Third, all trainees are instructed in these safe procedures.

We endeavor to develop job know-how on the basis of thoroughly planned procedures so that all personnel are mentally and physically equipped to deal with their day-to-day job routines plus any unforeseen and unsafe condition which may arise.

A good operator training program will have the following characteristics:

—Company management must be solidly behind the program and must be kept informed of progress. The training procedures will not be successful if management does not give its support, nor will they be successful if management is not advised of the benefits accruing from them.

—The development and execution of a training program rests solidly upon the capabilities of the personnel responsible. Competent people must be given full authority for carrying out the training program.

—Those responsible for developing the training program must also insure that trainees are selected. Selection doesn't insure successful training but it does make it possible.

—Adequate follow-up must be maintained to insure that training procedures are followed on the job and that the training program is revised as conditions warrant.

The results of the training program must be periodically evaluated in order to determine its effectiveness.

PROGRAM METHODS

Du Pont has used several methods for setting up and conducting training programs.

Some plants prefer the consultant method —a specialist in the field to be covered sets up the training program and actually carries out the instruction required. This method works best in the highly specialized areas, such as those of instrumentation and some phases of materials handling.

The second method is the organization of a training group in the plant which would consist of an instructor or several instructors whose main responsibility is to conduct training programs.

A third method is to have line supervision initiate and carry out the training. This method has two serious drawbacks: in that a technically competent person in line supervision may not be a good teacher; secondly, he may be so absorbed in day-to-day supervisory activities that he cannot devote sufficient time to the training program.

Obviously, combinations of these three methods can be used which lend flexibility so that training can be readily adapted to any local plant condition. For example, a technique which has been highly successful in our organization is the method in which a consultant instructs local plant instructors in the jobs to be covered and they, in turn, conduct the training program for the plant operators.

The local instructors are trained in the best methods of presentation, ease of delivery, keeping trainees' interest, gaining full group participation, answering questions, and giving explanations.

They are provided with articles on training techniques, data sheets on specific equipment on the plant, visual aids, and informed of recommended motion pictures and other visual aids available from manufacturers, governmental agencies, and libraries.

INSTRUCTION MATERIAL

An "Instruction Manual" is furnished to each plant instructor to be used as the basic reference in his training assignment. The increased trend toward higher utilization of mobile equipment in du Pont plants pointed out the need for soundly organized training techniques for operators of mobile materials handling equipment.

Our materials handling consultants had been providing consulting assistance on various plants on specific operating problems with mobile equipment. These problems, coupled with the shock of several accidents, resulted in the development of a program of training for fork lift truck operators.

One accident resulted in an amputated hand. Two employees were attempting to couple an empty coal car to a string of parked empty cars with a motorized car mover. When the cars didn't couple on the first try, one employee backed the mobile equipment away and got out to help the other employee line up the couplings. While the two men were working on the couplings, the car mover operator noticed that his motorized car mover was in motion. He ran back to stop it but, before he could reach it, the other employee's hand was caught on impact between the couplings of the coal cars. Investigation indicated that the hand brake was not fully engaged and the directional shift had been pushed beyond neutral into reverse.

HUMAN FAILURE

In another accident a fatality resulted when the operator of a fork lift truck attempted to straighten an adjacent pulp stock pile by standing on the bed of his truck and reaching between the upright tilting mast and the forward overhead guard bar. As he did so, he inadvertently engaged the tilting lever, apparently with his leg, causing the mast to tilt toward him. His head was caught between the upper part of the mast and the bar.

One result of these accidents was a broad study and concerted effort to improve fork lift truck operations. These operations were designated as a prime region of attack because of the rapidly increasing use of this type of equipment within the company.

A training program was developed by materials handling consultants in the engineering department based on their own experience in various industrial plants and upon the company-wide experience which was available to them. Having developed this training program, it was then necessary to establish certain criteria for the selection of operators.

SELECTING OPERATORS

Certain basic criteria are applicable to any job and these were also applied to the fork lift truck operator training program.

The candidate must have an aptitude for the position. This can be determined through both written and performance tests. The candidate's background must be one which is amenable to the new position. His personnel record will reveal this amenability by an examination of his education, experience, and job preference.

A trainee's ambition and safety attitude are difficult to determine, particularly if the employee is new. However, if he is an employee who has had some prior service in the company, his personnel records and his previous supervisors can usually give assistance in assessing these attitudes.

In our company, certain specific physical criteria have been established for the selection of operators of fork lift trucks, namely, 1. high degree of coordination, 2. good vision, 3. good health, 4. age, 5. hearing and 6. height and weight.

Most of these are self-explanatory. However, the age factor requires special consideration. We prefer an operator who has reached a certain degree of maturity, which usually means in the late twenties and on up. In actual practice this is a difficult obstacle to overcome. Many fork lift truck positions are low paying and are merely stepping stones to some higher position in the work force. Therefore, many times we must hire younger men for these jobs. This gives us the same problem as the insurance companies; the young cowboys tend to penalize our safety records.

We endeavor to avoid extremes in the physical characteristics of height and weight and we tend to select individuals who are fairly agile.

In the complex assessment of the candidate's motivation we try to determine whether the trainee has a definite interest in operating mechanical equipment. We look for people who possess enthusiasm for learning and who sincerely desire a job as a fork lift truck operator. To assess the trainee's maturity, we consider whether he takes his work seriously, accepts responsibility, follows prescribed procedures, makes his own decisions and works well under pressure.

We also require these same characteristics in the general managers of our industrial departments. However, facetiousness aside, many of those characteristics can be determined from a candidate's occupational background and from his personnel records. Also, through examination of the candidate's background, we gauge his intelligence, his ability to learn instructions, and to recognize potential safety hazards.

We also require the ability to read and comprehend and to write and record data in a log book.

Once the operator has been selected, he then goes through a program of classroom instruction coupled with operating practice on the equipment.

TRAIN AWAY FROM JOB AREA

We are firmly convinced that this practice must be away from job responsibilities and hazards. Training conditions are improved when away from the operating area because a classroom or obstacle course facilitates gaining the trainee's individual attention. Practice can be gained without interfering in regular plant operations. An opportunity is provided for complete discussion of the topic while ideas are still fresh in the trainee's mind.

Work in the classroom and on the obstacle course provides an easy means of noting shortcomings which can be corrected before real damage is done in the plant. Lastly, throughout the training, records are kept to screen out unsuitable operators whose deficiencies may not have been apparent in the initial selection. This secondary screening and evaluation would be

more difficult if training were done on the job.

The subjects covered in the classroom instructions are: description of a fork lift truck or trucks to which the trainee will be assigned and a description and practical application of fundamental operations performed by a fork lift truck; also, a description of the types of loads the trainee will be expected to handle on the job.

Both the generalized safety rules for operation of lift trucks and specific rules applicable to the specific job are instilled in the trainee throughout his training.

The operator is instructed in the reasons for careful operation of his equipment to keep it in a safe operating condition and to reduce maintenance costs. He is shown how to carry out simple preventive maintenance procedures using a check list established specifically for the equipment under his control.

Periods of study are devoted to the various truck attachments with which he may have to deal, such as the "Pul-Pac" attachment, barrel grabs, and the like. He is then given further instruction in the more advanced operations which will be required of him.

PRACTICAL LEARNING

All lessons learned in the classroom are put into practice at special sessions held in the plant using his assigned equipment. The interiors of railroad cars and highway trucks are simulated by standing pallets on end and having the trainee maneuver his equipment within these areas while handling typical loads.

Finally, the trainee undergoes both written and actual performance tests to determine the extent of his knowledge both theoretical and practical. At the conclusion of training, each truck operator is furnished with an "Operator's Guide" which can be kept as a handy pocket reference on recommended operating procedures.

The results of a training program should be evaluated. Since training deals with human beings, some persons may feel that a training program must be accepted on faith or because of someone's statement concerning the presumed value of the program.

EVALUATING RESULTS

We feel that whatever the subject matter, some measurements of effectiveness can be devised and the intelligent application of phychological measurement makes it possible to evaluate training objectively.

In the Fork Lift Operator Training program we are keeping records of:

1. The production time required for the job and the number of operators meeting the standard
2. Product damage and the use of consumable supplies
3. The number of accidents
4. Absenteeism
5. Labor turnover

Tests have been developed to measure technical skill and knowledge of company policy.

This program is still too new to permit a significant summary of benefits which can be attributed directly to the program. However, results at the plants where this program has been instituted have shown marked increase in manpower utilization, reduction of product damage, vastly improved housekeeping, and safer operations. As the program increases in scope throughout the company, we expect to present statistical data to show the benefits accrued.

We believe that a concerted attack must be made on the causes of material handling accidents to achieve significant reduction in overall accident frequency. We also believe that this attack can best be made through the application of a well-thought-out operator selection and training program.

ENGINEERING SAFETY INTO A MATERIAL HANDLING SYSTEM

by RITSON H. GRAVES

technical assistant to vice president & general manager, U. S. Metals Refining corp., Carteret, N. J.

Whoever heard of doing such an advanced thing as engineering safety into anything except last year's automobile? And that turned out to be a flop. People keep right on buying automobiles without safety rims, safety belts or foam rubber dashes. If the masses won't go for safety in an automobile do you expect them to act any different in an industrial plant?

I wondered why our plant made substantial gains during the last few years in frequency and severity. It wasn't just because the foreman told Joe to put on his goggles or safety shoes or don't fall over that or don't do this and don't do that. The foreman has been doing that many years with little if any gain because supervision can't be everywhere at once. It was due primarily to having a *real* safety program during the past three years which forced us to engineer safety into all operations.

We are smelters and refiners of most nonferrous metals. This is a dangerous business in general and more so in our plant because we are the largest single consumer of nonferrous scrap material. Every truck and railroad car received contains a new additional hazard. We could operate above the national average in accident frequency and severity and excuse our record by saying, "but we handle scrap." However, we now are operating equal to or below the national average for our business.

PROBLEM AND SOLUTION

It isn't possible to confine this subject to engineering safety into a material handling system. Our overall method is complicated, but in general we have done two main things:

1. We have made operating department heads and their supervisors responsible for safe practices and,
2. We have made these same people also responsible for safe engineering design.

We will omit all discussion of safety posters, protection equipment, on the job safety meetings, prizes and booby prizes for best and poorest departments, safety awards and housekeeping. All are part of our overall plan but are only incremental tools to help the plan along.

We are in business for one reason, which is to make money or a profit. Besides all the heartaches, sorrows and human relations associated with an injury, most companies must weight the cost of a safety program against the settlement costs of injuries. An entire profit could be spent on a safety program without the desired results. We believe that cutting the cost of safety is just as important as cutting the cost of any other operation if you obtain an improved product. The quickest way to cut safety costs is to reduce injuries.

The two things we have done are probably only used by five per cent of industry. How do we make supervision responsible for safe practices and also safe design? You probably will say, "We've tried that and you can't make it work." It is working at our company and accomplishing results we thought impossible a few years ago.

We get safe practices from supervisory appraisal. And it is this supervisory appraisal which forces supervision to insist on safe design.

How can a supervisory appraisal program accomplish this? We tried many rating and appraisal schemes, none of which were worth while. Perhaps what we are now doing would more correctly be called budgeting — budgeting safety.

The final résumé of all of the various increments contains the following subjects and the magnitude of each subject:

Safety	24%
Production	24%
Cost	24%
Quality	8%
Labor Relations	4%
Housekeeping	4%
Operation & Process Improvement	4%
Maintenance Practices	4%
Administration	4%
	100%

DESIGNED BY SUPERVISORS, ENGINEERS

These are the total items which make up the departmental management executives appraisal. It took four years to educate and sell it to those affected. It was not made up just by an expert but was actually designed by the department supervision and the industrial engineering department working together over a long period of time.

The standards, objectives, budgets or whatever one wishes to call them were set up by the people affected. When you set your own objective or goal you don't mind being appraised on the degree of accomplishment. It would be difficult to accomplish this in a plant which doesn't have accurate cost and production standards.

We have done the unheard of thing by making safety 24 per cent of the total responsibility of supervision. This 24 per cent item consists of the following items and their magnitude:

Frequency	6%
Severity	6%
Compensation costs	3%
Reports	3%
Safety Practices	6%

Frequency and severity are standard items. Compensation costs are figured in terms of cents per man hour on the departmental work force. Reports are those things we all have had trouble getting in the past such as accident reports.

Safety practices include many things such as hazards, inspection of equipment, safe working habits, on the job safety meetings and a general continued educational emphasis on the safety program.

From the inception of the program we emphasized that eventually this overall appraisal of supervision will become the basis for part of a supervisor's pay or a bonus plan. It has also been stressed that eventually it might even mean a man's job if he continually showed that he was way out of line.

Starting January 1957 we have paid a quarterly bonus to the top departmental executives strictly on a trial basis. Of course, there weren't any kicks from those receiving quite an amount and surprisingly, the kicks from those receiving a minor amount were very mild. Actually they are beginning to ask for help on how they can raise their appraisal.

I had to discuss our appraisal program and the magnitude of safety because that is the only reason we are able to get safety engineering into a material handling setup.

DEFINITION OF MATERIAL HANDLING

"Material handling" in our plant is any work which doesn't physically or chemically change the material or add to its value. By this definition, more than half the labor in most departments is handling material. We also continually change methods and processes to meet competition. This involves a great deal of engineering and expenditures of large sums of money.

All money must be obtained by the age old method of authorization requests. These authorization requests give us the opportunity to make departmental supervision responsible for producing a safe operation. It works as follows:

1. All during the engineering stage there is a free flow of information and ideas between the department involved and the engineering department.

2. When the idea is written up in Authorization Request Form and all prints are complete it is passed and signed by the chief design engineer.

3. The chief plant engineer then inspects, passes and signs it.

4. The chief mechanical and construction engineer also signs it to prevent any future alibis in planning or other impossible situations from developing.

5. The industrial relations head signs it which should prevent any union trouble in the future.

6. Finally the authorization request must be signed by the department head. It is our rule that a department head's signature on an authorization request is his guarantee that it will function and produce. This is the toughest test for any authorization request to pass. It may take days or even weeks. It must be understood by all supervision and their agreement obtained orally that it will work. Often even hourly paid operators are called in and the whole thing explained to them. If hourly people are in agreement with something new they will make it work.

It is the obtaining of the department head's signature which produces safety in design because an unsafe design can mean 24 per cent of his bonus. After a few years of this type of manuevering it works back to the engineering department people who have been educated to design safely by the department heads.

RESULTS OF PROGRAM

Either we have been increasingly lucky or our program is working. We like to think that the following results of the entire plant are due to the safety program.

				1st Half
	1954	*1955*	*1956*	*1957*
Frequency	17.70	7.24	7.88	8.66
Severity	51.10	37.61	723	275

We also like to think that the recent mild increase in frequency is due partly to New Jersey's constantly broadening scope of compensation payments.

Our experience during the past four years on our three major methods of material handling has been:

1. Standard gage railroad—one man claimed to have gotten a hernia from throwing a switch but this was not proven.

2. Mobile Equipment—one fork truck operator stepped in a manhole.

3. Narrow gage railroad—this thing has been a source of many injuries for half a century. It mashes people's hands and runs over their feet. It always seemed little could be done except tell people to keep their hands out of the couplers and their feet off the track. This hasn't happened in over a year.

We believe our program is working. Recently I heard our chief design engineer ask, "Is it safe?" Have you ever heard that?▲

LOW VOLTAGE—ACTION AND EFFECT

PHYSICAL ASPECTS OF LOW VOLTAGE ELECTRIC SHOCK

by W. B. KOUWENHOVEN

Professor Emeritus, School of Engineering, The John Hopkins University, Baltimore, Md.

Low voltages range from 120 to 600 volts. The term "voltage," applied to electric shocks, is perhaps erroneous because the current flows through the victim to produce the physical effect. We speak, however, of low, medium and high voltage shocks, because in our constant potential system the circuit voltage is usually the only parameter known.

When you close an electric circuit through your body, current will enter at the point of contact with the live line and will leave at the point of contact with the other side of the circuit. The fundamental law of electric circuits—current flows to a point flows away from that point—is obeyed. The effects produced by the passage of this current may be harmless, serious, or fatal, depending upon:

1. The points of contact.
2. The value of the current.
3. The duration of the shock.

POINTS OF CONTACT

If contacts are made between two points on the same leg or arm then no vital organs are in the current path and there are no injuries except possible burns. In the majority of electric shock cases the current path is from hand to feet, with two vital organs, the heart and lungs, in this path.

CURRENT

The current that flows through the human body obeys Ohms Law, where E is the voltage and R the total resistance or impedance of the circuit. The resistance of the human body is divided into two parts, of the skin at contacts and of the body tissues. The impedance of the external circuit is usually small and may be neglected.

Most body resistance resides in the outer layer of the skin, the epidermis. The epidermis is thin, but it is horny and contains neither blood capillaries nor nerve endings. Its electric resistance is lowest on the palms of the hands, the soles of the feet, the axillae, the groin and the face. Its resistance over the body surface is not uniform, for example, in crossing the midline of a finger from the palm side to the back of the hand there is a large and abrupt increase.

Although dry skin has a high resistance per unit area, it can transmit fairly large currents when the contact area is large. If the skin is damp from perspiration or washing, its resistance is reduced to a small fraction of its dry value. Wet conditions make 120-volt shocks very dangerous. Cuts, abrasions and blisters largely annihilate the protection offered by our skin.

If the skin is removed and contact made directly with the raw flesh, then the body resistance from hand to feet is of the order of 300 ohms. The same value of resistance has been measured on adults in electrocardiography where excellent contact is made using large electrodes attached to the wrists and ankles.

When an electric current enters the human body it flows in a more or less fusiform pattern since muscles, lungs, heart, liver and kidneys have nearly identical specific resistance, approximately 100 ohms. Bone has a specific resistance of some 900 ohms, and human fat of 5,000 to 15,000 ohms.

With good contacts of normal area the adult resistance, hand to feet, may be as low as 500 ohms, although with average contacts a resistance of 1,000 ohms is probably a more realistic value. With poor contacts the body resistance may reach values of 5,000 to 10,000 ohms.

DURATION

The duration of the current flow is important in determining the resulting effect. If the current flows for a second or longer, its duration covers an entire heart cycle, as our hearts beat about 70 times per minute. The resulting effect is not influenced by the heart cycle. As the duration of the shock decreases to a fraction of a second, its location in the heart cycle influences the result. There may exist a shock so brief to have no effect except sensation. If such a shock exists we have not found it. In our studies we have used shocks ranging from ten microseconds to five seconds in duration.

The portion of the heart cycle most vulnerable to A.C. shocks of 1 100 a second covers approximately 1 10 of the period of a heart beat. As the length of the shock increases there is a greater chance of the shock occurring during this vulnerable period.

These three factors, the path of the current, the value of the current, and its duration and position in the heart cycle, determine the physical effect of an electric shock. We will assume the current alternates commercial frequency, and flows through the body from hand to foot. Low voltages of 120 to 600 volts may send an electric current through the victim ranging from a small fraction to nearly two amperes.

PHYSICAL EFFECTS OF SHOCK

The most common effects produced by electric shock current in this range are:

Effect	*Current Value*
Sensation	1 milliampere
Sharp Pain	4-5 milliampere
Let Go	9-22 milliampere
Lose Consciousness	30-50 milliampere
Ventricular Fibrillation	0.1 to 2 or 3 amperes

Low voltage shocks seldom paralyze respiration, or cause serious burns. Paralysis of respiration generally occurs in shock cases where the current through the body is four or more amperes. An electric burn depends upon the resistance of the skin contact, the current density per unit area of contact, and the length of time the current flows. Low voltage shocks only produce severe burns when the current flows for a considerable time.

Currents producing sensation, pain, and below the "let go" value are not in themselves harmful. Dalziel has defined a "let go" current as a current one can release voluntarily without injury. If the shock current reaches a value that results in a severe muscular contraction that the individual cannot release his hold on the circuit, then the situation is desperate. Blisters will form, the skin protection lost, and the current may rise to values resulting in death.

Occasionally an electric shock case is reported in which an individual loses consciousness or faints without either the stoppage of his respiration or the cessation of his pulse. This phenomena is believed to be like surgical shock.

VENTRICULAR DEFIBRILLATION

Currents of 0.1 ampere sto 2 or 3 amperes, flowing for one second will upset the rhythm of the heart and throw it into a quivering state known as ventricular fibrillation. A.C. currents of 1.2 amperes, flowing for 1/120 and 1/60 of a second during the vulnerable period of the heart, may also result in fibrillation.

In fibrillation the pulse disappears and the circulation ceases. The victim will gasp for breath for about a minute, or until anoxia causes the respiration to cease. The human heart rarely recovers spontaneously and death occurs in a few minutes.

Manual artificial respiration should be applied promptly to save the victim. However, no known method of artificial respiration provides sufficient heart massage to maintain the circulation. For this reason the percentage of successful resuscitation of victims of low voltage shocks is so small.

Drugs are of little or no help in arresting fibrillation: The only reliable method is to send sufficient electric current through the heart to rest the twitching fibres and contract that organ in systole. If done promptly, the heart will usually resume normal beating.

Ventricular fibrillation also occurs in hospitals where the usual practice is to open the chest, expose the heart and massage it to

maintain the circulation while the defibrillating equipment is brought to the site of the emergency. When all is ready electrodes are placed directly on the opposite sides of the heart and a 60-cycle current of 1.5 amperes at 135 volts is sent through the heart for about one-quarter of a second. This will usually arrest the fibrillation and normal beating will follow.

The open chest method of defibrillation is not a field method, and even in the hospital unless the chest is already open it involves a second and a major operation.

SIMPLE DEFIBRILLATION OF HEART

We have developed a safe and simple method which avoids opening the chest and, if applied within less than two minutes after the onset of ventricular fibrillation, the chances of saving a life are excellent. In applying this method one electrode is placed on the sternal notch and the other on the floating ribs at the apex of the heart. When the electrodes are in position, the operator closes a switch sending five amperes at 440 volts through the victim's chest for one-fourth of a second. At the Hopkins Hospital the defibrillators have been used 11 times on human beings whose hearts have been in ventricular fibrillation for periods ranging from one to one and a half minutes. In every case the fibrillation was arrested and the heart resumed normal beatings. Closed chest defibrillation has also been used at other hospitals.

We are continuing our study of the problem with two principal objectives: one to find a method to drive electrically a heart enfeebled by anoxia, and two, to develop a simple equipment for field use.

MECHANICAL ENGINEERING AND SAFETY

FACTORS IN EXHAUST VENTILATION SYSTEM DESIGN FOR THE SAFETY ENGINEER

by K. M. MORSE
chief industrial hygiene engineer, U. S. Steel corp., Pittsburgh, Pa.

The increasing importance of air contamination to health and in nuisance problems has brought into greater prominence the need for an appreciation of the principles of good industrial ventilation design, as applied to contaminant control. While this has resulted, today, in a higher standard of industrial ventilation, the cost of good plant ventilation has continuously increased as equipment, labor and maintenance costs have increased. Therefore, the need for good engineering design to meet hygienic design objectives economically is paramount.

The National Safety Council, both in its "Accident Prevention Manual for Industrial Operations" and in "Data Sheet D-428," has stated that industrial ventilation for contaminant and comfort control is a responsibility of the industrial hygiene profession and gives recognition to the fact that contaminant-control ventilation has been principally developed by this profession. However, I believe that since the industrial hygiene engineer and the safety engineer have parallel objectives, the paths, through which we are endeavoring to reach our objectives, should be linked by a bridge of co-operation.

PURPOSE OF CONTAMINANT VENTILATION

Therefore, the safety engineer should secure some knowledge, or at least an awareness, of the general principles of contaminant-control ventilation, just as I believe it is necessary for industrial hygiene engineers to have some awareness and information on industrial safety. My reason for this has always been that both our professions comprise a realtively small group to meet the challenge before us, and that working together in an atmosphere of co-operation, where each recognizes the area where the other can best perform, but extends his co-operation to him, should result in benefits to our respective programs.

The ventilation which I will discuss pertains principally to contaminant-control ventilation, as represented by local exhaust ventilation systems. Other types of ventilation systems are important, but time will preclude discussion of them. The basic purpose of contaminent ventilation is the maintenance of health and comfort. The criterion utilized to determine the effectiveness of such systems is whether or not the atmospheric concentrations of the various contaminants have been reduced to below unhealthful or otherwise hazardous limits.

This has been a major activity of the industrial hygiene engineer for many years, and in this work, the engineering standards for contaminant-control ventilation systems were developed. However, in practice, the actual engineering design is conducted by plant engineers, based upon the engineering standards; as for example, the type of hood design, control and transport velocities, and collector efficiency, which are provided by the industrial hygiene engineer.

It is in the absence of the industrial hygiene engineer that the safety engineer should become allied with contaminant-control-ventilation problems to some degree. Good contaminant-control ventilation, therefore, results from integrating the efforts of the plant and industrial hygiene engineers, supplemented by the efforts of the safety engineer.

I shall concentrate on the design principles in contaminant-control ventilation and give practical design standards. In the event that there are those who desire a more complete practical knowledge of contaminant-control ventilation, there are, today, several excellent industrial hygiene and ventilation texts on this subject.

As a practical guide, and one which is extremely low priced, may I recommend the "Industrial Ventilation Manual," of the

Committee on Industrial Ventilation, of the American Conference of Governmental Industrial Hygienists. This has made an excellent addition to the library of the industrial hygiene engineer, would make an equal contribution to your plant engineering library, and to your own.

PRINCIPLES OF CONTAINED AIR FLOW

Certain basic principles are involved in ventilation design as in any phase of engineering design. The thoroughness with which these principles are understood, when integrated with practical experience, determines design skill, and awareness of these principles is required by all who may have a part in the establishment of good industrial-ventilation practices. Knowledge of fundamentals is basic to any understanding. These fundamentals involve the movement of air through ducts and the pressures, velocities and power considerations which are developed.

Pressures

Air flows between two points in a ventilation system because of a difference in pressure between these points. This difference may be induced by a fan; from a difference in air density, as in the case of the draft in a furnace resulting from a gravity stack; or from the wind effect on roof ventilators. In contaminant-control ventilation, as applied to industrial hygiene problems, generally only the first of these methods is of prime consideration.

The motion of air develops a pressure termed "velocity pressure" (VP). The velocity of air in a duct is calculated from this pressure from the following relationship:

$$\text{Velocity (V)} = 4005 \sqrt{VP} \quad \ldots\ldots (1)$$

where

V = velocity, fpm
VP = velocity pressure, in. of water

Equation (1) applies for air at standard density of 0.075 pcf. Velocity pressure is always exerted in the direction of flow and is always positive in value.

Air confined within a duct, whether or not in motion, also creates a pressure, termed "static pressure" (SP). This pressure is generally measured at right angles to the walls of the duct and is independent of the velocity of air. In an exhaust system, this pressure is negative when measured on the suction side of the fan and positive on the blowing side of the fan.

"Total pressure" (TP) is the algebraic sum of the velocity and static pressures which is expressed as follows

$$TP = SP + VP \quad \ldots\ldots (2)$$

These pressures are expressed in inches water gage.

The practical significance of these pressures is that their values must be determined to evaluate the characteristics and performance of a ventilation system, or in selecting a dust collector, fan or motor. These pressures vary from one end of the system to the other, dependent upon the desired duct velocities and the resistance that the air encounters as it flows through the system.

AIR FLOW

Our knowledge of air flow in front of exhaust openings has been largely due to fundamental research. Most prominent in this work has been the efforts of Dallavalle, Silverman, and Hatch.

The velocity of air passing through the hood face is termed "face velocity" while that required at the point of contaminant generation, at a specific distance in front of the hood, is termed "capture or control velocity." The velocity of air within a duct necessary to transport the contaminant through the system is termed "transport or conveying velocity." Tables 1 and 2 at the end of this paper indicate recommended control and transport velocities used in good engineering design.

More detailed information, when required on specific operations and materials, may be secured from any text on exhaust-ventilation design. This information should be provided to your design engineers and utilized in the engineering specifications for ventilation systems.

The volume of air passing through the face of a hood or in a duct, is expressed by the following formula

$$Q = AV \quad \ldots\ldots (3)$$

where

Q = air volume cfm
A = area of duct, or of hood opening, sq. ft.
V = average hood face velocity, fpm

The design engineer must not overlook the fact that exhaust-volume requirements as well as resistance charts are based upon air at 68 F and a barometric pressure of 29.92 in. mercury. When temperatures exceed 100 F or elevations exceed 1,500 ft., corrections are necessary.

Estimation of air flow at any distance in front of circular exhaust openings is expressed as follows:

$$V = \frac{Q}{10x^2 + A} \quad \ldots\ldots\ldots\ldots\ldots\ldots (4)$$

Q = cu. ft. of air through hood per minute
x = distance outward along axis, ft.
A = area of hood opening, sq. ft.

While this formula is for circular openings, it applies to rectangular hoods when the width-to-length ratio is greater than 0.1.

The velocity at distances in front of freely suspended exhaust slots can be estimated by the following expression when the ratio of hood width to length is equal or less than 0.1.

$$V = \frac{Q}{3.7 \times L} \quad \ldots\ldots\ldots\ldots\ldots\ldots (5)$$

where
V = velocity, fpm
Q = cu. ft. of air flow through hood per minute
x = distance from slot, ft.
L = length of slot, ft.

Equations (4) and (5) have practical application in determining the required volume of air through a hood, after the control velocity at the point of contaminant generation has been determined.

These expressions for estimating velocities in front of exhaust hoods indicate that the capture velocity depends chiefly upon the volume of air flowing through the hood (Q), and not upon the velocity across the hood face. One who is inexperienced overlooks this vital understanding of air flow.

There have been too many examples of this misunderstanding by reducing hood area to increase the velocity. Suction has very little ability to "reach out" and pull air contaminants toward it. The velocity at one diameter away, drops to 10 per cent of the face velocity, whereas, air can be blown for an appreciable distance before losing considerable velocity.

Air flows toward an exhaust opening from all directions. An appreciable amount of this air is drawn from behind the edge of the opening (edge effect). Such air has no value in capturing the contaminant. The use of flanges can reduce air requirements by as much as 25 per cent by drawing air only from in front of the hood. Flange width need not exceed six inches and, in general, is equal to the hood diameter. Flanging alters the expressions for estimating capture velocities in front of hoods and slots, as shown in Equations (4) and (5), by a factor of 0.75 in the denominator.

POWER

It is necessary to maintain a pressure differential between the inlet and outlet of a ventilation system to create and maintain a flow of air through the system. This is generally done in a local exhaust system by the use of a fan and motor. The power requirement for developing the necessary pressure differential across the system is determined from the following expression:

$$BHP = \frac{CFM \times TP}{6356 \times Eff} \quad \ldots\ldots\ldots\ldots\ldots\ldots (6)$$

where
BHP = brake horsepower required for a given exhaust system
TP = total pressure of system, in. of water
CFM = cubic feet of air per minute of system
Eff = mechanical efficiency of fan (for most centrifugal fans, this value is from 0.50—0.65).

Equation (6) provides a means for estimating probable exhaust volumes or estimating the capacity (CFM) of the system for a given motor size.

PRACTICAL DESIGN FACTORS

A contaminant-control system is generally considered to be of local exhaust-ventilation type. Such a system consists of the following essential parts: Hood, ducts, collector and fan.

HOOD

The function of the hood is to create a flow of air past the source of contamination and into the hood, sufficient to remove the major quantity of the contaminant. The shape of the hood, its size, location and air volume are the important design factors. Principle design factors are as follows:

1. Enclose the source of contamination as much as practical.

2. Do not endeavor to collect large dust particles, only those which are of hygienic significance, (under five microns[2] in diameter).

3. Locate the hood as close as possible to the source of contamination.

4. Use flanges in order to draw air only from in front of the hood.

5. Use downdraft or side draft hoods so as not to draw contaminants past the operator's face.

6. Use manifolds, multiple take-offs or other measures to create uniform air movement through the face of large or long hoods.

7. Eliminate cross air currents through the effective zone of the exhaust hood by the use of baffles, shields, or by relocating unit heaters, space fans or other air movers.

8. Position the hood to utilize air movement from hot presses and to utilize the normal contaminant travel (trajectory).

9. Use tapered connections between hood and duct to reduce the rapid contraction of the air stream and the corresponding entry loss.

10. Remember that the required control velocity at the source of contamination and the transport velocity in the duct are dependent on mass air movement (volume) rather than hood-face velocity.

Many suggested hood sizes are available for various industrial operations from the ventilation manual mentioned early in this paper, as well as from other texts. An excellent source of information for guiding ventilation design for open surface tanks is available from the American Standards Association.

DUCT DESIGN

Duct design is based upon sizing the duct for the required conveying velocity after establishing the required air flow through each hood, and the development of minimum pressure losses due to friction, elbows, transitions and branch entrances into the main. Two methods of design are utilized to insure a balanced system in which each hood is drawing the required air volume. These methods are the static pressure and blast-gate procedures. The design technique is a responsibility of plant engineering. Guides for adequate design are the following:

1. Elbows should have a radius of from two to two and one-half times the pipe diameter.

2. Ducts should be sized for the selected conveying velocity or higher.

3. Branches should enter at gradual expansions, (transition) and at an angle of 30–45 deg.

4. Branches should not enter directly opposite each other.

5. Changes in duct size should be gradual; a one-inch change in diameter to every five inches in length.

6. The system should be "balanced," i.e., the hood nearest the fan should not be robbing air from hoods farther away.

AIR CLEANER

Air cleaners are necessary in most exhaust systems handling dust and fume. The need for this provision is based upon good engineering standards and the complications which may arise from discharging heavily contaminated air into the outside air.

Air cleaners remove contaminants from the air. A wide variety of devices is commercially available, but they may be classed into two types; namely, air filters and dust collectors. Air filters are for removing light concentrations of relatively large-size dust particles found in heating, ventilating or air-conditioning systems. They are not designed for local exhaust-ventilation systems where the dust concentration (loading) may be 100-20,000 times that for which air filters have been designed. Collectors, on the other hand, may have varying efficiencies from the low-efficiency large-diameter cyclone to the high-efficiency fabric and electrostatic type.

Table 3 at the end of this paper is a tabulation of characteristics of commonly used commercial collectors from the work of First and Silverman. Kane also has presented important information on the operation, application and effectiveness of dust-collection equipment. Table 3 does not include all types of commercial collectors and the data should be considered liberally, for

instances in which equipment may perform better or poorer than indicated are not rare.

The selection of an air cleaner will rarely be a responsibility of the safety engineer, but there are factors in selection, such as fire hazard, in which he is interested. In selecting an air cleaner, efficiency alone should not be the sole criterion. Performance, as represented by all factors in Table 2, in addition to other factors, such as maintenance, water consumption, and so on, must be considered. Selection also should be based on an evaluation of the following important considerations:

1. Dust loading and particle size of the contaminant.

2. Collection efficiency required.

3. Temperature, moisture content, and chemical composition of air or gas stream.

4. Characteristics of contaminant such as corrosiveness, sticking and packing quality, specific gravity and shape.

5. Combustible and explosive characteristics of collected material.

6. Disposal or salvage requirements.

Efficiency ratings of manufacturers are "weight efficiencies." Such efficiencies are determined from a ratio of the weight of collected dust to the dust in the air entering the collector, on a per unit volume basis. The efficiency, however, in which we are primarily interested is a "concentration efficiency"; namely, one minus the ratio of the dust concentration in the discharged air to the dust concentration in the entering air.

RECIRCULATING AIR

Controversy has developed on the question of recirculating air from air cleaners. While this may be desirable from a heat-conservation point of view, most state regulatory agencies prevent recirculation. Therefore, in view of this fact, the present stage of air-cleaner maintenance, and inability to be assured of foolproof operation, recirculation should not be practiced in exhaust-ventilation-system design, except under a few special conditions involving nuisance dusts.

Each application involving recirculation should be most carefully considered before it is applied. Several factors must be considered, among which are the following: Concentration of contaminant in discharged air, maintenance schedule and provision for outdoor discharge in nonheating seasons.

A word should be said on the application of unit dust collectors. There are many limitations of this type of collector which have been overlooked very often. These low-cost collectors were intended to meet space limitations where recirculation may be practiced. They were developed for light dust loading from intermittent operations evolving nuisance dusts, such as from tool-room grinders.

They are not intended for continuous dust-producing operations releasing moderate or heavy loadings of small dust particles. Since they have limited dust-storage capacity, short-maintenance periods are necessary. In general, when a number of unit collectors are present in an area, their use in preference to a central exhaust system is questionable.

MAKE-UP AIR

Air must be replaced in any building from which air is exhausted, regardless of the method by which the air is removed. If this is not provided in the winter months, a building becomes air-bound. Cold air leaks through cracks, the effectiveness of exhaust systems is reduced and reverse air flow develops in stacks, ventilators and propeller exhaust fans.

The fan and motor combination is the final element in a ventilation system for contaminant control. Fans may be grouped into two general categories; namely, centrifugal and axial flow. Selection of the fan and motor is a plant-engineering responsibility.

Centrifugal fans, because of their ability to operate against high resistance, are principally used in exhaust systems, while axial-flow fans, due to the ability to move large volumes against low resistance, are used for general or dilution ventilation systems. The safety engineer naturally will be concerned with assuring nonsparking fan construction and explosion-proof motors where inflammable or explosive materials are involved.

The selection of the fan is based upon handling the required air volume at the fan static pressure with minimum horsepower. Additional factors to be considered are the following: type of drive, operating temperatures, space limitations and corrosion problems. The fan should be located downstream from the air cleaner in order to protect the fan from excessive erosion and abrasion.

Sharp elbows and inlet obstructions at the fan inlet should be avoided. The fan location should be chosen to allow easy access for service and inspection. The fan capacity, as in the case of the air-cleaner capacity, should exceed design requirements by a minimum of 10 per cent to provide reserve capacity.

CHANGING FAN SPEEDS

Knowledge of fan laws should be known by all interested in contaminant-control ventilation. Too often, the inexperienced will comment "speed up the fan" as the panacea of exhaust-system problems. When a new speed is desired for a change in exhaust capacity, the new operating point will be calculated from the following:

CFM varies directly as RPM

TP and SP vary as RPM^2

HP varies as RPM^3

These laws apply only to a given system when a change in exhaust volume is required without any physical change in the system. Any physical change in the system throws the entire system out of balance and requires rebalancing to insure adequate flow through each hood. Of equal importance, however, is the effect of increasing the capacity of an existing system. A 20 per cent increase in capacity will require a similar increase in speed. This will result in a 44 per cent increase in total or static pressure and a 73 per cent increase in horsepower.

EXHAUST SYSTEM MAINTENANCE

I believe that the safety engineer can best contribute to the effectiveness of exhaust-ventilation systems by insuring the development of an adequate maintenance and testing schedule. In my experience, few machines or equipment receive less maintenance and testing than exhaust systems, despite the fact that such systems are often costly to install and replace. The mere operation of the fan does not insure adequate system performance.

An adequate maintenance program should involve three phases:

1. Design, system sufficiently rugged to withstand the type of use and abuse expected.

2. Provision for the type of installation to insure convenient routine cleaning, inspection, removal or replacement of any part.

3. Establish a routine procedure for inspection and testing, including maintenance of adequate records.

A system is not adequate simply because someone says so. Only performance data can be accepted as indicating effectiveness. Records should include the following data:

1. Operating data. Fan speed, motor load, hood sizes, and volumes, branch and main-duct velocities, fan inlet and outlet velocities, suction and pressure readings at various points in the system and the dates the data were collected.

2. Name plate data and detailed ordering, descriptions of all equipment.

3. Copies of all construction drawings and sketches.

4. Parts list and spare-parts reference drawings.

All the data should be kept in such form that they will not be lost by the maintenance shop and a copy kept in the general file. The safety engineer may desire to secure a copy of the operating data.

NEW INSTALLATIONS

Measurements should be made to insure conformance with design specifications. Data should be secured on volume (CFM) and static pressure in each branch, and all future readings obtained at the location used. The pressure drop across the air cleaner should be obtained and air samples should be collected at the breathing zone of workers engaged in operations for which the exhaust system was installed. These data shall serve as "bench marks" to which to refer future tests.

EXISTING SYSTEMS

Existing systems should be checked to secure the data previously mentioned for new systems. In addition, the following checks should be made:

1. *Hoods.* Condition of hoods should be observed to note damage.

2. *Ducts.* Cleanout doors should be

opened and settling of contaminant observed. Condition of the duct work also should be inspected for leaks, corrosion or abrasion. Condition and setting of blast gates should be noted for evidence of tampering.

3. *Elbows.* Elbows should be observed for excessive wear. This is particularly important when abrasive dusts are handled as in foundries.

4. *Air Cleaner.* A U-tube gage should be mounted across the cleaner for periodic check of pressure drop. The amount of collected material should be checked and a regular removal schedule instituted. Collector efficiency should be checked periodically by determination of contaminent concentration in the entering and outlet air. Checks should be made for holes and leaks in fabric tubes, the adequacy of water supply and water level regulation in wet collectors, and the operation of rapping mechanisms.

5. *Fans.* Bearings should be checked for overheating. The tension or belt drives and the fan rotation checked. Fan blades should be inspected for accumulations and wear.

While not the most exact of methods, a Velometer or the Anemotherm air meter will provide a relatively simple method for the safety engineer to check air flow at hoods, in ducts and to determine static pressures.

For most purposes, it will be adequate to check velocities in circular ducts in a straight run, 5-7 diameters away from any major air-stream disturbance by determining the velocity in the center of the duct. However, the velocity so determined must be multupled by 0.90 to obtain the average velocity.

Either of the foregoing instruments provides a ready means of determining control velocities at the point of contaminant generation. These general-purpose instruments are in need of periodic and frequent checking and the manufacturer's instructions should be followed. In the case of the Velometer, the zero setting and balance should be checked afer each reading.

I have endeavored to provide some of the basic information on exhaust-ventilation systems. Only through the co-operation of our respective interests, together with the plant engineer, can we achieve a standard of engineering design commensurate with the needs of our common object.

Table 1

RECOMMENDED CONTROL VELOCITIES

Method of Generation	Control Velocity (Ft. Per Min).	Typical Processes
Released without noticeable movement	50-100	Evaporation of vapors; exhaust from pickling, washing, degreasing, plating, welding
Released with low velocity	100-200	Spray booths, sorting, weighing, packaging, mixers, barrel filling, low speed conveyor, transfer points
Active generation	200-500	Foundry shakeout, high speed conveyor, transfer points, crushing, screens
Released with great force	500-2000	Grinding, tumbling mills, abrasive cleaning

Table 2

DUCT TRANSPORT VELOCITIES

Material	Velocity (Ft. Per Min.)
Vapors, Gases, Fumes	1500-2000
Fine Dry Dusts	3000
Ave. Industrial Dusts	3500
Coarse Dust	2500-4500
Large Particles, Heavy Loading, Moist Materials, Pneumatic Conveying	4500

Table 3

CHARACTERISTICS OF COLLECTORS

Group Rating	Type	Approx. Particle Size Efficiency 1-5a Particles %	Installed Cost Per CFM of Rated Capacity $	Capacity 1000 CFM	Optimum Dust Loading Grains /CF	Pressure Loss Inches Water	Service Life Years	Limitations
1. High Eff. High Cost	Electrostatic Precipitators	80-99+	0.5 -2.0	0.1 -200	<1	0.2-0.75	5-20	Need pre-cleaner for coarse dusts. Limited to nonexplosive & noncombustible materials unless in inert carrier gas.
2. High Eff. Moderate Cost	Fabric filters	95-99	0.2 -1.0	0.05-200	0.1-30.0	0.2-2.0 (clean) 2.0-8.0 (loaded)	1-10	Only dry materials. Max. temp.—180°F cotton & 200°F wool.
3. Moderate Eff. Moderate Cost	Wet Packed Towers	20-60	0.4 -0.8	0.5 -5.0	<1	1-10	5-20	Not for solid particles
	Cyclones-Small Diameter	10-40	0.35-0.50	0.02-0.1 per unit 4-500 units per collector	0.5-10	2.0-4.5	5-20	Plugs at high loadings. Nonuniform air distribution in collector.
4. Low Eff. Low Cost	Mech.-Centrifugal	10-20*	0.2 -0.35	0.5 -10.0	1-10	—	5-20	Not for caking & sticky materials.
	Wet Spray Collector	10-20	0.1 -0.2	0.5 -100	<1	0.1-0.2	5-20	—
	Wet Baffle Tower Collector	10-20	0.2 -0.4	0.5 -5.0	0.1-2.0	0.2-0.75	5-20	—
5. Very Low Eff. Low Cost	Cyclones-Large Diameter	<10	0.1 -0.35	1-10	1+	0.5-2.5	10-20	Little value for dust of hygienic importance

* Efficiency for 5—10a particulates is 60—80%

MATERIALS HANDLING WITHOUT ACCIDENT

by JERVIS C. WEBB

president, Jervis B. Webb co., Detroit

While the subject is named "Materials Handling Without Accident" in the official program, what is meant is "Materials Handling *By Conveyors* Without Accident." While this still leaves a large area to cover, it does narrow the subject down to one with which I am more familiar and experienced because of the nature of our business.

This education in safety as related to conveyors is not just happenstance. Today's material handling systems, to receive the approval of an astute management, must not only deliver a predetermined volume of materials faster, more economically and with unimpaired quality, but must do so with perfect safety to employees and others approaching the moving conveyors. So you might say I am an exponent of safety by compulsion!

At this point, perhaps it would be amiss to give you some of the background on this safety movement. The first published Code on this subject came out in 1947, called the "American Standard Safety Code for Conveyors, Cableways and Related Equipment," known as ASA B20.1. Three years later, in February, 1950, I became chairman of a reorganized committee to revise and bring the Code up to date.

COMMITTEE B20

This committee then became known as Sectional Committee B20 on Safety Code for Conveyors and Related Equipment. The program was sponsored by the Accident Prevention Department of the Association of Casualty and Surety Companies and the American Society of Mechanical Engineers. Work on revisions to the Code was divided into four sub-committees:

1. Scope and intent
2. Nomenclature and definitions
3. Portable conveyors
4. Conveyors in general

Rough draft of the proposed revisions was sent to ASME headquarters in April, 1955, and the revisions were sent to members of the B20 Committee for their comments. At the December, 1955 committee meeting in New York, revisions and suggestions were discussed and sent to B20 members, legislative bodies and interested parties in industry. This resulted in further corrections and refinements. However, the Code is now at ASME headquarters, and awaits only sponsor approval.

DEFINITIONS OF MAJOR TYPES

So much for the background on the safety code. In this discussion, I will endeavor to do four things:

1. Give you my definition of the most commonly used conveyors
2. Comment on the overall safety aspects of conveyorized manufacturing versus manual methods, and touch on the desirability of finding the median or most practical point in considering safety measures—neither too little nor too much
3. What manufacturers can do to ensure safey consciousness among employees
4. Some practical suggestions gained from my own experience and that of other manufacturers and users of conveyors

Here are some definitions of different types of conveyors.

BELT CONVEYORS: Continuous fabric, rubber, leather or steel belt of any width or length, traveling on flat steel or wood beds, on flat or troughed roller beds, carrying packages, bags, parts, coal, ashes, salt, chips—almost anything.

APRON CONVEYORS: One or more, usually two, continuous strands of chain between which are suspended aprons, slats, pans overlapping or not overlapping, of almost any width or length, with or without sides, carrying all sorts of materials.

BUCKET CONVEYORS: Continuous belts, chains or chains, to which buckets are attached, carrying many types of materials in bulk—sand, gravel, stone, coal, chemicals and grain. Operated vertically, these conveyors are called bucket elevators.

CHAIN CONVEYORS: This term covers a multitude of designs and styles. Continuous chain or chains running over and driven by sprockets or caterpillar drives, supported by metal or wood track, or roller beds, sometimes called a drag chain. Material may rest on the chain, on carts or trucks fastened to and pulled by the chain. Sometimes the chain itself works and advances bulk materials along by itself operating in a trough.

FLIGHT CONVEYORS: This consists of single or multiple strands of continuous chain to which cross bars or flights are attached for pushing and scraping the material along in troughs.

GRAVITY CONVEYORS: Series of free rollers or wheels mounted on axles set in two or more parallel frames, the supports being so arranged that the materials are moved along by the force of gravity.

LIVE ROLLER CONVEYORS: Series of rollers motivated by belts or chains from underneath, or by sprockets and chain at the end of each roller. Materials are moved along as they rest on the turning rollers.

OVERHEAD TROLLEY CONVEYORS: Picture an overhead I-beam track on which are suspended trolleys, which are spaced and driven by a continuous chain traveling parallel to and beneath the track. Loads of all sorts are suspended on hooks, buckets, baskets or other hangers from the chain, or pulled in trucks or carts by the chain and trolleys.

SCREW CONVEYORS: Consist of helical screws in guide channels whose relative rotations advance the material handled.

In your mental picture of conveyors, bear in mind that in practically every industry one or more of these conveyors are an integral part of manufacturing assembly, are providing continuous mechanized processing facilities, are tied in with storage, warehousing, shipping and receiving activities; or at the least, are transporting raw materials, parts or fuel from one place to another in the plant or from one building to another. These units move powerfully and mechanically, and consequently safety features are as essential to them as to machine tools, power trucks or other mechanical devices.

The safety code treats these and other conveyors and related equipment generally and specifically. It speaks of general design in this way: Guard driving machinery; don't load beyond rated capacity; design mountings in such a way that catching sharp edges or possibility of pinching are minimized.

Keep lubricating points piped out to safe locations; enable adjustments to takeups or drives to be accessible. Use anti-backups and anti-runaway mechanical safety stops on slopes as protection in the event of chain breakage. Use load brakes as overload cut-out protection. Enclose counterweights. Use guard rails.

Interlock conveyors electrically to prevent jamming and danger which occurs when one conveyor shuts down and the one feeding it might still be operating. Watch design of transfer points from one conveyor to another as here lies the possibility of pinch and dangerous free materials. Make sure supports, particularly for portable conveyors, are substantial to support without tipping under loads.

GENERAL SAFETY NOTES

The Code covers clearance and accessibility. Leave space for maintenance and for operators. Provide visibility so oncoming loads may be seen. Up high, provide guarded catwalks. Wherever wall or floor openings occur, guard well with rails—these are dangerous points. Provide inspection doors and peep holes where conveyors are enclosed. Make proper provision for crossovers, aisles, passages, leaving ample clearance and headroom. With paint, signs and/or lights, clearly define these ways of travel.

Under inspection and maintenance, the Code suggests the importance of lubrication on a regular basis. Keep takeups properly adjusted; examine periodically cottered connections and couplings for weaknesses. Replace worn parts.

The Code advises that related structures such as tunnels, pits, hoppers and chutes where conveyors are used should be considered in the overall safety design.

General safety rules might be built around these admonitions: Obey rated load signs.

Mark stop and start stations clearly, and make them easily accessible, and where they provide a clear view of the conveyor. No riding on conveyors; no stepping on conveyors. Don't service conveyors unless on regular maintenance crew. While servicing, stop the conveyor and lock out normal starting push button stations. In case of overload cutouts, locate jam and use lockouts before starting or servicing.

The Code refers specifically to its relation and dependence on other codes. These include those of mechanical power transmission, electrical, elevators, dumbwaiters, escalators, cranes, derricks, hoists, buildings, bridges, walkways, floor and wall openings, railways, toe boards, dust explosions and boiler construction. The ASME, ASA and ASTM code numbers are listed therein.

CONVEYOR SAFETY IDEAS

Turning to specific conveyors, the Code suggests briefly that: A smooth cover should be used under slat conveyors where there is space between slats to prvent shearing hazards; safety provisions for men who must ride on trippers or belt conveyors; totally enclose bucket elevators; hand rails, smooth sides; guard plates along chain conveyors will protect hands, feet and clothing; stops are needed at open ends of gravity conveyors; try to eliminate all pinch points on live roller conveyors; substantial guards with sides under overhead trolley and power and free conveyors are desirable; use solid covers on screw conveyors when possible.

The Code is a good start. The revised edition will be of considerably greater help in minimizing accidents originating from conveyors. Of course, we all know that where the human element is involved, there is always a possibility of accident—through ignorance, carelessness or horseplay. The careful indoctrination of all employees with the provisions of the Code will be of material help in at least reducing accidents.

Now, let's leave the code and discuss the broad aspects of how far we should go in our safety measures . . . which brings us to the second of the four divisions.

We don't fence in our highways and streets so that trucks and automobiles won't hit people; we use traffic lights, signs, curbs and painted lines. Similarly, we can go only so far to protect operators of machine tools. They must use the safety features, be alert and safety conscious. Some elaborate guarding is as economically unsound as fencing the highways or streets. Sometimes the initial cost might be up to 40 per cent of the entire installation; and, further, might greatly limit the advantages and flexibility of the conveyor.

CONVEYORS REDUCE HAZARDS

The problem of safety in industry might be approached in another way . . . by stating that conveyors as a whole mean more safety. Here's why: Materials are brought to and taken away from operators. Lifting, carrying or wheeling is lessened or eliminated. The operator, therefore, need not leave his station and walk into trouble elsewhere; nor need he join that unfortunate group who sustain lifting injuries.

In *Occupational Hazards*, an article entitled "High Cost of Lifting," said the manual handling of objects accounted for 27 per cent of the total accidents in Illinois. Handling by conveyors eliminates this manual handling. Material coming to the operator mechanically eliminates momentary inattention to the machine he is operating.

Conveyors help good housekeeping because they are installed on definite lines of flow, and their continuous operation cuts down piles of subassembly goods in process. Less manual handling lessens fatigue and its tendency toward mistakes. Working along a conveyor at a constant uniform speed, being fed material on an even flowing basis, operators develop a rhythm in their work which makes for sureness and fewer mistakes.

Mechanized coal yards, foundries, paint shops, chemical processes—look at these in comparison to their old unhealthy, back-breaking, dangerous manual counterparts. The conveyor goes where a man cannot, or should not, into and through heat, bad atmospheres, cutting heads of machines—all kinds of conditions. Yes, industry is safer because of conveyorization.

Now we come to the third division. Users and conveyor manufacturers must work together to reach the right balance of safety in conveyor systems. Greater consumer safety consciousness is a must. In any competitive industry, there are those who skimp on safety features to have the lowest price. Users must study proposal specifications and demand that safety features be outlined as specifically as the conveyor itself, and then these provisions must be adhered to. They should consider carefully before they rule out a supplier because he includes what others might call excessive safety features.

Get copies of the Safety Code, and make sure the provisions are incorporated into your conveyor system. In considering the proposal, consider, too, these points: Has the system hemmed in workers too much . . . created fire hazards . . . allowed wide enough aisleways . . . left normal exit facilities? It is also wise to watch wall openings and floor openings as to their effect on the safety of employees on both sides of these walls and ceilings.

Now we come to the fourth division . . . just a few suggestions for safe use of conveyors in general. When you have installed a conveyor, don't start using it for production until it is formally turned over to you by the manufacturer or erector. The systems must be run, the bugs must be taken out of the automatics, clearances between guides and moving parts may need to be relieved.

It's practically impossible to design and build a conveyor system that does not need any field adjustment after shipment, and after the variations in the user's plant are taken into account. By far the most accidents have occurred at this point in our experience as manufacturers.

WATCH WHEN SERVICING

If a conveyor is being serviced and is shut down as it should be, watch that the work is not being done too closely to another moving conveyor. A number of serious accidents have occurred where the serviceman, absorbed in his work, leaned back into another moving conveyor, or a slowly moving load came along and squeezed or pinched him against the stopped conveyor, or to a wall opening.

Watch loading of conveyors. Be sure the hookup is secure if it is a hooking job. If materials are piled on the conveyor, watch that they aren't top heavy.

Remember clearances between conveyors and walls. Clearance for a man to walk through should be based on the largest load carried on the conveyor.

Authorize certain persons to operate certain conveyors just as you would a machine tool. Keep others from starting the system. Speed variations in conveyor lines should be entrusted to one who understands what effect these changes might have on the system as a whole.

CHECK JAMMING IMMEDIATELY

If overload cutouts are continually operating, or shear pins continually shear, contact the manufacturer of the equipment and find out the cause of jamming. Check as to whether the system is overloaded by means of a dynamometer. If the design is light, get it heavied up before trouble starts.

Have a number of push button stop stations along a conveyor line. Insist on electric ground wires, particularly on portable conveyors and systems operating in the outdoors or in damp places. Insist on heavy, high-quality electrical equipment. Stay on the high side of electrical codes.

Conveyors can be used safely, and their use has contributed substantially to the industrial worker's safety. If you set up definite rules, be sure that all are acquainted with them. If you insist that safety specifications be high in the conveyors you buy . . . then conveyors will be safe.

NUCLEAR POWER PRESSURE VESSELS

by CLAIR E. KEENE

vice president, Mutual Boiler & Machinery Insurance co., Waltham, Mass.

The purpose of this presentation is to explain some problems in the safe application of pressure vessels in nuclear power plants. My discussion is confined to general accident prevention in construction and use of pressure vessels.

There are several types of reactors in use or under development for power generation. Pressurized water reactors and boiling water types are favored, although sodium graphite, fast breeder, and aqueous homogeneous reactors are used. These reactors require pressure vessels to contain the moderator or coolant or other liquids or gases incidental to operating the reactor. These vessels are in addition to those usually found in a conventional steam-electric power plant.

Most nuclear power reactors are unique, requiring a steel air-tight container to house the reactor vessel and other radioactive components. The extreme toxicity of the fission products and other highly radioactive substances in the reactor systems makes this essential to prevent any possible release. Every precaution is taken in the design and protection of a reactor, however, a fuel melt-down or disruption of the primary system could occur.

TYPES OF PRESSURE VESSELS

Pressure vessels in a nuclear power plant may be roughly divided into three main categories:

1. *Reactor and primary coolant vessels, including shield tanks inside the final or outer containment vessel or housing.* The contents of these vessels are normally subject to high level neutron or gamma irradiation. Some of these would seldom, if ever, be accessible for internal inspection.

2. *The outer or final containment vessel housing the reactor vessel and primary system components.* This vessel may be subject to gamma radiation because of the activity induced in the coolant system. These containment vessels are not normally pressurized but are designed to withstand the maximum pressure from an explosion or rupture of the primary system in any credible accident. They are also expected to stop flying explosion fragments from penetrating the container.

3. *Secondary system vessels as found in a conventional power plant.* These vessels are not normally radioactive and are usually located outside the containment vessel. They are normally accessible for inspection and maintenance.

DESCRIPTIONS OF EACH GROUP

The first group consists of a reactor vessel with fuel, one or more heat exchangers or steam generators, a pressurizer, primary blow down tanks, and other vessels built for relatively high pressures. The operating pressures for vessels containing moderators and coolants may range from atmospheric pressure to over 2,000 p.s.i. Operating temperatures range from 300° to over 1,000° F.

Some of the primary system vessels are large with diameters from 10 to 20 ft. and 30 or 40 ft. long. This group has thin walled tanks which operate under little or no pressure to provide thermal or biological shielding. Some primary vessels, especially the reactor vessel, are subject to high thermal stresses, corrosion and radiation damage.

The second group operates under atmospheric pressure or a few pounds higher but withstands internal pressures and impacts that occur from a reactor incident without leakage or rupture. Some vessels are an unusual size with diameters up to 225 ft. and cylindrical lengths up to 150 ft. They are designed for internal pressures from a few pounds to 65 or more psig. Attention is also given to design against external pressure to avoid possible collapse. The size and shape of these vessels are determined largely by the equipment contained, the reactor incidents postulated, and economic factors. Both cylindrical and spherical shapes are used.

The third requires no description as it includes heat exchangers, evaporators, feedwater heaters, water tanks, air tanks, and other auxiliaries found in a conventional steam plant.

In my opinion the safety of nuclear pressure vessels under present pioneering conditions depends primarily upon:

1. the suitability and quality of material,
2. the adequacy of the design to meet the service conditions,
3. good workmanship in fabrication,
4. rigid shop inspection and testing.

In other words, for maximum safety we must have well designed and constructed vessels because there is limited access for maintenance and inspection.

Extra care is required to determine the quality of materials. Non-destructive testing must be used extensively. Inclusions or other defects must be kept to a minimum. Local stress raisers should be reduced to the greatest possible extent.

Extra precautions are required to insure sound welds. The mechanical properties of the steel must be thoroughly investigated, not only tensile strength and ductility but also endurance limit, creep-rupture, impact strength, and notch sensitivity properties.

STUDY RADIATION EFFECTS

In addition, the effect of irradiation on these properties must be studied. The effect of neutron bombardment and gamma radiation on some properties of structural materials is not known and pressure vessel designers need further research.

It seems that most conventional steel alloys become stronger and harder when irradiated. One important observation on carbon steels used for pressure vessels revealed that the impact strength was reduced appreciably.

Reduction in impact strength, if appreciable, will increase susceptibility to brittle fracture. In addition, the transition temperature from ductile to brittle fracture was raised considerably.

Radiation damage could seriously affect the safety of operation. The increase in brittleness may be nullified or minimized by the annealing effects at relatively high operating temperatures. Only time will tell the actual effects on a reactor in service for some time. Material deterioration from the combined effects of stress and corrosion also deserve attention. The sensitivity of austenitic steels to cracking at the edges of welds is another possibility.

These three groups of vessels are designed and constructed in accordance with the A.S.M.E. Boiler and Pressure Vessel Code. The Code does not adequately cover the design and material problems presented by vessels subject to atomic environmental conditions so special rulings to cover this new group of vessels had to be made.

DESIGN AND MATERIALS

Most of the pressure vessels in the primary system, particularly the pressurized water and boiling water types use a carbon steel, such as ASTM-A-302B, ASTM-A-201B or ASTM-212B clad with 304L or 347 stainless steel. Code Case No. 1226 requires that containment vessel shell plates be constructed from ASTM-201 or A-212 ordered to the requirements of ASTM A-300. Stainless steel is required to keep corrosion to a minimum.

Oxygen and hydrogen are released by water decomposition and make the water more corrosive. Special precautions are required to keep the water non-corrosive, to prevent a weakening effect on the pressure vessel and a build-up of corrosion products which become radioactive and present difficulties in inspection and maintenance of pressure vessels.

In fabrication close adherence to specifications and tolerances is necessary. The use of radiography, dye-penetrant, and ultrasonic testing of welds is strongly recommended. Stresses other than those due to pressure, sometimes referred to as secondary stresses, require special analysis in the design of nuclear vessels. Thermal stresses are particularly important in the design of the reactor vessel and coolant system.

In a power reactor intense radiation generates heat inside the reactor vessel whereas in conventional power and process equipment the heat is usually applied to the outside of a wall and transmitted through it. The temperature gradient in boilers and vessels is approximately a linear function, having the highest temperature on the fire surfaces and the lowest temperature on the opposite surface. In contrast, the temperature gradient caused by internal heat generation of a

reactor is not a linear function and the highest temperature is close to the outside surface.

Thermal stress problems limit the thickness of shell plates and heads of reactor vessels and thus limit vessel diameter. If the steel plate is too thick the heat generated cannot be reduced fast enough and high thermal stress will result. Thermal stresses increase with an increase in wall thickness. Nuclear vessels may also be subject to thermal stress cycling with the possibility of fatigue if the reactor is subject to frequent load changes. The rate of heat generation can change very rapidly in a reactor whereas in conventional equipment the rate of temperature rise is limited by the rate at which fuel can be supplied and burned.

EXPLOSION POSSIBILITIES

One major source of a reactor system explosion is that the superheated coolant contains much potential heat energy which, if released by a rupture, would flash into steam or vapor and cause a serious explosion.

An exothermic chemical reaction is also possible in many types of reactors under certain pressure and temperature conditions. Internal pressure and exothermic chemical reactions that develop within the containment structure and the missile velocities that are attained by any fragments striking the internal surfaces of the container have been analyzed by several investigators.

It is a relatively simple matter to determine the pressure build-up in a containment vessel from the rupture of a primary system containing water by pressure . . . volume relationships and thermodynamic tables. The pressures developed by metal-water reactions are more difficult to determine but can be calculated or approximated by chemical engineers on the basis of credible assumptions. It is assumed some fragmentation of the pressure vessel will occur.

This is possible, particularly if a brittle fracture occurs, but with the explosion of steel boilers and vessels nearly all failures are of a ductile nature and little or no fragments fly around, with one principal exception. When a head or cover plate becomes detached from the pressure vessel by circumferential cracking or failure of the bolts or other fastenings, the head may travel a considerable distance at high velocity.

In other words, if a rupture occurs in the shell of a vessel, it usually tears with high energy absorption, allowing the contents to escape. On the other hand, if a head or cover breaks loose there may be a considerable displacement of both the head or cover and the rest of the vessel itself.

For this reason we feel the results of the investigation are conservative in missile effects. Excluding a brittle fracture, the top cover blowing off a reactor vessel or other vessel set vertically inside the container presents the chief hazard of a fragment striking the container and here, in most cases, because of the mass, the velocity of impact should be relatively low.

We are most likely to experience trouble with pressure vessels in nuclear plants from cracking in or near welded joints. This cracking may or may not cause leakage of primary system contents into the containment vessel or secondary system. These cracks may result from fatigue, thermal stress, stress corrosion, or locked-in stresses from welding. We would not expect brittle fracture to occur, if suitable materials and design are employed, unless radiation damage is greater than expected. If an explosion occurs, particularly from internal pressure, we would expect a ductile type of failure and not much fragmentation.

TESTING FOR LEAKAGE

Preventing the escape of dangerous fission products and radioactive materials from reactor pressure vessels makes it essential to go to great lengths to assure vessel integrity. Several testing techniques are used to detect leakage. These include mass spectrometry, variations of which are the hood, boot and sniffing techniques, pressure-holding methods, soap bubble tests and, of course, pneumatic and hydrostatic tests. One or more of these tests should be preceded by radiographic examination of the welds combined with dye penetrant or other non-destructive investigation of the welds.

As far as the containment vessel is concerned, present standards do not require stress relieving of the finished structure. Other vessels built in accordance with the Code in the manufacturer's shop are, of course, stress relieved in accordance with Code requirements. The precautions now being taken in the strength and leak-proof testing are reasonably adequate for nuclear pressure vessel safety.

The safe operation of pressure vessels in a nuclear system depends upon many factors. Most reactors well protected against excessive pressures, temperatures, circulation failures, and other conditions which could be dangerous. The protective system for a reactor is elaborate and the safety devices will scram the reactor if an emergency occurs. These safety systems are of multiple design and made to fail safe.

Safe operation depends on keeping the reactor coolant outlet temperature below a safe maximum so that the fuel and structural materials will not be damaged. Safe, simple and reliable methods must be set up for normal start-up and shutdown of a reactor as well as for emergency scram conditions. Accessibility for inspection is difficult in most cases . . . sometimes it may be impossible.

It takes time for radioactivity to decay to a safe point for personnel to inspect and make repairs. From the standpoint of safety of nuclear power pressure vessels in service great dependence must be placed on the supervisory control and protective equipment and indications of deterioration, such as the rate of corrosion product formation or leak detectors, in evaluating the condition of the vessels. We presume that from time to time certain vessels or parts of vessels will be accessible for close inspection or at least methods may be devised for some type of remote examination.

This paper has dealt primarily with some of the principal factors affecting pressure vessel safety and the design and construction requirements. The design and construction of nuclear power pressure vessels, with particular attention to selection of materials suitable for the environmental conditions, is of paramount importance for safety and it is in this field that we, as mechanical and safety engineers, can render the maximum service.

NOISE CONTROL—SOME PRACTICAL APPROACHES

CONTROL OF NOISE AT THE SOURCE

by R. L. YOUNG
noise analyst, industrial hygiene div., Employers Mutual Liability Insurance co., Wausau, Wis.

If there is any phase of the industrial noise problem on which there is rather general agreement it is this—that the ultimate answer or solution is a well conceived noise abatement program. The avenues of approach to this goal are as wide and varied as those of any problem which industry has faced in recent years.

It has been said, and rightly so, that there is no cure-all package solution to this problem. We might go one step further and say, that frequently there is no one right answer to a specific noise problem and here an understanding of acoustic principles as well as a considerable amount of common sense is necessary to achieve the best possible answer.

COMPLEX OPERATION

The control of noise in many cases is a complex and costly proposition and the final solution in such cases may require a long range program of planning and research. In some instances conditions may be satisfied by a single type of treatment while others may require a combination of several methods. It is also true, that certain noise problems will require the services of a qualified acoustical engineer or consultant with experience in designing noise control installations.

On the other hand there are some relatively simple, well-known noise control measures which can produce substantial improvement. I have selected illustrations from a variety of industrial operations with the hope that some of them will give you ideas for similar applications in your own plants.

Muffler—Fountain Pen Manufacturing Operation

This is a small table-mounted air operated machine which performs a degating or trimming operation on molded plastic pen parts. It operates on an air line pressure of about 110 psi. The exhaust air was originally discharged directly into the atmosphere at the rear of the machine producing a maximum overall reading of 114 db. on the sound level meter. The noise produced by the air exhaust was intermittent and of short duration but occurred every few minutes.

A small commercial muffler was installed on the exhaust air outlet which reduced the overall noise level to 88 db. The high frequency noise was reduced to a level where it is hardly noticeable above the ambient noise in the room.

Although few noise sources lend themselves to as simple and inexpensive a control as installing a muffler, the results are particularly gratifying in a plant where they have many air operated machines operating at air pressures of 40 to 110 db. At present they have approximately 150 mufflers installed on machines throughout the plant with individual machines having anywhere from one to six mufflers.

Oil Immersed Chain Drive—Tag Manufacturing

Much of the noise produced by a custom built tag converting machine was contributed by a heavy cast gear train. The machine performs a punching and cutting operation as a narrow strip of paper is fed through. The entire chain and gear drive assembly was replaced with a "Speed Trol" fluid drive transmission and an oil immersed roller chain drive.

Noise level readings taken at the machine operators position showed that the overall noise level was reduced from 95 to 93 decibals. The noise measurements were made while the plant was shut down so that the background noise was well below the machine noise. The transmission noise is now less than the noise produced by the remainder of the machine mechanism. Only one of eight machines has been so modified at present but the remaining seven units will be converted during the next few years.

In a plant which manufactures air conditioning equipment, pneumatic hammers were formerly used to bend and close seams on sheet metal fan housings. The large noise radiating surface provided by a housing such as the one in the picture produced high intensity noise over a considerable area. Noise measurements made in the immediate area showed the overall noise level to be in the order of 106 db. with the highest octave band level being 103 in the 600 to 1200 cps. frequency band.

Pinch roller machines which are commercially available were first provided to perform this operation on the smaller fan housings of about 12 inches in diameter. When it was decided to use similar machines to perform this operation on housings of all sizes, the machines were not available to handle the larger housings. This pinch roller machine which can handle all of the large housings was built by the user and in addition to completely eliminating the high level noise the time required for this job has been greatly reduced.

TUMBLING OPERATIONS

Tumbling barrels are used for a variety of operations in many different industries and they frequently present a rather serious noise problem. Complete individual enclosures have provided a very satisfactory solution in one plant. In one particular case, slotted tumblers are used to separate scrap from the parts. The parts are cup-like objects stamped from either 18 or 20 gauge cold rolled sheet steel. The material is loaded or shoveled into the tumblers by hand. As the tumblers rotate, the thin, washer-like pieces of scrap fall through the slots in the tumbler wall into a pan on the floor. When the operation is completed, the scrap pan is removed and an empty tray is placed on the floor to catch the parts.

The enclosures consist of one-fourth inch tempered masonite over one inch thick fibrous sheathing on the outside of two by four studs and another one inch thick sheathing nailed to the inside of the studs. The studs are located about 18 inches on center and the four-inch space between the two surfaces of sheathing is filled with rock wool bats. The doors are of the same construction.

With tumbling cups four inches in diameter, the overall noise level was reduced from 111 to 88 db. at a point in the aisle about five in front of the tumbler. This was predominantly high frequency noise and reductions of 22 to 24 db. were obtained in each of the four octave bands between 600 and 10,000 c/s.

With tumbling smaller, washer-like parts one and one-quarter inches in diameter the overall noise level was reduced from 92 to 85 db. The noise level with the enclosure is approximately the same as the ambient noise level in this area under normal plant operating conditions. In other words the enclosure in this case is undoubtedly giving a much greater reduction than is indicated by these two sets of readings.

FOUNDRY OPERATIONS

A small foundry shakeout for brass and bronze plumbing fittings was enclosed with fairly good results. Since the shakeout is continuously fed by conveyor at one end and unloaded by hand at the opposite end it was necessary to leave an opening at both ends for this purpose. The openings were made as small as possible and curtains of heavy rubberized canvas were hung over the openings to reduce the noise radiated from them.

The enclosure consists of one-quarter inch masonite over one-half inch fibrous panel. The sides, ends, and top were fabricated as separate panels and can be partially or totally dissembled for maintenance purposes.

The parts are automatically dumped from pans on an overhead conveyor into a chute at the rear of the shakeout. The chute carries them through the rear opening on to the shakeout table. The degator operator removes the parts at the other end.

The greatest noise reduction was found to be at an inspection station about six feet directly to the side of the enclosure. At that location the overall noise level was reduced from 101 to 94 db. and the critical frequency band levels in the 600 to 1200 cps. and 1200 to 2400 cps. bands were both reduced 10 db. from 96 to 86 db.

PAPER MILL PRESS EQUIPMENT

Some of the highest noise levels measured in paper mills are due to the discharge from the vacuum pumps on suction presses. This vacuum pump is rated at 18 inches of mercury when operating at 360 rpm. Originally the pump discharged directly through a pipe into an open sewer under a metal grating in the floor. This arrangement produced an overall noise level of 120 db. at a point three feet directly over the sewer opening.

A commercial separator snubber which separates the water and air was installed in the discharge line from the pump. The separator snubber has the water outlet at the bottom extending down into the sewer and the air outlet at top. This single unit reduced the overall noise level from 120 to 112 db.

Because a greater reduction was desired, an additional snubber was connected to the air outlet of the separator snubber and this reduced the overall noise level from 112 to 102 db. This present noise level is considered reasonably satisfactory since the vacuum pumps are located in the basement pretty well isolated from all regular working stations.

In the same paper mill a separator and a snubber were connected to the discharge pipes of two vacuum pumps rated at 17.5 inches of mercury when operating at 680 rpm. The overall noise level at this location was reduced from 116 to 101 db.

TESTING SUPERCHARGERS

One of the highest noise intensities that I have encountered was in a small building where superchargers are tested. A 150 hp. DC electric motor drives the supercharges under test at 3500 rpm. The room surfaces are brick and concrete. Although workers must be in the immediate vicinity of the test stand for short periods to make adjustments and record certain data, most of their time is spent at a control panel.

A partition was constructed between the test stand and the control panel in an attempt to provide a quieter area at the control panel. The overall noise level at the center of the test area which is about 12 feet from the supercharger is 127 db. The overall noise level at the control panel in back of the partition which is also about 12 feet from the supercharger is 100 db.

Although a considerable improvement, this is not yet a satisfactory solution to the problem and it is anticipated that additional control measures will be taken. For example, further reduction in the noise could probably be obtained by providing a gasket around the door in the partition which is located several feet to the left of the control panel. The workers do wear ear protective devices at all times while in the testing room itself.

WOODWORKING PLANTS

One of the noisier machines in a woodworking plant was a large twin band resaw. As with most woodworking machines there is little if anything that can be done to reduce the noise at the machine itself.

In this case a partial enclosure consisting of plywood and one inch sheathing on two by four studding was constructed around the band resaw on an experimental basis. Only two openings were necessary on opposite sides of the enclosure for feeding and removing the lumber. There are two large hinged doors on opposite sides of the enclosure also which provide easy accessibility for either of the operators when the need arises for them to enter the enclosure.

No noise level measurements were made before this enclosure was installed so the noise reduction obtained can only be estimated. In all probability it has done little if anything for the two operators who are located directly in front of the openings, however, the workers located to the side of the enclosure report a noticeable noise reduction.

Boiler manufacturing has long had a reputation of being one of the noisier industries. A couple of the noisiest operations in boiler fabrication are called belling tubes and beading tubes, both of which are performed with pneumatic hammers. When this operation is performed in a large opening working area it produces noise of high intensity during intermittent by frequency intervals for considerable distances.

To confine this high level noise to the immediate area surrounding the operation a large accoustical enclosure was constructed. The enclosure consists of an outer wood surface and bats of sound absorbing material covering the entire inside wall and ceiling surfaces. It was constructed with large hinged double doors at one end providing the necessary access for small rail flat cars.

Noise level readings made before and after the enclosure at a work station 37 feet from the beading operation showed noise reductions in the 1200 to 2400, 2400 to 4800, 4800 to 10,000 cps. frequency bands of 14 db, 17 db. and 16 db. respectively.

This enclosure is no doubt giving larger noise reductions than those indicated by these values since the final readings with the enclosure were approximately the same as the background noise level.

The foregoing illustrations of industrial noise control are not intended as the only or even the best solution to the particular problems. They were presented rather as examples of control measures that have been applied with reasonably satisfactory results. In most of these cases the amount of noise reduction was substantial and in all cases the results were felt to be worthwhile by the plant personnel involved.

No doubt improvements could be made, particularly in regard to some of the enclosures, where a better selection of construction materials and greater use of sound absorbing linings would have produced larger reductions.

However, these examples illustrate some of the problems encountered with noise and some of the things which can be done to reduce noise at or near its source. The possibilities are unlimited once the problem is recognized. Nevertheless, each of you will have to meet the challenge somewhat on your own, either now or at a later date.▲

NOISE CONTROL BY ACOUSTICAL TREATMENT

by LYLE F. YERGES

merchandise manager, Industrial Sound Control, U. S. Gypsum co., Chicago

CONTROL OF NOISE AT THE SOURCE

The best idea yet developed in acoustical design is to avoid making noise. It's always the most effective, and it's usually the cheapest.

MEDICAL CONTROL OF HEARING LOSSES

It would appear that protecting the individual against noise would be the next best method. However, everyone has had painful experiences trying to get workers to wear gloves, goggles, safety shoes and hats. Imagine the difficulty to get them to wear ear plugs or muffs. Furthermore, it is very difficult to forecast susceptibility to noise damage or to measure hearing loss accurately when it does occur. Hearing losses can be determined only after the damage is done—and that is too late.

NOISE CONTROL BY ACOUSTICAL TREATMENT

So, I'm going to concentrate on controlling the acoustical environment—commonly known as sound control or acoustical "treatment." To most people, acoustical treatment means the application of acoustical tile or absorbents to the ceiling of a room. This is the commonest form of noise control, and its use is widespread.

Like the word "treatment," however, it suggests a "cure" or "correction" of an existing ill. Like most cures, it can be expensive and may not be completely satisfactory. For example, at the 100-plus decibel level of many factories, it is very difficult to remove even five decibels by absorption, whereas a simple process change or machine re-design could reduce the level by 10 or more decibels.

In those cases where the problem is to prevent passage of noise through walls, acoustical absorption is virtually useless, and the so-called "treatment" isn't really a treatment after all.

"Acoustical treatment" refers to the use of materials, constructions, systems, or combinations of all three to:

1. Absorb sound.

Keep noise in the plant?
Keep noise out of the office?
Reduce noise levels in the plant?
Quiet a noisy machine?
Isolate a noisy operation?

2. *Whom are you trying to protect?*
   The operator of the noisy machine?
   The workers in the entire plant?
   A single observer of a noisy operation?
   A few noise-susceptible individuals?
3. *Why?*
   Are you trying to avoid compensation claims?
   Is there evidence of noise damage?
   Is verbal communication impossible?
   Are workers distracted?
   Are operators unable to identify necessary sounds from their own operation?
   Are you trying to make a few neurotics happy?
   Is everyone complaining?
   Are the neighbors complaining?
4. *What are the alternatives?*
   Can you move the noisy machine?
   Can you protect the operator by putting him in an isolation booth?
   Can you move the operator and his controls, dials, and equipment to a quiet place outside of the noise?
5. *Will the resultant improvement be enough to justify the expense?*
   Will a five decibel drop do enough good? For example, will reducing the level from 115 db. to 110 db. be enough?
6. *Should you consider an entirely new approach?*
   Can you use a different process?
   Would a new plant or a new location be the only practical approach?

In a few words:

Identify your problem—THE DIAGNOSIS—then, decide on the proper solution to the problem—THE CURE—and finally, choose the proper materials, constructions, systems, or plans—THE MEDICINE.

Chances are the patient will recover, or at least feel a lot better.

MEDICAL CONTROL OF HEARING LOSSES

by **DR. WILLIAM FORD**
Green Bay, Wis.

The purpose of this presentation is to tell you how our various conservation of hearing programs were established in industry in Green Bay and northeastern Wisconsin and to offer a "how to do it" program which can be tailored to fit your needs.

For years the Wisconsin Manufacturers Association, the State Medical Society and the Industrial Commission have sponsored Industrial Health Clinics in several key areas. To them were invited the safety personnel, top management and interested physicians. Thus a back log of groups interested in meetings of this sort was established.

Green Bay's recent (October 1953) Cause Celebre—the case of Wojak vs the Green Bay Drop Forge resulted in increased awareness of the problem of industrial deafness but in reality only initiated our first efforts in this field. To show how unthinking we were, it was recalled that on many warm summer evenings on an open porch nearly three-quarters of a mile down wind from the Drop Forge Plant the thumping of the hammers was sufficiently loud to be a topic of conversation. In other words, it was not unusual to remark about the noisy hammers at the Drop Forge but no particular interest was aroused beyond noting that "the wind was in the west again."

NOISE CLINICS ORGANIZED

Several industrial noise clinics were then held in Neenah, Oshkosh and Green Bay sponsored by the groups mentioned above. In addition more clinics were planned by the safety committee of the Green Bay Association of Commerce and the Industrial Health Committee of our County Medical Society and held in the city of Green Bay.

These latter groups formulated a series of plans to offer industry which varied with the size of the plant, its medical and safety personnel and its location. A tentative schedule of fees was included with a preliminary report of these meetings.

Probably the best and most interesting part of these rather small meetings was the open-mindedness of the people involved and their willingness to discuss all phases of the problems presented by the various representatives of industry and medicine. In fact these meetings at the county level were most productive of immediate results and enabled us to go ahead with our planning.

HEARING TESTS MADE

In the smaller plants and those with a limited budget pre-placement hearing tests were made consisting only of an audiogram, a graphic record of the ability to hear certain pure tones in each ear under more or less standard conditions. In Green Bay these tests were made in the physician's office by a trained technician. In the smaller towns, if there was a local hospital with a room available, efforts were made to persuade the manufacturers in a nearby area to purchase an audiometer *jointly* and *the hospital to* allow a nurse to be trained in its use.

For example, in Oconto county such a station was established in the western half of the county at Oconto Falls and another in the eastern section. At these two points (in this particular county) the techniques in making the audiograms were similar.

At the other extreme in a small city in Kewaunee county the three local physicians each purchased an audiometer and divided the testing. *Admittedly in this last situation* there is a rather wide variation in the techniques employed but (also admittedly) it is much better than not having any tests at all.

In Green Bay the technician sends a copy of each audiogram to the mill. Somewhere in this procedure it is examined by the otologist and a diagnosis written across the back of the card. Any abnormalities in the curve are indicated and if necessary the employee is advised to have an ear, nose and throat examination. Rechecks are also suggested but the efficiency of the follow up varies.

. . . WITH LIMITED MEDICAL FUNDS

The next type of program is followed in some of the larger mills but ones still having a limited medical budget. These mills have either a part or full time industrial nurse who, understanding the value of the program, will be responsible for the follow ups advised at the time of the first audiogram. It has been found desirable for the consulting otologist to set aside time at regular intervals to discuss the program with the nurse and visit certain noisy areas in the plants.

This, of course, serves two purposes, (1) to further the physician's familiarity with manufacturing processes involved and (2) to stimulate the nurse's interest in the plan. *Thus it is possible to* lay the ground work for further studies in the mill regarding numbers of men working in noisy areas and their exposure time.

In other mills, where the main interest is still one of self protection, that is, from the insurance standpoint, in addition to the pre-placement audiograms, a complete ear, nose and throat examination is performed at the expense of the mill and a written report and recommendation filed in the mill office.

A few of the mills have in addition to the above, yearly general physical examinations which include a complete ear, nose and throat study with an audiogram. Frequent checks are made when an employee is in a noisy area or if there is an indication of hearing loss or unusual sensitivity. Annual evaluation meetings are held with management, engineering, medical and safety personnel, participating. This type of program is not as common as could be desired.

To simplify record keeping a specific sheet is used in the otologist's office. The first test is recorded as an easily demonstrated graph and that space is left for recording the findings of the ear, nose and throat examination.

The history is in two parts—the first, a simple check list of significant points as far as the ears are concerned and a record of the results of a more or less flexible questioning by the physician. A record of *his* previous employers and work done, is as important as the history of exposure to noise or to concussion in the military service, e.g.,

the noise experience of a rigger on jet aircraft differs from that of a rigger in the local shipyards.

On the reverse of the sheet hearing values are listed numerically and space is available for the interval histories.

If the goal of conserving hearing in industry is sought nothing is more helpful than frequent informal plant tours. The local otologists have been told that to understand and treat noise exposure deafness, "you must listen to lots of noises yourselves." To illustrate this point from a case history, an employee complained of ringing ears and deafness following his shift on a slasher—i.e., a circular saw and conveyor system which cuts logs into lengths acceptable to a barker.

On investigation it was found that the operator's area, while not quiet, was not especially noisy. It was decided that the individual probably just wanted a change. However, in later conversation with his foreman, it was found that the saws on that particular machine were changed daily with the diameter varying as much as eight inches. This, of course, would result in a much higher edge speed with an increase in noise level on some days.

FURTHER SERVICES TO PLANTS

The noise produced by most machines in industry has been recorded and evaluated. However, it is particularly true in the paper industry that individual modifications and improvements are frequently made with resulting noticeable variations in the noise level produced.

Acceptance by our industry seems to be at three different levels:

A few plants feel that the whole subject is better left alone. This is illustrated by some tool producers who stated "the men did not complain about their eyes until fluorescent lights were installed." "If we start examining ears and checking hearing they'll all complain about that too."

Some plants have a pre-placement audiogram or audiogram plus ear, nose and throat examination as a purely precautionary measure so that an existing hearing loss incurred elsewhere will not be charged to them. There are no rechecks in these plants. Obviously this is not a conservation of hearing program in itself, but several of these mills have had representatives at further conferences in our valley and at the state and national levels.

The safety glass program in our valley was slow in coming into use in some of these mills. In other words, the mills lagging behind in the hearing conservation program also lagged in the conservation of vision program as well.

Some mills have a good pre-placement program, adequate rechecks and follow ups and a fairly complete study as to numbers of employees in noisy areas and time of exposure.

RECHECKS ON HEARING

In this third group when it is known that an employee is exposed continuously to high noise levels a recheck of his hearing is made in 60 or 90 days. At that time if he shows a significant dip in hearing levels after being away from work for 48 hours or if he complains of ringing in his ears or as has happened occasionally, unusual irritability, the following procedure is instituted.

Following an examination in the otologist's office the nurse and/or safety man, a representative of engineering, if possible, and the otologist will review his record and the noise survey report on his machine or at his working area.

If it is decided that this is rightly a noise-induced problem a transfer is considered to a less noisy area. This usually is impossible due to loss of seniority, lower pay and loss of prestige. An attempt is then made to quiet the machine, meanwhile the man is given ear plugs. "The man is given ear plugs." It sounds easy doesn't it, particularly as noise levels in the majority of operations involved in industry in our areas are such that the wearing of ear plugs will reduce the individual's exposure to a relatively harmless level?

ENFORCING EAR PLUG RULES

Perhaps you will smile at some of our early attempts to "give" the men ear plugs. Obviously we now see that it is impossible to enforce a rule stating that everyone crossing a certain yellow line must wear ear plugs.

Another attempt was made insisting that every worker crossing an anteroom on the way to a noisy area should take his ear plugs from a shelf in this room and put them on before he left the far door with certain penalties if he was found without them while working in the noisy area. Neither of these plans worked.

Here is what we do now. We consider that ear plugs are our first line of defense for the individual employee's hearing and his fitting should be treated with much personal attention. The men have been told about ear plugs subtley and posters are usually on display either on the bulletin board or in the nurse's office. Certain key personnel including the nurse and some supervisors have been familiarized with the protection obtained by wearing properly fitted ear plugs and the man's name is given to one of these people for further indoctrination. Then the man is shown a display of ear plugs usually by the nurse.

DISPLAY OF EAR PLUGS

Psychologically it seems best that the employee should have an opportunity to help choose his own ear plugs at least up to the point of fitting them.

The first step, inserting the plug is much easier if the external auditory canal is straightened by grasping the external ear and drawing it upwards and backwards. Wash the ear plugs when washing up.

It would be well for each one of you contemplating such a program to try several types of ear plugs. Wear them while talking or chewing gum and while in a noisy place.

A well fitted ear plug is uncomfortably snug for a time and conversely if too loose annoying little leaks develop around the periphery so that the vacuum will "make and break" on chewing or yawning. The important point is how well voices can be heard in a noisy place while wearing ear plugs.

The fitting of ear plugs is the most important phase of our program as far as the individual employee is concerned. While waiting for the engineers to quiet a pump or gear box we can fit an employee suffering with ringing of the ears, or a post noise exposure deafness, with a pair of ear plugs which in most cases will relieve his symptoms and make him more comfortable at his job.

ELEMENTS OF SUCCESS

A few unusual elements contributing to the success of the program deserve mention.

▶ Green Bay has the oldest school for the deaf in Wisconsin and one of the oldest hearing conservation programs in the public schools. In counties around us programs similar to ours have been instituted—thus by the time a student graduates from high school in our area he has had three or four audiometric tests. This means that nearly every worker examined knows a little about these tests and does not "view with suspicion" its use as a part of the pre-employment examination.

▶ For nearly 15 years the Children's division of the State of Wisconsin has held hearing clinics in many counties annually where every child with a hearing defect is examined by an otologist chosen by the county medical society from a panel endorsed by the State Medical Society.

This work is done by the panel members on a voluntary basis and it has been considered a privilege to hold these clinics. Thus because of the careful screening given all participants a group of otologists have been trained who know something of the occurrence of disabling ear conditions among our school population and who are accustomed to think in terms of conservation of hearing.

It should then be evident that a labor pool plus the availability of a relatively unselfish and conservation-minded band of otologists has had much to do with the smooth running of our program in northeastern Wisconsin.

▶ Recently a group of Milwaukee industrial physicians supplemented in part by workers from the sub-committee on noise of the American Academy of Opthalmology and Oto-Laryngology, through their research and studies both in plants and at the Wisconsin State Fair have been a considerable source of inspiration and practical help.

▶ The exchange of information and techniques between the paper mills on the medical and safety levels regarding the establishing of hearing conservation programs has been free and complete. Almost the only limiting feature has been inade-

quate medical budgets which do not fit the expanding needs of these programs.

It was suggested that it would be of interest to your group to follow along with us as certain problems came up in the administration of one program. A report from a personnel director follows.

It is titled *A Trip Report to Green Bay Plant on Thursday, July 25, 1957.*

At the request of HN, a local engineer went to Green Bay on the above date and met with HN, RN, Green Bay Plant nurse, M.D., otologist from Green Bay, and Dr. RM, audiologist from Wausau. They discussed a problem which has arisen in Green Bay involving five employees whose follow up audiometric hearing measurements showed losses. These people are working in noisy areas in the converting department.

NO PRECEDENT ESTABLISHED

Since this is the first of such problems which have come to my attention in the company, there was no precedent for any type of follow up when subsequent hearing measurements show less hearing ability than earlier measurements. No Workmen's Compensation claims have been filed or requested by the employees to date.

M.D. recommended that it would be highly advisable to determine whether or not the hearing loss resulted from or followed some condition which might not be occupational. The first step would be a thorough otological examination which might not be the result of exposure to noise.

Dr. RM was of the same opinion. He felt that the first step would be to find out just what the condition was in each of these employee's cases. We might find different things and certainly the record of a complete examination with the doctor's opinion could be of value should a claim be initiated at some later date.

We discussed all of the angles thoroughly and agreed upon the following procedure to apply as of now in these five cases only, with no precedent being created.

These five people were to be sent for an otological examination and he would report to the Green Bay plant nurse on his findings and his opinion as to the man's condition and the causes thereof.

We all felt there was no point in making further plans until we know the results of these five examinations. When we have these we can discuss again any future steps or any plans to handle like situations.

OTHER CASE REPORTS

The Report: MG. This man was 22 years old, single and had three years of military service as a paratrooper. His mother was quite hard of hearing and it was felt that the boy was duplicating her hearing loss. He left his job and did not return so no further follow up was made.

The second 22 year old man DA—had a rather marked high tone hearing loss. He is in the Army Reserve and is going on active duty again in October. He says that his ears are so sensitive that they will ring after "even shooting a 22" and particularly after shooting on the rifle range. He stated that his ears were still ringing after being off work four days. He undoubtedly had rather sensitive ears but he had lost most of what he was going to lose and the remainder of his hearing could be protected with ear plugs.

The next patient is AL, whose audiogram showed a mixed type of deafness which fits with his history of repeated attacks of ear trouble with running ears as a child. There was some scarring of both ear drums and neither moved freely. This would indicate old pathology and might possibly mean that he is now possessed of a sort of "built in" pair of ear plugs; at least, sound is not transmitted very readily through his middle ears.

Patient DK age 24—has a rather marked hearing loss in his right ear for high tones. The only pertinent point in his history is that he has an aunt who is quite deaf and that he hasn't been able to hear a watch tick with his right ear for a long time. It was not felt that this should be treated in any other way but by the use of ear plugs.

Patient KC—has a moderate high tone hearing loss. His history dates back several years when he was in military service and operated a caterpillar and grader. At one time after flying from Japan to Korea in a flying box car his ears rang for sometime and he was unable to hear for three days. He stated that he had worked in the napkin department on a machine whose metal gears just "clanged in his ears." On his return for further study, he reported that he was now on a quieter machine which was run by felt gears and there was no more ringing in his ears.

NO SPEECH LOSS

In analyzing these five cases, not one had any significant loss in the speech range. They all had, it is true, a high tone loss. None of these cases can rightly be attributed to the environmental conditions of the mill and such a report was returned to the personnel director. End of report.

All plant physicians and consulting otologists were agreed that the studies of hearing in the plants had resulted in no new problems. No claims have been filed as a result of this program nor has any particular unrest developed among the men in noisy areas.

