types of asbestos, except anthophyllite may be responsible for mesothelioma.

Risk is greatest with crocidolite, less with amosite and apparently still light with chrysotile. Cigarette smoking is an important factor in enhancing lung cancer risk in asbestos workers.

Surveys of occupational groups have shown a small excess risk of types of cancer other than the bronchial and mesothelial, especially those of the gastrointestinal tract.

The most important item here of incrimination is, again, underlined, all major types of asbestos as causal agents for carcinoma, particularly mesothelioma.

Most of the other items only confirm or substantiate previous conclusions. Since most of us use substantial amounts of chrysotile asbestos in our formulations, association of this material with mesothelioma and other types of cancer is of serious concern.

I am skipping down to the next paragraph.
