle. Sizes: 36 in. long; 12 in., 18 in., 24 in., 36 in. wide; 1 in., 1 1/2 in., 2 in., 3 in., 4 in., 6 in. thick. K factor: 0.27.

**LT\* Cork Coverings**—low-cost, easy-to-apply insulations for lines operating at temperatures down to -30 F. Made of precision cut segments of corkboard, cemented to 3-ply vaporproof paper. Thickness: 3/8 in., 1 1/2 in., 2 in., 2 1/4 in.

**Armaflex\***—flexible plastic insulation for fast installation on copper tubing and other hard-to-insulate lines. For temperatures from 32 to 200 F. K factor: 0.28. Inside diameters: 3/8 in., 1/2 in., 1 1/2 in., 1 3/8 in.

**Armaglas\* PF Insulation**—all-purpose, easy-to-apply insulation for tanks, vessels and equipment. Size: 24 in. x 48 in. Densities from 3.5 to 9 lbs per cu ft.

**Armaglas AB Board**—a rigid glass fiber board for cold room walls, ceilings and partitions. Coated with asphalt. Size: 12 in. x 36 in. 6 lb and 9 lb densities.

## Heat Insulations

**Armtemp\***—strong, mineral wool insulation for tanks, ducts and other heated surfaces. In block form for temperatures up to 1900 F; in blankets for temperatures up to 1200 F.

**Armabestos\***—asbestos fibers formed into pipe covering and block. Pipe covering, A-7 for temperatures up to 750 F; A-12 for temperatures up to 1200 F. Block for use up to 1200 F.

**Armaglas Pipe Coverings**—a glass fiber insulation for temperatures up to 400 F. Plain or with aluminum foil vapor jacket. In 3 ft long sections for pipes up to 33 in. in size. Copper tubing sizes from 3/8 in. to 6 in.

**Armaglas WA Pipe Covering**—flexible, light-weight blankets for wrapping around lines operating up to 600 F. Furnished 3/4 in. thick and compressed to 1/2 in. in application.

**Armaglas Blanket Type Pipe Covering**—for irregularly shaped pipes operating up to 1000 F. 1 in., 1 1/2 in., 2 in., 3 in., 4 in. thick. Length: 2 in.

**Armaglas Low-Pressure Pipe Covering**—for cold water, hot water and low-pressure steam lines. Preformed of glass

fibers in 3 ft. molded half-sections. Fits pipe sizes up to 8 in. and copper tubing up to 3 in.

**Armaglas PF Insulation**—an all-purpose material for use on tanks and vessels operating up to 400 F. Comes in panels and boards; in 7 densities from 2.5 to 10.5 lbs per cu ft.

**Armaglas Insulating Wool**—comes in rolls, batts and shredded; for many industrial applications where temperatures go up to 1000 F. Thicknesses: 3/4 in. up to 3 1/4 in.

**Armaglas Metal Mesh Blankets**—for large, hard-to-insulate equipment. Made of glass fibers faced on one or both sides with wire mesh or metal lath. For temperatures to 1000 F. Sizes: 2 ft x 8 ft, 2 ft x 4 ft. Thicknesses from 1 in. to 6 in.

**Armaglas Block Insulation**—for boilers, breechings, tanks and other process equipment operating up to 400 F. 6 in. and 12 in. wide, 36 in. wide. 3/4 in., 1 in., 1 1/4 in., 2 in. thick.

## Duct Insulations

**Armaglas PF Duct Insulation**—low-cost insulation for exterior duct surfaces. Size: 24 in. x 48 in. Thicknesses: 1/2 in. and 1 in. For temperatures up to 400 F.

**Armaglas Coated Duct Insulation**—has a neoprene finish to provide good painting surface and prevent air erosion. Up to 250 F.

**Armaglas Vapor-Seal Duct Insulation**—both thermal insulation and sound absorber with built-in vapor barrier. For cool air ducts where condensation is a problem. 24 in. x 48 in. size; 3/4 in., 1 in., 1 1/2 in., 2 in. thicknesses. Up to 250 F.

**Armaglas Flexible Duct Insulation**—All-purpose insulating blanket and sound conditioning for fast application on hot or cold ducts of any size or shape. Up to 250 F.

**Armaglas Flexible Duct Liner**—Neoprene-coated and used as sound-absorbing insulation inside warm air or cooling ducts. 36 in. wide; 1/2 in. and 1 in. thicknesses. Up to 250 F.

## Armstrong Contract Service

This complete, nationwide service provides materials, engineers, supervisors, work crews, research and testing facilities. Your nearest Armstrong office will furnish prompt estimates, technical assistance and product information without obligation.

# CELOTEX

REG. U. S. PAT. OFF.

**Celotex Insulation Board Products** are made by felting long, tough cane fibers into strong, rigid boards. Manufactured under the exclusive Ferox\* Process. Ferox-treated Celotex board has been demonstrated by laboratory tests and years of use to be protected effectively against dry rot and termite attack. Integrally waterproofed.

**Celotex Insulating Sheathing**—For use in frame construction under wood siding, wood or asbestos shingles, stucco, or masonry veneer. *Double-Waterproofed*—integrally treated, then asphalt-coated on all surfaces. Exceeds government vapor permeability requirements.

Sizes: 4 ft wide x 8 and 9 ft long x  $2\frac{5}{32}$  in. or  $\frac{1}{2}$  in. with square edges. 2 ft x 8 ft x  $2\frac{5}{32}$  in. with V-type tongue and groove on long edges.

*Celotex 4 ft wide  $2\frac{5}{32}$  in. Sheathing, applied vertically without corner bracing, greatly exceeds racking strength requirements set forth in FHA Technical Circular No. 12 (racking strength at least equal to horizontally-applied wood sheathing with let-in bracing is minimum requirement).*

### Celotex Roof Insulation

**Regular**—Natural cane fiber board surface. Provides excellent bond for pitch or asphalt. Meets requirements for Roof Insulation Board (Class C) of Federal Specifications LLL-F-321b, Commercial Standard CS42-49 of U. S. Department of Commerce, and ASTM Specification C208. Sizes: 23 in. x 47 in., 24 in. x 48 in. Thicknesses:  $\frac{1}{2}$  in., 1 in.,  $1\frac{1}{2}$  in., 2 in.

**Preseal**—Coated with special asphalt on all surfaces and edges for additional moisture protection. Size: 24 in. x 48 in. Thicknesses:  $\frac{1}{2}$  in., 1 in.,  $1\frac{1}{2}$  in., 2 in.

**Channel-Seal**—Specially fabricated with  $1\frac{1}{16}$  in. x  $\frac{1}{16}$  in. bevel on underside of all edges to form interconnecting channels for equalizing air pressure between roofing and deck. Asphalt-coated all surfaces

and edges. Size 24 in. x 48 in., thicknesses 1 in.,  $1\frac{1}{2}$  in., and 2 in. Conductance, "C," of 0.33 Btu for nominal one inch thickness after coating.

**Flexcell\* Expansion Joint Filler**—Cane fiber felted into strong, resilient boards, then saturated with durable asphaltic compound. For expansion joint uses, perimeter insulation for concrete floors at grade, sill sealer, plate sealer, and vibration isolation. Thicknesses of  $\frac{1}{4}$  in. to 1 in. in various lengths and widths.

**Cemesto\* Structural Insulating Panels**—Completely fabricated panels for curtain walls, roof decks, partitions, air conditioning duct and roof machinery enclosures. Consist of cane fiber board core surfaced on both sides with layer of cement-asbestos board. Sizes: 4 ft wide x 6 ft to 12 ft lengths. Special sizes available. Thicknesses:  $1\frac{1}{16}$  in.,  $1\frac{1}{8}$  in.,  $1\frac{3}{8}$  in., 2 in.

**Celotex Spun Rock Wool Products**—Regular Blankets, full- or semi-thick, 15 in. x 96 in., 15 in. x 48 in., 15 in. x 24 in. Utility Blanket, 15 in. x 96 in. Reflective Blankets, standard thickness, 15 in. x 96 in. Also Loose, Granulated and Hand-Pouring Rock Wool.

**Q-T\* Ductliner**—Sound absorbing material designed for duct lining in air-conditioning systems. Made of rock wool and special binder. Withstands air duct humidity, is fire-resistant and will not support combustion. Thermal conductivity of 0.30.

**Celotex Sound-Conditioning Products**—Complete line of specialized acoustical materials to comply with every requirement, specification, or building code. Distributors in principal cities.

**Celotex Interior Finishes**—Tile Board, Finish Plank, Building board—triple-duty products that build, decorate, insulate. Variety of sizes and finishes.

\* Reg. U. S. Pat. Off.

## The Dow Chemical Company

Plastics Sales, Midland, Michigan

### STYROFOAM

**RIGID LOW TEMPERATURE BOARD INSULATION PROVIDES  
EXCEPTIONAL RESISTANCE TO WATER, ASSURES  
LONG SERVICE LIFE**

You'll find that Styrofoam® . . . Dow's rigid low temperature board insulation . . . is right for *your* job. Styrofoam combines *all* the factors you want: high thermal resistance, low original cost, long service life and a minimum of maintenance.

Commercial applications in many fields prove Styrofoam is an excellent rigid-type low insulation material. Its closed cellular structure provides exceptionally high resistance to water and water vapor. Styrofoam's low "K" factor (0.25 Btu/sq ft/hr/F/ inches at a mean temperature of 40°F) assures maximum thermal efficiency

Styrofoam is available in two grades: Styrofoam 22 (regular) and Styrofoam 33. (self-extinguishing). For more detailed information contact your nearest sales office. Atlanta • Boston • Buffalo • Chicago • Cincinnati • Cleveland • Detroit • Houston • Los Angeles • Minneapolis • New York • Philadelphia • St. Louis • San Francisco • Seattle.