The reaction of top management to the conservation of hearing programs has been varied but on the whole has been extremely favorable. One plant manager thought it was the most important of the fringe benefits that labor has obtained saying that "it would help the employees at home—even a pickle packer likes to enjoy music or hear his wife's high pitched voice." A paper mill executive stated that it was working out as a good method of improving mill—employee relations.

FAVORED EXAMINATIONS

Some of the examinees questioned said they never had as thorough an examination before and a few of them even offered to pay for it themselves.

One plant engineer said that through his knowledge of the program he had been (1) stimulated to put silencers on some of his vacuum pumps. (2) He had moved an operator away from a chipper to a less noisy area and he went on to say that purchases of all new machines were made with the noise that they would make in mind. He felt that there was a good program in his plant but he said that the plant itself was not doing enough active research in noise control.

Another engineer said that he had his eyes or rather his ears opened to the problem when a draft curtain was installed around a corrugater to help retain heat. Several other machine operators around this installation, mainly girls, seemed to improve in the efficiency of their operations after the installation of this draft curtain. He went on to say that the mill had given these people ear plugs when the draft curtain was later removed with a 10 per cent improvement in the efficiency of the operation.

Without much question, the plant nurses have been the most interested in the programs. Examples follow:

Memogram written by a nurse—August 9, 1957:

"M.D. is going to speak at one of the general sessions at the National Safety Congress in October. He talked with Mr. W. about gathering some data as to what improvements have been made since we had a noise level survey. Mr. W. said we should give him all the information we could (no companies will be named). He would like some information concerning the converting department and said he could study it over and then be able to ask some "intelligent" questions when he meets with B in converting."

Inter-office Correspondence—August 20, 1957:

"Insulation of equipment for noise is a continuing effort on our part. We do not have a decibel recording unit to indicate the severity of our machine noise, so it is impossible to give figures in noise reduction.

New equipment is installed on insulation pads to isolate the machine from the building. If objectionable air-borne noises are evident, a spun glass type of material is used.

SPUN GLASS REDUCES NOISE

We could write a case history of air-borne noise on what we did on the band knife log cutter. After installation of spun glass material the noise was reduced to the point where it was no longer necessary to use ear plugs. However, we did not stop there, because at a later date we discovered mechanical features in the machine that were at fault which were corrected and further reduced the hazard.

A case history in building-transmitted noise can be illustrated by what was done to the box facial cutting machine. Air-loc

vibration dampening pads, No. 4-17-4, were used to eliminate severe thumping noise that was being transmitted to offices on a lower floor."

This paper has proposed methods of conserving the hearing of individuals exposed to noise levels which may under certain circumstances cause permanent deafness.

The methods outlined are shown to be applicable to plants of various employee populations and containing noise exposure areas of varying sizes and intensity. Summaries are included of the experiences from the standpoint of safety personnel, management, the medical departments and the employees involved.

OFF-THE-JOB — THE BIG TWO-THIRDS

FIRST AID TRAINING — A PERSONAL SAFETY PROGRAM

by EARL H. BREON

director, First Aid Service, American Red Cross, Washington, D. C.

We frequently hear five misstatements, about first aid training, which show that the individual has had little or no personal experience with the program or else his contacts have been bad.

Safety by itself has no content. It is a philosophy, a way of life, a hope. Only when safety is attached to something does content appear. When safety is related to operating a lathe, a drilling rig, a steam shovel, or an automobile it becomes real. It can be seen and even felt. The consumer becomes a part of the operation, thus a degree of success is assured.

Safety or accident prevention follows a clear pattern of CAUSE—EFFECT—PREVENTION. First aid training follows the same pattern but adds the important missing fourth item—CARE. As long as humans perform tasks, accidents will occur. Any safety program which omits the fourth may be hard to explain or defend.

We all recognize the outstanding job safety engineering has done in industry. The record speaks for itself and management supports and encourages the efforts. However, the off-the-job accident record does not reflect this same high degree of efficiency.

In your plant you have certain advantages and certain controls. You have safety directions that even include *who* shall do the job. You can enforce your directives. You can build safety into the operation. The worker can be outfitted with clothing, goggles, masks and other paraphernalia. In fact, you can isolate the man and his work in an accident proof ward for the six or eight hour period he does his assigned tasks. What happens when he leaves his isolated booth?

The protective devices are no longer there. The restrictions on him that made him safe for this period are often resented because they are misunderstood, or the man's cooperation deemed unimportant. We often overlook the ability of the worker to contribute to safety and think safety. This is usually the key. When a worker becomes a partner in safety he feels a sense of ownership and a sense of responsibility. Safety takes on real meaning when the worker contributes.

The battery of first aid skills taught, and above all practiced by the individual, personalizes safety. When the worker translates "falls" in terms of fractures and physical pain, and uses hypothetical problems to practice immobilizing fractures on fellow workers and friends, the association becomes a lasting one. It becomes a sharing experience. It becomes a contribution *to* safety, not passive acceptance *of* safety.

Equally important is the atmosphere of learning, and first aid training lends itself admirably to this atmosphere. In addition the knowledge and skills acquired are "portable," the application universal, and the benefits tangible. Improved judgment in evaluating potential hazards are a natural by-product of first aid training. The remedial solution applied to accidents is of immediate use. Educators say attitudes must be built before behavior patterns will improve.

WHY BOTHER WITH FIRST AID?

First aid training builds better safety attitudes. Eventually improved safety behavior will follow. There are no "short cuts." This takes time. First aid is more than applying a splint or wrapping a bandage. *It is an integral part of safety.* It is not a special subject or activity for the few.

Severe hemorrhage, stoppage of breathing, oral poisoning, and chemical burns, espe-

cially those about the face, can't wait for medical assistance from a remote part of the plant. If the stricken person is to be helped, that help must be on the spot. The best piece of emergency equipment, 500 or 1,000 feet from the accident, is just as useful as an empty fire extinguisher at a conflagaration. Dire emergencies are not the only conditions we must face.

When someone is injured, either seriously or slightly, there seems to be a compelling need for those about him to move him "someplace"—it doesn't matter where—just as long as action is taken. There often isn't a reason for it. Untrained people just feel that action must be taken and they take it. Secondly, the injured person feels a compulsion. He *must get away* from the offending object and unless he is unconscious, he will exert every effort to do so.

Training all personnel, not just "key" personnel, provides an excellent accident prevention program AFTER THE ACCIDENT OCCURS. It teaches each employee to act promptly and efficiently when seconds count, react favorably when people insist on moving the injured for no good purpose, and protect injured workers from their own frightened actions. This training complements and supplements medical and health facilities; it does not replace them. Knowledge of simple first aid principles can save lives, prevent minor injuries from becoming major ones, and major ones from becoming fatalities. There is no substitute for "on-the-spot" remedial and preventive action by fellow workers.

Some people feel training is time consuming and costly. If you agree that first aid training is part of your safety program however, the time and cost factors disappear. But if you isolate first aid training, time and costs are terrific.

Spot training never has been successful. Increased incidences in other accident areas bring repeat performances of such spot training. If at the outset the needed skills are introduced as part of your on-going safety program, the temporary "one shot" costly training programs disappear. The entire safety program is better understood and appreciated, and the worker takes more interest in safety generally. Further benefits accrue when, in addition to life saving skills, common emergencies are discussed, recognition of skeletal injuries taught and the principles of transportation of the injured are practiced. Good industrial safety programs embrace all aspects of accident prevention. Knowledge of what to do when a serious injury interrupts normal operation is both time and money saving.

DO FIRST AID COURSES MEET NEEDS?

The "courses" are those prepared and recommended by the Red Cross. In some instances these courses are used instead of preparing a duplicate "plant" program for more specific needs. There are minor areas where specific recommendations from the medical department represent departures in standard program planning. But these are minor and do not concern hemorrhage, oxygen embarrassment, or external and internal poisoning. Basic care for these injuries follow the same principles. Geographic locations do not alter them.

If there is a difference, it lies in the quantity, type, and quality of materials on hand. Abundant first aid supplies readily available should produce better results than crude improvisions. If we deal with the principles and objectives, our problems in all areas are less. In first aid these principles are simple and well understood. Only when we make them complex do difficulties arise. First aid is pliable, adaptable. Red Cross courses or any other course in first aid can be tailored to fit any special need.

Any course can easily be a "part" of your program. It should not be so forceful that the application of "plant" training is not readily recognized in home and community accident situations.

ARE RED CROSS COURSES TOO SPECIFIC?

There is no first aid teacher who withholds information that may save lives. In his enthusiasm for the subject he may give you heated arguments about teaching only selected portions, but only because he is convinced that to do less is a disservice. Often the requesting group wants employees to receive the Red Cross first aid certificate, but feels when the company's requirements are satisfied, the certificate should be awarded. This is known as "putting the heat on" and causes "back stiffening."

Red Cross chapters are ready and willing to assist with your problems and give help. But when the work is identified by a completed course certificate, it must be done according to our standards. The quality and integrity of the program was built on high standards accepted nationally. To sell dollar bills for ten cents in one state and a dollar and a half in another would most certainly make a mess of things. To follow the same practice with our programs would create a similar situation. Thus when certification is involved, the course must be completed.

Finally our real job is training leadership for you so that your program can be "self-contained." If you will train key people in your plant (preferably foreman) to interpret and teach first aid at safety meetings or other opportune times, you will have added an important and effective step in both your on-the-job and off-the-job safety programs.

A new textbook accompanied by modern teaching outlines has just been published. Short first aid subject films are available to assist you. The American Red Cross first aid program started in industry. We think we can serve you better in 1957 than we did in 1907.

To summarize briefly—

- First Aid training *is* a part of safety and is preventive.
- Prompt remedial first aid given by those at the accident scene may save lives and most assuredly will help prevent aggravation of injuries.
- When first aid training becomes a part of on-going safety programs, cost and time factors disappear.
- First Aid training is pliable—adaptable. It can meet specific or general needs.
- First Aid training is "portable." It inspires appreciation for safety—sharpens the desire for safety. It's good on-the-job and off-the-job insurance. Those trained in first aid have a better appreciation for the total safety program.

VISION IN INDUSTRY

Responsibilities and Limitations of the

INDUSTRIAL NURSE IN THE VISION PROGRAM

by MARGARET S. HARGREAVES, R.N.
industrial health consultant, Forest Hills, N. Y.

Although an industrial eye program is considered just one of the components of a preventive industrial medical service, it is actually one of the most important. Eighty per cent of all human emotions are controlled by the eyes and our emotions, in turn, influence our state of health.

When a nurse has full time medical direction her responsibilities are lessened and her limitations are clearly defined. Many nurses working in industry today, however, have only a part-time or a consultant physician to guide the medical service.

This industrial nurse has responsibilities in five major areas in setting up and maintaining a vision program.

1—She must plan and sell the vision program to management, the employee and supervision.

2—She must assist in establishing company eye medical policies and procedures.

3—She must assist in providing adequate care using ethical medical direction and modern technics.

4—She must help to prevent eye injuries and diseases through proper testing, referral and eye protection for the employee.

5—She must assist in educating the employee in good eye health habits.

Many opportunities for a good vision program in industry have been lost because the program with its subsequent benefits was not planned, explained and presented properly to management. If the industrial nurse takes the trouble to secure informed, intelligent advice, if she does a survey of her industry to point up the eye hazards and the need for special visual skills, if she shows where spoilage can be reduced through improved employee vision, if she personalizes her examples—i.e., shows an instance where labor relations were improved by better eyesight or, through analysis of her monthly medical report refers to specific accident cases that could have been avoided through the use of protective eye equipment, she will gain the interest and support of management.

BAD SIGHT COSTS MONEY

One nurse convinced management it was losing thousands of dollars in customer claims because of an arbitrary company policy which would not allow waitresses to wear glasses. They were proud of the eye appeal their girls had without glasses but ignorant that, because of uncorrected vision, hot soup often landed in the customer's lap instead of on the table. An eye program introduced by this restaurant chain prevented many other accidents when cooks and kitchen workers found to have impaired eyesight were referred for correction.

Another nurse avoided a situation when an argument ensued over who would have window locations after a whole department moved from one floor to another. These employees were all piece workers and their livelihood depended on the amount and quality of work they produced in a given time. A quiet investigation by the nurse showed that the two complaining most bitterly actually needed vision care. When those two workers were fitted with proper glasses they were able and willing to perform their work in any part of the room.

A recent study of 1,107 ocular cases resulting from industrial injuries showed that of 11 cases of glass foreign bodies in the eye, 9 were caused by flying objects hitting *regular* spectacle glass which broke and scattered bits of glass. One nurse showed this study to authorities in her company and convinced management that prescription less

safety glasses were a good investment in their particular plant where flying objects were a distinct hazard.

Still another case can be described where faulty vision nearly caused a faithful employee to lose his job. This man was a truck driver for a beer concern. After 15 years of not having a single accident, he had three in a row, all costly and serious. He confided in the company nurse and told her of his concern and despair over the possibility of being demoted to a lesser paying warehouse job.

She persuaded him to have a complete physical checkup which was available to all company employees on a voluntary basis and he learned he had serious but correctible vision defects. This man has since completed three years without further accidents and his health, happiness and economic security are all improved.

The industrial nurse must be able to explain to management the difference between testing eyes and examining eyes. She should be able to explain the differences between an eye specialist, an optometrist and an optician.

She should upon request (if she does not have a plant physician) direct management to the county medical society or the local accredited hospital for consultation services and emergency eye care with a competent ophthalmologist. More than one eye specialist should be available in case of emergency. An eye panel should be set up and approved procedures outlined and posted.

One of our leading eye specialists told me about a $60,000 civil suit pending as a result of a claim by a railroad employee who had a pentrating injury of the eye. He was forced to lie in the company medical department without proper care for three hours because adequate emergency arrangements were not available for such a case. He alleges that the delay in treatment caused him to lose an eye.

In making an eye health appraisal to submit to management, the National Society for the Prevention of Blindness, the loss prevention department of the company's insurance carrier, the local or state health department, the Council on Industrial Health of the American Medical Association and private industrial health consultation firms will assist.

Lighting, color contrasts, work methods and work stations should be thoroughly studied as well as the more obvious hazards created by poor housekeeping, dangerous tools, processes and other elements which could burn, injure, infect or affect the eye. Aging processes, visual requirements and present seeing capacity should all be evaluated.

Once the vision program is accepted by management the next logical step is to draw up company medical eye policy and procedures by which this policy can be carried out. In establishing a guide for procedures, statements of policy should be carefully worded regarding the fact that threats to the employee's job security are not included in the program. *All procedures should be approved by a consulting ophthalmologist.*

It is not enough to state, for instance, that all persons with penetrating injuries of the eye must be kept lying down and placed under the care of an eye specialist at once. The method of doing this must be described, i.e., if the patient is to be taken to the physician he must have a sterile eye bandage and must go by stretcher and/or ambulance if necessary.

It is not enough to say visual testing will be done as part of the preplacement examination. The method of testing, what persons will test and what will be done with the results must all be spelled out.

It is not enough to say Dr. Jones will be consulted about emergency eye care, examinations and treatments. Dr. Jones should state what drugs will be stocked, how special eye cases will be treated and what follow-up care may be given. In other words —Dr. Jones will be an eye consultant to treat eye emergencies, to give medical direction for eye care and to indicate preferred methods of treatment before sending eye cases out for further care.

In the third area of responsibility most of the limitations exist for the industrial nurse. Several leading industrial ophthalmologists suggested limitations they would like observed.

- They unanimously disapproved of serious delays between the time they saw the patient and the time the injury occurred. They were not referring to the patient who delayed in reporting his

injury but rather to the persons who do not send a serious eye case to an eye specialist immediately after the person reports to the medical department. They urge that specialist attention be given at once to serious cases in order to lessen the number and severity of complications. They agreed that it would be impossible, impractical and unnecessary for them to see *all* industrial eye cases. But they were emphatic in requesting that serious eye cases be placed under the care of an eye specialist as quickly as possible.

- The second unanimous opinion was that the nurse should not be allowed to use ointments in emergency care. An ointment-filled eye often causes a delayed diagnosis and treatment.
- Next they urge that an eye containing an embedded foreign body in the cornea should have a sterile eye patch applied, and the patient should be sent to an eye specialist. Most of the physicians cautioned about the penetrating wound.
- They urged no suture treatment for a lacerated eyelid. When they were told suturing did not come within the scope of a nurse's duties they said some of them use "butterflies." All physicians emphasized the WATER IRRIGATE, WATER IRRIGATE, WATER IRRIGATE treatment for chemical eye burns.
- Some of the less serious but justifiable complaints were alleged rough handling while examining the eye, use of unsterile technic, failure to take an adequate history, giving the patient a prognosis or diagnosis.
- One physician deplored the use of dirty eye charts in testing and poor illumination in the testing area. He warned about a patient pressing his eyeball with his hand while covering it during an examination. He should be instructed to cup his hand or better still, use a piece of cardboard as a shield.
- Another physician deplored the lack of available modern technics such as plastic irrigating bottles and plastic disposable eye droppers. He said many industries still use outmoded eye cups and argyrol solutions.

The physicians critized medical personnel for failing to sell management on the values of eye testing, eye examinations and eye protection. They said many occasions occur when an adequate eye examination alerted the physician to other health impairments such as diabetes, high blood pressure, and brain tumor. The direct relationship of eyesight to general health is not appreciated enough.

The nurse should have a means to test visual acuity. It is important that *both* eyes are tested during the first visit to report an eye injury.

There are many methods by which an industrial nurse can educate employer and employee regarding good eye health. It is said that 90 per cent of all eye injuries are preventable. If so, it should be easy to persuade people to do themselves a favor by protecting their eyes from injury and maintaining good eye health.

One nurse who worked in a plant with numerous eye hazards made a campaign of assisting the employee in getting proper fitting prescription glasses. Her plant management installed a flashing red sign when dry grinders are in motion. She sets a good example by wearing necessary equipment in stated areas when she is making her rounds. Every morning she has an *extra* pair of goggles placed on each machine so there's no excuse like: "I forgot my goggles today."

She has well marked eye flushing machines in areas where chemical splashing could occur and once a year she conducts a safety meeting devoted exclusively to care and protection of the eyes. Perhaps you think this nurse is over-emphasizing a single phase of an overall preventive medical program. However, she reviewed several years of claims cases and found that the most costly and most frequent cause of injury in her particular plant was concerned with the eyes.

Another nurse worked in a printing establishment. There were daily hazards of close work and the additional hazard of an aging plant population with aging processes affecting the eyes. She sold her management, employees and supervisory men on an eye program. Production has increased, absenteeism decreased, and the economic state of the employees and the community has shown a gradual steady improvement.

The employee will be more apt to give his wholehearted cooperation if he's coavinced that preventive eye health measures will directly or indirectly benefit him.

Supervisors should understand and fully cooperate with the aims, objectives and procedures of the program so that they can answer all employees' questions regarding the purpose, scheduling of vision tests, referral system and use of eye protection methods.

In the eye health education area, the nurse must include all the key groups in the industrial family as well as the individual.

The personnel department is thus assisted in properly placing the employee, the safety department will be interested in reducing accidents of all types—not just those of the eye, the production department will learn that the working efficiency of the employee is directly related to his seeing ability at the work station.

Seeing is a universal and powerful factor in the everyday performance, efficiency, comfort, behavior, safety, health and happiness of every individual. We industrial nurses are in a position to help management build and maintain good eye health.

THE EMERGENCY TREATMENT OF CHEMICAL INJURIES TO THE EYE

by DR. RALPH W. RYAN
M. D., M. S. Ophth., Morgantown, W. Va.

This discussion will concern injuries of the eyes and lids caused by direct contact with corrosive, irritating, or otherwise injurious chemicals.

The type of tissue injury varies with the chemical properties of the substance involved and the effect of that chemical on live tissue cells and structures. The mode of injury for various groups of chemicals will be discussed later.

Whatever the chemical factors, the effects on the injured worker may be:

(1) Temporary, partial or industrial blindness: Inflammation or protein denaturation may make the clear cornea or window of the eye opaque or translucent, or the inflammation may cause so much swelling of the lids as to close the eyes,

(2) Permanent disability, ranging from partial to total, may come from scarring or distortion of the cornea or lids. Scarred tissue may contract or one healing surface may adhere to another.

Damage to the clear cornea of the eye is the most serious. Mild injuries may cause only temporary clouding of the cornea, but when the transparent window of the eye becomes translucent or opaque from scar tissue formation, useful vision may be seriously reduced or destroyed. The cornea may become white with many blood vessels through it. Sometimes the injury is severe enough to cause perforation of the cornea with loss of the contents of the eye. Repair of damaged cornea by corneal transplant is difficult and expensive.

Damage to the lids may be mild, the inflammation causing them to swell shut for a time. Permanent scarring and contracture may expose the cornea to drying, impairing vision. However, lids can more easily be restored surgically than can the cornea.

SEVERITY OF EYE INJURIES

Injury to the eye from chemicals varies widely in severity. The three primary factors determining severity are:

—*Properties of the chemical*
—Concentration of the chemical
—Length of exposure to the chemical

There are hundreds of chemicals which might injure the eye by contact. A large number of these have been studied and many are listed in a manual entitled "Toxic Eye Hazards," available from the National Society for the Prevention of Blindness, Inc.

Consideration of these many substances will be simplified by classification into groups by their chemical properties and hence by their mode of action on tissue cells.

A practical classification divides them into:

(a) Alkalis
(b) Acids
(c) Organic solvents
(d) Detergents
(e) Irritants and allergens
(f) Pharmacologically active chemicals
(g) Radioactive chemicals

Members of these groups exist in solid, liquid, or gaseous form, or can be finely divided into dusts, fumes, or mists in the air. The eye can be injured by any form of certain chemicals. Gases, solids, or mists, when in contact with the moist surface of the eye, may quickly form a liquid solution.

Classification is complicated by overlapping of the groups. As an example, dimethyl sulfate may injure the surface of the eye by its organic solvent action, but its most damaging effect comes from release of sulfuric acid as it hydrolyzes on the moist eye surface. Detergents and soaps may affect the eye by changes in surface tension, but they also have acid or alkaline effects on the eye.

DAMAGE FROM ALKALIS

Alkalis are in general the most injurious of all chemical substances to the eye. This is because of:

(1) Rapid penetration and denaturation of the tissue and particularly the cornea.
(2) Fixation of the alkali to tissue protein so that the burn continues to progress insidiously for hours.

Alkalis cause swelling and break down the skin surface of the eyeball and lids, the tissue becoming soft and jellylike. The alkali then penetrates rapidly through the tissue. Some alkalis have been detected in the aqueous humor of rabbit eyes within a few minutes after being placed on the cornea. The combination of the alkali with tissue substance makes it impossible to remove it completely even with long periods of bathing the tissue in water.

For that reason, alkali burns of the eye tend to become worse, particularly if the alkali was very strong, if it remained in contact with the eye for more than a minute or so, or if it was not irrigated for several minutes with water. The alkali seems to be released slowly from its combination with the cells and can affect other cells.

Fresh cement or plaster are common forms of alkalis which often cause severe eye injuries when not treated properly. Often the discomfort is minimal for hours, but scarring may result later from a deep burn of the cornea or lids.

Common alkalis are:

(a) Lye (sodium hydroxide)
(b) Lime
(c) Ammonia
(d) Fresh cement or plaster

DAMAGE FROM ACIDS

Acids tend quickly to coagulate or denature the protein of the skin covering the eye. This denatured protein does not immediately soften and break down; it thus acts as a barrier to slow further penetration of the acid. Since the acid is not significantly fixed in the tissue, it may be washed out completely enough to prevent continuation of the burn.

Damage from acid burns varies with the strength and type of acid. All cases are likely to show an inflammatory response. If not washed out of the eye promptly, the injury may be severe with much scarring. The effects of acid burns can be determined soon after the injury, if the eye has been well irrigated to rid it of acid.

Examples of common industrial acids are:

(a) Hydrochloric
(b) Acetic
(c) Sulfurous
(d) Nitric

DAMAGE FROM ORGANIC SOLVENTS

Organic solvents may penetrate the skin covering of the eye because it has about 100 times as much fatty material as deeper tissues. Penetration of the deeper tissues by such chemicals is slow. Since the injury is usually painful, it receives attention. Skin of the cornea and conjunctiva grows back quickly with little damage. Eye damages from this group of chemicals are not often severe unless the chemical has other deleterious effects besides its solvent action.

Common solvents are:

(a) Alcohols
(b) Gasoline
(c) Carbon-tetrachloride
(d) Ethers

Damage from Detergents

Detergents and soaps have come into widespread use and are present widely in industrial processes. There is frequent eye exposure to such substances, due to the tendency to consider them harmless.

They not only may penetrate the skin covering of the eye, due to their detergent action, but some have considerable alkaline or acid reaction in solution. Irritation is often marked, but serious damage is not common. There may be temporary incapacitation due to inflammatory reaction.

Common detergents in use are:

(a) Washing powders
(b) Soaps
(c) Zephiran
(d) Sulfonated oils

Damage from Irritants and Allergens

Irritants and allergens act in various ways to cause inflammatory changes in the skin and underlying tissues of the eyes and lids. Congestion, itching, and swelling may be caused, leading to lost time in industry. Long continued irritation of the eyes may lead to changes such as pterygium (a growth on the edge of the cornea) or spastic entropion (a turning inward of the edges of the lower lids). These conditions require surgery for correction.

Some of these substances encountered in industry are:

(a) Acrolein
(b) Formaldehyde
(c) Tobacco dust
(d) Wool dust

Damage from Pharmacologically Active Chemicals

The cornea of the eye readily absorbs significant amounts of many chemicals, the material passing through the cornea to the aqueous in a matter of minutes. These chemicals may commonly cause such changes as dilating or constricting the pupil and increasing or paralyzing the accommodative ability of the eye. Some of the more common chemicals of this type are:

Atropine
Scopolamine
Homatropine
Belladonna
Pilocarpine
Eserin
Phosphate ester insecticides
Di-isopropyl-fluorophosphate (DFP)

Damage from Radioactive Chemicals

This category, while relatively new, is likely to assume more importance yearly. Handling of radioactive materials has been extremely cautious, but as the use of isotopes becomes more commonplace, our carelessness is likely to increase. Chemicals which also have other injurious properties or are irritating are likely to be noticed and the injuries treated.

Non-irritating chemicals which are absorbed by skin of the eyes or which come in contact with the eye frequently would be expected to cause insidious damage. We have little actual experience to evaluate the extent of this hazard. The mining and processing of radioactive ores may lead to long exposure of the eyes to radioactive dusts and mists.

Damage from radioactive substances will vary with the type and amount of radiation emitted and the length of exposure. The effect is cumulative. Damage to the eyes would involve primarily the lens, retina, and optic nerve. Radiation cataract from lens damage is well known. Loss of lashes and brows might occur from radiation exposure.

Some radioactive substances that may be encountered industrially are:

(1) Dust from uranium ore
(2) Mists from uranium ore concentrates
(3) Radioactive luminous paints
(4) Pharmaceutical radioactive isotopes

TREATMENT AT WORK

First treatment of the employee suspected of having a harmful chemical in the eye must necessarily be at or near his place of work. Severity of the injury can be lessened by minimizing the length of exposure to the chemical. The loss of extra seconds before the chemical is being washed out with water may mean loss of useful vision in the eye.

Water is the universal solvent and is the most universally available irrigating material. Therefore, employees exposed to harmful chemicals should be trained in recognir-

ing the quickest means of washing an injured eye. Whatever the source of wash fluid, employees must know in advance the difficulty of opening an eye burned by chemicals.

Rather than merely flushing water on the eyelids, often a piece of paper towel or a pocket handkerchief will enable the fingers to pull the lids apart so that the water reaches its objective. If available, a few drops of such topical anesthetics as 0.5 per cent ophthaine or pontocaine remove lid spasm and greatly improve the effectiveness and ease of irrigation.

Almost any means of applying water may be used in an emergency. The commercial eye irrigating units, safety showers, jet drinking fountains, and shallow basins are best, however. Irrigating hose connections can be improvised along small cold water lines near working places if provision is made for controlling pressure of the stream of water.

In locations where hazards are great, a bottle of sterile water with siphon rubber hose connection may be arranged above a bench or low table where the injured worker may be laid on his back for eye irrigations. Pouring water in with a clean glass is better than use of eye cup. The principal objective is to keep clean water passing over all the exposed eye surfaces to remove the chemical as rapidly and completely as possible.

Effective irrigation should be carried out for at least 10 minutes, without stopping to move the employee to another location. While cleansing the eye, all available information should be obtained as to the exact nature of the chemical involved and all other pertinent details of the injury.

TREATMENT IN FIRST AID FACILITY

The person administering first aid may instill two or three drops of a topical anesthetic such as 0.5 per cent ophthaine or pontocaine in the injured eye. Irrigation can then be continued for 10 minutes under more favorable circumstances, while a history of the accident is pieced together. The eye should be carefully examined under magnification and any solid particles of chemical carefully removed. Fluorescein is then applied by one of the satisfactory techniques. If green staining results or if the chemical is suspected of being an alkali, another 10 minutes of eye irrigation should be carried out.

Disposition of the patient from this point will depend on whether the history and appearance of the injury warrant immediate referral to a physician. Any case showing fluorescein staining should be seen by a physician. The first aid nurse may instill topical anesthetic drops and place a tight eye pad over the closed eye. If not sent to the physician, it should be explained to the employee that pain-relieving drops were used. He should be required to return within 24 hours for removal of the eye pad.

TO RELIEVE PAIN

If "standing orders" call for further treatment in the first aid room, a combination of a pain-relieving ophthalmic ointment such as phenacaine or pontocaine and a bacteriocidal or bacteriostatic ointment containing sulfa or suitable antibiotic drugs may be applied before the eye pad. Penicillin ointment is not desirable because of frequency of allergic response.

Corticosteroid drugs such as cortisone or prednisone should not be used unless ordered by a physician. This is because of the danger of aggravating undiagnosed herpes simplex (fever blister) virus infections of the cornea. These sometimes may be increased greatly in severity even to loss of the eye by corticosteroids.

Handling all severe chemical burns of the eye should be left to a physician after the first aid treatment.

The use of buffered irrigating solutions has been considered for years. The purpose of the buffer is to neutralize any alkali or acid in the eye and restore normal pH. The idea is logical, but all attempts at such treatment have shown it to be impractical. The newest neutralizing buffers advertized commercially for industrial use share the disadvantages of the old.

First, all such solutions are designed for alkalis and acids, whereas it is often impossible to know quickly what chemical may be in the eye. Chemicals may have many injurious properties besides being acid or alkaline.

In the second place, buffered solutions cannot be made as universally available as water to the person who suddenly finds his eyelids clamped tightly shut after a splash of strongly irritating chemical.

THE PRESCRIPTION SAFETY GOGGLE PROBLEM

by DR. E. J. SCHOWALTER
medical director, Western Electric co., Chicago

The objective of a prescription safety goggle program is to facilitate wearing well-fitting, optically precise safety goggle lenses and frames selected for on-the-job needs of all industrial workers exposed to eye hazards.

To accomplish this objective to the complete satisfaction of employees, management, and the optical profession is the purpose of the prescription safety goggle problem. The various aspects of this problem differ within an individual plant, between plants and in various parts of the country.

Eye accident data, and job analyses by safety experts furnish the information to determine which workers are exposed to eye hazards.

Prescription safety goggle frames must have the same advantages as Plano safety goggles. They should be strong enough to withstand trauma and especially selected to protect the worker against the specific hazards of his job.

They must be rigid to achieve and maintain correct positioning of the lenses. Therefore, frames for round lenses, with flexible bridges and temples which can't be adjusted are not satisfactory for prescription safety goggles.

Management should select prescription goggle frames in accordance with the above principles not because of cosmetic reasons. However, safety frames need not be cosmetically unattractive. After all the requirements have been met, selecting cosmetically acceptable frames will promote wearing prescription safety goggles.

Prescription safety goggle lenses must meet the same standards for safety as Plano safety lenses.

The American Standards Association issued specifications for lenses in order for them to be "safety" lenses. Those lenses which meet these specifications must be marked with the manufacturer's trademark, so each safety processed lens can be identified.

It is good practice to test safety lenses on a "spot check" to insure they meet the American Standards Association standards for safety.

Workers needing safety goggles whose unaided vision does not meet a predetermined standard need prescription goggles. Our standard is as follows:

Snellen Equivalents			*Jaeger (12-14")*	
Far:	Both	20/25	*Near:*	Both .50
	Right	20/30		Right .75
	Left	20/30		Left .75

In addition workers needing safety goggles who have eyestrain complaints with Planos should have prescription lenses. If an employee complains of eyestrain when wearing Planos, check the Plano lenses to be sure they meet the American Standards Association Standards for Plano lenses.

If a worker needs safety goggles and his job entails special visual demands he needs the help of prescription lenses. The following information must be supplied to the refractionist:

1. The actual distance (measured) from the eyes to the visual surface of the job.

2. If more than one seeing distance is required, each should be measured and recorded.

3. Any job requiring out-of-the-ordinary visual positions should be carefully described, and if necessary, the refractionist should be requested to observe personally the job. In addition to prescribing single vision lenses and regular bifocals, it is sometimes advisable to prescribe inverted bifocals, or trifocals with one segment above and one below, or other combinations. If workers do not provide all visual requirements for the job their safety goggles should be refracted.

Deciding who should do the refracting is a problem. The overlapping interests of optometrists, ophthalmologists and opticians could hinder public relations unless company policy is carefully conceived and admin-

istered. Refractions for prescription safety goggles should be done by either:

A. An ophthalmologist interested in refractions (Most, but not all of them, are.)

B. An optometrist who is well trained in refraction techniques and has adequate training in recognizing the presence of eye disease.

An optometrist must work in collaboration with an ophthalmologist or a medical director, referring all cases of eye pathology to him.

The employee can be sent to his own refractionist especially if the employee pays for his own refraction. This results in the best possible public relations between management and the optical professions.

However, the employee can be refracted by a company employed refractionist. In my opinion this facilitates the best possible control over the prescription safety goggle program and is the most convenient program to administer. The "vision for the job" concept is easier to obtain, and results in fewer unsatisfactory prescriptions, and hence fewer lens replacements. Thirdly, the employee can be referred to a *panel* of refractionists.

Safety lenses should be fabricated from ophthalmic quality glass or plastic with the same optically desirable qualities as top grade prescription ophthalmic lenses. In addition, safety lenses will be thicker and must be heat treated.

OBTAIN OPTICALLY PRECISE LENSES

An optical supply house should be selected which can consistently turn out a quality product matching the refractionist's prescription.

False economy should not be attempted. There are many technical problems in fabricating top quality prescription safety lenses and only the best lenses will prove satisfactory.

A necessary step to insure optically precise lenses is routine inspection of lenses by the dispenser or refractionist.

To assure well fitting prescription safety goggles, there must be a correlation between frame and face measurements. Either the refractionist or dispensing optician must incorporate into the order the P.D., lens size, bridge size, and temple length.

When dispensing the goggles, he must give strict attention to the alignment of optical centers, distance of lenses from eye and fit and comfort of bridge, nose pads, and temples.

The final step is to send the employee to the refractionist for a final checkup, to assure all necessary requirements have been met. *This is desirable for public relations as well as for technical reasons.*

An employee could have the best goggle in prescription and safety, and it would be useless unless he wore it all times when exposed to eye hazards. The very provision of a quality product does much to insure the wearing.

The more acceptable goggles are cosmetically attractive. After all safety and refraction requirements have been met, the acceptance rate or "wearing" rate is higher with good looking frames. Goggle wearing must be enforced.

WHO PAYS FOR REFRACTION AND GOGGLES?

There are three possibilities — management, the employee, or the cost can be divided between them.

A. There are advantages if management assumes the entire cost.

1. There can be no resistance towards the program by the employee because of personal expense, either at the time the original goggles are supplied or when replacement becomes necessary because of job transfer, or a change in prescription needs.

2. Management can chose the method or plan for refraction, i.e.—own refractionist, outside refractionists, or panel.

3. This practice assures the quality of the goggles and the "eyes for the job" concept can be maintained.

4. Management can insist that goggles remain at the work location if this seems desirable.

B. There are advantages of the employee assuming the entire costs.

1. Best possible public relations between *management and the optical profession* because employee will choose own refractionist.

2. Some companies claim employees take better care of own personal property.

C. If the cost is divided between management and the employee, there will be a compromise between the advantages listed in "A" and "B" above.

If the goggles are paid for by employee, he should be allowed to use them outside the plant if he wishes. If paid for by management, management can control their use.

A. Advantages of keeping the goggles in the plant:

1. Many prescriptions are only satisfactory for the job and are not proper prescriptions for use away from the job.

2. Prescription goggles will always be at work—not left in the other suit, on the dresser, or lost.

3. There can be no adverse public relations reactions from optical professions who might believe they lost business because the company provided the worker with goggles he can use as personal glasses.

B. Advantages of allowing employees to wear goggles away from the plant:

1. Many eyes have been saved because men wore safety prescription goggles away from the plant.

2. If this practice is allowed, the employee must be given a note with his goggles which states his prescription is proper for vision at work, and not necessarily correct for use away from his job. He should consult his own refractionist before using goggles away from the job.

When employee leaves the company there is no advantage for management to keep the goggles, other than the slight value of reclaimed frames. Lenses cannot be used by others. We allow employees to keep prescription safety goggles when they leave, and hope we may occasionally save an eye.

Our plant began a prescription safety goggles program in 1925. There were approximately the same number of exposure hours then as now. Our plant had 522 disabling eye injuries in 1924. We have had no disabling eye injury since November 1954. The last eye lost due to an accident in our plant occurred in March 1952.

Certainly many eye accidents have been prevented as a result of improved job safety engineering. But as many have been prevented by our prescription safety goggle program.

VISUAL AID TRAINING

FLANNEL BOARD DEMONSTRATION

by D. D. MATEER
supervisor, safety & welfare dept., Jones and Laughlin Steel corp., Pittsburgh, Pa.

A few years ago, our general office safety department issued a revised edition of safety rules for electric overhead traveling crane operators, crane directors, hook-up men and repairmen (cab operated). We at the Pittsburgh Works division felt that a special course should be devised to explain step by step how to apply the various rules as they pertain to the operations and minor and major repairs.

As we pieced the course together, it became apparent that we needed unique visual aid materials to give our presentation a boost. It was decided that beside a blackboard and a flip chart for presentation of the material, we would construct a model crane and crane runway and assemble it piece by piece in front of the students.

LIKE JIG-SAW PUZZLE

Realizing that several sets of material would be needed because we had 5,000 people to train, the flannel board presentation was developed. We painted a crane scene with crane, crane runways and operating personnel on cardboard and then put them in sections to represent the various parts of the crane, crane runways and positions of personnel.

As we discussed the rules, we could make the full assembly similar to putting together a jig-saw puzzle. Of course, the main advantage of this flannel board presentation is that it enables us to put together a crane in front of all the group. We construct everything from the building columns to the crane indicator lights.

Naturally, the parts of the crane—hoist, indicator lights, etc., are made more familiar to the students, especially new employees. Besides this, we feel our flannel board visual aid is economical. The crane visuals were made by our sign shop at Pittsburgh Works for a moderate cost of $25 a set. The flannel boards may be home-made or purchased from a supplier for about $50.

Perhaps the main limitation of the flannel board is that it loses its effectiveness as the size of the group increases. As a group gets larger, students will be farther back and it is impractical to enlarge the pieces and the flannel board because they become cumbersome to handle. We suggest the group not be greater than 25 in number.

FLIP CHARTS

by T. F. WICKORD
safety supervisor, Commonwealth Edison co., Chicago

The printed word or picture tells the the story. Many pieces of hand-out material used at safety meetings or for safety instruction might be made more beneficial if the important points are emphasized. The safety story needs to be emphasized, and flip charts can give it that novel, yet positive, emphasis. Flip charts are eye catching and they simulate the thought provoking processes. There are various types and designs of flip charts.

The Safetygraph is a package job developed and sold by the National Safety Council. It has very fine acceptance because it tells a story, adds color, humor and stimulates thinking.

The cost of the safetygraph is about $9.50 per copy and about $4.00 for the easel. Volume printing permits this very liberal price schedule. About 30 different subjects are covered by safetygraphs.

The secret of the safetygraph is the audience participation that develops as the story unfolds. The audience sees the large, well drawn, colored picture while the one conducting the program stands behind the safetygraph looking at a similar, but smaller picture with prompting questions and a discussion outline printed with the picture. With just a little practice an interesting session will reward the discussion leader. The safetygraph is a simple but effective visual aid. It is easily transportable and the story is as good a year from now as it is today.

Safetygraphs are excellent for small groups of people gathered around it. This would be one of its major limitations.

SPECIFIC FLIP CHARTS

One type was used in conjunction with "Instructors Handbooks" to train 200 instructors and then used to carry to 16,000 employees, in various areas, the story of the new "Back Pressure Arm-Lift Method of Resuscitation" which our company adopted as the standard method.

It was a silk screen job with 18 charts bound and placed in an easel. This necessitated a different type of easel than the safetygraph because of the size of copy desired. We used about 150 copies at about $15 a copy. The chart is still being used for refresher courses to new employee groups.

SPECIAL CHARTS

This is an interesting type of flip chart to tell the story of "Attitudes." A single copy put together by a local show card writer ran about $12. This chart was used in 80 scheduled meetings around the company system and can be reused for new employee groups.

Charts used for management groups and for basic supervision courses are necessary to show where and what action must be taken by members of these groups. The charts portray the seriousness of the accident situation in their respective areas and also company-wide. It reminds them that a safety problem is one dealing with human beings and it also shows the terrific cost these people and their company pay for these accidents. The charts remind them that the hidden costs may be two to four times greater than the direct costs.

These charts were used in more than a dozen management personnel meetings. They were made by a local show card writer at a cost of $30 per set.

GOOD PLANNING, GOOD THINKING

A type of flip chart designed to embellish the printed story of material published by organizations such as, the National Safety Council, the Edison Electric Institute, and others, makes a perfect visual aid. The charts can be used to explain recent accidents or as a job training media with safety being keynoted.

If planning is discussed, and to a degree there is some, is it *good* planning? When thinking is discussed, is it *correct* thinking on the part of the foreman and members of the crew or the individual involved? If there is—what caused the accident? There is usually a lot of talking on the job. But, as a means of preventing accidents, we need more talking about the job.

All of us hear about *defensive driving*, being on the alert, watching the others, anticipating movement of others. What we need is more defensive thinking on our jobs as a means of preventing accidents.

This material published on the three R's of electric utility safety by The Electrical World—on Routine—Risk—Remedy—can be utilized in many types of meetings. Every job has its routine but there are risks involved in these jobs. But, by using the proper safety techniques, the remedy is made known and followed to prevent injury.

These charts were used in more than 50 meetings and can be used in training meetings for new employees. This set ran about $20 and was put together by a local show card writer.

PICTURE STORY

Another type of special flip chart is the "Picture Story." It was used in conjunction with a written script entitled "He Used to Be—," given below, which also covers attitudes. This was used as a windup to a safety meeting in this manner. We have used two sets of these cards to cover our company areas. A set of seven cards ran from $40 to $50, depending on the amount of copy required from the show card writer.

These are a few applications of flip charts which we feel have been used successfully at many meetings. We would, however, vary the use of flip charts with other media for other meetings during the year.

"HE USED TO BE . . ."

He used to be a real "hurry-wart." First one off the truck—first out of the plant. First one out of the yard. First one through the intersection . . . but there's no rush now. He's got lots of time—an eternity of time.

He used to be a great grumbler. Griped about all the stupid people he worked for. Griped at safety meetings about all the "dull guff" he had to listen to . . . but there's no grumbling now. He's quiet, real quiet.

He used to be the super-aggressive type. Bulled his way through. Pulled disconnects and cut wires without bothering to look or think . . . but there's no blind motion now. No motion at all.

[illegible] no jittering now. He's calm, real calm, and still.

He used to be the absent-minded kind. Forgot to signal. Forgot to look over the job. Forgot to check his rubber goods and ropes . . . but there's no forgetting now. No remembering, either.

He used to be the chip-on-the-shoulder type. Had all the answers. No foreman or crew leader could tell him what to do. He'd do it his way . . . but there's no back-talk now. No talk at all.

He used to be the real dare-devil. Loved to risk his neck. Loved to take the dangerous shortcut. Got a real kick out of taking chances . . . but there's no chance-taking now. No taking anything, not even a breath.

"He used to be . . ." A sad story that will be written again and again and again. As long as we don't eliminate our serious faults, there's an excellent chance that they will eliminate us . . . there's no exaggeration about that now. It's right. It's dead right.▲

COMPANY MADE FILMS

by A. F. HANS

assistant manager of safety, Standard Oil co. (Ind.), Chicago

Motion pictures are generally regarded as the most effective media in the field of training. However, the high cost of professionally produced films, which run between $1,500 and $2,000 per minute of finished production, has resulted in little use being made of this type of training aid by industry in dealing with subjects relating to specific company operations.

By application of the "do it yourself" principle so popular today, any company or group can produce a quality film for an amazingly low cost. As proof, the employee relations department of Standard Oil company (*Indiana*) produced "Blind Spot," a nine minute, 16mm color with sound motion picture for $1,500. The film deals with a specific problem, backing accidents, the most common type involving some 4,500 vehicles engaged in home and farm deliveries.

Here's a brief account of how the film was made to encourage others to attempt a project of this kind.

WRITING—FIRST STEP

The first step was writing the screen story. A straightforward approach was used, covering five typical situations most commonly involved in backing accidents. Human interest was added by opening with a dramatic example of the worst possible outcome of a backing accident — running over a little girl playing behind a truck which had just finished delivering fuel to a private home.

enthusiastic and competent amateur photographer. Although he had no experience in filming a complete sound production, he was willing to take on the job of shooting footage for this company picture. He worked out a detailed shooting script and planned long, medium, and short range shots in connection with each scene sequence.

The importance of this phase of planning cannot be overemphasized because it spells the difference between an amateur and a "professional" finished product.

Finding suitable locations was also done with care. Consideration had to be given to camera angles, shadows, and natural light density.

CAST SELECTED

Selecting the cast was not difficult. Home owners who were approached were easily persuaded to cooperate even though they were not Standard customers. People who lived in the neighborhood agreed to play the parts of the mother, the child, and other roles. Of a cast of 12, only the three main characters were Standard employees. The others volunteered, receiving only the basic $1 fee for their signed release, plus, as a

hours; 700 feet of film was exposed. Photographic equipment was a Bell and Howell 70DL three lens camera. Kodak Commercial Kodachrome was used to maintain color quality through production prints.

There were 55 scenes in the script as finally revised before shooting. A blackboard was used to identify each scene to facilitate editing. Final editing and laboratory work was handled by a professional film laboratory. Their technical services included preparing the rough and final cut, recording, mixing, and preparing the answer and release prints.

The film uses some short lip sync sequences, with the truck driver acting as the commentator throughout the picture. To place him in character immediately, an early shot shows him in the cab of his truck looking into the camera and talking. The sound was dubbed in at the laboratory with a professional commentator supplied by them.

"Blind Spot" has been well received by those whom it was intended to reach. The employee relations department is pleased with its first entry into movie making and is planning to produce another.▲

STAGETTE USED IN "THE DESTREHAN STORY"

by J. B. HAMBLEN

safety director, American Oil co., New York city

The stagette used in presenting "The Destrehan Story" enables the speaker to change quickly to either of three types of visual aids without distracting the audience. In fact, the change from one medium to another holds the attention of the audience and is the chief advantage of the equipment. Interest is never allowed to sag and attention is stimulated by changing smoothly from peg board posters to flannel board strips, to color slides in any order desired. The four hinged sections fold compactly like a "W" and fit into a case for easy portability and shipment.

Lights concealed back of the headboard illuminate the peg board and flannel board and are operated by remote control switch and cord by the projectionist. The projection screen also is concealed back of the headboard and is raised or lowered by the speaker as required.

The speaker wears a lapel microphone and has both hands free for removing peg board posters, changing flannel board strips, or lowering or raising the screen as called for in the script. Both the speaker and the projectionist have scripts marked with cue words for the color slides. There is no waiting for slides or saying "Next slide please"; the correct slide is there when the cue word is spoken; the lights in the stagette are snapped on or off when the speaker

raises or lowers the screen. All instructions for lights and screen and the slide numbers are marked in the right hand margin on the script.

CONSTRUCTION OF STAGETTE

The stagette is made of wood and masonite. The headboard is in two sections bolted together at the center, and the length is such that the two peg board wings are held at sufficient angle to the flannel board sections to make the stagette self supporting on the table. The flannel boards tilt outward at the bottom and are held out by the hinged 10" by four inch by three-quarter inch blocks.

The peg board chart "Safety" hangs on the top left of the board. The left half of the flannel board, bearing the strip "Safety Committee" is hinged at the top to another piece which is screwed to the front of another piece. The parts for the right half of the stagette are symmetrical with those on the left.

The screen is an ordinary commercial screen removed from the stand. The screen case is fitted with two slotted pieces of strap iron which hook over the two screws back of the headboard. The screen rolls up into the case when not required.

This equipment is not available on the market and the cost of construction will depend upon local conditions. A plant carpenter or a member of the staff with a home workshop will find it easy to build.

DO-IT-YOURSELF SOUND SLIDEFILMS

by C. F. SCHEER

public relations director, Zurich-American Insurance co., Chicago

Nearly everything is relative—even the effectiveness of various visual aids. Each visual medium has certain advantages and disadvantages, but the sound slidefilm has more important advantages than most other media:

1. Its educational effectiveness is greater than that of any other visual aid, according to independent, carefully-controlled and authenticated research.

2. It is flexible. It can be used equally well with large or small audiences.

3. It is relatively inexpensive to produce—four or five films can be produced for the cost of one movie.

4. Projection equipment is compact, portable, and more simple to set up and operate than a movie projector.

5. The scenes portrayed can be controlled rigidly (with art work if necessary) so that all attention is focused where desired with no possibility of distraction in the background.

6. Sound slide is superior to silent strip, slides, overhead projection, or demonstration, because the narration is carefully-predetermined and is convincingly delivered by a skilled professional speaker.

However, the sound slidefilm does have a few disadvantages:

1. It won't do an adequate job in cases where motion is essential.

2. It may disappoint some people who expect motion, having been brought up on movies and TV.

3. The need of special projection equipment will not appeal to those who have already invested several hundred dollars in a movie projector.

4. There is a possibility of "human failure"—failure of the operator to change frames on cue.

5. Rewinding of the film—a manual job—is a chore.

Comparatively, the advantages of the sound slidefilm far outweigh the disadvantages.

But there is one shortcoming common to all films, movie as well as sound slide: the lack of films dealing with the specialized problems of specific industries or companies.

You undoubtedly have met this obstacle. However, at a small cost it is possible for you to produce your own sound slidefilms on specialized subjects, using the talent and facilities available in your own organization. To show you how it can be done, the public relations department of the Zurich-American Insurance companies has prepared a home-made demonstration film which follows.

"DO-IT-YOURSELF" SOUND SLIDEFILMS

Title Card	MUSIC (Musical powder box)
Credit Card: Pertinent production pointers prepared by public relations department, Zurich American Insurance companies	MUSIC
Cartoon: Person wrestling with filmstrip	Narr.: Are you wrestling with a visual aids problem? Well, brother, relax. Quit worrying. If you really want to, you can make your own sound slidefilms.
Drawing: filmstrip & record: prize ribbon pinned to record	They may not win prizes in professional competition, but they will deal with your own special problems in your own company surroundings. And . . .
Hand emptying piggy-bank	. . . a small budget will swing them. How do you go about it? Obviously, the first thing you need . . .
CU of page of script	. . . it is a good script—and that means: Be selective. Don't try to include all known facts on the subject. Be content to discuss one problem—or one phase of a problem.
Split frame: Clock showing 12:15 (Title: "100 Frames"); Clock showing 12:05 (Title: "35 Frames")	If you're planning a full-length 15-minute film, it should have at least 100 frames; a five-minute film, about 35 frames.
CU of script. Title at left: "Describe picture." Title at right: "Explain picture."	On the left side—describe each picture, diagram, or cartoon. On the right side—explain the pictures clearly by means of the dialog or narration.
CU of paragraph of script as per dialog, with section blocked out to indicate that a long sentence was deleted.	Keep the frames short—no more than 35 to 40 words at the very most. The surest way . . .
Cartoon: Audience dozing. Only tops of heads showing.	. . . to put an audience to sleep is to keep the same frame on the screen while the narrator's voice goes on . . . and on . . . and on.
Man with eye-shade, working at cluttered desk. Desk-sign: "Editor."	The editor of your company publication should be able to help you write the script, making sure it says what you want it to say—in everyday shop terms. Also . . .

"DO-IT-YOURSELF" SOUND SLIDEFILMS—(*Continued*)

Drawing: *Pretty girl typing.*	. . . you may need *help in getting* a neat readable typing *job. When the script* is finished, test it.
Drawing: Man *reading;* dog slinking away, tail between legs.	Read it aloud to someone who'll give you an honest reaction. Remember, safety isn't interesting to everyone. You have to make it interesting. *Now* . . .
Rube Goldberg type of machine, script going into one end; film and record coming out the other.	. . . how to transform the script *into* a film and recorded narration. Your plant *may have* . . .
CU: Person with camera. Bird perched on end (of camera).	. . . a camera club—or at least a few good amateur photographers who can take *the* shots you need and give you . . .
4x5 photo mounted on *drawing of* frame-card, with punch-holes indicated *on card.*	. . . 8x10 blowups, like this—mounted *on 10x12* stiff cards. For your cast of characters . . .
Stock shot or stock drawing or stock cartoon.	. . . you can use the men on the job. Or, if you have to do your *shooting after working* hours, your plant may have . . .
Stage scene: Couple of actors in togas. (Or *indoor production-still* from one of our films.)	. . . a dramatic *club—or some* other organization that will *gladly* cooperate in providing your actors.
Repeat shot of Editor.	Another visit to your plant publication office may pay off *in* stock photos that will fit in with your film. *Then, too* . . .
CU washroom *wall with* drawing on it (Maybe a *frame from* "Disorderly Conduct.")	. . . you may *find a frustrated* cartoonist or artist in your plant. If so, get him to use his talent *constructively* . . .
Montage: *Title* cards, cartoons clipped from *SZ Bulletin* and pasted down on frame card.	. . . *preparing the 8x10* art cards, cartoons, and title cards you *need. Now* that you have *your pictures,* you will need the help *of a commercial film studio* . . .
Drawing of animation set-up.	. . . to "*animate*" *them.* This simply means *re-photographing* them—one frame at a time—*on a strip of* 35mm motion picture film. The cost of such a filmstrip negative will run . . .
Sections of old negative pasted on frame *card. Title: "75c* to $1 a Frame."	. . . *from 75* cents to a dollar a frame if your photos are *all* one size—8x10-mounted as we have shown you; about $2 a frame if your mounted photos are of different sizes.

"DO-IT-YOURSELF" SOUND SLIDEFILMS—(Continued)

Sections of bromide print pasted down. Title: "10 to 15c a foot. $3 to $5 Lab Charge."	Finished prints of your filmstrip should cost 10 to 15 cents a foot in small quantities —and there will usually be a minimum laboratory charge of $3 to $5. Don't make the mistake of thinking . . .
Paste-up of various 35mm cameras from catalogue.	. . . you can use a 35mm camera for your original photography and wind up with a filmstrip in one easy step. Remember . . .
Bromide print of strip from 35mm camera; bromide print of 35mm animated strip.	. . . nearly all 35mm cameras produce pictures horizontally on a filmstrip; but a standard sound-slide projector requires pictures arranged vertically on the filmstrip. Of course, you can shoot with a 35mm camera and present your show . . .
Small contact prints from "Winter Wise" pasted on drawings of slide mounts.	. . . with 2x2 individual slides. Remember, though—slides do have some drawbacks. Even with an experienced projectionist, there is always a chance that they'll appear . . .
Repeat any shot upside down.	. . . upside down—or in the wrong order. And . . .
Drawing: Tall stack of slides being knocked over by a hand.	. . . a mere slip of the hand may cancel the whole show. Therefore the cost of professional animating is a worthwhile expenditure. Now . . . what about . . .
Drawing: Person at microphone—*CU.*	. . . recording the voice? The most practical method is to use . . .
Paste-up: Clipping from ad for tape recorder.	. . . a tape recorder—because if you fine your fluffs . . . (all your fines . . . that is, if you fluff your lines—*which* is very easy to do—you can erase and correct your mistake. A word of caution:
Frame 49 from "The Right Combination."	Talk slowly. Most of us talk much too fast, and . . . (speed-up of tape a la Donald Duck). Well, maybe not that fast. If you, yourself, *don't* have a good speaking voice . . .
Frame 45 from "The Right Combination."	. . . get someone from the shop—or office —or sales force—to do the recording—someone with a convincing voice.
Paste-up of ad clippings: Tape recorder and filmstrip projector.	Your finished tape can be used directly with your filmstrip—or you can transfer the narration from tape to a home-made record—or you can have a recording studio do a professional job.

"DO-IT-YOURSELF" SOUND SLIDEFILMS—(Continued)

Title card as per underscored dialogue.	And there you are: Get 1. A good script (pre-tested). 2. Photos that tie in with the script. 3. A good recording. And you've got it made. Easily, too, if . . .
Title Card: As per dialogue, underscored words only.	. . . You spread the work. Get all possible help from the qualified people around you. You can plan, supervise, coordinate. Then, when the job is done . . .
Cartoon: Person with tremendous smile; chest puffed out.	. . . you can sit back and say proudly: "Isn't that a swell film we produced?"
	(MUSIC IN)
End card: Safety Zone Seal and Zurich-American logotype.	(MUSIC UP AND OUT)

Now that you have seen the demonstration film, you probably want the facts of production. Did we practice what we preach? Yes, we did.

Our total out-of-pocket expenditure was less than $50. We used talent and facilities available in our own organization, and we spread the work.

The narration was done on tape, but we went to the expense of having a record made, assuming that the projectionists here would be more accustomed to handling records with this type of presentation.

The "bells"—signalling a change in frames—were sounded by striking a length of wooden dowel against a large water glass. Opening and closing music was taken from a hi-fi record—but you can have "live" music just as easily if you can play the guitar or mouth organ or harpsichord. In a pinch you could even use the musical powder-box on your wife's dressing table.

With a little imagination, a little planning, and a lot of help from cooperative members of your own company, you can make presentable, effective sound slidefilms to fill a long-existing gap in visual aid facilities—films that will deal with those unusual but important problems that seem to exist only in your own plant.

OVERHEAD PROJECTION

by E. P. MARCONI

manager, safety branch, ARO Inc., Tullahoma, Tenn.

The chief advantages of overhead projection are:

1. The speaker remains face-to-face with his audience.
2. The discussion can be carried on in a well-lighted room. Usually it is well to reduce illumination in the vicinity of the screen.
3. The audience gets a big picture, as contrasted with the picture seen on flannel boards and charts.
4. As contrasted with sound slide or movie films, the speaker has an opportunity to express his individuality in the presentation.
5. The speaker is the sole operator and there is no chance of confusion between the speaker and a second person—the projectionist in the case of slides, for example.
6. The presentation can be selective. Frames may be interchanged to suit the audience.
7. By means of various devices, the attention of the audience can be focused on one part of the illustration at a time. This is done by the use of a pencil with which the speaker may write on the frame, point, or diagram. These writings can readily be erased. Furthermore, he may use simple devices such as lift-offs to concentrate attention on one point at a time. He may use successive overlays with which to develop a point progressively.
8. This form of projection provides for either black and white or color. Frames can be hand-drawn with ink on cellulose acetate in black or in color. Or, color may be obtained by using the ozalid machine or by the use of photographic color transparencies. The latter are, however, rather expensive.
9. It is possible to make novelty presentations such as those shown during this presentation. Objects may be moved across the screen; a wheel may be made to rotate on the screen; a dense black sheet may be scratched upon with pencil to produce white lettering on the screen.

DISADVANTAGES ENCOUNTERED

There are some points to consider in the use of the overhead projector which may prove to be a disadvantage unless watched. For example, the speaker should be careful not to place his body in the way of the projected illustration. He must learn to make movements with the pencil slowly lest they become distracting.

He must set the screen somewhat high so that the picture may be seen over the speaker's head, since the speaker normally stands beside the machine. If the screen cannot be set high enough and the speaker's head and shoulders obstruct the view of members of the audience, he may find it desirable to sit down beside the machine.

In such a case, he should vary his position and rise, occasionally, when obstruction of the picture is no longer significant.

During this presentation examples were shown of the use of diagrams on an overhead projector. For example, a diagram of the ear can be shown and the speaker can discuss dimensions, point to parts of the ear, and write on the frame as required.

USE OF PHOTOGRAPHS

Photographs may be used. The transparency must be made from a negative. The photographer who develops the positive transparency must make sure the positive is not too dense. This takes some skill in the beginning but once learned there is little further difficulty in getting a transparency just right. It is well to start from good contrasting photographs. Starting with a bad photograph almost insures that the transparency will be bad also.

The projector can be used as a blackboard. A clear frame of cellulose acetate is placed on the projector and the speaker may build up an organization chart or write data —all this while standing face-to-face with the audience. The use of the overhead projector as a blackboard is common in modern bowling alleys.

Cost: The cost of overhead projectors which use approximately seven inch by seven inch transparencies is around $350. The machine weighs somewhere around 30 pounds and unfortunately the box is somewhat bulky for handling.

The cost of slides varies considerably depending upon the subject matter. Pen and ink diagrams, etc., can be made for whatever it costs to furnish the time or professional skill. We frequently make our own amateur frames and have found them very successful.

The cost of simple frames in black and white, furnished by companies which specialize in this type of visual aid, may be obtained for around $1.50. The use of overlays will increase the cost depending on their complexity and number. As for lift-offs, which are simply card paper placed over the transparency and removed in sections—this can readily be installed by the amateur. In our company I have been told that the cost for a transparency statistics chart having a base matt, grid, and three overlays, mounted on the frame, including art work is about $3.50, when processed on the ozalid machine using the diazotype method.

TWO VISUAL AIDS USED IN BUREAU OF MINES SAFETY DEMONSTRATIONS

by G. M. KINTZ

district supervisor, Health and Safety, District G, U. S. Department of the Interior, Bureau of Mines, Dallas, Tex.

The two visual aids for demonstrating flammable limits of gasoline and ignition sources are "pop guns." These simple "pop guns" are merely thick plastic tubes, one with toy airplane engine spark plugs and one with a spark gap formed by two balls on rods. A Model-T Ford spark coil or a similar source of high-voltage current is used with the spark plugs, and static electricity with the other tube. Spark plugs cannot be used to demonstrate ignitions by static electricity in these tubes.

The top of each tube or gun is sealed with a paper diaphragm. We first used a cork but abandoned its use because the cork blown out could damage or spot a ceiling or an overhead light fixture. Once the cork landed in a pan of gasoline on the demonstration table, causing a serious fire. If the cork is inserted too tightly, the explosion may break the plastic tube.

The visual aids are developed and used to reproduce fundamental conditions that cause accidents, especially fires, explosions, or asphyxia, in the mineral and allied industries, including the petroleum and petrochemical.

The following are some of the methods and stories used in presenting the Bureau of Mines "Magic of Fire" demonstration.

"EMPTY" CONTAINER EXPLODES

The dangerous container—the one that does explode—is the so-called EMPTY container. . had gasoline in it, has been emptied, and perhaps has been on the shelf for six or eight months.

Once a railroad gasoline tank car had been on the side track for several months with dome cover and valve at the bottom of the car open. Yet it exploded when they started to weld on it.

To demonstrate we take an empty container, and move a cleaning brush in and out so the audience can see that it is clean. We place one drop of gasoline in this empty container, seal it with a paper diaphragm, and allow it to vaporize. Air is already in there. We add fuel and get the heat through the spark plug near the base.

Connect the spark plug to the spark coil, turn on the current, and—an explosion occurs. This depends on gasoline and other conditions. One drop may not explode. If this happens, say "You have seen what one drop will do; let's see what two drops will do," and add a second drop.

Pick up gallon can of gasoline. In this gallon can there is more than 155 thousand times as much gasoline as in the tube. You can imagine the tremendous noise if we had been able to amplify that explosion one *hundred and fifty-five thousand* times.

COMPARE DYNAMITE, GASOLINE

Dynamite and gasoline are not the same thing. The same laws controlling one should not control the other. However, they are both manufactured for the sole purpose of exploding. It is interesting to compare the energy in the two.

If a gallon of gasoline could be turned into dynamite, there would be between 13 and 95 pounds of straight 40 per cent nitroglycerin dynamite. That would be between 26 and 200 sticks of dynamite. Yet many people keep a glass container filled or partly filled with gasoline in a garage, bathroom or closet where it could be broken and vaporize. But they wouldn't keep one stick of dynamite in such places. However, dynamite will remain in place while the gasoline vapors will migrate.

Often when inspecting laboratories or other places where distillation tests are run or around filling stations where gas-heated tire-patching outfits are kept on work benches, the personnel are loath to accept the recommendation that they should not smoke. They say why shouldn't they smoke, they have a Bunsen burner on the table or they have a gas flame on the bench.

To show them why they shouldn't smoke, put the one drop of gasoline into the tube and seal it. Be sure that the spent gases have been swabbed out of the tube before starting this experiment. Do not shake the tube; allow the drop to strike as far [illegible] on the side of the tube as practic[illegible] The spark plug at the top of the tub[illegible] ill represent a Bunsen burner.

Apply electric current to the spa[illegible] ug, and no ignition will occur. Then light a cigarette and drop the burning match on the floor.

Have the lower spark plug on the tube represent the floor. Apply the spark through the plug, and an explosion will occur. This illustrates that the gasoline vapors, which are heavier than air, hang along the floor.

You know what one drop would do. Put in one, two, three, four, five drops, insert the paper diaphragm, and allow the gasoline to vaporize. Air is already in the tube: the fuel was added; apply the spark. To make this appear hazardous, leave the gallon can of gasoline on the table and then just before applying the spark, move the gasoline can to the floor and set the glass of gasoline aside. Nothing will happen.

To be sure it is an empty container, reseal it, shake out some of the vapors, apply the spark, and an explosion will occur. Sometimes the vapors may be so strong that it will be necessary to repeat the shaking two or three times, or even go so far as to place the brush in the tube and pull it out once.

Actually to have a fire, there must be AIR, HEAT and the ratio of the fuel to the air must be within certain definite proportions called flammable limits.

FLAMMABLE LIMITS

For gasoline to explode, 1.4 and 7.6 per cent volume-in-air is necessary; dry natural gas—or rather methane—needs between five and 15 per cent and butane needs between 1.8 and 8.4 per cent.

Percentages of gas below the lower flammable limit will not explode or propagate flame. One drop and the spark at the top of the tube did not explode—because the vapors present were not enough to bring it up to the explosive range.

Percentages above the upper flammable limit will not explode or propagate flame because with five or seven drops in the tube you had too much and had to shake the vapors out until they were down within the flammable limits. Speaking generally, the closer the percentage of ordinary fuel gases approaches the midpoint between the upper and lower flammable limits, the more violent the explosion will be.

GAS VAPORS REMAIN

Often a person thinks that because there has been an explosion in a tank, a building, a confined area, mine, or elsewhere there is no gas left and that it is safe to go in.

To demonstrate this replace the seal of the tube, apply the heat, and an explosion occurs. Just because there has been one explosion does not mean that there won't be two explosions. Sometimes as many as five explosions occur.

Generally speaking, any mixture that will burn, will explode. As a matter of fact, there is no difference between the gases that burn and those that explode. To demonstrate that blow out the Bunsen burner and allow the gases from the burner to fill an explosion tube.

Extinguish Bunsen burner and place it over the top of the cylinder; allow gas from the Bunsen burner to feed into the cylinder, leaving enough space so that it is free to flow out of the tube. Sometimes difficulty may be experienced in getting just the right percentage in the cylinder.

Often when visiting machine shops and other places, workmen are heard speaking of oxygen as air. Oxygen is not air, and it should never be used as such. Workmen have used cylinder oxygen to put tests on a gas piping system because they did not have compressed air handy. Welders who did not like the atmosphere in a vessel in which they were working released oxygen into the working space.

Oxygen is not air, and it shouldn't be used as such. To show this blow the tube out with oxygen, place in it one or two drops of gasoline and seal it. Use two paper diaphragms. If you use a cork, be very careful not to insert it too tightly in the tube, especially if you are using a plastic tube because plastic is pliable. When ignited, an instantaneous explosion occurs. You can see that oxygen is not air, and it should never be used as such.

SKITS FOR SAFETY SAY SCAT TO ACCIDENTS

by DR. EARLE HANNAFORD
safety engineer, Long Lines dept., American Telephone and Telegraph co., New York city

It's only natural for people to react to skits that re-enact or portray living situations, for life is something we all experience. We identify ourselves with the roles played and in so doing, a lasting effect is made upon us.

We learn best by seeing. We learn most permanently when seeing is reinforced by the senses of hearing, touching and even smelling and tasting when possible.

Since time began the impact of role playing or "play acting" has been known and used. Its effects are dual in nature and it is felt deeply by the role players as well as those viewing the skit. Emotions and reactions to them are far older in human experience than reasoning and logic. Safety skits make the fullest possible use of this fact.

Facts to Remember About Planning Safety Skits

Safety skits don't have to be super-colossal productions. All that's required are a few people, a script and, in some cases, a few props which are usually everyday tools.

The most effective skits are those done by employees themselves since they have more identification for both the audience and the role players. Naturally they won't have the perfection of professionals but just getting a group around a table to read the parts has a tremendous effect on those playing the roles.

It's surprising what a little practice can do. There's an unsuspected amount of "ham actor" in all of us and a great deal of talent for living life-like situations or we wouldn't be here!

SUCCESSFUL SAFETY SKITS

Success depends upon—

1. Skit must be life-like—not over-serious or over-humorous.
2. Not too long.
3. Can be merely conversation or include actual performance of work and safety operations.
4. Minimum of memorizing of parts by rote by using properly prepared notebooks.
5. Sufficient practice to put role players at ease.
6. Use of suitable aids and a good setting.

Since we will use a section of the demonstration of "Useful and Usable Safety Meeting Techniques" as our skit, large cards and easels are used to show what techniques are being used in the discussion.

Last and by far the most important is the type of script and notebook used by the leader and the participants. We use a "flip-over" type notebook which lies flat before each participant. Each player's notebook contains the whole script but each individual's notebook has his part typed in capitals and underlined in red. It takes only a little practice, three or four practice sessions through the script, to become familiar with the parts and the use of the notebooks.

I will give a section from the demonstration "Useful and Usable Safety Meeting Techniques." To set the stage, let me tell you that this is a construction line gang safety meeting with the foreman leading the discussion. Our subject is "Are on the Job Safety Meetings Worthwhile?"

Suggestions for Presenting the Skit

The skit illustrates by actual discussion the practical methods and steps in conducting on-the-job safety meetings. It requires 15 minutes for presentation.

If possible, participants should be selected with their particular parts in mind for a more natural presentation. However, a little coaching and assistance during practice sessions will work wonders in adjustments of participants to their parts. Spontaneity can be developed even though the nature of the demonstration requires close adherence to the script.

Practice Sessions

Advance practice is vital to a smooth, natural presentation. The first step should be a purely "reading through" session with each participant merely reading his part with no attempt at dramatization, since the purpose is to gain familiarity with the script and cue phrases. Following the "read through" session, an average of six to eight actual practice sessions will give sufficient "carry" to the demonstration without attempting to memorize the parts. After the third or fourth practice, attention can be given to developing spontaneity, naturalness and dramatization.

An important point is to make certain that participants speak at a level and volume to be heard and understood by the listening group. This is particularly important in small groups where a public address system is not used. Also of importance is using a rate of speech that is neither too fast for the audience to follow nor too slow to maintain interest.

SETTING AND ARRANGEMENTS

The participants should be seated at the table with the open or unoccupied end facing the audience and the skit leader at the end of the table farthest from the audience. This permits a view of the faces of all participants. Where possible, it is suggested that two small tables be used to form an open "V" with the opening facing the audience, with a small reading table for the skit leader at the point of the V. This permits a better audience view than with a single table. A lectern can be provided to one side for the use of the leader while he is presenting the material which is not actual group discussion, as this aids in separating the two in the minds of the audience.

Each participant should have an individual "flip over" ring type binder approximately seven and one-half inches by four inches in size, with the rings at the narrow end. All of the script should appear in each binder; however, the binder for each participant should have his own part typed in capital letters and underlined in red. Since the other parts are typed in lower case each participant can identify his part quickly and at a glance. Only one side of each page should be used and typing should be double spaced for each participant's part.

Display cards should be prepared as required in the text, with lettering large enough so that the cards can be easily read by the audience.

It is best to have two assistants, one who displays the cards in accordance with the directions of the other who is equipped with a script and signals for each card by number. The numbers are placed on the back of the cards in accordance with the numbers placed on the script used by the leading assistant. The leading assistant can use hand signals to indicate the length of time each card is to be displayed. These two assistants should participate in the practice sessions to insure proper coordination.

For large audiences or unusual room arrangements, two sets of display cards and three assistants may be necessary. In addition, individual table microphones should be supplied for the participants with a harness or lapel microphone for the leader.

Alternates

To avoid difficulty due to sickness or unavoidable absence of a participant, it is recommended that the leading assistant in displaying the cards be trained as a replacement. This can be done by selecting the assistant with this in mind and having the assistant actually act as a participant in a few practice sessions. In addition, the alternate should read all parts thoroughly, since it is best to have regular participants take only their own parts, leaving all "fill in" duties to the alternate including substitution for the skit leader.

USEFUL AND USABLE SAFETY MEETING TECHNIQUES
(A Skit)

DR. EARLE HANNAFORD

INTRODUCTION

Safety meetings are a time honored way of selling safety to individual employees. In recent years many people have been saying, are they worthwhile?—Do we really sell safety?—What are the things that make safety meetings click?

All too often safety meetings develop into a "selling them" with the group playing a passive rather than an active part in the meeting. We who hold the meetings are talking when we should be listening. Once the problem has been clearly stated there must be participation by those in the meeting. Without it there isn't much chance of convincing anyone. And yet, time is of the essence also. On-the-job safety meetings just shouldn't take forever.

This morning we will demonstrate for you some of the useful and usable safety meeting techniques. These techniques have been developed and learned the hard way through actual experience. We are not going to smother you with a lot of words and technicalities. We are going to tell you briefly what we are going to demonstrate and then do it right here before you.

During each discussion large placards will be displayed, pointing out just what technique is being demonstrated at the moment. (Hold up a placard.) In addition, on the easel to the left of the platform, a large card will show the subject under discussion during the duration of each discussion.

In all of our demonstrations we will assume that the necessary preparation has been made by the leader—which I assure you is the case. Thus, the safety meeting techniques we will demonstrate deal solely with the conduct of the meeting itself.

Our skit is designed to show the following things:

1. The value of group participation and how to get it—in other words, getting the gang in on the act.
2. The use of illustrative personal experiences of the group members—helping them sell themselves.
3. Getting reasoned voluntary group acceptance—checking to make sure they have bought the bill of goods.

We will now discuss the subject: "Are On-the-Job Safety Meetings by the Supervisor Worthwhile?" using group participation, illustrative personal experience of the group members and voluntary reasoned group acceptance. (Have assistants show placard using the three techniques.) (During the course of this skit the assistants will hold up card on each side of the stage with the appropriate item on it as that item is being demonstrated in the discussion.)

LEADER: I've just been making out the time schedule for the next month. Since we've been holding these weekly safety get-togethers on the job for quite a while now, I want to get your ideas about them. Should we keep on with them or lay off of them for a while? What do you think?

HRDLICKA: You mean you want us to tell you, boss—that's a switch.

LEADER: Yeah, Bill, I'd like to find out what you fellas really think about these safety meetings. Are they doing you any good?

(Hold up Group Participation card)

DALTON: Doing us any good? What do you mean GOOD?

NAUGHRIGHT: Aw, Ed, I know what the boss means and you do too. He means, does it help us to work safely to kick these things around now and then.

LEADER: Yeah, that's it, Amos, that's just what I mean. Work at it fellas.

KELLY: Of course, I'm new around here and can only say how it looks to a young sprout, but I think it has helped me a lot.

LEADER: Just why do you think that, Ed?

HRDLICKA: Yeah, Ed, what's so hot about it? Right now I've got that rush service order waiting for me to get at it.

LEADER: Ease off a bit, Bill, let's give Ed a chance to have his say.

KELLY: Well now, let me see.

(Illustrative Personal Experience card)

LEADER: Ed, have you got anything particular in mind where it helps you. Tell us about it.

KELLY: Yeah, I remember something. You probably don't remember it yourself but we had one of these safety get togethers just after I came on the job. I was helping Ed here. You remember it, Ed?

DALTON: Yeah, I remember your helping me, but what are you talking about?

KELLY: You remember Ed. At that meeting we discussed wearing safety goggles when soldering. Seeing as how I don't wear glasses I thought it would look kind of silly. I left them off one day and the gang jumped me about it, and just a short time after I put them on there was a little flash of hot metal and it lit on the goggles instead of my eye.

HRDLICKA: Yeah, but it wasn't the meeting that did it. We jumped you about it. We always jump a guy who breaks a safety rule.

NAUGHRIGHT AND DALTON TOGETHER: Now wait a minute, Bill, wait a minute.

NAUGHRIGHT TO DALTON: You tell him, Ed, I think we both are going to say the same thing anyway.

(Group Participation card)

DALTON: Maybe we'd jump him and maybe we wouldn't. Having these safety get-togethers sort of refreshes our minds and keeps us on the ball.

LEADER: Anything you want to add to that, Amos?

NAUGHRIGHT: Sure, just this. At these meetings we've been making it our plan to talk about the safety angles of the job at hand. I've been around here a long time; sometimes I think too long, but I've never seen the day when taking time to talk over the safety angles of the job didn't help me.

HRDLICKA: Yeah, in the meantime I still got that service order staring me in the face.

LEADER: That's right, Bill, but let's go on and make sure about how we feel about these safety meetings.

DALTON: Wait a minute fellas, I've been thinking maybe Bill has something there about our not needing these safety meetings.

LEADER: What do you mean by that, Ed?

DALTON: Well, just figure it out. After all we are a pretty small crew and we work together all the time and you are right here with us most of the time. Why do we need special meetings anyway? We can keep up with what is going on.

(Illustrative Personal Experience card)

KELLY: Maybe you old hands can, but I sure can't.

NAUGHRIGHT: Well, Ed, there may be something to what you say but I was just thinking about the times when getting the job done seems so important we forget some of the safety angles. It gets to be a habit with us, so much so that the wrong way seems like the right way. If we discuss the safety angles now and then it gets us back on the track.

HRDLICKA: You are right, Amos, about the job being important. Now I got that service order—

LEADER: Wait a minute, Bill, wait a minute. Let's see just what Amos has in mind, Amos?

NAUGHRIGHT: Well now, yes. I remember one and you were mixed up in it too, Bill.

HRDLICKA: Yeah, that so, what was it?

NAUGHRIGHT: You remember when we had that emergency call about the exchange cable being out and tests showed it was in the manhole at the corner of Washington and Lincoln streets.

HRDLICKA: Yeah, I remember it. It was about six months ago. The boss had been called into the office. You, Ed and me rushed out there.

NAUGHRIGHT: Yeah, that's right.

DALTON: Yeah, I remember it, Amos, now that you mention it.

NAUGHRIGHT: Remember, Bill, you rushed out and we got the cover off and in our hurry we sort of forgot to make tests for gas before entering the manhole?

DALTON: Bill should remember it. We sure had to get him out fast. Lucky he wasn't done in.

HRDLICKA: Yeah, I guess you fellas sort of got me. We did forget to make those tests.

(Reasoned Voluntary Acceptance)

LEADER: Well, we can all be glad that it worked out OK. What about these safety meetings though—do we want to continue them or not?

DALTON: Well, I guess we do all right. I take back my crack about being together on the job every day taking the place of these meetings.

NAUGHRIGHT: Yeah, that's the way I feel about it, too. Having been around here a long time I have seen these things come and go and we have always done a better job when we had these safety meetings.

LEADER: Ed, how do you feel about it?

KELLY: Well, there's no question that I'm new and need all the help I can get, and I'm aiming to be around here a long time like Amos.

LEADER: Well, Bill, you got anything to say?

HRDLICKA: Yes. I'll go along with these meetings, I guess. Maybe we do need to stand off and look at what we are doing now and then, just to make sure we are doing it safely. But I still got that service order staring me in the face.

LEADER: Well, fellas, are we all pretty much agreed now that we want to continue with these safety meetings on the job each week?

NAUGHRIGHT: Yeah, let's go ahead with them.

DALTON: I'm for it.

KELLY: I sure want them.

HRDLICKA: OK, OK, count me in.

LEADER: All right, next week let's talk about wiping joints the safe way. Ed, supposing you be ready to talk about it and show us some of the angles and have Ed Kelly help you.

DALTON: All right, we'll be ready, won't we, Ed?

KELLY: Sure will.

LEADER: Well, I guess that just about wraps it up for the day. Maybe we better let Bill get at that service order.

HRDLICKA: OK, boss, I'm on my way now.

I doubt if anyone in the audience missed the way in which group participation made the safety meeting really click, as compared to the first discussion in which the leader tried to carry the ball himself; also obtaining reasoned voluntary group acceptance really sells the ideas under discussion. People like to "get in on the act" and the selling power of being in on it yourself is tremendous when compared to just listening to someone else's logical presentation.▲

WIDENING HORIZONS IN OCCUPATIONAL SAFETY

THE OPPORTUNITY FOR STATE ASSOCIATIONS AND STATE AGENCIES

by CHARLES H. FULGHUM*

secretary, Mississippi Manufacturers Association, Jackson, Miss.

Most state associations represent special interest groups and are constantly involved in controversial issues. Even though we are convinced the cause we champion is right, we sometimes have a hard time getting this across to the public.

It's a nice feeling for a change to promote a non-controversial cause. Safety is the perfect answer. Our members love it. It takes some of the sting out of the public accusations that we are a self-serving bunch of "so and so's."

Every association must render a public service in order to survive and be tolerated by society. Safety promotion gives us an opportunity to go outside our membership and render public service.

As a result of this attitude by our Association, our governor appointed a citizens committee composed of a cross section of the state's citizenry. When the committee met, the Mississippi Manufacturers Association, because of public recognition of safety leadership, was called upon to do the formative and organizational work in forming the new Mississippi Safety Council.

Because of our leadership in safety promotion, we are consulted on proposed safety legislation. We are thus in a perfect position to head off ill-conceived safety legislation at the state level before it is introduced.

People are inclined to look on industrial associations as green-eyed, forked-tailed monsters out to suck the blood out of "the little man." Once people get to know us, they find that this "just ain't so."

Thus, safety promotion outside our own membership opens up an entire new "public" for us. It has placed us in the midst of practically every organized group in the state. Our public safety promotion has won us many new friends, influenced many new people.

When civic groups, women's clubs, town boards, chambers of commerce, police agencies, school groups and trade organizations start coming to the state industrial association for guidance on anything—Well, that is really something! That is precisely what is happening to MMA in the safety field.

All these things are "fringe benefits." Our basic motives for our safety program are the same as those of a business firm which has a good safety program. In addition to those motives, we have the same motives as the National Safety Council in its great program.

Over and above this, we are in a perfect position to reap numerous "fringe benefits." All combined and neatly packaged, they make up a very attractive and worthwhile program for any organization.▲

*(*Charles H. Fulghum replaced John E. Gregg, who resigned from the association shortly before the Congress.)*

OPPORTUNITIES FOR COOPERATION BETWEEN INDUSTRIAL ASSOCIATIONS AND INDUSTRIAL SECTIONS, NSC

by DONALD H. WORKMAN
executive vice president, Gray Iron Founders' Society, Inc. Cleveland, Ohio

This subject is a broad one—because there are so many opportunities for cooperation between the trade associations and the National Safety Council.

In our own safety activities—almost from the start—we have leaned heavily on the Safety Council, and particularly in the last few years during the initial stages of an expansion in our own safety program. Bob Currie of the Small Business and Associations Section of the Council has attended all of our safety committee meetings during the first year of the expansion program and he was of invaluable help to us in matters of modern safety techniques and in programming safety activities. Also, Al Baltzer, head of this section, has attended a number of our meetings and has given us much of his time.

We recognize that the Council is most prolific and generous in the production and distribution of fine safety literature, posters and films. The only shortcoming, and I can't reasonably call it an objection, is that most of this material unfortunately does not meet the specific safety needs of each and every industry—foundries in our particular case. In our industry 200 tons of material must be handled to produce one ton of castings. Here is where the industrial associations have their first opportunity—they must pick up the ball and tailor good safety programs to their own industry's needs with the help and encouragement of the Council.

PROVIDES MEETING GROUND

An important function of a trade association is to provide common meeting grounds for the exchange of good ideas among its members. As in the case of our own membership—no one executive or any one association has all the good ideas. Here then is the opportunity the Council has to increase its service as an industrial safety trade association so that more communications can be channeled to and fro and so that more good ideas can be exchanged between trade association safety men. This thought is not new—nor has it gone untried—witness our session today—but I believe special regional or national safety meetings for trade association safety men only would be welcomed and supported.

Here then is the second opportunity for all industrial associations—all we have to do is speak up, the Council will take it from there because they know that safety must be a two-way street. The Council realizes that it is easier to reach an industry through its association, and it has demonstrated this well by helping its many association members to help themselves in safety matters.

I was asked to review briefly our society's safety program, which can best be done by illustrating some of our safety publications and materials:

1. We publish a 15-page manual called *How You Can Work Safely*, designed for the foundry employee. Approximately 85,000 copies are now in use.
2. One booklet *Sight Conservation in Gray Iron Foundries*, published by National Association for the Prevention of Blindness is based on a survey of our member companies, which we helped to carry out.
3. Our Monthly Statistical Summary carries two columns on safety, 1) Number of Lost Time Injuries and 2) Injury Frequency Rate covering approximately 35 different industrial foundry centers from coast to coast.
4. To find what our safety problem really was, our society surveyed the industry two years ago. Only information indispensible to the safety committee was collected, and it has formed the basis for our present program and it will be a bench mark to measure future progress.
5. To augment survey data for our program, our committee held a brainstorming session and developed 134 good ideas for safety contests, cooperation with other organizations, project development, publications, safety publicity and training.
6. Step six, now in process, is the development of an Industry—Management Safety Manual.

Last week I was chatting with a representative of Pressed Metal Institute, an association which won a Safety Council award in the third year of its five year old safety program. So far they have helped reduce their industry's rate from 23.7 to 9.0. They insist that each year at least one of each of their regional chapter meetings be devoted to safety.

IKE, IDA AWARDS

A serious gimmick used by PMI is the creation of two little figures named Ike and Ida. These two figures, clothed in working dress, are presented each year to the district having the best safety record. The presentation ceremony is quite formal. If the winning district is overtaken the following year by another district another solemn ceremony occurs at a meeting when Ike and Ida are carefully laid away in a handsome mahogany casket for shipment to the other district.

In PMI, and at a member's expense, a sub-committee of their large national safety committee is invited to inspect the member's plant—the outside viewpoint. They also place industry suppliers on their committee—more of that "outside look." These suppliers carry good safety ideas from plant to plant and have an ideal opportunity and motive to look for the unusual in safety.

Also we can pick the brains of industries which have done the best job in safety—invite their own experts into our factories to look for things our experts can't see.

American Trade Associations have contributed greatly to the tremendous economic growth of this country. It is a matter of record that associations have been credited with furthering American industry's ability to lick any problem. Why then can't we use this ability and power to lick both traffic and industrial safety problems?

Therefore, our greatest opportunity is to turn safety from a problem into an opportunity in our respective industries. I am always distressed when I hear safety called "old stuff" or "shopworn." An association giving lip service only to safety can harm its industry and we are failing our industry if we don't go all out in this regard.

If we are to reduce the high cost of accidents and if we are going to prevent human suffering, all of us must work harder to make safety efforts more attractive and a must to all concerned.▲

THE OPPORTUNITIES FOR LOCAL SAFETY COUNCILS AND CHAPTERS OF ASSE

by JOSEPH M. KAPLAN
manager, Greater Los Angeles Safety Council, Los Angeles, Calif.

Too few chapters of American Society of Safety Engineers and local safety councils give themselves the opportunities to promote safety activities among small businesses and trade associations.

Our observations in this field show that such opportunities do exist, and that the time to do something about them is now. The potential is tremendous, for the field is virtually untouched. Studies have shown that the smaller businessman has a higher accident frequency rate and higher insurance rate than his bigger brothers. This extra cost not only narrows his profit but often makes the difference between operating at a profit or a loss.

A considerable portion of the time and effort of the industrial division of the Greater Los Angeles Safety Council is being exerted to take advantage of these opportunities.

CONTEST BEGINS PROGRAMS

We consider our annual business and industry safety contest as one of the mainstays of the entire industrial safety program, not only because it sustains interest in the program the entire year but because it is a tremendous influence in interesting new businesses, large and small, in the field of safety. Our contest started nine years ago and has grown to a present enrollment of 470 companies, employing more than 650,000 workers, and aggregating more than a billion and-a-quarter man-hours yearly. In 1949 the frequency rate was 10.41 and last year it was reduced to 5.98.

Approximately one-third of all the entries in this contest are small businesses with less than 100 workers. Obviously, since most of the large plants are already safety-minded, having their own programs and since a majority are already entered in the contest, the opportunity to secure new entries lies almost exclusively in the small business field. We have found, however, that, as the size of these potential participants gets smaller and smaller, it is becoming more and more difficult to get them started.

We believe that the contest is an excellent method for making an initial contact with the smaller plants, and helps many of them launch their own safety programs. Time after time we get telephone calls or letters from participants who remark: "We had only five accidents in our entire plant last year; I thought we had an excellent accident record. Now, when we compare it with other businesses in the same category, we find that it is quite high. What can we do to reduce our rates?" Then of course, we are off to launch a new program for such people.

The overall accident frequency rate of all our contest participants, as well as the individual rates of most of them is gradually going downward, slowly but steadily, year after year. This must indicate that the contest is exerting some influence on the rates.

Certainly, the contest is an excellent way of stimulating interest. Our annual Award Banquet, at which we present the annual plaques and trophies, is one of the Council's major events. In addition to the first, second and third place awards and perfect record winners, we give a sweepstakes trophy to the company with the best overall safety program and record.

STRESS SMALL BUSINESS

Two years ago, we added a junior sweepstakes award to this list of awards. This trophy is awarded to the company of less than 250 employees with the best overall program and record. The interest and competition for this recognition is just as keen as in the senior division, and shows another way in which the interest of smaller companies and agencies can be stimulated.

Another major factor in our program is the annual Western Safety Congress and Exhibits, held for a three-day period every March. In addition to the usual programs on general industrial safety, traffic, fleet and home, we offer separate sections for small businessmen. This year we are placing considerable stress on this phase of the program and anticipate an upsurge in interest and attendance in this section. Two new approaches that we are taking in this field are:

1. We have found that many businessmen who suddenly blossom from small 2, 3, or 4-man operations to 25 or 50-man plants practically overnight, no longer regard themselves as small businessmen in their own eyes. They no longer are interested in activities of small business, and actually resent the term *small business*. For this reason we are discontinuing the use of the term *small business*, and substituting the term *management* instead. We expect to attract both small, medium and large operators to these section activities.

2. We have found that small businessmen won't come out to hear safety men talk on safety, but they will come out to hear other businessmen talk about their own experiences. Consequently, we are scheduling only management speakers to speak at these management sessions. Both large and small business speakers will be programmed as another concession to the needs of smaller business.

SERVICES OFFERED

In addition to these major activities, we also have a number of routine services, such as a technical library, staff consultation service, visual aids library, and the resources of many committees. In checking the monthly activity reports, we find that an ever-increasing proportion of telephone calls and letters are from the smaller size businesses. Such requests are beginning to filter in from trade associations also, something unheard of in the past.

We also publish several magazines and newsletters each month. In addition to *Safetyscope*, which is general and all inclusive in its scope, we have separate newsletters published by the industrial, fleet and home and off-the-job divisions. Not only are the names of small businesses added to these mailing lists—as soon as any interest is evidenced by them—but our industrial newsletter has been devoting a page in each issue to small business and trade association safety news items of general interest. We feel certain that these activities are responsible for these new inquiries.

Our specific promotion in the field of association safety is really just getting under way. The association newsletter published by the National Safety Council has repeatedly stressed the fact that the smaller companies have higher rates than they realize and urged that associations heed this situation and do something about it. We consider this another opportunity to challenge us.

FIND LACK OF INTEREST

When we decided to systematize our association safety program, obviously the first step was to find out what such groups were already doing. We first prepared a list of associations, and sent them a short letter and brief questionnaire in which we asked them to outline their present program, needs, and interests in the field of safety.

The response to this preliminary questionnaire was somewhat startling. We received only a limited number of replies. A few of them indicated a vague interest in diversified subjects mentioned, several failed to fill out the questionnaire portion and two came right out flatly and said they were not interested.

It was quite apparent that, if we expected to accomplish anything worth while, we would have to revise our strategy. We screened the combined lists of many business and trade associations—1,000 in all—and created a new list of 266 associations which we now regard as our "potential contact" file. These groups represent associations whose activities should logically include safety, and with whom we hope to do business.

We have been personally contacting the managers or executives of these associations. The response to this personal contact technique has certainly been more encouraging. After a few contacts, one striking fact became apparent—trade association executives are not interested in generalities; they are interested only in specifics.

Merely outlining our services and leaving them a copy of the service guide, with a request that they select their own items from those available, does not produce results. We have yet to have a single follow-up from this approach. These men simply do not have the time to do this job.

They agreed they had a need of such services, and could use the services if the programs were tailored to the needs of their

individual members. Obviously, we do not have the staff time to perform this function.

Another opportunity thus presented itself. We redesigned the entire association program to fill this particular need and organized a special committee, the business and industry liaison committee.

Essentially, this committee consists of the executives or other officially-appointed safety representatives of the many separate associations concerned. The committee surveys the individual and collective needs of its members and reports these needs to the council. It communicates to its members the council's regular or special activities or services which may be of interest to them.

We just started this program, but already have 16 members on this committee. It is active in several different fields and we expect it will grow into possibly an 80 or 90-man committee. It should become a major factor in meeting this opportunity to serve trade and business associations, as well as to attract them into other activities.

SMALL BUSINESSES INTERESTED

We are attacking the problem of individual small business in much the same way. We already have a fairly comprehensive list of the larger and intermediate sized companies who have their own safety programs, but lately we have been making a concerted effort to add to this list the names of the smaller businesses. Occasionally, they call for information, or write for it.

Friends suggest their names or safety engineers or inspectors learn of their interest or need and advise us. As soon as we know, we make a file card for them and put them on the mailing list of the industrial newsletter, *Safetyscope* or other publications.

We have an active chapter of ASSE in Los Angeles who has been helpful in many phases of this program, particularly through its numerous standing and special committees. Certainly there are many opportunities offered for it to continue this fine service.

Their placement committee has secured trained safety engineers for many organizations. The ASSE speakers' committee assisted in supplying speakers for smaller plants having their first safety meetings or organizing committees.

Through its educational committee, there have been numerous safety courses offered in the Los Angeles area. At the present time there are five such courses and practically the entire attendance is comprised of plant managers, foremen, supervisors and others concerned with plant operations, rather than safety men. Safety is definitely making its way into many small plants through these courses.

Traditionally, too, the safety engineering sessions at the annual Congress have been sponsored by the ASSE. To conduct such programs a professional staff member is needed to handle this phase of the council's activities. Thus far there are only a relatively few councils which have employed their own industrial safety directors or engineers. I would recommend that many more consider such an addition to their staffs for these programs will be limited only by the knowledge and capacity of the man directing them. Without a program director to administer such a program, you will have no program to sell.

Let us reiterate that word SELL, for safety must still be sold. The pioneers in safety had to sell it, and we have to sell it. Small businesses and associations are interested in safety to a small extent. There is definitely an opportunity to get them activated in safety work BUT they must still be sold to take the desired action.

MUST SELL PROGRAM

They are not standing in line waiting to grasp at any safety program or suggestion that comes along. They will grasp only at suggestions, devices or planned programs designed to fit their needs. We must plan these programs and also the selling campaigns, in the same way we would plan a campaign to put a new soap, automobile or new perfume on the market.

The opportunities are there, if we but grasp them. If we don't, there is a good possibility that some agency will come along and grasp those opportunities which rightfully belong to our system of free enterprise.

OFFICERS OF THE

AMERICAN SOCIETY OF SAFETY ENGINEERS

NATIONAL SAFETY COUNCIL 1957-58

President—JOHN F. JULI, safety manager, Consolidated Western Steel div., U. S. Steel corp., Los Angeles, Calif.

First Vice President—ROBERT CLAIR,* assistant vice president, Liberty Mutual Insurance co., Boston, Mass.

Second Vice President—DONALD G. VAUGHAN,* manager, engineering & inspection dept., Aetna Casualty & Surety co., Hartford, Conn.

Secretary and Managing Director—J. B. JOHNSON, American Society of Safety Engineers, Chicago, Ill.

Treasurer—GEORGE F. NUERNBERGER, safety department, Kaiser Steel corp., Fontana, Calif.

Members-at-Large

Term Ending 1958—MICHAEL F. BIANCARDI, manager, safety services department, Allis-Chalmers Manufacturing co., Milwaukee, Wis.; H. W. HEINRICH, chairman, Uniform Boiler and Pressure Vessel Laws Society, Inc., New York, N. Y.; FRED H. KOBELY, manager, Safety & Casualty, Columbia-Geneva Steel div., U. S. Steel corp., San Francisco, Calif.

Term Ending 1959—FRED CLAIBORNE, safety assistant, Pan American Petroleum corp., Tulsa, Okla.; FRANK E. LADERER, associate director of safety, Nationwide Insurance, Columbus, Ohio; E. P. MARCONI, manager, Safety Branch Aro, Inc., Tullahoma, Tenn.

Term Ending 1960—GEORGE M. KINTZ, chief accident prevention & health div., U. S. Bureau of Mines, Region VI, Dallas, Tex.; CLYDE F. SCHLUETER, accident prevention manager, Employers Mutuals of Wausau, Wis.; VIRGIL L. WOMELDORFF, safety director, Illinois Power co., Decatur, Ill.

Regional Vice Presidents

Eastern Region—ARTHUR H. CHRISTIAN, corporate safety engineer, American Viscose corp., Philadelphia, Pa.

Northeast Region—WARREN J. PETERS, engineer, The Travelers Ins. co., Rochester, N. Y.

Southeast Region—P. W. LOGAN, division manager, Engineering department, Liberty Mutual Insurance co., Atlanta, Ga.

Central Region—JOHN F. JONES, safety supervisor, Commonwealth Edison co., Chicago, Ill.

East Central Region—MYRON L. MILLER, supervisor of safety, Westinghouse Electric corp., East Pittsburgh, Pa.

*ROBERT CLAIR resigned due to illness. He was replaced by DONALD G. VAUGHAN on Jan. 14, 1958. JOHN F. JONES, safety supervisor, Commonwealth Edison co., Chicago, Ill., was made second vice president.

West Central Region—HOLLEY P. BRADLEY, supervisor of safety, Service Pipe Line co., Tulsa, Okla.

Southwest Region—EDWIN B. LOCKE, manager engineering department, Texas Employers Insurance Assn., Dallas, Tex.

Western Region—S. KIRKLEN COLLINS, superintendent, accident Loss & Prev. Dept. Fireman's Fund Group, San Francisco, Calif.

Past Presidents: W. N. COX, JR., Professor of Safety and Industrial Engineering, School of Industrial Engineering, Georgia Institute of Technology, Atlanta, Ga.; EDWARD B. LANDRY, Benjamin Franklin Station, Washington, D. C.; HENRY B. DUFFUS, administrator, Accident Prevention, Westinghouse Electric corp., Pittsburgh, Pa.

Standing Committee Chairmen

Committee on Awards & Honors—PIERRE E. DERY, supervisor of safety, Dominion Rubber Co., Ltd., Montreal, Quebec, Canada

Committee on Chapters—OTTO C. HAIER, safety director, Standard Oil Co. of Ohio, Cleveland, Ohio

Committee on Cooperation with Engineering Colleges—FRANK E. LADERER, associate director of safety, Nationwide Insurance, Columbus, Ohio

Committee on Cooperation with Engineering Societies—JOHN V. GRIMALDI, consultant in safety services, General Electric co., New York, N. Y.

Committee on Finance—GEORGE F. NUERNBERGER, safety department, Kaiser Steel corp., Fontana, Calif.

Committee on General Publications—FRED H. KOBELY, manager of safety and casualty, Columbia-Geneva Steel div., U. S. Steel corp., San Francisco, Calif.

Committee on Membership—GEORGE L. GORBELL, safety director, personnel relations department, Monsanto Chemical co., St. Louis, Mo.

Committee on Public Relations—ROLAND C. BAUER, safety supervisor, Koppers co., Pittsburgh, Pa.

Committee on Research—MICHAEL F. BIANCARDI, manager, safety services dept., Allis-Chalmers Manufacturing co., Milwaukee, Wis.

Committee on Safety Laws and Regulations—THOMAS R. LEADBEATER, safety director, Todd Shipyards corp., New York, N. Y.

Committee on Safety Standards—CLYDE F. SCHLUETER, accident prevention manager, Employers Mutuals of Wausau, Wausau, Wis.

Committee on Technical Publications—HENRY G. LAMB Bronxville, N. Y.

Special Committee on Congress Programs—DONALD G. VAUGHAN, manager, engineering & inspection dept., Aetna Casualty & Surety co., Hartford, Conn.

Special Committee on Action Program—J. C. STENNETT, director, accident & fire prevention div., National Association of Mutual Casualty Cos., Chicago, Ill.

Special Committee on Junior Achievement—HOMER K. LAMBIE, El Cerrito, Calif.

Special Committee on Membership Services—E. PETER MARCONI, manager, safety branch Aro, Tullahoma, Tenn.

Special Committee on Motor Vehicle Operation—AMOS E. NEYHART, administrative head, Institute of Public Safety, The Pennsylvania State Univ., General Extension Annex University Park, Pa.

Special Committee on NSC-Society Relationship—DR. WILLIAM P. YANT, director of research & development, Mine Safety Appliances co., John T. Ryan Memorial Laboratory, Pittsburgh, Pa.

Special Committee on Review of the Constitution and By-Laws—WILLIAM N. COX, JR., Professor of safety & Industrial Engineering, School of Industrial Engineering, Georgia Institute of Technology, Atlanta, Ga.

Special Committee on Society Exhibit at Museum of Science and Industry—ARTHUR R. GRAHAM Safety Engineer Bituminous Casualty Co. Insurance Exchange Bldg., Rm. A-917 Chicago, Illinois

Historian—EDWARD B. LANDRY, Benjamin Franklin Station, Washington, D. C.

National Safety Council Representative—DAVID L. ARM, manager, Industrial department, National Safety Council, Chicago, Ill.

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

LABOR CONFERENCE

This volume is a record of the sessions held at the 1957 National Safety Congress by the Labor Conference. The conduct of these Congress sessions each year is only one of the many cooperative activities which the Labor Conference carries on in behalf of its members, and for the benefit of accident prevention work in the labor force. This section gives guidance in the preparation of a great variety of technical and educational material useful in the day-to-day safety programs of labor.

The activities of this Conference are under the direction of its executive committee, the members of which are listed at the close of this volume.

ACCIDENT INVESTIGATION

by JOHN GRUDEN
director, health & safety dept., United Auto Workers, Dearborn, Mich.

I am a representative of Ford Local 600, UAW, the labor organization which represents all hourly-rated employees of the Ford Motor company's giant Rouge Plant. My specific duties are to handle problems and complaints relating to health and safety which arise in that plant.

Before speaking on "Accident Investigation," which is my subject today, I should like to familiarize you with the physical composition and operations of the Rouge Plant, the Union's functions in the plant, and our health and safety grievance procedure.

The Rouge Plant divided up into 18 units. Our total membership is in the neighborhood of 37,000. Approximately 250 full-time Union committeemen represent these people. Each of those 250 representatives is authorized to handle matters pertaining to health and safety, however, each of the 18 units has a health & safety director who deals almost exclusively with health and safety.

PLANT UNITS

The 18 units in the Rouge plant, the number of members in each, and their principal operations are as follows:

1. Dearborn assembly plant—3,030 members—assemble cars.
2. Dearborn engine plant—2,624 members—machine cylinder blocks and assemble motors.
3. Dearborn iron foundry—3,462 members—make cylinder blocks, etc.
4. Dearborn specialty foundry—687 members—make valves, tappets, crankshafts, etc.
5. Dearborn stamping plant—4,472 members—stamp car bodies and weld them together.
6. Ford central parts depot—610 members—store Ford parts and ship to dealers throughout the country.
7. Frame plant—3,437 members—make car and truck frames.
8. Glass plant—1,185 members—make windshields and door windows.
9. Mercury parts depot—283 members—store and ship out parts.
10. Maintenance & construction—5,486 members—do all maintenance work throughout the Rouge plant.
11. Miscellaneous unit—1,123 members—coke ovens, blast furnace and by-products.
12. Motor plant—398 members—work on government project.
13. Open hearth—734 members—make special steel.
14. Rolling mill—1,933 members—roll out sheet metal.
15. Standard transmission & radiator plant —1,647 members—assemble transmissions and radiators.
16. Steering gear plant—179 members—assemble steering wheels.
17. Tool & die—4,000 members—do all types of tool and die work.
18. Transportation—1,245 members—trucking, railroading and portable cranes.

This gives you an idea of the variety of safety problems that can and do arise, and each must be dealt with individually. The Union recognizes that health and safety are management's responsibility; also that plant managers should provide leadership. However, Unions should assume the responsibility of protecting their members and seeing to it that the policies set up by the company are carried out. Unions should also establish some safety policies of their own.

We know that industries are not in business to kill people, however, as the old adage goes—"An ounce of prevention is worth a pound of cure." It is for this reason that plant inspection is important.

INSPECTION TOURS

The Union makes tours of inspection throughout all units of the Rouge plant whenever it deems them necessary. The members are also urged to report any and all problems pertaining to health and safety,

as well as potential hazards. Listed below are the things we watch for and check during our inspection tours; housekeeping is at the top of the list because management can be judged by its housekeeping.

1. Under housekeeping we look for—
   a. Loose material and objects underfoot.
   b. Loose material and objects overhead.
   c. Pilling.
   d. Projecting nails.
   e. Disposal of scrap and waste.
   f. Tool housekeeping.
   g. Marked aisle lines.
   h. Window cleanliness.
   i. Painting.
   j. General cleanliness.
   k. Orderliness.
   l. Fire hazards.
2. Material handling.
3. Adequacy of aisle space and working space.
4. Guarding of transmission machinery.
5. Point of operation guards.
6. Maintenance.
7. Hands tools.
8. Ladders and portable steps.
9. Hand trucks, power trucks.
10. Floors, platforms, stairs and railings.
11. Lighting.
12. Cranes, hoists, derricks, and plant railways.
13. Electrical equipment (particularly extension cords).
14. Elevators.
15. Other personal protection equipment.
16. Dust, fumes, gases and vapors.
17. Pressure vessels.
18. Exits.
19. Yards, roofs and roadways.
20. Eye hazards.

Speaking of eye hazards, I would like to relate to you an interesting experience we witnessed when, some time ago, management wanted to institute a 100 per cent eye protection program. The Union leadership in this particular plant objected to a 100 per cent program; in their opinion it was sufficient to have the men on the jobs wearing goggles. Management, however, insisted that everyone who entered the plant should wear protective eyeglasses.

Management called in representatives of the Local Union and asked them to help put the program over. After reviewing the program the local Union representatives felt it was a good one and then attempted to convince the Unit leadership that this was being done for their own good.

EXPERIENCE BLINDNESS

In an effort to get their idea across, the company asked the Union leadership to cooperate in an experiment where they would experience just what a blind person goes through. Each person was given a "Let's Pretend Kit" which contained a blindfold, a toothbrush, tooth powder, suit material, braille reading material, cigarettes and matches.

Each person then went through a routine such as a blind person must go through daily. He first went into the bathroom to brush his teeth. Believe me, the tooth powder went in all directions—everywhere except on the toothbrush. After breakfast he would want a smoke; he would pull out a cigarette and try to light it—there were many burned noses. He then attempted to read his newspaper in braille and later, when getting ready to go out, had to select his suit by touch.

As a result of this experiment the Union leadership in this building supported the eye protection program 100 per cent.

I shall now get on with my subject, "Accident Investigation." The purpose of accident investigation is to discover the causative factors, the hazardous conditions and practices which brought the accident about so that proper action may be taken to prevent a recurrence.

FIND CORRECTIVE CAUSES

It is important to obtain complete information as to the causes—all the corrective causes that led to the accident, not just the major cause.

This point brings out the importance of eliminating the factor of fixing blame. If part of the purpose of the investigation is to fix blame or if the workers think that is the purpose, vital information will often be withheld or the facts distorted.

The use of even the milder term "fixing responsibility" is questionable unless it is made clear that the purpose is to find out whose performance should have been better and in what way so that he may be helped to improve and not again contribute to an accident.

When an accident occurs and someone is injured, the first concern should be for the injured individual. He should be placed in the proper hands for treatment. Usually his condition is such that immediate interrogation should be avoided so as to give the doctor or first aid man an opportunity to make him comfortable, treat him for shock and take care of the injury. It is a mistake to run the risk of upsetting the victim by pressing him with questions. It is much better to wait until he has had a chance to collect his thoughts and get his nerves under control.

In a complete accident investigation report—made by men who report honestly, impartially and frankly—the word "carelessness" should not be used because it has little or no meaning. In one of our plants the "who-when-where-how" idea is used on the accident report and it simplifies matters.

We have a health and safety agreement with the Ford Motor company which provides for the following procedure to be used to correct complaints:

In the first stage, the committeeman who may have a health and safety problem in his district tries to correct it by discussing the matter with the foreman. If the matter is not satisfactorily settled in this step of the procedure, he turns it over to his unit safety director who tries to correct it through zone labor relations and the company's safety man.

If he fails at his level, the grievance is appealed to the second stage in which the local Union tries to correct the problem with the central office of the Ford Motor company. If it cannot be rectified at this level it is appealed to the International Union who takes it up with the top brass of the Ford Motor company.

If the problem cannot be resolved in this stage of the procedure, the Union then gives the company a 12-day strike notice. I am happy to say that we have thus far never had to resort to this last step of the procedure. The Ford Motor company cooperates with us very nicely in matters pertaining to health and safety and our relationship is excellent.▲

THE UNION'S ROLE IN SAFETY

by AL E. BROWN

vice president, United Papermakers & Paperworkers, Portland, Ore.

The majority of workers know little about labor union activities prior to the early 30's. Truly there are some within the movement who took active part in the struggles during and since the turn of the Century. However, by and large what most people know about the early history of the labor movement they have read and of course people's impressions about the labor movement are impressions gleaned from the newspapers.

The good deeds are not reported principally because they are not news. The pride and loyalty to one trade union which existed in the heart of the members in the past have passed away. The member is now demanding that his trade union constantly seek means of giving him service to protect his welfare and improve his economic position.

In the early 30's, the labor movement with which we are familiar, was born. In a number of instances the organizing was on a voluntary basis. However, we must remember that in the major industries organizing was difficult and was extremely time-consuming and costly. The first fight of workers and their unions was to gain recognition from the employers. Once this was accomplished the struggle was to regain the wages which the employer had taken away during the recession when organization was at a minimum.

SOUGHT FRINGE BENEFITS

After this the regaining and the betterment of working conditions became a focal point for activity. Upon being partially or totally successful the demands of labor turned to the so-called fringe items. Recently, the fight to stay ahead of the rising cost-of-living has demanded the attention of the worker and his trade union.

We have passed over rather hurriedly the general bargaining history of the labor movement since its rebirth in the early 30's and of course a number of items which have been important have not been mentioned.

During this time most unions had little time or energy to devote to protecting the safety of the members. In all fairness, however, there have been some outstanding jobs done by the unions in some industries and in some segments of industry.

The best job by the unions has been done, as far as safety was concerned, in those industries deplorable with safety records. This was accomplished principally because safety was foremost in the mind of the worker. He saw his fellow worker injured and killed and as far as he was concerned protection of life and limb took precedence over other demands.

UNIONS WROTE SAFETY CODES

A number of unions have devoted a great deal of time and effort in formulating and promoting safety codes to reduce fatalities and lost-time injuries. Safety codes are extremely important and worthwhile, however, without proper policing the expedient employer and employee can enjoy a field day. Each effort, put forth by the union, regardless of size, is important in the overall effect of preventing injuries to the wage-earner.

Each International Union has an obligation to make known to its affiliated local union that the union has an obligation to represent its membership in the field of safety whenever it can effectively do so. The International Union has a responsibility of encouraging local unions to affiliate with the National Safety Council to promote a united front for labor in the field of safety, irrespective of International affiliation.

International Unions should encourage local unions to participate in plant, community and state sponsored safety programs. Each International Union should establish a department headed by a competent director to assist in promoting safety within its local unions. International Unions with training departments or educational departments should add to their curriculum a course to prepare the plant union safety committeeman to do his job.

USE PUBLICATION MEDIA

Publications such as newspapers, journals, magazines and bulletins can most effectively be used in promoting safety in the mind of the membership. Usually these organs find their way into the home of the member, where not only he, but others can read them. The International Unions should enthuse their local unions with a desire to promote adequate industrial compensation laws so that the injured member will receive adequate care and compensation.

Many employers had little time for accident prevention as long as the community and charitable organizations took care of his injured and maimed worker and the dependents of his fatalities. When industrial compensation laws were enacted and the employers had to assume an additional cost burden, the employer usually became interested in his accident frequency. It is true there have been and there are employers who have been genuinely interested in the safety and the welfare of their employees. However, it is regrettable that in the past there have not been more, because there would be fewer people working at a reduced income because of an injury and there would be fewer widows working to support their families because of a fatality.

EMPLOYERS' ATTITUDES CHANGED

Generally speaking the attitude of employers regarding safety has been changed. This change has come slowly in some instances and rather fast in others. Some employers have the attitude that safety is the problem of management and the carrying out of safety programs is a sole function of management. Others have taken a realistic approach and have felt that a program of accident prevention within a plant must have the support of both labor and management and have created joint labor and management safety programs, giving labor the opportunity to assist in determining what an effective program should contain.

Some of the top management people in the Pulp and Paper Industry of the West Coast have in recent years stated that the most valuable asset this industry has is the people who work in it. Another industrialist stated that safety was on the same level of importance as production. They must have meant what they said because these managements and their unions have established a joint safety program and in a period of the past 10 years have reduced the frequency figure for mills in Washington, Oregon and California, a total of 45 mills with approximately 20,000 workers, from an average in 1945 of 38.99 to 6.04 in 1956.

OCCUPATIONAL HEALTH CONTROL THROUGH ENGINEERING

by FLOYD A. VAN ATTA

industrial hygienist, United Auto Workers, Detroit, Mich.

The engineering part of the occupational health program is concerned with the control of those aspects of the work environment which may have an adverse effect upon the health of the workers in the area. The most obvious conditions are those concerned with the temperature, humidity, lighting and ventilation of the place of work.

One tends to think of these items as concerned with comfort rather than with health but it should be quite obvious that if the temperature is excessively high, or excessively low it can be rapidly fatal and this is indubitably an effect on health, although not a chronic one.

Somewhere between the normal room temperature and humidity at which we are comfortable and efficient, and the temperature and humidity at which we die rather abruptly, there is a limiting value at which men can work, probably not in comfort but without permanent harm. It is part of the business of the industrial hygienist to determine this point and to arrange the working conditions so that the limit is not exceeded.

Sometimes the control of heat and humidity problems is through ventilation and it is always the first idea, when a man is working on a hot job to turn a fan on him. It always helps some but on most hot jobs it is only a part, and often only a small part, of the total control which is needed. To control properly the man's thermal environment it is necessary to consider and often to control both the humidity and the temperature of the air which surrounds him and the sources of radiation which are within sight of his working position.

INDUSTRIAL POISONINGS

The major interest of the industrial hygienist in ventilation comes in the control of industrial poisonings. There are a few cases in which industrial diseases are contracted as the result of swallowing some material or as the result of contact of some materials with the intact skin. But they most commonly arise from the inhalation of dusts, vapors, mists, gases or some other form of material in the air. The reason for this is clear after a moment's thought.

Such materials as the phenolic compounds (carbolic acid, cresols, resorcinols and so forth) and the aromatic amines (aniline, toluidines and so on) are easily and rapidly absorbed through the skin but the undamaged skin is designed to protect the body from attack and is a complete barrier against the vast majority of materials.

Because people do not make it a custom to eat the things which they handle in industry, industrial diseases caused by ingestion are also uncommon. They can and do occur, people do eat occasionally with their hands contaminated with toxic materials and eat as much as is required to produce industrial

disease. I recall one plant where the employees of a heat-treating department had discovered that they could have nicely toasted sandwiches by floating them on a piece of steel on the lead pot. This is one of the better methods for developing chronic lead poisoning by ingestion of lead.

Since this sort of thing is rather unusual, the major problems in the engineering control of occupational disease have to do with preventing various kinds of dusts, vapors, gases, or mists from getting into the air in a place where men can breath them. There are a variety of methods available.

SUBSTITUTE MATERIALS

It is sometimes possible to substitute a less toxic material for the one which is being used and avoid the problem. A rather common example would be the substitution of a water emulsion paint for a lacquer made up with solvents. This solves the problem of control of solvent vapors with no further effort. It does not necessarily solve the whole control problem since the pigment may also be toxic.

Occasionally, it may be possible to avoid the hazard by putting it somewhere where people do not go in the normal course of work. It should not be overlooked that isolated operations almost always require supervision and maintenance and the people who do this work must be protected. An isolated operation which is a serious source of air contamination is very apt to become a neighborhood nuisance.

A more generally applicable device is the enclosure of the process. This is most readily seen in the chemical industry where many processes are carried out in a completely closed system from the raw materials' tanks at one end of the packaged product at the other. When thoroughly carried out enclosure of the process unquestionably provides the most complete and most fool-proof protection for the workmen.

The type of control which is most common is removal of the contaminant, either from the general atmosphere by ventilation or at the source by local exhaust ventilation or by other means, such as wet operations which will prevent contamination from being dispersed into the atmosphere.

The industrial hygienist will generally consider protective equipment to be pretty far down the line as a primary method for controlling a hazard. It is useful as a primary means when the hazard is of short duration or occurs infrequently. The main use of personal protective equipment is as a second line of defense after the hazard is pretty well controlled by engineering means.

The main problem, in a great many instances is to recognize the exact nature and extent of the hazard. When this has been done, the appropriate means of control are apt to be fairly obvious. The fact that the particular condition has never been controlled by a particular procedure which looks correct is not an adequate reason for deciding that it never can be.▲

SAFETY—A MORAL RESPONSIBILITY

by DR. CAMERON P. HALL

executive director, National Council of the Churches of Christ in the U. S. A., New York city

Like the two bit coin in your pocket, safety has two sides. One side deals with what we do when safety fails; the other side concerns what we do to promote safety. Specifically, we are to dig beneath the program and method, beneath the device and technique to the moral basis for why we should do even more than we are in pushing our safety record higher and higher. At this safeguard-end of the safety problem religion has a place as significant as at the breakdown-end. A concern for safety measures is fed by a lively sensitivity to the welfare of the individual that is at the heart of the religious life of this nation. Judaism and Christianity are together in affirming this living truth: the individual is of worth because he is of worth to God. What we as a people do to express in practical terms the worth and dignity of the individual is a moral responsibility upon each of us as an individual and together in groups.

We are intimately involved in all the concerns and interests of organized labor. Safety is one of these, but it is not isolated from other issues which are also moral responsibilities. So before I plunge into the moral responsibility, I want to stress that safety is part and parcel of other labor programs which are also shot through with moral responsibility.

For instance, safeguards against unemployment are an accepted moral responsibility. We have the Full Employment Act of 1946, which makes the avoidance of unemployment a public policy. That a man should lose an opportunity to work is a moral issue; that industry, labor and the public have an obligation in putting a floor beneath the chance to be employed is a moral responsibility. When technological advances, such as automation, are introduced which threaten the availability of jobs, counter measures are promoted by labor, and receive a good hearing among us. Why? Because dealing with threats to unemployment is accepted as a moral responsibility in our American way of life.

UNEMPLOYMENT—A MORAL ISSUE

But whence come major threats to a man willing to work being unable to work? Cyclical, technological, and other causes, to be sure, stand out. But men are [illegible] too often—out of a job because [illegible] been hurt or maimed or disabled as well as fired because of some overall economic or technical squeeze. Loss of job [illegible] is due in large part to failure in safeguards against accidents. Safety is a moral responsibility because assuring the opportunity for employment is a moral responsibility.

Again, ethical practices by both labor and management are recognized as a moral responsibility of both. This phrase—"ethical practices"—has taken on specific reference to the right of the individual union member to protection against the misuse of union and welfare funds. But certainly he is equally entitled to protection from unnecessary accidents—through education and training, on the one hand, and through physical safeguards on the other hand. Blindness by a union toward, or tolerance by an employer of, any carelessness in safety measures is an unethical practice toward union members and other workers—it is a failure in moral responsibility.

SAFETY PROMOTES FREEDOM

And thirdly, American labor is out in front in helping bring the strength of the United States into the free world. A sense of moral responsibility for safety is at the heart of what the free world stands for—the worth and dignity of the individual. Many tests that we Americans have to meet before world opinion have to do with safety—tests that we are far from passing with the grade that we can always be proud of. Last fall, we had to expose to the world the hazard to their safety of nine Negro children in going to an Arkansas school. That kind of hazard to safety is a failure in our moral responsibility toward the worth of a child.

But turn to another aspect of our national life. Our march to ever greater abundance, ever greater productivity, ever greater technological prowess is impressive, even breath-taking. But we should be equally concerned with the pace we are setting in on-the-job, occupational safety. And beyond this we now stand on the threshold of the nuclear energy industry, with its reactors and isotopes, its fissionable fuels and their radio-active wastes. The hazards of radiation in this new industry give to moral responsibility for safety a new dimension and urgency.

Let me just mention three characteristics of the potential harm there is in radiation: 1. when you are hurt by over-exposure, you do not know it at the time and so start caring for it; you learn of it—later; 2. the harmful effects are not transitory; instead, they add up—accumulatively; 3. radiation can reach into the human reproductive system and hence blight later generations. While these dangers are near the surface in the use of radio-active materials, they can be kept under control by vigilence. Certainly safeguards against these risks should have top priority in a safety program.

When a stranger, say from the relatively underdeveloped countries in Asia and Africa, or from behind the Iron Curtain, should ask of us, "In your impressive rush toward mounting economic prosperity, and now into

the age of nuclear energy for industry, how expendable is the individual—his fingers, his limbs, his lungs, his very life?" That is a fair question in the light of what we profess as a free world. We had better make sure that the answer we can give at any time will also sound impressive.

These past few moments we have been seeing that safety does not stand off by itself as a moral responsibility; rather it stands inside many of today's moral issues. I want now to point out that by itself the preservation of safety is one of these great moral issues.

ACCIDENTS ROB INDIVIDUAL

For one thing, accidents hurt the individual. They rob him of his God-given life, or his God-given right to full growth as a person through health of body. "Thou shalt not kill" is the moral basis for any decent society; and a man may be killed not only by a gangster's bullet but through blindness or carelessness by others, including ourselves as citizens, to safety protection.

"Thou shalt not kill" means that directly or indirectly we are not to kill another's chance for personal development because he has been made a cripple or invalid through an accident. Of course we know of maimed or chronically ill persons whose spiritual poise and courage and cheerfulness put to shame many who carry no such handicaps. Resources for living are not, indeed, tied to hands or feet or even eyes. But the truth is that God has made men with capacities of the body for the protection of which the community as well as each person is morally responsible.

The promotion of safety is a moral issue, in the second place, because of the family. The family is, in a way, a spiritual and social body; and what happens to any of its members affects all of them. The price paid for accidents is paid by the family—often a high price. I am not thinking here only of the drain upon the family budget, although that can be important. A child and a wife and a mother are as much a victim of any accident as the husband and father himself; and with 22 million women now constituting 33 per cent of our labor force, the immediate victim may be a wife and mother. The drain upon the family at the time of the emergency, or throughout the convalescence, and in some cases extending on into an indefinite invalidism makes safety a moral responsibility.

Again, safety is just that because an accident weakens or deprives society of its greatest economic asset, the productive worker. We live in a God-given world of vast and still unimaginable natural resources; but what good are they for meeting human need apart from the work of men! An injured worker is a double drain upon our economic health. For one thing, a worker hurt becomes less of a worker or even a non-worker. His productive capacity, in part or in full, for long or for short, is lost to the work force. For another thing, a worker hurt becomes one upon whom the product of other workers has to be spent.

The resources of society have to go not to building on his strength but in salvaging his weakness. To be sure, God's world is richly endowed with the resources for healing; and we can take much pride in the doctors and nurses, in the hospitals and medicines which are a sign of our technical skills and our humanitarian ideals.

But at best these simply make up for men being hurt through ignorance, carelessness, inhumaneness, or man's other frailties as a human being. If we could cut, say in half, what we as Americans spend for the doctors, the buildings, the medicines and the other costs for healing those hurt through accidents, what riches we would have for schools and teachers, for housing and recreational programs,—yes, for the healing needs in underdeloped countries! Because of the costs of accidents to a nation's economy, their prevention is a moral responsibility.

Of course it is said that the prevention of accidents also costs, and perhaps we cannot afford this item of expense. I am reminded in this connection of the oft repeated assertion that slum clearance, for example, is so costly that we cannot afford it.

But the truth is that slum areas cost too much to be tolerated. With their overcrowded dwellings, their over-crowded classrooms, their pitiful recreational opportunities, these areas lead to economically wasteful costs—such as added police to enforce laws, added medical facilities to deal with the above-the-average sickness, added court programs to deal with broken homes and juvenile delinquency. Society saves money by spending it on neighborhood rehabilitation. The same principle works in regard to the prevention of accidents.

We have been counting up the human costs of accidents—the cost to the person, to his family, and to us, his neighbors and fellow citizens. To come at this thought from another angle, progress in accident prevention is important for the conservation of our human resources. In our best moments, we know that "this nation's greatest resource is its people, and that what we do on behalf of our human resources is the test and promise of a democracy."

CONSERVE HUMAN RESOURCES

What does it mean for a people like we Americans to take seriously our human resources? I suggest it means at least these four things. First, it means opportunity for the fullest development of each individual through education. Any society that proclaims to the world its worth of the individual owes each individual an adequate opportunity to develop his capacities—and by doing this for him we enhance our own human resources. Provision for free education, now all the way into the university, is our way of enhancing our human resources through helping each individual to become as much of a person as he can.

A second is provision for freedom of religion. Where men place their highest loyalty, and where they look for their deepest strength for the living of life, is a personal thing for each man. His choice must be a free one, uncoerced and unintimidated. The provision for freedom of religion in our Constitution, and the strengthening of our religious institutions—churches and synagogues—through voluntary action by our people enhance our human resources.

A third element is the employment of people according to their own choosing. Free labor we believe offers a better chance for men to give of their best in their work than a regimented or unduly restricted labor force. Not only full employment but freedom in the choice of employment is a means in the best use of our human resources.

Through our educational and religious institutions we work for the development of our human resources; through a free labor market we seek the best employment of our human resources; and through the safety program which this Congress represents we seek the fourth major pillar in a national policy on human resources—namely, their conservation.

Not only is a safety program a moral responsibility, but in its meeting the challenge from hazards to life and limb, this program shows a high level of moral responsibility. It stands for a maturing of our long efforts to deal with the threat in accidents. When we look at the road we have come, I see this safety program as being the third stage.

The symbol of the first step is the hospital. It was not so long ago in the story of mankind, that when men were injured, they were left to die, or to turn beggars, or to be cared for out of the meagre resources of their family or neighbors. But some centuries ago, elements in the community took compassion on those hurt or otherwise ill, and hospitals were started. Later on the social conscience of our communities did not leave this only to private channels of compassion; the provision of free medical care became a moral responsibility of citizens working through their levels of government. However, this kind of concern did not focus on the cause of accidents but rather on doing something for the victims of accidents.

The second step has its symbol in workmen's compensation laws. This was truly a large step ahead. These laws make at least part of the cost of industrial accidents a charge on the employer in whose work place the accident occurred; this, among other things, puts a premium on safety measures. These laws also set up a careful and orderly procedure for assuring that the injured worker does receive the care which he not only needs but to which he is entitled in the name of justice.

LAWS RELIEVE HARDSHIPS

These laws also recognize a most important fact about accidents: a disability means loss of work, and loss of work means loss of income—with all that that means to the worker, his family, and the economy. Hence these laws provide for not only taking the cost of accidents from off the person, but in at least some small measure they take off the economic hardship from the loss of income.

This is sheer gain, but these laws still focus on doing something for the man who has met with an accident, rather than on driving full steam into eliminating causes for accidents. When a ship is sinking, then the whole weight of responsibility rests on manning the life boats and getting the passengers and crew off the vessel. When an auto has gone hurtling off a thruway then the weight of moral responsibility is to rush medical care.

But neither life boats nor ambulances are the full measure of moral responsibility that rests upon us today when ships still sail the high seas and cars ride the highways. Our moral sense has grown up beyond that level of moral satisfaction. In its modern concept moral responsibility stresses preventing the worst from happening on the oceans and on our roads rather than being content with picking up the pieces after the worst has happened.

Total security is a goal that is beyond our reach, but great progress can be made when men of competence and good will and devotion join together to help each other in every way possible to promote safety measures against accident hazards. The symbol of this step is, I suppose, the National Safety Congress itself. It stands for moral responsibility toward these hazards at its best, for our deepest responsibility toward the victim of accidents is to see to it that all is done to keep him from becoming a victim. And that is a worthy cause for all of us, wherever we are—in labor and in management, in education and in government.

LABOR'S STAKE IN SAFETY

by A. J. HAYES

international president, International Association of Machinists; vice president, AFL-CIO, Washington, D. C.

I don't intend to stay within the limits of this title because I am certain little new information could be said about "Labor's *Stake* in Safety. It is obvious that no one could have a greater stake in industrial safety than the men and women who are the direct victims of industrial accidents.

To an employer — matters of industrial safety, occupational disease, accident prevention and workmen's compensation—are all tied up with economic considerations. They are important insofar as they affect—and can be made to reduce—insurance costs, training costs, and material costs. But these are all money costs—cash costs—costs that are measured in dollars and cents.

To a worker, on the other hand, an industrial accident is a matter of something that is even more tangible than money. It is a matter of a man's blood, bones and sinew—of tragedy, suffering and sorrow. And sometimes, in fact, more than 50 times a day—on every working day—it is a matter of life itself to someone, somewhere, in this country.

That is why I say that labor's stake in safety is pretty obvious. Therefore I will touch upon aspects of the subject that are not often discussed—aspects that are somewhat controversial. Perhaps they are not discussed because they are controversial.

ETHICS IN SAFETY

Since my views and public statements on the "corruption in unions" issue have been as frank and honest as I can make them, I see no reason to be any less candid in stating my views about matters of industrial safety. I assure you, however, that I am not injecting controversy for its own sake, but because these are matters that concern the men and women who run the daily risk of being injured, diseased or killed on their jobs.

Safety—and accident prevention—have an ethical as well as an economic side. I think none of us—whether we represent labor or management—would disagree with certain basic ethical principles in the field of industrial safety. We would all agree, for example, that the objective of industrial safety should be the preservation of human life and the protection of human health. We would further agree that an employer has a moral responsibility to protect his workers against disease, accidents, mental stress and infections from the conditions of employment.

We all profess to agree that human life is not cheap; that man is not something to be sacrificed to a machine. And yet, these ethical principles are not always applied in day to day life nor are they self-enforcing. In practical application they come into conflict with individual economic interests, and thus must be enforced either through group action, or by society as a whole through political action.

As a rule, society does not move as fast as the need would indicate. We all know, for example, that the first industrial revolution had run its course for more than 100 years before society got around to adopting and enforcing rules and regulations of industrial safety. For more than 100 years industrial workers were given no legal protection against the risks and hazards of industrial employment.

Here and there, a lone individual employer might attempt to provide decent and healthful working conditions for his workers. But on the whole, the story of factory employment in the 19th century—and through the early 20th century—was a pretty ghastly one.

I don't need to go into the details that are indicative of the cold indifference with which human life was held in American mines and factories. Suffice to say, it did not seem to matter how many men, women and children were killed or crippled in the course of a day. There were always more waiting at the gates the next morning—driven by raw poverty to plead for a chance to jeopardize their lives and limbs.

SOCIETY BROUGHT CHANGES

The point I am getting at, of course, is that change—when it came—was not the result of any regeneration of moral and ethical conviction on the part of employers. It came rather because society as a whole was thoroughly revolted. It came because the American people were finally shocked enough to correct a condition that had prevailed—and grown worse—for 100 years.

So we finally got factory laws—and workmen's compensation—and an organized effort to make mines, factories and mills safer places to work. But of all the legislation aimed at this objective, workmen's compensation was the key. For until employers were made directly and financially responsible for the results of workers' accidents, they had no economic reason to prevent accidents. The whole pattern and fabric of our industrial safety program throughout the nation rests entirely on how good and how effective our workmen's compensation and our occupational disease laws are.

ECONOMIC REASONS

Oh, of course, you can point to many other good economic rationalizations for industrial safety. You can say industrial accidents add all kinds of direct and indirect costs to production. You can point to the cost of hiring and training a new employee, of equipment damaged in a work accident, of the time lost by other employees when an accident occurs.

But I will throw them all right back to you and say that these considerations were present long before we had industrial accident programs—and that it wasn't until accident prevention was reinforced with workmen's compensation and occupational disease legislation that employers really became safety conscious.

So it seems that the thing that counts here is how good our workmen's compensation and occupational disease legislation really are.

And that's a good question! I've spent my whole adult life in the labor movement. As a matter of fact, I was projected into it by the very thing we are talking about here today—an industrial accident. I went to work at 17 years of age because my father was totally disabled by a work injury—an injury that eventually killed him.

In the course of many years of studying and dealing with the problems of my union —which are, of course, the problems of the members of my union, I realized that our present system of workmen's compensation and occupational disease legislation is completely and wholly inadequate to meet the needs of our complex industrial society.

I am not alone in that conclusion. There are, in fact, many men in the labor movement today who feel even more strongly

than I do—men who are firmly convinced that workmen's compensation has been a gigantic swindle on the American worker.

This nation has tried to deal with a national problem by having 48 seperate, conflicting — and in a sense — competing state statutes. And there is no doubt but that workmen's compensation is one kind of labor legislation that states use to compete with one another to attract industry.

In fact, whenever we go into the state legislatures to get improvement or expansion of existing laws, we invariably meet employer counter-arguments to the effect that any further improvement in coverage or benefit structure will shove industry into the waiting and sympathetic arms of states which are more concerned with payrolls—than with the people on those payrolls.

SAFETY INTEREST LACKING

Certainly the health and safety of the nation's work force should not be a pawn in any state's bid for new industry. But that is just what it is under a system that allows Mississippi or Arkansas or Georgia to compete for industry by offering low workmen's compensation benefits and a minimum of safety regulation at the plant level. Why should an employer pay $40 a week for a temporary total disability in Illinois—when he can go to Arkansas and pay $25 a week for the same injury?

The situation in workmen's compensation legislation is so bad, in fact, that the Secretary of Labor, Mr. Mitchell, although speaking for an administration that normally follows a hands-off policy in state legislation, has been constrained to speak out and to plead with the states to bring their laws into line with modern conditions.

But because employers can play off one state against another in this matter, the results have been somewhat negligible. There is no indication that the remedy will ever catch up with the need, until there is broader recognition that industrial accidents are a national problem—one that is truly solvable only on the national level.

The lack of a strong and equitable workmen's compensation system leads to a corresponding lack of interest in enforcement of safety codes and regulations. In many states the Bureau of Factory Inspection—by whatever name it goes under—is little more than a sop to the conscience of the state legislature. In fact, the inspection service in such states is not only understaffed, but the staff is underpaid, untrained and technically unqualified to do a competent job in a field that needs a high degree of competency.

But as bad as the situation in workmen's compensation and factory inspection may be, the situation in occupational disease coverage verges on the criminal. And this is a matter of more than just poor legislation. It is incredible to think that in the second half of the 20th century 20 states still either have no coverage or limited coverage of occupational disease.

But the greater problem is that there is too little understanding of the nature and complexity of occupational disease. The range and source of occupational disease in modern industry is practically limitless. None of the ways by which man makes a living is completely free of some hazard to physical or mental health. The risk of occupational disease grows greater every day as industrial processes become more and more dependent upon and saturated with toxic dusts, fumes, vapors, gases, acids and alkalies.

Every day thousands of workers are exposed to everything from arsenic to mercury poisoning, from benzine compounds to magnesium poisoning, from sulphuric acid to chromium poisoning. Thousands have no physical or legal protection whatsoever against the chemicals and poisons that are slowly killing them.

UNAWARE OF RISKS

In fact, many are not even aware of the risk. They will find out when it is too late. In many states they will also find out that they have no right to compensation under the occupational disease law. I wonder how you tell a man who has contracted carbon tetrachloride poisoning, for example, that he isn't entitled to benefits under the occupational disease law because the legislature of his state hasn't seen fit to recognize that carbon tetrachloride poisoning is an occupational disease?

I recently read a statement to the effect that "the scope of occupational disease is vast almost beyond calculation" and "it comes, in fact, unpleasantly close to being the major public health problem of our time."

If that is so—and I for one am inclined to believe it—it is tragic commentary on our time—on the ethics of a business community that has done so little about it. It is even more tragic in view of the fact that we are now entering a new phase in our industrial development—a phase of such sweeping change that some commentators have referred to it as a new industrial revolution. Think of that—we are entering a new industrial revolution without ever having fully solved the problems that attended the old one.

I wonder if it will again take us 100 years to make even a decent start on the health and safety problems that will arise out of automation and atomic energy. These problems are not a part of a distant tomorrow but are already a part of the world today. Now more than 1,500 industrial plants are using atomic materials in one form or another—in 1,500 establishments American workers are already exposed to the hazards of atomic radiation.

Can we say the state laws in existence today—indeed can we say that any system of state inspection and compensation — are adequate to care for the workers who will get leukemia or bone cancer because of exposure to atomic radiation?

DON'T KNOW PROTECTIONS

Personally, I feel somewhat discouraged about the prospects. How can the states protect and care for victims of industrial radiation when they haven't yet learned to protect and care for victims of occupational diseases that have been prevalent for generations? We need only look at silicosis and pneumoconiosis to see the failure. And failure to provide adequate treatment and compensation for these dreadful dust diseases is paralleled by the failure of industry to finance programs of research that would lead to their prevention at the source of exposure.

Related to the problems of occupational disease and radiation is another matter that has received almost no attention in industry, or in government. That is the matter of mental disease. We already know enough about automation to know that it will throw workers into a lonely and eerie world inhabited by monster mechanical devices.

We also know that our mental hospitals are already crowded with people who have broken down under the stress of life in a complicated, impersonal and highly industrialized society. But we don't know how much more stress people can take, or what effect automation will have on a worker's nervous system. At what point does the human mind crack up from sheer loneliness, lack of contact with fellow workers, from uninterrupted repetition and brainwashing boredom?

I am not just tossing questions out at random here. All of the things I am talking about—from workmen's compensation and occupational disease to radiation and mental distress—have a valid relation to industrial health and safety—and are proper subjects of labor interest.

LOOK FOR DANGERS

For safety is a broad term. It is defined as: (1) the state or condition of being safe; (2) freedom from danger or risk; and (3) freedom from injury.

Safety means freedom from any kind of danger, risk or injury. When we apply that definition to industrial conditions we must think in terms of hidden dangers as well. We must change our attitude toward occupational diseases—go out looking for them instead of trying to pretend they don't exist, or implying if they do exist, that they have no relation to industrial causes.

I am not exaggerating when I say that industry has taken a "head-in-the-sand" attitude up to now. It has tried to cover up occupational diseases rather than to isolate, prevent and care for them.

There has been *little research*—either governmental or private—in the field. The Public Health Service spends less than one cent for each worker each year on the prevention of occupational diseases. The National Institute of Health, which has made hundreds of research grants during the past three or four years, has made less than half a dozen in the field of occupational health. There is an iron curtain of secrecy around this whole subject.

Not only does industry fail to support and subsidize research in occupational diseases, itself, but men who have tried to do independent research find that it is virtually impossible to get facts, information, or cooperation from the people in industry who are in a position to help. Worse still, if a

research project does tend to show a correlation between employment and disease, the authors find it is almost impossible to get their work published or distributed.

The result is a deplorable lack of information about occupational disease. We are years behind other countries in this respect. One expert in this field said that research in pneumoconiosis in this country is 25 years behind that of Great Britain.

SECRETS PREVAIL IN INDUSTRY

Industry actively opposes objective research and free interchange of information on occupational diseases because it is more afraid of the possibility of paying compensation benefits than it is that workers will die from lack of proper information and adequate precaution.

Here are specific examples that will illustrate this point. There is some medical evidence that the chemicals used in the dye industry and in the manufacture of synthetic rubber cause or contribute to cancer of the bladder. In fact, one of these—amine—is so dangerous that it has been outlawed for all industrial uses in Britain since 1951. But efforts to prove, publicize and restrict the dangers of this deadly acid have hit stubborn resistance in this country. The large chemical companies have refused to find out if amine does contribute to cancer of the bladder and have strongly resisted independent research into this problem.

Much the same situation holds true in the asbestos industry. There appears to be decided after-effects on workers who produce asbestos in that there is a marked correlation between asbestos employment and lung cancer. Here again, the industry has been traditionally reluctant to cooperate in a full scale scientific study of this curious correlation. This reluctance to do research in health hazards recurs in industry after industry.

DOCTORS OFTEN BIASED

But even worse when workers do succumb to cancer of the bladder or the lung, or to some other equally horrible diseases, we are treated to the spectacle of company doctors who testify that the disease couldn't possibly have been caused by their employment. Doctors are supposed to be above reproach in our society. But as a labor official I have known of too many cases in which company doctors have testified against workers and for management in occupational disease cases even though they knew their testimony was biased.

It should not surprise us that doctors can be unobjective in these cases where their testimony is bought and paid for. We have only to look at the wide-spread difference of opinion among doctors as to the effect of cigarette smoking to see that their testimony can sometimes be something less than truthful. Most doctors who are not in the pay of cigarette companies are convinced by all the scientific evidence on record that cigarettes undoubtedly contribute to lung cancer. But the doctors on the payrolls of the tobacco companies either deny that cigarettes contribute to lung cancer, or at best maintain that there is not yet enough proof.

As we contemplate these conflicting views among professional men—and as we thoughtfully study the reluctance of industry to be honest about this matter of occupational disease—we cannot help but wonder whether the lust for profits has made many men forget the real purpose of life. What is the real purpose of life? Is it production and profit—or the well-being of the individual? If there is conflict between the two, do we sacrifice production and profit or the well-being of the individual?

The ethical answer is obvious. But the practical methods of reaching the logical ethical conclusion are more difficult.

FEDERAL ACTS NEEDED

We could make a start by enacting comprehensive federal workmen's compensation and occupational disease legislation to take the place of the chaos that results from having 48 different state systems. But I have no hopes for such a constructive approach in the foreseeable future. I am afraid the insurance lobby, and the employer groups that profit from weak administration are too strong for us at this time. So we'll just have to make that one of our long range objectives.

But there are some things we can do right now. We can try to have programs set up in the National Institute of Health and in the Public Health Service which would recognize the importance of occupational disease—and which would put the research effort in this nation on a par with that of other civilized industrial nations.

If we cannot get decent factory inspection from the state goverment, then we in the labor movement must resort to self-help. Many unions are thinking in terms of collective bargaining clauses which would require the employer to adopt the safety standards set by the American Standards Association as the minimum acceptable in the shop.

LABOR FIGHTS FOR SELF

We are also prepared to bargain for more supplemental injury benefits when the compensation provided by state laws is not adequate to sustain a worker and his family. Although our efforts will directly benefit only the 17 million organized workers, perhaps they will release new pressures that will eventually result in improved legislation benefiting all workers.

The American labor movement has but one purpose—one reason for existence in American life—to serve and protect American workers. There are times when we make ourselves pretty unpopular because we keep looking for the things that are wrong with American industry and American society.

I may have offended industry men with this indictment of the ethics and morals of our business community. But I would be derelict in my duty and false to my trust as an elected officer of one of America's greatest unions if I did not say frankly and candidly that we in the labor movement are not satisfied with present legislation relating to industrial health and safety, workmen's compensation and occupational diseases.

In a sense this is a great challenge to the National Safety Council—a challenge that can be met only if all facts are squarely faced. If we in the labor movement could count on your assistance in the fight for better legislation and more research on both the state and federal levels we might, together, make this a far happier, healthier and safer nation in which to live and work. ▲

GOOD COMMUNICATIONS HELP SAFETY

by GEORGE SCRIVEN

public relations director, United Rubber, Cork, Linoleum & Plastic Workers of America, AFL-CIO, Akron, Ohio

Our organization has been safety minded for many years. The record on that score speaks for itself in a loud and clear manner. The results of our efforts, in cooperation with enlightened managements, tell the story of how we have seen the number of accidents reduced in the plants in which our members work. I shall not go into specific figures on frequency rates and such.

I don't suppose any of you would dispute the flat statement that good communications help safety. But I'd like to try and give you some of the techniques, the how and the why of that statement.

First, let's do a little word analyzing. I certainly don't want to sound like the pontifical professor lecturing his class on semantics. But when we say *good* in our topic, "Good Communications Help Safety," we immediately infer that there is another kind besides good. And there certainly is. I think there is a lot of bad and fuzzy communications going on in all fields.

Within the subject matter at hand, I would say the word *good* means that type which gets some concrete reaction and results. In the United Rubber Workers, we think our communications have been *good* because we have the results to show for it.

MUST HAVE RECEIVER

Now for the word *communications* in the phrase. You can't have communications—the *good* type that is—unless someone is sending the message and someone is receiving it. I was in the Air Force in World War II, and I served as a radio operator in the Pacific aboard a B-29 Superfortress. When I sent a message and no one received it, I didn't have communications. I was

just talking to myself, and that wasn't enlightening and certainly was of no practical value.

You've got to get through or you aren't communicating. Even with good communications—yes the best—you must remember that the transmission of ideas and advice is just a part of helping to promote safety.

You can't have good safety unless you have safe conditions—no matter how good your communication system is. So that's why we must keep in mind that good communications is an aid to safety and just doesn't bring about safety automatically if proper safeguards are not taken in the first place.

Good communications then basically gets the word out to encourage us all to do what we should do. Remember, the word has to be heard to have a chance of doing any good.

What are some of the ways of getting that word out—and in a manner that there is a good chance that it will be listened to? I'll try to outline some of the ways that the United Rubber Workers has found to be most effective.

Our union is considered as one of the labor unions which pioneered well-established safety programs, and I believe some of our communication techniques have been big help mates in our efforts. So, I'd like to talk a little bit about: mass communications, individual and/or selected group communications, the checklist technique, accident follow-up communications, union classes and institutes.

MASS COMMUNICATION

First, considering the broad subject of mass communications as it applies to safety, I think it might be proper to point out you can't expect anyone to do something or not do something unless you clearly and concisely tell him what to do or not to do.

By that I mean that clear and proper direction is the responsibility of the sender—you as the safety man—in this business of communication. You've all no doubt heard that one of the biggest complaints that employees have about bosses is that instructions are not clearly given.

I think it's that way in using communication tools in safety work. The message must be clear, complete and there must be a reason for it. Anything short of that isn't going to get through and is a waste of time.

The pamphlets, booklets, posters and newspaper stories that we use in our safety work in the United Rubber Workers must meet the test of completeness, clarity and, most important of all, carry the reason, either directly or implied, for doing or not doing something to promote safety. I'm afraid there are times when we all write or draft messages that are clear to us, but are vague in mass appeal.

In some recent issues of the *United Rubber Worker*, the official monthly publication of our union, featured in a prominent spot, and boxed so that it can be easily cut out, is a list of "dos" for workers when filing injury compensation claims. This is a mass communication effort in helping safety.

PRAISE HIGH RECORDS

Another recent issue of our paper carried a story concerning the setting of a new safety record by one of our local unions in the East. It pointed up the tremendous record, comments by company and union officials, and named the committee members and the work they did in helping bring about this record.

Our *United Rubber Worker* is probably our most effective mass communication sprung board for getting across our safety message. Your union or company paper can do the same.

I think posters are effective too. I particularly like the "right way" and the "wrong way" illustrations on safety posters and literature. Another effective technique is to mix in a few household hints with a safety message so that you'll appeal to a wider audience—the whole family, we hope. Often overlooked is the fact that posters can be placed in places besides the company bulletin board or in the union hall. I'm thinking particularly that posters in a coffee stand or restaurant near a plant can be effective.

Remember, basically we're selling safety and one of the tools of selling is a program of constant and consistent reminding. That brings us to our second point—that of individual and/or selected group communications.

Here, for the most part, I want to deal with the safety committee in a plant. In the rubber industry, we have a number of joint labor-management safety committees.

Many of our committees made up of union representatives hold regular meetings with management representatives for the purpose of discussing safety problems that arise within the plant. Our policy is that our safety committees should be authorized either on a joint basis with management or on their own to make safety inspection trips throughout the plant. A good exchange of information between union and management goes a long way towards helping promote safety. That's good communications.

INDIVIDUAL, LIMITED MESSAGES

We have also found it advantageous to have minutes kept of safety committee meetings. Copies of these minutes can be provided to members of the committee and the business of handling safety problems can be expedited. That's another example of good communications.

Perhaps one of the most important jobs of the safety committee should be to help promote an educational program on a joint basis with management to point up the importance of the safety program.

Everyone likes recognition for a job well done. That's why a good awards system of some type can be developed on a joint labor-management basis or a local union level to give recognition to the department or division of the plant with the fewest accidents.

I know this is a familiar technique to many of you, but I want to point out that it is an effective communications technique too because the word is passed through departments, thus stimulating others to reach this award goal.

In another phase of selected group communications, I believe it is important that the safety committee members become acquainted with the state division of safety regulations or codes and the division of the state labor department which has the authority of enforcement of safety regulations or codes to find out how these state agencies can help their local union further their safety program.

The checklist technique—the third point in this discussion—dovetails to a great extent with the work of the safety committee. A good safety inspection guide should be given to the local union safety committee to make sure that certain items are looked into at each inspection made by the safety committee.

I like to compare this with the checklist that an airplane pilot uses before take off. He doesn't take a chance on remembering everything that should be checked. He and his co-pilot take checklist in hand and go down a list of dozens of items to make sure that all is right before take off.

A safety committee should follow a complete checklist. This, too, is a form of good communications helping safety. Such a check list—which guards against memory lapses, oversights and provides a complete record—should include such points as housekeeping, material handling methods, adequacy of space, points of operation, guards, maintenance, hand tools, floors, platforms, stairs, railings, cranes, hoists, elevators and railways. Other points should include electrical equipment, eye protection, other personal protection equipment, dust, fumes, gases, vapors and mists, pressure vessels, other explosive hazards, oiling methods, chains, cables, exits, yards, roofs, roadways and any other items peculiar to a particular operation.

ACCIDENT FOLLOW-UP

I have listed accident follow-up communications as a fourth point because I believe that we can learn from mistakes. But I believe we can only learn from those mistakes if we discuss them and—in short communicate.

The purpose of accident investigation is to discover hazardous conditions and practices so that further accidents from similar causes can be prevented. We attempt to tell —communicate, if you will—our members in safety work how to investigate accidents thoroughly to find how and why the accident happened and how and why it could have been prevented and can be prevented in the future.

Often, in investigating an accident you will find an allied hazardous condition that will enable safeguards to be taken before it is too late. We flatly say, as a part of good communications in safety, that the safety committee should completely investigate every accident and follow up the investigation with action. Keeping the lines of

communication open between union and management makes this follow-up possible.

As a further part of getting the word out —or communicating with our safety committeemen, we conduct classes and clinics, which is the fifth and final point of this discussion. At our compensation and safety clinics some time is spent in off-the-job safety, such as on the highway, in traffic, and in the home.

The International Union has a library of safety films used by local union safety committees as well as at our clinics. We try to bring in outside speakers such as safety division department heads and state factory division inspectors to give our safety committeemen a better understanding of how best to do their jobs.

Our committeemen — and this is again showing the value of communications—attend city and state safety conferences as well as the President's Conference on Occupational Diseases and the National Safety Congress. Incidentally, a good number of our local unions are affiliated with the National Safety Council, Labor Conference, and we had more than 30 delegates from widely-scattered local unions attend the Congress.

ROLE OF THE U. S. DEPARTMENT OF LABOR IN OCCUPATIONAL SAFETY

by S. J. BUTCHER

supervisor, safety & union branch, Bureau of Labor Standards, U. S. Dept. of Labor, Washington, D. C.

The U. S. Department of Labor has the responsibility for fostering the welfare of the nation's workers. This has been done in the past and is being done now—both directly and indirectly:

Directly it is being done through assistance to labor unions at the national and international level in suggesting safety organization plans and programs; through safety training courses for union representatives and safety committee members; through research and the preparation of promotional and educational publications.

Indirectly it is being done through training state factory inspectors to do a more thorough and comprehensive job of inspection to provide safer work places; through special industry safety programs promoted through state agencies and operated through both labor and management to reduce work injuries in specific industries in certain states; through support of improved workmen's compensation laws; through assistance to states in the development of safety standards and codes; through participation on committees developing and revising American Safety standards; and through a large variety of technical and promotional activities dedicated to the elimination and control of hazardous working conditions and the development and use of safe work methods.

While many of these activities are carried on in terms of services to other groups and agencies which are on the firing line and are directly responsible for accomplishments, the Bureau of Labor Standards is proud of its supporting role in helping to supply many of the services which result in safer working conditions for the working men and women of America.

The Labor Conference offers another common meeting ground on which those agencies and groups having facilities and personnel available may make these services known and make arrangements for their use.

As always, the Bureau of Labor Standards is prepared to assist not only state agencies, employers and unions, but also groups such as the Labor Conference in the promotion of safety. Fundamentally, this conference is concerned with three steps of safety promotion: organization, planning, and implementation.

The organization is now well established; we are, at this moment, in the process of planning: The Bureau of Labor Standards has the field staff to assist in implementing the projects of this Conference.

FIELD STAFF

Our field staff consists of regional safety consultants who service state, federal, maritime, union and industry activities within their areas. While there will be certain limitations of time, personnel, and funds, through this staff the Bureau will be able to allot some of these men to the field work with key officials in these activities:

Training—Conducting safety training courses for key union personnel in selected locations. Such courses have been conducted for the steel workers, auto workers, rubber workers, machinists, and several others, two courses having been given in Arkansas and Iowa this month.

Organization—Assisting in the development of plans and action in the organization of safety committees and safety activities at the national, international, and state central level.

Promotion—Developing and assist in conducting promotional safety programs for selected industries as is now being done for the construction industry in Pennsylvania, Kentucky, and Minnesota.

Publications—Conduct research and develop material for helpful publications. As an example of the type of publications that may be developed, here (demonstrating) is a "Union Safety Guide" which explains the procedures for establishing safety committees, from the International to the Local level. It also gives examples of policy and types of safety clauses used in union contracts. While the Department of Labor cannot provide sufficient copies of such publications for total distribution, the materials can be compiled and prepared for re-printing by your unions, the Labor Conference, or any other group.

The Bureau of Labor Standards is a Federal agency established to be of service to State Labor Departments, employers, and unions in the promotion of worker safety. It is our policy and our desire to provide these services where they are requested and where they will do the most good.

The Bureau has a field staff to conduct safety training and to assist in organizing safety committees. The Bureau can aid in the development of promotional methods and materials, and can prepare material for publication.

However, it is necessary that you make your needs known. Tell us what you want, and we will make every attempt to provide you with the services and materials to make your programs active and successful.

NORTH DAKOTA TAKES SAFETY TO THE SMALL COMMUNITIES

by B. M. RYAN

commissioner, Workmen's Compensation Bureau, Bismarck, N. D.

We all have had our troubles at times trying to put over our safety program but I think we should say with the Poet,

"When things go wrong, as they sometimes will,
When the road you're trudging seems all up hill,
When the funds are low and the debts are high,
And you want to smile but you have to sigh,
When care is pressing you down a bit,
Rest, if you must—but don't you quit."

Industrial safety in North Dakota is dependent largely upon the plant inspection program of the Workmen's Compensation Bureau and the various safety education and training projects of community safety

groups, Volunteer Fire Department and contracting employers promoted and assisted by the safety department of the Bureau.

The North Dakota Workmen's Compensation Bureau is administered by three commissioners. It has been my privilege to represent Labor on the Commission since 1945 and for several years have been the commissioner in charge of the safety department. A boiler inspection program authorized by the 1953 legislature was added to our safety department.

Mandatory compensation coverage in North Dakota applies to every employer who employs one or more, except domestic help, clergy, and farm labor. For this reason, particular emphasis is placed on plant inspections to obtain as complete a coverage as possible. A prescribed form is used as a reminder and upon completion of a plant inspection, is signed by both employer and inspector. The original is left with the employer and the carbon copy filed in the office. Fire hazards are also checked and reported by letter to the local fire chief and state fire marshal.

Unless unusual hazards are found during plant inspection, a follow-up letter is mailed to the employer listing the recommendations and enclosing an addressed postal card for convenience in replying. If no reply is received within 30 days following inspection, a second follow-up letter is mailed. This procedure results in reply from approximately 90 per cent of the employers. A personal call on those who failed to reply discloses the fact that more than half have complied with recommendations but neglected to report when the work was completed.

RECOMMENDATIONS TO EMPLOYER

Authority for plant inspection was strengthened by the adoption of a Basic Safety Manual in 1952 and a supplement to the manual covering the construction, maintenance and operation of Electrical Supply Lines was adopted in 1953. A plant inspection is of little value unless both employers and employees are convinced that the safety recommendations are worthwhile. For this reason, leaflets are passed out at the time of inspection and need for elimination of specific hazards is explained. I am, and I am sure you are, a great believer in plant inspection.

A fatal accident which occurred some time ago in a grain elevator at Max, N. D. Mr. Haroshanko, manager of this elevator for about 10 years, no doubt knew every nook and corner of the grain elevator. In this elevator where Mr. Haroshanko walked every day, there was a drive shaft with a key sticking out beyond the end of the shaft about two and one-half inches. This key revolved with the shaft. One day he walked around the end of this revolving shaft, the jacket sleeve caught on this key, threw the man around the shaft and killed him.

If one of the safety engineers had come in there for an inspection prior to this accident, he no doubt would have detected this hazard. But with limited personnel, we cannot be all over. What I am getting at is this: an old timer like Mr. Haroshanko who had been walking around the plant for years did not see this hazard and, consequently did not remove this key.

But if someone had called his attention to it, he would have cut it off or put a shield over it and thereby saved his own life. When I checked on this accident, I found this key was rusted and obviously there for a long time.

USE TRAINING FILMS

Supplementing the distribution of leaflets in our safety education program, is a film library of training films, representing different films and covering practically every phase of accident and fire prevention. These films are loaned to employers, but are used mostly by volunteer fire departments, community safety committees and groups of foremen and supervisors. Both basic and supervisory courses are established and upon completion of the course, each participant is presented with a certificate of award, signed by the governor, the commissioner in charge of safety, and the safety director.

The operation of the industrial safety program is made difficult due to limited personnel and the lack of field men trained for separate industries. So our field men must be a jack of all trades.

North Dakota is primarily an agricultural state—not a large industrial state. We have a great number of small plants in comparatively small communities such as machine shops, garages, creameries, and small manufacturing plants. We have too, the Petroleum industries which started about five years ago and are growing at a rapid pace. We have also some large construction projects such as building of the Garrison Dam, which is one of the largest earth fill dams in the world, and are building two large air jet bases.

However, neither the large construction project nor the large industries give us much trouble insofar as accident prevention is concerned because the large employers as a rule carry on within their own groups a good safety program.

Among the smaller employers who employ comparatively few people in their plants we find the highest accident frequency rate and this type of establishment constitutes approximately 80 per cent of all coverage in our state.

As a rule, a small plant seldom has a safety program and often objects to suggestions that would lower the accident rate, cost of operation and increase production.

This situation presents a problem we feel can be solved only by personal contacts. By contact we mean contacts with the employer personally and with as many of his men as possible. Now, to make contacts with all the small plants throughout our state when we are operating with limited personnel and funds constitutes a real problem. No doubt you have heard, as I have, in safety meeting conferences, "How can we reach out to small communities with the safety program?" This was our problem and is still not solved entirely.

PERSONAL CONTACT BY TRAILER

However, we overcame some of it by going to work purchasing a 36 foot house trailer. We equipped this trailer with a movie screen and made a place for a 35 mm and a 16mm projector. We call this a mobile class room. This trailer will seat 15 people. We take this trailer into the small towns where we often find no meeting hall and we also take it to large construction camps and into the oil field. We have even used this trailer for first aid courses. Inside of this trailer we have exhibits of first aid equipment and also some old unsafe tools such as mushroomed chisels and broken hammer handles.

I might say we have had good results as we take this mobile classroom to the smaller communities and we go to employers who may employ only 10 to 15 people. We ask the employer to let his people off for 30 minutes to an hour so that we can show safety films and talk with them personally, and the cooperation has been wonderful. I'll have to admit, due to lack of funds and personnel, we have not used this mobile classroom as much as we would have liked to during the last year.

Let me tell you that in addition to what our state industrial safety department has done, the extension service of the State Agricultural College, under the direction of John Zelskie, has carried on a good farm safety program. Zelskie has done a wonderful job of bringing the accident prevention program to the farmers by literature, correspondence, and setting up classes in the various parts of our state. We appreciate the help and cooperation of this service.

FOREMAN TRAINING PROGRAM

A word about our foremen training program may be of interest to you. Mr. Drew, our safety director and Mr. Miller, our safety engineer, have included standard first aid courses with foremen training. The arrangement for the first aid courses was made possible through the help and courtesy of the U. S. Bureau of Mines. In the past couple of years, we have been able to complete several such courses and we know from records that these courses have been instrumental in saving at least two lives. Let me tell you about it. One such class was held in the gymnasium at Tioga and was sponsored jointly with Amerada Petroleum corp., and the Oil Field Services co.

This class was originally planned for foremen and supervisors but when so many others asked to be included, we arranged for several additional classes. On September 18th, 1956, Earl C. Emerson, production foreman for Amerada corporation, one of the participants in our first aid course, rescued a fellow workman who was overcome by hydrogen sulphide gas while making a drill stem test. After carrying the unconscious man to the open air, he immediately applied artificial respiration and when the ambulance arrived 20 minutes later, the man had regained consciousness.

Emerson later received a life-saving award from the U. S. Bureau of Mines in a television presentation. On July 19, 1957, we were notified that he had also been awarded a medal of honor by the Joseph A. Holmes Safety Association.

COURSE SAVES LIVES

A thorough investigation was made before such an award could be awarded, that Emerson actually saved this man's life. We also believe that Emerson, who had just nine days prior to this accident completed the first aid course, and who prior to completing this course knew nothing about first aid, could not have saved this man's life if it hadn't been for the knowledge acquired through the course.

I can tell you about another man who we believe was saved because of first aid teaching in the coal mines. A couple of years ago a coal miner fell from a moving ore car, both legs were severed. Fellow workmen applied tourniquets, preventing bleeding to death. Then 10 of the fellow workers followed the car to the hospital ready to give blood for transfusion and actually nine of those men contributed blood. Again I believe that if those men had not just prior to this accident completed a first aid training course, they wouldn't have known how to take such immediate action.

George Easton, state mine inspector, in conjunction with the U. S. Bureau of Mines and our safety department, has been carrying on an extensive accident prevention program among the miners in our state. He had just completed a first aid course prior to the accident I just mentioned and we feel that this course also paid off well by a life saved.

In North Dakota we are endeavoring to carry the safety program to our small communities by using what we may sum up under three letters, C.P.A., not Certified Public Accountant, but contact—promotion—action.

Contact—Contact is made before and after a plant inspection and recommendations for correction of hazards are also made personally to management when possible. If the plant is too small for a program alone, we arrange for a community group if possible. This program may be sponsored jointly with a civic or commercial group as sponsor but best results are obtained when spearheaded by a community safety council.

Much can be accomplished if our program is presented in a manner that will convince the owner or manager that safety will pay in lower insurance premiums, increased production, and better morale. We are therefore making contacts with as many as possible by using our mobile classroom, by personal contacts to set up foremen and supervisors' training courses.

Promotion—Promotion, our second step, we feel is vitally important too for we must have the support and cooperation of management if our program is to be successful. Promotion is necessary to sell our services, to interest others in a program dedicated to conservation of human life, and the prevention of suffering.

After making contacts and successfully promoting our safety program, we come to our third phase of the program which we call Action.

Action—Action involves actually doing the job—a follow-up on our contacts and promotional work. If we are to hold meetings, the smallest detail cannot be overlooked. I am sure each of you have at some time served as a chairman of a committee. It is my guess that if you hadn't personally checked on some of the minor details, the program would have been a flop.

Action also means a follow-up on existing hazards of a safety inspector, a safety engineer, and a safety consultant.

ACTION INCLUDES STUDY

Last but not least, action means study to learn more so that a person can discuss problems in an intelligent manner. This study must include a study of accidents checked and recommendations made to prevent reoccurrence. These recommendations must be practical for a plant with few employees which is not financially able to install all the improvements found in a similar plant employing a greater number of employees. Study is needed so an employer can be advised as to the approximate cost of changes recommended. Cost is important in these days of cut-throat competition, but removing the cause of frequent accidents may mean only a change in the manner of work and may not require additional equipment.

We know there is a cause for every accident and a remedy for every cause. If we are to make progress, we must have action in the form of preventive measures. If enforcement is necessary, it is usually the result of improper contact and promotional technique. Invoking the law is a step that should be taken after all other methods fail. In this connection, we can be sure of the cooperation and support of other government agencies and conditions warrant their support.

We must be better salesmen if we are to avoid resorting to legal measures to enforce safety rules, for we have something to sell. Safety is a product everyone can afford whether employed in private or public industry. Our job is to interest them in the service we have to offer. The conduct of workers and of all of us is influenced by personal habits. Safe habits are formed by doing the job in a safe way—by being safety conscious but must start with proper attitude.

Therefore, our first task is to make sure there is a genuine interest in our program of accident prevention. Action means more contacts, more inspections, more meetings, and more work.

It is extremely difficult to evaluate a safety program. Statistics are often misleading. But if we can point out even two examples where safety and first aid training courses have saved a life, we feel repaid for our efforts.

Let us not forget, however, that all of this means that we must continue to be optimistic. We must continue to prevent accidents, loss of life, and most of all, human suffering.

THE OREGON SAFETY STORY

by WILLIAM A. CALLAHAN

chairman, State Industrial Accident Commission, Salem, Oregon

Realizing the necessity for social legislation in the aid of injured workmen, in 1913 Oregon was one of the first states to enact a Workmen's Compensation Law. However, the State Industrial Accident commission, established by this law, did not become self-sufficient until 10 years later.

Up until 1941, the primary concern of the commission was compensation of injured workmen. Seeing the need for accident prevention, the state legislature appropriated separate funds for the safety of workmen in covered firms and designated the Accident Prevention division to direct it.

This fund was a percentage of all contributions paid in and, justified by the demand for more services in this field. It has been raised from time to time to meet the demand.

Actually the real safety program in Oregon did not begin until 1943. A year later, the state industrial death rate dropped 21 per cent and ranked Oregon in the top five states in the nation in this reduction.

Safety inspectors visit operations throughout the state making inspection tours of the premises, writing correction orders on unsafe conditions of the physical plant, equipment and unsafe practices. The employer has an agreed upon length of time to make these corrections and unless the hazard requires a cease work, an immediate compliance order is written. About 150 to 200 such orders are written each year.

RED TAG MARKS HAZARD

If an employer refuses to comply, we may hang a "Red Tag." In 1956, we used the "Red Tag" only five times. A "Red Tag" may be placed on a machine, scaffold, excavation, any part of an operation or on the entire operation, and regular operations must stop until the corrections are made. Until the last session of the legislature, violation of a "Red Tag" carried a $100 penalty. It has now been increased to $1,000.

At the last convention of the Oregon State Labor Council, A.F.L.-C.I.O., a resolution

was passed unanimously calling on all members to respect a "Red Tag" as they would a picket line. This "Red Tag" law is a big help in securing immediate compliance. We have no intention of relaxing our inspection and enforcement work, but we believe our educational work is more important and less enforcement will be necessary in the future.

Realizing that safety education is the backbone of the Oregon accident prevention program, the chief objective is to train industry to train itself in safety.

Oregon has many small business firms engaged in hazardous employment, such as logging and sawmill operations. About 95 per cent employ fewer than 50 men, many with less than 25.

Such a situation necessitates a tremendous effort on the part of the accident commission's Accident Prevention division in promoting safety programs because firms with few employees do not maintain full or even part time safety personnel.

In telling the Oregon safety story I will describe a 15 point safety education program that is getting results.

SAFETY COURSES

"Hack the attack on accidents" is fast becoming a motto in Oregon industry. One method of attack is the safety training courses begun in 1943. They are primarily request programs from management and labor—originating with either the field representative (safety inspectors), the area office, or the central office in Salem.

Once a request is made, the area special services representative arranges the presentation, procures statistical information and teaches the course. Often he is assisted by the local field representative.

The courses are of two types: the standard or basic course of six hours and the advanced course. The basic course is presented in three two-hour class periods for supervisory personnel; however, anyone can attend. The subject matter deals with understanding the problem; determining the accident causes—the conditions and acts of persons which cause injuries, and their control—and the development of an accident prevention program.

The advance course is primarily for key supervisory personnel. It is stressed to the supervisor that he is the key man in the safety program. Economic and sociological costs are also pointed out, as well as the psychological factors involved.

Often a request calls for a combined safety and first aid course. In this case, parts of each course may be presented. At the conclusion of a course, the Accident Prevention division issues a certificate to each participant. These classes are presented in a "down to earth" fashion and a question and answer period concludes the presentation.

ASSOCIATION TRAINING PROGRAMS

The State Industrial Accident commission and the Columbia Basin Loggers association co-sponsored a safety training program for their member firms. This organization consists of many small logging and sawmill operations. By working closely with labor organizations having jurisdiction, the association could draw key supervisory personnel of the individual firms for a safety education program.

This "safety school" was conducted at dinner meetings by select accident commission personnel in eight areas. Some of the points covered at these meetings were: employer problems and costs, state logging codes and regulations, acts of persons and conditions which cause accidents, accident investigations and self inspection and implementing the safety program.

SAFETY COMMITTEES

Safety committees have been established in Oregon for many years. Large companies know the value of such programs and have given safety information to smaller concerns. Yet many of these concerns do not find a committee compatible, and therefore other methods must be used to acquaint them with safety precautions.

In Oregon, industrial safety committees vary. One type is a management committee which takes in key supervisory personnel. Another is the labor or union committee, composed of key union represenatives. The third type—most widely used—is the joint management-labor committee. Some plants use a variety of the three. Often management will not organize a committee without labor's representation since both are concerned with the same problem, and both stand to gain.

The State Industrial Accident Commission through its Accident Prevention field representatives and the special services section helped organize many committees and activate old ones. Field representatives meet with as many of these committees as possible—giving technical advice and moral support. These men are dedicated—dedicated to keeping the workers of Oregon alive and unhurt and aiding the employer in reducing his accident costs.

FIRST AID

First aid is a deterrent to accidents. People trained in first aid have 50 per cent fewer accidents. For this reason we have a working agreement with the American Red Cross to teach its courses.

This program began 15 years ago by certifying each fieldman of the Accident Prevention division as a certified first aid instructor. All first aid requests originate in the field and are certified and assigned through the central office. Since the activated educational program began in 1943 approximately 20,000 people have received first aid training from the Accident Prevention division.

At the Governor's Industrial Safety Conference held last Spring the American Red Cross presented the Commission's Accident Prevention division the American Red Cross Award for "outstanding service in the field of first aid."

As an outgrowth from the Columbia Basin Loggers training program, eight Northwest communities organized district safety councils primarily concerned with industry's problems in that particular area.

These have been spontaneous—originating with management and labor groups in the area and sponsored by the Columbia Basin Loggers association. The organizational patterns of these councils are similar. Each has an elected chairman, a secretary and five representatives from both labor and management who rotate from three to six months.

Statistical data, films and other safety material supplied by the commission are available to the councils. Accident Prevention division personnel attend the monthly meetings in an advisory capacity.

For any educational program, certain statistical information is necessary to stress essential points. The actuarial division disseminates much information, such as the accident analysis of firms under state coverage, and the experience rating statements.

The accident analysis gives the name of the accident victim, nature of his injury and the claim costs. It also gives the employer contribution over a specified time, frequency and other data. This is valuable in stressing the costs to employers. It also permits the commission to evaluate the needs of a firm when setting up a safety program.

The experience rating statement of any covered firm is available within minutes. This statement can sell the employer on the need for a safety program by showing his previous cost of accidents. It also indicates the success of a safety program when measured in terms of dollars.

The nature, location and type are shown on agency charts. These charts show the nature of the injury, the parts of the body injured, the type of injury and what caused it. They mark the area where accidents occur and indicate where improvements in a safety program should begin.

In a basic safety course to a small Oregon sawmill employing 18 men and using this statistical information, the actual claim cost was cut in one year from $8,703.00 to $64.50.

SAFETY RALLIES

In 1953, backed by local publicity and public relations, the Accident Prevention division began a new course in accident prevention. This was the formal organized safety rallies. One type was the community rally whereby all industrial groups in an area are invited to help promote industrial safety in the community with labor groups cooperating.

Another type is the company rally promoted within one firm. A third type embraces as many local industries and labor groups as possible. All are organized with a local sponsoring group in cooperation with the State Industrial Accident commission which arranges the program details and schedule. This is one way for employers with a few workmen and no organized safety program to receive safety aid.

STATE REGIONAL CONFERENCES

The Commission conducts a number of regional safety conferences each year. These are the backbone of our educational work, the "grass roots" program of conferences and takes safety to the local people. Problems are discussed and acted upon and workmen are urged to attend.

The program is the people's program. A regional planning committee is established with the assistance and guidance of the state commission. The program is presented similar to the state-wide conferences. Some are organized on a general assembly type panel discussion basis while others have industry type panels.

In safety programming, entertainment is important in securing larger attendance. Year by year more women—wives of workmen—attend because they realize they too have a vital stake in their husbands' on-the-job safety.

Speech contests, employer paid luncheons, safety skits, door prizes and music are some of the entertainment features to secure a better attendance. One regional conference secured the help of the local Junior Chambers of Commerce in naming "safety queen candidates."

GOVERNOR'S SAFETY CONFERENCE

Oregon had its first state-wide safety conference in the capital city in 1944. Attendance doubled and tripled and after five conferences, the conference site was moved from Salem to Portland, where there was more room, and the name was changed to the "Governor's Industrial Safety Conference."

Television, radio, newspapers, magazines and public appearances are utilized by the central planning committee of state, labor and management people to promote attendance.

The attendance was so high at that conference, that the Accident Commission decided to use the conference as a springboard of ideas for the regional ones. When publicity started for the last meeting, the aim was primarily to attract the top safety men and committees that organized and conducted the regional conferences.

Also the program was changed from an industry panel discussion to a general assembly panel. Top safety men in the Northwest and from across the nation were secured for speakers.

FOOD PROCESSING CONFERENCES

The Commission co-sponsors a food processing conference dealing with safety problems in the industry. Aside from mechanical and human elements in accident prevention, industrial hygiene is stressed to combat occupational diseases which occur in the various processes.

The Accident Prevention division has two capable industrial hygiene engineers. Their efforts, along with those of the State Board of Health, are proving valuable in this field.

More than 200 key industry people from both labor and management attend these conferences yearly—thus cooperating to perfect a sound safety program within the large and expanding food processing industry in the state.

SCHOOL TRAINING PROGRAM

Another program is the school training program to acquaint high school boys and girls with laws governing employment during seasonal farm periods and the precautions for safety at work.

Receiving a safety program in the schools, the youth can carry this training and knowledge into adult employment.

This program was co-sponsored by labor groups having jurisdiction, the State Bureau of Labor and the State Industrial Accident commission. A program is being developed with state educational authorities for the Commission to give safety education to students as a prerequisite to job opportunities in other industrial fields.

PLEDGE CARDS AND SAFETY AWARDS

In the summer of 1956, the commission began a new program which operates on the assumption that if an employee signs a pledge to work safely, he will be a safer worker for his own benefit and the benefit of his fellow workers.

This program is patterned after the "red hat" hunting pledge. For our particular use, the pledge cards are given to employers, and they secure employees' signatures. These cards are perforated—the workmen keep one portion in their billfolds as a daily reminder of their pledge, and the employers file the other part. When the employers have a 100 per cent "sign-up" of workmen, the Commission presents them with a "Certificate of Commendation."

The mere signing of a pledge card will soon be forgotten. Actually, this is really a "gimmick" to get our foot in the door to sell them on a complete program. But we begin slowly—first aid classes, basic and advanced safety courses and safety committees.

Once a company has met the requirements of the pledge card program, it is in line for the Commission "Award of Merit" for "outstanding efforts and achievements in the field of safety." At present there are 245 firms in the state employing 25,000 men who are in the program.

Frequency and cost reductions are not the only criterion for earning this award. A firm must also avail itself of other educational services and programs of the Commission.

Visual aids are becoming more and more beneficial to our program of safety education. Our safety film library has 85 films, and new films will be available, free of charge.

Other visual aids and educational materials available are: safety codes, illustrated fatality reports, statistical information, posters and displays.

While the state safety codes are the basis for corrective orders, they are nevertheless primarily educational.

For each fatality occurring in covered employment, our artist illustrates or depicts by drawing what happened and this, along with a brief description, is sent to a mailing list of approximately 2,000 persons.

SPEAKERS BUREAU

The State Industrial Accident commission provides speakers for various functions in the state. A speakers bureau has been established whereby competent speakers on any phase of the Commission's work may be assigned.

For example, should an organization or company wish a speaker to discuss accident claims, a qualified person from that division is assigned. When a request for a speaker on safety is received, a qualified person from the Accident Prevention Division is assigned.

These speaker requests come from employers, unions, social, fraternal, school and womens' groups.

Safer Oregon is the official state safety publication, dedicated to the prevention of industrial accidents in the state. The monthly magazine imparts technical information and presents changes in the Workmen's Compensation Law and the safety codes. It reports new accident prevention programs and their progress. It tells of activities of the Commission—what is being done to prevent accidents and how employers may reduce or eliminate claim costs which are attributable to accidents.

Safer Oregon is a medium of exchange for safety ideas and sound accident prevention methods. It might be called a "springboard of knowledge" because it covers every phase of our accident prevention program. It is published with a humanitarian feeling to keep our people from becoming injured.

RESULTS OF OREGON'S PROGRAM

The results of our program are far reaching. Many foreign industrialists have been our guests while studying our program.

Despite the fact that the man days worked have increased more than 150 per cent in the last 10 years, we have held the lost-time injury rate to a 30 per cent increase over that same period.

One peculiarity of the Oregon Law is that there is no waiting period in the payment of claims, and time loss is paid even for the first day. This means if an injured person is unable to report to work for his next shift, it becomes a lost-time claim. This tends to keep our frequency higher than in states where there is a waiting period.

There are three yardsticks which used together will give a very accurate evaluation of the safety program of any state. I refer to the benefit schedule, the premium rates and the solvency of the fund. Measured by these yardsticks, Oregon shows up extremely well.

We know we have made great progress against the severe handicap of having most workers employed by small employers. We know that we dare not relax, and we know we have a tremendous job ahead of us.

We are encouraged by our successes and from these, we draw the strength for the long hard climb ahead of us. We know that while our work may become easier, it will never be done. We are happy to toil and serve in this great humanitarian work.▲

OFFICERS OF THE

LABOR CONFERENCE

NATIONAL SAFETY COUNCIL 1957-58

Vice President for Labor—P. L. SIEMILLER, general vice president, International Association of Machinists, Chicago, Ill.

Chairman—LLOYD UTTER, director, Industrial Health & Safety div., United Automobile Workers, Detroit, Mich.

Vice-Chairman—CHARLES FERGUSON, director, safety div., United Mine Workers of America, Washington, D. C.

Secretary—G. G. GRIEVE, director, Labor div., National Safety Council, Chicago, Ill.

LABOR CONFERENCE REPRESENTATIVES TO NATIONAL SAFETY COUNCIL

Board of Directors—LLOYD UTTER; AL E. BROWN, vice president, United Papermakers & Paperworkers, Portland, Ore.; HARRY SEE, National Legislature Representative, Brotherhood of Railroad Trainmen, Washington, D. C.

CHAIRMEN OF LABOR CONFERENCE COMMITTEES

Congress Program Committee—JOHN R. KUMPEL; *Executive*—LLOYD UTTER; *Membership*—ELWOOD SWISHER; *Planning*—LLOYD UTTER; *Publications & Newsletter*—GEORGE EICHHORN; *State Labor Departments*—F. A. VAN ATTA

DAN ADAIR, coordinator of safety activities, Pacific Coast Assn. of Pulp and Paper Manufacturers, Portland, Ore.; FINLAY ALLAN, asst. to general president, United Brotherhood of Carpenters and Joiners of America, Indianapolis, Ind.; JOHN T. ATKINSON, safety director, International Woodworkers of America, Vancouver, B. C.; A. C. BLACKMAN, chief, div. of industrial safety, State Dept. of Industrial Relations, San Francisco, Calif.; FRANK BURKE, director, safety & health, United Steelworkers of America, Pittsburgh, Pa.; JOHN CALDWELL, education director, American Federation of State, County & Municipal Employees, Washington, D. C.; WILLIAM A. CALLAHAN, chairman, State Industrial Accident Commission, Salem, Ore.; FERNANDO J. CASTRO, director, Bureau of Industrial Safety & Accident Prevention, Department of Labor, San Juan, Puerto Rico; J. GEORGE EICHHORN, Grand Lodge Representative, International Assn. of Machinists, Chicago, Ill.; RODGER COYNE, director, Occupational Safety & Health, International Union of Electrical, Radio & Machine Workers, Washington, D. C.; GEORGE C. DU VALL, assistant to vice president, Communications Workers of America, Washington, D. C.; ARTHUR FRANCIS, chief inspector, Workmen's Compensation Board, Vancouver, B. C.; R. D. GIDEL, chief Div. of Safety Standards and Services, Bureau of Labor Standards, U. S. Dept. of Labor, Washington, D. C.; ARTHUR P. GILDEA, secretary-treasurer, International Union of United Brewery, Flour, Cereal, Soft Drink and Distillery Workers, Cincinnati, Ohio; JOSEPH GONEY, assistant director safety and health, United Steelworkers of America, Pittsburgh, Pa.; J. A. GREENE, safety representative, International Association of Machinists, Downsview, Ont.; JOHN GRUDEN, director, Health & Safety dept., United Automobile Workers, Dearborn, Mich.; HOYT S. HADDOCK, National Maritime Union, Washington, D. C.; BRYCE P. HOLCOMBE, general organizer, Brotherhood of Painters, Decorators & Paperhangers of America, Washington, D. C.; CARL HOLDERMAN, commissioner, Dept. of Labor and Industry, Trenton, N. J.; BARNEY HOPKINS, secretary-treasurer, Michigan CIO Council, Detroit, Mich.; PAUL A. IACCINO, secretary-treasurer, Cook County Industrial Union Council, Chicago, Ill.; MORRIS IUSECHEWITZ, secretary-treasurer, New York City CIO Council, New York, N. Y.; E. W. KENNEY, director, Research and Education, International Woodworkers of America, Portland, Ore.; JOHN R. KUMPEL, special representative, Safety and Compensation, United Rubber, Cork, Linoleum & Plastic Workers of America, Akron, Ohio; RAYMOND LEON, international representative, International Brotherhood of Pulp, Sulphite & Paper Mill Workers, Fort Edward, N. Y.; T. G. LINNERT, head, Engineering & Air Safety dept., Air Line Pilots Assn., Chicago, Ill.; THOMAS MURTHA, international representative, International Alliance of Theatrical Stage Employees, New York, N. Y.; JOSEPH PHILIPPS, apprentice coord., United Association of Journeymen & Apprentices of Plumbing & Pipe Fitting Industry, Washington, D. C.; S. C. PHILLIPS, assistant president, Brotherhood of Locomotive Firemen and Enginemen, Cleveland, Ohio; E. J. PLONDKE, director, Public Relations, Brotherhood of Maintenance of Way Employees, Detroit, Mich.; RAY E. ROBERTS, safety director, International Association of Machinists Lodge 763, Phoenix, Ariz.; FRED ROBLIN, associate editor, The American Pressman, International Printing Pressmen & Assistants Union of North America, Pressmen's Home Tenn.; JOHN R. ROONEY, secretary-treasurer, Ohio CIO Council, Columbus, Ohio; ELWOOD SWISHER, vice president, Oil, Chemical & Atomic Workers International Union, Denver, Colo.; DONALD THOMS, vice president, United Papermakers & Paperworkers, Chicago, Ill.; C. R. THORNBROUGH, commissioner of labor, State Dept. of Labor, Little Rock, Ark.; F. A. VAN ATTA, PH. D., consultant on industrial hygiene, United Auto Workers, Detroit, Mich.; HAROLD WALTON, business agent, International Association of Machinists Lodge 834, Wichita, Kan.; HUNTER P. WHARTON, asst. to general president, International Union of Operating Engineers, Washington, D. C.; ALBERT WHITEHOUSE, director Industrial Union Dept., Washington, D. C.

Other Volumes in this Series

Users of this volume will find much value in its companion volumes. Here is the list:

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

MARINE SECTION

This volume is a record of the sessions held at the 1957 National Safety Congress by the Maritime Industries. The conduct of these Congress sessions each year is only one of the many cooperative activities which the Marine Section carries on in behalf of its members, and for the benefit of accident prevention work in the maritime industry. The section gives guidance in the preparation of a great variety of technical and educational material useful in the day-to-day safety programs of the marine industry.

The activities of the section are under the direction of its executive committee, the members of which are listed at the close of this volume.

"KNOWING'S NOT ENOUGH"

by DAVID L. BUCHANAN

assistant to vice president—operations, Pittsburgh Steamship Div., U. S. Steel Corp., Cleveland

In 1955 four men sat in stony silence in a conference room on the upper floors of an office in Chicago. This was an unusual business day for they were on the threshold of the first step to the solution of a problem that has plagued American management for more than half a century.

The problem they were wrestling was the strange phenomenon of a normal human being, who without apparent cause, ignores all his instinct, reason and training and walks into an accident.

Certainly there was nothing new about this problem. But two particular aspects concerned these men.

First, what quirk of the mind motivates that impulsive action which leads to an accident? What is it that blocks out the normal awareness to safety and self-preservation and hurls a man headlong into danger? And second, how can you communicate to all people the urgent need to recognize and stifle these impules before an accident occurs?

INJURED KNOW BETTER

The greatest number of injuries occur in that segment of the working force which "should know better." Our own experience at Pittsburgh Steamship division in 1956 dramatically points up this fact. Only 14 per cent of our injuries occurred in the age bracket of 20 and under. Thirty-eight per cent occurred in the age group of 21 to 30, and men 30 and over made up 47 per cent, or nearly half of our accident experience.

The mature, experienced and trained worker is the one getting hurt. This first premise became the central theme of the entire program—"Knowing's Not Enough!"

The second part of the problem was to carry this message to all the men and women in the mines, mills, offices, quarries and transporting units of United States Steel—for the men in that 1955 meeting were members of the Corporation's Safety Advisory committee.

Because they were dealing in human behavior, they realized such a program should also encompass employees of other companies and the citizens of United States Steel communities.

SNOW WHITE'S INFLUENCE

At this point Snow White appeared on the scene. Having agreed on the need to identify these impulses which suddenly block out all safety awareness, the committee members considered Snow White's seven dwarfs as possible characterizations of the impulses that cause human failure. But poor Snow White had too many dwarfs.

People generally retain only the first three or four central ideas in any program. Four imps, it was decided, would be maximum. However, Snow White left her mark on this program's development, for the notion of personifying these accident producing impulses stuck like glue. United States Steel's four imps, Impatience, Impulsive, Improvising and Impunity were born.

The final step in the basic plan was a proper story to put this safety message across. In a serious attempt to capture the imagination of a widely diversified audience the committee set their stage at a sports car race.