### STYROFOAM GIVES YOU ALL THESE ADVANTAGES FOR:

Pipe Covering • Insulated Vehicles • Refrigeration Equipment • Low Temperature Rooms • Perimeter Insulation

- High Thermal Resistance
- Water Resistance, freedom from capillarity
- Long Insulation Life
- Low Cost Installation, Maintenance, Operation
- Odorless
- Resistant to Rot and Mold
- Light Weight
- Easy to Fabricate
- Sizes for any job

Thicknesses: 1,  $1\frac{1}{2}$ , 2,  $2\frac{1}{2}$ , 3, 4, 5 in.—Widths: 10 in. and 12 in.—Lengths: 36 in. and 9 ft.

## INSULITE®

### STRUCTURAL INSULATION BOARD

For 42 years engineers and architects have specified Insulite materials for architectural uses, interior finish, and for other thermal insulation and sound control uses. Insulite materials have proved their merit through actual performance on the job.

#### STRUCTURAL MATERIALS

**Condensation Control**—To prevent condensation within walls, authorities recommend "sealing the warm side and venting the cold side" of the wall. Insulite Insulating Wool Batts or Blankets provide the necessary vapor barrier on the warm side of the wall, thereby reducing the flow of vapor into inner wall areas. On the cold side of the wall, vapor-permeable Bildrite Sheathing allows surplus vapor to escape toward the outside.

**Bildrite® Sheathing**—A tough, durable, insulating sheathing material made from new wood fibers. Protected throughout by an integral asphalt treatment. Bildrite (4 ft width) has more than twice the bracing strength of horizontal wood sheathing.  $\frac{23}{32}$ -in. thick. Sizes: 2 x 8 ft (V-joint on long edges) . . . 4 x 8 ft to 4 x 12 ft (square edges). Thermal conductivity: 0.37 Btu per inch thickness. Also available is  $\frac{1}{2}$ -in. Graylite Sheathing.

Applying Bildrite Sheathing

#### SHINGLE-BACKER

Shingle-Backer is a fast-applying, insulating undercourse material for double-coursed, shingled walls. Made from  $\frac{5}{16}$ -in. insulation board, waterproofed throughout with asphalt.

There are two Shingle-Backer Systems. For wood-shingled sidewalls, Shingle-Backer panels take the place of low-grade wood undercourse shingles. Makes faster,

easier, better-looking shingled walls at low cost. Two widths: 13 $\frac{1}{2}$  in. for 12-in. shingle exposure, 15 $\frac{1}{2}$  in. for 14-in. shingle exposure. Four ft long.

Applying shingles and Shingle-Backer

A different Shingle-Backer System is used for asbestos-cement siding shingles. 11 $\frac{3}{4}$ -in. Shingle-Backer is used to give modern shadow-lines. Also protects against breakage, helps sound condition house.

Both systems give added insulation, greater structural strength and weather resistance. No building paper is required. Can be applied over Bildrite and Graylite® Sheathing.

#### ROOF INSULATION

Insulite Roof Insulation is fabricated from either Ins-Lite or Graylite insulation board. The  $\frac{1}{2}$ -in. thickness has square edges. The 1, 1 $\frac{1}{2}$ , and 2-in. thicknesses are multiple layers stapled or cemented together. Available with either square or offset edges. Size: 24 in. x 48 in.

#### INSULATING WOOL

Insulite Insulating Wool is made from famous "Fiberglast," consisting of millions of long glass fibers bonded together with a thermo-setting resin. Available in the following forms: roll blankets, batt blankets, utility batts, plain batts and pouring wool.

**Perimeter Insulation**—Fiberglass Perimeter Insulation guards against heat loss in basementless houses. Meets F.H.A. and specific job requirements. Type AE-6 (asphalt enclosed), Type PF-615 (paper faced) and Type PF-619 (paper faced, load bearing).

#### INDUSTRIAL INSULATION

Choose from Six Types

(1) **Low Density Ins-Lite®**—a low density board with high insulating efficiency and maximum sound absorption. Density 10.0 to 12.5 lbs/cu ft.

(2) **Medium Density Ins-Lite**—an insulating board which provides efficient insulation and structural strength. Density 12.5 to 15.0 lb/cu ft.

(3) **High Density Ins-Lite**—designed to be used where insulation and structural strength are required. Density 15.0 to 17.5 lbs/cu ft.

(4) **Low Density Graylite**—a highly efficient insulating board, integrally treated with asphalt for increased strength and resistance to water absorption. Density 13.5 to 16 lbs/cu ft.

(5) **Medium Density Graylite**—an insulating material integrally treated with asphalt. Has high strength and resistance to water absorption. Density 16.0 to 18.5 lbs/cu ft.

(6) **High Density Graylite**—an insulating material with maximum strength and resistance to water absorption. Density 18.5 to 21 lbs/cu ft.

#### INTERIOR FINISHES

**Roof Deck**—A 3-in-1 fiber board product for roofs that serves as decking, insulation and finished ceiling. Ceiling side has white, textured, flame-resistant surface. Available with or without vapor barrier. Size: 2 x 8 ft panels 1 $\frac{1}{2}$  in., 2 in. and 3 in. thicknesses.

**Graylite Building Board**—A durable board, integrally treated with asphalt for maximum strength and moisture resistance. Thermal conductivity is 0.37

Applying Insulite Roof Deck

\* Reg. U. S. Pat. Off.

Btu per in. thick. Sizes: 4 x 8 ft to 4 x 12 ft. Thicknesses:  $\frac{1}{2}$ ,  $\frac{3}{4}$ , and 1 in.

**Primed Graylite Building Board**—Graylite Building Board with a prime coating for easy painting. Sizes: 4 x 8 ft to 4 x 12 ft. Thicknesses  $\frac{1}{2}$  and  $\frac{3}{4}$  in.

**Smoothlite® Interior Board**—A natural-colored, factory-coated board, gloss finish. 67 per cent light reflection. Sizes: 4 x 6 ft to 4 x 12 ft. Thicknesses:  $\frac{3}{8}$  and  $\frac{1}{2}$  in.

**Wevelite® Interior Board**—A practical, low-cost interior board with flame-resistant finish in white. Sizes: 4 x 6 ft to 4 x 12 ft. Thickness  $\frac{1}{2}$  in.

**Durolite® Tileboard**—A textured flame-resistant finished board, in white and light ivory colors. Has flanged tongue-and-groove joint. Thickness:  $\frac{1}{2}$  in. Sizes: 12 x 12 in. to 16 x 32 in.

**Durolite Plank**—Flanged tongue-and-groove joints. Textured, flame-resistant surface finish:  $\frac{1}{2}$  in. thickness. Colors: ivory, pale green, sunlite yellow, and woodtone. Sizes: 8, 12, and 16 in. wide; and 8 and 12 ft long.

**Fiberlite® Acoustical Tileboard**—A low-cost, highly efficient acoustical tile, has effective flame-resistant white finish. Sizes: 12 x 12 in. to 12 x 24 in. Thicknesses:  $\frac{1}{2}$  and  $\frac{3}{4}$  in.

**Acoustilite® Perforated Tileboard**—A rugged, sound-absorbing tileboard for residential and commercial interiors. Standard tile units contain 484 cleanly-drilled holes.  $\frac{1}{2}$  or  $\frac{3}{4}$  in. thickness. Also random drilled Acoustilite Tileboard in  $\frac{1}{2}$  or  $\frac{3}{4}$  in. thickness. White finish has high light reflection. Has effective flame resistant finish. Size: 12 x 12 in.

Applying Random Acoustilite

#### HARDBOARD PRODUCTS

Insulite HardBoard is a rigid, durable, wood-fiber material with tremendous strength. Available in a range of densities from 55 to 68 lb per cu ft. Thicknesses from  $\frac{1}{8}$  to  $\frac{3}{4}$  in. Sizes from 3 x 4 ft to 4 x 16 ft.

### Home Insulation

Applying Spintex batts in new home

#### For Existing Homes and Buildings: J-M Spintex "Blown" Home Insulation

J-M Spintex Home Insulation is nodulated mineral wool which is blown pneumatically into the spaces between studs in outer walls and between roof rafters or attic floor joists. Insulation thickness in walls corresponds to stud depth, approximately  $3\frac{3}{8}$  in. The uniform fill assures maximum thermal efficiency. This type of insulation is sold and installed only by carefully selected experienced and officially franchised J-M Blown Home Insulation Contractors.

For complete information on J-M Spintex "Blown" Home Insulation and its application, write the address above or call your local Johns-Manville office.

#### Airacoustic® Sheets for lining Air-Conditioning Ducts

J-M Airacoustic Sheets provide a fire-safe, sound-absorbing material developed for use in ventilating ducts. Since they absorb a large percentage of the sound that strikes them, they provide a highly effective means of reducing

undesirable duct noises. Composed of rock wool and a suitable binder, Airacoustic Sheets are available in size 24 in. x 36 in., and in thicknesses of  $\frac{1}{2}$  in. and 1 in.

#### Spintex® Duct Insulations

Spintex Duct Insulations are incombustible... provide high insulating efficiency and long service life. Their low installed cost is the result of Johns-Manville's long experience in developing scientifically correct insulations and

proper methods of application. They are furnished as blankets and semi-rigid boards. The densities range from 2 to over 6 lb per cu ft, providing flexible and stiff materials for round or rectangular ducts.

#### For New Construction: Spintex® Batts and Blankets

Johns-Manville Spintex Batts and Blankets are made of spun rock wool. Instead of short, coarse fibers, this J-M spinning process produces long, fine fibers which make better, more firmly felted batts and blankets that are stronger, lighter in weight, more resilient, and have greater uniformity throughout. They are rotproof, fireproof, and assure the homeowner of maximum year-round comfort, protection and winter fuel savings.

SPINTEX BATTS are strong and sturdy. They will not break down under rough handling but hold their factory-made shape and uniform thickness... will not crumble or fray when cut to fit irregular spaces. Each batt has a vapor seal backing to protect against the passage of abnormal humidity and a tacking flange for ease of installation.