With competing cars streaking past the grandstand and skidding around corners, with film sequences taken in the cockpit, with the story of a driver in trouble trying to hold the lead position, United States Steel's 28 minute color motion picture, "Knowing's Not Enough" has little difficulty drawing its viewers quickly into the plot.

SHIP SAFETY PROGRAM

Because this film deals in the fundamentals of human attitudes and behavior, it automatically adapts itself to a safety program for steamship fleets. Pittsburgh Steamship division's safety program was designed to impart safety knowledge to our employees to develop good safety working habits, as well as a healthy respect for hazards inherent in marine operation. The program includes:

A. Pre-employment physical examinations.

B. Safety precaution booklet.

C. Personalized instruction and supervision by ship's officers and experienced crew members.

D. Monthly safety meetings.
   1. Safety subject of the month.
   2. Safe practice demonstration.
   3. Discussion of safety subject at fire and boat drill.
   4. Review of safety items in the United States Coast Guard publication, "Proceedings of the Merchant Marine Council."

E. National Safety Council posters.

F. Safety booklet included in the Good Reading Rack Service.

G. Lake Carriers' Association booklet "Recommendation for the Prevention of Accidents."

H. Monthly one page Division safety newsletter entitled "Safety Topics."

I. Articles and cartoons in our division employee magazine *Pittsburgh Sidelights*.

J. Recent publication of a booklet "Safety First in Verse" compiled from minutes of ship's safety committee meetings.

K. Fire fighting demonstrations before our ships sail in the spring.

L. Division safety contest.

M. Participation in Safety Contest of Marine Section of National Safety Council.

N. Shore Safety committee.

O. Presentation of "Knowing's Not Enough" to all shipboard personnel, implemented by special posters using the yellow flag.

IMPATIENCE IMPACTS

One of the chief assets of the "Knowing's Not Enough" program is the almost immediate identification of shipboard incidents with the four imps, Impatience, Impulsive, Improvising and Impunity. We find that in the minutes of the ship's safety meetings, crewmen connect the cause of an accident with the work of one of these imps. To show what we mean let me apply these imps to actual cases from our files.

Last season a fireman employed aboard our Steamer Myron C. Taylor decided that a lump of coal was too large for proper handling so he took the mallet and proceeded to break the lump. After striking the first blow, the lump parted and a number of particles embedded themselves in the man's right eye. He was rushed to the hospital and hospitalized for 10 days.

Investigation revealed that goggles were close at hand in the boiler room and the man with some 18 years experience at firing admitted he was in a hurry and did not wear the goggles on this particular job, although he had always worn them on previous occasions.

IMPUNITY IS SUBTLE

Impunity, the most subtle of the accident imps that block safety awareness, also had a hand in several lost time injuries. For example, one wheelsman had continuous sailing experience with our Division for 34 years. While his vessel was approaching the dock at Gary, Indiana, with a load of iron ore he apparently decided that he could jump to the dock before the ship was tied up, and allow himself a few minutes of additional shore leave.

The vessel was parallel to the dock and still moving as he jumped four to six feet from the deck to the dock fracturing his left foot. As a result he lost a total of 33 days from his job.

Impunity was on hand this season when a fireman with approximately four years sailing experience thought that the stokers were feeding coal into the furnace too fast. In his haste to rekindle the fire he threw some waste kerosene into the furnace. A flash back severely burned the man's left hand, forearm and face and resulting in 25 days lost time.

Both of these men with years of sailing experience attempted an act which they knew was unsafe and which could result in an injury. But even though they know better they could not deny Impunity's siren song, "Do It Any Way You Can Get Away With It."

BUSY IMPULSIVE IMP

If Impunity is the most subtle imp, certainly Impulsive is the busiest. Many injuries occur each season because seamen are somehow lured into acting without thinking of the painful consequences. Let's take the case of one, chief cook who was injured while off duty.

In leaving his quarters aboard ship he opened the screen door and stepped over the threshold with his right leg. At this point he inadvertently let go of the door and before he could get his left foot out, caught it between the steel threshold and door. His left foot was bruised severely causing a blood disorder which forced him to lose 22 days from his job.

Another example of impulsiveness on the part of an employee occurred while he was performing routine duties. A fireman with nine years experience while shaking grates was confronted with an oversized clinker which would not shake down. Instead of removing the clinker with the proper tool, he thought the clinker might go through by using extra effort on the bar used in shaking the grates.

The bar slipped out of its socket catching the man's ring finger between the bar and the front of the boiler. The proximal joint was fractured resulting in seven days lost time.

IMPROVING IMP IS BAD

Improvising is an impulse which has probably influenced all of us at one time or another. The best example of a shipboard injury caused by this imp is the use of the wrong tool on a job. There is another type of improvising, however, which does not involve tools as much as working procedures. Such was the case of a fireman injured while assisting the first assistant engineer to install an angle iron above the main engine.

While installing the angle iron from ladders, the angle slipped off a securing bolt, knocking the fireman from the ladder to the top of the main engine, and pinning the first assistant's arm between angle iron and an upright bracing angle. As a result the fireman with four years previous experience, suffered a fractured wrist and other contusions keeping him from his job a total of 46 days.

The first assistant with 10 years of experience suffered a severe bruise of the upper arm but was able to remain aboard ship. Had either of these men only thought to tie off the angle iron and hoist it into position, this accident would have been avoided.

The men who man the 57 ships of our silver-stacked fleet have felt the impact of this program. The device of the yellow warning flag has become a symbol of avoiding an accident. In the film, the yellow flag is flashed to drivers to announce an accident somewhere on the course. They must maintain their positions so an ambulance or a wrecker can get to the man in trouble and clear the track. The theme of the Knowing's Not Enough Program is simply—get the yellow flag out before the accident occurs.

HEED YELLOW FLAGS

Without any instructions from management, ship safety committees have painted yellow warning flags on ladders, hatch cranes and other high accident areas. They are identifying that yellow flag with the conscious act of pausing long enough to remember that any job done unsafely isn't done right. And that pause to let reason, knowledge and training take hold, is a pause that prevents accidents and saves lives.

United States Steel announced the program to its management people last year in a closed-circuit television broadcast. Management members and their wives gathered in theatres at various cities for the kick-off address by Corporation President Clifford Hood. After remarks by Hood and Executive Vice President—Operations, Harvey B. Jordan, "Knowing's Not Enough" was screened for the people who would help sell the program to all United States Steel employees.

This spring when Pittsburgh Steamship was fitting out its fleet at Great Lakes port cities, traveling teams from our Cleveland office showed the film to crewmen and explained the details of the program.

IMPS GAINED FAME

Shortly afterward, the benefits began to appear. The program had captured the imagination of our people. As I mentioned before, we began to see the yellow flag and its attendent philosophy blossom forth from ship safety committee activity. The four imps were quickly established as the cause behind that behavior of human beings that produces accidents.

To give you some idea of the popularity this film has already had, the film entitled "Miracle in Paradise Valley" which had the greatest sales of any safety movie ever produced, sold 400 copy prints in eight years. In the first eight months of the "Knowing's Not Enough" program, more than 200 prints have been purchased by outside companies. More than five million pieces of descriptive literature on the movie have been printed to date; 150 prints are in a circulating library; 125 prints are being shown in United States Steel plants over the country.

Many companies have adapted the entire program and have purchased quantity prints for screenings for all their employees.

Through the American Iron and Steel Institute a copy will be shown at the International Labor Organization meeting in Mexico. The script for the film has been re-written in three other languages. Prints of the film are available to the public. The magazine "Business Screen" made this announcement in a special story which included booklets as special inserts in this issue.

The story of the four imps has been honored with a number of awards, including a First Prize from the National Committee of Films for Safety.

There will be new accident prevention programs in United States Steel and throughtout industry in the future which will come even closer toward stopping the needless waste and pain that accidents incur. But certainly we feel we have seen an important forward step taken in establishing one important premise—that Knowing's Not Enough.

SAFETY PRECAUTIONS TAKEN ON INLAND WATER VESSELS TO AVOID ACCIDENTS . . . AND STILL THEY HAPPEN!

by S. B. PARSELL

operating manager, Inland division, Socony Mobil Oil co., Inc., New York city

Although newspapers, periodicals, and safety house magizines publish stories and pictures of gruesome accidents, men still take chances with their lives. These accidents are very costly both to the men and their companies. They are costly to the men because loss of wages, loss of limbs, loss of eyes and even loss of life results.

By the same token, they are costly to companies because they lose employees—many whose long service and special training make them difficult to replace. Companies also lose money when unsafe operations result in bad collisions and groundings. And lastly, law suits frequently follow accidents often resulting in high monetary settlements.

Our company operates a fleet of self-propelled tankers, barges and tow boats on the coast and inland waters of the United States, including the Great Lakes and the Mississippi River System. The personnel on these inland vessels are more likely to have accidents than men on ocean vessels, because they are in ports more often, work in more confined areas and perform these duties practically every day. The possibility of accidents to inland waterway personnel is even greater in the north with ice and snow during winter months.

Well aware of these conditions, we continuously preach safety to alleviate accident-charged situations. We publish a safety magazine, "The Life Preserver," to get our safety message across. We affix safety decals to the bulkheads of our vessels. We stencil safety messages on each cargo hatch and pump room entrances such as, "Is this

tank gas free?" "Is there anyone in this tank?", or "Do not enter without an attendant." Several years ago, we made a motion picture on marine safety.

We also established a new medical program *requiring marine employees to have* physical examinations on the following schedule:

Between the ages of 18 and 35 years, every three years.

Between 35 and 45 years, every two years.

Over 45 years of age, every year.

This was done because some men develop quirks and ailments which cause lapses in good, safe judgment.

BUT ACCIDENTS STILL OCCUR

In spite of these efforts, we still have avoidable accidents, caused by lack of training and lapses in safe thinking. Here are several instances where education would have helped. A deck hand working on a barge was missed. An inspection of the barge revealed the pump room hatch was open. Since this was contrary to company practice, the mate investigated and found the missing deck hand lying across a cargo pump unconscious. Why did such an accident happen; an accident caused by working in strict disobeyance of company orders?

The man in question formerly worked on a barge carrying No. 6 fuel oil. There it was customary for men to go into the pump room at any time to work on the pumps. Seeing this, the man in question, who was new, followed suit. When he was transferred to the barge carrying refined products he thought he could do the same thing. He saw the stencil on the pump room hatch, but ignored it. Education is the answer in this case but should we start with the new men or the older men?

Last winter aboard a tanker in Lake Michigan, a very peculiar accident occurred. The vessel had a very rough passage across the lake, and arrived at East Chicago, Indiana covered with ice. Due to a change in cargo, it became necessary to clean several compartments. The tank hatches were raised by turning long threaded rods through threaded blocks for the men to wash from the deck. They did not put the safety device, a forked rod, in place.

Two men handling the hose were leaning over the edge of the expansion dome, when the hatch started to close by itself. This was probably due to the weight of the ice on the hatch and ice on the rod threads. Before the men realized what happened, the hatch lowered and pinned them between it and the opening. Two men rushed to their aid, and pushed up on the hatch cover. However, one man had been squeezed enough to require hospital treatment thereby causing a lost time accident. This vessel had been without a lost time accident for more than over two years.

Why wasn't the forked safety rod put in place? Had it been, the hatch could not possibly have closed. Probably the old excuse—we've done it that way before, and nothing happened. This is a lapse in safe thinking as well as education.

CARELESSNESS CAUSES MOST ACCIDENTS

Continuous studies are made to eliminate every hazardous condition on vessels. Actually the percentage of accidents from hazardous conditions is much lower than accidents which happen from human beings' being careless.

Here are a few examples of avoidable accidents:

- A new employee while tying up a vessel, climbed aboard, not over the gangway, and hit his leg on a mooring bit.
- An old employee received lacerations on the forehead and the left eye because a wrench he used was not the size suited for the job and it slipped while he was tightening on the nut.
- A crew member cleaning the pilot house windows didn't watch where he was going, slipped on the deck and fell backwards, sustaining a painful back injury.
- A man cleaning an overhead grating received an irritated eardrum from cleaning fluid when he carelessly dripped the fluid in his ear.
- A man not watching his step, slipped on deck injuring his left ankle.
- One working in the pilot house let a small iron plate fall on his foot.

These are samples of careless accidents people become involved in. What can we do to make our employees think and act more safely in their daily tasks? The marine industry has a safety training job to do, particularly among unlicensed men. It lags

far behind the shore industries in such a program. Generally speaking, many marine companies give licensed men a hit and miss training program and then expect the officers to train the unlicensed people.

A more active training program should be laid out for unlicensed personnel. Practically all companies are adverse to negotiating or even talking of safety with the unions. However, much can be done along this line and perhaps the unions might be more than willing to cooperate with a constructive program. The health, welfare and workability of their people are as important to them as to employers. We should devise palatable ways and means of appealing to our unlicensed people to make them think, act, and work safely.

SAFETY MEASURES FOR INLAND VESSELS

So much for crew safety. Now here are cases considered safe vessel operations on inland vessels.

At the spring meeting of the marine section, National Safety Council, Capt. Hewlett R. Bishop, Atlantic Coast Director, U. S. Maritime Administration suggested that a visible signal such as an amber light be synchronized with the whistle for night operations. He called attention to two collisions in N. Y. harbor during the winter months that were preceded by unheard signals. This is already a requirement on Western rivers towboats and is favored by the U. S. Coast Guard on the Great Lakes.

We have an amber signal light on each inland vessel which flashes when the whistle is blown. One cold night, we had a collision in N. Y. harbor that developed into who blew first and what whistles were blown. The pilot said if the tugs had a visible signal synchronized with the whistle it would be very helpful in the daytime as well as at night.

I immediately recommended an amber light be installed on our harbor tugs, (which are diesel propelled) for night safety, and in less than a week, word came down from the "top" to install whistle lights on all inland vessels.

Several years ago, we had a crank case explosion on a tug which resulted in considerable damage to the vessel. Our investigation showed that prior to the explosion, white smoke was seen coming from the engine and then a small pop followed by the explosion.

I discussed this problem and learned that some foreign ships used CO2 gas as a prevention. In other words, if a shot of CO2 gas is injected when the white smoke is seen coming from the engine it will create a non-explosive mixture in the crank case and prevent an explosion.

RADIO-TELEPHONE PREVENTS ACCIDENTS

In addition, inland vessels are using the radio-telephone as a safety factor more than ocean vessels.

On Lake Erie and Michigan vessel lanes are laid out on all charts. On Erie there is an east bound lane and a west bound lane. On Lake Michigan there are lanes for north and south bound vessels. Once a Captain saw a south bound vessel close to the north bound lane and immediately called the vessel via radio-telephone. Both vessels established themselves, their destination, and prevented a possible collision. Radios can also be used in fog when a whistle is heard forward of the beam.

Once a Mississippi towboat, up-bound with 12 loaded oil barges approached a narrow point in the river near a bad bend. Some miles up river, the Captain saw the searchlight of another towboat, but didn't know which way it was bound. He called the other pilot on the radio-telephone and asked for identification, size of tow and the direction bound. In this manner, they arrived at a safe passing point since they were steaming in opposite directions.

However, the radio-telephone, like radar, is only an aid to navigation and does not excuse failure to follow all rules for safe navigation.

ANNUAL COMMITTEE REPORTS

REPORT OF THE GENERAL CHAIRMAN

CAPT. JONES F. DEVLIN, JR.
general manager, United States Lines, North River, N. Y.

Our membership has increased since the first of the year. As there are industry representatives present from all sections of the country I would like to take this opportunity to announce our new members:

United Fruit Company,
New York, N. Y.

American Foreign Steamship Company,
New York N. Y.

Luckenbach Steamship Corp.,
Brooklyn, N. Y.

M. & J. Tracy, Inc.,
New York, N. Y.

Coyle Lines, Inc.,
New Orleans, La.

McAllister Brothers, Inc.,
New York, N. Y.

Central Gulf Steamship Corp.,
New Orleans, La.

Charleston Stevedoring Co.,
Charleston, S. C.

International Cargo Gear Bureau, Inc.
New York, N. Y.

I am pleased to note that a discussion group has been formed for the Great Lakes Operators which extends the fine work now being done by the Cargo Vessel discussion group and the Tanker discussion group.

I would like to voice my personal thanks to Mr. Harold Wick for his outstanding work on behalf of the Marine Section; to Admiral Ed Holden who is always ready to assist with his vast knowledge of safety business, and to Mr. Les Dutton who graciously receives our complaints and problems; always managing to straighten them out.

It is regrettable to note that we are losing two of our members through retirement this year—Mr. "Nippy" Parsell, who has so excellently edited our Newsletter, and Mr. Carl Holmes, Past General Chairman and Chairman of our Awards Committee. I think we should give them a vote of thanks for the splendid work they've done over a period of many years.

I entreat you to keep an unflagging interest in this Marine Section of the National Safety Council as once you Executives become diffident or deputize your Safety Program I promise you it will shortly become decadent. Safety is an intangible which constantly needs prodding and alert executive attention. I repeat my gratitude to you all for your cooperation during my term as General Chairman and know that this same support will be given my successor. Thank you.

REPORT OF THE VICE GENERAL CHAIRMAN (STEVEDORING)

G. H. E. BUXTON
director, Safety Bureau, New York Shipping Assn., New York, N. Y.

At the Spring meeting, which was held in conjunction with the Annual Convention of the Greater New York Safety Council, three papers on stevedoring were given. The meeting was well attended, and we were most encouraged to find many people present from other ports.

The Management Advisory Cargo Handling Safety Committee, which represents steamship operators and stevedoring companies on the Atlantic, Gulf and West Coasts, the Great Lakes and Hawaii, has appointed a Sub-Committee to work in liaison with the Marine Section of the National Safety Council. In this way, every port in the country can be kept advised of matters concerning safety in stevedoring operations, while at the same time there is now a means of interchange of information.

REPORT OF THE ASSISTANT GENERAL CHAIRMAN (PROGRAMS AND CONVENTIONS)

HAROLD M. WICK
assistant vice president, American Bureau of Shipping, New York, N. Y.

During the past year this committee has arranged four sessions for the Marine Section. Two were general meetings of the Executive Committee of the Marine Section held in New York at the Maritime Exchange on January 15 and June 11. These meetings were very well attended and a good many reports were received from various committee heads.

The annual Spring meeting was arranged, this being a two-day session in New York and held as usual in conjunction with The Greater New York Safety Council Annual Convention and Exposition. This was held at the Statler Hotel, March 20 and 21. The committee secured nine speakers and the services of three session arrangers and eight presiding chairmen. There were three sessions, these being the annual Shipbuilding and Repair Yard Session, a Ship Operators Session and a Stevedoring Session. A joint luncheon was arranged with the Propeller Club, Port of New York, at the Waldorf-Astoria Hotel at which Rear Admiral Henry T. Jewell, Chief, Office of Merchant Marine Safety, U. S. Coast Guard, Washington, D. C., was the principal speaker.

The current annual meeting was also arranged, this being a three-day session, devoted primarily to ship operation, stevedoring and Coast Guard activities. Ten speakers were secured together with the services of seven presiding chairmen. A joint luncheon with the Propeller Club, Port of Chicago, was arranged as a concluding feature of the meetings. The principal speaker at this luncheon will be Vice Admiral John M. Will, Commander, Military Sea Transportation Service, Department of the Navy, Washington, D. C. The committee also arranged for the annual business meeting on the morning of October 23, and the showing of two movies during the course of the meetings.

The committee wishes to express appreciation to the staff of the National Safety Council at Chicago, in particular to Mr. L. W. Dutton for the considerable assistance rendered in arranging with the Morrison Hotel for the details of our luncheon with the Propeller Club.

The committee also wishes to express appreciation to various maritime organizations for assistance rendered in distributing copies of the Spring meeting program and the annual meeting program. These were the American Merchant Marine Institute, the Lake Carriers Association, the American Waterways Operators, The Shipbuilders Council of America, the New York Shipping Association, the New York Board of Marine Underwriters, the Propeller Clubs, Port of Chicago, Port of New York, and Port of Joliet, Ill.

MEMBERSHIP COMMITTEE REPORT

T. T. WILKINSON
superintendent engineer, Marine Dept., Sinclair Refining co., New York, N. Y.

The General Chairman announced at the Marine Section meetings last year that a campaign would be waged to enlist new members. A large number of companies in the Marine field were contacted and acquainted with the advantages of membership in the Marine Section. As a result 10 new members joined during the year October 1, 1956 to September 30, 1957.

There were seven cancellations during this period—some due to member companies going out of business, or for inactivity. In two cases no reason was given and efforts are being made to persuade these companies to reconsider their decision and re-join.

The present total of our membership is now 115 of which 85 are operating companies and 30 are associations, insurance companies, etc.

The Membership Committee requests that all members continue to cooperate and advise of any likely prospects for our Marine Section.

PUBLIC RELATIONS COMMITTEE REPORT

FRANK O. BRAYNARD

director, Bureau of Information, American Merchant Marine Institute, New York, N. Y.

The Public Relations Committee carried on its regular function of seeking to provide publicity both in the marine press and in the general press for the Marine Section. Our purpose was twofold:

1) to tell the story that American ships are the safest in the world;

2) to encourage safety thinking among personnel.

It was a privilege to cooperate with the Ship Safety Achievement Award Committee in publicizing the various award presentations. May I add here that a subcommittee of the American Merchant Marine Institute Public Relations Committee was appointed during the year to handle arrangements for these award presentations. This subcommittee was headed by S. R. Bross of the Alcoa Steamship Company. Dick Bross did a remarkable job in my opinion.

The recent *Reader's Digest* safety article holds a public relations problem of considerable dimension. We regret to say that aside from a strong address by Ralph E. Casey, President of the Institute, we were unable to take any action to correct the bad name that this widely read article may have given safety on American passenger ships. To properly combat this type of article would require a constructive public relations effort of no mean proportions both as to cost and time.▲

SHIP SAFETY ACHIEVEMENT AWARD COMMITTEE REPORT

MAITLAND S. PENNINGTON

assistant vice president, Moore-McCormack Lines, New York, N. Y.

The Ship Safety Achievement Award Committee now in its fourth year of activity, made three awards and created a new citation during the past year. Two of these awards and the new citation have been presented; the fourth will be presented before the calendar year is out.

The awards were made to the liner AMERICA, with presentation ceremonies aboard the ship; the freighter CAPE ANN, also with ceremonies aboard the ship; and the tanker GULF OIL—for which no presentation has been made yet.

The special award was created to honor the Military Sea Transportation Service. It is entitled "Distinguished Sea Rescue Award" and the first presentation was made to the transport FREEMAN in Seattle last May.

We are endeavoring to extend the Ship Safety Achievement Award to include special awards to individual seamen and officers. As you know, the present award includes a pennant for the ship and individually-named scrolls for every man aboard the ship except in certain instances where only segments of the crew participated.

I hope that a new series of awards will be set up next year for various types of individual safety achievements.

It is a pleasure to thank Ralph E. Casey of the American Merchant Marine Institute for his cooperation in making the Ship Safety Achievement Award program possible. As you know, these awards are a joint project of the AMMI and the Marine Section.▲

SAFETY POSTER COMMITTEE REPORT

M. BREECE

Esso Shipping co., New York, N. Y.

The objective of the Safety Poster Committee is to assimulate and select specific material pertaining to safety in the Marine Industry, presenting this material to the National Safety Council staff who will construct safety posters suitable for use by the Marine Industry.

The first meeting of the Safety Poster Committee of the Marine section was held on March 12, 1957. At this meeting various samples of posters previously utilized in the Marine Industry were reviewed, including the two previous Marine series issued by the National Safety Council.

After our first meeting, Mr. Les Dutton of the National Safety Council was contacted in reference to what material the National Safety Council Staff desired from us and what procedure they expected to employ in issuing further Marine safety posters. Mr. Dutton informed the Poster committee that the National Safety Council staff is primarily interested in obtaining specific poster subjects with necessary supporting material to enable them to construct one two colored 8½ x 11½ inch posters at each two month interval or a total of six posters a year. These posters would be made available to the Marine Industry, and also produced in miniature in the National Safety News and Marine Section News Letter.

With the assurance that the National Safety Council can issue Marine safety posters at two month intervals, it will be possible for the shipping companies to lay out their 12 month schedule interspersing suitable posters selected from the General Poster Directory.

The second meeting of the poster committee was held on April 30, 1957. At this meeting five suggestions for posters were submitted by the members.

The 3rd meeting was held on August 14, 1957 in which the following data for safety posters was submitted:

1. Don't be a railbird.
2. Careful use of culinary knives.
3. The hazardous use of bathroom clogs aboard ship.
4. Improper rigging of bos'ns chair shackles.
5. Know your equipment and how to use it. Safety equipment (Inhalator).
6. Test tanks and compartments before entering.
7. Don't leave open floor plates unguarded.

These slogans accompanied by photographs, were submitted for approval by the committee. I suggested that the slogan "Safety is Seamanship" appear on the Life Ring Preserver on each poster. Capt. Jones F. Devlin, General Chairman of the Marine Section, gave carte blanche authority and approval from his office for the recommendation.

The posters were then sent to Mr. L. W. Dutton of the Marine Section National Safety Council. I suggested that sketches of all these designs submitted be prepared for display at the Marine Section Meetings during the coming National Safety Congress. Mr. Dutton replied that every effort will be made to have at least some of them ready for display. He also agreed that others will appear at intervals through the coming year.

Mr. Dutton felt that the miniatures of these posters can be produced in the Newsletter and in the *National Safety News* as the posters are issued. He suggested that at the time the first poster appears that we feature in the Newsletter the fact that this is the first of a series and ask the members to watch for future issues.

The first poster is tentatively scheduled for announcement in Jan. issue *National Safety News.*▲

TANKER SAFETY DISCUSSION GROUP REPORT

C. A. CULVER

safety engineer, Atlantic Refining co., Philadelphia, Pa.

Meetings are held on the second Wednesday of each month at either the Board Room or the Library of the Maritime Exchange, 80 Broad Street, New York, N. Y., July and August excepted.

The following is a brief résumé of the meetings held since my last report dated June 11, 1957:

June 12, 1957—Joint meeting with Dry Cargo Group—Mr. Francis T. Brannigan, Safety Engineer, Safety and Fire Protection Branch of the Atomic Energy Commission, Washington, D. C. led the discussion on hazards incidental to the handling of atomic materials, particularly with regard to situations where there might be fire, collision, etc. *Approximately* 30 attended.

September 25, 1957—Planning program for 1957-1958. Tank cleaning and gas freeing operations were also discussed. 17 attended.

October 9, 1957—Mr. D. S. Wechsler, Safety Engineer for the Maritime Administration, Washington, D. C. led the discussion on dry scale removal from ship's tanks using a Lamb Air Mover. This system may be adaptable to tank cleaning operations on tank vessels. 18 attended.

We believe that we are growing each year and the good attendance is evidence that our programs are interesting. There are no recommendations to make at this time.

INLAND WATERWAYS COMMITTEE REPORT

F. A. MECHLING

vice president, A. L. Mechling Barge Lines, Joliet, Ill.

The inland waterways industry is now in its fourth year of concentrated marine safety activity. The program is satisfactorily progressing through the joint efforts of The American Waterways Operators, Inc., and the Marine Section of the National Safety Council.

Safety activities currently underway in the inland waterways industry:

1. AWO makes continuous distribution of Chart of Comparative Analysis of Western River and Inland Pilot Rules Applicable Jurisdiction to Inland Rivers and Waterways of the U. S. A.
2. The Inland Waterways Safety Contest jointly sponsored by the Marine Section of the National Safety Council and The American Waterways Operators, Inc., is now in its third year. Seven new companies are participating in the contest this year for a total participation of 42 companies.
3. AWO makes continuous distribution of printed booklet entitled "Accident Prevention Guide for Inland Waterway Industry."
4. AWO develops and distributes approximately 1700 copies of the monthly Safety News to Member companies and interested groups.
5. AWO renders continuous assistance to companies with their Accident Prevention Programs.
6. AWO in cooperation with the Marine Section of the National Safety Council, has designed a special insignia to be displayed on inland vessels receiving safety recognition commencing with 1958 awards.

GREAT LAKES AREA REPORT

D. L. BUCHANAN

director, Claims Division, Pittsburgh Steamship Div., United States Steel Corp., Cleveland, Ohio

During the past year, members of the Marine Section—Great Lakes Area—have been active in promoting and stimulating interest in Marine Safety. Some of the major activities have been as follows:

1. The addition of eight new members which will mean a substantial increase in participation in the Marine Safety Contest.
2. The promotion of an organization to be known as the "Great Lakes Discussion Group of the National Safety Council." This group is composed for the most part of members of the Marine Section—National Safety Council. Permanent officers have already been elected and the group plans to meet monthly to discuss problems with regard to safety on Great Lakes Vessels. Current injuries aboard ship of general interest will also be discussed fully.
3. Assisting the Lake Carriers' Association in the preparation of another Great Lakes Safety Calendar.

We plan to continue our efforts in 1958 to interest other vessel companies operating on the Great Lakes to actively participate in the Marine Safety Contest.

GULF AREA REPORT

ROBERT F. RADER

vice president, Lykes Bros. Steamship co., Inc., New Orleans, La.

I submit the following report of committee activities for the year 1957.

CHANGES

None.

ADDITIONS

None.

ACTIVITIES

The Delta Safety Society and its Marine Section and the Metropolitan New Orleans Safety Council and its Marine Section continue their activities in promoting the furtherance of accident prevention and safety into all phases of Marine Operations with the assistance and co-operation of local Steamship Companies, Stevedore Companies, the various Ship Repair Companies, the Coast Guard, the New Orleans Levee Board, the Board of Commissioners, Port of New Orleans, and other various companies related to the Marine Industry.

The Marine Section, Delta Safety Society sponsored a very successful Marine Section Program of the Louisiana Safety Association Conference, held December 10th and 11th of 1956. The Marine Section is again in process of sponsoring a similar program on the occasion of the Louisiana Safety Association Conference, December 9th and 10th this year. A very excellent group of speakers have been selected for this Marine program and with the many efforts being put forth by the Marine Section, we are looking forward to a greater attendance and a most successful program.

On January 14, 1957, in Chicago, a large group of Marine Industry Representatives from the East Coast, Gulf Coast, West Coast, and the Hawaiian Islands met for the purpose of forming a "Management Advisory Cargo Handling Safety Committee" in an effort to promote safety in cargo handling operations further throughout the United States. The Gulf Area has been well represented and very active in assisting to organize this committee, which was requested by the Bureau of Labor Standards.

The Metropolitan New Orleans Safety Council and the New Orleans Chapter of American Safety Engineers, Sponsors of the Seventh Industrial Safety Contest, which ended June 30, 1957, awarded certificates of achievement on September 18, 1957, to the following Marine Companies for their outstanding safety records:

Jahncke Service Incorporated ...	Marine #2	Frec. 2.27
Higgins, Incorporated		Frec. 5.15
Dixie Machine Welding & Metal Works		Frec. 5.96
Jahncke Service Incorporated ...	Marine #1	Frec. 8.54
Avondale Machine Ways, Incorporated		Frec. 8.75

The Marine Section, Delta Safety Society assists the Gulf Coast Offshore Oil Drilling Companies with safety problems when called upon and stimulates safety interest among other Industrial Marine Operations. There has been reported a 25 to 30 per cent increase in membership in the Marine Section, Delta Safety Society, this year.

PENDING MATTERS:

Mr. Elliot V. Parker, Chief, Division of Safety Standards, U. S. Department of Labor, attended various joint conferences of Steamship Associations and Stevedoring Associations, in Texas, Louisiana and Alabama, in 1955 for the purpose of outlining to these two groups Safety Standards proposed by the department for voluntary adoption by the Marine Industry. This matter yet remains under advisement.

RECOMMENDATIONS:

On account of time required to do the right kind of job, which is most important, a new Vice Chairman for the Gulf Area should be appointed forthwith.

As a result of the many supplemented efforts put forth this year by all members of the Marine Industry through their various safety organizations and individual company programs, the entire Gulf Area, should produce a very good record, safety-wise for 1957.▲

PACIFIC AREA REPORT

A. E. KIHN

president, California Shipping co., San Francisco, Calif.

The form of the report will take that of a few observations on safety as related to the Pacific Coast.

The record of marine casualties on the Pacific Coast was much better last year than it was the year before. In the year October '55-October '56 there were some five major collisions, a stranding and a vessel broken in half. This year, October '56 to October '57 there have been two serious marine casualties. One was an explosion in the fuel tank of a tank vessel in a shipyard which killed 10 men with more than one million dollars damage to the ship. The other was a collision in which a freighter sank a government dredge with the loss of three men.

These tragic accidents serve to remind us that constant vigilance is the price of safety.

Last year I reported on a safety problem on the Pacific Coast that is common to other areas. This had to do with the operations of small pleasure craft in waterways also used by commercial vessels, including seagoing vessels which, because of their size, cannot maneuver as readily as the small craft. Dangerous situations sometimes evolve when the larger vessels attempt to keep clear of the smaller vessels and at the same time avoid natural hazards.

Our good friends, the Coast Guard, have been cognizant of this problem and have taken action. I speak of the Mobile Boarding Units that have been organized and assigned to the various Coast Guard Districts. These units consist of a Chief Petty Officer with three men and a trailer boat and truck. They visit recreational boating centers where they check safety equipment in boats, distribute safety literature and otherwise strive to educate the boating public.

They take action where reckless or negligent operation of vessels is observed. This is a step in the right direction and it is our hope that the activities of the Coast Guard in this regard will be expanded to keep pace with the expansion of recreational boating.

During this last year we have had a trainee assigned to our firm from the Coast Guard Merchant Marine Inspection Service. The purpose of the program is to acquaint young Coast Guard officers, who will later be in the Inspection Service, with the overall picture of the marine industry to the end that they will be better equipped to discharge their duties. Lt. Bertrand Ronneberg is the individual assigned to our company.

He is a very personable young man and we are happy to have him with us. The association will be, I am sure, of mutual advantage to industry and government.

I close with my respects to you gentlemen and to the motives that brought you to the Safety Conference—the prevention of accidents with the avoidance of human suffering and the preservation of our ships and commerce.▲

PROTECTING OIL TANKER CREWS FROM ACCIDENTS

by CARL F. VANDER CLUTE

general manager, Marine Dept., Gulf Oil Corp., New York city

To cover the scope of the subject matter would fill a large-sized volume. On the other hand, I could give you a brief solution to the proposition. Safety means "NO ACCIDENTS."

Just as we are all against sin, so we all favor safety . . . that is axiomatic. It is also true that we are against those things that are unsafe. However, though we are against them and preach and try to educate crew members, we must realize that, like death and taxes, accidents will always be with us due to the vagaries of the human element.

It is our job to keep accidents to a minimum, especially since the courts have extended the range of liability to the point that the ship owner is the sailor's guardian angel. A seaman in the days of yore was considered the ward of the Admiralty.

In those days there may have been reason for such a doctrine. Today, that doctrine has been so expanded that the time has come when the courts should courageously repudiate antiquated doctrines of the horse and buggy era.

It behooves the ship owner to indulge in safety education as a protective measure. Educate the men to avoid the accidents to circumvent the need for the court to exercise its parental guardianship for the modern sailor. As a matter of fact, the men who go down to the sea in ships are well educated, intelligent men for the most part. They are, in the main, a credit to the high standards of the American Merchant Marine and need not be considered "Wards" of the Admiralty.

COURTS GUARD SAILORS

Nevertheless, today, the courts go far astray in treating seamen as Wards of the Admiralty. Seamen, as well as other men, have their frailties. A classic case is cited as follows:

The plaintiff, a seaman, rated as a fireman and watertender on the SS. _____, was injured while on shore leave in the port of Split, Yugoslavia. He had collected his pay and medical expense and now sued for 36 days maintenance. Going ashore about noon he resorted to a tavern where he drank one glass of wine.

He visited another liquid dispensary where he quaffed two glasses of similar vintage. There he met a woman who lured him to her room for purposes not particularly platonic; while there "consideration like an angel came and whipped the offending Adam out of him." The woman scorned was unappeased by his contribution and vociferously remonstrated unless her unregarded charms were requited by an accretion of "dinner" (phonetically put). The court erroneously interpreted the word as showing that the woman had a carniverous frenzy, which could only be soothed by the succulent sirloin provided at the plaintiff's expense.

MAN LOCKED IN

But, it was explained to denote a pecuniary, not a gastronomic dun; she then essayed to relieve his pockets of their monetary content. Completely thwarted, the woman locked plaintiff in her room. He kicked the door while he clamored for exit; not thus persuasive, he went to the window about six to eight feet above the ground and while there contemplating departure, he was quickened to resolution by the sudden appearance of a man.

So the plaintiff thus confronted leaped from the window and sustained injuries which hospitalized him in Yugoslavia and the United States. During the extensive period of his incapacitation his wages and hospital bills were paid by defendant; the only question confronting the court is his claim for maintenance over a period of 36 days.

ENTITLED TO SUE?

Consider the peculiar circumstances under which plaintiff met with his injuries: do they militate against the recovery of maintenance from the defendant? No authority with an analogous state of facts was cited by either side; the defendant contends the plaintiff accompanied the woman to her room and his leap from the window was tainted with his original immoral intent. Therefore, he is not entitled to sue for maintenance.

It cannot be consistently argued that plaintiff, having abandoned that original purpose and having sought to conserve his safety as well as the life of a good sailor, was acting on continuance of the initial immoral intent. In the court's opinion the proximate cause of plaintiff's leap from the window was not his original intent but was the concurrence of the locked door and the subsequent looming threat of the man.

FEAR CAUSED ERROR

The plaintiff's violent fear caused him to exercise an erroneous judgment to jump rather than drop to the ground. Under the circumstances, the window was the only solution presented to plaintiff in his emergency; at least he cannot be condemned for so conjecturing despite his starting on the wrong moral foot.

The court mentioned another case where a seaman on shore leave was not found to be definitely intoxicated from the consumption of three bottles of beer and his diving into a dry swimming pool was not construed as wilful or gross misconduct. The court did not find in the present case that drinking three glasses of wine rendered plaintiff intoxicated; nor did his jump from from the window denote inebriation. To hold otherwise would argue strongly against his ability to choose the means of escape and would indict him for an error of judgment which is not the law against one who chooses in an emergency one means of safety when another might have been more conducive to that end.

Peculiarly, the plaintiff chose the only means of escape even though it resulted in his injuries; had he elected to go out the door with the threatening man there barring the way, his injuries reasonably might have been more serious. Judgment was for the plaintiff for 36 days maintenance.

In another case a learned judge used the following language:

"Substantially all maritime risks are insured, and if we must suppose that the addition of this risk will show in the premiums, in the end it will be likely also to show in freight rates; and so far as it does, the recovery will be spread among those who use the ships."

COURTS FAVOR SAILORS

In other words, the court went all out to find against the ship because it was covered by insurance. It actually means that a ship owner must subsidize accidents to seamen caused by their own vices.

To take advantage of the beneficent attitude of the courts are some less desirable elements to whom education is of no value.

In this connection I again think that a U.S.P.H. certificate N.F.F.D. (Not Fit For Duty) is too broad. It makes no distinction between ratings. All are classed as seamen but the Public Health doctor doesn't know and cannot be expected to know unless industry tells him that there are different categories. A condition that would justify an N.F.F.D. for an A.B. or Oiler does not necessarily incapacitate a messman or wiper from performing his limited duties.

ELIMINATE HAZARDS

We must therefore conclude that while safety education is valuable and not to be discounted in any way, it has its limitations. It, therefore, is well for us to give considerable thought to the elimination of hazards wherever possible, or provide protective measures. In other words, reduce the exposure.

Assume that our sailor has navigated the voyage safely back from shore and to the ship's gangway. Here is a place where caution can be exercised in a preventive manner. Don't forget the ship is primarily responsible for the gangway even though it be furnished by the dock or shipyard. The gangway should have a proper approach and be properly rigged with man ropes or rails and well lighted after sundown.

A life ring with life line should be available at the gangway at all times. Above all, a life ring should be close by when a Jacob's ladder is being used for boarding. Every precaution should be taken to make sure the gangway is safe so that our sailor can get aboard without slipping, or if he slips, so he can't fall overboard. Proper treads and abrasive non-skid material between treads as well as well-rigged ramps when required, are essentials. Cleanliness is of importance.

ENSURE GANGWAY SAFETY

Recently, there was a case where a shipyard furnished the gangway and there was sand on it. The sailor slipped, but that's not all, one of the safety lines allegedly was missing and the sailor went over the side. The sailor was badly injured and it cost a large sum of money to dispose of the case.

The point is that the ship should make sure that the gangway is safe in all respects, regardless of whose gangway it is, because it forms the means of ingress and egress, and it is the ship's primary responsibility to see to it that such ingress and egress are proper and safe. This, then, is a matter of education of your ship's officers to realize that, even though someone else furnishes the gangway, it is their duty to see that it is safe and proper. As preventive medicine we supply the ships with the safest gangway we can buy.

Now our sailor is aboard. We must prevent his slipping for slipping cases outnumber all others. Here again, while all efforts are made to educate our sailor to watch where he steps and to maintain an even keel, it again behooves us to use preventive medicine.

We know ships are endeavoring to go all out and make all deck spaces non-skid. We have experimented with various items but find that the use of Fuller's Earth sprayed on the paint while wet establishes a very effective surface. However, nothing is perfect. A man without proper equilibrium must be regarded as unstable. He therefore becomes a hazard.

Our crews have developed several types of sprayers and thus created a competitive spirit, each trying to outdo the other. This competition, as well as the actual spraying leaves a lasting safety impression. The actual doing of the job is better than many lectures.

SHIP HOUSEKEEPING IMPORTANT

Good housekeeping aboard ship is always essential. Usually a ship that exhibits good housekeeping is an efficient ship which is conducive to a happy ship, and this all goes toward a safe ship.

Among others, the forecastle and the poop deck are places where good housekeeping is essential because of the gear and equipment—mooring lines, chains and stoppers, anchor windlass forward, winches aft. Pausing for a moment at the anchor windlass we, in Gulf, have experimented with anchor locking bars and brake bars. We are replacing the old heavy steel anchor bars with light-weight aluminum bars. We

also have provided a working platform to afford safe footing and a good position for a man when he has to lock a windlass in or out.

The forecastle deck is a location where non-skid decks are most important. Often wet, the possibility of oil from the windlass, mud from the anchor chains and wet mooring lines all contribute to the necessity for providing non-skid footing. However, failure of men to wear proper foot gear contributes materially to slipping and falling accidents.

PREVENT PUMP LEAKS

As we move along, let us stop at the pump room. The leakage of cargo into the bilge through the cargo pumps was a matter of concern to us. We have installed mechanical seals which eliminated this potential source of trouble. Incidentally, we have also utilized the mechanical seals on the fire pumps to eliminate wetting down the electric motor and putting it out of business.

We also advocate the installation of fog nozzles in the pump room. In the event of fire, if men are in the pump room the use of CO_2 would be disastrous. The fog nozzles permit fighting the fire and also give the men a chance to get out.

We feel that the use of good, light-reflecting paint—white, in our case—is helpful in preventing slips, bumps and other accidents.

After the pump room, it is natural to think of the tanks. We are experimenting with a deck eductor which is light and easy to handle. The type we are trying weighs only about 20 pounds and is easy to handle. It is kept on deck and only 1¼-inch hose is lowered into the tank. Whenever a piece of equipment can be made light enough to handle easily the hazards are reduced. The possibilities of dropping on toes, hernias, sprained backs and the usual run of injuries that can result from handling heavy equipment are reduced. This is the type of thinking I refer to as preventive medicine.

As do many others, we use the Coppus blowers, eliminating the old bulky and accident-prone windsails.

Mucking tanks still has its share of accidents. We furnish hard hats, rounded bottom-edged buckets and a special hook which is as near fool-proof as we can find. We have also reduced the size of the buckets to facilitate handling and reduce the weight. The latest plastic bucket we are looking at has no metal rim on the bottom, having only a top rim and a handle.

While we furnish hard hats, we know they are not always worn and by the use of the plastic buckets with no metal rim on the bottom, we hope that if a man is struck by one the results will not be as catastrophic as would be the case with the old metal buckets. With the deck eductor we are trying out, we hope to decrease the amount of mucking necessary and thereby reduce the exposure.

Apropos of our constant study to reduce weight to facilitate handling, thereby reducing the slipping, falling and straining cases, we have reduced the size of our laundry bags. This may sound like a simple proposition but we have found that one of these old laundry bags coming back with clean, folded sheets weighed up to 100 pounds. We have now cut the size of the laundry bag in half so that the maximum weight now is about 50 pounds, making it much easier for a man to handle. Since the institution of these smaller bags we have not had a claim resulting from carrying linen aboard or stowing it.

Throughout the ship ladders are constantly being checked to assure a good footing. Nevertheless, we still have men going up and down ladders "No hands" and, at times, winding up with an accident report.

CHECK LIST INSPECTIONS

We have a regular form which our safety inspectors use going aboard a vessel covering conditions in general, including safety items. We also have what we call a concentrated check list. Each month we select a group of items, usually eight and, in addition to the general inspection, have a specific examination and report on these selected items.

Our regular review of all accident reports sometimes suggests items for this list. For instance, one month might cover gangways, anchor windlass bars, screens on portholes, guards on fans, goggles, ullage opening screens, floor plates in the engine room, guards on gauge glasses, etc. The following month the list will contain different items. This check list not only is a preventive but

is also corrective if defects are found and aids in the instilling in the mind of all that safety is a mighty important commodity.

Through the courtesy and safety cooperation of the Navy Department we are sending as many of our officers as is possible to the fire-fighting school at the Philadelphia Naval Shipyard. As a result of this education, we feel our officers are more fire conscious and, hence, more aware of fire hazards and their elimination. After taking the course, one of our officers was asked what he thought of it. I believe he summed it up in good style when he said: "Before I went to the school I thought I could fight a fire, now I know I can."

PREVENTION EMPHASIZED

Again, the Navy has extended safety assistance (M.S.T.S.) and we are taking advantage of the opportunity afforded by sending our men to the Bayonne school, which covers damage control. The Radar school is another educational facility that we are utilizing as much as possible. This is all education, it is true, but is preventive medicine. It emphasizes safety through the interest we take in helping our men to prevent accidents.

Far be it from me to forget the Engine room spaces but our accident record in the Engine room has been good. This is a tribute to the men below and we hope we can continue to make this statement. Nevertheless, our inspectors have their items to check in the Engine room—the floor plates, leaky glands and guards.

Believing that repetition is one means of emphasis, we periodically replace the safety posters on the ships. We try to abstain from using signs that say WARNING because we are a peculiar people. Witness the WET PAINT sign which, for some reason, seems to have a hypnotic effect on many who must test the paint to see if it is wet. To many, a warning seems to have the same effect—a signal to take a chance and see if it is really true. Yes, people are funny but the pain and suffering of the man and the insurance costs that follow some of the consequences of the chance-taking establishes truths that create no hilarity.

Safety is serious business. It pays to play it safe and while the great importance of safety education is acknowledged it still behooves us to exercise all possible precautions to protect man against himself.

I publicly salute my staff, our ships' officers and men for we are proud of their response to our safety endeavors and grateful for their aid and cooperation for the common cause of safety.

PREVENTION OF ACCIDENTS TO CREW ABOARD FREIGHTERS

by ROBERT J. TARR

operating manger, Luckenbach Steamship co., Brooklyn, N. Y.

Our present "Shipboard Safety Program" was started in March, 1952, and is similar to the National Shipping Authority Safety Program and to the safety programs followed by other owners and operators of U. S. Flag Cargo Ships. It provides for the establishment aboard each vessel of a Ship Safety committee, with the Captain acting as chairman who, in the course of their safety duties, meet at least once a month to discuss all accidents since last safety meeting.

Also discussed are: New safety bulletins, safe practice pamphlets, safety directives and literature received since last meeting; report of, and action taken, by Ship's Safety Inspection committee; and report of action taken by "Home Office" to previous suggestions by Ship's Safety committee. Minutes of all meetings and recommendations of Ship's Safety committees, are promptly forwarded to our shoreside safety director in Brooklyn.

Now comes the most important part of the entire Shipboard Safety Program—the attitude and action taken by the "Home Office"—in our case our operating department—to these minutes and recommendations. Our safety director studies the minutes and recommendations as soon as received and forwards them to the operating manager with his comments.

The operating manager then reviews, together with the safety director's comments, and further discusses minutes and recommendations with his general marine superintendent, superintendent engineer, purchasing agent, port steward, supervisor-crew personnel claims, terminals superintendent and/or others in his shore staff that may be directly concerned with a particular safety recommendation.

HOME OFFICE FOLLOWS UP

Action is then decided upon and our general marine superintendent arranges for the necessary work to be accomplished—advising both our safety director and the master of the vessel originally submitting the recommendations. In the event a recommendation is turned down, both our safety director and master of the vessel submitting the recommedation are so advised—together with reasons for turn down.

It is this prompt follow up by the "Home Office" that is so necessary to the continuance of a high degree of interest by masters, officers and crew members in a Shipboard Safety Program.

Our "Safety Director"—the shoreside coordinator of our safety program—is also our port captain and Atlantic Coast pilot. This combination of duties works to the advantage of our safety program since it affords our safety director an opportunity, in addition to his overall shoreside supervision, to observe our safety program in actual shipboard operation at sea each time his piloting duties places him aboard one of our ships.

He thus often has the opportunity of "sitting in" on the Ship Safety committee meetings and presenting the company's shoreside views on many of the items brought up. On those vessels whose Ship Safety committee meeting minutes indicate a lack of enthusiasm, he utilizes this opportunity actually to take part in and rejuvenate, the interest so necessary to the success of any "Shipboard Safety Program."

I reviewed the minutes of all our safety meetings from March, 1952, and will relate some of the more unusual and interesting safety problems encountered by us in the past five and one half years, together with our solutions to these problems, plus a quick briefing on some of our present safety action and our safety training for the future.

OPERATE 16 VESSELS

We own and operate a fleet of 16 cargo vessels of C-2, C-3, and C-4 type, principally in the Intercoastal Trade but also in Off-Shore Service. Additionally, as general agents for the Maritime Administration, we have operated Mavi, Liberty, Victory and Mariner types of cargo vessels. Under Bareboat Charter from the Maritime Administration we have operated Liberty ships in the bulk grain, coal, and ore trades. Our review of our Shipboard Safety Program for the past five and one half years is based on this type of operation.

We have made nine subdivisions of our comments simply for ease of discussion rather than on the basis of safety importance since, with safety, every hazard is important.

GANGWAYS—LADDERS

Shipboard safety starts at the gangway. Gangways have been the subject of many of our safety meetings since a safely rigged gangway is important to everyone (crew, longshoremen, passengers, repairmen and officials) that boards or leaves a vessel in port. Our gangway problems have involved minor to major solutions.

Proper guarding of the gangway roller, after much experimentation, was accomplished in a simple and practical manner by extending the gangway floor boards about six inches beyond the end of the gangway—thus forming a guard over the roller.

The C-2 vessels of our fleet presented a major gangway problem since the gangways are rigged at cabin deck, rather than weather deck-level and with vessels in light condition the regular 38 foot gangway originally provided was too steep for safety.

After considerable study, we designed, and had constructed, aluminum 50 foot gangways for three of our C-2 vessels. The fourth C-2 could not properly house a 50 foot aluminum gangway and still clear the lifeboats—being slightly different in design. Therefore a 38 foot gangway with a 12 foot portable extension was designed and constructed of aluminum and our problems were solved.

GANGWAYS WERE HAZARDS

Originally our C-4 vessels had gangways fitted either between #3 and #4 hatches or at #6 hatch—both dangerous locations due to concentration of cargo handling activity at these large double-geared hatches. We relocated the gangways of our C-4's to the poop deck of the after house, just forward of the small single-geared #7 hatch, greatly minimizing the hazards from cargo operations.

Safety meeting minutes indicate a strong preference for "string-of-light" gangway illumination during darkness rather than a single makeshift light or a quickly rigged cargo light brightly illuminating only a small portion of the gangway and casting dangerous shadows over the remainder.

Safety nets are provided for all our vessels and our safety instructions require their rigging beneath ship's gangways not only at Pacific Coast Ports where longshore rules require their use, but at all Ports of Call. These nets have already caught, and saved from possible injury several late returning crew members who had lost their stability after faulty shoreside loading of liquid cargo.

A gangway hazard often complained of in our ship's safety meetings and one most difficult of completely satisfactory solution despite our best efforts, concerned a situation at our Pier 84, South Wharves, Philadelphia. Depressed railroad tracks run down both aprons of the pier. A large portion of our cargo, particularly steel, is loaded direct to ship from railroad car and some cargo is discharged direct from ship to railroad cars. This operation requires frequent "drills" of cars over the aprons.

CATWALK ACROSS DEPRESSED TRACK

The use of ship's gangway required persons to make their own way over the depressed tracks to, and from, the pier. As a partial correction of this hazard, a plank catwalk was provided across the depressed track from pier to edge of ship's gangway. This required "breaking" (uncoupling) each drill of cars just abreast of ship's gangway to position the plank catwalk. You can visualize the disadvantage of this plan.

Many crew members would not wait for the catwalk to be placed and, even when it was in position, some continued to make their way through empty freight cars or over the couplings between loaded cars—a most dangerous procedure. After considerable trial and error attempts to correct this hazard, we decided the complete solution required the design and construction of a shoreside, portable, platform type, lightweight gangway to span, not only the tracks, but loaded railroad cars as well and provide a safe, direct route from pier to ship, independent of ship's gangway.

We designed an aluminum gangway, swivel-fitted to a raised stairway platform on rollers at the pier end, but fitted with a special-alloy grooved slot for clamping to the sheer strake at the ship end. This design was a complete success. It spanned loaded railroad cars and eliminated necessity to "break" drills abreast of ship's gangway.

To insure only this one safe avenue is available, ship's gangway remains housed. This solution was costly. The gangway cost more than $2,000.00 and we have since purchased a second one for use when working a vessel on each side of the pier.

CUT PIPE RAILINGS

At certain periods we encountered gangway safety problems at Portland and, occasionally, at Terminal Island when the weather decks of our vessels, in loaded condition, dropped below the level of the dock. Our short, shoreside brows at these two locations when the above conditions prevailed did not form a smooth, even passage from dock to weather deck. Cutting the pipe railings on the cabin decks of our vessels to accommodate our shoreside brows (and fitting the openings with removable pipe railing inserts) corrected the hazard.

A hazard is usually created when a cargo hold ladder rung is damaged or knocked off during cargo operations which prevent prompt and permanent repair or replacement. We placed aboard each of our vessels several spare ladder rungs of a special type that can be quickly and easily clamped

in place of a damaged or missing ladder rung and perform safely until permanent repairs or replacement can be accomplished.

Safety meetings have endorsed aluminum step ladders aboard ship for gradual replacement of wood—based on the sturdier, lighter and more dependable properties of the aluminum from the safety standpoint. We gave them a trial and, although more expensive than wood, we find them a definite safety asset and feel their longer wearing qualities will minimize the cost differences.

PASSAGEWAYS—WALKWAYS

One of the frequent causes of falls appearing in safety meeting minutes is oil on decks. Oil in the vicinity of winches is a problem of good housekeeping requiring the cooperative clean-up efforts of both deck and engine departments. Poor footing conditions, however, resulting from fish oil compounds used in the maintenance and preservation of weather decks is a problem that has existed ever since the operation of ships with steel decks, and the solution to this problem seems to have been pondered just as long.

Despite the numerous weather deck coatings developed in the past years, fish oil formulas seem to remain as the best preservative, from the standpoint of economy, ease of application and results for maintaining weather decks on cargo vessels. Its use, however, presents slipping hazards even when intelligent precautions are diligently taken. We have tried, over the years, as have many operators, numerous recommended products to preserve our weather decks yet eliminate the slipping hazard associated with fish oil mixtures.

COAL-TAR DECK COATING

We had little success until a few years ago when we discovered a certain coal-tar base product and decided to try it as a weather deck coating—after properly preparing the test surface by shot blasting to bare metal. An experimental patch was applied alongside #5 hatch on a C-4—a most active location subject to extreme conditions of weather and cargo handling. This product dries quickly, forms a rather thick, protective, abrasion-resistant coating and produces a non-skid surface.

Our experiment worked so well that after six months of trial, we applied this product to the entire weather well deck of one of our C-4's. The product is relatively inexpensive. Initial application is costly since it requires bare metal preparation of surfaces and two or three coat original applications. Maintaining the coating and touching up abrasion spots is quick and simple.

Although our studies continue, I feel we will find, despite the original application expense of this product, we have eliminated the hazard of slipping, the sleep destroying noise of frequent deck scaling, the obnoxious odor of fish oil, also reducing the high deck crew costs of maintenance of the weather decks of this vessel. If this proves true, we plan to apply this coating to the weather decks of the remaining vessels of our fleet.

Our C-4 type vessels, when first acquired, presented a dangerous condition at sea for crew members to make their way over the weather decks, alongside hatches 3, 4, 5, and 6. This condition was more serious during bad weather and especially when vessels had deck cargoes stored in these locations. These engine-aft ships feed in the after house while the bridge and quarters for the deck officers and radio operator are forward, therefore it is essential a safe passageway be provided between the bridge and the after house.

NEED SAFE CARGO STORAGE

This hazard was discussed at many C-4 safety meetings. We finally devised a plan of installing portable deck stanchions, bolted to welded deck pads, in two rows on the weather deck, on both sides of hatches 3, 4, 5, and 6, to confine and provide a safe method of securing deck cargo and furnish a safe walkway on both sides of the hatch coamings. The outboard row of stanchions were installed as close to the sheer strake as possible, consistent with necessary allowance for bitts and shrouds and proper securing of deck cargo.

The inboard row were installed just far enough from the hatch coamings to provide a safe passageway alongside the coamings, on both port and starboard sides, for the crew. Pad eyes for lashing and securing deck cargo were also suitably arranged in rows close to the stanchions. This system completely corrected the hazard and provided a far safer and more economical method of securing deck cargo.

It required less shoring and lashing materials, lessened the time required by carpenters to secure (usually the last operation and almost always on overtime) and eliminated the expense of building last minute catwalks over the tops of deck cargo with the continual worry they might carry away with possible injury to, or loss of, a seaman.

This plan worked so well on our C-4's that we made similar stanchion installations on the weather decks of our entire fleet of C-2's and C-3's, abreast of hatches 1, 2, 3, 4, and 5. Several years ago the Maritime Administration indicated considerable interest in our deck stanchion arrangement for their "Clipper Class of Proposed Cargo Ships," since these vessels were also designed as engines-aft vessels and presented passageway safety problems similar to our C-4's.

STEEL CARGO CONTAINERS

Safe on-deck stowage and proper securing of the many small parcels of certain types of "label" cargo moving in the intercoastal trade was greatly improved safety-wise by our purchase and semi-permanent installation of large (20L x 8W x 7H) surplus, steel cargo containers for the stowage of this type of on-deck cargo. Again we found savings, as well as safety, resulted from our efforts. Expensive securing bins and elaborate covering arrangements were no longer necessary. The danger of "label" cargo coming adrift in bad weather was greatly minimized and our out-turns were greatly improved.

Providing additional lighting in emergency escape trunks of our C-4's has lessened possibility of injuries, as has installation of glass ports in all doors opening out into passageways.

Galvanized metal wind scoops, projecting at face heights into outside passageways, have been condemned in safety meetings. We have corrected this hazard by replacement with rubber wind scoops and, although about a third more expensive, they certainly are longer lasting.

To insure safe passage from engine room to steering engine room on our C-2's in rough weather, a door was cut in shaft alley escape to the stores flat, above the steering engine room, providing a completely inside route for the engine crew.

Longshoremen create hazards for themselves and the crew by their failure to leave walkways clear of pontoons, dunnage and assorted gear. Failure of longshoremen to replace rails when not working cargo is dangerous for the crew. Continual watchfulness on the part of ship's mates and relief mates is required to combat these hazards.

HANDLING GEAR SAFELY

Tip-top maintenance of all cargo handling and related gear aboard a cargo ship is essential to safety of crew and longshoremen. We maintain the cargo gear aboard our vessels in accordance with the very stringent rules of the International Cargo Gear Bureau, requiring annual inspection and Quadrenial Tests.

In addition, and most important, our mates are required to keep their "Register of Cargo Gear" up-to-date, properly logging every replacement or runner, shackle, block, chain, etc. Our general marine superintendent personally inspects the registers of every ship on call at New York during his general inspection of the ship and her gear.

All our C-2, C-3 and C-4 type vessels are equipped with ½ inch, improved plow steel cargo runners to provide a safe working load in excess of the rated single fall winch pull of the winches aboard these vessels.

HATCH COAMING SAFETY

Hatch coamings become scored from cargo runner abrasion and it is important from a safety standpoint that these scorings be built up with welding from time to time. If the grooves are allowed to cut deeply, a cargo runner will "hang up" temporarily in a deep groove and not follow the load, finally snapping out of the groove with a jerk, sometimes severe enough to upset the draft at the risk of those working below. Strict maintenance of hatch beam locking devices is essential to safety.

To modernize and improve the safety of our cargo gear and eliminate the use of rope for guys, we have equipped all our vessels with Guy Winches and Vang Stands and substituted more dependable wire for manila which has abolished entirely the need for preventers.

The positioning of cargo booms is often mentioned in safety meetings, and elsewhere in safety literature and discussions, as haz-

ardous and certainly the many booms dropped, with resultant injuries and near misses, give plenty of cause for concern. The favorite cause of boom accidents, from our experience, is the improper use of chain stoppers. The U.S.P.&I., in their Cargo Series Safety Letter #082057 entitled "Chain Stoppers," excellently covers this subject.

We have distributed copies to all our vessels for their safety program, as we do with all their fine safety literature. Many modern cargo vessels are equipped with topping lift winches as are our C-4's, which practically eliminate cargo boom topping hazards. Several years ago we purchased all the topping lift winches available from the conversion of C-4 type vessels and installed them after adaptation at the 10-ton boom locations on our C-2 and C-3 type vessels, for the prime purpose of safety as well as modernization of our cargo gear.

Hatch tent gantlines have carried away due to chafing by cargo runners. A safe gantline has received the study of safety people both afloat and ashore. After considerable experiment, we found ¾" chain pendants, rigged to allow hatch tent blocks to hang clear of gin blocks and cargo runners, to be the safest. We are just completing our program of chain pendant installations on all ships.

FIRE HAZARD ON BOARD

The worst hazard of all, and the most difficult to completely defeat, despite receiving the most attention, study and regulation, is fire. Smoking remains as one of the main causes of fire aboard ship. Careless smoking habits of the crew and illegal smoking by longshoremen during cargo operations, as well as by shipyard workers and contractors working aboard, have all contributed to shipboard fires.

It is amazing that we continue to run across cases of crew members smoking in bed and burning up bed clothing and mattresses, yet miraculously escaping serious burns themselves. Other companies may have experienced serious burns to their crew members from this absolutely foolhardy practice. In addition to constant hammering at this hazard via our safety meetings, we have found charging the guilty crew member for the bed clothing and mattress burned as a result of smoking in bed, has had some effect towards halting this practice.

Providing numerous inexpensive ash trays for crew use is helpful. At least with ash trays around crew members are not inclined to flick their cigar, cigarette, or pipe ashes into waste baskets where scrap paper provides the missing ingredient for a delayed action fire.

FIRE REGULATIONS DIFFICULT

Constant supervision is required to combat the smoking hazard. This is perhaps, our most difficult safety policing job aboard our ships. We have provided designated smoking areas for longshoremen aboard all type vessels of our fleet. These areas are permanently marked by signs and our chief officers are responsible for enforcing the smoking regulation program aboard ship.

Repairs aboard ship, involving welding and burning operations, present a potential fire hazard, utmost supervision on the part of vessel's Officers, Port Engineers and Job Foremen is essential to insure proper fire watch is maintained, adequate hose strung out, and other fire fighting equipment kept in readiness. Not only must the vicinity of the welding and burning operation be free of cargo, dunnage, paper and other combustibles but, even more important, a check must be made of the areas under the deck, or on the other side of the bulkhead from the area to be burned or welded.

A place where danger of explosion and resultant fire might not be expected but exists, is in motor lifeboats where gasoline fumes may accumulate under the boat covers and an attempt to unlash, uncover, and start the motor quickly could be disastrous. Motor lifeboats should be given an opportunity to air out after covers are removed and before attempting to start motors.

DECK PRECAUTIONS

Our experience indicates many more minor or "little things," aboard ship contribute to injuries than do major, or "big things." It is most important, particularly when working on deck handling mooring lines or working cargo gear, that only English be spoken. A misunderstood foreign word, exclamation or order could, and has caused accidents.

A clean chain locker minimizes the amount of rust and dirt flying around and endangering the eyes of the deck crew during anchoring. Wearing goggles during anchoring operations further guards against rust and dirt particles entering their eyes. The use of chain pipe covers at sea is also a safeguard to the eyes of the deck crew during anchoring since the use of cement is eliminated and, therefore, the hazard of flying cement particles.

The installation of lights under poop verandas has proven a safety aid during berthing and mooring operations in darkness.

INSTALLED RUNGS ON BOOMS

Whenever men are working over the side painting, a good precaution is to have a life ring on a suitable line floating under their staging. A sign, informing longshoremen that men are working over the side, is an added precaution guarding against the possibility of their throwing dunnage or other objects over the side, endangering the men on the staging. Securing the ship's whistle, while men are working around the stack, is good safety procedure.

As a result of recommendations in the minutes of safety meetings held aboard our C-2's we installed ladder rungs on the boom cradles of these vessels—making the task of securing booms safer, easier, and quicker.

Securing the bow and stern sections of lifeboat covers was made safer on our vessels by the installation of lifeboat ladders at the boat ends, fitted with safety rings to allow seamen safe use of both arms in securing boat covers. I have learned of a new design of boat cover with inboard, athwartship slots, instead of conventional fore and aft end slots, permitting the securing of the entire boat cover, in safety, from the sheltered inboard side of the boats, instead of from the exposed ends. We have arranged to give one a trial.

Another safety problem encountered by us, the solution of which resulted in some savings, in addition to increased safety, was the hazard to seamen painting over the side around the bows of our ships. Working from stagings in this bow flare area is precarious and the necessity of frequently shifting stagings results in a slow and costly job of painting.

We purchased a large, stable paint float, reconditioned it, equipped it with permanent, sturdy staking and a small outboard motor. This paint float is based at our Terminal Island berth and is used during loading and discharging operations by the intercoastal vessels of our fleet calling there.

Since weather is usually good at Terminal Island, we can easily complete the painting of both bow and counter areas plus the offshore side during the northbound call—completing the remaining side, by berthing opposite side to, during the southbound call. The small outboard motor is used to shift the float. When not in use, the paint float is chained to our terminal and the outboard motor kept in a locker ashore. Our experience has shown this paint float has not only greatly diminished a hazard, but has provided a quicker, better and less expensive method of maintaining the hulls of our fleet.

ENGINE ROOM HOUSEKEEPING

Constant engine room vigilance in keeping ladders, floor plates and catwalks, free of oil spots is necessary to insure good footing and avoid slips and falls. Flat bar coamings, installed around turbo-generators and steering engines to contain any oil leakage, prevent slipping injuries.

Often a simple modification to a projecting valve will eliminate a hazard to the engine room crew. Guards fitted over the exposed flexible couplings are a safety aid. Sometimes a few minutes spent in padding a particular overhead pipe or fitting that might catch that occasional extra tall member of the engine gang, could avoid a painful head injury.

We have eliminated the use of toxic carbon tetrachloride and substituted one of the safe chemical solvents now on the market for use in our engine rooms and electrical shops. (With the exception of carbon tet fire extinguishers in our motor lifeboats, we have practically eliminated the use of carbon tet on our ships).

Winch repairs seem to involve injuries too frequently to the engine force. It is essential that master switches to winches to be repaired, particularly in port, are turned off prior to start of repair work. Repairs should never begin on a winch next to an open hatch until a pontoon cover, or a section of hatch covers alongside the winch, have been replaced . To avoid lifting injuries to personnel, we have installed handles on the heavy brake housings of our winches for easier handling by two persons.

Insisting engine personnel use the inside route via shaft to steering engine room, in rough weather, has made for greater safety.

Expanded metal screen sections have been provided on operating level gratings over watch stander's stations to prevent injury from loose material above. We now obtain fire-brick for stores in packaged lots to reduce hazards from loose materials being handled in the engine room.

OTHER SAFETY MEASURES

Permanent welded pad eyes have now been installed in the overhead of upper engine casing on our C-3 vessels for safely securing paint staging and eliminating hazardous, makeshift rigging to inadequate beam lamps. We have provided new, lightweight, alloy chain falls, with extra length hoist chains, to enable safer removal of material from engine room to 'tween deck passageway, without transfer of load enroute.

Engine room ladders, at operating level, have been relocated on one of our vessels to provide safer pitch and existing hand rails extended for greater safety. We extended gratings and hand rails to certain machinery not originally fitted, to eliminate use of hazardous makeshift wood planking. We use portable steel ladders, with telescoping sections, during maintenance and cleaning inside the furnace of boilers. These ladder sections are also useful as supports for staging inside the furnaces—all contributing to safer working conditions.

On three of our C-3's, we have replaced burner registers with a different type to prevent dangerous flare backs and explosions from improper combustion. Signs are posted in all our engine rooms warning firemen to use torch when lighting-off rather than furnace brickwork or another burner. Combustion control system on these vessels was also modified to a later type to reduce possibility of flare-back from improper operation.

ALTERED, INSTALLED SAFETY

To insure proper ventilation for crew working in enclosed areas like tanks or boiler drums we have provided portable vent blowers with two ten foot sections of flexible hose.

Making minor alterations and providing simple installations and equipment has made our ships safer.

Providing a chute for dry stores on our C-2's and C-3's has eliminated the need of carrying stores down a steep ladder in a narrow passageway—thus avoiding lifting injuries to steward's department personnel previously experienced in this storing operation. Non-skid decks have been installed in the galleys of several of our vessels and the use of non-skid floor wax on regular galley tile floors has contributed to safety.

Prohibiting the use of tin cans as ash trays in crew mess areas and crew forecastles has avoided painful cuts. Many painful cuts results from careless dropping of glassware in the dishwashing sink. Providing plastic-covered glass trays has helped avoid broken glass and resultant cuts. Providing knife racks of micarta (U.S.P.H.S. Approved) and insisting chief stewards insure they are used prevent cuts from knives otherwise carelessly left lying around.

A can opener on one ship was condemned as a hazard! It was reported that the can opener was faulty and deposited metal shavings in the food during the opening operation— resulting in mouth cuts to several crew members. Even a seemingly harmless common household item like this may be a potential source of injury. We replaced all chipped enamel parts from galley slicing machines with stainless steel to prevent chips getting into food.

AVOID WATER IN GALLEY

Steward personnel must be continually cautioned against using a water hose for washing down the galley due to the hazard of water contacting the electric galley range. A rope safety line, rigged as a hand grab across galley ranges on our C-2's, has helped avoid accidents in bad weather.

Heavy refrigerator doors are bad medicine in rough weather, unless handled with extreme care. We have recently learned of a new type plastic door, weighing 90 pounds as against present doors weighing 500 pounds. This sounds to us like safety progress and we will certainly give one a trial.

Several of our C-3's were orginally designed and fitted with a lattice cross girder joining the king posts at the after end of #5 hatch. This girder presented a difficult and dangerous maintenance problem, due to continuous exposure to corrosive stack gases and resultant rapid deterioration. After study and consultation with regulatory bodies, we obtained approval to remove this lattice girder, during shipyard availability, and replace it with a one and one-quarter inch wire cross stay connecting the king posts. In this case economy rewarded our safety efforts.

Some years ago, we shifted our cargo operations from Manhattan to Port Newark, where aircraft activity at neighboring Newark Airport caused us some safety concern, since certain glidepath patterns ran fairly close overhead of our berths. A plane in trouble, attempting a landing during darkness, could be hazardous to our ships. We installed aircraft warning lights to the topmasts of all our privately owned ships to lessen this danger. There are several other ports where airports are close to berthed vessels.

PORT NEWARK TROUBLES

Heavy porthole glasses, in the passenger quarters of our cargo ships, worried us as a potential hazard to elderly passengers—ignorant as to their safe use. Winged at the top, a carelessly released chain could allow them to drop on a passenger's hand or fingers with serious results. We finally have devised a method to minimize this danger. A special alloy steel tension installed at the porthole hinge cases the port glass down—preventing it from slamming closed.

Heavy doors aboard ship have been the cause of many minor but painful injuries to crew's hands and fingers. By replacing those door knobs, that are too close to door frames to afford safe finger clearance, with handles, this type of injury has been minimized.

Minor head injuries to crew have resulted from badly placed bunk lights when a simple shift in location by the ship's electrician could end the hazard. We have installed chlorination and filter equipment to the drinking water systems of our fleet as a safeguard to the health of our seagoing personnel.

A Safety Educational Program aboard our ships has been undertaken with little lost time, simply by taking advantage of opportunities when crew are gathered together for regular ship duty purposes. On our ships we encourage instruction and demonstration immediately following fire and boat drills and while the crew is still assembled, in oxygen breathing apparatus, safety lamp, artificial respiration, portable lifeboat radio transmitter and fire extinguishers—giving one subject only at each drill, and each time by a different officer. Not only is this instructive for the crew, but each officer does some advance "boning up"—thus refreshing his knowledge of the subject he will instruct.

CREW'S INDIVIDUAL SAFETY

The individual crew member greatly controls his own "safety strings." His well being and safety aboard ship depend for the most part on himself. If he is careless in his working and living habits, no amount of thought and effort on the part of others can completely safeguard him from accidents.

Much has been written and discussed on the physical and mental fitness of crew members. I think the recent innovation of indexing both physical and mental histories of crew members will aid in sorting out those that are potentially dangerous to themselves and to their shipmates.

One would think all crew members would be conscientious about their own safety, wearing proper and safe foot gear aboard ship at all times, attending fire and boat drills properly clothed for the "real thing" (who knows when it might be?), keeping life jackets in racks provided under bunks, insuring electrical tools are properly grounded during use, taking those extra safety precautions against additional and unfamilar hazards while in shipyard or drydock, being careful about boarding, traveling in and leaving liberty launches—particularly in certain foreign ports where there is a tendency to overload and attempt longer trips in rough weather, practicing good housekeeping in accordance with U.S.P.H.S. regulations—these few things and so many more, should be only a part of the regular "safety thinking" of the individual crew member. Shipboard safety meetings are an excellent place to remind all to think and act safety.

From this you might construe we have solved all our safety problems. Unfortunately we, like others in ship operation, can never mark "finished" to the job of safety. It is a continuing effort and taxes the ability and ingenuity of us all. Cooperative effort and free exchange of information on safety problems and solutions among all of us will certainly speed our work in the safety field.▲

ACCIDENT PREVENTION IN PASSENGER VESSELS

by CAPT. L. A. RENEHAN
marine superintendent, Farrell Lines, Inc., New York city

The safety program of Farrell Lines has been in operation for eight years. The program was well planned, organized, conducted and well supervised. Initially it was accepted with great interest and enthusiasm. The ships' safety committees submitted interesting and well prepared minutes of safety meetings and made numerous intelligent suggestions for the improvement of conditions for prevention of shipboard accidents.

Manifold new practices were inaugurated, practices with which all of you are familiar, for you have tried them and they have been advocated in many safety publications. These were such things as paint schemes to emphasize danger areas, signs and posters cautioning and warning of hazards, various types of guards, non-skid treads, hand rails, safety locks, safety screens and new lighting plans. Ships were supplied with pounds of safety literature and posters. A safety magazine was published and it was an immediate success. It was widely circulated and read with interest.

But—let us not deceive ourselves, none of these procedures is the answer to a successful safety program. The key to reducing accidents is held in the hand of the seamen themselves by their adoption and exercise of safe work practices. To achieve this condition you must start to work at the top.

Throughout the promotion of this program, the importance of proper supervision by ship's officers was stressed continuously, and emphasis was made on safety and safety consciousness to such a degree that not only the members of the shipboard safety committee, but all of the licensed officers of every vessel were saturated with safety consciousness.

If the men in your ships have not yet reached this plateau of interest in safety talk and safety reminders, if they are still actively interested in a safety program and participate in this program with enthusiasm, then you are fortunate, but I must say that I feel that this condition is not permanent. The important question now is, how to ensure a continuation of this success that we have had and presently enjoy?

One of our shipmasters revealed to me the other day that the most odious task he performs in the course of a foreign voyage is the preparation of the minutes of the meetings of his safety committee. His explanation was that he was merely repeating dull, uninteresting material and repeating a worn out theme to his officers. As he described it, it was like requiring everyone in the ship to stay after school and stand at the blackboard and write, "I will be safe," several hundred times.

PERSISTENCE IN SAFETY

I am not for one minute going to deny the importance of persistence in safety education. The unrelenting emphasis on safety consciousness is what will develop safe work practices and eventually prevent accidents. This is the system that most of us employ today, let me call it the Punitive Approach. There may be raised eyebrows at this choice of words, but it is expressive of the current feeling of our responsible seagoing personnel.

The campaign starts with the safety director, in his talks with the captains, chief engineers, chief mates and chief stewards. By reminders, discussion and questions, he shapes the beginning of safety thought in their mind. He is exercising the primary responsibility of shore-based safety personnel. His interest, enthusiasm and tenacity sets the keynote of a safety program. By shipboard inspections and instructions to ships' officers, the groundwork is laid.

This must be the beginning, but it is only possible when the ship is in port. At sea, the Master must take up the cudgels and in turn convey this attitude to his officers. It is a matter of continuous education, by reminders and repetition. This method is a recognized necessity. By repetition and continuous remunders, the fundamentals of shipboard safety are established. We must persist in this! However, unless an effort is made to create new interests, a shipboard safety program will become a strongly resented bridge.

Let us look at some ways that spice may be added to this recipe. One way is through the use of financial statistics. All seafaring men are at heart conservative, money-conscious people. Most of them spend hours calculating their payoff. Also the more devoted they are to their job, the harder they work to save money for the company.

USE COST STATISTICS

This man responds quickly to cost and expense figures. He would be interested to know how much a lost time accident costs the company. I would recommend to you that this aspect of shipboard expense be illustrated to your responsible officers, not in general overall statistics, but in specific cases where an injury costs several dollars in time lost and claim settlements. The publication of specific cases from your claims experience would be of vital interest to your shipmasters.

The circulation of this information should be limited to the master and responsible officers, for if too widely publicized, it might serve to encourage an already claim conscious crew. There is a great value in this information when properly used, for once a shipmaster becomes aware of the actual dollars and cents costs of an accident, his interest in their prevention is a natural consequence. You are indicating to him your recognition of his position of responsibility.

It would be a good idea to explain to your masters the meaning of maintenance and cure, to show them the great facility with which a seaman becomes a beneficiary of this benevolent program. Properly inspired ships' officers could often take action that would prevent this much exploited financial drain. It would be well to explain how insurance is written.

NEED UNIFORM RATINGS

To continue with the statistical approach, I find that a certain amount of value of competitive statistics is lost in a lack of uniformity of accident ratings. You cannot expect a team to be interested in a contest in which each side keeps score in a different manner. There is a difference of opinion in the industry over what should be considered an accident.

The National Safety Council has developed an excellent formula for rating all industries by classifying lost time accidents. We find that in the marine field this system is not altogether feasible, inasmuch as so many claims are filed by seamen who have not suffered a lost time accident. Many a slight finger cut, or leg bruise will return to plague you as the spectre of a large claim in the form of an unreported accident.

Far better, we feel, to have the information and details of an accident than an impressive accident-free record. There is a happy mean to be established here, a system whereby a competitive spirit is maintained with the understanding that all accidents are to be reported. Perhaps the answer lies in an understanding between the ship and the office personnel. It is practically impossible to establish a clearly defined set of rules, but we have been working along these lines with notable success.

USE MAGAZINE, MOVIES

The prime mover in the campaign to encourage interest in safety in the fleet has been our Safety News. The value of a company publication, devoted to this subject, must be emphasized. Without using specific names of persons or ships, the embarrassing experiences, the boners and the accidents may be published and they invariably make good reading.

It is important to try to strike a humorous vein in this medium, for sailors dwell on views of other ships and a piece of such information presented in an amusing fashion is widely distributed. The message does get across and often without realizing it, your ships' officers are talking and thinking safety.

Shipboard movies are another excellent medium for transmission of the safety message. Most ships that carry passengers today, show films for entertainment. At various times during the voyage they are shown to the crew. If such feature films were preceded by a short reel on safety, you would have achieved an ad man's coup with a captive audience.

Unfortunately the number of such films is altogether too few. The U. S. Navy has

some good ones which, although not altogether applicable to merchant vessels, illustrate good shipboard practices. Perhaps some thought should be given to the possible production of additional films for shipboard use.

There is another matter which should be of vital importance to every operator of American flag passenger vessels. A strong movement is underway in the legislative circles of this country to enact laws and regulations intended to make safer, the ships that are already acknowledged as the safest in the world.

LAWS CAN'T BRING SAFETY

Much of this is a direct consequence of the tragic Andrea Doria/Stockholm disaster; much is part of a crusade of well intentioned but inadequately informed legislators. However, laws, rules and regulations do not make a safe ship. We have learned that the initiative must be ours, that this responsibility should remain with the shipowner.

At this moment there are over a dozen bills pending that would add additional controls and restrictions to the shipping industry. There are several committees that are now meeting with the intention of recommending regulations or legislation for ship equipment and cargo gear, ship construction, ballasting, stowage of bulk cargoes and the use of electronic and radio equipment. Some of this legislation is necessary and worthwhile.

It is not my intention to persuade or discourage the passage of any of it, but I will exhort you to take an interest in this development, to give it your close attention, to direct it to the attention of your associates, for without an active participation by everyone in this industry, we could be accused of falling into the same state of apathy that we try so hard to avoid among the men in our ships.

SAFETY IN SHIP REPAIR

by JAMES R. O'DONNELL

safety engineer, Avondale Marine Ways, New Orleans, La.

This paper will present the "human elements" of safety—those factors of safety which are inherent with each and every member of the production team. These elements are not exclusive; they may occur just as readily with a machinist as with a foreman or, for that matter, with management itself.

When an accident occurs we are prone to place the blame on machinery, equipment or conditions. It is a simple thing to attribute an injury to a faulty chisel or a piece of metal that was left in the middle of a passageway—but, what about the "human element"? Someone neglected to grind the "mushroom" off the faulty chisel. Someone neglected to remove the metal from the passageway. Although equipment was the instrument of injury, people were the cause.

There are numerous problems relating to Marine Safety which are common and readily identified as having accident potential: scaffolding, cranes and ladders. These are physical things that can be alleviated but, what about the other sources of accidents —the ones that present a hazard due to the behavior of people?

For the most part we assume that with proper instructions and adequate safety equipment the chances of an accident are almost eliminated. Actually, the chances are reduced but not eliminated.

INTANGIBLE HAZARDS

How about the "human elements" that we can not see? How about the inner reactions of a man when he must perform a job at great heights? How about the pattern habits that make a man reach for a cigarette before he considers the existing hazards around him? How about the physical condition of the man himself or the inability of the human body to resist the effects of a reduced oxygen area? These are the intangibles of safety—the "human element" that can knock the props from under any well planned safety campaign.

These factors can be held to a minimum only by the cooperation of every member in the plant. Fear of height is common with many men yet some will try to dispell the fear rather than let their foreman know that it exists. It is not a pretty thing to see a man freeze to a beam until he can be pried free and carried down by his fellow workers. It is still worse to see a man overcome with fear plunge to an unresisting steel deck, yet it has happened.

How can such a thing be prevented? How could I know what would happen? Such things can be prevented and it is part of your job to know that they will happen! If it is impossible to know each of the men in your plant at least know those who delegate work. Gain their confidence. Talk to them.

Learn all you can about the behavior pattern of the workers. Take time out to check the physical pattern of the workers. Take time out to check the physical examination records of the men who are called upon for unusual activity. Make periodic check ups a must and sell management on the idea.

CHART ACCIDENTS, CAUSES

Keep a chart on the number and kind of accidents that occur on each job. It may be a surprise to discover that the foreman with a fairly decent cost record is actually costing the company money through repeated accidents. These accidents are job costs, too, and have no more right to be charged to overhead than the steel plate that makes up a ship's hull.

The bull-of-the-woods supervisor is a thing of the past. A recent survey showed that autocratic supervision—again one of the "human elements"—was a definite cause of accidents. By considering injuries as "job costs" the burden is placed where it belongs. Although the books might reflect a good profit for a certain job, if the total insurance and settlement costs are placed against the job, what might at first appear as a highly profitable showing, may in reality turn into an astounding loss.

This procedure accomplishes two things, first, it definitely shows management the actual earnings of the job and, secondly, it makes the supervisory personnel liable for the safety of those who work for him. This responsibility, in turn, can be delegated to the foreman and leaderman who can effectively impress its concept on the men.

How rigid are your requirements about gas-freeing ships and barges? It is almost impossible to detect a lack of oxygen with the senses with which man is endowed—a casualty is usually his first indication.

HAZARD OF OXYGEN

Couple the knowledge that the workman can not identify a gas-laden atmosphere with the fact that a gas-free certificate is only good for the immediate period during which the enclosure is tested—even if the area is gas-free today, and you have a certificate from a reputable chemist to prove it, it may not be gas-free tomorrow. Nothing can be taken for granted! You must constantly check and re-check—you must be sure!

Men must be constantly reminded that they can not safely enter tanks and other closed compartments until they have been assured of the conditions. When this rule has been broken, and as long as we must fight the "human elements" of safety we know that there will be those who will violate it, the others must know not to attempt a rescue without proper equipment and a sound knowledge of its use. Otherwise, the would-be rescuer becomes another casualty.

The proper rescue equipment for this type of work must be on hand at all times as well as sufficient trained personnel to put it into use immediately—breathing apparatus, stretcher baskets for hoisting men out of holds and compartments, rope and other equipment for affecting an immediate rescue.

The men must be placed on deck, in a clear free air space, and resuscitation begun immediately. Where oxygen deficiencies are encountered it is the first few minutes of rescue that mean the difference between life or death.

Ventilation of all areas must be maintained at all times. Man feels that if he can breathe there is no danger. Assuredly, good ventilation is a definite requirement but it is not always a criterion of safety. Toxic vapors, inflammable gases and stifling smoke can be carried into compartments by inadequate ventilating equipment.

The practice of maintaining a watch at all potential danger points will pay real dividends. No man should be permitted to descend into any danger area without either a watcher or assistant standing by. In most instances it is advisable that the men entering the tank or compartment be attached to the watcher by means of a safety line tied securely around the waist.

A system of signals can then be arranged and constant communication maintained by jerking the line at periodic intervals. Watchers should maintain a tally of the number of men that enter a compartment and must never leave that area until properly relieved —even for a drink of water.

FIRE—ALWAYS POTENTIAL HAZARD

Fire is another hazard in all ship repair or construction where burning, cutting and welding are accomplished almost everywhere on board. Keep a constant watch and, when a fire starts, arrest it immediately. To assure its being kept under control, maintain sufficient extinguishers at strategic points on the vessel. Make certain that the extinguishers are fully charged and that the men know what kind to use for a given situation.

Lighting is extremely important. Well lighted work areas not only increase the efficiency of the workers but reduce the hazards. Keep the area well lighted and the lighting equipment in a condition conducive to prevent fires through sparking.

Air, oxygen and acetylene lines must be properly strung and maintained. A leaking line and a careless cigarette are a sure fire combination for trouble. Also, grease and leaking oxygen are another pair that can set the best laid plans of the safety department to naught. Loose lines scattered over the decks and across gangways are a constant tripping hazard.

There are many ways to overcome this housekeeping problem, depending upon the nature of your yard, and the equipment in use, but it can be done. Of course, it will take a little effort on the part of the men and their supervisors but it will pay off in safety.

One of the soundest pieces of advice in regard to safety and the "human element" that I ever heard was from an old chief engineer who had spent most of his life at sea. "You've got to use each of your six senses," he said, "to know danger before it strikes:

USE SIX SENSES

"Sight—to see fire, a frayed line or an obstacle in your path.

"Touch—to feel grease on a handrail, a bulkhead before it blisters from a fire on the other side or the warning heat from being too close to a hot pipe line.

"Hearing—to hear the hiss of escaping gas, the whine of a faulty machine or the warning cry of a fellow worker.

"Smell—the smell of smouldering rags, the pungent odor of gas or the hot smell of an overheated bearing.

"Taste—to taste the fumes of an overcharged bank of batteries, the acrid taste of an electrical fire or a spilled flask of acid."

"But," I said, "you said six senses. That's only five."

He chewed on his pipe stem a moment and then looked me full in the eyes. "Mister, I meant six and the last one is important. 'Don't trust any of them completely and learn to watch the other guy, too.'"

The "human element" in safety is something different than working with tangibles but people, too, conform to a pattern. The safety director must constantly observe and remind—actually he must never relax his guard or let those around him become lax in their attitude toward their own safety. Injuries cause so much suffering and unhappiness that to eliminate them is one of the most gratifying jobs a man could ask for.

NAUTICAL CHARTS FOR SAFE NAVIGATION

by H. ARNOLD KARO, Rear Admiral USC&GS
director, Coast and Geodetic survey, U. S. Dept. of Commerce, Washington, D. C.

The Coast and Geodetic Survey of the United States Department of Commerce has made an impressive record in promoting safety in marine navigation through significant achievements in charting the coastal waters of the United States and its possessions. The great progress achieved in improving the means and methods of conducting surveys at sea and improving charting techniques, has given the nautical chart its present high standard in precision and scientific status.

This basic product of the Bureau, together with related publications such as coast pilots, tide and current tables, and magnetic data for charting compass courses, provides an essential aid to safe navigation.

Since 1844 we have issued about 34 million copies of nautical charts. The total production for 1844, the first year, was only 169 copies. This rate increased steadily until by the Civil War period total annual output reached more than 50,000 copies.

By the turn of the century the volume of charts produced was raised to about 100,000 copies annually. Maximum production of over four million copies was achieved in 1945, in support of the war effort. The annual output of nautical charts now averages more than one million copies.

This impressive record was achieved in addition to the tremendous volume of aeronautical charts now being produced—a maximum of about 44 million copies for the present year.

Charting the vast coastline of the United States and Alaska, representing thousands of miles of tidal shoreline, is a challenging task. The U. S. Atlantic coast is over 28,000 statute miles. The Gulf coast is 17,000 miles, and the Pacific coast measures almost 8,000 miles. This seemingly endless zone of demarcation between land and sea takes on even here a greater significance when the 34,000 statute miles of Alaskan shoreline are added.

To survey this enormous stretch and portray it on charts so that land and offshore features including subsurface configurations are properly indicated, is no small undertaking.

A chart used by navigators is of maximum value only when it reflects completely reliable information. The great effort expended in producing a chart is not apparent in the finished product. The published chart represents thousands of man hours of careful work.

This work can be accomplished only after a vast amount of technical data are obtained by surveying ships supported by field parties engaged in geodetic, astronomic, gravity, tidal and magnetic observations. Both field and office activities represent never-ending labor that must be accomplished with a high degree of accuracy, often under adverse and trying conditions.

The nautical chart is a graphic representation on which the mariner may see, almost at a glance, many details of terrain, harbors and navigational features essential to safe navigation of his craft. The nautical chart gives warning of hidden dangers and enables the mariner to navigate in safe channels. The sea is never at rest and there are no landmarks to which the mariner can readily refer his position.

The fate of a ship and the lives of the crew, therefore, depend entirely on nautical charts published by the Coast and Geodetic Survey.

A small error in reporting a sounding could mean a costly accident—perhaps the loss of life. Yet every mariner has come to rely upon these charts implicitly and without question. Thus, the nautical chart is indispensable to the safety of maritime commerce. It is just as essential to the ship's equipment as are the engines or rudders.

The format and substance of nautical charts have come a long way since the days of the schooners and windjammers. In the early days charts consisted of an occasional sounding obtained with a hand lead and vague coastal features supplemented with

sketches of headlands and other landmarks. With the advent of modern shipping, new and more precise methods of recording the ocean bottom and adjacent coastal features became necessary.

The present nautical chart has been developed pursuant to that need. It is the ultimate in professional cartographic accomplishment demonstrated by the accurate delineation of survey data together with the skill and accuracy with which such data are portrayed on the chart manuscript.

The sea chart differs from a land map. Features on land are always seen and recognized, whereas at sea the greater part of features that are of vital importance to the navigator are hidden beneath the surface of the water. The navigator must have complete confidence in his chart for, unlike the user of the land map, he has no visible means of checking the information it provides and upon which the safety of his ship depends.

The nautical chart is a scientific instrument that should be treated just like any other instrument that has been carefully made and precisely calibrated. Rigid and minute accuracy is thus the first essential of every chart. The mariner must be furnished through his chart all information necessary for navigation, but essential details must not be confused by including information not useful to the navigator and which would result in needless congestion.

All charted details must be expressed with the utmost clarity and in the simplest possible form. Nautical charts, therefore, embody carefully selected data expertly portrayed by an elaborate system of symbols and precisely located by a rigid system of control. Every chart is prepared with one paramount consideration — to render the maximum possible service to the navigator in the clearest possible manner.

Until the advent of echo-sounding the mariner was afforded a minimum of soundings and had only limited means of visualizing the configuration of the ocean floor while navigating over deep water. This oldest of electronic surveying equipment is now used almost exclusively by the Coast and Geodetic Survey in determining water depths.

Thousands of soundings are now obtained in areas where formerly only a few scattered ones were economically feasible. Recorders connected with the sounding device provide a continuous profile of the ocean floor showing the ridges and depressions on a permanent visual graph. Many submerged features presenting great danger to navigation have been found by using echo-sounding methods.

The development of echo-sounding apparatus for general maritime use introduced a new factor in marine navigation. The navigator can now utilize the charted depths for fixing his position without stopping the ship and measuring the depth with a wire. This means that deep water submarine relief has become important to the mariner in a very practical manner. Significant changes in the appearance and usefulness of the nautical chart were necessary to make use of this new wealth of survey data.

Despite all of this progress in surveying and charting, undiscovered submerged rocks, reefs and unnatural obstructions still caused groundings and shipwrecks. Although we were able with the echo-sounder to effect intensive developments of underwater areas, obstructions were still missed with conventional hydrographic surveying techniques. It was therefore necessary that a safety technique be developed to detect the presence of small but dangerous submerged obstructions missed by regular depth sounding methods.