Spintex Batts are furnished Full-Thick and Semi-Thick. Full-Thick Batts have an average thickness of  $3\frac{1}{4}$  in.; Semi-Thick, an average thickness of 2 in. Both types are available in sizes 15 x 24, 15 x 48, 19 x 24, 19 x 48, 23 x 24 and 23 x 48 inches.

SPINTEX BLANKETS, made of the same firmly-felted long fiber spun rock wool, are fully enclosed in a permeable wrapping with an approved vapor seal backing and a tacking flange.

Thick Blankets, approximately 3 in. in thickness, are furnished in sizes 15 in. x 48 in. and 23 in. x 48 in.; Medium Blankets, approximately 2 in. thick, in sizes 15 in. x 64 ft, 23 in. x 64 ft, 15 in. x 8 ft and 23 in. x 8 ft; and Service Blankets, approximately  $1\frac{1}{2}$  in. thick, in sizes 15 in. x 8 ft and 23 in. x 8 ft.

### Pipe and Boiler Insulations

#### J-M FIBROCEL®

J-M Fibrocel Pipe Insulation is a molded silica insulation developed by Johns-Manville for use on hot, cold and chilled water lines, low pressure steam pipes, and dual service heating and cooling systems. It can't shrink or expand which means no more gaping, unsightly joints with accompanying heat leakage. Its firm, hard texture resists deformation and its combination of thermal properties and recommended wall thicknesses in the services for which it is designed provide maximum economical insulation effectiveness. Fibrocel resists decay, fire and vermin. Lightweight, precision-formed for exact fit, and easy to cut and work on the job, it speeds application and keeps costs at a minimum.

Fibrocel is furnished in three jacket styles: Fibrocel C with standard or special weight canvas jacket for steam, hot or cold water service from 60F to 300F; Fibrocel G with glazed white plastic-coated paper jacket for steam, hot or cold water service from 60F to 300F; and Fibrocel VB with vapor barrier jacket, recommended for use on pipes subject to sweating and particularly adapted for dual service heating and cooling systems between 35F and 225F.

#### PRE-SHRUNK ASBESTOCEL®

Cellular type insulation made up of alternate layers of plain and corrugated asbestos felts for use on pipes conveying low pressure steam and hot water. Three finishes: Glazed White, Asbestos Paper and Canvas. Furnished in 3-ft sections to fit standard pipe sizes\* and in standard thicknesses of 2 to 8 plies, each ply approx.  $\frac{1}{4}$  in. thick. Temp. limit, 300F.

#### ASBESTOCEL® SHEETS AND BLOCKS

For insulating medium and low pressure boilers, feed water heaters, warm air ducts, etc. Furnished 6 to 36 in. wide, 36 to 96 in. long, from  $\frac{1}{2}$  to 4 in. thick.

\* Also available to fit straight runs of copper tubing with nominal diameters of  $\frac{3}{8}$  in. and up.

#### J-M 85% MAGNESIA

The high insulating value and permanence of J-M 85% Magnesia Block and Pipe Insulation have been proved over many decades of satisfactory, trouble-free service. Blocks are furnished 18 and 36 in. long; 3 and 6 in. wide (flat or curved), 1 through 4 in. thick; 9 and 12 in. wide (flat only),  $1\frac{1}{2}$  through 4 in. thick. Pipe insulation is furnished in 3-ft lengths in sectional or segmental form for all standard pipe sizes, in nominal thicknesses up to 3 in.\* Temp. limit 600F.

#### SUPEREX® COMBINATION

Superex Combination Insulation (an inner layer of J-M Superex, a material with high heat resistance, and outer layer of J-M 85% Magnesia, a material with great insulating value) is recommended for temperatures from 600F to 1900F. Both Superex and 85% Magnesia are available in sectional and segmental pipe covering and in block form.

#### ROCK CORK®

Rock Cork is made of mineral wool and an asphaltic binder molded into sheets and pipe insulation for all low temperature service. It is strong, durable, and will not support vermin. Because of its unusual moisture-resistance, its high insulating value is maintained in service.

Furnished in sheets 18 in. by 36 in., (18 in. by 18 in. available in 1 in. thickness only), in 1,  $1\frac{1}{2}$ , 2, 3 and 4 in. thicknesses. Lagging, for curved surfaces, supplied 18 in. long by  $1\frac{1}{2}$  through 4 in. thick, 2 to 6 in. wide, depending on diameter. Pipe covering furnished in Ice Water, Brine, and Heavy Brine thicknesses, for all commercial pipe sizes.\* Discs also available to a 36 in. max. diameter.

#### DETAILS ON REQUEST

For further information about J-M Insulations and J-M Application Service, write Johns-Manville, 22 East 40th St., New York 16, N. Y.

## Kimberly-Clark Corporation

Neenah, Wisconsin

**KIMSUL** A PRODUCT OF  
Kimberly-Clark

**INSULATION** 

NEW YORK 17, N. Y., 250 PARK AVENUE  
ATLANTA 3, GEORGIA, 900 PEACHTREE ST., N. E.  
CHICAGO 3, ILLINOIS, 8 S. MICHIGAN AVENUE  
SAN FRANCISCO 4, CALIF., 155 SANSOME STREET

### Reflective and Pyrogard

**KIMSUL\*** is unique among building insulations and acoustical materials because it is made of many individual plies—each one a continuous separate layer of soft, clean, creped, asphalt-treated cellulose fibers. Each ply is controlled carefully in manufacture both as to thickness and crepe structure. The result is

a flexible blanket, inherently uniform in thickness—an important factor in a thermal or sound insulating material. The Kimsul plies and cover of the creped Pyrogard\* or creped Reflective Vaporseal are held together with rows of strong stitching that prevent sifting and settling. No heat-leaking thin spots, no money-wasting thick spots in the Kimsul blanket. Reduced to  $\frac{1}{2}$  its installed volume for easier shipment, handling and storage, the Kimsul blanket is expanded in installation. The stitching controls expansion to the density of a high degree of efficiency.

**KIMSUL IS NOW MADE IN THREE TYPES—KIMSUL 48 SHEATHING BLANKET—PYROGARD KIMSUL REFLECTIVE KIMSUL.**

**Kimsul 48—Sheathing Blanket** is Reflective Kimsul Insulation manufactured by the Kimberly-Clark Corporation to a width of over 48 inches, pre-cut to eight foot lengths which makes it possible to build a more heat-tight, air-tight and vapor-tight dwelling wall at lower cost than ever before.

**Kimsul "48" Sheathing Blanket** retains the recognized insulating qualities of chemically treated wood fibres arranged in multi-ply layers of air cells that are well known in Kimsul insulation material. It is a recognized fact that this construction of an insulating material produces outstanding results.

**Sheathing Blanket's** wood fibre construction, extremely tough, three-ply, heat reflective, vapor sealing cover give the American home building industry a material which minimizes the problems of vapor and heat transmission which have always been most difficult to solve economically.

#### SOME FEATURES OF KIMSUL 48 SHEATHING BLANKET

Positive insulation in close framing areas. No heat loss or cold air leaks in areas that couldn't be sealed before Kimsul "48".

Positive insulation around electrical receptacles and behind conduit. Repairs and replacements of these items do not damage the insulating material.

Complete insulation between the cold exterior wall and metal ductwork. Minimizes heating expense... gives greater comfort.

\* T. M. Reg. U. S. Pat. Off.

Positive seal of exposed sub-floor ends. Eliminates cold drafts and heat losses.

### Pyrogard and Reflected KIMSUL\*

Kimsul is also available for all conventional ceiling, wall, and floor construction in Pyrogard and Reflective types. . . The differences in the two types are: Reflective Kimsul has a cover of aluminum foil that acts both as a vapor barrier to shut out condensation, and as a highly efficient reflective surface to turn back radiant heat. Reflective Kimsul has strong reflective tacking flanges for easy, secure attachment to framing. For heat flow downward, Reflective Kimsul provides additional insulating value. Pyrogard Kimsul has the fire-resistant cover.

**Fire-Resistant**—Special permanent chemical treatment makes Kimsul resist fire. **Pyrogard\* Fire-Resistant Cover**—(safety feature of Pyrogard Kimsul) resists flame-spread.

**Creped Aluminum Foil Cover**—(a feature of Reflective Kimsul) reflects heat, shuts out condensation.

**Moisture-Resistant**—asphalt treatment of each ply sheds water.

**Resists Mold, Rot, Vermin**—The materials of which Kimsul are made offer no subsistence to vermin or insects. Special chemical treatment resists mold and fungus.

**"k" Factor**—0.27 Btu/sq ft/hr/F.

**Air Space**—is a prime requisite. Use a vapor-permeable building paper under exterior finish. Ventilation in attics and floors should never be omitted. Use approximately one sq ft of louver area for 1000 sq ft of ceiling area.

Reflective KIMSUL insulated. Edge of fastening flange folded over face of framing completes the vapor seal.

#### APPROX SQ FT PER ROLL OR CARTON ("48")

| Kimsul "48" | Grade | Approx Sq Ft Per Roll or Carton ("48") | Approx Shipping Weight Per Roll or Carton ("48") |
|-------------|-------|----------------------------------------|--------------------------------------------------|
| "48" A      | 3.28  | 640 Sq Ft                              | 75 Lbs                                           |
| "48" B      | 3.28  | 832                                    | 97                                               |
| "48" C      | 3.38  | 1024                                   | 120                                              |

#### SOUND DEADENING AND ABSORPTION

Kimsul is effective both in deadening sound and absorbing it. It will absorb sound originated by diaphragmatic action, and sound leaks, as well as cushioning furring strip type construction. Kimsul prevents bridging or short circuiting of sound-resisting construction during erection. The average coefficients of sound absorption of Kimsul are:

Double Thick 75%  
Standard Thick 55%  
Commercial Thick 40%

Kimsul should be spaced from one to six inches from reflecting surface, with cover side away from sound source to obtain greater absorption at lower frequencies.

#### CONSTRUCTION DETAILS AND HEAT FLOW (U) FACTORS

| KIMSUL GRADE                | HEAT FLOW HORIZONTAL |    | HEAT FLOW UP |    | HEAT FLOW DOWN |    | HEAT FLOW DOWN |    |

## Lockport Mills, Inc.

Thermal and Acoustical  
INSULATION

Dept. C.

Lockport, N. Y.

**Moisture-Resistant**—Chemical treatment, combined with natural protective coating on cotton fibres, enables cotton to effectively resist moisture. Prevents rot and mildew.

**Smooth Texture**—No sharp particles to irritate the skin.

**Flexible**—Cotton batt may be expanded or contracted to fit any enclosure.

**Easy to Warehouse and Handle.** Offers far more "compressibility." Requires one-third the trucking and warehouse space of ordinary insulation.

**Simple and Economical to Install.** Saves from 25 to 40 per cent in costs.

**Designed to Maintain Maximum Utility.** Resists all types of deterioration. Won't sag or settle. Packaged in Rolled Form.

**Thicknesses**—inches: 1, 1½, 2, 3, 3½. **Width**—16, 20, 24 in. centers. **Lengths**: Standard from 12 ft up.

INSULATING VALUE OF VARIOUS INSULATORS<sup>a</sup>

The coefficients of conductivity (k value) are expressed in Btu per hour per square foot per degree Fahrenheit per 1 in. of thickness.

| Type of Insulation                                    | Wgt. per Cu Ft | k <sup>b</sup> Value |
|-------------------------------------------------------|----------------|----------------------|
| Cotton: Insulating Batt                               | .875           | 0.24                 |
| Rock Wool: Fibrous material made from rock            | 10.00          | 0.27                 |
| Mineral Wool: Fibrous material made from mineral slag | .....          | 0.27                 |
| Glass Wool: Fibrous material made from glass slag     | 1.50           | 0.27                 |
| Rigid Insulation made from sugar cane fibre           | 13.50          | 0.33                 |
| Chemically treated wood fibre between layers of paper | 3.62           | 0.25                 |
| Pei grass between layers of paper                     | 3.40           | 0.25                 |
| Stitched and creped expanding fibrous blanket         | 1.50           | 0.27                 |
| Shavings: Various from planer                         | 8.80           | 0.41                 |
| Corkboard: No binder added                            | 7.00           | 0.27                 |
| Rigid insulation made from wood fibre                 | 15.90          | 0.33                 |

<sup>a</sup> Compiled from Chapter 9, 1954 Edition.

<sup>b</sup> "k" indicates temperature conductivity.

**Thermal Conductivity**—The "k" value for cotton is 0.24 Btu/hr/sq ft/degree F/inch. (See table.)

**Light Weight**—Weight of 1 cu ft is 7½ lb. (See table.)

**Flame-Proofed**—Withstands 1800° blow torch heat.

## The Pacific Lumber Company

100 Bush Street, San Francisco 4, Calif.

IDEAL FILL INSULATION

FOR REFRIGERATION OR

AIR CONDITIONED STRUCTURES

## REFRIGERATION REQUIREMENTS COMPLETELY FULFILLED BY VOID-FREE PALCO WOOL

Extremely low thermal conductivity over a wide range of mean temperatures is due to low conductance through the material itself, void-free application providing full insulation without pockets or joints, and virtual elimination of convection current losses. Initial and operating economy result from low material cost, simple structural requirements, ease of installation, efficiency minimizing refrigerating equipment requirements, and permanent effectiveness proved through exhaustive in-place field tests. Fire retardant by nature, *Palco Wool* is further protected by the unique *Saferized* process. Odorless, repellent to rodents and insects, and moisture resistant, *Palco Wool* is ideal for freezers, coolers, controlled atmospheres.

## AIR CONDITIONING EFFICIENCY INCREASED BY PALCO WOOL IN HOME OR COMMERCIAL USE

Maximum performance of home or commercial air conditioning and heating equipment is assured by *Palco Wool's* unique combination of qualities. It is recognized to have one of the highest efficiency ratings of all insulations. Permanent resilience guards against settlement, providing full insulating effectiveness for the life of the building. Not only is natural fire retardance increased by the unique *Saferized* process, but *Palco Wool* also resists breakdown or melting under high temperatures. Free from odors, non-irritating, moisture resistant, repellent to rodents and insects, *Palco Wool* has proved its effectiveness for public or private building insulation. Low cost, ease of installation, and light weight recommend it from the standpoint of architects, designers, applicators and users.

## NEW REFRIGERATION INSULATION MANUAL

Handy illustrated reference manual covering details of design and construction for freezers, coolers, and controlled atmospheres. Vapor proofing, void-free application of *Palco Wool* Insulation, U values of various types and thicknesses of insulated walls and ceilings, and other valuable data are presented in easy-to-follow drawings, photographs, charts and text, compiled by experienced refrigeration engineers.

## FACTS ABOUT HOME INSULATION

Attractive new booklet outlining the economic and comfort advantages of proper home insulation, showing where, how and when to insulate. Written in layman's language to help air conditioning and insulation merchandisers present a sound effective sales story.

**OTHER TECHNICAL DATA AVAILABLE**—*In-Place Tests*, design data developed through refrigerated wall tests. *Engineering Reports*, on-the-job findings covering operation over periods of several years. *Samples of Palco Wool Insulation*.

**Tectum**®

**SIDEWALL INSULATION**

**Sales Offices:**

ATLANTA, GEORGIA—333 Candler Building

CHICAGO 4, ILLINOIS—855 Board of Trades Building

COLUMBUS 15, OHIO—3560 Le Veque-Lincoln Tower

PHILADELPHIA 3, PA.—Suite 2713-2719 Lewis Tower

Tectum is composed of fine grade select wood fibers and a chemically-stable, inorganic, water-insoluble hydraulic cement binder. Widely used in commercial and industrial buildings, Tectum's benefits are so numerous that it practically obsoletes other type materials of comparable cost.

- It's insulating
- It's structural
- It's acoustical
- It's non-combustible
- It's good-looking
- It's light weight
- It's easily worked
- It's fungus, termite and rot-resistant
- It's dimensionally stable

Tectum gives you everything you want in sidewall insulation *plus* low original cost... long service life... and negligible maintenance. Seldom do you find a product that fills so many needs.

Use Tectum to form insulated outside walls or partitions between areas—it also provides a noncombustible fire barrier. Meeting or exceeding normal insulating requirements, Tectum has high thermal qualities because of the nature of its cellular structure. When used as a roof deck, with built up roofing, Tectum provides "U" values from 0.22 to 0.15. This same structure provides acoustical values, supplying noise reduction coefficients up to 0.85, depending on thickness.\*

Install Tectum Sidewall Insulation with screws or clips—it's quickly erected and may be sawed, kerfed, mortised or nailed with standard woodworking tools. Once installed, Tectum may be spray painted or left its natural, off-white shade.

For complete information on Tectum see your nearest sales office, or write for *Bulletin No. C-100*, (Sidewall Insulation) or No. A-100 (Roof Decks).

**EFFICIENT INSULATION FOR EVERY NEED**

For many years a leader in the insulation field, Wood Conversion Company manufactures a complete line of flexible fiber and rigid insulation for all industrial and domestic purposes. This insulation is the product of scientific research, and is especially designed to embody the most desirable qualities for every use. Backed by the name of Wood Conversion Company this insulation assures high efficiency and long, satisfactory service.

**Balsam-Wool\* Sealed Blanket Insulation** is a flexible insulation. The insulation blanket is made from new wood fibers, completely enclosed on both sides and edges with heavy asphalt saturated and coated kraft liners.

Years of practical application and constant testing are behind each of these Balsam-Wool features—

- Integral, continuous vapor barrier
- Sturdy wind barrier
- Special spacer flange

- Double bonding of mat to liner
- Rot and termite treatment
- Highly fire retardant

In addition, Balsam-Wool is manufactured under rigid quality control; proved by more than a quarter century of experience.

**Tufflex**—A soft, felted blanket material with exceptional insulating and cushioning qualities. Tufflex is made from clean, new, cellulose fibers, felted and bonded into a fleecy, homogeneous mat, processed to resist mold and vermin.

It may be moisture resistant or absorbent. Surfacing of kraft paper can be furnished on one or both sides; cottonette or scrim can be applied to one side of the plain mat. Where the use requires, Tufflex Type "U" can be furnished with a fire retardant treatment.

The soft, but firm, felted construction of Tufflex gives the properties of low transmittal of heat, sound or vibration, and of holding its shape after being cut.

Applying Nu-Wood Interior Finish

Applying Balsam-Wool Sealed Insulation

**NU-WOOD\* STRUCTURAL INSULATION**

**Nu-Wood Interior Finish**—A multiple-purpose wood fiber material available in tile, plank and board. Nu-Wood insulates, decorates and quiets noise. Nu-Wood's colors are soft and harmonious—will not fade. The Nu-Wood interior finish line includes Sta-lite, an insulating interior finish with more than 70 per cent light reflection.

\*Reg. U. S. Pat. Off

**Nu-Wood Sheathing**—A strong, structural insulating sheathing in 1/2 in. and 25/32 in. thickness, asphalt impregnated offering complete moisture protection.

**Nu-Wood Roof Insulation**—Will fill all requirements of Federal specification LLL-F-321b. Furnished in any practical thickness.

# Ferro-Therm

Reg. U. S. Pat. Off.

### METAL INSULATION

FULLY PROTECTED BY U. S. AND FOREIGN PATENTS

Ferro-Therm is Stapled Permanently in Place

Ferro-Therm Metal Insulation, available from sheets of aluminum or steel with a special alloy coating, reflects 90 per cent to 95 per cent of all radiant heat. This high reflectivity, combined with extremely low heat storage capacity, provides maximum insulating efficiency in a minimum overall thickness.