WIRE DRAG METHOD

To provide for this contingency the Coast and Geodetic Survey developed prior to World War I a unique method to supplement the ordinary methods of sounding in areas where pinnacle rocks, boulders or coral reefs were likely to exist. This apparatus consists of an extended length of wire, sometimes a mile or more long, supported at an adjustable depth by floats and buoys. The wire will snag on any obstruction which extends above the depth to which it is set. Many dangers to navigation have been found by this method along the rocky coasts of California, Alaska, the Gulf of Maine, and elsewhere.

The function of a hydrographic survey is to reveal hidden dangers. The function of the chart is to show them accurately. Once the obstructions are charted the navigator is aware of their existence and can shape his course accordingly. In recent years the wire drag method has been used effectively in locating and charting many wrecks along our Atlantic seaboard resulting from enemy submarine warfare.

The great advancements in navigation have steadily increased the demands for more complete and exacting charts. Improved techniques in cartographic presentation, the great strides made in hydorgraphic surveying methods and equipment, and modern advancements made in lithographic processes are reflected in the modern nautical chart of today.

About two decades ago the Coast and Geodetic Survey introduced a new type of nautical chart on which depth curves were given special prominence. Experience indicated that the most useful method of making full use of the wealth of survey data now available was by means of contours. Bottom irregularities that could not be charted by soundings alone were revealed by the system of depth curves which made use of all the soundings obtained on a modern hydrographic survey.

This entirely new technique of nautical charting marked the first radical change in the cartographic treatment of the nautical chart since the introduction of lithography with the use of multicolors in chart production. Prior to this time nautical charts were distinguished by many soundings and few depth curves. In contrast, the new charts are characterized by many depth curves and a minimum of soundings.

The choice of depth curve intervals to insure the most value to the navigator is a factor always given careful consideration. The thoroughness of available surveys, the nature of the submarine relief, and the scale of the chart enter into this decision.

Each depth curve appearing on a chart is equivalent to charting a continuous line of soundings of any given depth. The more irregular the bottom, the more applicable it is within limits to depth curve navigation. Submarine topography is now disclosed in many areas comparable in magnitude and extent to some of the major topographic formations found on land.

Depth curve navigation is especially effective in clearing dangerous headlands or foul areas during bad weather when visibility is poor. By selecting a curve which would represent the minimum depth that a navigator would wish to cross, the echo-sounding machine could be used in following a selected curve, thereby keeping clear of the danger area.

The increasing number of complex navigational instruments and aids which are now considered necessary for safe navigation sometimes cause considerable apprehension on the part of navigators. It should be made clear, however, that most of these new devices are worthwhile developments which make navigation easier and also safer, but certainly not simpler.

Navigators should never become so involved in the intricacies of supernavigational devices as to lose sight of the basic fundamentals of navigation. The qualified navigator need not be reminded of the importance of accurate nautical charts, complete in every detail, yet so simple in presentation as to be easily understood.

Modern nautical charts, when compiled from present-day basic surveys, have no parallel in the history of marine navigation. Regardless of how complex, automatic and seemingly infallible our modern navigational aids, systems and instruments are, the fact remains that they are tied to the chart upon which they depend for their ultimate accuracy in use.

Constant vigilance by navigators, using all the tools at their command, is essential in this modern age of high speed navigation. Any slackening of vigilance, including too great a dependence on any single instrument or method, may place a vessel in jeopardy.

The modern nautical chart is a superior product, a safety tool which, when used in its proper relationship with other aids, provides safe passage in marked as well as unmarked waters. But charting is not static —changes are inevitable and must be taken care of in any progressive charting program. Over the years experience by the Bureau has provided an unerring barometer to the lack of stability in our coastal areas.

Forces of nature resulting in unnatural changes create problems of instability of shorelines, inlets and bottom areas apart from uncharted rocks and other submerged obstructions. Moreover, sea-going ships are made larger and speedier. Navigational aids are continually being revised. New coastal structures and developments constantly create new hazards. Safety of navigation de-

pends upon accurate delineation of all these changes on the published chart.

The objection of our charting program is to furnish the mariner with charts which will show existing conditions at the time he is navigating the area covered by the chart. Therefore, new editions are printed at frequent intervals. Changes reported between revisions are hand-corrected on the charts so that copies are correct when issued.

Thus our nautical charts have been designed and maintained by an intensive system of revision so as to insure maximum usefulness of our coastal waters with the fullest measure of safety in marine navigation.

The Coast and Geodetic Survey is not alone in furthering the safety of marine navigation. Many other agencies play an important part in the overall safety program covering our navigable waters.

Special tribute is paid to the United States Coast Guard in this connection. This great organization has a long and most commendable record in safeguarding the waterways of the Nation. The establishment of navigational aids, the constant patrol and radio communications, search and rescue operations, and a notice to mariners provide an immense measure of security to maritime commerce.

The expanse of activities carried on by the Corps of Engineers in the dredging, improvement, maintenance and regulation of waterways is evident to all. Mention should also be made of the fine surveying and charting accomplished by the United States Lake Survey and the Mississippi River Commission. Both of these great organizations have specific responsibilities in promoting safety and facilitating navigation on large segments of our national waterways.

The United States Navy also has broad responsibility for the collection and prompt dissemination of critical information affecting sea navigation. Daily broadcasts from Naval radio stations, and weekly notices published by the Navy Hydrographic Office provide services of inestimable value to navigators.

In addition to providing this essential information on new dangers and shipping conditions, the Hydrographic Office has the major task of providing nautical charts and other information of extensive foreign coastal and oceanic areas.

The Weather Bureau issues storm warnings and other Federal and State agencies, as well as port users, furnish information of importance to the marine navigator and charting agencies.

The responsibility of safeguarding the lives and property of both passengers and mariners navigating the waters under the jurisdiction of the United States is a great one indeed. This great and important mission is accepted with a deep sense of dedication to the public welfare by the engineers and cartographers of the Coast and Geodetic Survey.

CURRENT DEVELOPMENTS IN INFLATABLE LIFERAFTS

by COMMANDER JOSEPH W. NAAB JR.
chief, production dept., U. S. Coast Guard, Curtis Bay, Md.

Anything said about inflatable liferafts is a report on a recent development because they are so new. The lifeboat is only a little more than 100 years old. The United States first required certain vessels to carry "longboats" in 1838, and Great Britain, in 1854. Since that time we have seen considerable improvement in ships, but little change in lifeboat design except to add buoyancy tanks or blocks and in launching details such as gravity davits, power winches and quick releasing gear.

Conservatism of mariners and [illegible]ation of the seafarer and the passengers are the reasons for the changes.

Once a law requiring certain types of equipment is in effect, ship owners spend large sums to meet its requirements. Obviously, changing the type of equipment demanded by the law would be an uneconomic and highly unpopular move.

World War II focused attention on lifesaving equipment because of the tremendous loss of life at sea. Figures from the British Admiralty show that more than 100,000 men of the Royal Navy died at sea. Two thirds were lost *after* abandoning ship safely, and about 35,000 men died after they reached a lifeboat or liferaft.

Our Navy did not lose as many men in the water as the British because the larger part of our effort was in the Pacific where conditions for survival were better. But even then, when the Cruiser *Indianapolis* was sunk by a Japanese submarine, more than 900 men who safely abandoned ship in good condition died in the three days before rescue came, even though weather and water conditions were almost ideal. These figures showed the need for a re-evaluation of lifesaving gear, particularly on combatant ships.

During the War we used lifeboats, balsa rafts and so-called life nets on combatant ships. The same equipment was used in the Merchant Marine.

AIRMEN USE RUBBER RAFTS

While we were suffering frightful losses at sea, 26,000 Allied airmen were saved by inflatable liferafts. The success of inflatable craft directed the attention of the U. S. and British Navies to using similar rafts in place of traditional wood and metal boats and floats.

Over a period of years, lifeboat requirements have been set down by necessity, custom or law: reliability, seaworthiness, capability of being launched under all conditions, ease of boarding, resistance to damage, provision for shelter for survivors, capability of locomotion, provision for distress signals, and capability of being found.

Reliability of inflatable liferafts can be improved. The Civil Aeronautics Authority recently conducted tests with commercial airplane rafts and 10 per cent of the rafts failed completely while 90 per cent had some deficiency. This is partly because the specifications for these rafts do not require performance tests for acceptance. In Great Britain, to be accepted, a newly designed raft must be moored two weeks to a buoy in the North Sea with a full load of sand bags, as well as other tests.

One difficult problem was developing a satisfactory inflation system. All rafts now use carbon dioxide gas. In most cases this is satisfactory, but in cold weather inflation may be extremely slow. Raft manufacturers and other companies are developing a better system. One new system uses the jet or injector principle in which a small quantity of high pressure air is expanded through a nozzle at high velocity, entrapping large amounts of atmospheric air with it, and inflating the raft to its designed pressure of 2 psi in seconds. The obvious disadvantage is if the injector is underwater when actuated.

Reliability is improving by greater attention to details of manufacturing, including better cementing or vulcanizing of seams, lighter and stronger materials, and more rigid inspection and testing at the factory.

Part of the answer to insuring reliability after manufacture is periodic inspection. The CAA requires airlines to inspect rafts under a prescribed procedure every six months. If liferafts are used in large numbers, a similar inspection by highly trained technicians is necessary.

The seaworthiness of the inflated rafts is astounding. The record voyage was made by three airmen in the Caribbean who survived in a rubber raft 139 days before rescue.

RAFT EASY TO LAUNCH

In ability to launch, the liferaft has no equal because it can be rolled, carried, or thrown over the side and inflated in the water. A 20-man liferaft with all equipment weighs 300 pounds in stowage case, or about 15 pounds per man. In favorable conditions one man roll this raft over the side. Even under unfavorable conditions, three or four men can launch such a raft without difficulty. Smaller rafts of six and 12 man capacity weigh about 120 pounds and 200 pounds. In the case of the steam trawler *St. Celestin*, which collided May 1956, the

ship sank so fast the men didn't have time to put on their life jackets, but they safely launched their liferafts.

Liferafts are easy to jump into, and even to get into from the water. However, if survivors must swim in very cold water, or are impeded by life jackets or clothing, or are feeble or injured, it may be difficult to get in, even with the boarding ladders provided. The recent development of a boarding ramp has eased this problem somewhat. Getting passengers aboard rafts from large ships with 60 feet of freeboard or more is a particularly knotty problem. The solution appears to be ladders, or some sort of power lift such as the one recently patented by a Coast Guard officer.

The liferaft has good resistance to damage, as in the case of the *Gudrun*. Because of its resilience and tough fabric it can lie alongside a ship and withstand battering that would sink a rigid lifeboat. On the other hand, it is vulnerable to sharp projections and stowage deteriorating from creases in folding, heat, oil and sunlight.

However, a new fibreglass re-enforced plastic case improves stowage conditions. Rafts have a number of separate buoyancy chambers, so that a puncture in one will not sink it. In addition, the low pressure makes small leaks easy to control with the hand pump, mechanical leak stoppers and temporary repair kits that are part of the raft's equipment.

RAFT SHELTER FOR SURVIVORS

The provision of shelter for survivors is one of the most important considerations. Surprisingly enough, the inflatable raft does this better than open, rigid boats. All newer rafts have canopies, automatically erected when the raft inflates. Another feature may be a manually inflated rubber mattress-type floor to insulate the bottom. The latest model U. S. Navy raft has an entrance, which can be closed with a draw-string. There is an identical opening on the other end, and boarding ladders. A similar raft was tested in Newfoundland by having ten volunteers, wearing life jackets and outfits from dungarees to heavy parkas, jump over the side of a vessel into 34°F water and swim 25 feet to the raft. Then, without any heat except from their bodies, they stayed there five days. The average air temperature outside the raft was about 40°F but inside the raft it dropped below 70°F only briefly on two occasions.

For locomotion, the inflatable liferaft may have paddles, but even then it is difficult to move in any direction except down wind. However, with modern communication and airplane searches, it may be an actual advantage to remain in the vicinity of the disaster. If a good position is given with the distress call, and a number of rafts are in the vicinity, rescue is almost certain because their drift can be estimated. If the liferafts are propelled they are likely to be separated within a few days, and since their courses would be unpredictable, the search problem is intensified.

To send out distress signals, some lifeboats are equipped with radio. Some inflatable rafts are also, although the increased weight, expense and difficulty of maintenance have discouraged their use in commercial models. With transistors and new batteries, however, a two-pound two-way radio is available. In addition, the Armed Forces are developing a crash locator beacon, which is ejected automatically and sounds a radio call continuously for many hours. As with boats, liferafts are equipped with pyrotechnic signals.

Any other features that will help find survivors are desirable. It is difficult to see a small boat or raft from a ship in any seaway, and even more difficult from an airplane. Radar has eased this difficulty, but not eliminated it. Because they are larger and of solid material, boats give better radar response than do inflatable liferafts. However, this disadvantage can be overcome by using highly efficient metallized cloth, some of which is now incorporated in the canopies of the latest U. S. Navy rafts. Fluorescent dyes make rafts easier to find. A raft with a canopy of the best of these colors can be seen three or four times as far as the conventional one.

In addition to the standard rafts there are a number of special designs. One is the Arctic Shelter type. By using special materials, air spaces for insulation and special provisions for ventilation, this shelter can keep 20 people warm even under Arctic conditions. It is not yet in production.

The Navy has a special one-man liferaft to rescue men who fall overboard. It is ejected from its container and inflates automatically while flying through the air. The arch above the man's head has the metallized cloth radar reflector material, and a light activated on contact with the water.

The Air Force has one-man rafts for pilots, and it is working toward a parachute, liferaft and survival kit, all in one compact package which is ejected with the pilot.

The Coast Guard is working on a large raft to take people off sinking ships or ditched aircraft, and rugged enough to be a fender and landing platform for boats coming alongside the ship with survivors in rough weather. This raft is a self-bailer, because it is completely reversible, with the deck between the two supporting tubes. Even with a full load of passengers, breaking seas will drain out of the raft. In calm weather, the drains, which are reversible sleeves of the same rubberized cloth as the raft, may be closed to keep water out.

What are the prospects for increased use of inflatable liferafts? Obviously, because of weight and spare requirements, the airlines will continue to use them. For these same reasons, and others, the U. S. Navy and the U. S. Coast Guard have adopted inflatable liferafts to replace all other types of floats and rafts. In Great Britain, since October 1956 all fishing vessels 50 to 145 feet long are required to carry one or two inflatable rafts. Inflatable liferafts are also required on cross-channel passenger ships, cargo ships on coastal and short international voyages, ocean-going tugs and other small craft.

In general, every category except large vessels on international voyages is required to replace the present buoyant apparatus with liferafts. Vessels on international voyages are excluded because they have regulations for life saving equipment set up by the International Convention for the Safety of Life at Sea. The Convention forbids using devices dependent on inflation by either air or gas as mandatory equipment on the various types of vessels. Liferafts may be carried in addition to the required equipment, however.

Recent reports say the British Government has agreed with the Scandanavian countries, and other European countries to change the Convention to use inflatable liferafts in lieu of the present buoyant apparatus and possibly to replace some lifeboats, even on passenger vessels on international voyages.

RAFTS MAY REPLACE LIFEBOATS

The United States, as one of the signatory nations to the Convention, is precluded from approving inflatable liferafts on vessels in international trade. In addition, the United States Revised Statutes 4488, which lists the required "Lifesaving Appliances on Ocean, Lake, Bays and Sound Steamers and Foreign Vessels" specifically states "No boat may be approved, the buoyancy of which depends upon the previous adjustment of one of the principle parts of the hull."

Therefore, unless the law is changed, inflatable liferafts may not be substituted for lifeboats on United States vessels required to have them.

The Coast Guard is studying this problem with the other agencies affected. It may be some time before a decision is reached as to whether or not a recommendation by the United States for a change in the Convention should be made; or a recommendation to Congress for a change in R.S. 4488.

The use of the inflatable liferaft is becoming more widespread, and will increase as its reliability is increased and its cost reduced. It is already replacing the older type balsa and Carley rafts in many countries. One might be tempted to say that the inflatable liferaft will never replace the lifeboat entirely—but in this changing world "never" is a risky word.

RADAR PLOTTING ON MERCHANT SHIPS

by LOUIS M. THAYER, JR.
United States Coast Guard, Washington, D. C.

The collision between the Swedish motor vessel Stockholm and the Italian steamer Andrea Doria, in July 1956, awakened people both in and out of the marine industry to the fact that radar in operation aboard ship is not necessarily a means for preventing disaster. The public is now aware that unless proper use is made of the information radar provides, the equipment is of little use for averting collision. The Andrea Doria-Stockholm collision would have been prevented if the information provided by radar had been properly used.

It is the purpose of this paper to discuss the information radar provides, and to illustrate how to use it properly. In this discussion radar is a navigational aid—perhaps the most useful aid to safety of navigation ever devised—from which the direction and distance of an object are obtained.

A pip is a bright spot which appears on the radar screen when an object is within range of the instrument; and a radar Reading is the bearing and range of the object at a given time. The Object is called a target, regardless of its true identity. Bearings may be either relative or true and ranges are in nautical miles and tenths. You are in charge of the bridge in a ship which is underway with way on.

RADAR READINGS

The information which radar provides is the instantaneous value of the bearing and range of a target. Since you are underway and moving, it is immediately apparent that each new reading on a target must be different from the last one (unless the target happens to be on exactly your course at precisely your speed—a most unlikely possibility). What does this mean?

Suppose that you should make a point with a grease pencil, directly on the screen, indicating the position of the pip each time it appears. If you then draw a line through this series of points, you will be making a trace of the Relative Movement Line (RML) of the target, and not its true course.

A series of readings on a buoy of known position, and then plotted in this manner, will result in a RML. Any target plotted in this manner will show relative movement, regardless of whether it is stopped or moving.

The relative movement line of a target is the course the target seems to be on; that is, if you are headed directly toward a buoy, and make a plot of readings taken on the buoy, a RML will develop: the buoy will seem to be on a course opposite to yours.

PLOTTING CHART

Likewise if you make such a plot on a moving target, the resultant RML will be the course the target seems to be on; and if there is danger of collision with this target, requiring you to maneuver to avoid her, it will do you little good to know the course she seems to be on: you must know her actual course, and her true speed. True course and speed of a target are obtained from a plot. If you plot and interpret radar information accurately, you are making proper use of it.

For the purpose of illustration, assume you are underway on course 000 true at speed 15 knots. You make radar contact, and take the readings which are recorded in the upper lefthand corner of the diagram. Proceed to plot as follows:

(Editor's note: Readings are plotted on a standard maneuvering board. Referring to the description which follows, point e is the center of the diagram; point g is seven and one half spaces along the 0 meridian; point 1100 is at 012 on the circle marked 10; points 03 and 06 are marked at actual bearing points of the pips; point a is the end of the line faired through the three points above extended to any point in the lower part of the circle. Line ex is drawn perpendicular to RML from point e to a point, x, on RML.)

1. The first line you draw is one to represent your own true course and speed. It is the line *eg*. The direction is 000. If you assume that one space between circles is equal to a speed of 2 knots (two nautical mph), then 7½ spaces equal 15 knots.

2. You then plot the readings: the first one, taken at 1100, was at bearing 012, range 10 miles. If you assume that one space is equal to a distance of one nautical mile, this reading will plot on the circle marked 10, at bearing 012. Label it 1100. The other two points, taken three and six minutes later, are labelled 03 and 06, respectively. A line faired carefully through the three points, and extended is the line 1100—a. As before, this is the Relative Movement Line.

3. Measure the distance between the first and third points: it is 1.2 miles. The target has moved 1.2 miles in six minutes; or, her speed along this RML—her Relative Speed—is 12 knots.

4. From *g*, lay down a line parallel to RML, and in the same direction. Make it long enough to represent the target's relative speed: six spaces equal 12 knots. Label the extremity of the line *m*.

5. Connect *e* and *m* with a straight line. This line, *em*, represents two things: by its direction, it is target's true course, 311; and by its length, 2.8 spaces, it is target's true speed, 5.6 knots.

6. Note the line *ex*. It is drawn perpendicular to RML. The point *x* is 1.4 spaces from you, and it is the closest point of approach of the target (CPA). In other words, when the target bears 290 degrees, she will be at her closest approach—1.4 miles.

HOW TO CHART

This is the plot. From first contact to its completion you should have used no more than 10 minutes, at which time the range would still be eight miles. You know now that the target is on your starboard bow; that she is on a northwesterly heading, at about 5.6 knots; that when she is dead ahead of you she will be four miles distant; and that when she bears 290 she will be 1.4 miles distant.

You check her progress, at convenient time intervals, and plot the readings. If they fall along RML, you know that there has been no change in target course or speed. If they do not fall along RML, you will know immediately of such a change, a glance at the plot will show you how the new RML is developing, and new course and speed can be calculated.

Suppose your master has left standing orders that you should never permit your vessel to come closer than three miles to another when you are underway at sea. If you decide to change course to comply with these orders when the range drops to seven miles, your new course, at 15 knots, is found quickly, provided you have already solved for target course and speed. It is 013; and CPA is three miles on bearing 304 true.

RECHARTING IN 10 MIN.

The entire time elapsed during recording the first few radar readings, and then constructing any plot should never be more than 10 minutes. Only three or four minutes of this time are used consecutively during the actual drawing of the RML and triangle. Of the other six or seven minutes, perhaps two minutes are used in taking readings and recording them; and the rest of the time the officer on the bridge can be away from his radar and plot, if other duties require his attention.

Is this too long? Does the process require that you spend too much time away from the ordinary duties expected of you? I think not. If there is another vessel in your immediate vicinity, it may be that your most important duty is to see that you clear her. What of additional readings, as a check of the progress of the target?

They should be taken, and plotted; but to take a reading and then plot a point along a RML require only a few seconds. If you should then find it necessary to make a change, you may do so, with full information.

Almost all ships in the merchant service today, and a great many other types of vessels, are equipped with radar. There is ample evidence to support the claim that if radar is properly used, it can do much to reduce the risk of collision to a minimum. A logical question is then, has there been a reduction in the number of collisions since the general installation of radar beginning about 10 years ago? This is a difficult question to answer. However, MSTS Magazine, in the January 1957 issue, carried the following revealing data:

> An average of nearly three ships a day collide. Lloyds of London lists 6,110 ships involved in collisions in the last

6 years—more than 1,000 a year. This listing does not include collisions involving ships of less than 500 gross tons. Nor does the figure include collisions in inland waters.

Last year in U. S. coastal waters and harbors alone more than 500 collisions occurred! This shocking statistic from the records of the Merchant Vessel Inspection Division at U. S. Coast Guard Headquarters excludes ferry boats, towing vessels, fishing craft, foreign registry ships and small craft.

Some of these collisions occurred in fog; others, in clear weather. Some took place in confined water; others, in open sea.

It is my personal opinion, based upon experience over the last ten years, that the vast majority of officers do not make proper use of radar to avert collision. There is widespread conviction among our officers that plotting such as this is not practical, that it consumes too much of the officers' time, and that, if the target changes course, the plot becomes useless.

I do not concur in these objections. I have talked to a great many officers about this subject, and have taught some. They agree that plotting is desirable, and that it is not too difficult. But I repeat, my experience is that the vast majority of them do not plot. Why? I think the reason is that they do not fully understand how easy it is, in spite of the fact that an instruction diagram looks complicated. They shy away from it because they are not proficient in its use. Some carry the plot only so far as to draw in the RML.

If this line indicates that the vessels will clear satisfactorily, no further information is derived. This is better than nothing, but my objection is that unless the plot is developed further, the officer cannot determine whether the target is approaching, crossing, or being overtaken, under certain conditions.

DIRECT PLOT USED

Some officers make what is known as a direct plot: that is, they make the plot directly over the screen, using grease pencil and some built-in features of certain types of equipment. There is no objection to this method. The same principle is used, and the same results can be obtained. I prefer the maneuvering board for at least two reasons: greater accuracy is gained, and it is a lasting record of your plot, to be used, to demonstrate before a hearing how and why you altered course and speed.

Some officers claim they use a method not involving relative movement. If this procedure is used, you lay down your true course on an ordinary plotting sheet, and step off your positions along this track line to indicate where you were when you took your readings. You then plot points to indicate where, with respect to each of your advanced positions, the target was when you took the readings.

A line faired through the points so plotted will be the target's true course. You can then calculate her true speed by using distance sailed along true course during recorded time intervals. You can also discover changes in course and speed. But this method is not recommended. It is too long and involved, requiring great care and accuracy.

An officer who makes such a plot is indeed spending too much of his time away from other duties, because if he develops this plot far enough to be of real value, he has little time for anything else while there is a target in range. It is somewhat like using addition rather than multiplication to arrive at the answer to the problem 10 times 12.

U. S. REQUIRES PLOTTING

If I am correct in my opinion that most officers do not plot, we are permitting a dangerous practice to survive. Are we doing anything about it? The United States is doing something; we are requiring that any applicant for an original license in the merchant marine must demonstrate his ability to plot; and we are also requiring the same sort of demonstration of any officer who desires to raise the grade of his license.

Great Britain is requiring something more: after the Andrea Doria accident, the United Kingdom took action to increase the requirement for a deck officer's license to include the submission of a certificate of proficiency as a radar observer.

The courts of Great Britain, Canada, and the United States have added stimulus to the need for plotting: they have found that any vessel involved in a collision is at fault if she is equipped with radar and is not making proper use of it; that is, unless the officer on watch is making proper interpretation of the information his radar provides, the vessel is at fault!

New types of equipment are now in use, and others are being developed and/or evaluated. The Decca company, a British concern, has a type on the market known as True Motion Radar. American companies are in the process of evaluating models of equipment of the same general type. These equipments will show the mariner his own true motion and also the true motion of targets within range.

Stopped targets are recognized at once as being motionless, and thus the mariner has a sort of bird's eye view of his immediate surroundings. No plotting is necessary with this gear. The equipment is not in general use at this time. It may become the answer to our current problem when more ships install it.

In the meantime, deck officers must learn to plot. More important, they must make complete plots if they are to rely on radar for the purpose of averting collision. If they do not, they are permitting themselves to be trapped into a frightening sense of false security. Properly used, radar should build a reassuring sense of true security; but improperly used, it can do more harm than good.

No deck officer would think of failing to work out a sight after he has taken an observation with a sextant. His observation is of no value; but his line of position is. Why then should the same man fail to make a plot of radar information? A series of unplotted readings is of little value; but a proper plot is invaluable. Such a plot on the bridge of both Stockholm and Andrea Doria would have saved lives, anguish—and vast amounts of money and property.

Remember, many accidents have happened because the officer was too busy to plot, but none, of which I have any knowledge, has occurred because the officer was too busy plotting.

THE NEW NUCLEAR—EQUIPPED, GUIDED MISSILE NAVY

by VICE ADMIRAL J. M. WILL, USN

commander, Military Sea Transportation Service, Dept. of the Navy, Washington, D. C.

There was a time when sailors who wanted to retire would say that they would begin to walk with an oar over their shoulder and, if someone asked, "What is that?" then they would settle down in that particular place. It is no longer even possible to joke that way because the Navy has become an integral part of your defense, a sizeable customer of your products, and a patron of your research.

I know safety is a theme that needs to be sounded in these remarks. First, I want to talk briefly about safety on an operational level, and then about safety in terms of national defense.

We are proud of the fact that when an SOS goes out, MSTS ships are in a position to answer quickly. They are often the first ships there. We are proud of the "Distinguished Sea Rescue Award" that the USNS FREEMAN received from the American Merchant Marine Institute and the Marine Section of the National Safety Council.

MOST DANGEROUS INDUSTRY

The National Safety Council now rates the maritime industry as the most hazardous industry in America today. Avoidance of hazards becomes a matter of economics as well as one of humanity, for every good administrator knows that he saves money when he succeeds in having a good safety record. MSTS feels that it is responsible to its customers, the military services, for

economical operations. We pass on our overall savings to the military services and eventually to the taxpayer.

Therefore, we feel that it is important to us that our operation be as safe as we can make it. In 1956, you recall, 12 commercial companies competed for the National Safety Council's Marine Section Safety Award. First place was awarded to a commercial line with an accident frequency of 5.58 for each million crew man-days worked. Although MSTS could not be included in the contest category, we were proud of our over-all accident frequency rate for 1956 of 3.86.

While the national accident rate average is declining, accident costs are increasing. For instance, in naval aviation, even though the accident rate has decreased, the cost of major accidents in aircraft damage alone has increased from $150,000 per accident in 1956 to $222,0000 in 1957. Only persistent attention to two factors, personnel and material, can reduce accidents.

As equipment becomes more complex, the selection and training of personnel becomes a critical consideration. The advent of nuclear power on merchant ships will present operators with the same problems of training and retaining qualified men that the Navy now faces. Management must continue to promote safety consciousness with new developments. Of course, the improvement of equipment is a primary consideration. We need to devise systems to reduce accidents, and then to find the money to install those systems.

Let us talk now about safety at the level of national safety.

SEA STRENGTH THREATS

I am not simply stretching a point: I believe safety is a matter of avoiding risks and being prepared to cope with emergencies and I think that "The Nuclear-Equipped, Guided Missile Navy" does just that. I was asked to present to you a closer look at the new nuclear-powered, guided missile Navy which will give our nation a margin of safety. We know the necessity of building up our defense capabilities because we know the threat to our sea control has become more and more evident. Let me emphasize this with some examples.

Consider for a moment the relative sizes of the submarine fleet of Hitler's 57 submarines at the start of World War II compared to that of Russia's present 475 submarines. We remember the disastrous result of our early inability to cope with the submarine menace to shipping in World War II.

During the year 1942, the United States and her allies lost 1,144 ships, and a total of more than eight million gross tons were sunk. During this time only 106 German and Italian submarines were destroyed. It is the Navy's primary responsibility to give merchant ships safe passage. We must be prepared to meet this real sea threat.

Another example of this growing sea threat occurred not too long ago. Television carried the newsreel picture of the Soviet cruisers steaming through the Suez Canal. The Russians are aware of what they have termed "gunboat diplomacy." This was an inconsequential ship movement, but it is symbolic of a total picture in which we find ourselves pitted against the rapidly growing sea power of Russia.

INSURE CRUCIAL TRADE

Our strength and the strength of the free world allies ultimately rests in our use of the sea lanes. Every day more than 2,000 merchant ships steam the North Atlantic sea lanes. The Navy must be ready to protect this shipping, for our real power lies in this maritime capability.

One of the strengths of our peacetime economy—a cold war strength—rests in our selling four billion dollars more than we purchase. During peacetime, our standard of living is maintained by this trade, and during a war this trade becomes critical to our industries. Of our leading imports, 66 are considered of strategic importance. It is significant that there are only a handful of these imports in which we can be self-sufficient. In a very real sense we are a "have not" nation—dependent upon vital imports.

Of course, our allies are definitely dependent upon us. It is a necessity then for our economy and for our national defense that we control the sea lanes: Sea power insures that sea control. Sea power, the naval capability, and the merchant ship delivery ability, will deter and may prevent war.

In understanding naval sea power, however, it is important that we do not think in terms of matching Russia ship for ship. It is estimated that she now has 2,700 ships, of which a good many are ships of the line. This exceeds our Navy in number, but not in striking potential. Our new Navy is built on a concept of mobility: Mobility on the sea, under the sea, and in the air—a mobility which extends vastly the range of our effectiveness by the use of high speed nuclear propulsion, guided missiles and supersonic aircraft.

Recently, for instance, aircraft of a carrier on the west coast flew non-stop to a carrier on the east coast. And, not long ago, this same type Navy plane crossed the United States in three hours and 23 minutes to break the speed record.

The mobility of the new Navy is a part of our strategic concept that we need to be capable of applying appropriate force, controlled in degree, to precise targets rather than be capable of delivering mass annihilation. Too often we structure our thinking to the concept of all-out nuclear war. The feeling that limited wars are a thing of the past is not justified for instance by the experience of the limited wars in Korea and Suez. Nor is it justified theoretically: Mr. Murray of the Joint Committee on Atomic Energy summed it all up very well when he said:

> "The alternative to limited war is moral indignation, but whatever its value, moral indignation is not an adequate instrument to insure the success of the American mandate over the Communist mandate."

NEED ALL ARMED BRANCHES

Our defense must not be limited to one strategy, one weapon, or one service. Our national safety necessitates that we guard against the "all eggs in one basket" idea. We need all "four services"—the Army, Navy, Air Force, and the Merchant Marine. No one of them has the ultimate weapon, nor the ultimate answer. To discharge the Navy's responsibility in defense, we must have a versatile fleet—one that is mobile and packs a real punch.

Let's look now at the Navy's plans for a mobile fleet. These plans are centered around the fast carrier task forces. At the center of this task force is the attack carrier. The Navy plans to begin building one of these nuclear-propelled carriers in 1958, and it is contemplated that five more will eventually be built.

By 1965, then, with the conversions of existing conventionally-powered aircraft carriers, and the addition of new ones already authorized, we will have 15 aircraft carriers, of which six are programmed to be nuclear-powered carriers, and the others will be the big FORRESTAL type, capable of handling the present heavy aircraft. The costs of a conventional aircraft carrier and a nuclear-propelled one are comparatively equal at about 350 million dollars—equal if you consider that the conventional carrier necessitates the cost of operation and maintenance of an oiler.

What do we gain with this nuclear-propulsion? Speed, endurance, and safety. The flight deck has been redesigned without the stacks; without these vulnerable uptakes, the air-tightness against fallout is improved and we are independent of a critical oil supply. These are among some of the advantages in addition to the tremendous mobility gained in being able to steam at full power for an extended period of time.

PLANNED FOR '61

Now, out in our disposition around the carrier center are our guided missile cruisers. By 1961, we will have 12 of them, one of which will be new construction and the others will be conversions. The armament on these ships reflects the fact that World War II guns simply cannot combat the aircraft of today. The Navy's research and development in rockets and missiles goes far back in time, but it has been only within the last two years that production and installation have been made possible. Even now, some of the types of missiles are not in a production status.

These cruisers are big enough for the TALOS missile. Some of these cruisers will have TALOS twin launchers fore and aft. The TALOS is one of the five different missiles which are now operational. It can use either high explosive or nuclear warheads against ships or shore bases as well as against high-speed aircraft and other missiles. It is considered a surface-to-air missile and can deliver to any altitude that airplanes fly. Powered by a ramjet engine of 30 inches in diameter, it has a velocity several times the speed of sound.

Beyond the cruisers in our task force ring—dispersed at long distances because of the nuclear bomb threat—are the new frigates. The frigate is larger and faster than a destroyer and it has a longer operating range. It is about two-thirds the size of a World War II cruiser. There will be 10 of them completed by 1959; eight more are planned for 1962 at which time we will have a force of 18 frigates equipped with the TERRIER guided missile.

The TERRIER is smaller than the TALOS—it was a preliminary development to the TALOS and was so good, it was kept. It is 15 feet long and weighs about 1,100 pounds. Now you all have heard of the missile cruisers, the BOSTON and the CANBERRA, and the destroyer GYATT. They are now operationally carrying the TERRIER. The frigates will be equipped with twin TERRIER launchers fore and aft. With long-range radar and long-range sonar, these ships become part of the anti-submarine defense, as well as the anti-aircraft defense.

TARTAR—NEWEST

The destroyers in the carrier screen will be carrying a smaller missile called the TARTAR. The TARTAR, which is still highly classified, is the newest and smallest of the surface-to-air missiles and is being installed in guided missile destroyers under the 1957-1958 conversion program.

The REGULUS I is a 30-foot swept-wing pilotless aircraft capable of delivering everything from an atomic punch to photographic reconnaissance. It is operational in the fleet. The REGULUS II, its successor, is longer ranged and is supersonic. It has undergone extensive tests and will soon be operational in the fleet.

Time does not permit a complete rundown on the shipbuilding plans of the Navy, but I know you are all interested in the submarine planning. So much has been said of the NAUTILUS that it need not be repeated here. The SEAWOLF, of course, with a different nuclear coolant, had difficulties with leaks. I understand that it is limited to 80 per cent of its capacity and that the sodium coolant system will not be used in future plants.

The Navy plans to build three guided missile nuclear-powered submarines which will carry the REGULUS II weapon. By December 1961, it is expected that we will have four nuclear-propelled and four conventionally-propelled guided missile submarines. These submarines will have four torpedo tubes in addition to the REGULUS II.

By 1961, too, we plan on having 15 nuclear-powered submarines which are designed for destruction of ships and other submarines. They will follow the plan of the NAUTILUS, incorporating what has been learned to increase speed and save on weight.

In addition to the major missiles in the fleet arsenal, we have the SIDEWINDER, the SPARROW, and the PETREL carried by our aircraft. They are all air to air missiles.

FLEET BALLISTIC MISSILE

Of special importance in the future will be the fleet ballistic missile, the POLARIS. Essentially, a ballistic missile is a space missile. It gets only an initial guidance, and thereafter it follows a predetermined trajectory path above the atmosphere in free space. The guided missile, on the other hand, has a mechanism which homes onto the target. The ballistic missile must be fired at a fixed target whose geographical location is known.

For this reason, the ballistic missile cannot very well be fired at a ship or task force underway. It can be fired, however, from a ship against a fixed land target, and we have already commissioned a ship to secure the data from tests and evaluations necessary for effective firing. The fleet ballistic missile expands our range of firepower: we can lob nuclear warheads 1,500 miles, effectively demolishing the source of the enemy's seapower strength. With the Navy's carriers and submarines we do not need an intercontinental ballistic missile.

The Navy consistently emphasizes that its role is the control of the seas, not the strategic destruction of inland targets. But you can readily see that such a weapon whose base does not depend on the use of land in foreign countries, and whose location cannot be determined, actually extends our total capability for sea control.

Let me draw together here some salient points. First, Russia has been a political, economic, and moral threat to the United States for a very long time; recently, she has become a mighty military threat and even more recently, she has become a threat to our sea power: We must be able to move merchant ships when and where we please, both for our peacetime economy and in a wartime situation.

USE NAVY FOR DEFENSE

We must be ready to utilize our Navy not only as a sea lane protector, but as a siege weapon during wartime to prevent the enemy from utilizing his harbors, his shipbuilding facilities, and his exits to the sea.

We must have a force which can move rapidly, which is sufficiently mobile to cover strategic areas to deter wars, not with the threat of nuclear annihilation, but with the threat of limited and controlled force.

In order to play it safe, we have planned for 1958 the building of 19 new ships and are converting five existing naval ships as well as converting seven merchant ships. Our building program includes carriers, cruisers, frigates, destroyers, submarines, amphibious assault ships for helicopter platforms, ocean radar station ships, and a survey ship to get precise data for ballistic missile launching.

We must face the fact that defense does cost. Defense has always been a major item in any nation's budget. Not only are we faced with rising labor costs and rising material costs, but we are faced with the tremendous expense of this new equipment. Personally, I feel that security is worth paying for, but I know that we must face these growing costs with a determination to find ways to reduce all nonessential expenditures. We must work diligently to improve the quality of our weapons. We must continue to do our utmost to attract and retain men of high quality. I am confident that the nuclear powered Navy armed with guided missiles, even though costly, is economical for it helps to insure our security.

OFFICERS OF THE

MARINE SECTION

NATIONAL SAFETY COUNCIL 1957-58

General Chairman—L. H. QUACKENBUSH, vice president, States Marine Corp., New York, N. Y.

Executive General Chairman—CARL F. VANDER CLUTE, general manager, Marine dept., Gulf Oil Corp., New York, N. Y.

Vice General Chairmen (Atlantic Area)—JOSEPH S. BLACKETT, general operation manager Grace Line, New York, N. Y.; W. N. DAMONTE, vice president & manager, Marine dept., Sinclair Refining Co., New York, N. Y.; R. K. KELLY, manager, Transportation dept., Eastern division, Tidewater Oil Co., New York, N. Y.; J. V. C. MALCOLMSON, general manager, Marine dept., The Texas co., New York, N. Y.; HAROLD W. NORTHCUTT, manager, Staten Island Yard, Bethlehem Steel Co., Staten Island, N. Y.; ROBERT E. O'BRIEN, vice president, Operations, Moore-McCormack Lines, Inc., New York, N. Y.; ROBERT J. TARR, operating manager, Luckenbach S. S. Co., Brooklyn, N. Y.; PARKER WISE, general manager, Marine Transportation dept., Socony Mobil Oil Co., New York, N. Y.

Vice General Chairman (Gulf Area)—GEORGE GRISWOLD, vice president, Gulf & So. Amer. S. S. co., New Orleans, La.

Vice General Chairmen (Pacific Area)—CAPT. T. C. CONWELL, vice president, Ship Operations, American President Lines, San Francisco, Calif.; A. E. KIHN, president, California Shipping co., San Francisco, Calif.; RANDOLPH SEVIER, president, Matson Navigation co., San Francisco, Calif.

Vice General Chairmen (Great Lakes Area)—DAVID L. BUCHANAN, Director, Claims division, Pittsburgh S.S. division, U. S. Steel corp., Cleveland, Ohio.; JOHN L. HORTON, assistant manager, Marine dept., Cleveland Cliffs Iron co., Cleveland, Ohio.; REAR ADMIRAL CHARLES R. KHOURY, USNR, president, Pittsburgh S.S. division, U. S. Steel corp., Cleveland, Ohio.

Vice General Chairmen (Inland Waterways)—Operations—F. A. MECHLING, vice president, A. L. Mechling Barge Lines, Joliet, Ill.; *Membership*—WILLIAM C. McNEAL, vice president, Oil Transport co., New Orleans, La.

Vice General Chairmen (Passenger and Cargo Services)—L. S. ANDREWS, vice president, American Export Lines, New York N. Y.; CAPT. L. A. RENEHAN, marine superintendent, Farrell Lines, New York, N. Y.

Vice General Chairmen (Tankers)—CHARLES L. BOYLE, manager, Marine Dept., Sun Oil co., Marcus Hook, Pa.; ADOLPH B. KURZ, vice president, Keystone Shipping co., Philadelphia, Pa.;

Vice General Chairman (Stevedoring)—G. H. E. BUXTON, director, Safety Bureau, New York Shipping Assn., New York, N. Y.

Vice General Chairman (Coastal Regions and International Safety Conventions)—VICE ADM. ALFRED C. RICHMOND, Comdt., U. S. Coast Guard, Washington, D. C.

Chairman, Nominating Committee—WILLARD F. JONES, New York, N. Y.

Secretary (Admiralty and Maritime Counselor)—HENRY C. EIDENBACH, Hagen & Eidenbach, New York, N. Y.

Advisory Committee (Past General Chairmen)—REAR ADMIRAL EDWARD C. HOLDEN, JR., USNR (Chairman), president, United States P. & I. Agency, Inc., New York, N. Y.; CAPT. JONES F. DEVLIN, JR., general manager, United States Lines, New York, N. Y.; JOHN D. ROGERS, exec. vice president, Esso Shipping co., New York, N. Y.; HARRY X. KELLY, president, Delta Line, Mississippi Shipping co., New Orleans, La.; JOHN G. PEW, JR., vice president., Sun Shipping & Drydock co., Chester, Pa.; REAR ADMIRAL GEORGE WAUCHOPE, executive vice president, Farrell Lines, New York, N. Y.,; FREDERIC R. PRATT, Socony Mobil Oil co., New York, N. Y.; LEIGH R. SANFORD, president, Shipbuilders Council of America, New York, N. Y.; LOUIS B. PATE, Scarsdale, N. Y.; REAR ADMIRAL ROBERT C. LEE, USNR (ret.) vice chairman, Moore-McCormack Lines, New York, N. Y.;WILLARD F. JONES; CARTER KENDALL, chief safety engineer, Bethlehem Steel co., Bethlehem, Pa.; Carl E. Holmes, Cranford, N. J.; CAPT. E. W. FISKE, JR., vice president & manager, Mobil Overseas Tankers co., Fort Lee, N. J.

Assistant General Chairman for Tankers—J. R. THOMPSON, assistant general manager, Marine Dept., Gulf Oil corp., New York, N. Y.

Assistant General Chairman (Programs, Conventions)—HAROLD M. WICK, assistant vice president, American Bureau of Shipping, New York, N. Y.

Assistant General Chairmen (Membership)—CAPT. JONES F. DEVLIN, JR.;T. T. WILKINSON, Supt. Eng., Marine dept., Sinclair Refining co., New York, N. Y.

Director, Public Relations—FRANK BRAYNARD, director, Bureau of Information, American Merchant Marine Inst., New York, N. Y.

Assistant Director (Public Relations)—JOHN K. TENNANT, Special assistant to Atlantic Coast Director, Maritime Administration, New York, N. Y.

Director, Maritime Associations—Safety Cooperation and Attendance—R. J. BAKER, secretary-treasure, American Merchant Marine Inst., New York, N. Y.

Director, Safety Information and Posters—CAPT. MILTON BREECE, manager, Esso Shipping co., Port of N. Y. Office, New York, N. Y.

Editor, Marine Newsletter—WARREN D. LINDSAY, director of Safety, United States Lines, New York, N. Y.

REGIONAL ACTIVITIES AND COMMITTEES

Assistants to vice General Chairman (Coastal Regions and International Convention)—REAR ADMIRAL HENRY C. PERKINS, Commander, Third Coast Guard District, 80 Lafayette St., New York, N. Y.; COMMANDER ALEXANDER W. WUERKER, Exec. Secy., Merchant Marine Council, U. S. Coast Guard, Washington 25, D. C.

Assistant Chairmen (Atlantic Region) Tanker Operations—CAPT. WM. G. ANDERSON, Mgr. of Operations, Marine div., The Atlantic Refining Co., Philadelphia, Pa.; CAPT. WILLIAM B. CHATFIELD, Keystone Shipping co., Philadelphia, Pa.; A. E. FISCHER, manager, Inland div., Marine Transport Dept., Socony-Mobil Oil Co., New York, N. Y.; J. R. THOMPSON, assistant general manager, Marine Dept., Gulf Oil co., New York, N. Y.

Assistant Chairman (Atlantic Region) Cargo and Passenger Vessels—JAMES T. CROWLEY, director of safety, Moore-McCormack Lines, Inc., New York, N. Y.

Gulf Region—Ships and Stevedoring—T. C. BRYANT, supervisor, Accident Prevention, Lykes Bros. S. S. co., Whitney Bldg., New Orleans, La.; EARLE SMITH, safety director, Waterman S. S. Corp., Mobile, Ala.; O. P. VILLARRUBIA, claim agent and safety manager, T. Smith & Son, New Orleans, La.; E. R. SEAMEN, safety director, Mississippi Shipping co., Inc., New Orleans, La.; CAPT. J. B. RUCKER, Marine Inspection Officer, 8th Coast Guard District, New Orleans, La.

Pacific Region—Ships and Stevedoring—JOSEPH H. TRAVERS, manager, Accident Prevention Bureau, Pacific Maritime Assn., San Francisco, Calif.; HARRY E. AVERY, safety engineer, Matson Navigation co., San Francisco, Calif.; CAPT. F. A. McGURN, marine inspection officer, 12th Coast Guard District, San Francisco, Calif.

Great Lakes Region—Bulk Carriers—WM. ECKERT, Mgr., safety dept., Interlake S. S. co., Cleveland, Ohio.; L. C. MATIA, Secy., The Wilson Marine Transit co., Cleveland Ohio.; COMMANDER C. E. LEISING, marine inspection officer, 9th Coast Guard District, Cleveland, Ohio.

Director, Inland Waterways, operating and shipbuilding—BRAXTON B. CARR, president, The American Waterways Operators, inc., Washington, D. C.

Assistant Directors, Inland Waterways, Operating and Shipbuilding—ROBERT L. GRAY, superintendent, River Transportation Dept., Ashland Oil & Refining co., Ashland, Ky.; G. A. PETERKIN, JR., president, Dixie Carriers, Houston, Texas.; DAVID M. BROWN, JR., The American Waterways Operations, Inc., Washington, D. C.; CAPT. C. H. STOBER, marine inspection officer, 2nd Coast Guard District, St. Louis, Mo.

SPECIAL SERVICE COMMITTEES

Chairman, Ship Owners Associations Committee—RALPH E. CASEY, president, American Merchant Marine Institute, New York, N. Y.

Chairman, Statistics and Contests Committee—CAPT. C. M. Lynch, manager, safety and training, Sinclair Refining co., Marcus Hook, Pa.

Shipbuilding and Ship Repair Committee—R. B. CHAPPELL, JR., industrial relations manager, Electric Boat div., General Dynamics corp., Groton, Conn.; R. D. DAUTERICH, safety engineer, Maryland S. B. & D. D. co., Baltimore, Md.; T. R. LEADBEATER, chief safety engineer, Todd Shipyards corp., New York, N. Y.; ROBERT G. LEWIS, safety engineer, Bethlehem Steel co., Bethlehem, Pa.; HERMAN J. NORDSTROM, safety engineer, Newport News Shipbuilding and Dry Dock co., Newport News, Va.; JAMES O'DONNELL, director of Safety, Avondale Marine Ways, New Orleans, La.; J. A. STAFFORD, safety engineer, Ingalls Shipbuilding corp., Pascagoula, Miss.; GILBERT WIDDOWSON, safety engineer, Sun S. B. & D. D. co., Chester, Pa.; I. C. YATES, director of safety, Alabama Drydock & Shipbuilding co., Mobile, Ala.

Chairman, Engineering and Minimum Standards Committee—CAPT. R. A. SMYTH, assistant chief, Office of Merchant Safety, U. S. Coast Guard, Washington, D. C.

Chairman, Liaison Committee for Cargo Ship and Tanker Discussion Groups—CAPT. R. H. SMITH, manager safety department, United States P. & I. Agency, Inc., New York, N. Y.

Chairman, Tanker Safety Discussion Group—CHARLES A. CULVER, safety engineer, Atlantic Refining co., Philadelphia, Pa.

Chairman, Cargo Ship Discussion Group—CAPT. ROBERT CORNWELL, safety director, Isthmian Lines, New York, N. Y.

Chairman, Great Lakes Safety Discussion Group—ROBERT E. KRATZERT, Vessel Personnel mgr., Columbia Transportation co., Cleveland, Ohio.

Awards Committee—CAPT. ROBERT E. MACKEY (Chairman), assistant manager, Operations div., Marine Dept., The Texas co., New York, N. Y.; CAPT. E. W. FISKE, JR.; J. M. DEMPSEY, JR., manager, Marine dept., States Marine Lines, New York, N. Y.

SPECIAL GOVERNMENT COMMITTEES FOR SAFETY IN NATIONAL DEFENSE

Chairman, Safety Policies for Regulations, Ship Inspections—R. ADM. H. T. JEWELL, U. S. Coast Guard Headquarters, Washington, D. C.; R. ADM. HALERT C. SHEPHEARD, USCG (Ret.), Washington, D. C.

Chairman, Committee for Safety in National Defense Transportation—VICE ADMIRAL JOHN M. WILL, USN, Commander, Military Sea Transportation Service, Washington, D. C.

Atlantic Area—R. ADM. DONALD T. ELLER, Commander, M.S.T.S., Brooklyn, N. Y.

Pacific Area—R. ADM. H. S. PERSONS, Commander M.S.T.S., Fort Mason, San Francisco, Calif.

Eastern Atlantic and Mediterranean Area—R. ADM. FRANK L. JOHSON, Commander, London, England, c/o Navy 100, Fleet P.D., New York, N. Y.

Western Pacific Area—R. ADM. G. C. WRIGHT, Commander M.S.T.S., Yokosuka, Japan.

North Pacific Subarea—CAPT. N. A. LIDSTONE, Commander, M.S.T.S., Pier 91, Seattle, Washington.

Gulf Subarea—CAPT. J. H. BROWN, USN, Commander M.S.T.S., Gulf Subarea, New Orleans, La.

Chairman, Safety Committee for U. S. Coast Guard—Safety Within the Service—CAPT. LAWRENCE M. HARDING, safety director and assistant engineer-in-chief, U. S. Coast Guard, Washington, D. C.

Chairman, National Defense Transportation- Readiness—CAPT. M. I. GOODMAN, Maritime Administration, Washington, D. C.

Chairman, Safety Committee for Longshoremen, Harbor Workers—RALPH W. NETTERSTROM, Marine Safety Advisor, Bureau of Labor Standards, U. S. Department of Labor, Washington, D. C.

Chairman, U. S. Naval Shipyards Safety Committee—CAPT. H. L. MATHEWS, CEC, USN, director of safety, Office of Industrial Relations, Navy dept., Washington, D. C.

Staff Representative—L. W. DUTTON, National Safety Council, Chicago, Ill.

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

THE METALS SECTION

This volume is a record of the sessions held at the 1957 National Safety Congress by the Metals Section. The conduct of these Congress sessions each year is only one of the many cooperative activities which the Metals Section carries on in behalf of its members, and for the benefit of accident prevention work in the metals industry generally. The Section gives guidance in the preparation of a great variety of technical and educational material useful in the day-to-day safety programs of metals plants.

The activities of the Section are under the direction of its executive committee, the members of which are listed at the close of this volume.

In addition to selecting and developing men to supervise in good safety work, we promote an active program by providing our supervision and workers with the proper tools, environment, and incentives to work safely. These include the following:

GOOD HOUSEKEEPING

Good housekeeping, proper sanitary facilities, and adequate locker rooms are important in developing the worker's safety attitude. If a plant is well kept, the safety record will be good and the efficiency of operation will be high because plant morale is high. Men work better and enjoy their work more in clean and attractive surroundings.

In promoting cleanliness and good housekeeping, we do not favor the periodic clean-up campaign. We keep a plant clean by *never letting it get dirty.*

We believe in organizing and supervising so that the plant is always clean and neat. Each department head has an area and HE —no one else—is responsible for the housekeeping. Each department head has supervisors assigned to definite areas for which they are responsible.

In 1956, we spent nearly one million dollars for personal protective equipment such as hard hats, flame retardent clothing, goggles, face shields, prescription safety glasses, hand cremes, respirators, gas masks, and special purpose equipment. It is the supervisor's job to see that these devices are used by developing among his men an understanding of the value and need for this equipment plus a willingness to use it.

INDUSTRIAL HYGIENE AND MEDICINE

The Industrial Hygiene division checks the atmosphere in working areas for toxic gases, vapors, fumes, and proper lighting. Drinking water and in-plant feeding facilities are also checked regularly.

Our safety and training departments assist department heads in safety training and education programs.

The worker's safety education consists of an indoctrination session, followed by on-the-job instructions from his foreman. He receives a rule book which is reviewed with him by his foreman. He is either contacted on the job about safety or attends group safety meetings showing safety movies and slides. Employees are encouraged to report unsafe conditions promptly to their foremen. Safety bulletin boards of various sizes and shapes are located throughout the plant.

Each year more than 10 per cent of our employees are trainer or retrainer in a three-hour modified course in first aid. As a climax, an annual first aid contest is held. Competition is active and the winners are honored at an award luncheon. During 1956, 2,194 employees received *first aid training.*

In addition to the first aid program we have two other group programs training men to deal with hazards present in a steel mill—gas and fire. About 1,448 employees were trained in Gas Protection Procedures and 2,194 employees in our Fire Squad Commander Program.

The first few seconds are the most important to control a fire. And the person closest to the fire is the most important in the plant at that moment. But he is no value if he can't operate the available equipment. Three years ago we developed a training program to teach employees to use fire extinguishers. The departmental instructor is trained by the Inland fire department.

STRESS LOCK-OUT PRECAUTIONS

The departments set up fire fighting squads according to jobs. For instance the hooker calls the fire department, the shearman blows the fire whistle, the mechanic and helper lay the hose line, the roller and feeder bring an extinguisher to the fire location.

About 2,000 employees are trained each year to put out fires *by actually using* portable extinguishers. This training has paid off, and has made our employees more fire conscious. They respect the fire fighting equipment, and seldom block access to the equipment.

As in most plants, our general safety rule "machinery shall be stopped, locked out and tagged while adjustments or repairs are being made," was *too* general. Some adjustments have to be made while a mill is running, and in many cases supervisors saved time by pulling a switch—not locking it out. As a control measure, every six months department heads are required to submit a status report on the Lock-Out Procedure.

Our safety department recommended that written procedures covering every conceivable type of work done on that equipment be developed for all movable equipment in the plant.

In 1956, after the lock out program was in effect two years, we analyzed our accident records, and noted that in 1953 and 1954, we had 15 disabling injuries, four of them were fatal. Two years under this program we had two disabling injuries and no fatalities. In two years, an investment of 3,000 supervisory man hours in preparing these procedures, saved four lives and 13 disabling injuries. Here is proof that good supervisory performance results in better safety performance.

Visual aids are used in our safety education programs, especially model cranes and electrical demonstration boards.

Because injuries occur more frequently off the job than on the job, we have an off-the-job safety program emphasizing traffic, home and public safety. In six months this year 46 employees were injured on the job, none fatal. However 124 employees were injured off the job, and nine were fatalities.

RECOGNITION ACTS AS INCENTIVE

Recognition is a primary motivation for most people, and for this reason we have recognition program of awards, dinners, publicity, and letters of commendation.

Employees in departments with 365 days or a million man hours without a disabling injury are presented with individual merit awards. Employees who prevent or minimize an injury to a co-worker receive individual awards. Employees who develop a useful safety device are given individual merit awards.

Supervisors know their safety performance is a major criteria in considering promotion and merit reviews. We will not approve promotion or raises for supervisors *whose safety performance is not* good.

Safety in a plant is the company's responsibility. Under our system of privately operated enterprise this responsibility can not legally, morally, or logically be shifted to either the employee or the community. The law, courts, and society hold the company responsible for on-the-job safety. Unsafe workers and unsafe conditions are an indication of poor management. A good safety record, therefore, is a characteristic of *good management.*

Our management functions to insure that the health and well being of our employees are not jeopardized by their jobs. Any supervisor who does not continually promote safety is not representing management, and is failing in an important aspect of his job.

Better working conditions, safety equipment, safety procedures, safety engineering, safety training, safety motivation, good housekeeping, and a friendly, firm enforcement program have *convinced workers and* the union that management is sincerely interested in safety. As a result, our workers demonstrate a greater respect and awareness of potential hazards in their work.

THE PROS AND CONS OF SAFETY MERIT AWARD PROGRAMS

by J. L. RIDINGER

director, Safety & Plant Protection, Inland Steel co., East Chicago, Ind.

Safety awards are token awards helpful in motivating workers to be more safety conscious, not only as individuals but also as co-workers.

Safety award programs at Inland are not new. At the Indiana Harbor Works, in 1917, monogrammed cuff links, tie pins, belts, key rings and pocket watches were awarded workers for safety suggestions and devices. These awards promoted safety consciousness during an era when both workers and supervisors regarded unsafe conditions and unsafe acts as part of the day's work.

Safety is fundamentally a selling job. First management must be sold on the need for safe equipment and safe working procedures.

Top management in most companies prod their staffs to do a better safety job, because they don't want their people to get hurt, and also because a safe plant is good public relations and low injury rates reduce insurance premiums.

Like any phase of the industrial business, safety is expensive. However, one company has as its slogan, "If you can't afford safety you can't afford to be in business." Many companies learned from experience that good safety performances more than offset financial investment with returns such as good morale, efficiency, increased production and better quality.

SALESMANSHIP WITH EMPLOYEES

Promoting safety to management is simple, compared to selling safety to the workers. It takes more than safe equipment and good working conditions to make workers safe on the job. Even with adequate supervision, a screening process for new employees, job placement and on-the-job instruction programs, accidents continue to happen if the workers do not have the proper safety attitude.

During the past 10 years, many industries have reduced their injury rates. But each succeeding year they find it more difficult to reduce frequency rates by one point, than they did 10 years ago by five to 10 points. This is especially true in industries with low frequency rates. As any plant nears the irreducible figure of "0" injuries, it becomes difficult to hold the attained safety position and more difficult to improve.

Management is confronted with similar situations when attempting to establish new safety records. Safety equipment, good working conditions and know how are not enough. Employees must have a continuous desire to work without injuries.

The United States Steel corporation has an excellent safety film, "Knowings Not Enough." This film cautions trained workers against improvising, impulsiveness, impatience, and impunity. Most injuries caused by human failure can be attributed to one of the four "Imps."

It is generally agreed that 85 per cent of industrial injuries are caused by human failures; sometimes the injured is at fault, the co-worker, the supervisor or in other cases combination of human failures. This is the field in which we must do an effective job, if there is to be an appreciable reduction in industrial injuries.

To improve the safety attitude of supervisors and workers, we must use more than the basic reasons for preventing injuries — — — loss of human life, pain and suffering, family hardships, and injury costs. Other forms of motivation can stimulate a continuous safety interest in workers as individuals and a working team.

Since children, we have had some motivation to encourage us to do a better job. In grade school a star would be placed after our name for knowing our lessons and for excellent attendance. In sports we were given numerals and sweaters as individual awards, and for team play we shared in various trophies.

People are only grown up children, and desire and respond to effective motivation programs. This is one reason why the Inland Steel company has had individual safety award programs.

TYPES OF AWARD PROGRAMS

There are many safety award programs, such as national awards, company awards, and individual and company awards. National awards can be obtained from the National Safety Council and trade associations. Your company can win one of the four National Safety Council safety awards if it meets the following qualifications:

AWARD OF HONOR—A perfect record of 3,000,000 or more man-hours brings the award automatically if the record covers an entire calendar year. The award is given on application if the record covers any period greater or less than a calendar year but not less than 30 days.

AWARD OF MERIT—A perfect record of 1,000,000 to 3,000,000 man-hours receives an Award of Merit. The award is given automatically if the record covers an entire calendar year. The award is given on application if the record covers any period greater or less than a calendar year but not less than 30 days.

CERTIFICATE OF COMMENDATION—A perfect record of 200,000 to 1,000,000 man-hours will be recognized by a Certificate of Commendation, to be given automatically, if the record covers an entire calendar year, or on application if the record covers two or more calendar years.

PRESIDENT'S LETTER—A perfect record of 10,000 to 200,000 man-hours is recognized by an appropriate letter from the President of the National Safety Council, automatically, if the record covers an entire calendar year, or on application, if the record covers two or more calendar years.

Most companies usually have two kinds of awards—plant awards of plaques or trophies to plants that improved their safety performance over the previous year. The major safety award is usually the President's award, which is awarded to the safest plant in the company. This award may be in the form of a plaque, trophy or a statuette. Some companies award special safety *trophies to foremen. The most effective* type for any company are those that are tailor made for the needs of a plant.

INDIVIDUAL AWARDS

Lotteries: Many individual award programs are set up on a lottery basis, with a specified number of prizes allotted for a given number of workers. Qualified workers *are given tickets, which allow them to par*ticipate in the drawing.

Safety Buttons: In some companies safety buttons are awarded to workers who complete one or more years without a disabling injury.

Special Awards: Annual supervisors' dinners, short vacation trips for supervisors and their wives, or time off and tickets to a football or baseball game.

Some Other Types: One of Germany's large steel plants has a safety bonus system. Bargaining unit employees are divided into 160 groups, the salaried employees into 10 groups and each group has a handicap, based upon their injury experience of the previous year. During 1956, the first year the bonus system was used, disabling injuries in this plant were reduced by 37 per cent compared with an 8 per cent reduction for the German steel industry. $25,000 was paid out in bonuses which averaged $13.00 per man. An additional bonus of $8.00 was paid to workers in groups that completed both 1955 and 1956 without a disabling injury.

This year the Automatic Transporation company in Chicago gave free coffee to *their employees when they broke their safety* record. Ordinarily coffee costs 7c a cup at the machines, but each machine had a special button switch which poured the free cupfuls all day.

INLAND STEEL COMPANY SAFETY AWARD PROGRAMS

Before the United States went off the gold standard, *the supervisors in each de*partment with the best safety record were awarded a $20.00 gold piece. This program was unsatisfactory because of a limited number of gold pieces and dissatisfaction among supervisors in the departments with several perfect safety records.

Departmental Safety Slogan Contest

(a) *Ten dollar monthly awards.*

Each month a winning slogan was selected from those submitted by workers within each department. The winner received a $10.00 bill, and the slogan was posted throughout the department as the safety slogan for the next month. To check the worker's observance of the posted slogan, safety engineers occasionally would ask workers in each section to repeat the slogan. If they could, they were given a one dollar bill.

(b) Thanksgiving Turkey Awards.

Employees who turned in a safety slogan were eligible for a turkey drawing. An allotment of turkeys was made for each department based upon their work force. However, *this program* was dropped because the drawing methods did not make for proper distribution of turkeys. Too many turkeys were won by one section of a department.

(c) Family Safety Cartoon Contests.

To create family interest in on-the-job and off-the-job safety, we published three safety cartoons from the National Safety Council, in our plant publication. One cartoon described an industrial shop, another the home and the third, traffic conditions. Employees listed the unsafe acts and unsafe conditions they saw in each cartoon. Their lists were turned in to the Safety Department. Their names were put in a container and a drawing was held for turkeys. There

was an excellent response to this program, which helped reduce injuries to our employees and their families.

Safety Smokes Contest

This contest awarded a cigar, a package of cigarettes or two candy bars to each employee in a section or department which improved its total injury experience 25 per cent over its five year average. Since a check of the previous ten years' injury experience showed injuries highest during the months of June, July and August, the contest was started in June. As a result our injuries were reduced considerably during the peak period.

The Safety Smokes Contest ran from June 1950 to January 1, 1956, and during this period total injury frequency rate decreased 278 to 121. This program was dropped because it was losing its effect, and secondly because of award conflicts in production departments. Production record cigars were distributed at the same time Safety Smokes were distributed, and confusion resulted.

MILLION MAN-HOUR AND 365 DAY AWARD PROGRAM

Our present award program, which replaced the Safety Smokes Program in 1956, awards workers who have worked a million man-hours without a disabling injury. The 365 day provision permits smaller departments to qualify for an award within a year, otherwise some departments would have to work 10 or more years to attain the million man hour mark.

All employees are eligible for additional awards if the plant works three million man-hours without a disabling injury. As yet we haven't attained the three million man-hour mark but we have been close twice.

The value of individual awards increases when a department works more than two million man-hours without a disabling injury. In addition supervisors of departments that work two million or more man-hours without a disabling injury can attend a safety dinner.

Million man hour plaques and desk trophies are presented to assistant general managers, department superintendents and foremen with a million man-hours without a disabling injury.

In 1956 our Tin Mill with more than 800 employees, worked three million man-hours without a disabling injury. In 1957 two departments, Mechanical with 1,290 employees and the 76" Hot Strip with 1,156 employees, worked more than two million man-hours without a disabling injury. Nine departments and 12 sections worked more than one million man-hours.

Acts of Merit. Employees may be considered for Merit Awards for one of the following reasons:

1. First Aid. Applying artificial respiration, proper application of tourniquet in cases involving arterial bleeding. Rescuing an injured worker.

2. Reporting unsafe conditions that could cause a serious accident such as defective lifting racks, broken rails.

3. Removing a worker from a dangerous area.

The awards range from $25.00 U. S. Savings Bonds to wrist watches.

4. Suggesting safety gadgets or gimmicks that have proven to be effective. Persons who qualify for these awards are eligible for lesser awards.

Our Local Union Safety Committee, with 22 members, has been quite enthusiastic in supporting our various safety award programs.

During the past 10 years the disabling injury rate at the Indiana Harbor Works reduced from 6.09 in 1947 to 2.24 in 1956. Our frequency rate for total injuries (minor and major) decreased from 347 in 1947 to 104 in 1956.

Because top management emphasized safety in general, a better job has been done on guarding machines and equipment. Working conditions have improved, the plant is cleaner and the morale is better. Fewer unsafe acts are reported and injury and compensation costs have reduced. We are doing a better job of selecting and placing workers and supervisors. Supervisors are doing a better job of training employees.

From the standpoint of good business, the quality of our products has improved. We are producing more steel than ever before and our earnings are above the average for the industry.

For these reasons a safety award program that has produced positive results is worth every cent paid for it.

MERIT AWARD PROGRAMS THE PROS AND CONS OF SAFETY

by D. D. MATEER

supervisor of safety, Jones & Laughlin Steel corp., Pittsburgh, Pa.

HISTORY OF SAFETY AWARD PROGRAMS AS THEY HAVE BEEN INSTALLED IN OUR WORKS BEGINNING IN 1918.

A. Monies paid to "straw bosses" for accomplishing work with their men without lost time accidents (rate of pay about $2.00 per week).

B. Plaques.
   1. Departmental
   2. Plant
   3. Company

C. November "No Accident Month"
   1. Large kick-off meeting usually held outside of the plant with an invitation to men and their families.
   2. Departmental signs, slogans, etc.
   3. Drawings among winning departments.
   4. Turkeys and radios.
   5. Above awards were based on lost time cases—this created condition where every effort was to avoid lost time cases and sometimes things were a bit shady.

EMPLOYEE AWARDS

D. Individual award programs. Considerable criticism was made to a single month safety campaign so then it was spread over a number of months depending on the size of the department, to an individual award program set up in the following manner:
   1. A lapel pin designating the department and indicating that the wearer was a part of a team that had worked 250,000 man hours without a lost time accident.
   2. Watch fobs for 500,000 hours worked without a lost time case.
   3. Mechanical pencils for 750,000 man hours worked without a lost time accident.
   4. Pocket knives for 1,000,000 man hours worked without a lost time accident.

Only two departments in our Works completed a 1,000,000 man hours record without a disabling injury.

This program cost several thousands of dollars and from a review of our accident statistics, the return of investment was not as great as one would expect. There were too many mountains and valleys in our accident curve.

WAR DECREASED PROGRAMS

During the war years, little was done in the way of safety award programs—more stress was put on production for the war effort. In the post-war era, beginning in 1948, our President and Chairman of the Board of Directors, Admiral Ben Moreell, believed that industry could operate with a fewer number of accidents and he made many speeches in favor of our safety movement.

In that year, he inaugurated in the J&L Steel corporation what was known as the Admiral Award Program which constituted the presentation formally of a placque bearing the likeness in bronze of Adm. Moreell with a famous inscription on this plaque "If we can't afford safety, we can't afford to be in business." This was awarded on a basis of 1,000,000 man hours worked without a disabling injury, and a unit which worked one year without a disabling injury was awarded a plaque.

This program received a wide acceptance among the employees of the J&L Steel corporation and at our plant it created the spark needed in our accident prevention work. At that time, we had operated more than 90 years in the manufacture of steel and steel products and for the first time it was recorded that during an operating period our Works completed 1,000,000 man hours without a disabling injury. With this interest by top management and the

award program in full swing, some people doubted the intentions of management—that it was more for money rather than for humanitarianism.

In the issue of our J&L Steel corp. magazine in 1949, Admiral Moreell made the following statement:

"Jones & Laughlin does not want to make money out of safety, nor do we want to profit from our Safety Campaign insofar as safety contributes to the health and contentment of our employees and their families.

"So, in order to clarify this matter, the corporation is instituting a procedure whereby savings which are effected in our insurance and compensation payments on account of reduction in the number and severity of accidents, as compared with the average record over the previous five-year period, will be used for improving welfare and hospital activities in the communities where we operate."

These awards were based on a record for any one year that was better than the record of the past five years, having a fixed amount set in the reduction of fatalities, permanent disabilities, etc.

AWARDS TO CHARITY

E. The awards to charities were designated and agreed upon by a committee of Union-Management representatives. In our Works in 1949 to 1952, we gave to charities $30,625.00. This money was used for iron lungs, special operating rooms in hospitals, special care for deaf people, training for deaf people, the cancer fund, the heart fund, the boy scout movement and the crippled children. All, you will agree, are worthy of help. In those years mentioned, the J&L Steel corp. in all of its operations and in the communities where our plants are located, distributed $211,675.00 in the ways in which I have related to you.

As you know, all programs tend to run stale after a period of time regardless of how worthy they seem to be. That was true with this program so in 1953 we inaugurated a new program of safety awards and this was on an employee basis. The procedure used was to split up major departments into 100 man units.

The unit that would accomplish working a calendar month without a disabling injury would be eligible for participation in a drawing of prizes. The number of prizes covered about 10 per cent of the unit. The units that failed to complete the calendar month without a disabling injury had their awards divided up among the other eligible groups in the major department. This created a constant challenge, unit versus unit.

DISADVANTAGES OF PROGRAM

There are three disturbing factors in an award program of this kind.

1. It was possible for a man, under the laws of chance, to win more than once. This created dissension. Some people wanted to disqualify the man after he had won once in a year. This could not be done for the reason that the unit depended on him to work safely as an individual for all to participate.

2. The integration of transferred employees into a unit. For instance, an employee would have a three-day disabling injury in No. 1 unit, causing them to lose their chances of receiving awards. Then, due to production conditions, he would be transferred to No. 2 unit the same calendar month and be eligible to participate in the No 2 unit drawing for awards.

3. Only 10 per cent of the employees in a unit received an award. This award program continued until 1955 when it, like many others, lost its popularity. Management decided after considerable deliberation that an award program would be inaugurated where the steel plant divisions would compete with each other for the lowest severity record and an appropriate statue representing the steel worker be awarded to the division having the lowest severity for the calendar year. This program is continuing.

In 1956, one department at our Works was permitted to operate an award program of their own. This was set up where supervision had an award given to them for the foremen that had no disabling accidents in his division. The men in his division were also given individual awards; this was not on a drawing basis where chance was the factor. The results in 1956 in this department were most encouraging both in frequency and severity of disabling injuries. In 1956, we had a production pattern which gave us a regular work force with a minimum of personnel changes.

The forecast of production for 1957 indicated that we could have a high frequency of transferring people from one production unit to another. The 1956 safety award program would be difficult to administer in 1957; therefore, it was not adopted. So far in 1957, this department has had a most disturbing increase in severity and frequency in disabling injuries.

EMPLOYEES LACKED EXPERIENCE

The first reason given for the reverse of our experience was that we discontinued the safety award program. After a careful analyses of the circumstances surrounding these accidents, we felt that a safety award program would have been of little or no help. The primary cause was the injured employee lacked experience. The procedures that we must follow in transferring employees up and down the job line and from unit to unit causes a condition where an employee may work one turn at one job, the next turn on another job.

The frequency of these changes in job assignments make it difficult for the foreman to carry on an effective training procedure. We felt the increase of accidents was due to lack of experience and training by supervision. If we had carried on the 1956 safety award program in this department in 1957, it would have been interesting to observe the results obtained by it under changed working conditions.

USED CARTOONIST

We have tried essay contests and limerick contests where employees and their families have participated and one time we had a well-known cartoonist draw a figure of a person who we were going to use as a safety reminder and asked the employees to participate in the contest and give this person an appropriate name. We did not get the participation we wanted; however, we did get a good name for the individual—Ray Minder.

I believe that from 1918 to the present time we have used all of the known means in producing safety award programs. True, we have had a nice reduction in frequency and severity of accidents; however, we cannot point to any one of the programs mentioned as the one that has given us the most help. The greatest award that can be given one of our employees or the families of our employees is the ways and means of living without injury. We have in 1957 inaugurated certain programs in training in our company that we believe will have a far reaching effect and a lasting one on our employees and their families.

As we see it at this time, based on our recent experiences we feel that if in the future we again try individual employee safety award programs they must be designed to include the employee on the job, the employee on the highways, and the employee in his home—and his family. We can only visualize that the future participation of the worker must be with the worker and his family.▲

ELECTRICAL HAZARDS IN ALUMINUM REDUCTION

by G. B. S. RICKETTS

administrative chief engineer, Reduction Div., Kaiser Aluminum & Chemical corp., Oakland, Calif.

To quote our Director of Safety—"People get hurt because either they do not recognize or they underestimate a hazard." It is a simple statement, but it sums up a complex situation. As you think about it you might wonder why the hazard existed in the first place. However, experience tells us that no matter how much engineering effort is exerted to design and build a safe plant, we will wind up with some hazards in the project as completed. It is unreasonable and imprudent to go beyond a certain point in our striving to build a safe plant.

The need for emphasis on the reduction of electrical hazards becomes apparent when statistics show one fatality in every 15 electrical injuries as compared to one fatality in every 200 industrial injuries of all types. To achieve this emphasis requires that the problem be attacked as a joint effort of all concerned—we must build plants as safely as possible—then we must train the workers in the plants in the ways of safety.

To guide us in the general design of plants, we have various sets of nationally recognized engineering and operating standards ordinarily known as codes or safety orders. Regardless of whether or not they are designated as safety codes, they all represent the conscientious and considered effort of people with specialized knowledge to guide us toward building safer plants. Rigid adherence to these codes as a minimum standard normally produces a design that represents good industry practice and good safety practice.

In special situations the opposite may be true—particulary when a code is adapted to an area it was not specifically designed to cover. In many locations this situation only calls for careful review by the design engineer and the safety engineer (and possibly others) to establish the safe practices to be followed.

FACE LEGAL PROBLEMS

In those locations where adherence to the applicable code is enforced by law serious legal problems arise. For an example, look at an aluminum reduction potroom. The approach here is to avoid all possible points of contact with ground and thus keep to a minimum the possibility of a worker completing the circuit through his body from the potline to ground. In essence, we try to operate the potlines in an insulated box.

From time to time it is necessary to use AC-powered arc-welding equipment in the potroom for special repairs. We do not ground the case of the unit since to do so would make continuously available, within our insulated box, a point of contact with ground. On the other hand, the National Electrical Code specifies that the case of such equipment be grounded—this is to protect against the hazard of insulation failure within the unit putting the case at AC source potential. In the potrooms this is, by far, the lesser hazard.

This, in an area where the National Electrical Code is enforced by law the safe approach is legally wrong—and the whole problem arises because the Code is being applied in an area it was not designed to cover.

INTERSTATE POLICY CONFLICTS

Such occasional special problems only emphasize the need for better codes—codes, for instance, that have sections written specifically to cover the peculiarities of electro-chemical plants in their many variations. In the meantime, a company operating in several states has other problems. As previously mentioned, some states enforce the National Electrical Code by law; some states have their own electrical codes which have legal status; yet others have no electrical code requirements.

Thus, an interstate company, to avoid internal confusion must adopt some policy. Ours adopted (in 1951) the California General Industry Safety Orders as minimum safety standards for plant design. These Orders are more comprehensive and more exacting than the National Electrical Code which governs in most states in which we operate. In this way we give our people the best protection we reasonably can, and at the same time are not likely to find ourselves in violation of future codes in other states.

Recognizing (as pointed out earlier) that codes must sometimes be followed in principle rather than "to the letter" our policy includes this paragraph:

> "If for any reason compliance with these standards is impractical, the matter is to be reviewed by those concerned and the Safety Supervisor in order to plan for other equivalent practical protection or control."

No matter what code or policy may be adopted as a guide there is still no substitute for a clear concept of the major principles of safe electrical design. This is especially true in aluminum reduction plants, or for that matter in any other branch of the electro-chemical industry, where none of the recognized codes makes provision for conditions peculiar and necessary to the potroom or cellroom. In our thinking, these major principles are four:

1. Insulation—Covering conductive surfaces with materials through which electricity will not travel in sufficient quantities to create a hazard.
2. Isolation — Making energized parts inaccessible to accidental contact by persons or objects—this can be by distance or grounded metal enclosure.
3. Overcurrent Protection—This is the function of a device designed to de-energize an electrical circuit when the circuit is subjected to excess current.
4. Grounding—The providing of a low resistance path through which current may flow to ground in the case of a fault.

Principles 1 and 2 have to do with electrical protection during normal conditions. Principles 3 and 4 have to do with electrical protection during abnormal conditions and I do not plan to discuss them. They are no less important than the first two, but they have received much publicity and attention in general industry literature. As a result there is more general understanding of them—therefore they get better attention than the first two in practice.

INSULATION

Our first principle is of prime importance to aluminum reduction plants—in fact it is the basis of electrical protection in the potrooms. Since it is so important in this area, we need a reasonable basis for evaluating it to determine what "sufficient quantity" might be. Here are some figures on human reaction to direct current taken from a paper published by Prof. C. F. Dalziel of the University of California. Dalziel reasoned that electric shock is a function of current flow and not a voltage effect.

The figures are based on tests on human subjects at the let-go threshold and below —on data from accidents and animal subjects for the higher values. However they were obtained, they are only a guide since people vary so widely in physical condition. As a guide they are valuable since they at least give us a starting point.

All the current values are in milliamperes, and one milliampere equals 1/1000 of an ampere. Generally there is no sensation up to one milliampere. In the range from one milliampere to nine milliamperes we have the transition from a slight tingling to a mild muscular reaction. Above nine milliamperes the muscular reaction becomes stronger, finally reaching the let-go threshold with painful shock at about 75 milliamperes.

In the common multiple Christmas tree lamp—the type where when one burns out the others stay lit—the current could cause painful shock in many people and is close to the let-go threshold. This is not to say that the Christmas tree lamp is dangerous, but to point out how really sensitive the average human being is to the flow of electrical current. Returning to the let-go threshold, as we pass beyond the region of 75 milliamperes the victim can no longer let go and, unless something is done to interrupt the current flow, a fatality can occur under these conditions at currents not much above 75 milliamperes.

SHOCK AVOIDANCE

If we are to avoid any shock hazard, there must be no way in which a worker can become part of a conducting system where the current would be more than one milliampere; that is, our insulation must not pass in excess of one milliampere. When I say any shock hazard, I am thinking of the accidents that can and do happen when a person only senses the passage of current. The surprise frequently produces an involuntary reaction that results in physical damage—such as a worker stabbing himself with a screwdriver, hitting himself in the face with a wrench, or losing his balance and falling, in which fall he is hurt.

If we are to hold insulation leakage currents to less than one milliampere, we must use insulation resistance measuring devices. The device selected must use a test voltage in excess of the line voltage. The practice of using test lamps or a voltmeter to determine the quality of insulation produces unreliable results and therefore is hazardous.

An example of this approach in testing is found in the wall-mounted "air drops" common to many potrooms. The details vary, but generally a short length of rubber air hose is used to insulate the portable hose connection from the air header which is grounded. Several potroom workers received mild electric shocks when, in the course of their work, they touched the pot and the "supposedly" insulated air hose con-

nection at the same time. Preliminary tests revealed that the air hose section that was supposed to do the insulating was not doing the job well enough.

Since there were many of these drops in each potroom this meant that they all had to be tested. We calculated that if no more than one milliampere was to flow with the possible maximum potline voltage of 750, then the resistance of the piece of air hose must be no less than 750,000 ohms. As a safety factor we doubled this value to 1,500,000 ohms or 1.5 megohms.

Using a resistance measuring device we quickly and reliably tested all the insulating hoses—replacing all those that had resistances lower than 1.5 megohms. It turned out later that instead of the hose originally specified, some hose with a high carbon black content had been used on a number of the drops and this was the cause of our trouble.

COLOR CHART EXPLANATION

Before discussing my first example, I will take a moment to run over the configuration of a typical potroom— and before doing so I will explain the color code system used on the charts which I will describe.

RED indicates exposed electrically energized items. For maximum safety the adjacent areas should show as insulation.

BLACK indicates metal neither grounded nor electrically energized. Such conditions should be kept to an absolute minimum as they are hazardous due to their uncertain nature. Generally, such items should be treated as though they are electrically energized.

BLUE indicates metal at ground potential. Any area where blue shows up close to red indicates a hazard. On the other hand, an area that shows all blue equipment has its electrically energized parts well isolated.

YELLOW indicates insulation which we would look for around exposed electrically energized equipment.

GRAY indicates masonry, or concrete which, depending upon the circumstances, can be considered as a practical substitute for better grades of insulation.

BROWN indicates soil.

So much for the chart color coding system. Now let us take a look at an aluminum reduction plant's best claim to uniqueness from the electrical safety standpoint—the potroom. This chart shows a typical potline, with walls and roof omitted, consisting of, say, 144 pots distributed in two potrooms. Here is the bus in red under the floor at the ends of the potroom and at the center passageway. Elsewhere it is attached to the pots (shown here in red) and exposed. Each pot operates at a nominal 5 volts.

POTLINE VOLTAGE

With these pots connected in series, and allowing for a few volts drop in the interconnecting bus, the total potline voltage is about 730—current about 70,000 amperes. Practice in a large portion of the industry is to have no intentional ground on such a system, so the midpoint of the line is usually at ground potential or close to it—and the ends of the line are at a potential to ground of one-half the line voltage.

If we should happen to get a ground at one end of the potline, then the pot at the other end goes above ground potential by the full line voltage and the pots at the physical midpoint of the line are now above ground potential by approximately one-half the line voltage. Thus we must assume that any pot may at sometime be at a potential of several hundred volts with respect to ground. To protect the potroom workers when in the immediate vicinity of the pots, we must plan so that no points of contact with ground are within easy reach.

The usual solution is to cover with insulation all potential points of contact with ground. Some aluminum companies ground the midpoint of the potline through a low resistance which means that no pot can ever be at more than one-half potline voltage to ground. This safety feature is achieved at the cost of other problems which are beyond the scope of this discussion.

INSULATION METHODS

The next chart is a section through the potroom here looking toward the rectifier station. This serves to illustrate the insulation methods used. The pot, supported and reinforced by its cradles, sits in the middle of the room on a concrete slab which acts as insulation. Frequently concrete piers are placed on the slab under the pots to improve the insulation. With or without piers, the quality of insulation at this point has no bearing on safety in the potroom.

On each side of the pot are aisles about 10 feet wide. The floor in the aisles is brick over a reinforced concrete base. The brick (shown in yellow) is installed primarily as a matter of reduced floor maintenance. A secondary benefit is that it also provides better electrical insulation than bare concrete. Many potrooms have been built without the brick as a matter of reduced first cost. A potential hazard with concrete floors is that spillage of molten bath or metal causes spalling. This can result in baring the steel reinforcing bars which, of course, are grounded.

Returning to this particular example—the distance from the pots to the wall is such that wall insulation is not deemed justified. An additional margin of safety comes from the opening for the ventilating doors being continuous, with the doors almost always open. The concrete sill against which the door fits when closed is topped with a heavy timber (shown in yellow) as, during the servicing of the pots, there is a short period when the "butts" or used carbon anodes are placed with the rods resting on the sill.

Without the timber the repeated laying of these rods on the sill would result in chipping of the concrete with ultimate exposure of the steel reinforcing. A rod in contact with this reinforcing would bring a source of ground contact several feet closer to the pot.

CRANE COLUMNS

There is left then the question of the building and crane columns. In our typical potroom these would be sheathed in plywood from the base of the column to a point six feet or more above the floor. Where we have experienced excessive damage to the wood, the base of the column has been encased in concrete for the first 30 inches. Our success with this method has led us in a recent design to insulate with concrete for the full height of insulation required.

To illustrate the real electrical hazard in extending sources of pot potential and ground contact beyond their normal planned position, here is an artist's rendering of the scene of an accident in a Soderberg potroom. In the Soderberg potroom the pots are arranged end to end in two rows with a wide center aisle and relatively narrower side aisles. Note that the channel cart is next to the pot and in contact with it through the gas-hole bar, bringing pot voltage several feet closer to the potroom walls.

Note also that the stud cart is next to the wall with its tongue resting on the only grounded item in the vicinity—the exposed door frame. Now pot voltage and a source of ground contact are within a foot or two of each other—a space easily bridged by a man.

Unfortunately, a potroom worker came along while this condition existed and *attempted to walk through the space between* the two loaded carts. He was found with one arm on each cart corner. Following the accident the potential between the two carts was measured at 260 volts. Note the series of events preceding this accident:

1. The channel truck left adjacent to the pot.
2. The presence of a device (the gas-hole bar) to connect the truck to the pot.
3. The stud cart left adjacent to the door at one of the two pots out of 72 in the room where the exposed metal door frame existed.
4. The tongue leaned against the grounded metal door frame instead of on the floor or back against the cart.
5. The electrical hazard present in the exposed grounded door frames (there were a number of them) had existed for a number of months before it was recognized. An order had been written to correct the hazard but the accident happened before the work was completed. As a matter of background, these doors were not part of the original design and for some unaccountable reason did not receive the same treatment as the two insulated columns that flank it.
6. The failure of the accident victim, despite his training, to recognize the hazard to him and exercise normal caution—also the quirk of human nature that caused him to try the

congested route as compared to ready passage around the other side of the channel cart.

With this example in mind, let us observe that there is a trend, dictated by economics, to potline voltages well above those now common in the United States. Industry literature has carried articles on potlines built or building outside the United States with ratings of 850 volts—970 volts—and 1,100 volts—all in the 100,000 ampere range.

VOLTAGES INCREASING

With this trend in mind, some engineering and safety people are inclined to take the untenable position of crying "unsafe" when we talk of potline voltages appreciably higher than 750. The fatality cited occurred at 260 volts—many occur at potentials common to every household. We know that any voltage in excess of some point below 100 volts is hazardous—and it is up to us to cope with these higher voltages with better engineering standards and improved safety practices.

Returning from my digression on potline voltages to the subject of insulation, let me explain an aspect of the use of concrete for which you should be on the alert. For an example, in one potroom the concrete slab is in contact with the soil underneath it. We used to store the week-end's supply of new rodded anode carbons on the floor a few feet from the end pot. The area used was bare concrete. Due to the necessity for keeping the potroom aisles open, as well as the end aisle between potrooms, the first row of carbons began just a few feet away from the end pot. One day an operator in the course of his work happened to touch the carbons while he was also in contact with the pot—receiving a severe shock.

Investigation revealed that the same hazard existed in other potrooms. As a result this procedure was stopped and arrangements made to store the week-end's supply of rodded anode carbons in locations that did not create a hazard even though they were less convenient.

CONCRETE ABSORBS MOISTURE

To understand what happened, consider that concrete is porous and contains a certain amount of free alkali. With the soil covered, moisture is no longer removed by evaporation from the surface of the soil, thus moisture is available to be absorbed by the concrete. As long as the surface of the concrete is exposed to air of relatively low humidity or in some other way is kept dry, it will act as an insulator.

As soon as we store an object on top of the concrete, the evaporation of moisture from the surface layer of concrete stops and we have moisture extending from the soil through the concrete to the surface of the object. The free alkali in the concrete combines with the moisture to make a pretty good electrolyte (a solution in which current flows readily).

Depending upon the amount of moisture in the soil, the area of the object in contact with the concrete, the porosity of the concrete, and other variables, the object may or may not present a point of ground contact. In any event it does present a hazard due to its indeterminate nature. Certainly when the area of surface covered is in excess of several square inches, let alone several hundred square inches, as it was in the case of the anode carbons stored side by side, the item becomes a point of ground contact within our insulated box.

With all this talk about concrete conducting you may wonder why we consider it acceptable as column insulation. Remember that it takes area of contact and moisture to cause current flow through concrete. Certainly if we rest a steel handled rake against a column insulated with concrete we aren't going to get much area of contact. In addition, concrete in this position is going to be relatively dry due to the potroom heat—the only source of moisture is up through the concrete footing.

INSULATION—CRANE HOOKS

Before leaving the potroom area in our discussion of insulation, a few points relative to crane hooks are worth looking into. The crane hooks must be insulated from ground not only as a safety measure but also to avoid shorting out the potline when performing such operations as filling the ore hoppers, installing crucibles, and so forth. A mechanical hazard also enters the scene at this point, since if current flows up through the hook to the cables, to the drum, and then to the steelwork, and to ground, the arcing at the pulleys and the drum will damage the cable. This can mean sudden

failure of the cables the next time a heavy load is lifted.

Providing insulation is easy until we see what conditions must be met. The installation must be rugged, it must present a minimum hazard to the man handling the hook (setting carbons for instance) and the required increase in building height over that for an uninsulated hook must be held to a minimum.

So far our insulating has been done between the lower block and the hook. Here are some examples of insulated hooks in the range of six to 10 tons. All three are adequate from the standpoint of voltage alone. The "A" hook accomplishes insulation (note the yellow area) without requiring an increase in building height—but look at the hazard it presents to the man handling the hook. A slight miscalculation in placing a sling or otherwise engaging the hook would result in the man being in contact with ground.

If he should happen to be standing with any part of his body in contact with a pot (such as when digging a pot) he would be a candidate for electrocution. There is also much danger of grounding a piece of energized equipment through the grounded part of the hook when engaging the hook with resultant damage to the cables. You wouldn't expect us to use such a hook in our plants and we don't. However, such a hook could be acceptable under conditions I will outline later.

REDUCES HAZARDS

The "B" and "C" hooks greatly reduce the hazards present in the hook on the left. The distance between the point of the hook and the nearest grounded part is several times that of the "A" hook. The "B" hook has an additional feature in that the insulation projects slightly, making is difficult to develop a leakage path across it and making the insulation readily apparent, thus tending to remind the man handling the hook of the hazard.

Note that with the "B" and "C" hooks that some 13 inches and 18 inches, respectively, of addition building height is required (for a given hook to ground maximum distance). This will add in the order of $15,000 per potline (two rooms) for increased building costs.

Primarily to obtain increased safety, but also to avoid spending some of the $15,000 per potline, we are considering insulating the drum and gear box while using the simplified insulated hook as per "A". Then the insulation at the drum and gear box protects the potroom worker and the hook insulation protects the crane cables. With the insulation so arranged there is virtually no hazard to the regular potroom workers who constitute the major exposure.

Since the crane only has workers on the bridge when it is being serviced, the exposure to the hazard is greatly reduced. Also the crane service crews specialize in that activity so they can be more readily made cognizant of the possible hazard. The insulation at the hook keeps the cables from being energized when the load is touching some part of the potline. Then if the crane men break the rules of good crane operation with a sidewise pull there is no arc as the cables touch the bridge girders.

There is one note of caution about insulated crane hooks—assembly must be to exacting standards with respect to clearances and cleanliness of the insulated areas. We had an insulation failure recently in a type "C" crane hook that caused us both equipment loss and production loss—no one was hurt fortunately. It turned out that incorrect clearances at the ends of the center bolt (black) plus dirt had caused the breakdown.

The hooks are tested regularly with a resistance measuring device—and this one had passed its last test. Subsequently it was determined that the test voltage used by the resistance measuring device was of the same order as voltages that the hook insulation would normally experience—so there was no safety margin.

In the future the hooks will be tested with voltages at least twice the potline voltages to provide a reasonable margin of safety. The dirt and incorrect clearances in the assemblies was due to our failure to impress on the outside machine shop doing the work the exacting standards needed for this assembly. So it is not enough to design a good safety device—it is necessary to see that it is built the way it was designed.

Another area in aluminum reduction plants that has stressed the insulation aspect is the rectifier station. In this elevation of a

common rectifier station arrangement the major electrical elements have been depicted with some artist's license. To run over them briefly, one block represents the rectifier frame which consists of a steel framework mounted on insulators. Installed on the framework are 12 steel rectifying tanks with associated bus-work, and various auxiliary devices.