### Reflects Heat from Either Side

Ferro-Therm's high reflectivity enables it to resist the penetration of heat from either side. During the winter it reflects heat in; during the summer it reflects heat out—assuring year 'round comfort and a considerable saving in fuel. Installed in ceiling (or roof) and exterior walls, Ferro-Therm reduces fuel costs by

an average of 25 per cent to 30 per cent. In ceiling (or roof) alone, Ferro-Therm will reduce fuel costs by 15 per cent to 20 per cent. During the summer, the installation of Ferro-Therm metal insulation will reduce temperatures in the house by 10 F to 12 F.

### Gives the Protection of Metal

Because Ferro-Therm is metal (1) It is not only non-combustible, it is an effective fire stop for wooden framework; (2) It prevents the penetration of termites, rodents and insects; (3) It does not absorb moisture or convey any wood-rotting moisture in framing members; (4) It does not settle or pack down, as the sheets are stapled permanently in place. (5) It is absolutely permanent.

### Ferro-Therm is Easy to Install

Ferro-Therm takes up considerably less space than mass insulation of equivalent efficiency. Laboratory tests and thousands of applications have demonstrated that a wall of Ferro-Therm will provide insulating efficiency equivalent to mass insulation approximately twice as thick. And Ferro-Therm can be installed easily, quickly and economically. The sheets take up considerably less space than mass insulation. And they are light—easy to transport and handle. One man can install 1000 to 1200 sq ft of Ferro-Therm in a day.

1678

## Infra Insulation, Inc.

525 Broadway, New York, N. Y.

Telephone: WOrth 4-2241

NOTE  
FULL-DEPTH, JOIST-TO-JOIST  
INSULATION

NOTE FULL ONE-INCH EXTRA AIR SPACE

FOR COLD  
STORAGE,  
CRAWL  
SPACES

FOR  
CEILINGS,  
WALLS,  
FLOORS.

Infra Insulation Type 6 has 3 tough, aluminum sheets, 6 heat-ray-reflective surfaces, two outer, and four rows of inner reflective spaces. (Total, 6 reflective spaces.) Easily and quickly installed between wood joists, furring strips, steel trusses, studs, purlins, metal beams and girders, it gives the entire area between, up to the very edges, full, uniform-depth protection against heat flow and vapor flow. The normal installation rate between wood joists is 2,000 sq ft a day per man. The 2½ cu ft carton contains 500 sq ft, weighs 52 lbs. For 12 in., 16 in., 20 in., and 24 in. centers.

Heat flow through wall space, which is air, is about 7 per cent by Conduction; 15 per cent to 28 per cent by Convection; and by Radiation, 65 per cent to 80 per cent.

**RADIATION:**—Each of Infra's 6 aluminum surfaces has a low absorptivity and emissivity of only 3 per cent, and a high reflectivity, 97 per cent, for radiation. The surfaces of most building materials have an absorptivity and emissivity of about 90 per cent with about 10 per cent reflectivity.

**CONDUCTION:**—Infra's 6 deep air spaces have low density, therefore slight conduction. One sq ft of Type 6 weighs only 1¼ oz, a ratio of 296 parts air to 1 part mass.

**CONVECTION; VAPOR:**—Each of the 3, continuous, 375 ft long, tough aluminum sheets has almost ZERO permeability to heated air, cold air, and water vapor. Infiltration under flat stapled flanges is slight. Each of the 2 fiber separators and 3 aluminum sheets retard flow of heat by CONVECTION.

**NON-CONDENSATION-FORMING:**—The 2 fiber separators which permanently prevent metal-to-metal contact, and the 3 aluminum sheets create FOUR inner rows of reflective air spaces. This scientific construction, and the low heat storage capacity, minimize condensation formation on or within this type of insulation.

Infra Insulation uses 99.4 per cent pure aluminum, made to special 3 per cent emissivity specifications, 0.002 in. and 0.0009 in. thick where exposed. It has 52 lb and 17 lb bursting strength (Mullen Test), and 80 grams and 28 grams tearing strength. This is up to 2600 per cent tougher than commonly used foils of less than 0.0005 in. thickness. Even tougher are Infra's newest, 3-ply, laminated aluminum sheets.

**FIRE:**—Because its aluminum surfaces have very low emissivity (3 per cent) and a high melting point (1220F), Infra has often prevented the spread of fire.

**SANITARY:**—Infra is inhospitable to insects, and DOES NOT RETAIN odors. Mechanics like to work with Infra. It is CLEAN, free of DUST or lint, permanently free from floating particles.

Write for a free copy of "Heat Flow by RADIATION in Building Structures, Simplified Physics," a new, 48-page, illustrated manual by Alexander Schwartz, president of Infra Insulation, Inc.

## Silvercote Products, Inc.

161 East Erie Street, Chicago, Ill.

### SILVERCOTE\* REFLECTIVE INSULATION

**Silvercote Heat Reflective Surfaces**—The silver-like surface of Silvercote reflective insulation consists of a polished, heat reflective coating applied to a special kraft paper. The importance of using a Silvercote radiant heat reflective surface in modern building construction is obvious when it is realized that from 50 to 80 per cent of the heat transferred across a normal air space is in the form of radiation.

#### REFLECTIVE SHEET INSULATIONS IN ROLLS

**SILVERCOTE DUPLEX**—A thin flexible vapor barrier and insulation consisting of two sheets of Silvercote paper bonded together with asphalt. This material, containing two exposed Silvercote surfaces, weighs approximately 50 lbs per thousand sq ft and is manufactured in 500 sq ft rolls in widths of 36 in. or 52 in. to span two 16 in. or 24 in. standard framing spaces. These widths permit bow-in of the Silvercote over the room side of the framing members to form an air space between the insulation and the interior finish. The water vapor permeability of Silvercote Duplex is 0.23 grains per sq ft per hour per inch of mercury vapor pressure difference.

**SILVERCOTE SIMPLEX**—An economical vapor permeable reflective insulation designed for use where a vapor barrier is not required. Silvercote Simplex is a single sheet of special kraft paper coated on both sides with the Silvercote surface. It weighs approximately 30 lbs per thousand sq ft and is manufactured in 500 sq ft rolls in 36 in. or 52 in. widths to span two 16 in. or 24 in. standard framing spaces. These widths permit bow-in of the Silvercote over the exterior side of the framing members to form an air space between the insulation and the exterior sheathing. The water vapor permeability of Silvercote Simplex is 99.2 grains per sq ft per hour per inch of mercury vapor pressure difference.

Silvercote in rolls distributed by: Bird & Son, Inc., and The Flintkote Co.

## Silvercote Products, Inc.

161 East Erie Street, Chicago, Ill.

### SILVERCOTE\* REFLECTIVE INSULATION

#### ON BLANKETS

#### SILVERCOTE REFLECTIVE SURFACE ON VAPOR BARRIER SIDE

A popular building insulation available in various thicknesses and faced on the vapor barrier side of the blanket with Silvercote paper. Manufacturers of this type of reflective blanket apply an asphalt coating to the back of the Silvercote paper for the twofold purpose of bonding the insulation material to the Silvercote paper and to lend vapor resistant properties to the blanket at the room side of the insulation.

#### SILVERCOTE REFLECTIVE SURFACES ON BOTH SIDES

A deluxe insulation material utilizing the full insulation value of blanket insulation, air spaces and two heat reflective surfaces. This double reflective blanket is manufactured with Silvercote Paper on the vapor barrier side and the breather side.

#### AVAILABLE UPON REQUEST

Silvercote's Handbook of "U" Values, 108 page illustrated booklet listing 12,852 "U" values of various walls, floors and ceilings—Silvercote's Handbook of "U" Values is unique in that it provides summer as well as winter "U" values. The Handbook's special listing of ceiling "U" values, indicating characteristics of downward heat flow will be of interest to those who are concerned with summer comfort as well as winter fuel savings.

#### SILVERCOTE REFLECTIVE SURFACE ON BREATHER SIDE OF BLANKET INSULATIONS

Silvercote paper is vapor permeable and can therefore be used on the breather side of a blanket. When space permits the use of only one air space in conjunction with thick blanket insulations, it is desirable that the air space be adjacent to the cold side (breather side). For this reason, many prominent manufacturers of mineral wool now furnish their reflective blanket with Silvercote on the breather side.

# ALFOL

INSULATION

## Reflectal Corporation

A Subsidiary of Borg-Warner Corp.

310 So. Michigan Ave., Chicago 4

### ALFOL MULTIPLE LAYER REFLECTIVE INSULATION

Introduced in 1929, ALFOL was one of the first reflective insulation blankets. Today, after nearly three decades of continuous development, ALFOL still is in the lead. Its patented blanket design insures high thermal efficiency, positive condensation protection and rapid, low cost application. Ideal for all types of residential, commercial and industrial use. ALFOL is also favored in air conditioned structures, where the superiority of reflective insulations provides substantial cooling economies.

**What ALFOL is:** Insulation consists of multiple aluminum foil sheets that automatically space themselves on application to form two, three or four reflective air spaces. The number of these spaces varies with ALFOL Type, but all types have a liner sheet of rugged, vapor-proof paper that provides continuous moisture protection and positive application support.

**How ALFOL works:** Radiant heat, as you know, normally accounts for 55 to 80 per cent of all heat loss through walls, roof or floor. Of all radiant heat, ALFOL foil sheets instantly, continuously reflect 95 per cent (or emit but 5 per cent). And the captive air spaces between these foil surfaces curb heat loss through convection and conduction to check all forms of thermal loss.

**Practical advantages of ALFOL:** Thermal efficiency is the big factor, but there are other reasons for ALFOL popularity. Its heavy liner provides sag- and rip-resisting application and a continuous vapor barrier. Its light weight ( $\frac{1}{2}$  lb/sq ft) cuts rafter load. And ALFOL is as clean, odorless, durable as aluminum itself. Priced low . . . with compact design offering added savings in handling and application.

#### Other REFLECTAL insulation products

**ALFOL ASBESTOS:** for central gas and oil heating equipment, water heaters, ranges, radiant heating seal and for all high temperature insulating requirements.