The entire assembly operates at the positive bus potential with respect to ground. There is no enclosure which you might be led to believe by this simple block. On the right there is the anode breaker and on the left the cathode breaker. These breakers operate to disconnect part or all of the frame under various abnormal conditions.

These two breakers probably should be shown in red rather than yellow since, even though a large part of their structure is of insulating material, in most equipment some of the metal parts protruding through or past the insulating material are energized. The cubicle shown in blue to the left of the frame houses all the electrical auxiliary and control equipment for its associated frame. As indicated by its color, it is grounded. It is apparent then that the major hazard is presented by the proximity of the grounded firing cubicle and the energized frame.

Before going to the next chart to discuss the safety measure taken in this area, let me just point out a few areas where we use isolation as a safety measure. Due to the relatively low floor to ceiling height in this area, the two bus systems below the floor are surrounded with expanded wire mesh. The negative bus near the ceiling of the second floor is also protected by isolation—this time by location.

On a plan of the operating floor of the same rectifier station are the firing cubicles and the rectifier frames. The yellow strip represents the rubber mat kept in the operating aisle. Between the cubicles and the frames we also have these rubber mats indicated by these yellow strips. To be sure that in the course of normal operation somebody does not walk from the operating aisle to the hazardous area, we have a movable barrier between each cubicle as indicated by these yellow lines.

When work is to be done on a given frame, plywood insulating barriers are installed in these locations so that there is virtually no opportunity for anyone to make contact with the surrounding energized equipment. In addition certain test operations are performed with the energized frame under test, surrounded with part or all of these guards. To date our accident experience with this type of construction has been very good.

RECTIFIER STATION—ENCLOSED FRAME

In my last two charts we stressed the matter of insulation as the principal protective device. Now let us look at a rectifier station of a newer type which stresses the principle of isolation almost exclusively. In this section you will notice that all energized parts are completely isolated. The buses on the ceiling of the first floor are isolated with guards as before. The buses on the ceiling of the second floor are isolated by distance, and the rectifier frame and breakers are all installed inside a grounded metal enclosure.

All of the doors on the metal enclosure are suitably interlocked with the breakers so that when they are opened the breakers are tripped—de-energizing the equipment. Arrangements have been made to perform various test procedures with the doors closed; that is, leads will be brought out from test terminals through special openings to the test equipment.

We expect that certain service operations previously performed on energized equipment can be performed with equipment de-energized by revised techniques. This particular approach to rectifier station design is slightly controversial, but on the other hand so was the transition from motor controllers mounted on slate panels to the present accepted practice of metal enclosed motor controllers.

This plan view only serves to emphasize (by the lack of red) the complete absence of exposed electrically energized equipment on the operating floor. This is not the whole story for new procedures must be worked out for some of the normal test and service operations. Experience will tell us if we have gone forward in rectifier station safety.

I have linked this discussion of electrical hazards in aluminum reduction with the four principles of electrical protection in order to bring up the subject of a new electrical safety program planned to start on a company wide basis in the near future.

With the aid of several consultants, this electrical safety training program has been developed on a framework of these four principles. This program is aimed at increasing the worker's electrical safety consciousness. We do not expect to make electrical engineers out of each worker. We do expect to develop each principle in layman terms for a clear understanding by the individual worker.

SAFETY CONSULTANTS

I might also mention that within the Reduction Division we have already placed additional emphasis on electrical safety by forming an Electrical Safety committee at each plant. This committee, constituted of electrically qualified people, functions in addition to the General Safety Committees. With this function assigned to technically qualified people we expect much more rapid progress in the recognition and elimination of electrical hazards—as well as the training of the workers.

And I bring this matter of electrical safety training in so that I may make the point—no matter how much effort we put into designing electrical safety into an aluminum reduction plant, that is only half the job—the other half is an effective electrical safety training program—and a continuous one.

This is the more important half because without it, we can spend capital funds for electrical safety until we are no longer competitive and still not produce the electrical safety record we are striving to achieve.

A SAFETY PROGRAM FOR AN EXTRUSION PLANT

by R. L. DEBENON
safety director, Reynolds Metals co., Phoenix, Ariz.

A business analyst described the sort of safety program needed to handle employee health and safety in an extrusion plant. In addressing executives from the industry he pointed out that competition and a definite market made it imperative that ineffective production methods be scrapped.

"The time has come," he stated, "that every individual, department, plant, works, or company in the extrusion business become more productive. This will require greater maturity of business concept and better economy in work programming.

The history of business shows that with good, stiff competition, economic survival depends upon sound business management. Every individual and department must meet the economic and moral responsibilities owed the investment and people served, or fall by the wayside.

This includes all safety people and their respective safety programs.

In the face of this challenge, a good safety program of any extrusion plant has the maturity of concept to know the purpose for which the business was established and to detail its particular activities to insure the success of that enterprise.

What constitutes maturity? When do we judge a safety program has graduated from the level of the juvenile?

A MATURE SAFETY PROGRAM

Many safety programs have a false appearance of maturity. In reality they are juvenile. They possess high organizational status, command a respectable budget, and boast considerable action programs. Tests show however, they are babes in the woods in inspiring people to the proper attitude towards safety.

Age is not a reliable gauge for measuring maturity. A safety program may be of ancient age but in controlling unsafe plant conditions and unsafe acts of people it is still in swaddling clothes.

Bulkiness of organization and procedure does not insure a successful safety program.

What is the plant frequency and severity rate? How much do accidents cost? How much human suffering are accidents and occupational diseases inflicting upon our employees? These things determine how successful is a plant safety program.

An extrusion plant safety program is mature if it successfully contributes economically to the investment supporting it; if it makes reasonable provisions for the safety and health of employees; if it commands respect and has the cooperation of management, supervision, workers, and the union. If it merits and enjoys the prestige so hard won by the safety profession, it must establish its reputation on the basis of quality performance.

In short, it must justify its existence by showing all plant personnel how to discharge the legal, economic, and moral responsibilities to provide a safe work environment and how to perform safely in that environment.

SAFETY BRINGS PLANT PROFITS

In many industrial plants today, the safety programs are little value to the successful operations of those plants. Such reputation is gained because the purpose for a plant safety program is unknown.

Some imagine the sole functions of safety programs are employee benefits. They visualize the plant safety program as nothing more than an industrial welfare unit.

Certainly, a plant safety program has the responsibility for the health and safety of the employees. But, it has an equal responsibility to help the plant make a profitable return to the investment. This is done by reducing the cost of industrial accidents and occupational diseases.

For an industrial safety program to have "rank," "status," or "recognition," it must have this dual concept ever in mind and furnish activities which reduce human suffering and control the high cost of work accidents.

It is impossible to eliminate the physical risks of living. A mature safety program does not carry the torch or wave the flag for such a hopeless cause. Someone has well suggested that only the dead are safe from the perils of life. The only 100 per cent safe plant is the one shut down. We must continue to provide practical physical safeguards. But our big job is to teach and inspire people to live wisely in the presence of danger.

SAFETY CAN'T REST IN BALCONY

Another reason why a plant safety program does not command respect is that it speaks the balcony language. Not long ago, an extrusion plant safety engineer made a speech. He maintained that a plant safety program would be as successful as the safety department was in selling the line foremen on the importance of accident prevention. He also said operating personnel should not be allowed to let production have precedence over safety. He said safety should be first and production second in all work planning and function.

This is balcony language of the first magnitude: The success or failure of a plant operation does not rest upon supervision. The man who sits in the front office must shoulder that responsibility. Therefore the success of a plant safety program depends on the attitude of the plant or works manager.

What about safety vs production? These two terms do not denote different and distinct things. The principles of accident prevention are nothing but the best, the more efficient, the most economical way to do a job or perform a work. An accident is a work disruption. It is truly an unplanned and unwanted event, causing people to be hurt, increasing the cost of producing, and wasting materials, machines, and men.

The sooner we start convincing management and department heads that safety is built-in operating efficiency, the sooner we will bring our plant safety programs down from the balcony and into the arena where they belong.

Did you ever hear a safety man complain that he could not get things done—that he did not have proper management support or cooperation of department heads and supervisors? Did you ever hear the folks in the plant say "Safety in this plant is a big joke. Nobody pays any attention to safety rules"? This is prima-facie evidence the safety program is still perched in the balcony.

What is needed to correct this? We must present a program that will help each department head get his production job done safely and economically. We must provide the tools which safeguard the welfare of our people.

We must evaluate and grasp the full impact of the economic and moral value of our work. When we realize safety has the greatest potential for future growth and recognition, and when we prepare for greater responsibilities, we are definitely on our way to success.

SAFETY—THE TALK OF THE COUNTRY

Safety is becoming a most important subject in the American consciousness and vocabulary. The hue and cry for greater safety in the American way of life is constantly heard. Industrial managements consider it a must. Unions demand it in every labor contract. Government is enacting more and more legislation to insure it. In business, schools, homes, farms, clubs, associations and in every human activity today we find strong, active safety programs.

Safety people must meet the leadership requirements to pilot a quality safety program in the extrusion industry. Every safety program must function on a sound business basis. This means greater conceptual, technical, and human skills be acquired by safety specialists.

What are the marks of maturity in an extrusion plant safety program?

1. When our organizational unit has all the related plant activities under the jurisdiction of the plant safety administrator.
2. When we have a team of management, supervisors, employees, and union which work together to insure plant safety.
3. When we have an action program which produces a safety record that denotes success.
4. When the plant safety administrator has been moved into staff position in the plant organization.

A divided world cannot solve international problems. Neither can a safety department function intelligently and efficiently when broken up into separate sections under departments of unrelated interests and activities. For efficiency of operation, we group related functions.

It would be just as reasonable to break up the plant accounting department and place accounts payable under the engineering department and accounts receivable under the purchasing department. To separate these activities is to create organizational boundaries which slow down functions necessary to plan and execute adequate accident-cost control measures.

No one individual or group can carry on an effective control program alone. Management, supervision, workers, and the union must recognize that each group is an integral part of the safety team. Each group must face its personal, legal, moral, and economic responsibilities to cooperate fully, within the boundaries of its prerogatives and duties. The successful safety program will weld these groups into a task force for a solid frontal attack upon accidents.

TEST SAFETY PROGRAMS

The old saying "the proof of the pudding is in the eating" can determine whether the plant safety program is doing a man's job. What is our standing in the National Safety Council contest for the Non-Ferrous Metals Section? Are we winning our share of the Awards presented by the Council? How does our plant frequency and severity rates compare with the National average—with the rates of other units, works, or plants within our own company? Do our monthly and annual reports to management show decreasing accident costs?

What about attitudes? Is management receptive to our budget recommendations? Do department heads and supervisors regard us as worthy help and call on us for solutions to health and safety problems? Do the workers speak of "our safety program?" Has our safety activity gone from the plant into employees' homes? Are we as plant safety people discharging our civic duties by joining the forces combating all accidents in our communities?

The answer to these questions will indicate the success of any extrusion plant safety program.

The final mark of identity to show that maturity has come to the plant safety program can be resolved upon this question: "where is the safety department located on the plant organization chart?" Does the

safety administrator have prestige? Does he report directly to the plant manager or has his department been relegated to the sub-department status? Has he been made to report to a department head who neither understands nor is directly concerned with efficiency of plant operations?

In the smaller plants, it is practical to combine the safety activities with the functions of some other department. When any plant can economically justify a safety department, however, the safety administrator should not be cluttered with red tape, nor forced to battle frustrations which inevitably arise when he must report to a department head who is not conversant with the principles of administering a plant health and safety program.

Here is a simple formula to insure getting plant safety programs out of the balcony and into the arena.

First, every person in the safety business should hold the strong convictions that his profession is one of great worth and value. He not only contributes to the economic success of his companies, but he is making a vital contribution to enhance human values. Be proud of your profession.

Second, be a booster of your profession. It is very obvious why the great state of Texas has become so well known. Yours is a noble and most useful endeavor. Make its virtues known wherever you go.

Third, have confidence that you can and will bring to your particular safety program the respect and dignity justly entitled.▲

TOP MANAGEMENT'S RESPONSIBILITY FOR SAFETY

by HUBERT C. SMITH

vice president, in charge of operations, Eastern Division, The Colorado Fuel & Iron corp., Claymont, Del.

Industrial safety is simply applied common sense and good business. Naturally, we are concerned with costs. A poor safety and accident record is a very expensive thing. But we are more concerned with the health and welfare of our employees, and with the reputations of our companies as good and safe places to work.

To succeed, a safety program must be well organized and carefully run. However, in any social grouping an element of danger exists because of people moving and working in close proximity. Their very lives may depend on their knowledge of the situation, and their treating it with the seriousness it deserves.

Safety is a joint responsibility and is unique because accident prevention cuts straight across every industrial organization and involves everybody—without exception. Management has the responsibility for developing an effective safety program, one that will furnish the necessary guidance and direction to make our plants safe places to work. The employee must accept and utilize the advice and guidance offered and follow the rules and regulations prescribed.

CREATE "SAFETY CLIMATE"

However, management has a further responsibility in accident prevention—it must establish and maintain the proper "safety climate." The climate must create a condition will induce every employee from top management down the line, to think, breathe, feel and live safety at all times.

This climate, if properly developed, will be reflected in safe practices at work and also in the home and the community. An employee who trips on a tattered stair carpet and injures himself is just as much a loss to the company as one injured on the job.

American industry has accepted and promoted this idea of a safety climate throughout the years. American management recognizes that failure to create and maintain such a climate is dangerous to management and labor alike.

Success or failure depends upon a close working relationship between management and the employees. There can be no disruption of communications, none of the "let George do it" attitude, no abrogation of the mutual responsibility for accident prevention.

Since management directs the safety program and the employee cooperates by following the direction, who administers the program, calls the signals and runs the plays?

Most ideally situated in the management structure is the supervisor. His position as first line of management with direct contact with the employees makes him the ideal person to implement a safety program. But he must have complete support of all levels of management.

GOOD HOUSEKEEPING

A plant manager or department superintendent who condones cutting safety corners, who procrastinates remedying a dangerous condition or feels human lives are secondary to production cannot justifiably criticize his supervisor if he acts in a like manner. The practice of safety is a continuing process for all levels of management. It is mainly in the normal things a supervisor does that his orientation shows through, and he sells or destroys a safety program.

A high correlation exists between a good safety program and a good housekeeping program. We want our people to think and act in an orderly fashion. A plant with strict housekeeping standards is conducive to such thinking, and to such behavior. We are often judged by employees and visitors on the basis of our appearance.

But in addition to appearance, a good and continuing housekeeping program means everything in its place, and the by-products of work promptly removed. Things are not left around to become hazards and our people are trained in orderly methods of doing things.

A safety program depends on seriousness of attitudes; there is no room for pranks or horseplay. The factory clown is a menace to every other job, and a menace that is accentuated when he is the foreman. If the supervisor approves, or actually participates in jokes or horseplay, they may spread to uncontrollable proportions. There's nothing as tragic as a little joke which backfires and brings pain instead of laughs.

The one irreplaceable essential value is human life. An organization exists only for what service and value it can give to humanity. We can replace anything in our concern within a matter of days except our people. A safety program is essentially designed to protect our most valuable assets.

STEEL MILLS ABOVE AVERAGE

Statistics indicate that today's steel mill is about twice as safe a place to work as an average mill or factory. Year after year the accident rate in the steel industry has been reflecting the efforts of management and labor alike to make our plants safe.

The watchword "Safety First" was born in the steel industry around the turn of the century and the industry has continued to lead the way in teaching safe practices to its people.

In 1955 steelworkers suffered 4.16 accidents for every million man hours worked compared with 6.96 for all industry. In 1950 statistics reveal that steel workers suffered 4.63 accidents for every million man hours worked. Continued diligence and application of safety principles will result in even more remarkable records of achievement for safety in our industry.

A carefully organized and well managed plan must meet certain specific criteria.

SAFETY PROGRAM CRITERIA

1. It has the complete and enthusiastic endorsement of top management. This does not mean that management issues some vague statement or appears periodically at dinners to present awards. Rather, it should make its support of the safety program clear, forceful and unmistakable, and emphasize safety as a management function.

2. Collective bargaining representatives should be included in planning and promulgating a safety program. Their support and ideas should be actively solicited.

3. The individual charged with the maintenance of the program must be qualified and imaginative. He must be a person of vision and a super-salesman; a person short

of this, means a program short of full success.

4. A safety program is a moving and continuing thing. As well as the constant program to create the proper attitudes, each job must be *continually studied, and the entire force continually on the alert to eliminate hazards and make the plant a safer place.*

5. Front line management must be continually sold and resold on the basic need for good safety practices and an active safety program. Further, they must be continually trained themselves in safe practices. They cannot spread the safety doctrine unless they understand it, and they will not unless they believe in it. Without their active and intelligent support, your entire program is doomed to failure.

6. An active program for helping the accident-prone employee should exist. Very often it develops that he is not accident prone at all. He just has never been trained to work safely.

To those responsible for maintaining a safety program, I recommend a policy of the same combination of firmness and fairness *evident in all employee relationships.* You must insist that safety is taken in the utmost seriousness, and never is allowed to become a joke or a light matter.

All safety rules and procedures must be followed, and supervisory employees reflect, by their attitudes, what safety means to them. Fairness in listening carefully to all safety complaints, investigating promptly, and correcting immediately where necessary will help make a successful safety program.

To be effective, you must seek and earn respect as an individual and also command professional respect. The National Safety Council, through its conferences, publications and displays, offers you excellent opportunity to do this.▲

SAFETY COMMUNICATIONS IN THE FOUNDRY

by EDWIN W. BURNE

manager, Employee Relations, Foundry Dept., General Electric co., Schenectady, N. Y.

Everybody enjoys a smorgasbord since it affords him the opportunity to select as much or as little of a variety of foods according to his own tastes and needs. What I offer is a smorgasbord of ideas—ideas for reducing foundry accidents by communication techniques. Every idea has a valid use in accident prevention. Some cost money, others cost the time and effort of management. Some will be adaptable to your business, others you will find less useful.

There is important money to be added to the profits of your business by effectively preventing accidents and occupational disease. Important and appealing as the humanitarian aspects of safety may be, the fact is that a safe foundry pays off in cold, hard cash, and can be sold to management on that basis.

Most effective methods and techniques used to create and maintain interest in accident prevention are not new. Many are used in industry and practically all are included in the National Safety Council's bag of tricks.

COMMUNICATION METHODS

New, novel, and fresh approaches and variations can be used to maintain employees' and management's interest in the safety program. *But, too often, a safety director's* desire to be original closes his eyes to the true value of the more basic parts of a safety program.

A comprehensive communication program should include both individual and group approaches. The personalized approach takes into account individual differences in ability, interests, and learning time. However, most people are gregarious by nature and respect the group's opinions. Thus it is also necessary to use the group approach.

The combination of methods and techniques should provide for periodic repetition of safety messages that motivate and instruct. Forgetfulness, and carelessness daily underscore this need. A safety rule is worthless *if it is merely words on a paper, circulated* to management by the safety director and then forgotten. It must be taken out of the files and made into a living thing. Safety rules should be formalized, put into writing, explained to employees, and then re-explained when necessary and on a regular basis.

FACE TO FACE COMMUNICATION

Face to face communication is the oldest method and remains one of the most effective. In industry this type can be used best *by the employee's immediate superior* because he is closer to the employee, knows him best, and has the greatest opportunity for establishing rapport. To the average employee his foreman *is* the company, and it is essential that a good job of communication be done at this level.

Where face to face communication fails, other methods are of questionable effectiveness. For example, if a first-line foreman merely gives lip service to safety, if he is unconvinced of the moral and economic necessity of a safe operation, then any printed or spoken word from top management would probably be meaningless to his employees.

Other distinct advantages of using face to face communication are: a personal approach enables the communicator to tailor his communication to the individual, and it appeals to the employee's pride and prestige, for almost everyone likes to be consulted personally. It's a quick way to deliver the safety messages included in the daily instructions to employees. It disseminates information when it is impractical or inconvenient to bring the group together. For best results the foreman should talk to each employee individually at least once a week.

Face to face communication is one of the most effective ways to instruct an employee on the safety precautions for his particular job. The first-line foreman must know what the hazards are. To assist our foremen in detecting these hazards systematically, we instructed them in the technique of making a job hazard analysis for each job they supervise.

The form used questions the hazards involved in each important step of each job, the safe work habits to teach the worker, and the safety equipment needed. Foremen are encouraged to enlist their employees' aid *in making these analyses.* In this way the employees' job knowledge is utilized. It is easier to convince an employee to abide by the safety rules if he helps formulate the rules.

When an analysis is completed it is used to instruct new employees and re-instruct old employees. Only if safety rules are soundly conceived, thoroughly understood, and strictly enforced by disciplinary action when necessary, are they effective tools for prevention of accidents.

Group behavior can differ widely from the behavior of individuals who make *up* the group. Everyone is subjected to the opinions, taboos, prejudices, and propaganda of his group. The round table discussion is a group approach potentially one of the most effective techniques to communicate with the employee.

ROUND TABLES

These small, informal group meetings are held by the foreman for his workers and should be conducted in a friendly atmosphere. This is conducive to a free discussion of the operations, *and questions* are welcomed and completely answered, suggestions solicited, discussed, and appraised. Usually round table meetings are held in a conference room, in the boss' office, or some other place with privacy.

The main danger in this communication technique lies in the fact that round tables are actually guided conferences and can degenerate into time-wasting gripe sessions if not skillfully handled. The degree of success achieved is determined by the skill of the conference leader.

WORK PLACE SAFETY MEETINGS

A short safety meeting on the factory floor is another valuable communication technique. It is one of the fastest means for a foreman to deliver an urgent message to all his employees. When these meetings are held often, but on an irregular schedule, the urgency of the meeting may be concealed if desirable.

These informal meetings are easy to hold since no advance preparation is needed inso-

far as meeting room facilities are concerned. However, the content of the meeting should be carefully planned. Such a meeting can follow an accident or near accident somewhere in the shop with an analysis of the causes and steps necessary to prevent a recurrence. The National Safety Council has available ten books of canned five-minute safety talks. They also publish a new talk every month in INDUSTRIAL SUPERVISOR.

The canned talks are excellent when used as source material. But when they are merely read to the employees, they are of questionable effectiveness. The more closely a foreman can relate the subject matter of these meetings to his own problems, the more effective they can be.

BULLETIN BOARDS AND BILLBOARDS

Bulletin boards and billboards are two other communication methods which successfully sell everything from toothpaste to automobiles. They are also being used effectively to sell safety. For several years the National Safety Council has offered a variety of colorful, eye-catching, bulletin and billboard posters and cloth banners with terse copy and vivid illustrations. Some are dramatic, some are comical—all are effective.

These posters are changed semi-monthly. For best results bulletin boards should be located at the ends of aisles where employees see them while walking towards them, near drinking fountains, lunchrooms, or wash rooms, or in any location frequently passed or visited often by the employees.

The center of the board should be located at eye level approximately 60 inches from the floor. The board should be attractively painted, glass enclosed, and restricted to safety posters exclusively. Posters should be changed frequently for they lose their effectiveness if left up too long. It's best to "program" the posters to make certain that the major hazards of a given area such as back strains and eye injuries, are covered periodically and given proper emphasis.

One effective way to stimulate employee interest in posters is to conduct a poster contest and award a suitable prize to the best poster submitted during the contest period.

Letters from the manager mailed directly to the employee's home are well received This personal contact with the manager appeals to the employee's pride and desire to be consulted. The safety letters work best if they are part of a systematic letter campaign covering all phases of the business.

SAFETY SUGGESTION PLANS

Another valuable aid that enables employees to communicate with management about safety hazards or improvements in the safety program is the suggestion plan. Suggestion boxes well supplied with blank forms are placed throughout the plant. Posters on the boxes urge employees to turn their ideas into cash.

Good posters promote participation but the best advertisement for any suggestion plan is the way it is administered. If the suggestions are promptly acknowledged, thoroughly investigated, carefully evaluated, equitably awarded when adopted and thoroughly explained when rejected, employees will have confidence in the plan and participate frequently.

Employees have used the suggestion plan to pressure foremen to correct certain unsafe conditions. A few employees told investigators that they notified their foreman of the hazards but the foreman failed to take corrective action. They say that their reason for submitting the idea as a suggestion is not to collect the $5 or $10 safety award, but rather to get the hazard eliminated or minimized.

There have also been instances where the award has been made before the suggested work was completed. The suggestor complained that he turned in the suggestion not for the award but to get the unsafe condition corrected.

SAFETY COMMITTEES

A communication technique that has been tried and talked about often during recent years is the use of safety committees. These committees may be comprised of employees from a single foreman's group, from several foremen's groups, or even from several departments within a given plant.

They assist in solving the safety problems encountered when they inspect their facilities, or in solving problems presented to them by other employees or by management. The major advantages of this approach are that the employees accept the safety program more completely because they are a part of it. It is also a good way to teach safety.

In the General Electric company the basic responsibility for safety lies with the foreman or the first-line supervisor. For that reason we do not advocate the use of safety committees in the generally accepted sense of the designation. However, our foremen are helped by safety observers.

The number of observers a particular foreman appoints would depend on the layout of his facilities, the number of employees he manages, and the extent of the hazards. Our safety observers accompany the foremen on their weekly safety inspections, and also conduct their own daily inspections. Safety observers are also trained in the back pressure arm-lift method of artificial respiration.

MANAGEMENT NEWSLETTERS, MEETINGS

Many companies send management newsletters to their foremen and first-line supervisors. When the newsletters are carefully edited to ensure a balanced, complete, brief coverage of timely, interesting, informative, and helpful items, they are well read and are a valuable communication media.

If you have or are planning a management newsletter, include an item in every issue which deals with some phase of the safety problem. There are newsletter services available, such as *Management Information For Foremen and Supervisors* published weekly by the Elliott Service company, Inc. *The Foreman's Letter* is published bi-weekly by the National Foremen's Institute and features articles on safety regularly.

Regularly conducted safety meetings with foremen and first-line supervisors is another effective communication technique. They afford middle and top management an excellent opportunity to re-emphasize the importance they place on their safety program.

The foremen discuss their safety problems, or problems that affect the entire group. Most important—it is an opportunity to emphasize to management that the impetus for a safety program comes from the top man.

We use this technique and call our meetings "Quarterly Program Reviews." It takes approximately one week to prepare this meeting which is partly based on a quarterly safety inspection.

Each foreman's area is inspected individually by the foreman, his safety observer, and the staff safety man. The inspections are thorough and include a careful examination of the facilities, housekeeping, personal protective equipment, unsafe work habits, and an appraisal of the safety consciousness as revealed by spot interviews with employees.

PLANT INSPECTIONS

The safety specialist takes extensive notes on each inspection. After the foremen's areas are inspected, the safety specialist submits a written report to the manager of the foundry operation. The report classifies the observations as being items requiring routine maintenance or major problems.

Routine maintenance items, such as replacing a broken guard or repairing defective equipment, are the foremen's responsibilities and usually the orders are placed or the work is done before issuing the written report. However, they are still included so the report fully indicates the condition of the foreman's area at the time of the inspection.

Major problems are momentarily unanswered since they are intricate and involved. They require intensive investigation, or are problems which at first seem to involve sizable expenditures to correct. The report is carefully studied by the foundry manager and by other interested members of supervision. Then the meeting, or quarterly review, is called.

At these reviews past performances are compared, significant mistakes and revealing successes analyzed and future plans introduced and explained. Suggestions in program administration are solicited and the report on the quarterly safety inspection is thoroughly discussed. Most of the discussion centers around the items classified as major problems.

COMPANY NEWSPAPERS AND MAGAZINES

Company newspapers and magazines can be important parts of a safety communication program. Top management can use them to tell employees, middle management, and first-line supervisors simultaneously their desire for an accident free operation. They can stimulate interest in the various clubs

established to encourage employees to wear their personal protective equipment.

A picture of a new member of the Wise Owl Club holding the shattered safety glasses that saved his eyesight or an employee showing the dent in his hard hat that saved his life and gained him entrance into the Turtle Club impresses employees. Another picture of the safety shoe that protected a worker's foot from injury and qualified him for membership in the Happy Foot Club provides documented proof of the wisdom of dressing safely.

Company newspapers and magazines can also promote safety contests and report on significant safety achievements. Cartoons help train and motivate employees to work safely. The National Safety Council will provide several excellent cartoons drawn by nationally known cartoonists free of charge for use in company newspapers or magazines.

They also have mats available for letterpress publications and proofs for reproduction by other methods. In addition they offer a monthly newsletter for industrial editors with valuable suggestions on how their publication can effectively teach and promote safety.

INSPECTIONS REVEAL TRUTH

When safety and housekeeping inspections are conducted regularly by experienced investigators, accurate written reports to middle management reveal objectively and clearly the current condition of all facilities. The inspections may be organized to cover safety alone, safety and housekeeping, or housekeeping alone.

The inspection teams may be composed of employees, foremen and first-line supervisors, safety personnel, or other members of management. The methods to conduct the inspections also vary. Some teams tour the facilities as a group, others separately.

Some teams hold meetings after the inspection and issue a joint report; others hold no meetings and submit written reports individually. Some assign a numerical score to each section inspected based on a predetermined value for each of the basic parts of the inspection.

Written safety and housekeeping inspection reports provide information that the busy members of middle management, the general foreman and the superintendent might not otherwise receive. However, reports are a poor substitute for actually "walking the shop" informally and on a regular basis.

PERSONAL CONTACT BEST

This old and effective technique keeps both employees and first-line supervisions on their toes. Often problems are more clearly discussed when the facilities in question are observed first hand.

When this technique is applied better understanding results in improved employee relations. The employees' confidence in management is strengthened when they know the boss is concerned over their personal welfare and determined to stop the needless human suffering from accidents.

EMPLOYEE NEWSLETTERS

Another effective way of communicating safety messages to employees is through the employee newsletter. The copy used should be brief and to the point. Here also safety cartoons can be used successfully.

The Alfred M. Best co. Inc. offers a four-page employee newsletter for industry to use called *Your Safety News* that deals exclusively with safety. The copy is excellent and the art work and the layout make easy reading.

Successful safety programs motivate employees to work safely to eliminate injuries. Safety programs that stress good health as the sole reward for working safely can actually fail to be effective. The employees may unconsciously and unrealistically regard the reward as something they already have, always had, and always will have.

SAFETY CONTESTS

Thus it becomes expedient to offer additional recognition. Safety contests provide an effective method of offering such additional incentives. Contests are usually based on the accident experiences of a particular group during a given period of time. The group usually competes against other similar groups or against its own previous record. Most contests require the contestants to operate accident free during the contest period to qualify for an award.

Often when several groups do this, the one with the most man-hours without an accident is declared the winner. Some contests are more liberal and in addition to accident free performance also recognize and reward significant improvements.

Contests are available in a variety of sizes and shapes. Some are national, some industry wide, others for plants in a multi-plant company, departments within a company or foremen's groups within a department. Each year the National Safety Council's contests involve more than four million workers and nine billion accident free man-hours to win hundreds of awards.

Many industry associations, such as the Steel Founders' Society, conduct annual safety contests for their members. The Associated Industries of New York State conducts state-wide safety contests annually to "lower the accident rate in the Empire State."

WIN A CHICKEN DINNER

For almost two years a contest has been a key part of our safety program.

On the premise that our employees associate themselves more readily with their foremen's groups than with the department or company, we organize our Chicken Dinner Contest. Here is how the contest works:

Whenever all the employees of a foreman's or first-line foremen's group work for 12 consecutive months without a disabling injury, they are their foreman's guests at a chicken dinner. If a disabling injury occurs, the contest starts anew. Our contest is specifically designed to encourage friendly competition between different foremen's groups.

The winners usually remind the losers of the fine time they had and express *concern* over their missing the affair. However, the secret of the the contest's success seems to be that one employee's negligence can postpone the dinner for all for 12 months. As a result, our employees *are* becoming their brothers' keepers. If one employee observes another exposing himself to possible injury, he is warned with our battle cry, "Take it easy! Don't kill *our* chicken."

No one wants to take something away from the entire group. When a disabling injury does occur and the employee is at fault, his coworkers usually reprimand him before the foreman has had an opportunity to do so.

BULLETINS PROMOTE CONTEST

To assist our foremen and first-line supervisors in generating interest in this contest, bulletin boards were erected in each foreman's section. These bulletin boards show the group's progress toward a chicken dinner on a 12-months bar graph.

They show employees that they personally can help their group win by learning and obeying safety rules. A terse statement of a different safety rule and a photograph of a worker complying with the rule is posted on all of the bulletin boards every two weeks.

We send the pictures and posters stating the rules to our foremen with a canned presentation about the rule to use for their own meetings. They are encouraged to conduct their weekly 10-minute safety meetings around the safety bulletin board and use the board as a visual aid.

The 12-month bar graphs on the bulletin boards have at three months a picture of an egg, at six months a small chick, at nine months a larger chick, and at 12 months a roasted chicken. The publicity gimmicks for such a contest are endless. We have used pictures of eggs in a nest, pictures of live chickens taken at the home of one of our employees, and countless trick shots.

THE PAY-OFF

The results we achieved from a planned communication approach are sufficiently substantial to indicate its effectiveness. During the 15-year period immediately preceding 1956 our Schenectady Foundries had an average frequency rate of 18.75.

We ended 1956 with a frequency rate of 4.16 which was by far the lowest rate we had ever achieved in our 58-year history. That is conclusive proof that something has happened and we believe the planned communication approach is primarily responsible.

If your foundry has a frequency rate of more than zero, there is work to be done and dollars to be added to the profit side of the ledger. No safety program will work unless it has the active interest and backing of the man in the front office. Secondly, the best safety program for your foundry is the one you conceive and develop to meet your own needs.

INVESTIGATIVE PROCEDURE AND REPORT WRITING

by WILLIAM H. CORRIGAN
manager, Security department, Ford Motor co., Dearborn, Mich.

The word "investigation" means "to follow up or make research by patient inquiry and observation, and examination of facts." The investigator must be patient and methodical to insure thoroughness and his efforts must be directed toward the gathering of facts. Investigation is fact finding.

In his fact finding, an investigator must be impartial. He is not out to obtain a one-sided story to make a case for his company. He is seeking the exact facts of a situation to determine a course of action. In the safety field, the safety investigator must find out exactly what happened and why it happened. It would serve absolutely no purpose to obtain a biased story which would tend to whitewash any individual or group of individuals.

INVESTIGATIVE PROCEDURES

To guarantee best results and be certain all proper investigative steps are taken, an investigation must be planned in advance. The emergencies in a plant require immediate action from the investigator to obtain facts and interview eye witnesses, but he must not stampede into impetuous or illogical action. He must train himself to follow a logical planned procedure which becomes habitual to the point that he can determine and record vital facts almost automatically.

However, the investigator must never allow his actions to become completely automatic. He must retain a natural curiosity and an inquisitiveness to distinguish one incident from another. An investigator must not slip into a rut giving minimum attention to each incident and furnishing standardized or trite explanations which offer no basis for corrective action.

NOTE TAKING

Because the human memory has its limitations, the investigator should record his findings at all times. At the Ford Motor company, we found that a small bound notebook serves the purpose and is convenient to carry. When completely filled with investigative notes, the notebook can be filed as a permanent record of the investigative findings; and, if necessary, used in court to refresh the recollection of an investigator.

In taking notes, our past experience has established certain principles:

1. When investigating a major case, such as a fire or explosion, start with a fresh book for only that one investigation.

2. Use a separate page for each person interviewed in any investigation. This will prevent intermingling of the facts from different persons, and will simplify assembling notes and dictating from them.

3. Indicate the date of each interview or investigation at the top of each page since it may differ from the date of the case.

4. Identify each interview with full name, badge number, and title or classification of the person, and his address if he is not an employee. In obtaining the person's surname, spell it back to insure accuracy. It is advisable to include the business telephone extension and the home telephone number of the person interviewed so he may be reached quickly.

5. Notes should be made unobtrusively and the person interviewed should never be interrupted merely to fill out the notes. The original story can be recorded in the form of key words or phrases and the entire story filled out later by the investigator for a complete recollection.

The notes taken during the interview help you to question him further on details. Make as many notes as possible on what he tells you, and add notes to remind you of the questions you wish to ask later. A good idea is to identify these reminders by some simple symbol such as a star.

6. If taking notes creates any reluctance in the interviewee, stop taking notes immediately and talk freely with the person. Thereafter, when you must write down a name or number, start taking notes at that time and work gradually into a more complete recording.

You also can tell a reluctant witness that notes prevent misquoting or misunderstanding what he says. In cases of extreme reluctance, it may be advisable to dispense entirely with note taking during the interview. In such cases, the investigator should save sufficient time after the interview to record all pertinent details before proceeding with the investigation.

7. Do not neglect to record negative information. Where persons interviewed say they did not observe the accident or can furnish no information, identify these persons and note that fact. This may not help determine the cause of the accident, but it can later prevent these persons from giving false testimony that they saw the accident and that they noted it was caused by a particular set of circumstances.

INTERVIEWING TECHNIQUES

At least 50 per cent of interviewing is being a good listener, and recording what you hear. You must make interviewees want to confide in you, by creating mutual respect and trust between yourself and the person being interviewed. To reach this objective, the following procedures are suggested:

1. Identify yourself with credentials if necessary, to the interviewee leaving no question in his mind who you are, and which component you represent. Speak clearly and with authority. You must sell him the idea that you know your job and you can be trusted.

2. Explain the purpose of your work. Confide sufficiently in the person so he knows what you are trying to achieve, and will feel he can help by furnishing information. Show him that safer working conditions can be created for all employees, including himself, by determining the causes of accidents to eliminate them.

3. Control the course of the interview. When interviewing eye witnesses, ask the person to tell you, in his own words, what he saw. Do not interrupt him at any time, even if he strays slightly. If he rambles entirely away from the subject matter then insert sufficient comment to bring him back to the proper course. This should be confined, however, to a minimum of questioning.

Remember you are there to hear what he has to say, and you will not obtain any information listening to yourself talk. Although you may have vital questions to ask on a particular phase of an accident, do not interrupt him when he is telling his own version of what happened.

4. When the person finishes talking, go over the entire story to fill in any gaps, and to make sure you correctly understand what he said. At this time ask specific questions to obtain greater detail and any additional facts he may have overlooked. This is the time to ask questions which occurred to you while he was telling his story.

As you ask each question you starred for a reminder, check off that reminder so you can review the sheet quickly to see all desired points were covered.

5. In interviewing witnesses, be sure you get all primary details, such as:

   a. What he and the injured employee were doing immediately before the accident.
   b. What did he observe at the time of the accident itself.
   c. Was he close enough to hear what the injured employee said immediately after the injury. Usually statements made immediately after an accident are the truth, as they are made on the spur of the moment. They reflect the first thing that comes to the injured employee's mind, and are usually different from those logically thought out many moments or hours afterward. Examples of such statements could be: "The darn thing repeated itself." "I knew I should have kept those glasses on."
   d. What happened immediately after the accident.

This line of questioning gives a complete picture of the facts. If you record only the witness' or the injured employee's statement, he will tell only what he thinks important and may neglect to relate pertinent facts.

6. Witnesses may tell conflicting stories regarding an accident. You must determine how much weight their version should carry by:

   a. Asking what they were doing when the accident occurred.

b. What was their position at the time—how far away were they?
c. Were there any obstacles to prevent seeing the accident as described by the witness?
d. Was there any noise to interfere with their hearing statements they claimed to have heard?

7. In talking to a witness or an injured employee regarding an accident always find out: Who was involved, What happened, when, where, and why it happened.

If you secure these answers, your investigation will reflect the facts as they actually exist.

ATTITUDE OF THE INVESTIGATOR OR SAFETY INSPECTOR

Be aggressive without being antagonistic. Remember, you must obtain a clear picture of what actually happened. You are the person to determine who is to be interviewed and what must be reported. Take suggestions from others but if you feel they will not help, continue on your own plan of investigation.

Be impartial. Your purpose is to get the facts as they actually exist. Do not try to whitewash either an employee or the company. If your facts show an accident was caused by the failure to install proper safety precautions say so—this is the only way to prevent future accidents.

Do not ask leading or negative questions, such as:

"He slipped and fell, didn't he?"

"He didn't forget to put his goggles on, did he?"

It is your function to be impartial and seek the truth facts. Your opinion is not to be reported—only the facts as they exist.

Be inquisitive. Do not rely on one man's opinion that no witnesses are available. Inquire for yourself in the vicinity of the accident and take down the name and badge number of persons. Your report should show each witness and his story, and also that no witnesses were obtained if such is the case.

Do not accept a statement as fact without checking it. If a person says something happened, ask him if he saw it personally. If so, you can place him in his position at the time of the accident so his version may be properly evaluated. However, if he says this was told to him by others, it is only hearsay and not important. Determine who told him and locate this person. Trace facts to the one who started the story. His personal knowledge may be far different from the repeated version. *Stories magnify with repetition.*

Express no opinions to those you are interviewing. Take facts as received and report them as such.

Be methodical and thorough. Attempting to move rapidly usually results in overlooking important facts. Don't stop at the first possible cause found. A more thorough investigation may reveal additional and more serious factors.

Treat each investigation alike. Do not classify them into minor or serious accidents. Handle the minor accidents properly and the more serious ones will follow naturally in proper fashion.

If you ever doubt what actually occurred, have the injured employee go over the incident step by step, or have a witness take you to his position of observation so you can better see and understand his story.

REPORT WRITING

A perfect investigation is of absolutely no value, unless it can be communicated to the person who will determine whether or not any administrative or corrective action should be taken. Because such facts are kept on record for future reference, and also routed to more than one person, most companies use written reports.

Form Reports

Where the volume of investigation justifies the practice, it is customary to set up a standard report form for reporting various incidents. In most larger companies a separate report form is provided for safety investigations.

In our company, this report first identifies the basic company location where the accident occurred; with spaces for the plant and department and the shift of the accidents. We next have spaces for identifying the employees involved and classification, age, and badge number of each employee. The next line is for the specific location of accident and the date and time of the injury.

A larger space is provided for describing the extent of injuries, and a still larger space for the causes of such injuries. Following this, approximately one-third of the page is set aside under the label, "Describe What Happened." The next labeled spaces are for identification of witnesses by name and badge number.

Approximately one-quarter of the page then is reserved for actions taken to prevent recurrence of the accident. Space is then provided for the name of the supervisor where the accident occurred, plus the signature of the safety engineer making the report and the date. The final line is for a code number for statistical purposes.

AVOIDING LIMITATIONS OF THE FORM

In providing this form to safety engineers, company representatives emphasize that the form is a guide and convenience, not a limiting, inelastic container of information. The safety engineers are instructed to fill out each and every space and encouraged to add additional relevant information. For example, they indicate the length of time the injured employee spent on the job he was handling when the accident occurred. This could indicate whether or not failure in supervision or training might be involved.

The safety engineers are also instructed to elaborate on any part of this report on the reverse side or on additional blank sheets.

The safety engineers are told not to list the witnesses merely by name and badge number, but to show what facts can be attributed to each witness. When witnesses duplicate facts from another witness, the safety engineers indicate that the second story confirms the first instead of recording the facts a second time. In such cases, they identify each witness preferably by full name and badge number. In a case where witnesses disagree, the safety engineer highlights the variance by a short notation showing the essential point of disagreement.

Negative information is listed, which prevents rebutting a later fictionalized report by such persons, and indicates the thoroughness of the investigation.

While it is not usual for signed statements to be taken from witnesses in safety investigations, the safety engineer or investigator should know how to prepare such statements to present to a witness after an interview. A statement should be prepared after an interview, when the facts have already been obtained. Don't begin an interview by asking a witness to sign a statement, because some witnesses may be reluctance to furnish information on learning the facts will be embodied in a signed statement.

SIGNED STATEMENTS

A signed statement can be justified by telling the witness that the investigator would like to record the entire story to insure he does not misquote the witness. If the investigator prepares a statement for a witness who then refuses to sign, the investigator can ask the witness to read it. The investigator then notes, above his own signature, that the witness read the statement and acknowledged it is true, but does not wish to sign any statement.

If a stenographer records and transcribes the statement, it can be in question and answer form, or in a first-person narrative statement. Where a statement is taken under emergency conditions, the investigator can write a short narrative of the facts, which is then signed by the witness.

Regardless of the type of statement, the date and place should be shown in the upper right hand corner; and the beginning should identify the witness by his name and badge number or addess. The investigator should be identified by name and title or position. The first paragraph also should mention that the statement is being made voluntarily.

The second paragraph should begin the narrative of the witness. If the witness uses bad grammar, so should the statement. This is necessary to present the actual story of the witness, without any interpretation of the investigator.

OBTAINING SIGNED STATEMENTS

The statement should close with a paragraph which reads: "I have read the above statement consisting of three pages, and find that it is correct to the best of my knowledge," followed by the signature of the witness on the right and of the investigator and other witnesses on the left.

The statement should be submitted to the witness for his reading and approval. Inci-

dentally, the investigator should make sure the witness can read. Where a witness cannot read, the statement should be read in the presence of at least one witness, and the closing paragraph reworded to show that this procedure was followed.

If the witness, upon reading the statement, finds any error, a hand-written correction should be made in ink, preferably by the witness himself; and the witness should initial the statement opposite the correction In a statement covering more than one page, have the witness sign his initials at the bottom of each page as he reads it.

Again, investigation is fact finding. You must find the facts, and then pass on the same facts, through whatever type of report is desired, without coloring them with opinions, interpretations, explanations, or excuses. In safety investigations, of course, there is a place for interpretation and explanation. But those functions must be kept in their proper places, and not interfere with or obscure the basic facts which you obtain from your witnesses.

OFF-THE-JOB ACCIDENTS

Statistics are such boresome things
And figures rather dull.
It's hundreds, millions, billions, trillions,
Over which we mull.

But facts are facts where ere we go
Regardless of amounts.
So here's some facts on accidents,
And that's what really counts.

It isn't always big machines
With blades of sharpened steel
That rob a man of arm or leg
And make his senses reel.

Nor is it always "on the job"
Most accidents take place,
But just the opposite is true
And figures prove our case.

It's carelessness in little things
At home and on the street
Neglect in moving objects small
Away from running feet.

A makeshift ladder, sliding rugs,
Electric cords that spark
A disregard for cellar stairs
And stumbling in the dark.

Crossing where no crossings are
While looking at the sky,
Driving on a slippery road
With milestones whizzing by.

These are the things that take a toll
We all should frown upon
So watch for them when off the job,
As well as when you're on.

—Humble Pipe Line Company, Houston, Texas

A PLANNED GAS JOB
(A Skit)

CAST

Narrator ..... John Lowey, Cleveland
Superintendent of power & steam ..... John Alexander, Cleveland
Superintendent of industrial relations ..... Edward Mandry, Cleveland
Superintendent of blast furnace ..... P. Johnson, Chicago
Superintendent of coke ovens ..... H. Kelly, Chicago
Superintendent of combustion engineering ..... G. Gockstetter, Chicago
Superintendent of mechanical department ..... R. Kraus, Chicago
Safety Supervisor ..... Philip Lapish, Cleveland
Superintendent of engineering ..... C. W. Bruce, Chicago
Pipe foreman ..... W. Ryder Chicago
Demonstration of the job cast:
Pipe foreman ..... W. Ryder, Chicago
Man on manometer and telephone ..... R. McConnachie, Chicago
Safety man ..... P. Lapish, Cleveland
Four men in pit ..... P. Wright, Chicago
G. Cox, Chicago
N. Wiberg, Chicago
W. Heitner, Chicago
Man on oxygen tanks ..... J. McCaslin, Chicago

NARRATOR (Spot on narrator, alone at lectern. Stage is dark.): Gas is one of the most useful fuels available to man. It is also one of the most dangerous. Today we are going to consider a typical problem involving gas. There are a number of ways to tackle this problem, but for demonstration purposes, we shall show you how it would be tackled at the Cleveland district steel plant of Republic Steel corporation.

Similar methods are employed elsewhere in the corporation. This demonstration is a joint effort of the Cleveland and Chicago Districts of Republic Steel corporation.

(Spot fades; light comes up on meeting of committee on stage, all face audience). At the Cleveland plant, any problems involving gas are handled through our gas committee. A typical meeting of the Gas committee would look like this.

The chairman of the gas committee is the superintendent of the department in which the work is to be performed. In this case, the power superintendent, a regular member of the committee, is also chairman.

The other members are the blast furnace superintendent, the coke plant superintendent, the combustion superintendent, the mechanical superintendent, the safety supervisor, a representative from the engineering department, and the superintendent of industrial relations.

The main purposes of the committee are to eliminate, where possible, working on gas mains which are under pressure, or, to set up safe proceduses where this is not practical; and to make any recommendations that it feels necessary to insure safe operation, isolation and repair of the gas distribution system.

The committee passes on all procedures, breathing equipment, scaffolds, and gas pressures prior to starting any job. No work shall be done on any gas main under pressure, or where it is necessary to use gas masks, or on any questionable job involving gas, without the approval of this committee. A very important function of the chairman is to see that minutes of the meeting are kept carefully. Eventually these minutes will be the "bible" of the job and they must be accurate and complete.

But the meeting is getting underway. Let's turn up the sound and hear what is going on.

POWER SUPT.: (Project map of area; point out places mentioned.) I have called this meeting to find a safe way of blanking under pressure a 24 inch gas line carrying coke oven gas from the No. 1 coke battery to the main power station. I want all of you to be aware of what is involved, so we can provide gas connections to tie in the new C boiler.

This will involve two additional connections to the 24-inch gas main to extend the gas to the main burners on C boiler. The end of the existing line has a 24-inch blind flange. This connection involves no welding or burning, but will involve opening the end of the line to remove the flange and the blank.

The second connection is to make a six inch saddle weld connection to the existing eight inch line, which supplies coke gas to the pilot on A and B boilers. The six inch gas connection will supply coke gas to C boiler pilot.

This work will be done by outside contractors after the line has been isolated and purged. This means that the coke gas line must be shut down. Inasmuch as this is an old valve, we cannot rely on the valve to give a positive shut off so we'll have to treat this job as a gas job.

Now our problem is this—the 24 inch valve won't shut down completely. We know this because when we tried to shut off the valve, we can give it only 53 turns when we should be able to make 56. I believe we can do this job with gas under the maximum allowed four inches of water pressure, by shutting the valve, dropping the pressure and inserting a blank.

INDUSTRIAL RELATIONS SUPT.: If we are going to have outside contractors in, we should have a meeting between our people and the contractors to see they thoroughly understand their job.

POWER SUPT.: I've already made arrangements.

COMBUSTION SUPT.: Where are you going to get gas to operate the power house while this is going on?

POWER SUPT.: We will fire coal on A and B boilers to replace the gas and provide a positive flame in case we lose our blast furnace gas supply.

SAFETY SUPVR.: What do you intend to use for a purge on the line? And where do you plan on bleeding gas?

POWER SUPT.: Because of the great volume of gas in the length of the pipe, we do not believe either steam or nitrogen gas should be used. There will also be a great loss of the purge gas during the time the blank is inserted, so we will use our purge machine set up by combustion department.

(Project map of this area) We'll have the purge machine at the west end of the River Terminal bridge and we'll tie it in to a 12-inch stub on coke oven gas line at that point. The purge gas will flow about 200 feet northerly to the shut off valve and about 2,000 feet to the power house.

It will take about an hour to do the purge job. The combustion department will regulate bleed off at the shut off valve. We'll purge through the pilots on A & B boiler.

COKE OVEN SUPT.: How long will this take? There will have to be some arrangements made to take care of the surplus gas that I will have at that time.

COMBUSTION SUPT.: We will dispose of your surplus at the strip mill by using it to replace natural gas. If you have more than they can use, you will have to make arrangements to bleed and burn it. All in all, we'll have about 300,000 cubic feet of gas per hour to handle.

MECHANICAL SUPT.: Let's look at the job. It involves work in a pit and we can't do much until the power house drops the pressure down.

POWER SUPT.: I can do that in half an hour.

PIPEFITTER FOREMAN: It will take my pipefitters about 15 minutes to close the valve. By having every other bolt out of the flange prior to the actual blanking, we can speed up this first part of the job to about an hour at most.

COMBUSTION SUPT.: I reviewed the blanking job with the mechanical department and I believe this will take approximately four hours.

ENGINEERING SUPT.: Why not try a water seal? This is a dual type gate valve with tapped connections provided on the bottom between the gates and also with tapped connections on the bonnet. We could supply city water on the west side of the valve and putting a 10-foot riser pipe on the other connection would give us 4.3 pounds pressure. That's 1.3 pounds in excess of the coke gas pressure on the oven side of the valve.

POWER SUPT.: We can try water seal for blanking, but we must have a blank in the line at the time that burning and welding is done. I don't believe a water seal would be safe for the burning and welding work on the pipe line.

BLAST FURNACE SUPT.: What day of the week are you planning on doing this job?

ENGINEERING SUPT.: The contractors will have their work completed by Tuesday and I think we should start this job Tuesday afternoon.

BLAST FURNACE SUPT.: We will have a stop on #4 furnace on Tuesday to repair a cold blast valve. You better do this job on Wednesday if you want normal blast furnace gas to the boilers.

INDUSTRIAL RELATIONS SUPT.: This job had better start first thing in the morning. As you know, we do not normally plan gas work after dark. We'll have to complete this work before dark.

SAFETY SUPVR.: I just want to remind you fellows that this is a gas job and you know what that means. The pipefitters will have to wear work masks and you will have to supply your own standby safety men to work in the pit.

INDUSTRIAL RELATIONS SUPT.: All these men should be reminded of the safety aspects of this job and have their equipment inspected before starting work. We want to be sure that these men know what they are doing and how to do it.

SAFETY SUPVR.: Who is going to supply the manometer?

COMBUSTION SUPT.: We'll supply the manometer. We have to tie in the coke plant and check the pressure so the power house can bleed on the other end. We'll set up sound-powered phones so we'll have instant control at all times. I believe that we will be able to regulate the gas pressure down to within one inch of equivalent water pressure. We shouldn't go below this because of the volume of the gas and the possibility of drawing air into the line and creating an explosion.

POWER SUPT.: We'll regulate pressure in the gas line at the boilers with our valves to the burners. We will compare pressure readings with the combustion manometer at the job.

MECHANICAL SUPT.: Inasmuch as this is a coke gas job, we'll make sure that all of our people have nonsparking tools and spreaders. We certainly don't want any explosion or fires.

BLAST FURNACE SUPT.: Why can't the pipefitters change all bolts prior to the job and then remove all but four prior to the actual shutting down of the valve? Won't be down so long that way.

MECHANICAL SUPT.: We'll go along with removing every other bolt, but I won't go along with removing all but four. There is too much change of gas leaking that way, and the men in the pit might get hurt.

INDUSTRIAL RELATIONS SUPT.: We certainly want the job done as quickly as possible, but we are not going to sacrifice safety for speed.

BLAST FURNACE SUPT.: Why not arrange to have gas checks taken in the pit while the men are removing the bolts and at the first trace of gas, put their masks on?

SAFETY SUPVR.: That's OK while the men are removing every other bolt, but once that's done, the masks must go on.

MECHANICAL SUPT.: Who is going to be there from the safety department? And who is going to be the coordinator to be sure the job is done in the proper sequence?

SAFETY SUPVR.: I'll be on the job representing the safety department.

POWER SUPT.: I have lined this job up to coordinate between combustion, mechanical, engineering and the outside contractors. I will be in a position to call all signals on this job. If you have any questions, see me.

SAFETY SUPVR.: Since this is going to involve burning and welding after the line has been purged, the combustion department should have their heat prover available to analyze the purge and I will check the analysis against the explosimeter. (voices fade to mumble as . . .)

NARRATOR: And so the meeting continues until all plans are prepared and the minutes which have been taken distributed to all concerned after the meeting. These minutes are extremely important as they are the bible of the job. Now all the preliminary work has been completed, and we are ready to shift to the pit where preparations for doing the actual blanking are just getting underway. (Lights fade on committee and come up on pit scene.)

PIT SCENE

NARRATOR: This is a model of the 24 inch gas line discussed a few moments ago in the gas committee meeting. To those of you who are accustomed to gaining access to

pits from manholes, this pit may look a little ovesize. At our Cleveland district, however, we do not do any gas work through manholes. Over the years, as it became necessary to do any work in pits, we dug out and enlarged them. The openings were then covered with large plates which could be removed easily.

(Over-all lighting dims, and spot picks out two access ladders.)

Let's just take a closer look at this pit for the moment. You will notice first of all that there are two means of access to the pit . . . here . . . and here. There is also a safety block and tackle to remove an injured man. This is a must in our district. We also have fire extinguishers, brass wedges, scrapers, hammers and wrenches which minimize the possibility of sparks and eliminate a fire hazard.

On every job of this type we always have a manometer. We install the manometer to know the exact pressure reading in the line and hence to regulate it accordingly.

These manometers are capable of reading down to one-tenth of an inch of water pressure. You will note, too, that as an additional safety feature the man at the manometer has a sound-powered telephone which permits him to talk directly to the spot where the gas is being bled and regulated. This gives him instant control at all times.

The men working on the line are using gas masks of a constant-feed positive-pressure type. The masks are fed from oxygen cylinders with 2,200 pounds pressure roughly equivalent to 200 cubic feet. No manifolds are used. Nor do we use compressed or washed air.

Each two oxygen cylinders are carefully watched by another workmen to see that the proper pressure is maintained at all times and to adjust it if it is not. This man is also responsible for notifying the man in the mask when supply falls to 500 pounds. That gives the man in the mask ample time to leave the area. Normally we keep the flow reading on the dial at 15 to 20 pounds per square inch.

Each employee checks his gas mask before he puts it on. After it is on, the foreman checks it and a final check is made by the safety man. Each man's oxygen cylinder is identified with his name to simplify regulating the oxygen to him.

Each man actually working on the job is guarded by a co-worker in a chemox gas mask who acts as that worker's personal safety man. At the first sign of trouble, he can take the necessary steps to remove the man on the job from the area. The safety supervisor or one of his assistants is present to check the job and the equipment being used. One man is appointed as a coordinator of the entire job.

No burning, welding or open lights are permitted in the near vicinity to this work. Any electric lights needed are of the explosion-proof type.

All bolts around the flange were changed the day before this job to simplify their removal today as well as their tightening after the blank has been put in place. Every other bolt is removed prior to starting the actual blanking. A few bottom bolts are left in place to keep the pipe in line.

(Use CO_2 bottle to simulate escape of steam as line is opened.)

After the bolts have been removed, spreaders and wedges are used to spread the flange. Scrapers are used to clean the joint and to remove any old gaskets. After the joint is cleaned, the blank is inserted and a new gasket is inserted on the pressure side of the line. Now the spreaders are removed and every other bolt replaced. When the bolts have been tightened, the safety man takes a check of the air to be sure that it is clear of gas.

If the air is clear, the gas masks may be removed by the workers. Now the remaining bolts are replaced and tightened. Gas pressure may now be put against the blank. You have just witnessed one way to do this job. As an alternate method we have also developed a means of swinging large goggle plates which we will also quickly demonstrate for you.

The common practice is to remove all the bolts except the pivot bolt. Then by means of chain falls which require a double hookup and, in some cases, sledging, we swing and position the plate.

We have fabricated a circular channel around the goggle plate and have wrapped a rope cable around this channel.

The end of the cable is fastened to a block and tackle rigged up outside the gaseous area. This can be pulled by an employee without fear of gas exposure which eliminates the need for him to wear a gas mask.

This method requires only one man in a work mask to be present in the actual gas area. That man is there to direct the actual spotting of the plate and to drop the bolts in when the plate is positioned. When the plate is in place the remaining work crew returns, puts in every other bolt and tightens them. This same method was demonstrated previously.

OFFICERS OF THE

METALS SECTION

NATIONAL SAFETY COUNCIL 1957-58

General Chairman—J. D. HOLTZAPPLE, director of safety, Blaw-Knox Co., Pittsburgh, Pa.

First Vice Chairman—R. I. PISLE, superintendent of Industrial Relations, Chicago District, Republic Steel Corp., Chicago, Ill.

Second Vice Chairman—A. G. WHISMAN, general supervisor of safety and sanitation, Gary Steel Works, U. S. Steel Corp., Gary, Ind.

Third Vice Chairman—W. R. GILLILAND, assistant safety director, Aluminum Co. of America, Pittsburgh, Pa.

Secretary—D. D. MATEER, supervisor, Safety & Welfare Department, Jones & Laughlin Steel Corp., Pittsburgh, Pa.

Newsletter Editor—W. H. WILSON, supervisor of safety, American Bridge Division, U. S. Steel Corp., Ambridge, Pa.

Newsletter Co-Editors—W. J. M. REDWOOD, safety supervisor, Algoma Steel Corp., Ltd., Sault St. Marie, Ontario, Canada; G. C. PETERS, acting superintendent, Safety & Welfare, Jones & Laughlin Steel Corp., Aliquippa Works Div., Aliquippa, Pa.

Program Committee—E. D. MORGAN (Chairman), superintendent, Plant Protection & Safety, Bethlehem Plant, Bethlehem Steel Co., Bethlehem, Pa.; J. G. CULLEN, supervisor of safety, Engine and Foundry Div., Ford Motor Co., Dearborn, Mich.; H. K. LAMBIE, safety consultant, Kaiser Aluminum & Chemical Corp., Oakland, Calif.; W. T. McLEAN, general supervisor of safety, United States Steel Corp., Youngstown, Ohio; R. M. MASSENBURG, safety engineer, U. S. Steel Corp., Pittsburgh, Pa.; A. T. POCHIBER, safety director, West Leechburgh Plant, Allegheny Ludlum Steel Corp., West Leechburg, Pa.

Engineering and Consulting Committee: R. A. McRÄE (chairman), safety engineer, The Colorado Fuel and Iron Corp., Pueblo, Colo.; R. S. B. HOLMES, general staff supervisor, Training & Safety, National Tube Div., U. S. Steel Corp., Pittsburgh, Pa.; P. N. LUNDQUIST, safety director, Acme Steel Co., Riverdale Station, Chicago, Ill.; L. C. PARKER, director of safety and fire prevention, Granite City Steel Company, Granite City, Ill.

Membership Committee: J. W. TYSSE (chairman), manager of safety, Republic Steel Corp., Cleveland, Ohio; E. J. NAGELE, management's representative, Chicago Works, Bethlehem Steel Co., Chicago, Ill.; J. C. BRADRICK, safety engineer, Armco Steel Corp., Butler, Pa.; G. LUNDIE, assistant director, Safety and Plant Protection, Inland Steel Company, East Chicago, Ind.

Contest and Statistics Committee—K. I. WARD (chairman), assistant to supervisor of safety, The Youngstown Sheet and Tube Company, Youngstown, Ohio; H. L. LOWE, general supervisor, Industrial Relations Analysis, United States Steel Corp., Pittsburgh, Pa.

Visual Education Committee—A. D. MURPHY (chairman), director of safety and suggestion plan, Crucible Steel Company of America, Pittsburgh, Pa.; G. F. GRACE, product manager, Industrial Chain Division, Columbus McKinnon Chain Corp., Tonawanda, N. Y.; R. I. REICHLE, supervisor of safety, The Youngstown Sheet and Tube Company, Youngstown, Ohio.

Foundry Industry Committee—G. G. WALTERS (Chairman), supervisor of safety, General Steel Castings Corp., Granite City, Ill.; J. A. DOWNEY, JR., director of personnel & safety, U. S. Pipe & Foundry Company, Birmingham, Ala.; G. L. MITSCH, plant manager, American Car & Foundry Division, St. Louis, Mo.; W. B. GREENE, personnel & safety director, Blaw-Knox Co., Union Steel Castings Division, Pittsburgh, Pa.; G. L. HUGHES, safety director, The Shenango Furnace Company, Sharpsville, Pa.

Steel Industry Committee—S. J. CROREY (chairman), supervisor safety unit, Steel Div., J-1-19 Rolling Mill, Ford Motor Co., Dearborn, Mich.; W. W. BRANT, safety engineer, Bethlehem Steel Company, Johnstown Plant, Johnstown, Pa.; J. L. MacKENZIE, general supervisor, safety & sanitation, South Works, U. S. Steel Corp., Chicago, Ill.; C. S. WINDVAND, safety engineer, Republic Steel Corp., Republic Building, Cleveland, Ohio.

Non-Ferrous Industry Committee: J. E. NICHOLS (chairman), director of safety, Reynolds Metals Company, Third and Grace Streets, Richmond, Va.; B. D. KENT, safety director, Aluminum Company of America, Davenport, Iowa; E. R. BURNETT, superintendent of security and safety, The Dow Chemical Company, Madison, Ill.; C. A. CONKLIN, personnel coordinator, St. Joseph Lead Co., Zinc Smelting Div., Monaca, Pa.

Fabricating Industry Committee: E. W. ENGERER (chairman), management's representative, Pittsburgh District, Bethlehem Steel Co., Pittsburgh, Pa.; C. P. VORHES, supervisor-safety, training & employment, Jones & Laughlin Steel Corp., Cleveland, Ohio; R. E. ALDEN, assistant director of industrial relations, The Steel Co. of Canada, Limited, Hamilton, Canada; W. A. CAVANAGH, safety administrator, Cutler-Hammer Inc., Milwaukee Wis.; M. S. McALLISTER, safety supervisor, Engineering Works Div., Dravo Corporation, Pittsburgh, Pa.

Steel Warehousing Committee: M. R. YATSKO (chairman), superintendent of industrial relations, Warehouse Div., Republic Steel Corp., Youngstown, Ohio; R. L. PIERCE, staff assistant, Safety & Employee Benefits, United States Steel Supply Div., United States Steel Corp., Chicago, Ill.; R. F. SCHROEDER, manager, safety div., Joseph T. Ryerson & Son, Inc., Chicago, Ill.

Luncheon Awards Committee—W. D. WILLIAMS (chairman), assistant supervisor of safety, The Youngstown Sheet and Tube Co., East Chicago, Ind.

Off-The-Job Committee—C. L. RIENZO (chairman), supervisor of workmen's compensation, Revere Copper & Brass, Inc., Rome, N. Y.; F. A. GERARD, safety manager, Olin Mathieson Chemical Corp., New York, N. Y.; L. R. MORRISON, safety manager, American Car Foundry Industries, New York, N. Y.

Advisory Committee—*G. J. EIGENBROD (chairman), superintendent of industrial relations, The Colorado Fuel & Iron Corp., Wickwire Spencer Steel Division, Buffalo, N. Y.; *E. H. HOUCK, superintendent of safety & welfare, Jones & Laughlin Steel Corp., Aliquippa, Pa.; *G. O. GRIFFIN, director of safety, Dravo Corp., Neville Island, Pittsburgh, Pa.; *J. J. NOLAN, safety engineer, Bethlehem Steel Co., Bethlehem, Pa.; *H. S. SIMPSON, manager-safety, Caterpillar Tractor Co., Peoria, Ill.; H. HOLLAND, supervisor of safety, The Youngstown Sheet & Tube Co., East Chicago, Ind.; *J. L. RIDINGER, director, Safety & Plant Protection, Inland Steel Co., East Chicago, Ind.; *P. E. GRUNDMAN, safety engineer, Armco Steel Corp., Rustless Div., Baltimore, Md.; *C. M. ALLEN, chief safety engineer, Armco Steel Corp., Middletown, Ohio; *J. F. COLLINS (Retired), Youngstown, Ohio; *R. H. FERGUSON, assistant director of industrial relations, Republic Steel Corp., Cleveland, Ohio; *D. A. FARRELL, director of safety, U. S. Steel Corp., Pittsburgh, Pa.; *F. W. KELSEY, supervisor of safety & welfare, Jones & Laughlin Steel Corp., Pittsburgh, Pa.; *H. G. HENSEL, 1660 Highland Oaks Ave., Arcadia, Calif.

Staff Representative—L. C. SMITH, National Safety Council, Chicago, Ill.
*Past General Chairman

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

AUTOMOTIVE & MACHINE SHOP SECTION POWER PRESS AND FORGING SECTION

This volume is a record of the sessions held at the 1957 National Safety Congress by the Automotive and Machine Shop Section and Power Press and Forging Section. The conduct of these Congress sessions each year is only one of the many cooperative activities which the Automotive and Machine Shop Section and Power Press and Forging Section carry on in behalf of their members, and for the benefit of accident prevention work in automotive and machine shops and power press and forging operations. These Sections give guidance in the preparation of a great variety of technical and educational material useful in the day-to-day safety programs of plants operating automotive and machine shops and power presses.

The activities of these Sections are under the direction of their executive committees, the members of which are listed at the close of this volume.

Automotive and Machine Shop Section

SUPERVISING THE YOUTHFUL WORKER

by R. L. HARGRAVES

district engineer, Hartford Accident & Indemnity co., St. Louis

The key to a good department safety record is a good department supervisor. Therefore, if safety people raise the quality of supervision they can achieve a better safety record.

It is an axiom of modern industry that the supervisor is responsible for the conduct of his department. A supervisor gets results through people. Essentially the "people handling" part of the supervisor's job breaks down into two parts. He must instruct or train and he must lead. Some large plants may have training departments. But in the final analysis, the supervisor is responsible for training—passing his knowledge of the job to the people who do the work.

Up to now, the term "people" has been general. There is a special group of people, however, who deserves special attention—the youthful worker.

WHY SPECIAL ATTENTION?

These youngsters enter a strange new world when they take their first jobs. It is a change from their usual way of life and changes usually cause problems. Learning to be good workers means not only acquiring job skills, but developing safe work habits and constructive attitudes. It is a chance for them to grow up, a chance to fulfill their desire for adulthood.

Good supervision can aid youth by developing work habits and attitudes which will help them throughout life. For management, this supervision can be the foundation of good employee attitudes and job relations. The youthful worker of today is the adult worker of tomorrow. Negative attitudes developed from dissatisfaction and frustration may carry over into the whole field of labor-management relations. Good supervision can develop wholesome, constructive attitudes and habits that will last a lifetime.

All business needs youth. Their sharp eyes, quick fingers, energy and readiness to learn are assets. Yet young workers on unskilled entry jobs account for much of the labor turnover and high accident frequency.

So whether you have a few or many young people working, whether they work part or full-time, it's important that they get started right. Important for them. Important for you. Important for our country.

WHO ARE THESE YOUNG WORKERS?

Each year one and half million young people take their first job. During one year, seven million teenagers work part or full-time.

Some are school dropouts—about three out of five are boys who think they will be happier working than going to school. Some are temporary school vacation workers. Some are high school graduates with serious career plans. Apprentice machinists fall in that category.

One principle of good supervision is that people are individuals and must be treated as such. So it is with youth. Each one is different.

How Do They Grow?

During the teens physical growth may be steady or in spurts. Some muscles may grow faster than others—this makes young people awkward and unsafe on some jobs. Long bones may grow faster than muscles and a tall boy may not be as strong as he looks. Doctors say the heart doubles in size during this period and the tall boy's heart may not yet have started its spurt to growth.

If a small heart must pump blood through a grownup body, the youth tires quickly. This is not laziness. The alert supervisor must be aware of, and give consideration to such physical characteristics.

Glands too develop unequally, and could make the youth emotionally unpredictable. It doesn't mean he is basically undependable. Growing bodies need plenty of sleep and rest. Their reaction time and capacity for speed and coordination in small movements are fully developed, but they need training on specific jobs.

How Do They Think and Learn?

The young adult, especially the young man, wants to reason things out. He wants to know *why*—not just how. He may ask questions such as "why do you want it that way?" "Why should I do so and so?" He wants and needs to understand the principle behind the action.

You'll probably find a sharpness of mind—if you look for it. A bright lad may resent being talked down to. Establish good relations by respecting and letting him know you respect *his* opinion.

Judgment may be poor. Getting youth to accept the fact that judgment is gained only through experience, will save them from many mistakes. They will learn from and imitate other workers—especially those they admire—as well as you.

Youth—boys especially—do a great deal of intellectual and emotional exploring. This is what adults call day dreaming. They search for ideals, values and understanding. This idealism makes them responsive to appeals for team work, loyalty and high standards.

How Do They Feel?

They may feel insecure. If so, they hate to be laughed at. They may act grown-up and self-reliant one day and like children the next. When in a confident phase, they are prone to treat all adults as old fuddy-duddies. In this mood, the world is their oyster. Everything to them is so simple.

At another time they may be very critical of themselves. Even when self-critical they are reluctant to admit errors to others and are easily discouraged if ridiculed or criticized too harshly.

Youth wants and needs to be accepted as a person in his own right. When treated as an adult, he usually responds with adult behavior. If he knows you are for him, he will accept you as a friend and advisor.

What Does Youth Want?

They don't really know, and are a bundle of contradictions. They want to be treated as individuals but are fearful of being considered a square by their crowd. The fear of being an outsider compels them to conform to current trends and customs in dress, slang, even the way they stand and walk.

Still they want to be accepted by adults on equal terms, and this sometimes results in ridiculous attempts to appear sophisticated. To cover lack of self-confidence, they may resort to slang, profanity or affect "toughie" mannerisms. Human relations are important to them. They want to like the people they work with and to be liked by them.

If boy-girl, girl-boy relations look silly to you, change your perspective by remembering your own youth. They must learn, however, that social interests must not interfere with their jobs. Their sense of values has not been fully developed and they may need your help in getting the right perspective.

HOW CAN SUPERVISORS DEAL WITH YOUTH?

The formula is simple. Apply all principles of good supervision, but remember some principles take on special importance when dealing with youth.

The youth has no shop "know-how." He has never experienced what an older worker takes for granted. You can expect him to react differently from an adult. Remember your first days on your first job. Develop good attitudes by making him feel he belongs. Stress the "we" and not the "I".

Show him how his work is important and fits into the overall job. If possible, tell him in advance about changes that will affect him.

The language and behavior of fellow workers will influence the youthful worker's behavior too. Encourage the kind of atmosphere you'd consider suitable for your own sons and daughters. Attitudes are caught, not taught. If you command respect, you won't need to demand it.

Start Them Right

You probably have a well planned indoctrination routine for all new employees. Take special pains and pay special attention to details with the young worker. They are probably scared stiff so it's up to you to relieve the tension. No one can learn while frightened. A friendly word can be a life line . . . a friendship line.

If possible, segment beginners' jobs into short units. Young people are not used to sticking at one task for eight hours. Don't just tell them how to do a job. *Show* them —one step at a time—no more than they can master. On the other hand don't underestimate their capacity to learn and do. They will respond quickly and enthusiastically to a challenge.

Explain the purpose of the steps. Remember they want to know *why*.

Encourage questions and then let them try it, so you can put them on their own soon. *Of course, it is important to check* frequently at first, and often reinstruct if necessary. However, you should remember—"if the worker hasn't learned, the instructor hasn't taught." Haphazard instructions to young workers often result in a serious personal injury or accident.

Safety Guidance

Young workers need more guidance in safety measures than adults. They are curious. Lack of experience and judgment can make this curiosity a dangerous handicap. They like to experiment. With proper guidance experimenting may be useful—without guidance it can result in disaster.

They take more chances. Physical exuberance leads to "horse play" and other dangerous practices. Be certain they understand safe practice rules and regulations, and remember—youth wants to know *why*.

Show Them How

Show them how to lift and carry and be sure they understand. The safest jobs are best for young fellows. Safety habits learned on first jobs pay off for young workers and their employees for years to come.

*Special attention to supervising the youth*ful worker is vitally important to the youth of this country, to management and to the promotion of safety. By recognizing and understanding how youth grows, thinks, feels and wants, the supervisor is equipped to do a better job. Special emphasis should be given to indoctrination, work attitudes, job training and safety.

If you wish to improve your safety record this year and guarantee a better record in years to come, see that more attention is paid to the supervision of the youth in your organization. ▲

Joint Sessions

POSSIBILITIES VS. PROBABILITIES

REMARKS OF J. B. HYNES

safety supervisor, Oldsmobile division, General Motors corp., Lansing, Mich.

This topic covers some of the basic fundamentals of safety.

The primary objective is not to present new basic elements in safety but rather to establish a practical viewpoint of safety elements as they show up in the early stages of planning for new and rearranged facilities.

In addition, this will establish a plan for progressive improvement in the over-all safety climate in plants.

To begin with, any plant, regardless of size, has a master operating plan. Such a plan involves a definite capacity to produce certain specific products. It involves production schedules, and quality standards, and sales objectives.

It also involves labor contracts, employee relations, and public relations. The safety of employees and the provision of safe facilities in the plant is a combination of employee and public relations. It is a management responsibility which must be interwoven into the master plan.

A safety program should not be an extra activity divorced from the master plan of operation. If it is a casual activity, emphasized only when accidents domineer, the safety program loses its effectiveness.

On the other hand, with safety part of the master plan, there is no need for safety drives and campaigns or safety weeks and contests to keep it going. Safety is a day in and day out job.

With safety a part of business in plants, someone must have the job of safety coordinator. In small plants this may be a part-time job combined with other responsibilities. In other cases, the plant may be large enough to assign several people to the job.

CENTRALIZE SAFETY JOB

In any event, a person should be assigned as the safety spokesman to see that safety is integrated into the everyday operating practices of the plant. This person should study safety objectively and put himself in a position to advise management on safety policies. His decisions should be based on studies of accident causes, hazards and safety devices. However, even after sincere consideration of the safety problem, accidents do occur.

Any safety effort, a weak gesture or a concentrated drive, will reduce accident-frequency. But to reach the goal of a perfect safety record is another story.

Apparently the approach we have used is effective, because industry has become the safest locale known to man—safer than our homes and many times safer than our highways.

But we are not satisfied with being the best in an area where there is so much left to be desired. We must be just as keen in our search for better safety as we are in solving other problems confronting industry. Far too many safety decisions are made as "hindsight" instead of "foresight."

Hazards that are as plain as the nose on your face are somehow overlooked until an accident investigation. In many cases, repeaters occur where exact duplicate circumstances account for a second accident. We do a lot of re-doing in programs too, such as replacing safety devices lost in the shuffle.

In this never ending fight for life, we consistently go back to the ABC's of accident prevention in the cause analysis of accidents. We follow the dictates of the same ABC's when we act on the accident cause to prevent a recurrence.

Decisions are made hundreds of times *each day by many individuals. The big* question is whether these basic safety facts, the ABC's are in true focus in the picture.

We say "No" because many people doing the planning have never been asked for basic safety as a part of their plans.

The next two writers are engineers, who have had what, in the career of the average engineer, might be a lifetime of experience in their fields.

These men feel that the safety coordinator can get about what he wants in physical plant safety if he gets to the right people with the right safety story.

BEGIN WITH BASICS

Since engineers work with the basic principles of chemistry, physics, and the other sciences, the science of safety would be readily accepted by them. These two gentlemen have torn safety apart to see, first hand, what it is, what it does and how it could be made to perform better in industry.

To them, safety is no big, insurmountable problem. They feel that certain knowledge gained from this study of safety, accidents, and hazards makes the problem relatively simple—providing a common understanding is reached with safety people about the ABC's of safety. ▲

REMARKS OF W. A. CRICKMORE

supervisor, Plant Layout, Material Handling & Special Assignments, Oldsmobile div., General Motors corp., Lansing, Mich.

In applied accident prevention, one must diagnose the cause before prescribing a cure. After a lifelong study of accident causes in industry, H. W. Heinrick, superintendent of engineering and inspection for Travelers Insurance company, concluded there are really a limited number of ways to get hurt. He contends and our experience at Olds-

mobile backs him up, that there are only *10* ways to get hurt in industry.

The safety department at Oldsmobile analyzed 1,738 Oldsmobile accidents, and found the percentages lined up perfectly with Heinrick's. At Oldsmobile 7.55 per cent of injured people were hurt in falls. The 10 ways to get hurt are:

1. Falls 7.55%
2. Struck by an object 41.00%
3. Striking against an object..... 15.00%
4. Caught in, on, or between objects 23.00%
5. Exposure to temperature extremes and radiation 1.70%
6. Strain or overexertion 10.00%
7. Exposure to electricity ..... .50%
8. Inhalation, absorption, ingestion ..... .20%
9. Exposure to chemicals 1.00%
10. Explosion ..... .05%

The safety devices are designed to guard against one of these 10 different exposures.

● A guard over a pair of gears will keep employees from being "caught between" the gears at their mesh point.

● An air hoist installed on our cylinder block floor prevents "strain or overexertion" when it is necessary to remove manually a block from the roller conveyor.

● The ventilation system in our assembly plant repair pits prevents the "inhalation" of carbon monoxide gas from automobiles driven in the area.

Every safety effort in our plants is directed at one of these ten exposures.

Any engineer in industry, regardless of his particular capacity, should be familiar with these 10 accident types and use this knowledge in his basic designs and plans. The solution to most safety engineering problems is simple if recognized or anticipated before the engineer has gone too far in his thinking or in his design.

BET ON POSSIBILITY

So far, we have covered the high points of safety engineering theory down to the concrete hazards. Now we must recognize a hazard and know how people get hurt. We must visually place an employee in the picture to see what will happen—or *could* happen—or might happen.

It's a question of probabilities weighed against possibilities. There is a little gambling spirit in all of us but in safety engineering, you are in a position to put your chips on a *sure* thing.

In safety engineering, it is advisable to bet your life on *possibilities*. When a question arises about guarding a power saw blade, it might be assumed that the hazard is so obvious it couldn't be ignored. It could also be assumed that any employee assigned to such a machine would be experienced and probably would not be injured on the saw.

This is a decision based entirely on *probabilities* and when an engineer thinks in terms of probabilities, he gets us all in trouble. The same engineer would order parts for a machine on the assumption that the parts would probably fit.

A safety engineer thinks in terms of *possibilities* no matter how fantastic. If it can be done, he must assume that it will be done and prescribe accordingly. This line of thinking should be followed by all engineers because safety engineers are not unreasonable in asking for designs, guarding, and machine controls. They merely say that if the pendulum swings long enough, a hazard will pop up and an employee will be injured.

That's why the safety engineer says "it may not be probable but it is possible." That's why he is asking engineers to be alert for hazards in the design stages of engineering.

PLANNING MACHINES, CHANGES

In long range planning for new machines, plant rearrangements, processes, buildings and other changes, safety should be a factor in every decision. If safety is not satisfied in each step of the plan, it becomes lost and trouble is inevitable. In such cases, somebody is usually injured before the hazard is recognized.

Many factors must be considered before large expenditures are made for machines, tools and buildings and safety is only one of numerous problems.

Time and money are saved, and accidents prevented when safety requirements are "built-in" instead of added. "Built-in" safety enhances both the productivity and dependability of the finished equipment.

On the other hand, the slow and costly process of re-engineering new equipment for safety is an expensive, time consuming delay which usually does not completely satisfy the requirements of either production or safety.

This waste of time and money can be greatly reduced and safety improved during initial runs on new or altered equipment if the planning group understands the basic principles of mechanical safety and their application.

DEFINITION OF HAZARDS

To understand the problem, we must first define the terms used by safety engineers in describing hazards and their elimination. We must then analyze typical safety problems to see how the various terms are used.

There are two varieties of controllable hazards, mechanical factor hazards and personal factor hazards.

Mechanical factor hazards are usually created during the basic design of equipment, machine tools, buildings and layouts. "V" belts and sheaves, chains and sprockets, gears and racks, are examples of mechanical hazards. Mechanical hazards account for about 20 per cent of all industrial accidents.

Personal factor hazards are those created by people in their behavior while in the plant. Examples of personal factor hazards are running to the time clock at the end of the shift, unsafe piling of material, poor housekeeping in the plant, reaching into dies instead of using tongs. Personal factor hazards account for about 80 per cent of all industrial accidents.

In some cases, a fine line of demarcation exists between mechanical and personal factor hazards. For example at Oldsmobile, we have a "hands out of dies" policy. Dies are designed on this basis and production standards established accordingly.

If an employee has been instructed to use tongs in closing dies but he ignores the instructions and reaches into the dies exposing his hands, the hazard is a self-created or personal factor hazard. However, any injury he might receive would be a mechanical hazard.

Operating policies established to avoid mechanical hazards are not nearly as positive as guards and safe engineering. People "goof" but well designed safeguards serve faithfully.

An engineer is very realistic about the physical strength and properties of the equipment he designs. He is very exacting about the size of bolts, rivets, braces and other parts forming the complete assembly of a roof truss or a bridge crane. In his designs, he deals in the known facts of chemistry, physics, and mechanics.

When his designs are completed and the equipment installed, he is positive it will serve its intended purpose. However, the one factor some engineers pass over lightly is the association of the equipment with the employee who must operate it.

An engineer deals with facts concerning the inanimate things of his work. Where people are concerned, he often expects too much from them.

ABOUT THE MECHANIC

Here are certain facts about the operator of the machine that the engineer must consider in his design:

1. People make mistakes
2. People forget
3. People take short-cuts
4. People do not always do what they are told
5. People do not always do what they know they should do
6. Some people feel an immunity to accidents
7. Obvious hazards are not obvious to all people
8. People are subject to preoccupation

This is an average employee. This is the person who will operate or work on the engineers' finished product in the factory, on the highway or in the home.

Engineers must develop the skill of recognizing hazards in their designs. At the pace we are moving today, in technological advancement at Oldsmobile, we expect our engineers to become just as skillful at this part of design as they are at mechanization.

Engineers, as members of the planning team, must recognize a hazard and do something about it in their basic planning.

There are five things that can be done about mechanical hazards in general through engineering.

ABOUT THE MECHANICALS

1. We can *eliminate* the hazard—
2. We can *guard* against the hazard—
3. We can *reduce* the hazard—
4. We can *avoid* the hazard—
5. We can *ignore* the hazard—

Naturally, the hazard that is eliminated is no longer a problem. In this manner the engineer is in a good position to do away with hazards before they present themselves by altering basic plans.

- When a choice is made of a machine using a water soluble coolant over one using a kerosene base coolant, a fire hazard has been eliminated in the planning.
- When a layout of a grinder floor is made so that the operators stand out of line with the grinding wheels of his or other machines, the hazard of flying wheel fragments, should a wheel break, has been eliminated —in the basic layout.
- When an industrial washer is specified instead of open vats for cleaning parts, a hazard has been eliminated in the processing.
- When hazards cannot be eliminated, the engineer must guard against the hazard by boxing the hazard.

When a hazard is accepted as a necessary evil and the engineer must include it in his design, he must make provisions for guards, two-hand controls, and barriers to cover the hazard. If possible, *in the design*, the hazard should be located remote from the operating station for the equipment. But even though isolated, the hazard must be guarded.

When a hazard can neither be guarded nor eliminated, it must be *avoided* by the employees exposed. This technique is *questionable* because of the high degree of personal factor involved.

For instance, on a foot pedal operated punch press where both of the employee's hands are "free," he is apt to reach between the dies even though he knows without question what the result will be should the dies close on his hands.

For safety to be "built-in" in industry, designers, engineers, and technicians must reflect in their planning activities a conspicuous interest in, and appreciation of the fact that safety cannot be an accessory but must be a basic ingredient applied constantly.

To summarize the principles of safety, there are two kinds of hazards:

1. Mechanical factor hazards—20 per cent of all industrial accidents—

2. Personal factor hazards—80 per cent of all industrial accidents—

A mechanical factor hazard can be—

- Eliminated—best approach
- Guarded against—second best approach
- Reduced—better than ignoring the hazard
- Avoided—questionable as to effect—no good (we do not recommend it)
- Ignore the hazard

The reasons for not favoring the "avoid" method of hazard control are:

——People make mistakes
——People forget
——People take short-cuts
——People do not always do what they are told
——People do not always do what they know they should do
——Some people feel an immunity to accidents
——Obvious hazards are not obvious to all people
——People are subject to preoccupation

Around these facts and through these few techniques is built the entire complexity of accident prevention. It's not really a complex problem. Instead, it is a multitude of simple little problems involving a mixture of buildings, equipment, machines and people.

When members of the planning team keep safety alive in their thinking and faithfully build safety into their designs, layouts and alterations, the problems dissolve. Instead of making expensive changes in a plant "at a later date," we do it economically and intelligently—in the planning.

REMARKS OF R. H. MOONEY

senior methods engineer, Oldsmobile div., General Motors corp., Lansing, Mich.

A safety engineer is required to study all new and revised installations to weed out hazards. He searches for pinch points, catch points, shear points, squeeze points, the possibility of flying objects, falling objects, run-in points, exposure to electricity, harmful gases and other atmosphere contaminants.

Heavy objects manually lifted, unsafe storage and handling of chemicals, the possibility of exposure to temperature extremes and radiation, the possibility of striking against sharp or pointed objects and exposure to slippery surfaces are also checked.

If none of these physical hazards present themselves, the installation is considered safe. It is a safely designed and installed piece of equipment.

At the pace of modern industry, especially in General Motors, we do not have time to do things twice. We cannot keep on doing safety work on a re-engineering basis because in so doing, we pay twice for the same thing. We pay once when a hazard is engineered into a piece of equipment and then again to re-engineer the hazard out of the equipment.

This is not good business and cannot go on forever. Our management expects all engineers to reduce to a minimum, through intelligent planning, the necessity for making basic changes and doing basic guarding on equipment.

This is done through recognizing basic hazards and applying basic accident prevention principles by all members of the planning team.

HAZARDS ARE CREATED

There are 14 basic hazards:

1. Pinch points
2. Catch points
3. Shear points
4. Squeeze points
5. Flying objects
6. Falling objects
7. "Run-in" points
8. Electricity
9. Gases
10. Heavy objects
11. Chemicals and flammables
12. Hot and cold objects and radiation
13. Sharp and pointed objects
14. Slippery surfaces

Hazards are never things apart from other objects. A hazard is a condition created by the relationship of objects and their association with one another. Therefore it's an abstract thing—sneaky, maybe uninteresting, but vicious.

However, to eliminate hazards through engineering, we must have a clear understanding and a vivid mental picture of the constituents of all the hazards.

Pinch points are formed when two separated objects move and come in contact with one another. Examples are: dies, riveters, spot welders, machine stops, clamping and holding fixtures, chucking and centering devices on machines.

To keep this hazard under control we can:

1. Eliminate it—in design
2. Guard it
3. Install two hand controls to occupy employee's hands and control the position of his body while the pinch point closes
4. Reduce opening to ¼" or less

Catch points are created by objects, either stationary or in motion, which have sharp corners, splines, teeth, or other rough shapes and surfaces, capable of catching the operator or his clothing.

Some examples are: rotating drills and reamers, spline shafts on radial drills and lathes, milling machine cutters, broaches, nails sticking inside of kegs, keys and keyways.

Action on such hazards include 1. eliminate it or 2. guard it.

Shear points are created by two objects, one or both in motion as they pass one another. The two objects are close enough together, as they pass, to cause a shearing action on fingers, hands, feet and legs inadvertently placed in the shear point.

Examples are: shears, dies, paper cutters and reciprocating mechanisms.

To stop "nip and cut" when they form a shear point:

1. Eliminate it
2. Guard it
3. Install two hand controls

Squeeze points are created by two objects, one or both in motion, as they move toward one another. The objects do not come into actual contact but the distance between them reduces. A crushing injury will result if an employee is caught in the reduced area.

Examples are: machine tables when at extreme traverse position form squeeze points with other machines, building columns and walls. Large transfer type machines and objects moved by power conveyors create squeeze points with fixed objects along the conveyor.

To guard against this hazard:

1. Relocate equipment to provide 18 inch minimum operating clearance
2. Install sweep bars with micro-switches wired in series with the control circuit of the equipment
3. Provide tunnel guards with 18 inch minimum clearance at guard entrance

GROUND FLYING OBJECTS

Flying objects are encountered on some operations because of the equipment used and the material processed.

Examples are: wood working operations, forging operations on power hammers, grinding operation, drilling and tapping operations, concrete breaking, impact hand tools, chipping operations and compressed air ejection and cleaning.

To ground flying objects:

1. Eliminate if possible
2. Guard against them

Falling objects are encountered when tools or equipment used overhead are dropped or when equipment loosens from its fastenings. It is good safety engineering to anticipate such conditions and to plan accordingly.

Examples are: press drive motors working loose from mountings, hoists and balancers falling at mounting, counter weights becoming detached and falling, parts falling from poorly designed storage racks and containers, unit loads of material collapsing when tiered, tools and equipment dropped through floor openings and parts dropped from conveyor hangers.

Action on hazard is to:

1. Provide guards to catch and hold parts carried overhead by conveyors
2. Provide safety cables and chains to catch equipment when it falls
3. Over-engineer all mountings for overhead equipment, conveyor hangers and hooks
4. Provide toe boards and screen panels at all floor openings
5. Design material handling containers, racks and unit loads to assure against falling objects

ENCLOSE "RUN-IN" POINTS

"Run-in" points are created by two objects in contact with and rotating toward one another. Some examples are: belts and sheaves, chains and sprockets, gears in mesh, rolls, conveyor chains and traction wheels, ropes and pulleys, cables and drums, gears and racks.

The best way to guard against "run-in" points is by complete enclosure. If equipment can be reversed, all "run-out" points should also be guarded.

Electrical hazards are usually the result of careless use and faulty maintenance of electrical equipment. However, the engineer must make certain provisions in his design if the original installation is to be safe.

Examples are: poor quality electrical apparatus, poor quality cords and cord fittings, poorly located electrical equipment and wiring, electrical equipment not grounded, high voltage at control buttons, lack of conveniently located lock-out type disconnect switches, border line horsepower of motors specified, exposed instead of buried high voltage lines and conventional instead of vapor proof electrical equipment in high hazard areas.

There are several precautions necessary with electrical hazards:

1. Specify electrical equipment according to J.I.C. standards
2. Guard and isolate electrical lines and equipment
3. Keep the machine operator and the maintenance man in mind when electrical equipment is specified. Remember that they are exposed to the hazard while operating and repairing the equipment

HARMFUL GAS, VAPORS

Gases and vapors capable of causing industrial illness or injuries are considered occupational hazards. Explosive gases and vapors are fire hazards.

Examples of hazardous gases and vapors are: carbon tetrachloride, trichlorethylene, cyanide fumes, chlorine gas, hydrogen gas, acetylene, propane, carbon monoxide, hydrocyanic gas, caustic soda fumes, city gas, gasoline and kerosene vapors, lacquer thinner vapors, ammonia gas and acid vapors.

The hazard of harmful gases can be controlled as follows:

1. Eliminate hazardous gas or liquid if possible
2. Ventilate all points of usage
3. Provide for fixed fire extinguishing equipment if liquids or fumes are flammable
4. Isolate incompatible chemicals in the design of the equipment

Heavy objects, either parts or tools, are hazardous if they must be manually handled. These hazards cause back, abdominal, and foot injuries.

Examples are: broach bars, crankshafts, lathe chucks, plating racks, forgings, dies—or in general—heavy objects weighing over 50 pounds.

To prevent accidents resulting from this hazard provide hoists, balancers or conveyors to handle heavy parts and tools.

Chemicals and flammable liquids used as industrial processing materials are trouble potentials.

Examples are: plating chemicals, solvents, cleaning agents used in industrial washers, pickling acids, heat treat salts and paint stripping chemicals.

Action on this hazard are:

1. Identify components of all chemical compounds purchased under trade names
2. Select low hazard chemicals when a choice is possible
3. Isolate as much as possible in storage and use
4. Provide adequate ventilation where necessary
5. Provide emergency equipment such as deluge showers, fire blankets, masks and fire extinguishers
6. Establish definite procedures and facilities for storage and use of chemicals and flammable liquids and supervise accordingly

Objects which become extremely *hot or cold* during industrial processing are dangerous. Some are: forgings, forging flash, parts being heat treated, parts reduced in size through refrigeration in assembly process and parts soldered and welded.

TEMPERATURE EXTREMES

To reduce the hazard of temperature extremes and radiation provide:

1. Personal protective equipment such as gloves, aprons and masks
2. Mechanical handling devices such as conveyors, special tubs and racks
3. Heat shields for controlling radiant heat
4. Radiation shields

Sharp and pointed objects are naturally dangerous, such as: sheet metal trimmings, sheet metal stampings, parts made of glass, nails and tacks, rough forgings and castings.

Action on such hazards is to:

1. Design dies to eliminate needle pointed trimmings
2. Handle trimmings mechanically
3. Personal protective equipment such as gloves, wrist protectors and aprons

Slippery surfaces are the last hazard such as: oil, grease, compound and water on floors, slippery stair treads, work and walk surfaces, hand tools with slippery handles, parts in process with slippery coatings, ice, snow, sleet and rain.

Action on this hazard is to:

1. Install slip-proof surfaces on stair treads, work platforms and catwalks
2. Provide slip resistant floor coverings and surfaces
3. Provide drip pans and splash shields to keep coolants off the floor

4. Design hydraulic equipment to cause hydraulic fluid leaks to drain back to equipment and not on the floor

Now that we have had a good look at these hazards, we should strive to eliminate re-engineering machines, plants and equipment through more attention to safety in the original design. We must remember to count possibilities—not probabilities— and as members of the planning team, we should keep safety in mind while making every decision. ▲

STANDARDS (A SYMPOSIUM)

TRADE ASSOCIATION STANDARDS

by HENRY G. LAMB

safety engineer, American Standards Assn., New York city

A standard is a solution of a recurring problem. For instance, if the boss says that beginning Monday morning you will receive a 55-gallon drum of trichloroethylene for degreasing, how do you know how toxic it is or what ventilation is needed for its use? If you can find a technical society standard, a trade association standard, or even an American Standard Maximum Allowable Concentration of Trichloroethylene, you have a good start to the solution of your problem.

If in addition to this you know that standard requirements for the ventilation of open surface tank operations, such as degreasing, are included in the American Standard Safety Code for Ventilation and Operation of Open-Surface Tanks, Z9.1-1951, then you probably have the facts to decide whether you can use this new chemical in your present equipment or whether you must request the plant engineering department to provide you with additional ventilation. Many others have had the same problem before you and have already developed a standard solution to the problem.

In general, trade association standards are developed by committees, as the result of discussion and agreement. If each organization on the committee sends its best qualified technician as a member of the committee, then the final standard is the best agreement that can be developed on that particular subject. The standard represents good sound technical advice.

As a comparison, trade association standards are available for voluntary adoption; whereas, government standards may have the full force and effect of law. Trade association standards are generally on subjects of broad over-all interest; whereas, an individual corporation makes its own corporation standards to fit its own needs.

These latter standards may be better solutions for that particular company than either government or trade association standards. But the corporate standards of one company may not be much use to any other corporation.

For instance, one company may make a company standard not to purchase or use carbon tetrachloride at all in any of its operations. This may work out very well for that corporation, but it might not be the best answer for many other companies.

AVAILABLE STANDARDS

Joint Industry Conference

The Joint Industry Conference developed electric, hydraulic and pneumatic standards for industrial equipment. These standards provide specifications for the application of electrical, hydraulic and pneumatic devices to industrial equipment to promote safety of personnel.

The standards also promote uninterrupted production, long life of the machine, equipment or tool. They will not limit or inhibit new developments. Copies are available from Joint Industry Conference, Post Office Box 182, North End Station, Detroit 2, Michigan.

Association of Casualty and Surety Companies.

This Association has put out many helpful publications for accident prevention. One is the "Handbook of Industrial Safety Standards." The ninth edition was published in 1954, and is available from the Accident Prevention Department of the Association of Casualty and Surety Companies at 60 John Street, New York 38, New York, at $1.40 per copy.

Manufacturing Chemists' Association.

This Association has a series of safety data sheets for an individual chemical such as sulphuric acid or metallic sodium. There are now 68 data sheets available. They cover such subjects as: properties, hazards, engineering control of hazards, employee safety, fire fighting, handling and storage, tank and equipment cleaning and repairs, waste disposal, medical management, and first aid. These may be obtained from the Manufacturing Chemists' Association, 1625 Eye Street, N.W., Washington 6, D. C.

American Society of Mechanical Engineers.

This is a technical society rather than a trade association. They have developed and printed many standards which have a bearing on safety. Perhaps the best known is the ASME Boiler and Pressure Vessel Code. This has been developed by the ASME, but because it has been so widely adopted by state regulatory bodies, this code could be considered a governmental standard.

These are illustrations and examples, and the list is far from complete. There are also standards of such groups as the Associated General Contractors of America, the National Electrical Manufacturers Association, the Compressed Gas Association, and the Powder Actuated Tool Manufacturers Institute. This latter group published their recommendation for a "Uniform State Code Relating to Powder Actuated Tools Using Studs, Pins and Fasteners." Their address is 250 East 43rd Street, New York 17, New York.

I have refrained from listing standards approved by the American Standards Association because these are not trade association standards. Safety standards approved by the ASA are developed by joint committees including representation from trade associations, technical societies, employee organizations, governmental groups, insurance groups and independent organizations such as the American Society of Safety Engineers and the National Safety Council.

These standards, when approved, are available for voluntary adoption and are acceptable to all parties concerned. Many form the basis of state regulations, and practically all are widely adopted by industrial organizations on a voluntary basis because they represent good sound technical information.

Another group is now getting into the picture. The International Organization for Standardization includes representation from the national standardizing bodies of the various countries throughout the world, and they are beginning to approve recommendations. One of their projects is on safety color codes, and the work done by the ASA project on Safety Color Code, Z53, sponsored by the National Safety Council, is used as the basis for the international study of this subject. ▲

CORPORATE STANDARDS

by J. A. CHURCHILL

safety engineer, safety services section, Allis-Chalmers Manufacturing co., Milwaukee

The need for standardization on a national and international basis is well recognized. In the past 50 years thousands of standards have been developed covering materials, engineering specifications, and methods. The American Standards Association, index of available standards, alone covers 13 double column pages. Add to these standards the multitude of standards or codes sponsored by Federal and State

agencies, trade groups, insurance and engineering societies and other sources, and the number of items covered by existing standards is astounding.

In view of this, why is there a need for corporate standards? Particularly why is there a need for corporate *safety* standards?

The Magazine of Standards July issue contained an article entitled"The 'Not Invented Here' Problem." This article by L. B. Moore was slightly critical of corporate standards. One part of this article states, "Important to every company are the many standards that are available externally and that are in some fashion appropriate to its operations. Typically, however, these standards never seem to fit, and too often need re-work to be acceptable to the company standards group. The explanation given is "The external standards are too general or too all embracing. Our company situation is different and unique and its needs are specific. We must have our own standards to suit our own conditions."

NEED FOR CORPORATE STANDARDS

In my work as a safety engineer, I lean heavily on existing external standards of all types. Use of such standards eliminates countless hours of investigation and research and utilizes the ideas and skills of numbers of people who are experts in their field. Nevertheless there is also a need for corporate safety standards to guide and direct the safety effort for the following reasons.

1. In spite of the large coverage of existing standards, there are numerous problems for which there are no standards available. In fact, there are less than 200 American Standards Association *Safety Standards* available today to cover the wide range of safety problems encountered in industry.
2. A national standard must be broad in scope and therefore is frequently not in sufficient detail or leaves an area of selection of approved construction or method open to the user. The ASA "Safety Code for Industrial Power Trucks B-56.1" for example covers six means of providing acceptable steering mechanisms.

   It may be that your plant experience has shown a definite preference for one type of steering and indicated that this preferred type must be covered in greater detail for uniformity of operation. This, along with other items of truck construction, then indicates a definite need for a corporate standard.
3. The benefit of actual use of safety standards depends on the distribution and acceptance of the standard throughout the many levels of industrial management. With the stress of other supervisory activities is there any reason to believe that such supervisors will be able to read, digest, and remember much of the 74 pages of information contained in the ASA code for "The Use, Care and Protection of Abrasive Wheels," for example?

   The need for corporate safety standards therefore is to supply the manufacturing, engineering, and purchasing sections with short, yet clear, regulations, tailored to the specific needs of the corporation, written in clear terms and available in a form which will promote their active use.

FOUR PUBLISHED STANDARDS

To supply these safety standards at the Allis-Chalmers Mfg. co. we have a choice of four methods of publishing standards material.

The first type is the Allis-Chalmers Process Standard which is issued through our Standards Department. As the title indicates, this group is composed of process specifications which potentially may have general application. This method is used when the use of the standard will be largely confined to engineering departments. For example ACP 6-25 covers "Radiographic Inspection of Alloy Steel Chain." This standard covers:

1. Scope
2. Requirements
3. Preparation for radiography
4. Radiographic technique
5. Acceptable quality
6. Inspection records

Another type of standard issued through the Standards Department is the Allis-Chalmers Material Standard. This group of standards controls the type and quality of purchased materials. Allis-Chalmers Material Standards are issued for items of protective equipment such as gloves, ACM #67 for instance covers specifications for grain leather mittens for use by railroad switchmen in our yards. This standard covers:

1. Material—leather, thread, binding
2. Size
3. Construction pattern—welting, seaming, stitching
4. Workmanship

Use of these standards by the Purchasing Department to obtain competitive biddings on glove requirements has enabled us to hold glove costs closely in line with costs incurred in years prior to 1950 in spite of increased coverage on many operations and increased general glove manufacturing costs. More important, it has provided hand protection of uniform quality to do the protective job required.

SAFETY HYGIENE DATA

Several years ago a third type of standard was started originating directly in the Safety Services Department. This group called "Safety and Hygiene Standards and Data" covers items of equipment, processes, or materials which through their use have been shown to be a safety problem.

The investigational work and preparation of these standards is done in the Safety Services Department or may be done by one of the plant committees designated by the Works Safety Council. In either case, the first draft of the standard is referred to interested parties in management for comment and the final draft is then recommended for approval by the Council.

Since these standards are used by both shop and engineering personnel, the standard drawing form was adopted because it is the usual form from which they obtain information and is therefore familiar to them. It also lends itself to revision or correction and subsequent re-issue without confusion.

As an example of this type of standard "Steel for Fabricating Hitching Equipment," standard 95-100-012 covers:

1. Scope
2. Application
3. Specifications—physical properties
4. Welding procedure
5. Inspection procedure

for all types and shapes of acceptable material.

The fourth type of standard is that published in handbook form covering a group of operations particularly important in the safety program. Such standards cover methods and use of equipment and are intended for application by manufacturing supervision and for employee distribution.

These standards are prepared as a committee function as directed by the Works Safety Council. Typical membership of such a committee would include supervisory members of the affected manufacturing sections, one or more tool engineers or maintenance personnel, and a member of the Safety Department who acts as secretary of the committee. Where indicated, representatives of Plant or Product Engineering sections, Research Department specialists or other specialists may also be requested to serve on these committees.

Standards manuals of this type have been prepared for:

1. Crane Operation & Hitching
2. Maintenance and Construction
3. Trucking
4. Grinding Practices
5. Railroad Rules
6. Field Service

Corporate standards of the types mentioned have, we feel, filled the need which as stated earlier was to supply short but clear standards, tailored to the specific needs of the corporation, written in easily understood terms and made available in a form which will promote their active use.

FIRE STANDARDS

by ALLEN L. COBB
safety director, Eastman Kodak co., Rochester, N. Y.

Fire standards in the United States and Canada principally are produced by the National Fire Protection Association, 60 Batterymarch Street, Boston, Massachusetts. These standards have been used as the basis of state and municipal codes and often are adopted by means of an enabling act indicating the "compliance with NFPA standards is evidence of satisfactory installation."

When standards are used with almost the force and effect of law, they must be developed under democratic procedures with ample opportunity for free discussion and by committees composed of technically competent personnel.

The National Fire Protection Association was formed in 1896, urged by fire protection insurance organizations, industries, particularly the electrical industry enforcement officials and individuals.

The Association has two classes of membership: organization membership limited to associations, and associate membership of individuals. There are now about 200 organization members including the American Institute of Electrical Engineers, American Management Association, National Board of Fire Underwriters, National Electrical Manufacturers Association and the Association of Canadian Fire Marshals.

ASSOCIATE MEMBERSHIPS

The most important NFPA membership is the 18,000 individual associate memberships. The majority are individuals who either pay dues in the Association or have their organizations pay dues. Associate memberships are held by industrial concerns. However, most industrial concerns assign memberships to individuals who represent the company. Many companies have more than 50 associate memberships.

More than 100 technical committees set up the standards. They report to the Board of Directors and their membership and scope is directed by a Technical Advisory Committee. Technical secretarial and editing assistance is provided by the paid staff of the Association, under the direction of Robert S. Moulton, technical secretary of the National Fire Protection Association.

Each committee has representatives to serve public interest, insurance interest, equipment manufacturing groups and consumer or user groups such as industrial concerns. A balance of interest is established. In the case of manufacturers, committee membership is limited to representatives of associations. Such a representative, of course, may work for one of the interested concerns. But in the committee he represents the entire group, not his individual company. Often committee members even agree to changes which have an adverse effect on their own business, to achieve the best fire standards.

VOTE AT CONVENTION

After developing a draft, approved by a majority of the committee, the committee submits it to the National Fire Protection Association office by March 15 of the year it is to be considered. It is printed in Advance Reports, and distributed to all interested NFPA members.

Each committee report is voted on by the annual membership. Often vigorous discussions develop on the convention floor, modify the standard, refer it to committee, or to the Board of Directors to adopt after certain changes have been made.

The Association guards this democratic feature of standards procedure to give everyone interested an opportunity to be heard, and to see nothing is overlooked. Sufficient safeguards prevent hasty modifications of a standard at a general meeting. An actual modification is seldom made at a general meeting except for a very minor editorial point. The work is referred back to the committee with suggestions, sometimes to the Board of Directors.

New standards must remain tentative for at least one year before final adoption. Revisions of standards, however, can be made without going through this tentative adoption procedure.

For convenience, some of the committees are grouped, such as, the Electrical Section with jurisdiction over the National Electrical Code. Another group of committees with jurisdiction over types of extinguishing equipment, is the Special Extinguishing Methods committee.

Some other groupings are Standard #10 on Portable Fire Extinguishers, Standard #13 for the Installation of Automatic Sprinklers and Standard #101 for Building Exits Code. One which caused much discussion recently with many revisions is Standard #58 on the Storage and Handling of Liquefied Petroleum Gases.

The standards are useful in fire protection and safety work, and everyone in this work should become familiar with them. These are intended as standards, not texts or installation manuals. In a number of cases, appendix material is attached to help understand and use these standards. But each person using a standard must have a good general knowledge in advance. The standard simply states the performance and material requirements for good installation or satisfactory fire protection. They are minimum standards and in many cases additional protection should be provided.

The National Board, a member of the National Fire Protection Association, helps develop these standards and prints them over its own name as "Regulations of the National Board of Fire Underwriters."

These Underwriters' regulations, therefore, are identical with National Fire Protection Association except for the format, wording on the cover, and the printed foreward attached to the bulletin. In a few instances minor text changes were made, such as the type of authority having jurisdiction. These are issued for implementation by the National Board and its associate organizations.

Some of the National Fire Protection Association standards are also listed as American Standards. But the certification procedure of the American Standards Association requires a considerable amount of time and in this field it is exceedingly important that the standards be issued at the earliest possible date. Acceptance of the standards, promulgated by the National Fire Protection Association, has been entirely satisfactory and American Standard Association certification is not required in most cases.

Other information on fire protection is issued by a number of organizations. One is the loss prevention bulletins of the Factory Mutual Insurance Companies, issued as a guide to industries insured by these organizations but based on broad experience in fire protection. They supplement and extend the National Fire Protection Association standards and include a great deal of explanatory material which is most useful. Data sheets are also prepared, some by the Manufacturing Chemists Association on the storage and handling of a wide variety of chemical materials and include fire protection sections. In general, however, the basic fire standards most useful to the safety engineer and particularly to the fire protection engineer are the standards of the National Fire Protection Association.

Power Press and Forging Section

OPENING REMARKS OF GENERAL CHAIRMAN

C. H. DUGGER

director, Health & Safety Div., Albuquerque Operations, U. S. Atomic Energy Commission, Albuquerque, N. M.

This year marks the 30th anniversary of the Power Press and Forging Section as a separate section of the National Safety Council.

I am proud to have been associated with the men on the Executive Committee of this Section during the past nine years. I am proud also to be associated with an organization which can boast of having had among its members such men as August Kaems of the State Industrial Commission of Wisconsin, and for many years safety director of the Simmons Co. in Racine, Wisconsin. Kaems was the father of most of the semi-automatic power press feeds we think so highly of today.

ACTIVE MEN IN SECTION

Such men as George S. Thompson of the Detroit Insurance Agency, now the Michigan Mutual Insurance Co., who made the first formal speech on the Power Press and Forging Section's first National Safety Congress program in 1927; Ted Meisner, safety director for the American Can Co., who was the first General Chairman of the Power Press and Forging Section Executive Committee; J. W. Henning of the Automatic Electric Co. of Chicago, who was the first Vice Chairman and the second General Chairman of this Executive Committee; Robert A. Shaw of both the Murray Corp. and the Ford Motor Co.; E. F. Clark of the Ternstedt Manufacturing Co. of Detroit; A. F. Dunnebach, safety director, General Motors Corp.; and Gus A. Kichenmeister of Dominion Forge Limited, Walkerville, Ontario.

My own tenure with this group dates back to 1948, and there are several men on the Executive Committee today who were active long before I became a member. In fact, we still have one active charter member, Edward J. Wallman, district safety supervisor of the American Brake Shoe Co. I could name others but the list is too long. These men promoted the use of safeguards on power press operations, and devised most of the methods and feeding devices in use today.

ACCIDENTS LIKE HEN'S TEETH

In 1919 Kaems made the first speech on power press safety ever made at any National Safety Congress. In that year, for want of a better place to schedule this speech, it was included in the Automotive Section's program. From that year on, there was constant agitation for separate Sectional status.

Seven years later, at the 1926 National Safety Congress, Kaems made another speech. *His subject this time was:* "Why a Power Press Section." In his speech, Kaems mentioned that in 1919 he had brought two wooden models of press feeding devices to the National Safety Congress. He mentioned how the exhibit had grown between 1919 and 1926, because of the contributions of many of the progressive companies in the United States. Then he said, and I quote:

"There is no doubt in my mind, and I know that there are at least a dozen men in the audience today who will stand up and tell us that punch press accidents in a few years from now will be as scarce as hen's teeth."

If only Kaems had been a better prophet . . . I don't know what happened between 1926 and now . . . Kaems must have had some sound basis for his optimistic prediction . . . The sad facts are these:

1. We are saying exactly the same things today that were said 38 years ago. The only way to eliminate power press injuries is to keep the hands out from between the dies.
2. There is no panacea—no cure-all, there is no universal guard. Every job is a little different, but every job can be, must be, made safe.
3. Safe tools and safeguards cannot be built unless the head of the firm is interested and willing.

We must all confess some responsibility for the over-all failure to sell the idea of power press safety to plant executives—the only people who can establish the policies and authorize the expenditures necessary to safeguard power press operations.

MUST APPLY IDEAS

It seems pretty clear that we do not need to find more and better guards and feeding devices to eliminate power press accidents. The thing we do need to do is to find some factor—some appeal which will make plant management really apply what we already know about guarding power press operations.

In his speech in 1926, Kaems mentioned that the exhibit of guards that year was much larger than the original exhibit of two wooden guards in 1919, that they intended to make the exhibit five times larger, and that it would be housed in a room where someone would be on duty at all times during the Congress—a place where anyone, who came to the National Safety Congress, could go and talk over his power press safety problems and there would be someone present to help him.

Somehow—over the years—this project died. It is the hope and intent of the present Executive Committee to revive that service, and we intend also to reinstitute the power press guard exhibit. We aren't quite sure yet just how we will manage it, but we have made a start.

Now—this is my swan song as General Chairman of this Executive Committee, but I am not through as a member. I'm happy to report that in the nine years I have been a member, I have seen steady improvement in the functioning and in the accomplishments of this committee. This year it completed a difficult three-year project in developing a Power Press Safety Manual which will be published soon. I am sure you will find it helpful.

Over the years, this committee has developed most of the power press and forging safety material available from National Safety Council. It furnishes the material for the Power Press and Forging Section Newsletter which is edited by one of our members and published by the Council. It has a long range program that will keep it busy for years to come. The only thing wrong with this program is that the materials, Newsletter articles, and Congress programs are what the committee members themselves think will be the most useful and interesting to you.

To render better services, this committee needs your help. It needs to know what types of materials and what subjects should be covered to best meet your needs. Please write in and tell us.

The Power Press and Forging Section Newsletter is your Newsletter. We believe that most of you have, or have had, incidents in your plants, the knowledge of which would be helpful to others. I am sure that many of you have ideas that you want to pass along. I am sure also that most of you have developed some safety gadget that has done a good job for you, and you would like for others to benefit from it.

SAFETY MATERIAL

I beg you to participate in the exchange of power press and forging safety information through your Newsletter . . . Please write up these incidents, ideas, and gadgets and submit your drafts, along with appropriate illustrations, to the Power Press and Forging Section at National Safety Council headquarters. Your contributions will be passed on to our Editor for inclusion in the Newsletter at the first opportunity. Through the free exchange of ideas and information you can contribute much toward the realization of August Kaem's dream that in a few years power press accidents will be as scarce as hen's teeth.

SAFE OPERATION OF INDUSTRIAL FURNACES AND HEAT EQUIPMENT

by LARRY I. JAFFE

supervisor, manufacturing research laboratory, Frigidaire Division, General Motors corp., Dayton, Ohio

General Motors, several years ago became aware of the increased frequency of explosions and fires due to industrial furnaces and heat treat equipment. In the past three years, they have had two very bad accidents: an explosion in a core baking oven injuring 27 men, and a still more serious accident in an atmosphere brazing furnace which exploded and killed three men.

These two major explosions are not the only accidents due to furnaces and heat treat equipment however. During the second quarter of 1956, according to the Fire Protection Bulletin published by G. M., there were nine other explosions and fires in heat treat departments in General Motors plants. Two of these accidents were explosions of considerable extent caused by furnaces. One caused $2,500 damages, and the other a $10,000 loss.

Six others were fires involving heat treat quenching oil. Most were minor, the most costly having $2,000 damages. However, such a fire can get out of control. These quenching oil fires have one thing in common—they have plenty of fuel on which to feed.

The reason General Motors' data is cited here instead of industry-wide data is because the information is readily available in the G. M. Fire Prevention Bulletin. G. M., as a manufacturing organization, has a wide variety of manufacturing operations and should be fairly representative of all metal fabricating plants.

WHY MORE EXPLOSIONS?

Why use data for the second quarter of 1956? Actually, that was the latest data available last year, and is very representative of G. M. plants at that time. Since then, a strong campaign was instituted to promote safe operation of industrial furnaces and heat-treat equipment, and the figures for 1957 are considerably improved.

We are having more explosions and fires from furnaces and heat treat equipment than in the past, even though more and better safety devices are available today than ever before. Examining the facts, the reason becomes obvious. There has been a tremendous increase in the number of furnaces and other heat-treat equipment in use the past few years and the furnaces themselves are becoming increasingly complicated and diverse.

The Buick plants at Flint contained more than 1,000 furnaces and ovens for heat treating and other operations. At the time, 125 new pieces of similar equipment were scheduled for installation. The 1,000 industrial furnaces had more than 80,000 individual gas burners and pilots. In other words, this division, with approximately 30,000 employees, had almost three burners or pilots for every person. The malfunction of any one of these could result in a serious explosion.

This indicates the amount of equipment involved; now look at the variety. The plants had low temperature furnaces, used for paint drying, core drying, tempering, nitriding, stress annealing and many other operations. The division also had high temperature furnaces for forging, annealing, hardening, porcelain firing and porcelain enameling. Besides these, there are the atmosphere furnaces, with associated atmosphere generators, used for bright annealing, brazing, carburizing and carbonitriding.

The furnace atmospheres are usually produced in atmosphere generators. These may vary widely, depending on the raw materials and on the type of atmosphere required. They may, however, be classified as either exothermic or endothermic generators, or as dissociators.

Besides these furnaces, ovens, and generators, there are salt baths, molten metal baths of various types, and the oil quench tanks.

Such a variety and quantity of equipment proves the immensity of the problem of heat treat safety. A furnace is no longer just a heating device. It is a tool designed for a specific purpose. As such, it has its own peculiarities and its own hazards. Each piece of equipment, therefore, must have safety devices designed for the particular things that can go wrong with it.

The hazard common to most industrial furnaces, ovens, and generators, is flame failure. In order for fuel to burn, three things must be present; fuel, air, and a source of ignition. Usually, the source of ignition is a pilot. If it goes out, particularly in furnaces operating at low temperatures, air and gas will enter the furnace unignited, resulting in conditions for an explosion. Most furnace burners are equipped with a flame protective device, which cuts off gas supply if the pilot or flame goes out. This is an absolute must on low temperature furnaces. The gas furnace in your home and your automatic gas hot water heater are equipped with similar devices.

GAS ACCUMULATION HAZARDS

A second hazard is unignited gas from leaks and other causes, which collect in the furnace before it is lighted. If you have ever lighted a gas furnace at home, the instructions told you to keep the furnace door open for five minutes before igniting the pilot. This ventilating period is necessary to insure that gas collected in the furnace from leaky valves or some other cause, is removed by purging. Otherwise an explosion could occur.

The same precautions are necessary in lighting industrial furnaces. With certain types of modern furnaces, the purge time is controlled by an electrical timer interlocked with the starter mechanism. This prevents lighting the burners until the furnace has been properly ventilated.

A third hazard is connected with certain types of operations performed in ovens and furnaces, which produce combustible fumes. Core drying ovens and paint drying ovens fall in this category. For example, thinners are volatilized from paints and lacquers when they are dried. If these accumulated in the oven, they would interfere with proper paint baking, and would build up concentrations within the explosive range of the solvent. Ventilating and exhaust fans are necessary to prevent this. The fans are interconnected with safety devices which prevent the oven being used unless the ventilating and exhaust fans are operating.

This last hazard possibly caused the core oven explosion mentioned above. Fumes from the core baking operation might have collected in the oven and then became ignited. The exact cause of this explosion was never determined.

STILL DIFFERENT PROBLEMS

Atmosphere generators and furnaces have their own peculiar problems and hazards. Most generators use natural gas for their atmosphere. This is combined with a fixed proportion of air in the generator. The type of generator used and the type of atmosphere produced depend on the proportion of air and gas. With exothermic generators, enough air is suppled to burn the gas to a degree where sufficient heat is generated to maintain the reaction. With endothermic generators, the air supplied is insufficient to develop heat of reaction to keep the generator hot, so external heat must be used.

In either case, if the generator loses its heat the reaction no longer takes place and a mixture of raw gas and air is passed into the furnace. The result is perfect conditions for a violent explosion. This caused the brazing furnace to blow up last February. To guard against it, some temperature sensing or flame sensing device must be installed in the generator.

The problems dealing with atmosphere furnaces are principally connected with starting up and shutting down. In starting up, a furnace full of air must be replaced with combustible gas. If done properly, no hazard is involved. If done improperly, anything can happen. The same thing is true when shutting down. The only difference is that the gas atmosphere in the furnace is replaced by air.

Another hazard occurs with certain types of atmosphere furnaces when the front and rear doors of the furnace are opened at the same time so that a draft of air passes through. This air becomes intermixed with the gas in the furnace, and a source of ignition, such as, the hot walls of the furnace can set it off. Interlocks, which keep

the front and the rear doors from being opened at the same time, prevent this.

These are some of the principal hazards connected with operating fuel fired furnaces. There are others. Many of these are associated with the failure of utilities such as gas, air, water, and electricity. Failure of any of these can result in explosions, particularly with atmosphere furnaces. Furnaces and generators, therefore, should be equipped with safety devices which shut off the fuel and air supply if a utility fails.

In most cases, such a shutdown is probably the safest thing that can be done. However, with certain types of equipment, particularly with atmosphere furnaces, it can lead to other hazards. When the atmosphere is turned off on an atmosphere furnace, air begins to infiltrate. The air which enters the hot zone will immediately react with the furnace atmosphere and cause it to burn.

The air, which infiltrates the cold zone, will not react with the furnace atmosphere since a source of ignition is not present. Instead, it will mix with the atmosphere, and might diffuse back into the furnace. If it should travel to the hot zone, it will become ignited and the entire contents of the cold zone will explode.

This can be prevented, when a shutdown occurs, by either replacing the atmosphere in the furnace with a natural or neutral gas, such as nitrogen, or else by removing the atmosphere *from* the furnace by the burn-out method. Any operator properly instructed in the correct methods can do either safely. However, he must be aware of the emergency.

TRAINED WORKERS ESSENTIAL

At no time should an atmosphere furnace be operated unless a trained operator or *someone thoroughly familiar* with the furnace and emergency procedures is present. The failure of a utility or flame or heat failure in the atmosphere generator might lead to a serious explosion if no one were at hand to take the necessary safety measures.

For these same reasons, any safety device should have a visible, audible signal to show the operator the device has acted. The visible signal indicates which device has acted, while the audible signal is a general alarm covering several devices.

Closely related to these hazards are those involved with operating molten metal, salt baths, and oil quench tanks. Molten metal and salt baths have the same hazards as hot molten materials. They splash, burn and form steam or vapor which may erupt with explosive violence when mixed with any liquid, such as water or oil. One exception to this is a low temperature nitrate-nitrite *tempering bath to which water is sometimes* added to lower its melting point.

One hazard of salt baths, which is not too well known, is that the two types of *salts—oxydizing salts and reducing salts*—react violently together. For example: cyanide baths are reducing; nitrate baths are oxydizing. The erroneous addition of one material to a bath containing the other will result in an explosion. Nitrate salts will also react with any other reducing substance, such as, oil, soot, magnesium, or aluminum alloys containing magnesium. Because of this, nitrates need to be carefully identified and it is recommended they be procured containing a red dye for this purpose.

BEWARE QUENCHING OILS

Quenching oils have all the hazards of flammable liquids. When it is considered that red hot parts are quenched into these flammable materials, the possibilities for accidents can readily be seen. Furthermore, these flammable liquids must be close to furnaces and salt baths. This leads to all *kinds of hazards. Safety* devices are used to prevent overheating the oil, but the only real way to eliminate this hazard is by finding a suitable and practical non-flammable substitute. Non-flammable hydraulic oils are developed, so why not non-flammable quenching oils?

Besides fire and explosion equipment and industrial furnaces there are still other hazards connected with heat treating operations. For example, some common salts used in heat treating are cyanides.

They are poisons and should be handled with gloves, kept out of cuts, and care should be taken not to inhale their dust.

Another well known danger found in furnaces and gas generators, is carbon monoxide. If a fuel is burned with a deficiency air, carbon monoxide is formed. This means any fuel burning device, under certain conditions, can produce this poisonous gas.

Unfortunately, it has no odor so the only safeguard against it, *is adequate ventilation.*

Atmosphere generators are particularly efficient carbon monoxide producers. They work on the principle of reacting natural gas or some other hydrocarbon with a deficiency of air. The result is an atmosphere rich in carbon monoxide. A typical exothermic generator operated on natural gas at an air-gas ratio of six to one will produce an atmosphere containing 10 per cent carbon monoxide. Endothermic generators are used at lower air-gas ratios. Such a generator maintained at a three to one air-gas ratio will produce an atmosphere containing 18 per cent carbon monoxide.

Ten minutes exposure in air containing one per cent of carbon monoxide will result in death. Therefore the products of these atmosphere generators are extremely lethal. Any gases from the generators or furnaces should either be vented to the outdoors or burned. Also flame curtains at the outer doors of atmosphere furnaces will prevent explosions, lessen the contamination of the furnace atmosphere and burn *combustible* gases, including carbon monoxide, from the furnace. However, the combustible content of the atmosphere can be so low that it will *not* burn, and yet in the case of carbon monoxide could still be highly toxic. To prevent this, the outer doors of atmosphere furnaces should be surrounded by ventilating hoods.

SAFETY SUGGESTIONS

Six steps should be taken to minimize these various hazards and attain safe operation of this equipment.

1. Make sure furnaces and other equipment are safe and have all the necessary safety devices. Review each piece of equipment to make sure in the event of any utility failure, flame, temperature failure, or instrument failure the safety devices will operate. Much of the safety equipment is required by the insurance companies. But, in many cases it is necessary to go beyond the insurance companies requirements for safe operation.

2. When additional furnaces or heat treat equipment are purchased, make sure that they are adequately protected by safety devices. The safety devices should be considered as an integral and necessary part of the equipment, not as an extra. Be sure that *low bids are not made on the basis of* leaving off some of the safety equipment.

3. Maintain safety devices in good condition, and inspect them at least once a month to see they are operating. Records should be kept of the results of these inspections. The insurance companies have standard forms for such results.

4. Be sure you are *following* approved procedures. Make certain that furnaces and ovens are adequately purged before lighting and that proper methods are followed for *introducing and removing* furnace atmospheres.

5. Make sure all piping and valves are adequately identified. Piping should be identified *by some standard color code.* Valves should be readily accessible and their open and shut positions clearly visible from the floor.

6. *The last and most important factor* of all is well trained operators. This can not be too highly stressed. Even though a furnace has the latest and best safety devices, a *well trained operator* is still necessary for its safe operation. This is particularly true of atmosphere furnaces. No safety device has been invented which will properly introduce atmosphere into these furnaces or shut them down safely.

Similarly, when wrecks occur in the furnace, only a trained man knows how to handle them without causing an explosion. In the event of utility failures or flame failure, the presence of a trained operator is necessary for the required emergency procedures. As mentioned previously, an atmosphere furnace *should never* be operated unless trained personnel are nearby.

PREPARE INSTRUCTIONS

Complete instructions for each furnace should be prepared and the operator should be made thoroughly familiar with them. These instructions should include emergency procedures. A copy of the instructions should be posted near the equipment, and a second copy retained by the foreman. The foreman should review the instructions with the operator at regular intervals.

These are some of the things that must be done to insure safe operation of industrial furnaces. General Motors has gone

beyond this. They hold a series of meetings to outline the necessary precautions for safe operation of furnaces and heat treat equipment. Personnel from many of the G. M. divisions helped in this work. Present at the meetings were safety engineers, metallurgists, plant engineers, heat treat supervisors and others. Their recommendations were *incorporated in the* Heat Treat Section of a G. M. book entitled, *Plant Engineering for Hazardous Materials.* This book is used by all General Motors divisions as a guide in the safe operation of their plants.

Another publication on this subject, recently issued by the Factory Mutual Engineering division is their Loss Prevention Bulletin No. 14.15 entitled, *Safe Installation and Operation of Industrial Ovens and Dryers.* This can be purchased for $1.

G. M. is taking one other step to insure safe furnace operation. An educational course for heat-treat foreman and operators has been organized, and covers all phases of the subject including the principles of combustion and the causes of explosions. In time, this course will be presented at all of the G. M. divisions concerned with this problem.

The latest data available for 1957 show a 50 per cent reduction in fires and explosions in General Motors plants, due to furnaces and heat-treat equipment. We think this is the result of G. M.'s campaign for furnace safety. As the educational program continues we hope accidents due to these causes will become even more infrequent.

You, as safety engineers, know that education along the general lines of safety has paid off. It has saved hundreds or, perhaps, thousands of lives, and prevented the maiming and injury of countless people. Education along the specialized lines of furnace and heat-treat safety should prove equally effective.

CLUTCH—BRAKE CONTROL VALVING

by A. B. HUNTINGTON

chief engineer, Ross Operating Valve co., Detroit

Reduction in the frequency and severity of industrial accidents is of prime importance to everyone. All of us are adversely affected by the real and the intangible costs of industrial accidents. The machine operator wants a full paycheck, safe working conditions and reliable tools and equipment. Management wants a minimum of personnel lost-time, material damage, machine down-time and insurance cost. Down at the end of the line, that old down-trodden character, John Q. Public, is looking for a price tag that is not inflated by accident cost.

Power presses, because of their function, present major industrial hazards. The most disastrous of these hazards can be accidental press stroking, often referred to as a "press-repeat." This hazard is often created unintentionally, or it results from a mechanical, electrical, or pneumatic failure in the press control system.

The application of mass production principles in the metal-working industry has brought about the development of fast-acting pneumatic clutches and brakes for all types of power presses. In the usual device of this type, the clutch is air engaged, spring dis-engaged; the brake is spring engaged, air dis-engaged. This provides a desirable fail-safe arrangement in the event of loss of primary air pressure.

CONTROL AIR POWER

To control the air power, which can disengage the brake and engage the clutch, a solenoid operated, 3-way air valve is usually used.

This is a 3-ported valve, having an inlet, an outlet and an exhaust connection. It can also be described as a normally closed, 2-position valve—in one position, with the solenoid de-energized, the inlet is spring and/or pressure closed; and the outlet, or brake-clutch device, is open to exhaust. In the other position, with the solenoid energized, inlet pressure is open to the brake-clutch device, and the exhaust is closed.

Here again, a desirable fail-safe feature is provided in the event of loss of primary electrical power. Obviously, a valve of this type could control a single-acting cylinder which, in turn, could operate a mechanical or positive type brake-clutch mechanism.

To reduce electrical power requirements, to allow higher maximum cycling rates without unduly sacrificing life, and to improve overall valve response time, press valves are usually an air-piloted type rather than direct solenoid operated.

Where a single valve, as described above, is used to control a clutch, any failure of the valve to return to its normal, or inlet-closed position at the proper time, may cause a press-repeat. If the inlet orifice partially closes while the exhaust orifice remains partially open—the exhausting capacity of the valve may then be enough greater than its pressurizing capacity to reduce the receiver pressure to a safe value. It should be noted that most valves of this type have an oversized exhaust port.

UNSAFE CONDITIONS

In a direct solenoid operated valve, an unsafe valve condition can be caused by a freezing of the solenoid in the energized position, a return spring or linkage failure or some internal mechanical interference. In the more usual solenoid actuated, pilot operated valve, mechanical failure in the pilot section is an additional possibility.

Some presses utilize one simple 3-way, normally closed valve for the clutch and another for the brake. This provides a slight safety improvement due to the improbability of the two valves failing simultaneously. If the clutch valve remains sufficiently open at the end of a stroke, press advancement is powered and opposed by the brake. If the brake valve remains sufficiently open at this portion of the cycle, press advancement is dependent upon the kinetic and potential energy provided for coasting.

To reduce the possibilities of valve failure due to solenoid and pilot section malfunction, a slightly different 3-way valve can be used. This normally closed press value has a clapper or "El" type solenoid, a 3-way, spring-less, pilot section and an over-sized exhaust port.

Normal wear on this type of solenoid or any coil burn-out, is unlikely to cause the solenoid armature to freeze or hang-up in the unsafe or energized position. By inverting the valve from the more usual solenoid-up position, gravity, as well as pressure, will assist return of all the internal parts, including the solenoid, to the safe position upon control circuit opening. Many press valves of this type are used in automotive metalworking shops.

INVERTING VALVE

There are several other methods, beyond good preventive maintenance, of making the pneumatic valving safer for both the press operator and the equipment. These methods rely primarily on the doubling up of valve units, so that failure of any one unit will not unduly jeopardize safety—the possibility of simultaneous failure in both units, causing complete loss of safety is unlikely. If the air flows through the two units in succession, the units may be said to be in series, pneumatically. If the air flows through the two units simultaneously—the inlets interconnected and the outlets interconnected—the units may be described as being in parallel, pneumatically.

One of these improved safety methods is to use two 3-way, normally closed valves in series pneumatically and in parallel electrically. With this arrangement, when either of the valves malfunctions and remains open in the absence of the proper electrical signal, the other valve, operating properly, will exhaust the brake-clutch device and there will be no possibility of a press-repeat.

Unfortunately, in this method, there is little audible or operational indication of a malfunctioning valve and one must therefore rely on periodic and careful inspection procedures to make sure that both units are operating properly. Obviously, with this set-up, whenever one of the units is struck in the energized position, safe press operation then depends entirely on the proper operation of the other unit.

To overcome the principal lack of safety in what we may call the simple "series" method, one press manufacturer has used two valves in series, each modified to in-

clude a valve-parts-position indication stem, in combination with limit switches. With this added and highly desirable feature, the individual valve actions can be electrically indicated and interlocked.

Adequacy of the improved safety here depends primarily on the ability of the electrical circuit to prevent further press cycling whenever one of the limit switches indicates something is wrong. We suspect that it may be difficult to obtain mechanically operated switches with sufficient life for this application. It may be possible in the future, however, to eliminate this problem by using magnetically operated proximity switches.

DUAL UNIT VALVE

A second and more complicated variation of the series method is a multiple, or dual unit valve. This item consists of a 3-way, normally open, so-called "safety-unit," a 3-way, normally closed, so-called "operating unit," a safety verifier, a permissive pilot and various interconnecting passages. The safety unit is ahead, or upstreams, of the operating unit (a series type connection) and the pilot solenoids are in parallel elec trically. The safety unit is a stand-by type and has a feed-back operated lock-out feature.

In the event that pressure remains momentarily on the brake-clutch in absence of the proper electrical signal, line pressure should trip the "safety" or stand-by unit and dump the brake-clutch. Re-setting or re-cocking this valve can be done after removing the inlet pressure on the "safety-unit." The manufacturer recommends that this be done with a manual 3-way valve upstream of the dual valve. A special electrical test circuit can be used to safety-check this valve.

A second simple method of controlling clutch action consists of using two 3-way, normally closed, solenoid valves, in parallel both pneumatically and electrically. With this "parallel" arrangement, a hazardous condition exists whenever either of the two valves malfunctions and remains open in the absence of the proper electrical signal. This condition can be somewhat alleviated by providing each valve with an over-sized exhaust.

If the de-energized valve that is operating properly can pass sufficient air, from the malfunctioning valve, to exhaust—the pressure at the common outlet or clutch connection may be reduced enough to disengage the clutch and engage the brake. If the press action does not indicate a valve failure, it may be noted audibly after completion of a valve cycle when normally there should be no sound of air exhausting.

PRESSURE SWITCH SHOWS AIR LOSS

There is at least one dual, or multiple unit valve of the parallel type presently available. It consists of two 3-way, normally closed valve elements with a common inlet, a common outlet and two over-sized exhaust ports. To lock-out electrically the valve and prevent continued press operation when one of the valve elements has failed, a pressure switch, connected to a reservoir ahead of the valve inlet can be used to signal loss of air to exhaust.

The so-called Lifeguard valve represents another, dual-valve of the same parallel type. It consists of two identical 3-way, normally closed units each with its own pilot section and solenoid, in parallel both pneumatically and electrically. The units have a common ¾" inlet port, a common one-inch outlet port and two one-inch interconnected exhaust ports, the last providing the desirable safety feature of an exhausting orifice considerably larger than the pressurizing orifice.

The two 3-way, normally closed pilot sections are symmetrically supplied through a sensing unit which will cut off the pilot air supply in the event that the two valve units do not open or close together. This sensing unit is a pressure operated spool valve. One end of this spool valve is internally connected to the outlet chamber of one valve unit and the other spool end is connected in a similar manner to the outlet chamber of the other unit.

Even at high rates of press cycling—failure, or sluggish operation of either half of the main valve, due to foreign matter, a broken part, a malfunctioning pilot section or solenoid, will result in a pressure unbalance on the ends of the spool. This will cause the sensing spool to shift, cut off further pilot air supply and mechanically lock-out. Removal of pilot air pressure makes certain that the main dual-valve units cannot thereafter be operated to cause a press-repeat.

OTHER SAFETY METHODS

All of the previously mentioned press valves are electrically actuated control elements. Because of the possibilities of electrical and mechanical malfunctions in conventional type relay circuits, a great deal of development work is underway on what is broadly called "logic function" control. At the same time, and for the same general reasons, much interest has recently been shown in a different approach to safer press control—namely, all-air control circuits.

These circuits can be developed to include such features as two-hand or two-station control, emergency stop, top stop, continuous cycling, inching or jogging, single stroking and guard device inter-locking.

Two valves that can be used in all-air control circuits have special characteristics. The first is part of an air circuit element controlling the starting of a press cycle. This valve is used when necessary—for safety—to make sure that the press operator uses both hands nearly simultaneously to initiate each press cycle.

Because of its function, this valve can be called a "Non-Tie-Down" valve. The right and left hand halves of the valve are identical, each half having its own inlet, and the single outlet, or receiver connection being in the exact middle of the valve. A 3-way, normally closed, palm button pilot valve is used to supply each Non-Tie-Down inlet. If the flow through the Non-Tie-Down valve from each pilot valve is not balanced, one of the Non-Tie-Down valve pistons will shift and vent any outlet pressure to exhaust.

This makes certain that the press operator uses both hands simultaneously to initiate a press cycle. If the operator engages only one of the hand valves, after a very short delay, the Non-Tie-Down valve will automatically prevent downstream pressure build-up until that hand valve is released and both hand valves are tripped in unison. Release of either one of the hand valves will cause the Non-Tie-Down valve to dump any downstream pressure. Similar to some of the other press valves, the Non-Tie-Down valve has built-in "fail-safe" features.

Downstream of the press-starting air circuit element, a second special valve can be used, a "Single-Stroke" valve. This valve can follow a Non-Tie-Down valve or it can be supplied directly from one or more 3-way, normally closed, press-starting pilot valves. The Single-Stroke valve first allows a receiver or clutch valve pilot line to be pressurized and then automatically closes, remaining in this safe, closed, position until the manual start valve, or valves, are released.

Safetywise, the valve can therefore be used to force the machine operator to maintain the manual start valves open until a cam type, top-stop valve is opened by rotation of the press shaft. Initiation of a succeeding press cycle can only be accomplished after the Single-Stroke unit has been re-set by exhausting its inlet pressure back through the 3-way manual start valves.

READ SAFETY CODE

The recently published Canadian Standards Association, Code Z-142, entitled "Guarding of Punch Presses at Point of Operation" is recommended reading for anyone interested in industrial safety. This code establishes safeguarding requirements dependent upon the method of feeding the press, the press operating speed in strokes per minute and the type of clutch used.

Several all-air press control circuits have been developed to meet these code requirements. One such circuit—featuring a Non-Tie-Down cycle starting element and an interlocked, cylinder operated, gate guard—is applicable to positive type clutch presses single stroking at a speed of less than 100 strokes per minute. Clutch tripping and ram motion is accomplished only after the point of operation is completely enclosed by positioning of the gate guard. The operator must trip the manual start valves in unison and hold them until the gate guard is fully extended. When this point is reached, the press action becomes automatic.

Another all-air control circuit, with both Non-Tie-Down and Single-Stroke valves, can be used on positive type clutch presses cycling at a rate of 100 or more strokes per minute.

For presses with pneumatic clutches, still another all-air circuit can provide these major safety features—two hand tripping with a non-tie-down action—and automatic stopping of the ram if either hand is removed from the manual valves during the down stroke of the press. A 2-way cam

valve, operating from the press shaft, is used to interlock this circuit.

There are many different ways to air valve a press clutch or brake. Depending on the specific application, certain ways may be less hazardous than others. For the best in safety, other items, such as adequate guarding and interlocking, are very important and must also be given careful consideration.

OFF-THE-JOB ACCIDENTS

Statistics are such boresome things
And figures rather dull.
It's hundreds, millions, billions, trillions,
Over which we mull.

But facts are facts where ere we go
Regardless of amounts,
So here's some facts on accidents,
And that's what really counts.

It isn't always big machines
With blades of sharpened steel
That rob a man of arm or leg
And make his senses reel.

Nor is it always "on the job"
Most accidents take place,
But just the opposite is true
And figures prove our case.

It's carelessness in little things
At home and on the street
Neglect in moving objects small
Away from running feet.

A makeshift ladder, sliding rugs,
Electric cords that spark
A disregard for cellar stairs
And stumbling in the dark.

Crossing where no crossings are
While looking at the sky,
Driving on a slippery road
With milestones whizzing by.

These are the things that take a toll
We all should frown upon
So watch for them when off the job,
As well as when you're on.

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

THE MINING SECTION

This volume is a record of the sessions held at the 1957 National Safety Congress by the Mining Section. The conduct of these sessions is only one of the many cooperative activities which the Mining Section carries on in behalf of its members, and for the benefit of accident prevention work in the mining industry generally. The section gives guidance in the preparation of a great variety of technical and educational material useful in the day-to-day safety programs of mining companies.

The activities of the section are under the direction of its executive committee, the members of which are listed at the close of this volume.

SAFETY INCENTIVE AWARD SYSTEMS IN THE MINING INDUSTRY

by T. C. HECKER

safety engineer, the M. A. Hanna co., Iron River, Mich.

Safety award systems are the means of offering something tangible to employees. It is difficult for us to understand the intangible benefits derived from safety, but they far outweigh anything tangible. The intangible benefits are, for example, the morale of the employees, the increase in production, and the greater earnings of employees when lost-time accidents or injuries are reduced. The big problem is to stimulate awareness of safety and a safe attitude in employees. To do this, a safety award system is used because of its tangible benefits. However, it should be realized that a safety award cannot replace the constant effort of employees, foremen, and supervisory personnel in maintaining an interest in safety. It can be used only as an aid.

There are various types of safety awards. The yearly award is presented on a calendar-year basis for a no-lost-time accident or for achieving a predetermined frequency and severity and it builds a competitive spirit among groups or organizations. This is good. However, if the group or mine has an accident during the first of the year, there is a letdown because the men have two years to go before they can hope to receive an award.

The safety award that is presented only after a good record has been achieved does not seem to have a lasting effect. It is usually spontaneous and unexpected; in other words, it acts as a slap on the back. This type of an award, however, is good as a supplement to a regular award system.

The individual award or the award presented to an employee working a predetermined period without a lost-time accident is good and has brought about desired results in some organizations. This type of an award, however, stresses individual safety. If we are to be our "brother's keeper," we must have group safety and responsibility for others. Also, in the individual award, the injured employee suffers of hurt feelings when awards are issued. His accident may have been the fault of another employee or due to a condition beyond his control.

Monthly awards tend to keep safety interest alive throughout the year. This type of award can be supplemented with a yearly award. Economically, the monthly awards must be small if the program is to stay within reason. Sometimes the value of the monthly award is increased for a consecutive period. This award is good because employees' interest in safety—with a little additional urging—builds up after an injury occurs.

This type of an award was used by the M. A. Hanna Company in the Michigan District prior to 1952. But due to handling a great number of prizes and the feeling of not receiving the value per cost, it was decided to try a system or combination of systems—using the good points and eliminating the objectionable features of the monthly award system.

We tried a safety award system based on an accident-free period of three months. Each mine in the district would be eligible for a safety award when three calendar months had elapsed since the last lost-time accident. The value of the award would increase with each successive accident-free three-month period. It would become stable at the end of a year's time, or four awards, and continue at that value in each following three-month, accident-free period.

Because the number of employees varies at each mine, amount of the award was determined by setting up a hypothetical base mine employing 300 men. This base mine would receive an award valued at $3.00 for a three-month, accident-free period; $6.00 for a six-month period; $9.00 for a nine-month period; and $12.00 for twelve months with no lost-time accidents. If the mine went 15 months without a lost-time accident, the value would be $12.00.

If any accident resulting in lost time occurred, the mine would start over at the beginning of a three-month period. To com-

pute the value of an award, the average number of employees is multiplied by the period and again by $3.00 and divided by 300 (the exposure or number of men in the base mine).

$$\text{Cost of Award} = \frac{\text{Average number of men} \times \text{period} \times \$3.00}{300}$$

For example, if a mine which employs 239 men goes six months without a lost-time accident, each man would receive an award valued at $4.78. This is computed as follows:

$$\frac{239 \times 2 \times \$3.00}{300} = \$4.78$$

In a mine where only a small number of men were employed, the prize would be of much value, so a guarantee or minimum was set up. This guarantee provides a prize of 75 cents for three months, $1.50 for six months, $2.25 for nine months, and $3.00 for twelve months with no lost-time accidents. Either the guarantee or the result of the formula is used, depending on which one is higher.

After the value is determined, samples of five to seven prizes are sent to the mine for the men to choose. Greater interest was maintained when an employee had a choice rather than one item picked for the group. This entails more work at the mine office, but the results have been worthwhile. In offering a choice of prizes, one item is usually selected for hunting, fishing or some other sport. There is sometimes an item for children; another item for the home workshop; and one item for the home. This last type of award is valuable because it brings industrial safety into the home and to the employee's family. A wife can promote a safe attitude in a man if some of these awards are directed toward her. Some of the prizes—varying in cost—have been fishing reels, fishing rods, fishing creels, hunting jackets, wool shirts, camp stoves, small tricycles, saws, hammers, vises, clothes baskets, step ladder stools, and kitchen knife sets.

One aid we use in conjunction with this safety award system—and is considered very necessary—is a bulletin board showing the number of days worked since the last lost-time accident. This board is mounted in a place—usually the dry or the entrance of the shaft tunnel—where all the men can easily see daily how many days they have worked since the last lost-time accident. They will then go to work with safety in mind and a desire to extend the accident-free period.

Another aid is in our monthly safety inspections with the Union. After inspecting the mine and discussing safety recommendations with the mine supervisory personnel, the safety committee selects a development or stope contract for its good housekeeping. The men working in this contract are awarded a prize—which averages $2.00 in value and is usually a choice of a lunch bucket, jackknife or pocket watch—for having a clean and orderly working place.

We feel certain that the incentive safety system has done much to lower our frequency and create an interest among our employees in our safety program. Lowering the frequency will, in turn, help to lower the severity. It is true that this type of safety award system costs money. In a year's time, the 300-man base mine would earn prizes worth $9,000, but many claims managers or mine superintendents would be glad to have $9,000 as their total liability for a year without a day lost due to an accident. Because of the cost and the intangible benefits derived—such as a high morale among the men and an increase in production—most would welcome the chance.

Any safety award system is only a part of an accident prevention program and it requires the constant effort of employees, foremen, and supervisory personnel to maintain a good safety attitude.

SAFE USE OF DIESEL EQUIPMENT IN UNDERGROUND METAL MINES

by JOHN C. HOLTZ

chief, Diesel Test & Research Section, U. S. Dept. of Interior, Bureau of Mines, Pittsburgh, Pa.

Operators of mines became interested in internal-combustion engines as prime movers for underground mining equipment soon after such devices were invented.

When the Bureau of Mines was established in the United States Department of the Interior in 1910, gasoline engines were being used in mines and tunnels sometimes with fatal consequences. The hazards from these engines in underground service were:

1. Fire or explosion during the handling or use of liquid fuels.
2. Unhealthful conditions caused by the discharge of toxic and objectional constituents of the exhaust into the underground atmosphere.
3. Ignition of flammable atmospheres by the hot surfaces or the intake and exhaust openings of the engine and by its electrical equipment.

From practical experience with gasoline-powered equipment it became evident that these hazards were difficult to control. The exhaust gas contained high concentrations of toxic carbon monoxide which created dangerous local conditions, even when large volumes of air ventilated the mine. These conditions were recognized by state authorities, and most states developed laws or regulations that prohibited gasoline or other volatile fuels in mines except in very limited quantities and under careful supervision. Because of these conditions, gasoline-powered equipment has virtually disappeared from modern mines.

Modern high-speed diesel engines have the same flexibility as gasoline engines and are less hazardous when used underground. As a consequence, the number used in metal mines and tunnels is increasing rapidly. The Bureau began to evaluate their performance in mine service about 20 years ago. Both research and practical experience have shown that diesel engines are not safe in underground operations. However, with proper precautions and adequate ventilation they can be used safely. Although most states prohibit liquid fuels in mines, many permit diesel engines underground through special exemptions, provided that strict control regulations are followed.

Essentially the same hazards exist in mines using either diesel or gasoline engines. However, the less volatile fuel and less objectionable exhaust-gas characteristics of diesel engines, when properly adjusted, reduce the degree of hazard. Bureau of Mines Schedule 24 describes tests design characteristics, and other requirements for approval of diesel-powered equipment intended for application in metal and other noncoal mines and tunnels. The present discussion will consider the need for more important approval requirements, as well as other important practical precautions needed for the safe use of diesel equipment in underground metal mines.

CHARACTERISTICS OF DIESEL FUEL

An important factor in the safety of diesel engines in mines is the characteristics of the fuel. Diesel fuel is a petroleum distillate considerably less volatile than gasoline which has little tendency to form an explosive mixture with air at normal temperatures. To maintain this characteristic, the Bureau recommends that the flash point be 140° F. or higher. Otherwise, the fuel should conform to the engine manufacturer's recommended specifications, except the sulfur content should not exceed 0.5 per cent.

This restriction on sulfur controls concentration of the toxic sulfur oxides in exhaust gas and by this means restricts the concentration of these oxides in the mine atmosphere to safe hygienic limits when ventilation is satisfactory for other constituents of the exhaust. Therefore, this restriction on sulfur is an important part of the specifications for fuel.

All manufacturers recommend diesel fuel free from water, sediment, and dirt. Unless clean fuel is used in the engine, excessive maintenance and malfunctioning of the fuel-injection system can be expected. Badly worn or improperly functioning injection valves increase the hazards from objectionable and harmful constituents in the exhaust gas.

Although diesel fuel is less hazardous than gasoline, it is a flammable liquid and should be handled accordingly. Only limited amounts should be taken underground and stored in a well-ventilated location to restrict the flow of fuel if a container leaks or fails during a fire. Fuel tanks of mobile diesel machines should be filled only near this storage, when facilities to handle spillage are available. Firefighting equipment should be available nearby and on each diesel machine.

The advantages gained from less volatile fuel should not be sacrificed in the starting system for the engine. Electric or hydraulic starting should be used. Electric starting may be assisted by properly installed glow plugs, if necessary. Gasoline starting engines or other devices using volatile fuels are not accepted on approved equipment.

Undiluted exhaust gas from any internal-combustion engine is an unsatisfactory environment for workmen, and that from the diesel engine is no exception. Thus, a safe atmosphere in mines and tunnels can be maintained only when adequate positive ventilation is supplied to dilute and remove the exhaust gas and to maintain oxygen at a safe concentration.

DIESEL EXHAUST GAS

Evaluation of the health hazard involves determination of the concentrations of toxic and objectionable constituents in the exhaust. These constituents include carbon dioxide, carbon monoxide, aldehydes, oxides of sulfur (if the fuel contains sulfur), soot, and oxides of nitrogen. When the volume of these gases has been determined, safe ventilation can be calculated. From engine tests the operating conditions that produce the least quantity of some of the harmful gases can be specified.

At a given speed the normally aspirated diesel engine draws in an essentially constant charge of air. Various load conditions are met by changes in the quantity of fuel injected into this charge of air and ignited spontaneously. Thus, under mine conditions the composition of exhaust gas from mobile diesel machines is changing more or less constantly.

When the fuel : air ratio is below 0.06, the chief gases in the exhaust are carbon dioxide and oxygen, plus water vapor and nitrogen. The last two gases do not have harmful effects when the atmosphere contains enough oxygen. In this range of operation the concentration of carbon dioxide increases as the fuel : air ratio increases, while that of oxygen decreases.

Carbon monoxide is always present in low concentrations, and other products of incomplete combustion may be present in low concentrations, if at all. Engine speed has little effect on these general relationships. However, the volumes of these constituents in the exhaust will increase more or less in direct proportion to engine speed, and at higher engine speeds more ventilation will be needed to dilute and remove these products from the mine atmosphere.

Operation of diesel engines in the range of fuel : air ratios above 0.06 is considered undesirable in underground mines and was achieved in these tests by deliberately increasing the fuel-injection rate. In this range of fuel : air ratios, products of incomplete combustion appear in important concentrations, which increase as the fuel : air ratio increases. Thus, carbon monoxide, hydrogen, and methane increase in concentration while carbon dioxide achieves a maximum and then decreases. These changes in concentration occur because too little oxygen is available to burn the fuel completely. Another characteristic of operation in this range is a smoky exhaust from soot or unburned carbon.

These results show that diesel exhaust gas may contain dangerous concentrations of toxic carbon monoxide comparable with those in the exhaust of gasoline engines. Smoke will create safety problems by decreasing visibility, and the volume of air for safe ventilation must be increased. Therefore, diesel-powered equipment in mines should be adjusted to operate in the normal range of fuel : air ratios below 0.06, where hazards from toxic gases in the exhaust are reduced and the volume of ventilating air to remove exhaust gas from the mine is decreased.

In the normal operating range of fuel : air ratios diesel engines deliver power in almost direct proportion to fuel : air ratio. This direct proportion decreases, beginning at fuel : air ratios near 0.06; but maximum power is delivered at a fuel : air ratio of about 0.08, after which power decreases slowly. The change in fuel : air ratio from 0.06 to 0.08 increases power output about 10 per cent, whereas fuel consumption increases about 35 per cent. Thus the cost for fuel increases, while the hazards from toxic carbon monoxide become intolerable. Operation of diesel engines in mines within this range of adjustment must be avoided.

Even in the normal operating range the exhaust of diesel engines will contain low concentrations of carbon monoxide. Though low, these concentrations generally are greater than 0.01 per cent by volume, the accepted safe hygienic limit for exposure of workmen. Engine speed generally has less effect on the concentration of carbon monoxide than fuel : air ratio.

This relationship for other engines may be slightly different, depending upon the design of the combustion space and the fuel-injection nozzles. However, the concentration is nearly always less than 0.25 per cent in the normal operating range below 0.06 fuel : air ratio.

Because the concentration of carbon monoxide increases so rapidly at high fuel : air ratios, Schedule 24 specifies that diesel equipment be adjusted so the exhaust contains less than 0.25 per cent carbon monoxide. With this adjustment the ventilation of carbon monoxide presents no problem, as the volume of air required will be the same as that needed to dilute and remove the carbon dioxide from the mine.

ALDEHYDES

Odor and nasal and eye irritation of diesel exhaust gas appear related chiefly to the concentration of aldehydes. Observed concentrations are erratic, probably because of the heterogeneous nature of combustion in the diesel engine, and often are higher at low engine loads. In no instance during approval testing has the concentration of aldehydes been the controlling or critical factor in safe ventilation. That is, safe ventilation for some other constituent of the exhaust is always more than adequate to dilute the aldehydes to a safe hygienic concentration for exposure of workmen. Thus, in properly ventilated mines aldehydes are not a hazard from the viewpoint of their toxicity. In any event, they give ample warning of their presence by odor and nasal and eye irritation before the concentration reaches a toxic level.

OXIDES OF SULPHUR AND NITROGEN

Experiments with a high-sulfur fuel have shown that all of the sulfur appears in exhaust gas as sulfur dioxide or trioxide. The relationship of concentration to fuel : air ratio is similar to that for carbon dioxide in the normal operating range; that is, the concentration increases with fuel : air ratio. Hazards from these toxic and irritating oxides can be controlled most easily by limiting the sulfur in the fuel. When the sulfur content of the fuel is below 0.5 per cent by weight, ventilation to control other constituents of the exhaust will be sufficient to control the hazard from sulfur oxides. Fuels with higher concentrations of sulfur may cause hazardous and irritating conditions underground.

Toxic oxides of nitrogen are formed whenever air is heated to a high temperature. Consequently, these oxides are always present in diesel exhaust gas. Their concentration depends partly on the maximum temperature attained during the power stroke and partly on the concentration of oxygen when this temperature is reached. There is little evidence that the chemical composition of the fuel has any important effect on their concentration; the combustion of fuel simply provides the high temperature necessary for their formation.

Two oxides of nitrogen are especially important—nitric oxide (NO) and nitrogen dioxide (NO_2). Initially nitric oxide is formed in the combustion chamber. Subsequently nitric oxide reacts with excess oxygen in the exhaust system of the engine or in the mine atmosphere to form nitrogen dioxide. Exposure to either oxide is hazardous, but the dioxide is more toxic and for safety must be diluted to a lower concentration.

Routine analytical methods are not available to determine each of these oxides, and

possibly others, in undiluted exhaust gas. Instead, the phenoldisulfonic acid method is used to determine all the oxides of nitrogen together, except nitrous oxide (N_2O). The results are calculated as equivalent nitrogen dioxide.

Although the maximum concentration of oxides in the exhaust of each engine is different, the variations in concentration are similar in many respects. Low concentrations are observed at low fuel : air ratios where the combustion temperature is relatively low. In each engine a maximum concentration is reached as the fuel : air ratio increases, after which the concentration decreases.

MINE ATMOSPHERES AND COMBUSTION

The maximum concentration generally occurs at a lower fuel : air ratio in engines with indirect-injection combustion systems and usually is lower than that formed in direct-injection combustion systems. However, the maximum concentration is an individual characteristic of each diesel engine and has been observed to range from 400 to 1,600 parts per million. In most engines the maximum concentration of oxides decreases slightly as the engine speed is increased.

Results of approval tests show that the safe ventilation rate for diesel engines is determined by the concentration of oxides of nitrogen in the exhaust, but the operating conditions that control ventilation are difficult to predict. For this and other reasons it appears undesirable to base practical mine ventilation on limited field tests of diesel equipment. In one instance, approval tests showed that safe ventilation was determined by the formation of oxides of nitrogen at part load and medium speed. It would have been difficult, if not impossible, to discover these conditions in field tests.

Discussion so far has been limited to the operation of diesel engines in normal air near sea level. However, in practical mines using diesel equipment the atmosphere always will contain low concentration of exhaust gas, and local areas may exist where contamination with similar blasting gases is relatively high. Similarly, combustible gas (usually methane) may seep into the mine atmosphere from underground formations. The presence of such contaminants in the intake air of diesel engines will alter the normal characteristics of the exhaust and may cause increased hazards.

Effects From Exhaust Gas

In mines the exhaust from mobile diesel equipment enters the mine atmosphere near the engine. Research has shown that exhaust gas recirculated into the intake air of diesel engines may cause undesirable changes in the composition of the exhaust. Chiefly the concentration of carbon monoxide is increased because the oxygen supplied to the engine is decreased and may cause an increased fuel : air ratio.

However, some carbon monoxide probably is formed by further reactions of the recirculated carbon dioxide. These effects can be extremely important and serious at low engine loads with high concentrations of exhaust gas in the intake, or at high engine loads with relatively low concentrations of exhaust gas in the intake. Under either condition the composition of exhaust gas can be nearly the same as when a diesel engine is operated normally at a high fuel : air ratio above the normal range.

When the ventilation rate is adequate to maintain the mine atmosphere safely, these effects have little practical significance. However, it is desirable to dilute the exhaust gas rapidly so that it cannot recirculate directly into the air intake of the engine. Furthermore, these undesirable effects may develop where ventilation is locally inadequate. Prolonged operation of diesel equipment in such an area causes hazardous conditions that become progressively worse and decidedly dangerous in a short time particularly if the engine is operating at a high load. Diesel engines should not be operated anywhere in mines unless ventilation is positive and adequate.

Effects From Gassy Atmospheres

Operation of diesel engines in a gassy atmosphere was simulated in laboratory tests by adding natural gas to the intake air. The concentrations of carbon monoxide, aldehydes, and oxides of nitrogen in the exhaust all increased more or less in proportion to the concentration of natural gas up to the lower explosive limit. These effects increase the hazards from toxic gases, even when the engine is operated in the normal range of fuel : air ratios.

Combustible gas in the intake air also supplies extra fuel to the engine. This effect raises the fuel : air ratio and at high loads may cause operation in the rich range where carbon monoxide is produced in large quantities. Thus, a serious hazard from toxic carbon monoxide could develop in metal mines where gas may be encountered inadvertently.

It also has been demonstrated in the laboratory that flammable atmospheres can be ignited by diesel engines with unprotected intake and exhaust systems. A full description of these experiments is beyond the scope of this discussion. Diesel equipment approved under Schedule 24 is intended for use only in nongassy mines and should not be operated where a flammable atmosphere may exist.

Ample ventilation obviously will reduce the possibility of serious effects from these sources.

MANIFOLD PRESSURE AND COMBUSTION

Metal mines often are at high altitudes, where low barometric pressure reduces the density and weight of air aspirated by diesel engines. Laboratory experiments simulating operation at a high altitude have shown that the normal relation of composition of exhaust gas and fuel : air ratio is unchanged. However, because the weight of air charge is lowered, the maximum fuel-injection rate must be decreased to prevent operation in the rich range of fuel : air ratios where excessive carbon monoxide is formed.

To maintain operation of the engine in the same desirable range of fuel : air ratios, the maximum fuel rate must be reduced in direct proportion to the barometric pressure. When the engine is so adjusted, the same volume of air will provide safe ventilation at any altitude. The safe-ventilation rate and the maximum fuel-injection rates at various altitudes are given in the caution statement that accompanies all approved diesel machines.

Conditions similar to those at high altitudes will develop whenever the flow of air in the intake system of a diesel engine is restricted. An obvious cause for such a condition is a dirty air cleaner. For this reason, oil-bath air cleaners rather than dry-air filters are required on approved diesel equipment. The maintenance schedule should include regular measurement of the pressure drop in the intake system, as well as periodic cleaning of the air cleaner. The caution statement for approved equipment recommends the maximum pressure drop in the intake manifold for safe operation. Usually this pressure drop is reported for full-throttle, no-load operation, a condition that can be reproduced readily in the field.

Other tests showed that back pressure in the exhaust system, within reasonable limits, had no important effect on combustion in a four-cycle diesel engine. The caution statement also includes a maximum back pressure, which, if exceeded, signals the need for cleaning the exhaust system. Tests have not been made to determine the effect of back pressure on a two-cycle engine. In this instance, back pressure may have a more important effect on combustion because the flow of scavenging air, and hence the fuel : air ratio during the combustion process, would be affected.

Supercharging and turbocharging are two relatively recent developments in diesel-engine design that affect manifold pressure. Each system increases the air pressure in the intake manifold and thereby the weight of air available for combustion. Thus the power output of the engine can be increased by increasing the maximum fuel-injection rate without causing undesirable combustion effects with respect to carbon monoxide in the exhaust.

However, failure of either system to supply extra air to the intake of the engine may cause combustion at high fuel : air ratios, with resulting high concentration of carbon monoxide, as well as smoke, in the exhaust at high loads. Failure of such a system on diesel mine equipment is cause for removing the equipment from underground service immediately. Preventative maintenance on such equipment should include frequent tests for tightness of the intake manifold system.

Although most constituents of exhaust gas from supercharged or turbocharged diesel engines vary with fuel : air ratio in the same manner as in normally aspirated engines, the concentration of oxides of nitrogen appears to be an exception. The results of a few tests have suggested that the increased air pressure causes an increase in concentration of oxides of nitrogen at higher loads.

This effect may require that the safe ventilation rate be increased more than in direct proportion to the increased maximum fuel rate.

Approved diesel machines for mines must be equipped with an exhaust-gas cooling system capable of reducing the temperature to 160° F. under any condition of operation. So far, all satisfactory conditioners utilize the principle of adiabatic saturation of the exhaust gas with water vapor. The hot exhaust gas is bubbled through water to obtain the contact area necessary for rapid evaporation of water and cooling of the exhaust. This design suggests that conditioners also may act as scrubbers to remove some of the objectionable and harmful constituents from the exhaust gas. Both aspects of conditioner performance will be considered.

Conditioners as Coolers

Bubbling-type conditioners cool the hot exhaust gas by transforming its sensible heat into latent heat of evaporated water and thus lower the temperature of the final exhaust. In this process sparks will be quenched, and some of the soot that is a normal constituent of diesel exhaust gas at high engine loads will be removed.

Efficient conditioners may be either a batch type, operating with a variable water level, or a constant-level type, controlled by a float valve supplied with water from a makeup tank. In either type under equilibrium conditions the temperature of the water and cooled gas will be saturated with water vapor. The cooling system on approved diesel equipment is designed to need refilling only after use for an 8-hour shift. Either type of conditioner requires essentially the same amount of available water for the same cooling action.

Conditioners of this type cannot be designed to cool exhaust gas to a predetermined low temperature, because the minimum temperature must be high enough for the cooled gas to remove the evaporated water as vapor. The temperature of the cooled gas is related chiefly to the temperature of the hot gas when it makes contact with the water. However, the fuel:air ratio at which the engine is operating, the humidity of the intake air, and the barometric pressure all have perceptible effects.

When these conditions are known, the temperature of the cooled gas can be calculated. On approved diesel equipment the temperature of the cooled gas will not exceed 160° F. at full load. Within reasonable limits, the volume of hot exhaust gas flowing through a well-designed conditioner has no effect on the temperature of the cooled gas. The weight of water evaporated is directly proportional to the gas-flow rate.

In practical cooling systems the hot exhaust gas loses some heat by radiation and convection as it flows to the conditioner. This desirable effect reduces the temperature of the cooled gas and decreases the water needed for cooling. However, it may be offset by spray loss in the cooled exhaust. Therefore, conditioners for approved diesel equipment are tested to determine the actual water loss when the engine is operated at full load.

The actual and calculated water loss must agree within about 15 per cent. Approved equipment must have an effective cooling-water supply equal to one-third that required for continuous operation of the engine at full speed and load for eight hours. These tests are made at an elevation of 1,000 feet, and the water requirement so determined is more than adequate when properly adjusted, approved diesel machines are operated at higher altitudes.

Conditioners as Scrubbers

Bureau experiments have not verified the popular impression that conditioners remove most of the toxic and objectionable constituents in diesel exhaust gas. Practical conditioners filled with water have a significant effect only in removing aldehydes. Up to 50 per cent of the aldehydes may be removed by simple solution in water, but the solubility decreases at the higher water temperatures associated with operation of the engine at higher loads.

The solubility effect also diminishes as the water becomes more nearly saturated with dissolved aldehydes and increased water temperature may release dissolved aldehydes into the final exhaust. Other observations indicate that there are similar but less pronounced solubility effects on acid gases sufficient to cause corrosion that is eliminated when conditioners are constructed of stainless steel.

Many other experiments have been made on practical conditioners filled with aqueous chemical solutions. Such solutions maintain the cooling action, but only one solution has a significant effect in removing objectionable constituents of exhaust gas. A 10 per cent aqueous solution of sodium sulfite inhibited with 0.5 per cent hydroquinone to prevent rapid oxidation of the sulfite will absorb all the aldehydes and eliminate the odor and irritation of diesel exhaust gas. This effect is not dependent on the design of the conditioner as long as it will cool exhaust gas efficiently.

Caution should be exercised in the practical use of sodium sulfite solutions. In batch-type conditioners evaporation of the water may concentrate the solution and cause precipitation of salts. Ultimately such action may block gas passage in the conditioner. This effect was not observed in the laboratory, where the operating level was maintained by the constant addition of makeup water.

Many other full-scale experiments have been made in a search for solutions effective in removing other constituents of diesel exhaust gas, particularly oxides of nitrogen. So far no solution has enough effectiveness to recommend its practical use. Small-scale tests have been somewhat more encouraging. However, the most effective solutions either lost their activity at temperatures expected in practical conditioners, required multiple absorption units, or were hazardous to handle.

At least one dry-type exhaust-gas conditioner is available commercially that will eliminate most of the carbon monoxide from diesel exhaust gas, if it is maintained at a suitable temperature. No claims appear to have been made for the effectiveness of this device with respect to its action on other toxic constituents of exhaust gas. Unless this device has similar effects on carbon dioxide and oxides of nitrogen, it will be ineffective in reducing the volume of air for safe ventilation of diesel engines in mines. If for no other reason, mines using diesel engines must be ventilated to replace the oxygen used in the combustion process.

Earlier considerations have shown that toxic constituents in the mine atmosphere may be increased when exhaust gas is aspirated into the air-intake system of a diesel engine. To avoid this effect, as well as exposure of miners to undiluted exhaust gas, Schedule 24 specifies that the exhaust gas must be diluted before it enters the mine atmosphere. A very effective means of accomplishing this is release of the exhaust gas into the air from the radiator. A well-designed dilution system can reduce the concentrations of exhaust-gas constituents to nontoxic levels before the diluted gas reaches the mine atmosphere near the machine.

The most rapid mixing of exhaust gas with radiator air is when the gas is released through small holes in a multiported pipe or through a narrow slot. The gas outlet should be placed as close as practicable to the fan and arranged to distribute the exhaust uniformly in the air stream. The diameter of the holes or width of slot should be as small as possible, because the size of the opening affects the distance in which mixing is completed.

Secondary turbulence also is a factor in rapid and complete mixing within a short distance. With a well-designed dilution system there is little possibility that exhaust gas will reach the breathing level of miners or the air intake of the engine in undesirable concentrations.

DILUTION OF EXHAUST GAS

Need for an exhaust-gas dilution system is suggested also by recent developments about the physiological effects of oxides of nitrogen. New information on the toxicity of nitrogen dioxide recommends that the former hygenic limit of 25 p.p.m. for total oxides of nitrogen be changed to five p.p.m. of nitrogen dioxide. Safe ventilation in metal mines is frequently determined from the concentration of oxides of nitrogen in diesel exhaust, and it is important to consider the effect of this change on ventilation requirements.

Chemical and kinetic studies show that nitric oxide (NO) is formed during combustion in the diesel engine. As the exhaust cools, this oxide reacts with oxygen to form nitrogen dioxide (NO_2). The reaction probably begins in the exhaust system of the engine and continues in the mine atmosphere. The rate of reaction is a function chiefly of the concentration of nitric oxide; and, when its concentration is reduced to 25

p.p.m., the formation of nitrogen dioxide is greatly retarded.

Tests of diluted exhaust gas flowing from well-designed dilution systems suggest that there will be few instances where the concentration of nitrogen dioxide exceeds five p.p.m. before further dilution takes place in the mine atmosphere. Thus an exhaust-gas-dilution system is desirable on all diesel equipment used in mines. When such dilution is practiced, the present method for calculating safe ventilation is satisfactory.

SAFE VENTILATION

Information on the composition of exhaust gas makes it clear that positive ventilation must be supplied in mines using diesel equipment (1) to dilute and remove the exhaust gas and (2) to maintain a safe concentration of oxygen. The rate of ventilation for this purpose may be calculated from the results of comprehensive engine tests. Details of the calculations have been reported elsewhere. They involve the volume of exhaust gas generated in a given time, the concentrations of harmful constituents, and the safe hygienic limits of the harmful constituents. From these data the volume of air necessary to dilute the exhaust gas adequately to a condition safe for the exposure of miners can be calculated.

On the basis of physiological effects and quantity in exhaust gas, the important harmful constituents are carbon dioxide, carbon monoxide, and oxides of nitrogen. The generally accepted safe hygienic concentrations for these gases are: Carbon dioxide, 0.5 per cent; carbon monoxide, 0.01 per cent; and oxides of nitrogen (calculated as equivalent nitrogen dioxide), 0.0025 per cent.

The quantity of normal air necessary to dilute a particular constituent of exhaust gas to the safe hygenic concentration can be determined with close approximation from the relation:

$$Q = V \times \frac{C}{y};$$

in which—

- Q = the volume of normal air required for ventilation (cubic feet per minute),
- V = the volume of exhaust gas produced by the engine (cubic feet per minute),
- C = the concentration in the exhaust gas of the particular toxic constituent under consideration (per cent by volume), and
- y = the safe hygienic concentration for the particular toxic constituent under consideration (per cent by volume).

The values of V and C are determined from the engine tests. Results from several operating conditions must be explored to determine which condition and which toxic constituent requires the greatest volume of normal air to dilute it to the hygenic concentration. The maximum volume determined anywhere in the operating range of the engine is multiplied by a safety factor of two to find the safe ventilation rate in mines.

The safety factor of two is used to allow for possible physiological effects of mixed gases. The safe hygienic concentrations of various gases were determined for exposure when only that particular gas was present. Experience with disasters and air pollution in industrial areas during static atmospheric conditions suggests that these concentrations should be reduced when several toxic or harmful gases are present simultaneously.

Investigation after the Donora disaster indicated that no one known constituent in the static atmosphere reached or exceeded the generally accepted safe hygienic concentration. The exceptionally high number of deaths after exposure to the atmospheric environment for several days suggests that effects from mixtures of harmful gases may be additive or cumulative. The safety factor of two will be helpful in eliminating possibly delayed effects where miners are exposed to similar mixed gases daily.

In the foregoing discussion of safe ventilation, certain objectionable constituents of the exhaust gas were not considered. This procedure is possible because of certain interrelationships between the constituents of exhaust gas and other experience from engine tests. For example, carbon dioxide is one of the constituents that uses oxygen in its formation during combustion. With normal fuels it is possible to show that safe ventilation for carbon dioxide will supply enough air to maintain a safe concentration of oxygen in the mine atmosphere.

Sulfur oxides are controlled by limiting the sulfur content of the fuel to 0.5 per cent. With this limitation, ventilation for carbon dioxide also will be adequate for sulfur oxides. With respect to aldehydes, experience in approval investigations shows that safe ventilation for other constituents of exhaust gas is always more than sufficient for aldehydes. In any event, odor and irritation from aldehydes give considerable warning of their presence before dangerous concentrations are reached.

Although general relationships between the constituents of exhaust gas can be predicted, others are variable for each individual diesel engine. Consequently, it has not been possible to develop accurate empirical relationships for calculating safe ventilation. Most frequently, safe ventilation must be based on the concentration of oxides of nitrogen in the exhaust. In a few instances the maximum ventilation required for either carbon dioxide or carbon monoxide. For these and other reasons no diesel engine should be placed in underground service until engine tests have been made from which safe ventilation can be calculated.

Some time ago it was suggested that 75 cubic feet per minute per brake-horsepower at maximum speed and load was enough ventilation for diesel engines in mines. Since then, more experience with a larger number of engines has indicated that safe ventilation on this basis ranges from 100 to 250 c.f.m per b.-hp. Because so many factors affect the ventilation of diesel engines in mines, prediction of safe ventilation from a simple empirical relationship seems impractical, if not dangerous in some instances.

EFFECTS OF VENTILATION

The rate of ventilation specified for approved diesel equipment will maintain satisfactory mine-air conditions under any condition of operation of the equipment, if the engine is adjusted as specified and the air for ventilation reaches the place where the engine is operating. Obviously there will be times when the ventilation appears excessive. For example, when a diesel engine is idling, less exhaust gas is delivered into the mine atmosphere than when it is under load at a higher speed.

The exhaust of many diesel engines may contain a higher concentration of aldehydes when idling; and odor near the equipment may be more noticeable, even though the condisioner water is cooler and should dissolve more aldehydes. For this and other reasons it is recommended that the engine be shut off when diesel equipment is idle.

Ventilation also may seem excessive at times in haulageways. When a diesel locomotive or other haulage equipment travels opposite to the direction of air flow or exceeds the air velocity in the same direction, the effect for a single trip may be the same as though the locomotive were running through fresh air excessive to normal ventilation requirements. However, during cyclic operations the equipment will pass repeatedly through previously contaminated air and ultimately will cause local areas to become hygienically unsafe, unless the overall rate of ventilation is satisfactory. In one instance involving haulage with less than approved ventilation, periodic tests showed that contamination of the air reaching a loading station increased as time passed and occasionally was somewhat excessive by approval standards.

Observations at another mine showed insufficient ventilation by approval standards, but fresh air reached the loading station. Thus the only exposed workmen were the trainmen on a moving trip. Fortunately, the normal cycle of operations involved travel outside the mine portal, so that contamination in the haulageway was less than might otherwise be expected.

In contrast to these examples, areas of excessive local contamination might develop in small haulageways from the ram effect of moving diesel equipment or in very large rooms where ventilation could bypass the immediate location of the machine. An adequate dilution system for the exhaust gas tends to counteract such possibilities.

Reports on practical mining conditions indicate that diesel equipment often is operated in dead ends with little or no ventilation. Simple calculating shows that operation of a 50-horsepower engine at full load in a 10- by 10- by 50-foot entry without ventilation can produce undesirable hygienic conditions in two or three minutes.

In a few minutes more, the nearby mine atmosphere will become decidedly more dangerous because of oxygen depletion and a progressively rapid increase in the genera-

tion of carbon monoxide. Hence, operation of diesel equipment where ventilation is inadequate should be discouraged vigorously. All diesel equipment should be shut down immediately when positive ventilation is interrupted for any reason.

It is self evident that safe ventilation for several pieces of diesel equipment is an additive function of the requirements of each and should be provided in addition to ventilation required for other purposes. It is conceded, however, that, when several diesel units are operated in the same mine, this additive requirement may be relaxed to some extent, if each operates on a different load pattern. Any such relaxation can be decided only after a careful survey and study of individual mines.

MAINTENANCE OF DIESELS

So far the Bureau has had little opportunity to make a carefully planned study of requirements in diesel-engine maintenance. Much more experience is needed before a fully reliable discussion of the many aspects of satisfactory maintenance can be presented. Nevertheless, some interesting information has been accumulated.

Obviously, fuel injection may have an important effect on combustion. Bureau of Mines laboratory tests have shown that identical injection valves in proper mechanical condition and adjustment can be used interchangeably without causing a significant change in composition of exhaust gas. Also, the opening pressure of spring-loaded injection valves in indirect-injection engines could be varied within reasonable limits without producing a significant change in the concentrations of toxic constituents.

In two indirect-injection engines, leaking injection valves caused only a slight increase in the concentrations of carbon monoxide and aldehydes. In one instance, only one injection valve was leaking, while in the other all four valves were leaking. This condition would increase the hazard from diesel engines in working mines, and conditions that might cause such leakage should be avoided. Among other precautions only clean fuel should be provided; and the fuel system, particularly the filters, should be well maintained.

Only limited experience is available that indicates similar effects from injector condition in direct-injection combustion systems. Injectors for these systems usually have multiported tips that direct the distribution of fuel in the combustion chamber. A stoppage or excessive wear in one or more of these ports would cause a change in fuel distribution and probably an undesirable change in the composition of exhaust gas.

In maintenance operations imperfect injectors should be replaced only with perfect ones of the same design. One instance has been observed where a change in injector-nozzle design caused a substantial increase in the concentration of oxides of nitrogen in the exhaust, although the power performance was not affected. This change in the exhaust gas necessitated an increase in the ventilation rate needed for mine applications. This experience emphasizes the importance of engine tests before diesel equipment is used underground, as well as the danger of permitting changes in the design of engine components without additional tests.

Some interesting practical results have been reported in England, where the performance of diesel locomotives in coal mines was observed carefully for about two years. At "full" load, pulling a train upgrade, the carbon monoxide in the exhaust increased with time or mileage in service and eventually exceeded the statutory limit of 0.2 per cent. In one instance the concentration of carbon monoxide after 10,000 miles of travel had increased to about 0.4 per cent. No similar increase was observed for "racing" or "idling" when considerable excess air is present during combustion. A major overhaul invariably restored the original desirable performance under "full" load. Other results showed no increased hazard from oxides of nitrogen under these conditions.

PROBLEMS IN FIELD TESTING

Results also were reported on the performance of new and used engines in laboratory tests. Used engines produced more carbon monoxide but less oxides of nitrogen.

Many states have control regulations requiring that diesel equipment be adjusted suitably to avoid high concentrations of carbon monoxide in the exhaust before it is placed in service underground. Specific directions for these tests are seldom, if ever, included in the regulations, but the implication is frequent that they may be made in the field. Hence, some consideration of problems in field testing may be pertinent to this discussion.

Diesel engines in good mechanical condition usually generate excessive carbon monoxide only at high loads when the maximum fuel injection rate is used. Such conditions may occur during rapid, prolonged acceleration, as on a long upgrade. To be most informative, samples should be taken during constant conditions, which are difficult to maintain with the equipment in motion. Furthermore, sampling of moving equipment may be dangerous. However, if the exhaust shows black smoke under such conditions, it is an almost certain indication that the engine is adjusted improperly for mine service.

When engines transmit power through a torque converter, the equivalent of full-load combustion performance can be obtained by running the engine at full throttle with the output shaft of the torque converter locked. Although the engine is operating at an intermediate speed, the composition of exhaust gas is nearly the same as at full load and speed though the volume of exhaust is considerably less. Again, a smoky exhaust indicates improper fuel adjustment for underground service. During such tests the diesel equipment must be anchored so that it cannot run away, and the operating time must be short to avoid excessive overheating of the oil in the torque converter. The sampling procedures must be well-planned and executed quickly.

Interpretation of analytical results is not always easy, either. Samples have been received at the Bureau marked "full" load, but the analysis shows three per cent carbon dioxide and about 200 p.p.m. oxides of nitrogen. Obviously the engine probably was operating at full throttle, no load, and the results suggest that very little carbon monoxide should be expected. Such a sample gives no information about conditions that may be critical with respect to either carbon monoxide or oxides of nitrogen. For example, the maximum concentration of oxides of nitrogen in the exhaust of indirect-injection diesel engines is usually observed at an intermediate load at any speed. Such a load cannot be predicted precisely or attained easily in field tests.

Such practical difficulties are the reasons why the Bureau recommends that only approved diesel-powered equipment be used in metal mines and tunnels. Engine tests during approval investigations examine performance throughout the possible operating range. Safe ventilation is then calculated from results at the most hazardous operating condition. Equally reliable results cannot be developed from field tests.

Considerable care must be exercised in evaluating field performance through the use of portable instruments. For example, the Bureau of Standards carbon monoxide detector is used frequently to indicate carbon monoxide. The indicator tube shows a green or blue-green color related to the concentration of carbon monoxide, provided interfering gases are absent. Unsaturated-hydrocarbon gases may intensify the color, but oxides of nitrogen bleach it. Qualitative tests of undiluted exhaust gas may show no color, even though carbon monoxide is present, because of the strong bleaching action of oxides of nitrogen.

Such an obviously incorrect result can be improved by first passing the sample through a filter containing specially treated charcoal. Later a few tests were made on diluted diesel exhaust gas with the filter in place. Results showing seemingly reliable and uniform coloring of the indicator were interspersed with other determinations showing intense local coloration on the inlet end. Obviously such results must be interpreted with considerable care. Furthermore, the sampling period with this instrument is about 45 seconds, so that some judgment must be used to decide whether uniform conditions prevailed at the location for sampling.

Care must be taken also to select reliable locations for sampling in evaluating practical mine atmospheres. Samples showing little or no contamination must be interpreted with caution, as such results may be inconsistent with the ventilation rate. Such results suggest that some nearby area is excessively contaminated. Sometimes the analytical results and other observations may suggest that contamination came from blasting gases rather than diesel exhaust gas as these gases are frequently similar in composition.

ADVANTAGES OF APPROVAL

Approval investigations are undertaken only after formal application for the investigation by the manufacturer of diesel equipment. The application must be accompanied by the fees for the work to be done. These fees are placed in an escrow account until the work is completed. A subassembly, including the engine and conditioner, must be submitted to the Bureau laboratory near Pittsburgh for complete tests. Later a complete machine must be available for final inspection and tests of the exhaust-gas dilution system.

Upon satisfactory completion of all tests and inspections, the machine must be completely identified by drawings, bills of materials, and specifications for the Bureau's records. Only then does the Bureau issue approval papers to the applicant and announce that approval has been granted. Approval entitles the manufacturer to identify the equipment with an approval plate signifying that is is constructed in accord with the records filed at the Bureau. This plate shows the model number of the machine, its serial number, the approval number, and the minimum ventilation rate for safe operation of the equipment in underground mines.

All records and test results of the Bureau are confidential, and such information is appropriately safeguarded against disclosure. Detailed results of satisfactory tests are available only to the Bureau's engineers and not released to the applicant or any others. Unsatisfactory results are disclosed to the applicant as a guide in correcting defects. Approvals of diesel equipment are issued only by the Branch of Electrical-Mechanical Testing at Pittsburgh.

Several advantages of approved diesel-powered equipment in underground metal mines and tunnels are:

1. The exhaust-gas composition is suitable for the use of the diesel-powered machine underground when the engine is in proper mechanical condition and adjusted to the maximum rate specified in the approval papers.

2. The conditioner has been tested in a subassembly with the engine and will cool the exhaust gas satisfactorily for an eight hour shift without replenishment of the water supply.

3. Exhaust gas is discharged into the mine atmosphere through a dilution system that greatly reduces the possibility of local areas where dangerous concentrations of harmful gases may exist.

4. The ventilation rate has been determined from engine performance tests and is ample to dilute and remove the exhaust gas from the mine and to maintain a safe concentration of oxygen in the mine atmosphere under any approved condition of engine operation.

5. The caution statement provides information for satisfactory adjustment of the maximum fuel rate of the engine for safe operation at any altitude, with the approved ventilation rate as well as recommendations for satisfactory maintenance and suitable repairs.

6. Fuel-metering and governor adjustments are sealed, so that tampering by unauthorized personnel can be readily detected.

7. A fuel-shutoff valve is provided for emergency use.

8. The electrical system has been inspected for safe construction and operation.

9. A fire extinguisher is available for prompt use in an emergency.

10. The manufacturer understands his responsibility to construct approved equipment in accord with record drawings and specifications and maintains inspection records to show that this responsibility has been recognized and applied.

The provisions of Schedule 24 are not intended as a static and questionable limitation on the use of diesel-powered equipment in underground metal mines and tunnels. Instead, these requirements should be accepted as effective aids and guides in the safe use of such equipment. Furthermore, the history of the Bureau's administration of similar schedules for other specialized mining equipment should make it evident that all schedules are guides in underground safety that recognize the dynamic forces in the American mining industry.