**ALFOL JACKETING:** for refrigerator cars, trucks and other low temperature work.

ALFOL is quick and easy to apply: You simply cut to length and staple across the faces of studs, joists or rafters.

#### An ALFOL Type for every purpose:

Type 1—2 reflective air spaces. 12 in., 16 in., 24 in. widths.

Type 1A—2 reflective air spaces, for furred-out masonry. 16 in. widths only.

Type 2—3 reflective air spaces, our top seller! 12 in., 16 in., 20 in. widths.

Type 3—3 reflective air spaces with foil base layer. 12 in., 16 in., 24 in. widths.

Type 4—4 reflective air spaces for top efficiency. 16 in., 20 in., 24 in. widths.

All ALFOL Types immediately available in handy 500 or 250 sq ft rolls.

Write Dept. ASH for free data book.

## B. F. Goodrich

SPONGE PRODUCTS DIVISION

274 Derby Place, Shelton, Conn.

### B. F. Goodrich SPONGEX® Molded Cell-Tite® TUBING for moisture-proof insulation

Spongex Molded Cell-Tite tubing is made of tough, flexible rubber with uniform non-connecting cell structure. Especially efficient and convenient for pipe insulation, it will not absorb moisture nor support combustion. Insulation value is excellent.

#### Easy application

Wherever used, Spongex Molded Cell-Tite may be easily secured with air-drying adhesive. Short lengths of tubing may be slipped on; longer ones may be slit lengthwise, snapped over pipe and adhesive applied to cut edges. These edges will not absorb moisture.

#### Low water absorption

Spongex Molded Cell-Tite meets ASTM specifications. Weight gain is under 10 per cent after 24 hours immersion in water; under 5 per cent after 3 minutes additional atmospheric pressure.

#### Efficient insulation

Thermal conductivity of Spongex Molded Cell-Tite is 0.28 at 75F with no deterioration in service.

#### Low shrinkage and aging

Spongex Molded Cell-Tite has no appreciable change after 7 days at 200F. Resistance to weather-aging is good. Linear shrinkage, when aged 4 weeks at 158F is under 10 per cent, most shrinkage occurring in the first week.

#### Wide range of density and firmness

Standard grades of Spongex Molded Cell-Tite are ASTM 12 or 13 (from 5-13 psi to compress a one square inch disc to 75 per cent of its height). Can be made in practically any firmness. Density varies, depending upon size and firmness, averaging 10 lb per cubic foot for soft, 15-20 lb per cu ft for medium, and 20-30 lb per cu ft for firm.

#### Many sizes

Spongex Molded Cell-Tite tubing is made with standard outside diameters of  $\frac{3}{4}$  in., 1 in.,  $1\frac{1}{4}$  in.,  $1\frac{1}{2}$  in., and can be made  $1\frac{5}{8}$  in.,  $1\frac{3}{4}$  in., and 2 in. Almost any inside diameter is available up to  $\frac{1}{4}$  in. of the outside diameter. Lengths up to 50 ft facilitate ease and simplicity of installation.

#### Variety of colors

Black is standard and can be furnished as non-staining to lacquer, enamel or plastic. (Tested for 24 hrs under ultraviolet light or for 10 days at 158F). Any one color available for requirements of 7,500 ft or more. White, if specified, would be off-white.

Please write for more information

## Kaiser Aluminum & Chemical Sales, Inc.

General Sales Office, Palmolive Building, Chicago 11, Illinois

EXECUTIVE OFFICE, KAISER BUILDING, OAKLAND 12, CALIFORNIA

### KAISER ALUMINUM SHADE SCREENING\*

\* Patented

Kaiser Aluminum Shade Screening is scientifically designed to keep interiors cool by blocking hot sun rays. Shade Screening is being widely used in conjunction with air conditioning systems to reduce the solar load—thus permitting more economical operation by reducing the work load.

The effect of using Kaiser Aluminum Shade Screening is shown on these

graphs prepared by Kaiser Aluminum engineers following a test procedure similar to that used at the ASHAE Laboratory (1, 2) during experimental work on the shading of sunlit glass. The accompanying charts illustrate the amount of instantaneous heat gain to a room both through unshaded windows and windows protected with Kaiser Shade Screening.

Kaiser Aluminum Shade Screening has 17.5 louvers per inch permanently tilted at a downward angle. This stops sun rays before they hit the window glass. With sun angle (apparent) at 37 deg 100 per cent of sun rays are blocked. At 30 deg, 85 per cent. At 25 deg, 75 per cent. At 15 deg, 55 per cent. At 0 deg, 30 per cent. Thus Shade Screening can reduce the amount of instantaneous heat gain through unshaded windows by as much as 78 per cent, while still providing insect protection.

#### TYPICAL CALCULATIONS OF COOLING LOAD REDUCTIONS

DURING PERIOD OF EXTREME MIDSUMMER SOLAR RADIATION AT 40° N. LATITUDE.

Shade Screening reduces the load on air-conditioning units . . . permits use of smaller units. These typical calculations show how this is possible:  
FIGURING 24 WINDOWS ON THE EAST SIDE 3 1/4' x 6'

Total area 3 1/4' x 6' x 24 = 504 Sq. Ft.  
Use 10:00 A.M. peak load  
Instantaneous Heat Gain through Unshaded Windows BTU/HR  
504 Sq. Ft. x 138 BTU/HR per Sq. Ft. . . . 69,500  
Instantaneous Heat Gain through Windows shaded by Kaiser Aluminum Shade Screen  
504 Sq. Ft. x 35 BTU/HR per Sq. Ft. . . . 17,650

Quantity of Heat Gain Blocked by Shade Screen . . . 51,850  
Heat Blocked = 4.31 tons\* of refrigeration

FIGURING 23 WEST WINDOWS 3 1/4' x 6'

Total area 3 1/4' x 6' x 23 = 483 Sq. Ft. BTU/HR  
Use 4:00 P.M. peak load  
Instantaneous Heat Gain Unshaded Windows . . . 111,000  
Instantaneous Heat Gain through Windows shaded by Kaiser Aluminum Shade Screen . . . 34,800

Quantity of heat blocked by Kaiser Aluminum Shade Screen . . . 76,200  
Heat Blocked = 6.35 tons\* of refrigeration

FIGURING 11 SOUTH WINDOWS 3 1/4' x 6'

Total Area = 3 1/4' x 6' x 11 = 231 Sq. Ft. BTU/HR  
Use 12:00 noon peak load  
Instantaneous Heat Gain Unshaded Windows . . . 26,800  
Instantaneous Heat Gain through Windows shaded by Kaiser Aluminum Shade Screen . . . 8,550

Quantity of heat blocked by Kaiser Aluminum Shade Screen . . . 18,250  
Heat Blocked = 1.52 tons\* of refrigeration

\* 1 ton of refrigeration = 12,000 BTU/HR

### KAISER ALUMINUM SHADE SCREENING

The instantaneous heat gain measurements included *transmitted* direct solar radiation plus the *absorbed* heat gained by convection and re-radiation plus transmission of heat through the glass caused by inside-outside temperature differentials. Kaiser Aluminum Shade Screening reflects more heat than other

commonly used materials thus the screening itself remains cool and emits at a very low rate.

These factors of high reflectivity and low emissivity combine with the sun-blocking feature of Shade Screening to produce cooler interior temperatures.

----- Total Solar Load  
----- Instantaneous heat gain through unshaded windows.  
----- Instantaneous heat gain through windows protected by Kaiser Aluminum Shade Screening.  
..... % of heat blocked.

**T. R. FINN & COMPANY INC.**

Industrial Division

200 Central Avenue Hawthorne, New Jersey  
Specialists in Shock and Vibration Control**RUBBER-IN-SHEAR VIBRATION MOUNTINGS**

Widely used for isolating vibration, shock and noise on air conditioning and similar machinery. Rated load from 40 to 4000 lbs. Complete, ready-to-use. Catalog RS-55.

**"FLOATING PILLOW" VIBRATION MOUNTING**

Heavy duty, high-deflection rubber-in-shear mountings for efficient isolation of vibration, shock and noise of medium and heavy weight air conditioning equipment. Load range from 500 to 2500 lbs. Catalog FP-55.

**FLOATING RAIL VIBRATION MOUNTINGS**

Rubber-in-Shear bases for use under pumps, compressors and fan-motor sets. A complete, ready-to-use mounting supplied to specification. Catalog FR-55.

**VIBRATION HANGERS**

Two types, Rubber-in-Shear (35-1500 lbs.) and Steel Spring (50-1000 lbs.), prevent transmission of noise from suspended equipment and piping systems. Catalog VH-55.

**SOUNDZORBER**

Wire-reinforced, fabric-wrapped rubber pipe for reduction of water line noise and vibration. Sizes from ½ to 12 in. I.D. with I.P.T. male fittings or with integral full-faced rubber flanges backed up with Series 15 or 30 steel flanges. Catalog SZ-55.

**ISOLANT**

The unusually high structural strength and resiliency of this special material provides excellent isolation of vibration, shock and noise. For use under massive air conditioning equipment and heavy machinery. Load range up to 6000 lbs per sq ft. Catalog IS-55.

**STEEL SPRING VIBRATION MOUNTINGS**

For superior vibration, shock and noise isolation of difficult-to-isolate low speed machinery, heavy air conditioning equipment, and for protection of delicate instruments. Load range from 100 to 6500 lbs. Catalog SS-55.

**FLEXZORBER**

Seamless flexible bronze tubing covered with woven wire braiding and with standard copper tube female "slip fittings" welded on both ends. Used to minimize noise and vibration in rigid piping conveying Freon in air conditioning and refrigeration units. Slip fittings sizes from ½ to 8 in. I.D. Catalog FZ-55.

**EXPANDZORBER**

Stainless steel, welded diaphragm type packless expansion joints used for control of vibration, expansion, and contraction in steam, chemical, oil and gas lines. Working pressure from vacuum to 1000 psi at -300 to +1800 F. Sizes from ½ to 72 in. with steel flanges or welded fittings. Catalog EZ-55.

**ENGINEERING COUNSEL**

Our engineering staff is always at your service to solve your individual problem. We shall be pleased to submit to you our analysis and recommendation for an efficient and economical solution to your vibration problems.

**The Korfund Company, Inc.**

48-01R 32nd Place, Long Island City 1, New York

Representatives in Principal Cities. See "KORFUND" in local phone directory or in "Thomas" Register.

Specialists in Vibration &amp; Noise Control for Over Half a Century.

For a discussion of Vibration control theory and chart for determining deflections required, see "Controlling Vibration From Machine Mountings" at end of Chapter 41. If in doubt about product selection, submit data on make, type, rpm and model number of equipment and type of floor for specific recommendations, without obligation.

**Series L Isolator****Vibro-Hanger****Elasto-Rib Pad****Vibracork****New Motor Base with Built-in Slide Rails****Duplex Bases**

**STEEL SPRING VIBRO ISOLATORS** provide greater deflections with isolation efficiencies approaching 100 per cent. Though more expensive than rubber or cork, they are satisfaction guaranteed and provide maximum overall economy because: they eliminate bolting, speed equipment installation, usually eliminate special foundations, permit trouble-free upper floor installations, and will usually outlast the machine. **THE SERIES L VIBRO ISOLATORS** contain from one to twelve steel springs of proper stiffness depending upon the loading and deflection desired. Loading: 75 to 23,000 lbs. Maximum deflection 1¼ in. (special designs available for higher loads or larger deflections). Isolators are usually installed directly under machines (occasionally under steel bases or foundations supporting equipment). They have adjustable snubbers to control movement and built-in leveling bolts, a Korfund feature for over 30 years.

**SERIES V VIBRO HANGERS:** load range 20 lb to 3,800 lb. Maximum normal deflection 1 in. (larger deflections on request). For suspended equipment installations, also as vibration-absorbing pipe hanger.

**RUBBER AND CORK** provide good sound insulation. However, rubber is not very effective as a vibration absorber for disturbances below 1200 cpm, is fair from 1200-1800, and good above 1800. Cork is effective only above 1800 cpm.

**SERIES R RUBBER-IN-SHEAR HANGERS:** Similar to spring hanger illustrated but incorporating rubber mountings of varying stiffnesses for loads from 10-1,000 lb.

**ELASTO-RIB** has a core of high-grade cork plate, permanently bonded between two layers of deep-grooved, Neoprene rubber. Just set the machine on Elasto-Rib—no fastening to floor is normally required but can be cemented or bolted if desired. Excellent sound insulation characteristics. Loading up to 60 lb per square inch. Also furnished as Elasto-Rib Dampers with load distributing top plate and built-in leveling bolt.

**ARMSTRONG'S VIBRACORK & KORFUND LIGHT DENSITY MACHINERY CORK** are strong, durable machinery isolation plates made of pure cork granules compressed and baked under pressure with accurately controlled density. Furnished in three densities for loads from 400-8,500 lb per square foot. 1 in., 2 in., 3 in., thicknesses. Plates 12 in. x 36 in.

**DUPLEX TWIN RAIL FAN & MOTOR BASES:** Rugged construction and built-in chocks to maintain alignment. Rubber or cork isolation. Advantages of separate fan and motor bases: no motor noise transmitted through ducts—complete adjustability permits job-site changes in motor position, belt length, rotation, equipment bolt location—quicker delivery of drawings and bases—easier handling—lower transportation costs. Integral type bases also available.

Structural Steel Vibration Bases for Fans and Motors, Pumps, Compressors and Air Handling Units prevent motor misalignment, excessive belt wear and reinforce cast iron pump bases. Bolt hole locations are predetermined and fixed so that the vibration base becomes a template for lining up the equipment and securing it in place.

Rubber-in-Shear is generally used where a static deflection of  $\frac{3}{8}$  in. maximum is adequate. Mountings are permanently fastened between structural channels and flat steel base plates, as shown in Figures 1 and 2.

Spring Mountings with bonded acoustical pads are recommended for the more critical locations. Static deflections up to  $1\frac{1}{2}$  in. provide isolation efficiencies approaching 100 per cent. Structural angles form a rigid floating platform for the equipment as shown in Fig. 4. The mounting used is shown in Figure 5.

Individual Mountings are used under equipment that does not require a supplementary base. Rubber-in-Shear mountings typically illustrated in Fig. 7 can be furnished for individual loads of 5 to 2,000 lbs. Spring mountings as illustrated in Figures 5 and 8 support loads ranging from 50 to 18,000 lbs. Spring mountings are manufactured with built in leveling and damping devices.

Vibration Hangers using either rubber-in-shear or steel springs or a combination of both prevent the transmission of vibration and noise through the suspension rods. Open housings, not shown, or closed housings as shown in Figures 3 and 6 are made for attachment directly to the ceiling or insertion in the suspension rods. Standard hangers are made for loadings of 50 to 1,000 lbs. Special units on request.

## Air Conditioning, Heating and Ventilating

Engineering magazine for the men who design systems and specify equipment

This monthly engineering magazine (established 1904) is read by the engineers—by whomever employed—who design, specify, install, and maintain systems for heating, ventilating, air conditioning, piping, plumbing, industrial refrigeration, process steam, and related services. These systems are installed in industrial plants, hospitals, office buildings, hotels, stores, schools, colleges, theaters, churches, institutions, government buildings, military installations, housing projects, etc. Readers include: Consulting engineers; engineers with architects, with large engineering-type contractors, with utilities; engineers with industrial plants and with large buildings; and others. To these men AIR CONDITIONING, HEATING AND VENTILATING brings, month after month, a steady stream of crisply-written articles on the best current practice, boiled-down research results, mathematical short-cuts, handy tables, charts and Data Sheets.

Subscription rates in U. S. and Canada:  
One year, \$5; two years, \$9;  
three years, \$12. In all  
other countries, \$7  
per year.

## Heating & Plumbing Equipment News

The "new equipment" magazine serving Contractors and Wholesalers

This monthly "new equipment" magazine, published in tabloid format, reaches by controlled circulation 35,000 contractors, wholesalers and other groups concerned with the sale and installation of heating and plumbing equipment. Only publication that reaches all these categories: Radiator and warm-air heating contractors, oil-burner dealers, gas-burner dealers, plumbing contractors, and the wholesalers and distributors who supply all the foregoing. Editorial content consists of concise, illustrated articles describing new and improved equipment, materials, and tools placed on the market, also new catalogs and bulletins issued by manufacturers. Inquiries total over 100,000 per year for information about specific products such as: Boilers, furnaces, gas-burners, oil-burners, toilets, sinks, pipe, fittings, valves, pumps, pipe-cutting and threading tools, hot water heaters, room coolers, water softeners, dishwashers, controls, insulation, and many others. Sample copy and advertising facts upon request.

## American Society of Refrigerating Engineers

234 Fifth Avenue, New York 1, N. Y.

The most rapidly growing magazine in the refrigeration field

**L**ONG acknowledged the most authoritative periodical in the field, *Refrigerating Engineering* has added steadily to the practical value of its contents, and its number of readers has grown in proportion. This magazine is a must for men who keep in touch with all that is new and important in refrigeration and air conditioning. The annual subscription price is \$4.

### ASRE DATA BOOKS

Published bi-annually since 1932, they now consist of two volumes, one issued each year. The Design Volume is a standard reference work containing fundamental data, refrigerant tables, description of the different cycles, systems, and component parts—a gold mine of information—\$10.00 a copy. The Applications Volume is crammed full of how-it-is-done information on the use of refrigeration in many different applications. A must for the design or application engineer—\$7.50 a copy.

### REFRIGERATION ABSTRACTS

A Journal devoted to brief condensations, by specialists, of all articles of refrigerating interest appearing in hundreds of periodicals and reports published

internationally on refrigeration and allied subjects. Five issues and an index annually at \$7.00.

### APPLICATION DATA SECTIONS

The APPLICATION DATA Sections tell precisely how refrigeration is used in various fields, giving examples and specific information on the best practice known to date. A complete list of the subjects covered is available on request. Some 17 bulletins are available separately at reasonable prices for single copies or quantity orders and can also be had bound with a paper cover, the complete set for \$3.50.

### CODES AND STANDARDS

ASRE further contributes to refrigeration progress by establishing codes and standards in the industry. These standards cover approved methods for testing and rating various types of air conditioning and refrigerating equipment. Also included is the B-9 Safety Code for Mechanical Refrigeration. Sold separately, or a complete set for \$5.00.

### REFRIGERANT TABLES, CHARTS, AND CHARACTERISTICS

A handy 6¼ in. x 9 in. volume containing the thermodynamic properties of all refrigerants now in use (reprinted from ASRE Data Book), forms a convenient reference for design and application engineers, contractors, professors and students. Cloth bound, \$2.00, paper bound, \$1.50.

### MEMBERSHIP ACTIVITIES

**I**T is the policy of the ASRE to treat in its meetings current subjects touching upon all phases of the art of refrigeration. Membership is in several grades with dues from \$10 to \$20. Sections hold meetings in 40 principal cities. More detailed information will be sent on request.

To keep abreast with progress in refrigeration and air conditioning, read the publications and follow the activities of THE AMERICAN SOCIETY OF REFRIGERATING ENGINEERS, 234 Fifth Avenue, New York 1, N. Y.

## Coal-Heat

New York City, MUrray Hill 6-3772

### To Get the Facts

about heating and fuel requirements, heating costs, operating and maintenance problems, the equipment situation, personnel, performance standards, fuel economics, sales and service—this is what we are trying to do, here at COAL-HEAT.

These are the fundamental factors that affect the market, the use and sale of fuel and equipment, one's job, or business.

So, it is our aim to get and print "the low-down" on these in each of the following markets:

- |                         |                              |
|-------------------------|------------------------------|
| 1. Apartment houses     | 8. Institutions              |
| 2. Churches             | 9. Laundries                 |
| 3. Dept. & other stores | 10. Municipal & govt. bldgs. |
| 4. Dairies              | 11. Mfg. plants              |
| 5. Greenhouses          | 12. Office bldgs.            |
| 6. Hotels               | 13. Residential              |
| 7. Hospitals            | 14. Schools                  |
|                         | 15. Theaters & other bldgs.  |

To find out what each of us concerned should know about the particular needs, problems and possibilities in each of these fields, and to help make more of the facts known where they will do the most good—this is our purpose!

Together, these groups represent some 20-million plants, buildings, homes, 160-million tons of coal annually—the nation's largest fuel market, in either number of tons or customers. See "Heating-Fuel Markets"—\$1.00 a copy.

Many of these plants and buildings are old, the equipment is in poor condition, operation leaves much to be desired, costs are excessive.

Since most janitors, building owners, members of school and hospital boards are not well informed about heating or the proper use of fuel, we face a tremendous educational job—a job that rests largely on the retail dealer and the salesmen because they alone come in periodic contact with these 20-million fuel users. To help provide the essential educational sales and service tools—that's what we're trying to do.

To help keep more customers happy, get into more of the new buildings, help develop new business—these are the objectives of COAL-HEAT. It can help you get more business!

FUEL AND HEATING EQUIPMENT—SALES AND SERVICE

## Domestic Engineering Publications

1801 Prairie Avenue, Chicago 16, Illinois

### DOMESTIC ENGINEERING MAGAZINE

Editorially, DOMESTIC ENGINEERING Magazine is keyed to the total business interests of the qualified contractor-dealers who specify, sell, install and service all types of heating, air conditioning, plumbing and related products and appliances. It covers every phase of the contractor-dealers' functions on domestic, commercial, industrial and institutional projects.

Now in its 66th year of service, DOMESTIC ENGINEERING Magazine has consistently maintained its position of leadership in this field. In recognition of its continuing "Leadership in Action" campaigns, it has won 15 major awards for outstanding editorial achievement in annual competitions with hundreds of business magazines.

Year after year, through its meritorious editorial programming, DOMESTIC ENGINEERING has earned, and continues to hold, the loyalty and confidence of its large audience of subscribers—a loyalty and confidence that pays dividends to the DOMESTIC ENGINEERING advertiser.

Member Audit Bureau of Circulations  
Published Monthly  
Subscription rate: \$5.00 per year

### DOMESTIC ENGINEERING CATALOG DIRECTORY

Here is the industry's most comprehensive, single source of specifying and purchasing information on heating, air conditioning, plumbing and allied products. Its directory lists all known products used in this field and its various sections supply the catalogs, names and addresses and trade names of the leading manufacturers of these products.

Published annually. Price \$12.50

Together DOMESTIC ENGINEERING and DOMESTIC ENGINEERING CATALOG DIRECTORY constitute the backbone of every well-conceived promotional program in the heating, air conditioning and plumbing industry. Together they afford the manufacturer effective two-way coverage of the important buying factors that make up this field.

## Heating & Air Conditioning Contractor

92 Martling Avenue  
Tarrytown, New York

Subscription rates—\$4.00 per year, U. S., Canada and Pan Amer. Foreign \$5.00. Advertising rates on request.

Subscription rates—\$4.00 per year, U. S., Canada and Pan Amer. Foreign \$5.00. Advertising rates on request.

Heating & Air Conditioning Contractor, formerly Sheet Metal Worker, is the oldest magazine in the warm-air heating, air conditioning, ventilation and sheet metal contracting industry. The magazine is edited primarily for the contractor, but is also read by the wholesaler and manufacturers who supply the necessary equipment and materials.

Heating & Air Conditioning Contractor is a co-sponsor of the now-famous All-Industry Air Conditioning Conferences, the most widely recognized forum of its kind in this field.

"The 1955 Air Conditioning Industry" by Heating & Air Conditioning Contractor's editor-in-chief, is a detailed study of the residential and packaged commercial market. It has been distributed to several hundred manufacturers in the field. (Copies available on request).

Heating & Air Conditioning Contractor appears in the new, easy-to-read, King-Size format. Through a combination of paid and controlled circulation, based on Dun & Bradstreet ratings, Heating & Air Conditioning Contractor provides maximum market coverage available in the industry.

## The Journal of Plumbing, Heating & Air Conditioning

Scott-Choate Publications 92 Martling Avenue Tarrytown, New York  
The JOURNAL of Plumbing, Heating & Air Conditioning, formerly Plumbing and Heating Journal, is in its 75th year. It is edited primarily for contractors who sell, install, service and guarantee plumbing, heating and air conditioning equipment, and for the wholesalers and manufacturers who supply this equipment and other necessary tools and materials.

The JOURNAL is a co-sponsor of the All-Industry Air Conditioning Conferences, the most widely recognized forum of its kind in this field.

More editorial material has been reprinted from The JOURNAL's pages than from any other magazine in the industry. Some of the subjects covered include:

Air Conditioning-Temperature Controls-Oil Heating-Baseboard Heating-Domestic Hot Water-Water Conditioning.

The JOURNAL provides dissemination of technical, business and other industry news to the plumbing, heating and air conditioning contractors. All selected contractor and wholesaler readers are Dun & Bradstreet rated.

The JOURNAL appears in the modern, easy-to-read, King-size format.

KEENEY PUBLISHING COMPANY  
6 North Michigan Avenue, Chicago 2, Ill.

Heating, Piping & Air Conditioning carries the JOURNAL of the ASHAE as well as its own regular editorial section. Its field is that of industry and large buildings. It is devoted to the design, installation, operation, and maintenance of heating, piping and air conditioning systems in plants, commercial, institutional and public buildings.

Each January issue includes a complete directory of commercial and industrial heating, piping, and air conditioning equipment, which lists all products, their trade names, and the manufacturers' addresses. It is the established buying and specifying guide of the industry.

H. P. & A. C. is read by consulting engineers and architects... contractors... and engineers in charge of heating, piping and air conditioning in industrial plants, and other large buildings, federal, state, and city governments, school boards, and public utilities. Most of ASHAE members are subscribers.

Such coverage means, for the advertiser, consideration at all points in the selling of a heating, piping, or air conditioning product... consideration in its selection during the preparation of plans and specifications; in its actual purchase for installation; in its year-'round buying for operating and maintenance requirements. Without waste, the manufacturer of air conditioning products and equipment can reach through H. P. & A. C. those from whom he is seeking the necessary engineering acceptance.

Subscription Prices—U. S. \$3 per year. Subscription Prices—U.S. \$3 per year.  
Canada, Spain, Central and So. America—\$4.00 per year. Elsewhere \$6 per year.

AMERICAN ARTISAN covers the field of warm air heating, residential air conditioning, and sheet metal contracting. Its readers are warm air heating and sheet metal contractors, dealers, jobbers, manufacturers, and public utility companies.

Special features of each issue have been devoted to air conditioning since 1932, when it first became apparent that air conditioning for homes was to be along the lines of the central forced warm air heating system. As a result of the ready adaptability of this type of heating system to all air conditioning factors, hundreds of thousands of homes today have winter air conditioning—supplied through forced warm air heating with air cleaning and humidification. Cooling apparatus can be attached to these systems readily whenever year-'round air conditioning is desired.

Each January issue includes a complete directory of residential air conditioning, warm air heating, and sheet metal products and equipment, which lists all products, their trade names, and the manufacturers' addresses.

The key man in the residential air conditioning picture is the warm air heating and sheet metal contractor—the one man experienced in "treating air" at a central place and getting it properly distributed. And American Artisan is the key publication—because it reaches these key men with information that has made it the recognized authority on residential air conditioning practice.

## Snips Magazine

5707 W. Lake St.

Chicago 44, Ill.

This Friendly, Close to the Reader  
Periodical Provides

### The Real Push Behind Sales

To those Contractors who handle Warm Air Heating, Sheet Metal Work, Ventilation and Air Conditioning.

PREFERRED as an effective advertising medium by many notable industrial advertisers year after year, and many Prominent Jobbers who know their market well.

During the past year over 400 firms used space with us. These valued patrons see in our 14,574 readers, a carefully selected and substantial buying group, worthy of "talking to" month after month.

SNIPS is packed each month, from cover to cover, with hundreds of live news stories and exclusive pictures including practical applications of latest advancements of the Sheet Metal, Heating, Air Conditioning and Ventilation trade. No long contributed stories. It's all field gathered material, secured the hard way, rubbing shoulders with the readers. Such work gets for the periodical a reader interest seldom found in a trade publication. You'll find this feature the basis of the sensational inquiry pulling power and sales producing value of advertising space in SNIPS.

Rates for space have always been conservative. The carefully figured current rate with cream coverage available at an extremely low rate per thousand distribution is truly an exceptional value at this time.

These advertising people always alert to serve you: H. F. Hoy, Nick Carter, and Ed Carter in the Home Office. In the East R. F. Duysters, 70 East 45th St., New York 17, New York, MUrray Hill 6-3772. In the West, Maurice A. Kimball Co., 2550 Beverly Blvd., Los Angeles 4, California, DUmkirk 8-6178, and Rm. 767, 681 Market St., San Francisco 5, Calif., EXbrook 2-3365.

SNIPS is now Standard size—8¼ in. x 11 in.

### SPECIAL ISSUES

JANUARY ANNUAL & WINTER MARKET NUMBER—MARCH ANNIVERSARY & SPRING MARKET ISSUE—SEPTEMBER FALL MARKET ISSUE—DECEMBER HOLIDAY GREETING ISSUE—Further information gladly sent on request.

### ABOUT SNIPS' MAILING LIST

It's truly a select group that gets SNIPS. They are the outstanding firms and individuals in the trade whom the better supply houses are selling or trying to sell. They are the contracting and installing concerns whom the principal jobbers and distributors of the industry—people who really know their territories best—consider worthy of cultivation by mail, promotion and salesman's calls.