CONCLUSIONS

Diesel-powered equipment can be operated safely in underground metal mines and tunnels only when adequate, positive ventilation is supplied to dilute and remove the exhaust gas from the mine and to maintain a safe concentration of oxygen in the mine atmosphere. The concentration of toxic and objectionable constituents in diesel exhaust gas is related chiefly to the fuel : air ratio at which the engine is operated. The maximum fuel-injection rate must be controlled and restricted to avoid the production of excessive quantities of carbon monoxide. Such an adjustment does not restrict unduly the maximum power output of the diesel engine but allows its use underground with a relatively reasonable ventilation rate. In approval investigations, engine tests are made to determine the exhaust-gas characteristics and to obtain performance data from which a safe ventilation rate can be calculated. A safe ventilation rate cannot be predicted with assurance from any general empirical relationship, chiefly because the generation of oxides of nitrogen appears to be an individual characteristic of diesel engines.

Odor and eye and nasal irritation of diesel exhaust gas appear to be caused chiefly by aldehydes. They reduced to a safe concentration in the mine atmosphere when adequate ventilation is provided for other constituents of diesel exhaust gas.

Toxicity and irritation from sulfur oxides in diesel exhaust gas are controlled by restricting the sulfur content of the fuel to a maximum of 0.5 per cent.

Conditioners are used on diesel equipment to cool the hot exhaust gas. Cooling is accomplished usually by adiabatic saturation with water as the hot gas is bubbled through water. This action will dissolve some of the aldehydes in exhaust gas but has no important effect on other constituents or on the volume of air required for safe ventilation. Effective sustained removal of aldehydes can be obtained when water in exhaust-gas conditioners is replaced by a sodium sulfite solution inhibited against oxidation with hydroquinone.

Otherwise no practical solutions are known to be highly effective in removing other toxic or objectionable constituents of exhaust gas. So far no exhaust-gas conditioning device has been developed that by its action on exhaust gas will allow an important reduction in volume of air needed for safe ventilation of diesel equipment in underground metal mines or tunnels.

A well-designed exhaust-gas dilution system reduces substantially the dangers from local areas highly contaminated with exhaust gas, as well as the increased hazards that may develop when exhaust gas is recirculated in the intake system of a diesel engine. Rapid dilution of exhaust gas also decreases possible hazards from formation of nitrogen dioxide in the mine atmosphere.

Approved diesel-powered machines are tested to determine exhaust-gas characteristics throughout their load range and are equipped with a satisfactory exhaust-gas conditioner and dilution system. The ventilation rate specified in the approval papers is safe for any condition of operation, provided only that the maximum fuel-injection rate is adjusted according to the caution statement for the altitude at which the diesel machine is being operated.

An approval plate on a diesel-powered machine shows that it has been constructed in accordance with record drawings and specifications on file at the Bureau of Mines by a manufacturer who must maintain inspection records to show that his responsibility for constructing an approved machine has been recognized and applied.

INCENTIVE AWARDS FOR GOOD SAFETY RECORDS IN THE MINING INDUSTRY

by JOHN McKENNA SMITH
safety engineer, Asbestos Corporation Limited, Thetford Mines, Quebec, Canada

This paper deals with the application of safety incentives at Asbestos Corporation Limited in Thetford Mines, Quebec. Awards for safety achievments have been used by this company for the past six years. This period compared to an equivalent period before the award program shows the accident experience has improved appreciably.

To attribute the improved experience solely to safety incentives would be incorrect because supervisory training and revised and improved methods have helped our accident prevention program. Nevertheless, no single feature has been more instrumental in making our workers safety conscious than safety incentives.

Asbestos Corporation Limited is engaged in the mining and milling of asbestos ores in the Thetford Mines—Black Lake district of Quebec. Some 2,000 men are employed, operating three plants with a large expansion program in progress at one of them. Each plant consists of a mine, a mill, maintenance shops and facilities for the storage and shipping of bagged asbestos.

INCENTIVE PLAN

Six years ago the safety department of Asbestos Corporation Limited examined several plans to improve the safety record of the company. If accident prevention could be constantly before the worker, the accident frequency and severity would decrease. This would lower the compensation rate, since this company operates on a merit rating basis within the rate structure set by the Quebec Workmen's Compensation Commission for the Quebec Asbestos Mining Association.

A safety incentive plan was proposed to management based on the following principles:

1. The goals for safety awards should be realistic and possible to attain by any group which would pay particular attention to accident prevention.
2. The employees should know their standing during the time the plan is in operation.
3. The awards or incentives should be distributed to as many employees as possible.
4. One group of employees should not be penalized for the poor performance of another group.
5. Tangible prizes are better than monetary awards.
6. The safety incentive plan must be understood by all employees.

Management accepted a safety incentive plan based on these principles, and it began on November 1st, 1951. It is still in operation.

I will elaborate on each principle and show how these principles were applied by our company. The success of the plan is due to strict adherence to the basic principles.

GOALS EASY TO ATTAIN

Before proposing any safety incentive plan, it is advisable to review the past experience of the company and of other organizations in the same industry. This review or survey will guide in setting objectives for safety awards.

It would indeed be unrealistic to base objectives on a yearly frequency of five lost time accidents per million man hours of exposure when your best previous frequency has been 20 and that of the industry 12. In other words examine your records and set your objectives so they may be reached by extra effort in the field of accident prevention. Do not expect miracles and do not set the objectives so high the employees will feel they cannot attain these objectives.

At Asbestos Corporation Limited, our survey of past experience and local conditions indicated that consecutive man-shifts worked without a lost time accident would be the best basis on which to make awards. This basis had several advantages, among which were:

a. Within our reporting or labor accounting set-up, this figure could be easily reported by the timekeeping departments daily.
b. If a lost time accident occurs on any day during the month, it is not necessary to wait until a new period before another no-accident record can start.

The objectives were set so that once the first was reached, the group continued to amass consecutive shifts since the last lost time accident. When the second or third objectives are reached, awards of greater value are distributed.

To be more specific, groups or plant divisions are awarded safety incentives after 10,000, 25,000 and 50,000 shifts without a lost time accident. The value of the award at 25,000 shifts is approximately two and one-half times the value at 10,000 shifts although only 15,000 consecutive shifts have been added to the total.

EMPLOYEES KNOW WHERE THEY STAND

The employees should know their relation to the objective when the plan is in operation.

This principle is extremely important in any work where an objective is being attained. Everyone is familiar with the thermometer chart used in charitable campaigns and war bond drives. For the safety incentive plan at Asbestos Corporation Limited, bulletin boards at the plant entrances or in the punch clock rooms, showed the number of consecutive man-shifts worked since the last lost time accident for each group operating as a unit. These boards are kept up-to-date daily by the timekeeping department at the plant.

MANY AWARD WINNERS

The awards or incentives should be distributed to as many employees as possible.

Several plans operate with the supervisory employees rewarded for safety records established by their workers. Other plans allow so many awards per department or per 100 employees. We distribute awards to each employee of the department or plant division eligible under the plan. The cost and selection of awards will be explained later in this paper.

By every employee receiving an award we are eliminating two employee oppositions to an incentive plan:

a. They feel they work to establish the safety record and then the supervisor receives the reward.
b. Many feel if their names were placed in a box and one name drawn for a safety award, their name would certainly not be drawn. In other words, they are just not lucky in lotteries.

All production and maintenance employees, the plant supervisory and clerical staff, and watchmen are eligible for safety awards. Head office staff, laboratory employees and a group at our non-operating properties are not included in the plan.

One group of employees should not be penalized for the poor performance of another group.

When setting up a safety incentive plan based on group incentives, have groups or units of employees who do the same work. The groups should not be too large. Too many employees might be penalized for the poor safety performance of a small proportion of the group. Since this is a group effort, it requires good teamwork and it is amazing to see how older employees advise new men on unsafe manner.

The breakdown of each plant for the safety incentive plan followed the main working divisions: i.e., mine, mill, shops or maintenance, and general or yard labor. Each group is a unit which operates independently in the plan. If a lost time accident occurs in the mill, it does not affect the records of other groups.

The groups are not equal in size but by setting the objectives on the basis of consecutive man-shifts worked since the last lost time accident, the exposure to injury is equal for all groups.

The objectives are the same for all groups. There were several objections to this; many employees maintained their work was more hazardous and should therefore receive a handicap. Our experience however, has shown that the equal objectives for all groups were justified. This is a point to study carefully before an incentive plan is put into operation.

It is preferable to distribute useful items as safety awards than to give the equivalent in cash. Many companies distribute individual pins, or departmental trophies. This certainly advertises the accident prevention program but a pocket knife, wallet or some small tool is a constant reminder of accident prevention. The distribution of useful items has been quite popular among our employees.

The safety incentive plan must be understood by all employees. This basic principle applies to any incentive plan initiated and operated by a business organization. When the safety incentive plan began, notices were posted on all company bulletin boards explaining its operation. Meetings with supervisors illustrated in more detail just how the plan would work. When new employees are hired, the plan is explained in the pre-employment interview.

To recapitulate briefly the safety incentive plan of Asbestos Corporation Limited: Each operating plant is subdivided into four sections which operate independently in establishing safety records of consecutive man-shifts worked without a lost time accident. When one of the following objectives is reached, 10,000, 25,000, or 50,000 and so on in 25,000-shift increments, each employee is entitled to a safety award if he has worked at least 75 per cent of the time in that section during the period the record or objective was being established. If a lost time accident occurs in a section, the cumulated man-shifts drop to zero and a fresh start is made.

SELECTING AWARDS FOR SAFETY

The selection of suitable awards is important. When employees are eligible for awards, they are entitled to the choice of one of five or six items.

The system used by Asbestos Corporation Limited entails more work and possibly has some disadvantages but it is more acceptable to our employees. If we decided everyone was to receive a flashlight or a pen knife there would be many complaints about how many our men already had; therefore, it is wise to allow a choice of awards.

The decision of the five or six items is made along the following principle: two personal items, i.e., pocket knife, flashlight, lighter; two items for the home, i.e., Pyrex ware, table lighters, mixing bowls; two tools, i.e., hand axe, pliers, tapes.

To illustrate the range of awards distributed over the past five and a half years, the following list for each series of awards has been compiled:

First Award (10,000 shifts)

Mixing bowls, flashlights, table lighters, playing cards, ash trays, pipes, thermos bottles, wescot wrenches, combination squares, hammers, tinners' snips, hand axes, wrench sets, ball point pens and razors.

Second Award (25,000 shifts)

Steak knives, Silex coffee makers, billfolds, vises, can openers, casting rods, pipe wrenches, pocket watches, a cash allowance on a pair of safety shoes and First Aid kits.

Third Award (50,000 shifts)

This is reached on an average of once a year by one of the sections within the company. The awards consist of: safety footwear, flash camera, carving set, socket wrench set, aluminum chairs and in some cases, combinations of two 25,000 shift awards.

Fourth Award (75,000 shifts)

This mark has been reached once by one section. At the request of the majority of the employees in this section and with the approval of management, instead of increasing the value of the individual awards as we do for the first three objectives, each employee received an award in the 25,000 shift range and a drawing was made for two television sets, installed in the employees' homes complete with outdoor antenna.

Needless to say this created considerable interest in accident prevention throughout the company. The president, the general manager and other top company officials, were present for the drawing. The event was covered by the local press and some local correspondents for the Metropolitan dailies. When another group reaches the 75,000 shift mark a drawing for an expensive award will be made only if it is the expressed wish of the majority of employees of the section.

Anyone in accident prevention knows it is difficult to attribute improvement in safety experience to any one item. Asbestos Corporation Limited has been constantly changing and improving working methods, and has had an active supervisory training program during the past five years. I shall indicate the improvement in the safety experience since the inception of the safety incentive plan and point out some features which might be directly attributable to accident prevention awards.

Table I is a breakdown of our accident experience from 1947 through 1956. This period was chosen because it illustrates a period of five years, 1947 through 1951, prior to the introduction of the safety incentive plan and a five year period, 1952-56, that the plan has been in operation.

Tables II and III are a compilation and average of these two five-year periods.

These records indicate an improvement since the inception of the safety incentive plan. When the compensation cost plus the incentive cost for the 1952-56 period is compared to the compensation cost alone for the 1947-51 period, we find a yearly average saving of over $30,000, and this in a period when the compensation benefits as well as the wages were increasing.

A downward trend has started in the accident frequency, severity and costs when the incentive plan was introduced. However, it is quite definite that the introduction of safety awards accelerated the improvement in accident prevention.

One prominent feature after the initiation of safety incentives with the sharp reduction in lost time accidents involving one to three days lost time. When the employees realized that this was a "team" or group contest, everyone co-operated in not losing time for minor injuries, a practice prevalent in previous years.

The company encouraged employees to return to work by allowing them to relocate to a less arduous task for a short period of time if the work would have to be done during the course of operations.

The application of safety incentives at Asbestos Corporation Limited in Thetford Mines has achieved the results desired since the plan was formulate and introduced, i.e., an improvement in our safety record and a decrease in compensation costs.

Safety incentives when properly applied will produce the following results:

a. The workers will become more safety conscious.
b. The compensation costs will decrease.
c. Accident frequency and severity will improve.
d. Workers will accept the safety program more readily when they will realize that management is willing to compensate them for safety achievements.

TABLE I
ANALYSIS OF ACCIDENT EXPERIENCE, COMPENSATION AND SAFETY INCENTIVE COSTS, 1947-1956

Year	Lost Time Acc.	No Lost Time Accidents	Days Lost	Hours of Exposure	Frequency	Severity	Compensation Cost	Incentive Cost
1947	392	196	8,834	4,441,228	88.0	1988	$121,017	
1948	188	302	10,127	4,429,187	84.1	2150	22,615	
1949	207	158	12,322	3,742,108	82.8	4850	60,081	
1950	132	209	15,026	4,482,137	29.5	3409	102,686	
1951	94	215	1,802	4,361,790	20.8	367	22,914	
1952	54	139	8,482	4,142,227	13.1	2055	22,172	$ 2,855
1953	40	305	7,743	4,062,886	18.5	1906	20,219	6,613
1954	39	305	7,721	4,177,223	8.9	1865	20,988	9,738
1955	32	267	1,543	4,287,010	11.5	363	21,362	7,878
1956	36	332	1,188	4,230,542	8.8	272	20,172	7,384

TABLE II
COMPARISON OF ACCIDENT EXPERIENCE, COMPENSATION AND SAFETY INCENTIVE COSTS, 1947-1951, 1952-1956

Period	Lost Time Acc.	No Lost Time Accidents	Days Lost	Hours of Exposure	Frequency	Severity	Compensation Cost	Incentive Cost
1947-51	715	1,044	47,820	21,075,472	33.9	2270	$228,296	
1952-56	295	1,152	26,725	21,040,846	11.2	1265	146,818	$40,722

TABLE III
COMPARISON OF AVERAGE YEARLY ACCIDENT EXPERIENCE, COMPENSATION AND SAFETY INCENTIVE COSTS, 1947-1951, 1952-1956

Period	Lost Time Acc.	No Lost Time Accidents	Days Lost	Hours of Exposure	Frequency	Severity	Compensation Cost	Incentive Cost
1947-51	143	209	9,564	4,215,094	33.9	2270	$ 57,059	
1952-56	47	231	6,345	4,212,969	11.2	1265	29,364	$ 8,147

The shops depend largely on artificial light for illumination. Windows are glass block installed as a long strip about 12' above the floor. Most other windows in the plant are thermo pane glass, eliminating the need for installing storm windows and giving frost free service in winter.

Floor panel heating is used only in the heavy repair section of the general shops. Men are frequently working on floor gliders in this area; in addition such floor heat tends to remove snow and frozen mud from the bottom of vehicles. It has been our experience that panel heat is undesirable in areas where men are required to work standing in one spot for any length of time; foot disorders generally result from such work conditions.

An enclosed steam cleaning room is serviced by a turn table and track. The track extends through the room and a short distance outdoors enabling steam cleaning to be done in the open in the summer time. The room itself has a separate exhaust unit and adequate drainage facilities in the floor. This installation permits rapid steam cleaning of heavy equipment prior to being worked upon by the repair crew.

In the welding shop a 10' curtain wall protects the machine shop from welding flash yet permits the ten ton overhead crane to serve the welding shop area. Moveable screens are used wherever needed.

A full basement below the wing housing the miners' change rooms is used for storage. Narrow gauge track with turn tables and spurs serve a large portion of the storage area; an elevator connects the basement with the shop. Motor truck service to the basement is made available by a ramp to the outside surface. A tunnel connects basement and shaft. This enclosed and convenient storage area is invaluable as it totally eliminates handling ice covered items that would otherwise be stored outdoors.

The plant boiler room is adjacent to the south end of the above mentioned basement. Loaded coal cars are spotted in an enclosed thaw shed at ground level above the coal bins. Coal is gravity emptied from railroad cars into the bin and is moved by a bin-fed stoker into the boilers. Ashes are removed by mechanical screw and elevator into a bin on the roof for disposal into trucks. This heating plant is practically automatic except for an occasional inspection and periodical removal of clinkers from the boilers. Boiler room attendants are not used.

All oil and grease are stored separately in a storage room located at the end of a wide driveway adjacent to the shop building. This location provides easy access for removal of supplies for shop or underground use. Blacksmith coal is also stored in a small bin in this driveway. The balance of the available space along the south wall of the driveway is used for steel storage.

ENGINE HOUSE

The engine house is reasonably spacious with electric control panels enclosed in an adjoining annex thus keeping the main floor clear. The noisy M. G. sets are located in the basement thereby curtailing noise. As a consequence the first floor, or working floor, is relatively quiet and is a very pleasant place to work. All the usual safety devices are installed on the hoists, air compressors and other equipment located in this building. The ore hoist is a semi-automatic operation requiring attention only when the hoist cycle is being changed from one level to another. Some consideration has been given to making the man and supply hoist fully automatic.

Extensive use is made of tunnels between buildings and work areas. A double deck over-and-under tunnel connects the main buildings and shaft, permitting man-loading both floors of the cage at one time. The upper tunnel continues on to the engine house with the north wall of the tunnel extra thick to accommodate conduits for electrical lines. Placing such lines within the wall gives a very clean tunnel with no protruding brackets to snag passers-by.

At a lower elevation another tunnel, double tracked, extends to the timber yard area. This facility keeps empty or loaded timber trucks out of the snow in winter. The warmer air in the tunnel also melts much of the ice and snow from the timber before it is sent underground, thus minimizing handling hazards. The timber yard is served by a speed swing loader and two Ensley cranes if needed.

A panel-heated slab is used under the rock bins in the truck loading runway. This eliminates frozen build up in winter and minimizes the need for jack hammer work

required to maintain adequate truck clearance from December through March. Up in the head frame the usual overwind safety switches are located at the point of skip discharge. In the storage or surge bins swing type switches prevent overfilling the bins.

Fire hydrants are located at strategic points throughout the plant area. A fire alarm system is installed in the several buildings. Fire fighting demonstrations are given at regular intervals.

STOCK PILING

Stock piling of ore is accomplished by using a pan feeder, screen, crusher, pan feeder to conveyor installation. The screen operator stands or sits by the screen to remove wood or tramp iron. A locally designed trap gate is used on the end of the screen to permit the operator to catch large metallic objects before they fall into the crusher. This gate has been quite successful. However, an expanded mesh screen has been installed over the crusher to prevent metallic objects from being ejected upwards from the crusher jaws. Switches to operate the several units and phone and bell communication facilities are located adjacent to the screen.

On the conveyor belts mine personnel have installed scraper bars on all drive pulleys, turn pulleys and return training idlers not so much to remove any build-up but rather to maintain a uniform circumference on the pulleys. These scraper bars have eliminated all manual cleaning of the pulleys and idlers. Speed regulator control devices are installed on each belt to shut off the drive motor if the belt slows below a critical speed. These units give some protection if a piece of tramp iron or a chunk were to punch through the belt and start ripping it. One instance is known at another mine in the area where such a device shut off the belt when a man became entangled in a turn pulley thus saving his life. The usual emergency stop cords are installed along the sides of these conveyors.

The stock pile galleries are flat roofed, with protective railing on each side. Wire fencing is installed on the side railing to prevent anyone slipping or rolling under the lower bar of the railing. Electric power for the stock pile shovel is carried in conduit on top of the gallery. The shovel itself is served by drop cable. This installation has kept the stock pile area completely free of pole lines, buried electric conduit and ground level power outlet boxes.

The company has spent a considerable amount of money developing several basic safety features in the underground portion of the property. A second exit was provided by repairing an old shaft called Tracy "B" which lies about 2,500 feet west of the Tracy "A" or main shaft. The two shafts are connected by a drift on the second level which is located about 1,000 feet below ground level. The Tracy "B" shaft has complete service facilities permitting hoisting of men by man cage if necessary.

UNDERGROUND

A 5 foot aerodyne fan, located in the underground connecting drift draws air down the "B" shaft. In winter operation the down draft air at "B" shaft is preheated by oil fired boilers. This, of course, makes the main shaft up draft and eliminates all ice and frozen conditions at that point.

Jones & Laughlin makes no claim for anything particularly spectacular about the Tracy Plant. However, the plant has a clean functional design well adapted to the job at hand and the area in which the plant is located. Design decisions were based first on safety, next on functional use and finally on economics. To date all the built-in safety features of the plant have more than justified their inclusion in the basic plant design.

SAFE USE OF AMMONIUM NITRATE COMMERCIAL FERTILIZER AS A BLASTING AGENT

by H. J. GRAFTON

chief mining engineer, Eureka Casualty co., Fire Assoc. of Philadelphia Group, Philadelphia, Pa.

The ingenuity of man through the years has contributed vast scientific and technological advances to our free way of life and to our various economic problems. The cost of explosives has long been a problem of the mining industries. Therefore, should we not consider the use of commercial fertilizer as an explosive or blasting agent as somewhat ingenious?

Ammonium nitrate fertilizer is manufactured, transported, stored and used in tremendous quantities. While this inorganic nitrate has widespread commercial use, it can hardly be said it has general use as a blasting agent when compared to all other explosives. It is, however, used quite extensively in strip or open-pit mining in coal, ore and quarries and in other surface blasting as a field compounded blasting agent in place of such conventional explosives as dynamite or black powder.

The common name for ammonium nitrate NH_4 (No. 3) is norway saltpeter, 1.725 times heavier than water, melting point 337.1°F (169.6°C), boiling point decomposes at 410°F (210°C), is classed as oxidizing material. It does not qualify as a high explosive but could be a dangerous substance and requires an understanding of the hazards peculiar to nitrates and the control measures which should be applied.

STORAGE PRECAUTIONS

1. Bags should be stored not less than 30 inches from walls of storage building, in piles not more than 12 feet in width, with at least 30 inch aisleways. At least three feet clearance should be maintained from top of bags to eaves of roof or supporting and spreader beams overhead.

2. Roofs and floors above masonry or concrete walls should be of light weight construction, not concrete or masonry.

3. Explosives should not be kept in storage area.

4. Storage areas should be maintained in good housekeeping order.

5. Ammonium nitrate fertilizer should not be stored over or under organic materials, flammable liquids, corrosive acids, strong oxidizing agents, finely divided metals, sulphur or other readily combustible materials. Storage should be located at least 30 feet from such materials.

6. A clearance of at least three feet should be maintained between storage and sources of heat, or ignition such as steam or hot water pipes, radiators, heating devices and electric wiring.

7. Bags should be stored on concrete floors or on wooden pallets resting on any type of clean floor. Drains or similar openings into which molten nitrate can run during a fire should be closed or plugged.

8. Spilled materials should be cleaned up promptly. Broken containers may be placed inside clean over-slip bags, which should then be securely closed.

9. Smoking, open lights or flames should be prohibited in or near storage area.

The inorganic nitrates evolve oxygen as a result of decomposition upon heating or as a result of direct chemical action, thereby increasing the intensity of fires and thus supplying oxygen to increase rate of combustion of burning material. Ammonium nitrate is particularly hygroscopic and is readily soluble in water, thus accounting for another serious fire hazard since containers are usually paper or burlap bags and may be saturated with nitrate solutions. When containers become dry, they are impregnated with nitrates and therefore are highly flammable.

Most field compounded blasting agents can be purchased ready-made, or may be mixed by the user in the vicinity of blasting operations. Due to the cost item, the job-site formulation predominates. Some operations have erected a field compounding plant, while others mix the blasting agents directly at the drill hole. The first mentioned are usually practical and economical only when large quantities are regularly used in one area. There are, however, some users of large quantities who claim that mixing at the drill hole has proven entirely satisfactory as to results obtained.

There appears to be no universal standard relative to the amount of combustible material added to the ammonium nitrate fertilizer. It has been observed that where fuel oil is the mixing agent, the amount varies from three quarts to one and one-half gallons per 100 pounds. Other mixes vary in percentage as to weight. Each operation must experiment to some extent, depending upon the depth of drill holes, nature of the over-burden and the desired fragmentation.

Observation appears to indicate ammonium nitrate in drilled form is more satisfactory than the granular or crushed type. It is also indicated that in many localities vertical drill holes obtain better results, although some companies do both vertical and horizontal drilling. Full column and deck loading are accomplished.

FIELD COMPOUNDING PLANT

While these blasting agents are considered non cap-sensitive, they are not entirely "fool proof," so to speak; therefore, it would be advisable to regard them as explosives and the plant and magazines should be located in accordance with the American table of distances.

For optimum protection, the plant should have separated areas for each raw material, finished product, and external mixing and packaging.

(a) Floor of mixing room should be concrete for safety in case of fire, since molten ammonium nitrate cannot contact the fuel.

(b) Corrugated aluminum roofing and siding on wood-stud framework is satisfactory. To facilitate proper cleaning of the mixing room, wood studs should be on the outside of metal siding. A natural-draft vent should be provided in the roof.

(c) Heat should be provided only from a source outside the building.

(d) A wash-down hose and drain should be provided.

(e) All electric switches, controls, motors and lights should comply with "hazardous locations" as provided in national electrical code. They should be located outside the mixing room and properly grounded. The frame of the mixer and any conveyors should be grounded.

COMPOUNDING

These compounded blasting agents are a mechanical blend of ammonium nitrate fertilizer and a mixing agent or combustible material. This is usually a fine carbon black fuel oil and in some instances coal dust has been used. These materials in pre-determined proportions are placed in a mixer and blended. The mixer-motor switch should be operated by a pull cord located in the mixing room. At the end of each mix, the compound is packaged in expandable polyethylene tubing closed at each end by copper ties.

At the end of each day's run, the following procedures should be considered:

(a) Unused bags of ammonium nitrate should be removed from the mixing room. Empty containers should be burned in an isolated section.

(b) Mixer should be thoroughly washed and left open to dry.

(c) Contaminated areas, platforms, floors, walls and stairs, should be hosed down.

(d) Concrete floor should be sprinkled with lime and hosed, to prevent corrosive action.

GENERAL PRECAUTIONS

(a) Smoking in and around mix house should not be permitted.

(b) Oily waste and rags should be stored in covered metal containers outside operating or storage building.

(c) Loose or spilled ammonium nitrate or blasting compound should be cleaned up and removed from premises.

(d) Metal tools should be of non-sparking materials.

(e) Doors and passageways should be kept free from obstructions. Ammonium nitrate is an oxidizing agent, readily sup-

The shops depend largely on artificial light for illumination. Windows are glass block installed as a long strip about 12' above the floor. Most other windows in the plant are thermo pane glass, eliminating the need for installing storm windows and giving frost free service in winter.

Floor panel heating is used only in the heavy repair section of the general shops. Men are frequently working on floor gliders in this area; in addition such floor heat tends to remove snow and frozen mud from the bottom of vehicles. It has been our experience that panel heat is undesirable in areas where men are required to work standing in one spot for any length of time; foot disorders generally result from such work conditions.

An enclosed steam cleaning room is serviced by a turn table and track. The track extends through the room and a short distance outdoors enabling steam cleaning to be done in the open in the summer time. The room itself has a separate exhaust unit and adequate drainage facilities in the floor. This installation permits rapid steam cleaning of heavy equipment prior to being worked upon by the repair crew.

In the welding shop a 10' curtain wall protects the machine shop from welding flash yet permits the ten ton overhead crane to serve the welding shop area. Moveable screens are used wherever needed.

A full basement below the wing housing the miners' change rooms is used for storage. Narrow gauge track with turn tables and spurs serve a large portion of the storage area; an elevator connects the basement with the shop. Motor truck service to the basement is made available by a ramp to the outside surface. A tunnel connects basement and shaft. This enclosed and convenient storage area is invaluable as it totally eliminates handling ice covered items that would otherwise be stored outdoors.

The plant boiler room is adjacent to the south end of the above mentioned basement. Loaded coal cars are spotted in an enclosed thaw shed at ground level above the coal bins. Coal is gravity emptied from railroad cars into the bin and is moved by a bin-fed stoker into the boilers. Ashes are removed by mechanical screw and elevator into a bin on the roof for disposal into trucks. This heating plant is practically automatic except for an occasional inspection and periodical removal of clinkers from the boilers. Boiler room attendants are not used.

All oil and grease are stored separately in a storage room located at the end of a wide driveway adjacent to the shop building. This location provides easy access for removal of supplies for shop or underground use. Blacksmith coal is also stored in a small bin in this driveway. The balance of the available space along the south wall of the driveway is used for steel storage.

ENGINE HOUSE

The engine house is reasonably spacious with electric control panels enclosed in an adjoining annex thus keeping the main floor clear. The noisy M. G. sets are located in the basement thereby curtailing noise. As a consequence the first floor, or working floor, is relatively quiet and is a very pleasant place to work. All the usual safety devices are installed on the hoists, air compressors and other equipment located in this building. The ore hoist is a semi-automatic operation requiring attention only when the hoist cycle is being changed from one level to another. Some consideration has been given to making the man and supply hoist fully automatic.

Extensive use is made of tunnels between buildings and work areas. A double deck over-and-under tunnel connects the main buildings and shaft, permitting man-loading both floors of the cage at one time. The upper tunnel continues on to the engine house with the north wall of the tunnel extra thick to accommodate conduits for electrical lines. Placing such lines within the wall gives a very clean tunnel with no protruding brackets to snag passers-by.

At a lower elevation another tunnel, double tracked, extends to the timber yard area. This facility keeps empty or loaded timber trucks out of the snow in winter. The warmer air in the tunnel also melts much of the ice and snow from the timber before it is sent underground, thus minimizing handling hazards. The timber yard is served by a speed swing loader and two Ensley cranes if needed.

A panel-heated slab is used under the rock bins in the truck loading runway. This eliminates frozen build up in winter and minimizes the need for jack hammer work required to maintain adequate truck clearance from December through March. Up in the head frame the usual overwind safety switches are located at the point of skip discharge. In the storage or surge bins swing type switches prevent overfilling the bins.

Fire hydrants are located at strategic points throughout the plant area. A fire alarm system is installed in the several buildings. Fire fighting demonstrations are given at regular intervals.

STOCK PILING

Stock piling of ore is accomplished by using a pan feeder, screen, crusher, pan feeder to conveyor installation. The screen operator stands or sits by the screen to remove wood or tramp iron. A locally designed trap gate is used on the end of the screen to permit the operator to catch large metallic objects before they fall into the crusher. This gate has been quite successful. However, an expanded mesh screen has been installed over the crusher to prevent metallic objects from being ejected upwards from the crusher jaws. Switches to operate the several units and phone and bell communication facilities are located adjacent to the screen.

On the conveyor belts mine personnel have installed scraper bars on all drive pulleys, turn pulleys and return training idlers not so much to remove any build-up but rather to maintain a uniform circumference on the pulleys. These scraper bars have eliminated all manual cleaning of the pulleys and idlers. Speed regulator control devices are installed on each belt to shut off the drive motor if the belt slows below a critical speed. These units give some protection if a piece of tramp iron or a chunk were to punch through the belt and start ripping it. One instance is known at another mine in the area where such a device shut off the belt when a man became entangled in a turn pulley thus saving his life. The usual emergency stop cords are installed along the sides of these conveyors.

The stock pile galleries are flat roofed, with protective railing on each side. Wire fencing is installed on the side railing to prevent anyone slipping or rolling under the lower bar of the railing. Electric power for the stock pile shovel is carried in conduit on top of the gallery. The shovel itself is served by drop cable. This installation has kept the stock pile area completely free of pole lines, buried electric conduit and ground level power outlet boxes.

The company has spent a considerable amount of money developing several basic safety features in the underground portion of the property. A second exit was provided by repairing an old shaft called Tracy "B" which lies about 2,500 feet west of the Tracy "A" or main shaft. The two shafts are connected by a drift on the second level which is located about 1,000 feet below ground level. The Tracy "B" shaft has complete service facilities permitting hoisting of men by man cage if necessary.

UNDERGROUND

A 5 foot aerodyne fan, located in the underground connecting drift draws air down the "B" shaft. In winter operation the down draft air at "B" shaft is preheated by oil fired boilers. This, of course, makes the main shaft up draft and eliminates all ice and frozen conditions at that point.

Jones & Laughlin makes no claim for anything particularly spectacular about the Tracy Plant. However, the plant has a clean functional design well adapted to the job at hand and the area in which the plant is located. Design decisions were based first on safety, next on functional use and finally on economics. To date all the built-in safety features of the plant have more than justified their inclusion in the basic plant design.

SAFE USE OF AMMONIUM NITRATE COMMERCIAL FERTILIZER AS A BLASTING AGENT

by H. J. GRAFTON

chief mining engineer, Eureka Casualty co., Fire Assoc. of Philadelphia Group, Philadelphia, Pa.

The ingenuity of man through the years has contributed vast scientific and technological advances to our free way of life and to our various economic problems. The cost of explosives has long been a problem of the mining industries. Therefore, should we not consider the use of commercial fertilizer as an explosive or blasting agent as somewhat ingenious?

Ammonium nitrate fertilizer is manufactured, transported, stored and used in tremendous quantities. While this inorganic nitrate has widespread commercial use, it can hardly be said it has general use as a blasting agent when compared to all other explosives. It is, however, used quite extensively in strip or open-pit mining in coal, ore and quarries and in other surface blasting as a field compounded blasting agent in place of such conventional explosives as dynamite or black powder.

The common name for ammonium nitrate NH_4 (No. 3) is norway saltpeter, 1.725 times heavier than water, melting point 337.1°F (169.6°C), boiling point decomposes at 410°F (210°C), is classed as oxidizing material. It does not qualify as a high explosive but could be a dangerous substance and requires an understanding of the hazards peculiar to nitrates and the control measures which should be applied.

STORAGE PRECAUTIONS

1. Bags should be stored not less than 30 inches from walls of storage building, in piles not more than 12 feet in width, with at least 30 inch aisleways. At least three feet clearance should be maintained from top of bags to eaves of roof or supporting and spreader beams overhead.

2. Roofs and floors above masonry or concrete walls should be of light weight construction, not concrete or masonry.

3. Explosives should not be kept in storage area.

4. Storage areas should be maintained in good housekeeping order.

5. Ammonium nitrate fertilizer should not be stored over or under organic materials, flammable liquids, corrosive acids, strong oxidizing agents, finely divided metals, sulphur or other readily combustible materials. Storage should be located at least 30 feet from such materials.

6. A clearance of at least three feet should be maintained between storage and sources of heat, or ignition such as steam or hot water pipes, radiators, heating devices and electric wiring.

7. Bags should be stored on concrete floors or on wooden pallets resting on any type of clean floor. Drains or similar openings into which molten nitrate can run during a fire should be closed or plugged.

8. Spilled materials should be cleaned up promptly. Broken containers may be placed inside clean over-slip bags, which should then be securely closed.

9. Smoking, open lights or flames should be prohibited in or near storage area.

The inorganic nitrates evolve oxygen as a result of decomposition upon heating or as a result of direct chemical action, thereby increasing the intensity of fires and thus supplying oxygen to increase rate of combustion of burning material. Ammonium nitrate is particularly hygroscopic and is readily soluble in water, thus accounting for another serious fire hazard since containers are usually paper or burlap bags and may be saturated with nitrate solutions. When containers become dry, they are impregnated with nitrates and therefore are highly flammable.

Most field compounded blasting agents can be purchased ready-made, or may be mixed by the user in the vicinity of blasting operations. Due to the cost item, the job-site formulation predominates. Some operations have erected a field compounding plant, while others mix the blasting agents directly at the drill hole. The first mentioned are usually practical and economical only when large quantities are regularly used in one area. There are, however, some users of large quantities who claim that mixing at the drill hole has proven entirely satisfactory as to results obtained.

There appears to be no universal standard relative to the amount of combustible material added to the ammonium nitrate fertilizer. It has been observed that where fuel oil is the mixing agent, the amount varies from three quarts to one and one-half gallons per 100 pounds. Other mixes vary in percentage as to weight. Each operation must experiment to some extent, depending upon the depth of drill holes, nature of the over-burden and the desired fragmentation.

Observation appears to indicate ammonium nitrate in drilled form is more satisfactory than the granular or crushed type. It is also indicated that in many localities vertical drill holes obtain better results, although some companies do both vertical and horizontal drilling. Full column and deck loading are accomplished.

FIELD COMPOUNDING PLANT

While these blasting agents are considered non cap-sensitive, they are not entirely "fool proof," so to speak; therefore, it would be advisable to regard them as explosives and the plant and magazines should be located in accordance with the American table of distances.

For optimum protection, the plant should have separated areas for each raw material, finished product, and external mixing and packaging.

(a) Floor of mixing room should be concrete for safety in case of fire, since molten ammonium nitrate cannot contact the fuel.

(b) Corrugated aluminum roofing and siding on wood-stud framework is satisfactory. To facilitate proper cleaning of the mixing room, wood studs should be on the outside of metal siding. A natural-draft vent should be provided in the roof.

(c) Heat should be provided only from a source outside the building.

(d) A wash-down hose and drain should be provided.

(e) All electric switches, controls, motors and lights should comply with "hazardous locations" as provided in national electrical code. They should be located outside the mixing room and properly grounded. The frame of the mixer and any conveyors should be grounded.

COMPOUNDING

These compounded blasting agents are a mechanical blend of ammonium nitrate fertilizer and a mixing agent or combustible material. This is usually a fine carbon black fuel oil and in some instances coal dust has been used. These materials in pre-determined proportions are placed in a mixer and blended. The mixer-motor switch should be operated by a pull cord located in the mixing room. At the end of each mix, the compound is packaged in expandable polyethylene tubing closed at each end by copper ties.

At the end of each day's run, the following procedures should be considered:

(a) Unused bags of ammonium nitrate should be removed from the mixing room. Empty containers should be burned in an isolated section.

(b) Mixer should be thoroughly washed and left open to dry.

(c) Contaminated areas, platforms, floors, walls and stairs, should be hosed down.

(d) Concrete floor should be sprinkled with lime and hosed, to prevent corrosive action.

GENERAL PRECAUTIONS

(a) Smoking in and around mix house should not be permitted.

(b) Oily waste and rags should be stored in covered metal containers outside operating or storage building.

(c) Loose or spilled ammonium nitrate or blasting compound should be cleaned up and removed from premises.

(d) Metal tools should be of non-sparking materials.

(e) Doors and passageways should be kept free from obstructions. Ammonium nitrate is an oxidizing agent, readily sup-

ports combustion and enables fires to burn independent of any air supply. Under certain conditions it may explode at temperatures over 300°F. Any fire should be controlled in incipient stage with large volume of water. In fire fighting, caution must be exercised to prevent spreading boiling oil compounds where these additives are incorporated in the mix.

COMPOUNDING AT DRILL HOLE

Mixing directly at, or near the collar of the drill hole could result in conditions that might endanger life and property. This operation is being done by many operators and they apparently feel it is a safe method. It should be remembered, however, that when the detonating charge or primer has been placed and the compound is being poured in a confined area, the same precautions should be taken as involved conventional explosives.

Methods of loading the blast holes are varied in many instances. In dry holes the ammonium nitrate may be poured and the mixing agent subsequently added to flow or trickle through the column. In some cases the nitrate and mixing agent are fed simultaneously. Depth and diameter of drill holes vary according to type of strata and amount to be moved. Detonation has usually been accomplished by dynamite, electric caps and primacord, although there are other means used.

To prevent any accidental detonation, electric blasting caps should not be transported in same vehicle with other explosives.

Blasting agents, dynamite and blasting caps at the job site should be stored in magazines as prescribed by the fire prevention code of the national board of fire underwriters. They should be unheated and with no lighting. If artificial light is required, an approved flashlight is permissible. Magazines should be kept locked against unauthorized entry. Field compounded blasting agents should be handled only by experienced personnel and with the same plosives.

IMPROVEMENTS TO UNDERGROUND HAULAGE SYSTEM AT TCI'S ORE AND COAL MINES

by J. D. F. EVANS

mining engineer, Ore Mines & Quarries, Tennessee Coal & Iron Division, U. S. Steel corp., Fairfield, Ala.

Do you want to reduce your haulage accidents by 66 per cent? Do you want to increase your haulage capacity by 59 per cent? The Tennessee Coal & Iron Division of United States Steel Corporation did this in approximately seven years. The decrease in accidents and increase in capacity can be attributed to only one factor, improved haulage systems.

Today's production requires an efficient, economical and safely operated underground transportation system. We are constantly seeking ways to improve underground transportation in the coal and ore mines. Haulage capacity limited our individual ore mines to 1,100 tons per eight-hour shift in 1949; today, the same mines produce 1,400 tons per shift and the haulage capacity is 25 per cent more.

Such improvements are not just stumbled upon. They are based on engineering studies and a planned program for eliminating the faults.

At TCI this evalution began with studies which revealed faults such as improperly spaced passing points, improperly located derails, ineffective manually operated block signals and constant stopping and starting trips to throw hand switches. One of the most important conclusions was that the rails were too light. Alignment and grade could be improved by proper study and

engineering in new track installations. Similarly, it was difficult to maintain good track because of the magnitude of the haulage system.

The first step to overcome these difficulties was writing standard specifications on construction and maintenance of underground mine track. The specifications are revised periodically as changes in practice occur. This book is distributed to those concerned. All construction and maintenance complies with these specifications. Particular emphasis is placed on clearance, grading, tamping, drainage, alignment, gauge and elevation on curves. A project engineer is assigned to develop and maintain standard track practice specifications.

An efficient, economical track haulage system is dependent upon trained personnel, suitable locomotives and mine cars, adequate power supply, an efficient signaling and dispatching system, and good track. TCI has attempted to integrate these factors to achieve the maximum return from the system in safety and in reducing operating costs.

SUCCESSFUL TRACK SYSTEM

The foundation of a successful track haulage system is, of course, good track. Heavy rails laid on treated ties with a good subgrade, substantial ballast and welded rail joints make good track. Cross ties are of mixed hardwoods, properly seasoned and pressure treated with creosote.

Total trackage in the operating mines is 147 miles. The average haul distance for ore is 1.7 miles, the longest haul being 2.3 miles. The average haul for coal is 3.2 miles and the longest haul is more than five miles. Track grades are limited to plus or minus six per cent.

Formerly, haulageway center lines were set by grade alone. Today, they are located by the position of the block of ore plus or minus six per cent allowable grades together with the economics of grading top or bottom.

Before standardization of haulage systems, all track construction work was performed by hand. Coarse ballast and fill consists of loose broken ore or rock. This material was hand loaded on material cars and distributed by hand.

Today, mechanized equipment has eliminated the costly hand methods. Mechanical loaders and underground bulldozers, powered by electricity or diesel engines, load and distribute coarse sub-grade material. Bulldozers perform rough grading by leveling the loose ballast to sub-grade elevations.

Slag or ballast cars of various designs are used for track construction. These cars have been fabricated in the local maintenance shops. The cars have drop-bottoms and adjustable feed openings which eliminate loading, unloading and distributing ballast. Ballast is dumped from the delivery truck into the cars. Cars are hauled over newly constructed track with the bottom set to distribute the material in the amounts required.

Available to each track laying crew is a specially constructed work car which carries a 105 c.f.m. air compressor. Tools on the car are spike hammers, picks, shovels, spud wrenches and pneumatically powered spike drivers, tie tampers and impact wrenches. Approximately 200 feet of new track are installed at a time and joined by splice bars. The track laying crew is followed by a welding crew, after the track is in service. The welders remove and salvage the splice bars, one joint at a time, and weld the joints.

The haulage studies found that the standard 60-pound ASCE 6040 rail section could not withstand locomotives and tram cars loads. Derailment often destroyed the conventional splice bars and bonds joining these sections, reducing the efficiency of the electrical return through the rail. Derailments and reralling operations distorted track alignment and led to more derailments.

TCI USES WELDED TRACK

The generally accepted opinion was that the rolling stock would be replaced with heavier equipment as it wore out. This led to the adoption of the 90-pound ARA-A 9020 rail section for mainline track. The faults of the bonding practice led to preliminary discussions of welding track. At TCI rails are used as the electrical ground return. Welded track provides a continuous metallic cross-section for current flow far superior to bonded track. In turn, more current is available for the locomotives and other equipment and thus saves power.

Welded rails also provide a continuous surface enabling traffic to operate at a faster and safer speed. No traction loss at joints results in less sand consumption, longer rail life and a reduction in locomotive tire replacements.

A trial installation of welded track was made to overcome electrical power loss from broken or loose bonds and to alleviate the costly, inadequate maintenance of splice bar joints. This installation indicated an initial savings of 75 per cent and joint maintenance cost was reduced by 75 per cent. Five years ago, welding rail joints were made standard in the ore mines and 32,500 feet of main line track were welded. The coal mines began welding rail joints about a year ago and 18,000 feet of track have been completed. (This is completed track, not single rail distance.)

Welded track is a permanent installation and planned only for main line haulage. Welding on new haulage, extensions and active haulages was accomplished without interrupting production.

The 60-pound secondary haulage track is temporary and joined by splice bars and bonds. The bonding material used is scrap 6/0 trolley wire or scrap shuttle-car cable bronze-welded to the track by a fusion welding cartridge and mold. The method of igniting the cartridge is simple and eliminates transporting and using bulky oxygen-acetylene welding apparatus.

Using super-elevation on curves in haulageway construction decreases maintenance cost and lessens interruptions caused by derailments. Proper super-elevations are outlined in the track specifications. TCI uses no super-elevation less than one-half inch nor more than five inches. These data are computed for different locomotive speeds and radii in our operations. In conjunction with super-elevation on curves, track gauge is widened to specifications. This practice prevents binding of wheels, overturning and wearing of the rail and spreading the track.

For standardization, all turnouts from the mainline haulage are driven on the minimum radius negotiable by the locomotives. By following a standardized pattern, any turnout may be salvaged and re-used at any other location. Complete turnouts are purchased from an outside supplier. No turnouts, except standard turnouts, are used thus eliminating delays due to derailments on improperly designed turnouts.

Included in the turnout are the switch points, straight and curved closure rails, frog, guard rail assembly, a standard switch throw stand complete with linkage, and switch plates. At turnouts, ties to extend under both tracks are ordered in sets simultaneously with the turnouts.

STEEL TIES INCREASE HEADROOM

In the coal mines, steel ties are used on secondary haulage track where vertical clearances are critical. They provide approximately four inches more headroom than wooden ties. Track gauge is fixed permanently fixed by riveted or bolted steel clips which maintain an accurate, constant gauge. Alignment is accomplished and maintained by roof bolts set into the footwall at intervals. Steel ties reduce installation and maintenance costs, and offer light weight, fixed gauge, no tie plates, less ballast, require fewer ties and are all re-usable.

Water on haulages is very detrimental to track stability. A rotary drill improves drainage in the coal mines. Eight-inch diameter holes are drilled through pillars along haulageways to drainwater by gravity. Pumping has been eliminated in several cases by strategically located drill holes.

Electric current is delivered to operating machinery by feeder cable and trolley wire suspended from insulated pipe hangers. To provide a larger contact surface between trolley slide and wire, the 6/0 grooved wire is gradually replacing figure eight wire.

The feeder cable is suspended from the roof or back on insulated 1¼ inch pipe supports. The trolley is suspended from the feeder cable at the mid-points of the pipe supports. This provides a cushioned trolley with reduced wear on slides.

At man and material loading points, trolley wire is shielded using a collapsible rubberized trolley shielding. At points where vertical clearance is less than six feet, shielding is also required.

At present, TCI mines use 117 locomotives, equipped with air brakes, dynamic brakes, manually operated brakes, air-operated trolley stands and air-feed sanders. The newest are powered by four motors of either 90 or 120 horsepower each. This

locomotive has an end, armored cockpit for the two-man motor crew. All locomotives carry rerailers.

All mine locomotives have radio-telephones, known as trolley phones, powered by trolley voltage and trolley wire to carry the signal. Radio-telephone instruments are also in the dispatcher's station, for communications between the dispatcher and motorman.

Rubber cushioned draft gear has been under test for some time. Test results indicate this type gear, where practicable, will be advantageous.

A total of 3,530 steel mine cars are used by TCI. The newer cars are the eight-wheel, double truck, design equipped with automatic rotary couplings. These cars replaced four-wheel, all steel cars with link and pin couplings. The new car bodies are constructed of Man-ten and Cor-ten steel with a fillet at the bottom and side joints which makes the cars self-cleaning. These materials were chosen for their abrasion and corrosion resisting qualities.

Extensive tests on rebuilt car wheels were concluded recently. The tests indicate a saving of 70 per cent a year in the cost of car wheels by rebuilding worn wheels.

Mine jeeps are provided for supervisors and engineering personnel. They transport personnel from point to point over long haulage distances and haul maintenance tools and parts to broken down equipment. The haulage schedule is not interrupted and no motorman is required for their operation. Jeeps have trolley phones and are guided by the dispatcher and block signals.

Material and equipment is hauled underground on low flat cars and eight-wheeled double trucked material cars. Cars marked indicating the mining section to which they will be hauled, and material for one section is loaded on the same cars. By following this system, secondary handling of material is reduced to a minimum.

AUTOMATIC SIGNALS REDUCE HAZARDS

To increase haulage efficiency and reduce hazards of underground haulageways, all mainline haulage units operate over track completely controlled by automatic block signal systems. These signals allow only one locomotive in any one block.

Motormen operate their trips by the signal indications without dismounting or stopping unless the track ahead is occupied. There is less delay, less starting and stopping, and safer operation than with any other transportation control. In mechanized mines, automatic block signals are the only efficient means to keep mechanical loaders supplied with empty cars.

The mainline is divided into sections called blocks. On entering a block, the trolley slide on the locomotive contacts a relay switch which operates the block signals. The entering locomotive on an unoccupied block immediately receives a green light, while red lights are simultaneously set at all other entrances. These indicators remain set until the locomotive leaves the block where the same type of trolley slide contactor device darkens the lights.

If two or more locomotives approach a block from different points, only one receives a green light and the others a red light. The trolley contactors are direction sensitive and operate only for the intended direction of trip movement.

At passing points, the loaded trips take the mainline and empties take the siding. The switch alignment at the passing points is so arranged that no switch throwing is required. This is accomplished through the use of spring split-switches. The switch alignment can be changed if necessary by using a manual switch throw.

Passing points are located, following haulage time studies, so that haulage times from point to point are nearly equal. Automatic block signals, controlling the entrances of locomotives to blocks, enable locomotives to operate at the maximum safe speed, almost without stopping, with no danger of collision.

When feasible, passing points on the main haulages are equipped with automatic electric switches. The devices for actuating the switches are the same as the contactors on the block signals.

In conjunction with the automatic block signal system and automatic switches, TCI has installed automatic time controlled derails. Company safety rules require the installation of derails at specified intervals on all grades and other locations.

For protection from runaway cars and locomotives, the derail is open at all times

except while a train is passing. The derail opens and closes automatically by contact devices on the trolley wire. A speed control feature forces locomotives to travel at a safe speed toward the derail point. The locomotive's speed approaching the derail is timed between two trolley contactors approximately 100 feet apart.

If the locomotive's speed is greater than the pre-determined safe speed, the derail remains open an the locomotive and cars are derailed. A push button is provided opposite the derail for test purposes and for the motorman's use in the event of a trolley contactor failure.

At TCI "Safety First" is not just a motto; it is a way of life. Realizing that the underground haulage system is the life stream of a mine, we strive for the latest developments in control and safety devices and methods into our haulageways. For a safe, economical and efficient haulage system, adequate engineering studies followed by the formulation of specifications are required. Once the specifications become standard and are rigidly followed, improvements in cost, safety and productive capacity should become apparent.

TCI through the use of welded rails, automatic block signals, switches and derails, mechanized construction methods and improved rolling stock, reduced haulage accidents 66 per cent. At the same time, productive capacity increased 35 per cent with a 25 per cent haulage potential in reserve. In addition, the costs of hauling ore and coal have been substantially reduced.

What We Are Doing to Prevent
FALLS-OF-GROUND ACCIDENTS

by **PHILIP GRAVES**
safety engineer, Homestake Mining Co., Lead, S. D.

What we are doing at Homestake to prevent falls-of-ground accidents is both a separate and integral part of our overall safety program. Certain phases of our safety program deal specifically with falls-of-ground accident prevention; other phases prevent accidents from falls of ground indirectly.

To present adequately our present activities to prevent falls-of-ground and other accidents, we must review previous mining practices and the changing conditions which increased the need for a dynamic, effective safety program.

The government shut down gold mines in October 1942. For twelve years prior we had a stable crew of men as reflected in our accident rate. The overall frequency ran between 30 and 40, with 11 fatalities from falls of ground in the 12-year period.

When the mine reopened in 1945, we were shorthanded. By 1947 we had a full crew, but it was highly unstable. Ther were too many Johnny-Come-Lately-and-Leave-Quickly characters who had about as much serious intent of becoming miners as the average two-year-old. This hectic period accomplished one thing: it pointed out the need for a forceful safety program concentrated on the individual worker.

The two years following proved the point, for our frequency after World War II reached a high of 99 in 1949 with three fatalities from falls-of-ground that year. There were ten fatalities from falls-of-ground in the years from 1947 to 1954.

We made several changes in mining which helped prevent falls-of-ground accidents. Before 1952, about 67 per cent of our mined ore came from the open shrinkage stopes, and 33 per cent from timber stopes. The shrinkage stopes started at the bottom of the ore and worked upward to about 30 feet above the next level.

Before any stopes were started, development crosscuts were driven through the ore body every 100 feet, and from these crosscuts "raises" were driven in the ore from one level to the level above. The shrinkage stopes were laid out across the ore body and were usually 60 feet wide (30 feet each way from the crosscut). This left a 40-foot pillar between stopes which was taken up with timber after the shrinkage stopes were mined, ore extracted, and the stopes filled with waste and sand. A stope 60 feet wide extends from the hanging wall to the footwall of the ore body and sometimes reaches over 250 feet in length and 150 feet in height.

"BELLIES" GREAT HAZARDS

In this type of mining it was sometimes necessary to leave "bellies" over the extraction raises so that the back would not get too far from the rock pile to be mined. This condition presented a potential hazard and many falls-of-ground accidents occurred when these "bellies" would loosen and fall.

After the mining was completed in these stopes, barmen would "ride" the pile of broken rock down as it was pulled out. Their job was to bar the pile and dress down the sides, taking down the loose rock so that all the ore could be removed safely from the stope. This operation usually took several months, and ground movement would sometimes loosen rock in the exposed walls causing some to fall and developing a hazard to workers in the stope.

After the stopes were mined out, before mining could begin in the pillars, pillar crosscuts were driven through the center of the pillar on the sill, then raises through the pillar from one level to the next, and subsill drifts through the ore halfway between levels.

The upper part of these pillars was taken out first. Mining started on the subsill, 75 feet below, and the pillars were taken up in sections.

Ore from the first floor had to be shoveled. After the first floor of timber was in, chutes were installed and the rest of the ore was drawn through the chutes into cars, dumped into a raise and pulled out on the level below.

After the third floor was mined out and timbered, an observation line was laced off on the second floor and from there extended a manway partly open on one side for inspection purposes. The mining floor and the working floor below were kept lagged over. The openings in the floors below were checker-boarded to turn rock through the chute. The pillars were nine floors of timber. After the first section was taken up, the pillar was left with only one solid wall. After a section was mined and cleaned nine floors high, the entire section was filled with sand tailings.

Sometimes in the larger pillars three sections would work at the same time. Under these conditions, quite frequently a block of rock too large for the timber to hold would loosen and come down, caving several floors of timber with it.

About one-half of our falls-of-ground fatalities in the 1930 to 1954 period occurred in timber stopes, and about one-half in shrinkage stopes.

In Homestake's new improved method of open cut-and-fill mining, mining begins from a raise at the bottom of the ore. All ore is mined from hanging wall to footwall, lying east and west, and from 100 feet to 300 feet in north-south direction.

The first lift is mined to about 18 feet high. After the broken rock is in the raise, an 11-foot timber bin line and manway is placed over the raise and laced with tongue-and-groove slabs. With this type of mining no pillars are left, eliminating pillar crosscuts and raises and most subsill drifts. The stope is filled with sand to the top of the manway and plank floor laid leaving seven feet between the floor and the back.

WALLS CAN'T LOOSEN

This same cycle is continued on up through the ore. With this method few bellies are left and the walls are never exposed more than 18 feet high and never long enough to allow the walls or back to loosen. Only a few days elapse between the broken ore slushed from the stope to the stope backfilled with sand. Any loose rock on the back or walls is rock-bolted as the stope is cleaned out.

The timber cut-and-fill stopes are taken up similarly to the old timber stopes except that each floor is filled as it is finished. The rock is all slushed into an ore pass called a bin line or chimney instead of turning the rock through the sets. Some

of these stopes are taken all the way from the hanging wall to the footwall and from waste to waste on each end while others are limited to 50 feet in length. By not breaking through the arch between the hanging and footwall, the danger of a cave-in is eliminated when the back is properly cribbed to the timber.

The five-year average of falls-of-ground accidents from 1949 through 1953 was 17 per cent with seven fatalities for the entire period. The overall frequency had dropped from 99 in 1949 to 56 in 1953. In 1956 our overall frequency dropped to 28. There were *11 falls-of-ground* accidents in 1954, seven in 1955, and four last year with only one fatality for the three-year period.

Rock-bolting throughout the mine is important in reducing falls-of-ground accidents. Rock bolts were used extensively in the development drifts on the lower levels where the weak rock can buckle and fail. Heavy mesh screen is rock-bolted to the drift walls and back in some places.

Use of rock bolts in our shaft sinking and stripping operations has enabled Homestake to complete approximately 2,600 feet of shaft in the past three years without a lost-time injury from falls of ground. In the same period we have driven five 900-*foot raises, two 700-foot raises,* and several 300-foot raises without a lost-time injury due to falls of ground.

By these changes in methods, Homestake has provided its miners with conditions as free as possible from working hazards. However, mechanical changes can avail little if each individual worker is not constantly alert to safety. This has been, still is, and will remain the eternal challenge and nemesis of every safety engineer.

HOMESTAKE FOLLOWS N.S.C. CAMPAIGN

In 1953, Homestake participated in the National Safety Council's campaign to reduce the number of falls-of-ground accidents. That year there were seven accidents, one fatal. This was half our average for the previous three years. In December of 1953 the safety department started taking every new man, hired for underground work, for a half-shift mine trip no later than two weeks after employment. The trips are conducted by me, or the chief assistant in the department. The number in the group is kept small, and the attention personal.

On these trips, we stress the importance of doing every phase of work in the safe way. We point out potential hazards, and tell each man how to avoid injury. Special emphasis is placed on keeping a working place always barred down.

The trip and conversation cover all areas and situations applicable to the new man. The coverage is thorough and unhurried, and the new man has ample opportunity to observe and question.

When the new man has worked long enough to be a miner, the head of the mine crew gives the newly approved miner further specific instructions for protecting himself.

Some convincing statistics from research started this program. Employees' records showed that nearly one-half our accidents occurred during the first two years of employment. Examining the files of all mine employees in 1955, the records showed the first year of employment accounted for 23.3 per cent of accidents and the second year an even 23 per cent. Obviously then, the two most accident-likely years are the first two years on the job.

For this reason a 15-minute sound picture of the Homestake Mine showed a new employee touring with the safety department man. Several minutes of this film are on barring down and the consequences of leaving loose rock, along with other examples of work that are safe or hazardous, depending on the individual working.

The film is shown to all underground men and groups of new men after two months employment. The waiting period has a twofold purpose. A man is naturally cautious and careful when brand new. After this initial period of caution he can become potentially dangerous to himself and his fellow workers. Bringing the safety film to him at the beginning of a period of overconfidence again stresses the need for constant safety. Also after two months, things in the film will be meaningful, which wouldn't be earlier.

To keep the miner safe, part of our program aims at his immediate superior, the "boss" of the beat. It is his job to see that

all working places are properly barred down, and working conditions always at their best. A monthly bonus is paid the shift bosses completing a month's accident-free work.

To make accurate comparisons, the safety department maintains files of accident figures on the 24 underground bosses' beats. Statistics show which crews are improving, static, or more accident prone. From these reports the mine superintendent can single out bosses with increasing accidents and encourage them to work harder with their men to avoid accidents.

At least three times a year safety department men talk to each crew. This 15-minute talk stresses the importance of barring down, and covers other safety measures.

Members of the safety department take unscheduled trips through the mine. This gives us firsthand knowledge of conditions, and we can offer concrete suggestions to improve specific areas. It also keeps the men aware of the safety department and on their toes to maintain safe working conditions.

Additional monthly inspection trips are made by four members of the Mine Workmen's safety committee. These men are recommended by the foremen and appointed by the mine superintendent to serve one year. In this way each man makes every mine beat once a year. After the inspection trips, the committee meets with the safety department to discuss their findings. Recommendations for improvements are sent to the mine superintendent. These men also report unsafe practices or conditions they observe during the month.

In addition to the Workmen's committee, there is also a central committee of the general manager as chairman, the safety engineer, and department heads. This group meets monthly to discuss suggestions and improve safety practices.

SAFETY PAYS OFF—IN CASH

Homestake has several incentive awards for the individual miner. One is a monthly safety suggestion program which offers cash prizes for the three best safety suggestions. First prize is $25.00, second $15.00, and third $7.50. Any other suggestion adopted during the month, but not rated with the top three, is worth $5.00 to the author.

A bonus system started in 1954 presents $10.00 to every underground employee working 275 shifts or over in a year without a lost-time injury. On his fifth accident-free year, he receives $20.00. If accident-free for an additional four years, he receives the $10.00 yearly bonus and on the tenth year another $20.00 bonus. The cycle then repeats through the succeeding five-year periods.

Since 1939 the Homestake Mining Company awards watch fobs for outstanding individual safety records. A gold watch fob is presented for 15 consecutive accident-free years, a silver fob for 10 consecutive years, and a bronze fob for five consecutive years.

Since 1939, there have been awarded 215 gold watch fobs, 521 silver fobs and 726 bronze fobs. Several men had the five and ten-year awards and wanted the third to complete the set. Other reasons for wanting fobs were varied, but the men wanted the practice continued even though watch fobs are outdated today.

In 1955 the company started giving a Hamilton Guardsman I wrist watch to each underground employee with 20 consecutive accident-free years. These watches are presented annually at a company dinner for the recipients and their wives. The ceremony is informal, but impressive and friendly. In addition to giving the individual a well-deserved award, the watches prove to others that working safely for years is not only possible, but also profitable.

In summary then, what we are doing at Homestake to prevent falls-of-ground and other accidents are these things:

First: We maintain the safest possible working conditions through new and improved mining methods.

Second: We give each new man the knowledge needed to work safely with a comprehensive printed rule book and a conducted tour of an actual working area.

Third: We have responsible supervision for the worker through a qualified shift boss constantly vigilant in keeping working conditions safe.

Fourth: We offer incentive awards to both workers and supervisors so that safety will be recognized, honored, and further encouraged.

Fifth: We promote safety constantly through talks, banners, mine trips and other types of reminders from the safety department.

Sixth: We are searching always and all ways for better means to keep "Safety First" uppermost in the mind of the individual worker, for he must be fully convinced that "Accidents Don't Just Happen".

THE SAFETY PROGRAM OF BETHLEHEM STEEL COMPANY

by CHARLES R. NEIL

management's representative & safety engineer, Bethlehem Comwall corp., Bethlehem, Pa.

The Bethlehem program is grounded on fundamentals and is essentially very simple. For almost 40 years the keystone is that safety is not a separate or diverse activity; it is production *with* safety. As our President, Mr. A. B. Homer, has said: "Safety is an integral part of the production process."

The manager of compensation and safety, reporting to the vice president in charge of industrial and public relations, administers the safety program of the company, with a staff of safety engineers. He also administers the company's workmen's compensation and liability coverages. He is informed on the operations and functions in a consulting and administrative capacity, developing operational safety organizations, procedures in accident prevention and exchanging safety information. Through safety agencies, he is informed on pertinent developments in the field of safety.

Our management has established that the individual operations—the plants, the shipyards and the mines—are responsible for product quality, maintenance of production capacities and activities to eliminate accidents.

INDUSTRIAL RELATIONS STAFF

The safety engineer at each operation reports to the local staff member in charge of industrial relations, who has full-time assistants. At Bethlehem the safety engineer at the operational level is not "in charge of safety"; rather, he is a consultant and advisor to people in charge of the operations. He plans and directs safety activities in concert with all phases of operations. When a facility is constructed, altered or reviewed, the safety engineer participates. This insures safety of operation —engineered safety.

By comparison, our safety departments are not large in relation to the work force. For example, at one steel plant employing 20,000 persons, the safety engineer has a staff of seven, including clerical assistants. However, more than 50 departmental safety inspectors are assigned by and report to operating supervision to assist operating personnel.

BETHLEHEM ACTIVE IN SAFETY GROUPS

Bethlehem's program, while designed for and directed to its operations, participates in safety organizations to exchange information with other companies in the steel, shipbuilding, steel fabricating and mining industries.

We are a participating member of the National Safety Council and of local safety councils. We are members of the Seven Steel Company Safety Exchange, comprised of the seven largest American steel companies; of the Atlantic Shipyard Safety Exchange, comprised of ship repair and shipbuilding companies operating on the east coast of the United States; and of the Coal Mines Safety Exchange, comprised of representative mining companies in the areas where we have such facilities. These exchanges are voluntary, informal groups organized to exchange information, statistics or mutual problems and to hold meetings covering prepared agenda.

Representatives of the Bethlehem general office and of our operations attend the National Safety Congress. Before the Congress, we have a one-day meeting of all Bethlehem representatives, normally about 50. Our agenda last year was typical:

1. Announcements
2. Using monthly safety topic
3. Discussion—Safety Interchange Bulletin (Form 18095)
4. Interpretations of recent rulings on unusual accident cases by A. S. A. Z16.1 code committee
5. The safety program and injuries to third parties
6. New ideas that helped 1956 safety program
7. Discussion of cause code of injuries
8. Questions submitted by operations for discussion

The latter item is not intended to solve safety problems requiring immediate attention—such problems are resolved as they arise. It is, rather, an exchange of ideas and elicits comment on questions from all operations.

GOOD HOUSEKEEPING LOWERS COSTS

In addition, we have periodic meetings with safety engineers from our steel plants, shipyards and mines, at a selected operation and usually covering two days. The first day is a physical inspection of the facility and individual comments on safety practices and items observed. The second is devoted to a prepared agenda covering currently pertinent subjects.

Many approaches are used for accident control—for example, good industrial housekeeping. Mr. E. G. Grace, Chairman, has stated: "Good industrial housekeeping has been a fundamental policy of Bethlehem from the start, making for more efficient production, a better product and lower cost operation . . . a smoothly running plant means more production, greater security of employment . . . Bethlehem's good housekeeping practices reflect the cooperative effort of the employees as a whole."

Good housekeeping in a steel plant, shipyard or mine is as important as in the home, and results in pleasant, healthful working conditions—efficient and safe.

Safety and the individual are firmly intertwined. Safety advances human relations consistent with technological progress and because it enlightens the self-interest of men and management, we consider it our first responsibility. When you specify working conditions, employees' safety and health take paramount priority. Our job is to give each man conditions we ourselves should like. This is not only a human obligation, it is also self-preservation. It's a prime factor to bring into our working forces desirable and competent young men, and to compete for them with other industries.

At Bethlehem, we emphasize the way an individual performs his job; hazards encountered on the job, and how we can best accomplish this job efficiently and without accident. We term such studies Job Safety Analyses. Each is a studied, recorded analysis of how the job is done, prepared by the supervisor with the workers for the direct purpose of preventing accidents. As each hazard is recognized, a decision is made whether to change the job process or protective equipment, or a combination of both to eliminate or guard against the hazard. These completed studies are discussed with the men on the job so each step-by-step phase is understood.

The studies follow a standard pattern which includes: (1) principal steps of operation (list each step in the order it normally occurs); (2) hazards (list the hazards found at each step of operation); and (3) safety controls (list steps to eliminate the indicated hazards or the necessary safety precautions taken).

PRACTICAL SAFETY SUGGESTIONS FROM ANALYSIS

A job safety analysis not only results in a safer operation but facilitates production. For example: *Job* No. 1: Man working inside a large ingot mold casting is seated in a bosun-chair suspended from overhead crane; *Hazard:* Possibility of crane being bumped, shoving man in chair against side of mold; *Correction:* Fabricate working platform, set it inside mold, provide access to platform, properly identify job at hand and semi-isolate mold; *Result:* Hazard eliminated, job worked smoother and over-

head crane released for other shop movements.

Job No. 2: Clean slag from mixer ladle hole requiring six to eight men one day a week; *Hazard:* Pick-and-shovel job, close quarters, flying objects and metal splashes; *Correction:* Set U-shaped scrap bars in pit to catch slag, hook onto bars with overhead crane once each week to remove residue; *Result:* Elimination of work exposure and men released for other assignments.

Such studies are disseminated through personal safety contacts, on-the-job planning meetings and daily observation of work habits.

Frequent departmental inspections, proper maintenance of equipment, use of personal protective equipment, industrial hygiene surveys, including studies of air contaminants, welfare room facilities, medical treatment and allied functions, are the procedure at Bethlehem, and contribute to accident elimination.

ACCIDENT CONTROL—A JOINT JOB

Through the years, a joint safety responsibility of management and employees has developed. Accident prevention is the responsibility of everyone, although it is primarily a *management* responsibility. In our steel division, employees are active through safety committees both permanent and rotating. Meetings take place during regular working hours on company time. Departmental committees meet and review the experiences, offer and discuss, recommendations to eliminate hazards, report on inspections of their departments and review progress in eliminating unsafe acts or practices.

The membership of the general plant committees include representatives of each departmental committees. In their meetings the broader aspects of safety work are discussed, with plant, inter-plant and intercompany experience as the theme. Recommendations of the departmental committees are discussed. Representatives of the general manager's staff attend these meetings. The general managers meet with their department heads to discuss accident-prevention matters. In the Bethlehem program, production meetings are also safety meetings.

The foremen are the management people in closest contact with actual physical production, and, therefore, are responsible for the safety education of their employees and the development and enforcement of safe practices.

PUBLICATIONS PUSH FOR SAFETY

Each year before December, all operations are advised of the monthly "safety contact topic" for the ensuing year. This topic is featured in the lead article of our monthly Safety Bulletin which goes to all supervision. The bulletin, in addition to the feature article, contains information and articles to assist supervision in conducting the safety program and educating the employees.

To assist foremen in their personal contacts, "Contact Topic Cards" are available on a weekly basis. Such cards contain a brief outline of the current safety topic and make "talking" to employees easier. However, a foreman is not limited to these topics but is encouraged and expected to discuss the job at hand.

Another educational factor is our Safety Interchange Bulletin which describes safety devices developed at one operation but applying to others. The interchange bulletin customarily displays pictures of the device and detailed drawings and narrative description.

While every effort to prevent injury is made by providing properly designed and adequately guarded facilities and well-lighted work areas, personal protective equipment plays a major role—hard hats, safety glasses and protective clothing. We also advocate wearing safety shoes and proper apparel. Our primary effort is to make the place and the machine as safe as possible through mechanical engineering, and then protect the men from hazards which cannot be eliminated.

Our personal protective equipment program is of long standing, and experience through the years confirm its value. One of our operations has not had a disabling eye injury for 20 years—more than 64,900,000 man-hours.

In our experience first-aid training is essential. An employee so trained can give proper, immediate assistance to an injury whether at work, home or on the highway. Moreover, the employee trained in first-aid is a safer employee on his own job.

Safety codes play a major role in our program. A code, prepared after studying the operating phase is a guide showing how an operation may be safely performed. A positive approach is most effective, that is, we teach what to *do* rather than what *not* to do.

BE POSITIVE, NOT NEGATIVE

The economic factor of safety is compelling but we firmly believe a safe operation is a profitable operation, both to employees and to the company. The employer's cost is not the only benefits contemplated by the Workmen's Compensation Act. It is the loss of a valued employee, the cost of training a replacement, plus the production loss resulting from the accident.

What is the cost of no-lost-time cases requiring medical care? How many do we have in a given period and how much time is spent in treatment? What about production loss while an employee is at the dispensary? In an accident involving damage to facilities, what is the cost of repair or replacement, the cost of down-time and loss of production? Cost, properly used, is a valuable sales feature.

Our accident experience is measured by frequency and severity as defined by the American Standards Association in its Code Z16.1-1954. Frequency is the number of disabling injuries per 1,000,000 employee hours of exposure; severity is the total days charged per 1,000,000 employee hours of exposure.

Our concept of production with safety began in 1916. In 40 years, our accident frequency rate was reduced by 90 per cent. Our corporation-wide frequency rate for the year 1956 was 4.16, or a little over four disabling injuries per 1,000,000 man-hours worked. In four of our integrated steel plants, the frequency ranged from .56 to .78, or less than one disabling injury per 1,000,000 man-hours worked—a rather striking experience in what has been said to be a very hazardous industry.

It is not by coincidence that a Bethlehem operation has won the National Safety Council's metals section contest among large steel plants for the past 15 consecutive years. In 1956 our operations received more than 30 awards from the National Safety Council for safety performance. In addition, our operations received awards from the United States Bureau of Mines.

A consistent safety accomplishment must be built on a firm foundation, properly designed and kept up to date to cope with ever increasing production objectives. In a large measure, safety programs throughout Bethlehem meet specific problems at a given operation, but they are uniform in thought and direction.

Our management has long been convinced that production with safety is paramount—because it has to do with men and their individual significance—because it reflects the responsibility of leadership—because it fulfills one of our primary human obligations—because safety and efficiency are actually one and the same—and because of its growing significance to the total national economy.

SAFETY PROGRAM FOR THE BUTTE DISTRICT OPERATIONS OF THE ANACONDA COMPANY

by HERBERT A. WENDEL

chairman, Bureau of Safety, The Anaconda Co., Butte, Mont.

The Butte District operations are an integral part of The Anaconda Company's Western Operations. The Company operates 13 underground mines and two open pit properties, plus complete shop and service department facilities. The number of active mines depends on economic conditions, and less than half the mines are currently active.

Except for two block caving mines, all underground operations use selective mining methods. A considerable amount of hydraulically placed mill tailing is used as stope filling, and will become standard practice in the future. Rock bolting techniques are used, especially on new sill development work and in horizontal breast cut and fill stopes.

The principal products produced from the Butte mines are copper, zinc, and manganese ores, which contain smaller amounts of silver, lead, gold and accessory metals. During normal operation 5,000 to 6,000 men are employed on the Butte hill.

SAFETY PROGRAMS SINCE 1914

Safety programs for Butte operations are developed, promoted, and supervised by the Bureau of Safety, established in 1914. Information on successful safety projects is sent to the management of all Anaconda Company operations for consideration and possible use. Monthly injury reports are sent from all Anaconda Company and subsidiary operations to the Bureau of Safety, where quarterly and annual reports are compiled to determine lost-time-injury-rates.

Each year the operation with the greatest reduction below its previous 5-year lost-time-injury-rate receives the Kelley trophy for the year. Safety departments are maintained at every Anaconda Company's world wide activities.

The Bureau of Safety's staff consists of the chairman and a clerk. The Butte District organization includes a chief safety engineer, five to eight safety engineers, an artist and a part time artist and clerk. Each safety engineer supervises one large mine and smaller operations. The duties of the safety engineer include:

1. Supervises mine or plant safety programs.
2. Trains workers and supervisors.
3. Inspects working places and operations, reporting natural hazards, safety rule violations, faulty behavior, fire hazards, poor housekeeping, defective equipment or materials, unsafe mining or work practices and conditions, ventilation and industrial hygiene environments, lack of or defective protective clothing, equipment or devices, and recommends corrective procedures.
4. Follows through to see all hazards are corrected, within a three-day period.
5. Investigates and reports on all injuries.
6. Conducts weekly supervisors' safety meetings.
7. Takes new employees on a tour of surface facilities and explains the general safety factors involved.
8. Secures safety pledges from all men and distributes rule books or job safety instruction sheets.
9. Assists mine management officials in conducting employee safety meetings with Union committees.
10. Is alert to improve efficiency, safety methods and practices.
11. Sees all men are equipped with proper safety clothing and protective equipment.
12. Looks after first aid supplies, facilities, equipment, training, and treatment of injured.
13. Is available for calls at all hours for any emergency, such as serious accidental injuries, disasters, or mine fires.
14. Supervises display and distribution of safety posters, warning signs, reminder cards, news bulletins, and safety literature.

Under the Bureau of Safety, Butte District operations have achieved a gradual decline in frequency and severity rates of lost-time injuries. But the total injury rate, including accidents without a loss of time, has not reduced as much as the lost time injury rates. In fact, several years when the lost-time rate declined, the total injury rate increased.

Therefore, we are confronted with a serious problem: How can we lower the total accident rate? It must be done since even the slightest injury could result in a lost time injury, depending on factors such as age, environment, physical or mental conditions, marital status, financial position, and temperament.

Many different solutions have been tried in the past including:

1. Incentives such as pictures and cigars for the safest crew each month; chances for prizes of cash or savings bonds; National Safety Council badges, theater tickets.
2. Periodic "Going on shifts" safety talks.
3. Posting "No Accident" records for supervisors' crews.
4. Use of safety flags.
5. Bonus for supervisors.
6. Safety suggestion boxes.
7. Reminder cards at working places.
8. Safety pledges.

Each project reduced the lost-time-injury-rate but again, the effect on the total accident frequency was not up to expectations.

After a thorough analysis and study, we decided to promote a new approach to safety, based on a progressive, intensified, concerted training program. It would be a long-range project, including training sessions in preliminary safety education before the new employee is hired, and continuing progressively throughout employment. While on-the-job-safety is particularly emphasized, off-the-job-safety is also stressed. The plan embodies a program of safety education for the worker, and similar training projects for supervisors. This is essential because the supervisor is responsible for the task of selling safety to his crew, and influencing their attitudes and behavior through daily personal contact. Constant awareness of safety can become "a way of life" instead of a duty. This is the aim of present and future safety programs of the Anaconda Company for its Butte operations.

Advanced and diversified mining operations and methods increased the need for more adequate safety controls. Recently some newly inaugurated programs alleviated the major obstacles in inducing safety consciousness.

We are developing and instituting a safety training program. The projects are not new or original; many safety organizations have used similar plans. But we intend to try each point, then alter and adapt to the best performance. Finally, the separate objectives will be coordinated into a procedure flexible to changes in mining progress. The ultimate goal is accelerated action on accident prevention through safety training and education.

The large labor turnover in Butte is due to: migratory and transient workers, labor shortages in summer and early fall from miners taking temporary outdoor jobs, and fluctuating economic conditions which affect production requirements. Because of these factors during a normal year about 2,000 new men are employed and less than half remain more than one year. Our accident records show more than one-half of all lost-time injuries happen to employees with less than a five year service record.

SAFETY ORIENTATION

If we can impress the new employee, before he is hired, that the Anaconda Company is interested in his welfare and safety, he will be more attentive and responsive. Anaconda believes well-informed employees make better and safer workers.

The project consists of a lecture utilizing diagrams, posters, signs, pictures, and displays of safety clothing, required protective equipment, and safety devices. Slide projector illustrations are being developed.

After passing a physical examination, prospective employees are required to attend the Orientation and Safety Indoctrination course conducted by a safety engineer before rustling cards are issued. We present much information to help the new employee get a proper and safe start on the job, and to acquaint him with our accident prevention policies.

Information presented includes:

1. Company policies in regard to welfare and safety.
2. Size, scope, and purpose of the Anaconda Company's world wide activities.
3. Description and magnitude of local operations.
4. Wages, differentials, work week, hours, overtime pay.
5. Functions and duties of the employment office.
6. Operation of the personnel department and how it affects employees.
7. Procedure to secure job.
8. A guided, informative tour of the surface plant, conducted by a safety engineer or foreman.
9. Safety pledges.
10. Employee benefits including: group insurance, hospital medical plans, paid vacations and holidays, employees' club, pension plan, opportunities for advance-

ment, purchase of Savings Bonds on payroll deduction plan.

11. Brief description of various local mining operations and methods.
12. Résumé of general hazards of the job and ways to prevent accidents.
13. First aid facilities, equipment and training programs.
14. Proper procedure in event of accidental injury.
15. Communications program.
16. Benefits from making a permanent home in Butte.

SAFETY TRAINING FOR PROSPECTIVE SUPERVISORS

This is a proposed activity for use during full production when management staffs have a shortage of experienced supervisors. A prospective supervisor attends special courses in safety training so that when he takes on supervisory duties, he will know his responsibility in his crew's safety and welfare.

SAFETY TRAINING FOR SUPERVISORS

Each year the Mining Research Department conducts a three-day training course for all Butte supervisors. At these sessions new and review information is presented on all phases of the mining operation. A two-hour safety class is sponsored and conducted by the Bureau of Safety.

Pertinent new safety promotions are presented and discussed along with a thorough review of principles and accomplishments, using visual aids produced for slide or Vu-Graph projection.

ADDITIONAL TRAINING FOR SUPERVISORS

Safety performance records are compiled for all supervisors to determine the nature and classification of injuries. The safety engineers report periodically on the supervisor's safety attitude and the amount of training imparted to his men.

From these records and reports we determine safety performance deficiences of a supervisor, particularly those whose accidental injury rates are unsatisfactory. Then special safety conferences and reviews are conducted to improve attitudes and performances.

Letters are sent periodically to all supervisors by the chairman, presenting safety news, congratulations for records or accomplishments, information on new ideas, or requests for more effort in accident prevention.

The supervisor is naturally responsible for most employee training. In a mining operation, the average shiftboss should see every crew member three or four times a shift. Here is the best opportunity for safety indoctrination.

A competent, conscientious supervisor, alert and safety-minded, can exert a tremendous influence in promoting and inculcating safety consciousness in his crew. The safety engineers constantly stress this phase of shiftboss training.

Much psychological training is accomplished by presenting on posters particular behavior problems which contribute to poor safety performance. The effective poster must appeal to the observer by showing working environment, and aiming at the intelligence level of the average employee.

The carton poster offers the greatest attraction to the average Butte worker. We exhibit new or different posters weekly, some on surface bulletin boards, others at strategic locations underground.

To obtain consistent safety behavior and habits, the employee must be reminded constantly about hazards and how to guard against them. To do this, we post a series of safety practice reminder cards for all employees according to specialized occupations. These cards appear at conspicuous places around the work site.

SAFETY IN COMMUNICATIONS PROGRAMS

A communications program presents another vital tool to promote safety and accident prevention. The Butte district communications program consists of the News boards and periodic management letters to employees. Safety grams on the news boards are ideal for safety announcements, accomplishments, and congratulations.

Editing and publishing a monthly safety magazine for employees is a communications project. *The Headframe*, first published in June 1957, provides safety news and information for all members of an employee's family in the home. Subjects deal with safety on the job, at home and at play. The object is to extend the psychological training approach to the entire family and induce a "safe way of life" in all its actions.

Presenting workers a safety rule book or instruction sheet has only a momentary, psychological effect. But if the supervisor reads a safety pledge, explains it and the employee's responsibility to himself and his fellow workers on safety and then the man signs a pledge—this creates a more lasting impression.

Consequently signed pledges are required for the hazardous occupations, such as miners, motor crews, chute tappers and open pit miners.

SAFETY TALKS

Short safety talks are used by safety organizations. But these, like other accident prevention campaign activities, must be changed periodically to maintain interest and produce beneficial results. Due to lack of interest or tangible proof of merit this was discontinued, on the Butte hill, a number of years ago.

Occasional short "Going on Shift" safety presentations and demonstrations assist the training program. A series of Vu-Graph projections, depicting actual accidental injury cases and object lessons on safety, is being processed to emphasize the value of "thinking before doing," on all actions.

The Bureau of Safety is revising and promoting a number of accident prevention campaigns instituted years ago:

1. Annual first aid and helmet training—new and review courses.
2. First aid team contest each year.
3. Publicity and awards for outstanding safety accomplishments and life saving deeds.
4. Development and use of specialized safety rule books.
5. Research and engineering is safety promotions, projects, methods, equipment, devices and ideas.
6. Better industrial and public relations by extending cooperation and assistance on safety programs to: government and state agencies; law enforcement offices, schools, scouting activities, civic projects, service clubs and labor unions.

An amicable relationship between management and labor was achieved largely *through recognition* and utilization of union safety committees. At all mines and plants regular weekly safety meetings are held, when the mine superintendent or foreman and the safety engineer, meet with appointed safety committee members of the local miner's union. At these sessions the union safety committee presents hazards which are discussed by management's representatives and decisions are rendered. Corrective measures are reported by the safety engineer. The end result is better understanding and cooperation between labor and management.

Any safety endeavor to be successful must be: conscientious and exhaustive, flexible enough to meet changing conditions, developed through trial and error, and based on practical common-sense principles. Reducing suffering, hardship and sorrow from injury to our fellow man offers the greatest challenge and reward of any undertaking in industry today.

OFFICERS OF THE

MINING SECTION

NATIONAL SAFETY COUNCIL 1957-58

General Chairman—H. SLOANE, director of safety division, Mining Association of B. C., Vancouver, B. C.

First Vice-Chairman—S. E. SHARP, Tennessee Copper co., Copperhill, Tenn.

Second Vice-Chairman—C. R. NELL, Bethlehem Cornwall corp., Cornwall, Pa.

Third Vice-Chairman—ROGER F. A. THEW, safety engineer, Steep Rock Iron Mines Limited, Steep Rock, Ontario.

Newsletter Editor—R. G. WARNCKE, Bureau of Mines, Washington, D. C.

Assistant Newsletter Editors—Lake Superior District, F. D. WOLEBEN, Oliver Iron Mining Division, U. S. Steel corp., Virginia, Minn.; *Eastern District*, JOSEPH WEEKS, New Jersey Zinc company, Franklin, N. J.; *Southeastern District*, M. F. THOMPSON, American Zinc company, Mascot, Tenn.; *Western District*, W. LYNN HART, American Smelting and Refining company, Wallace, Idaho; *Central District*, H. B. HUTCHENS, Eagle-Picher Mining and Smelting company, Miami, Okla.; *Southwestern District*, PAUL HUNTER, Chino Mines division, Kennecott Copper company, Hurley, N. M.; *Ontario District*, ROGER F. A. THEW, safety engineer, Steep Rock Iron Mines Ltd., Steep Rock, Ontario, Canada; *Quebec District*, J. E. BERRIDGE, Quebec Asbestos Mining Association, Montreal, Quebec, Canada; *Eastern Canada District*, JOHN ABBISS, Buchans Mining company, Buchans, Newfoundland, Canada; *Western Canada District*, IVAN H. SLOANE, director of safety division, Mining Association of B. C. Vancouver, B. C.

Entertainment Committee Chairman—J. T. RYAN, JR., Mine Safety Appliances co., Pittsburgh, Pa.

Engineering Committee—J. M. SMITH (Chairman), Asbestos Corporation Ltd., Thetford Mines, Quebec, Canada; JOHN B. BIKER, Consolidated Mining & Smelting co. Ltd. of Canada, Trail, British Columbia, Canada; DALE J. BROWN, Nevada Mines division, Kennecott Copper corp., Magill, Nev.; GEORGE A. BORGESON, M. A. Hanna co., Hibbing, Minn.

Membership Committee—AL KOLU (Chairman), Pickands Mather & co., Duluth, Minn.; WALTER E. MONTGOMERY, Montreal, Quebec, Canada; CLIFFORD GIBSON, Mines Accident Prevention Association of Ontario, Timmins, Ontario, Canada; EMMETT K.OLSON, JR., Kennecott Copper Corp., Utah Copper Div., Salt Lake City, Utah; NEAL H. GEORGE, Quebec Metal Mines Accident Prevention Association, Quebec, Canada.

Program Committee—JOHN A. JOHNSON (Chairman), U. S. Bureau of Mines, Washington, D. C.; A. W. NESS, American Smelting & Refining co., Salt Lake City, Utah; MAURICE LA FONTAINE, Department of Mines, Montreal, Quebec, Canada; JOSEPH HALL, Reserve Mining company, Silver Bay, Minn.

Poster and Visual Aids Committee—HERBERT A. WENDEL (Chairman), The Anaconda company, bureau of safety, Butte, Mont.; A. W. NESS, American Smelting & refining company, Salt Lake City, Utah; A. J. STROMQUIST, Cleveland-Cliffs Iron co., Ishperming, Mich.; M. C. M. POLLARD, National Gypsum co., Buffalo, N. Y.; J. M. HARKINS, The Anaconda co., Butte, Montana; P. C. SIMMONS, Phelps-Dodge corp., Morenci, Arizona.

Statistics Committee—JOHN C. MACHISAK (Chairman), chief, Accident Analysis Branch U. S. Bureau of Mines, Washington, D. C.

Safety Promotion Committee—ALLEN D. LOOK (Chairman), U. S. Bureau of Mines, Federal Building, Duluth, Minn.; GEORGE SALL, Mining Congress Journal, Washington, D. C.; ALVIN W. KNOERR, Engineering & Mining Journal, New York, N. Y.; GEORGE O. ARGALL, JR., Mining World, San Francisco, Calif.; CHRIS MAMEN, Canadian Mining Journal, Gardenvale, Quebec, Canada; DAVID N. SKILLINGS, Skillings Mining Review, Duluth, Minnesota.

Hygiene and Ventilation Committee—JOHN W. WARREN (Chairman), Anaconda co., Butte, Mont.; ED. LEONARD, Inland Steel co., Ishpeming, Mich.; DONALD S. KINGERY, Mine Ventilation Section, U. S. Bureau of Mines, Pittsburgh, Pa.

Members-at-Large—*R. F. WILSON, Oliver Iron Mining div., U. S. Steel corp., Duluth, Minn.; *JOE T. WILLIAMS, Bunker Hill and Sullivan Mining and Concentration company, Kellogg, Idaho; *GEORGE GEDGE, Phelps Dodge corp., Copper Queen Branch, Bisbee, Ariz.; *OSCAR A. GLAESER, U. S. Smelting, Refining and Mining co., Salt Lake City, Utah; *A. J. STROMQUIST, Cleveland Cliffs Iron co., Ishpeming, Mich.; *CLIFFORD GIBSON, Mines Accident Prevention Association of Ontario, Timmins, Ontario, Canada; *GEORGE GERRY, Pickands Mather & co., Ironwood, Mich.; *R. F. WILSON, Oliver Iron Mining Division, U. S. Steel corp., Duluth, Minn.

Staff Representative—CLINTON H. HOCH, National Safety Council, Chicago, Ill.

*Past General Chairman

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

THE COMMERCIAL VEHICLE SECTION

This volume is a record of the sessions held at the 1957 National Safety Congress by the Commercial Vehicle Section. The conduct of these Congress sessions each year is only one of the many cooperative activities which the Commercial Vehicle Section carries on in behalf of its members, and for the benefit of accident prevention work in the motor transportation industry generally. The section gives guidance in the preparation of a great variety of technical and educational material useful in the day-to-day fleet safety programs.

The activities of the section are under the direction of its executive committee, the members of which are listed at the close of this volume.

ANNUAL REPORT

by K. N. BEADLE, CHAIRMAN
director of safety, Pacific Intermountain Express, Oakland, Calif.

Safety has grown in importance and influence since the first Commercial Vehicle meeting 35 years ago. Although it is impossible to say what the fleet accident picture would be today if the safety movement had never started, we could project the early recorded fleet experience and calculate a probable picture of our traffic safety if it had continued at the rate that existed over 25 years ago. According to the National Fleet Safety Contest the accident frequency rate was double what it is today when the contest began in 1932.

If we projected that early experience to the present number of professional drivers —11,000,000 for all types of vehicles—we would find that the 76,000 accidents reported by contestants during the past National Fleet Safety Contest would have resulted in an astounding figure of 3,500,000 accidents involving professional drivers. These, of course, are accidents of all types from fender dents to complete losses.

If accidents occurred at the same rate as they did 25 years ago the figure last year would have been seven million accidents. Drivers today average more than 66,000 miles between accidents as compared to 33,000 in those early days of the contest.

RESULTS PROVE PROGRESS

Many of us may feel that safety progress is slow, that results are intangible and that our efforts are not appreciated. Yet, the above experience and many more evidences of progress are apparent when we check the records.

To cite a few examples, there are in excess of 2,000 fleets currently enrolled in the National Fleet Safety Contest. This is 10 times as many as 26 years ago. There are 10 times as many drivers enrolled in the contest and they operate 25 times the mileage as was reported by their earliest predecessors.

Just during the last decade seven times as many drivers received the Council's Safe Driver Award. Four times as many drivers are now enrolled in the program. The national average of awards earned has improved from one out of three drivers to one out of two drivers during the last decade. In 1957, the Council will issue about 150,000 awards—as many as were earned during the first eleven years of the program.

EXPANDING RAPIDLY

Use of Motor Transportation safety materials has doubled in the last five years. The Motor Transportation Division represents the fastest growing section in the Council. The Commercial Vehicle Section, the largest section in numbers of affiliations continues to out distance all other sections in new affiliations.

Motor Transportation Services now extend to police departments, state highway patrols, school bus transportation systems, the United States Post Office Department and other governmental agencies as well as fleets of passenger car drivers in sales and supervisory positions.

From a salesman's coupe to a mammoth truck trailer combination, persons who earn their living by driving are setting a pattern of safe operation unequalled in our country's traffic records.

By their example, they have proven that motor vehicle accidents can be prevented. The ingredients for this accident prevention formula have been studied in detail and are presented in the manuscripts which follow. These ingredients are the positive elements of driver selection, training and supervision. ▲

ACCENTUATE THE POSITIVE

by LORNE F. PURVES
fleet superintendent, The Toronto Star, Ltd., Toronto, Ontario, Canada
program chairman, Commercial Vehicle Section, N.S.C.

Safety is not just a traffic light flashing its amber caution beam down the highway, or the roadside sign indicating the dangerous curve or bad hill ahead, or is it a hard hat worn by an oil refinery worker. Safety is a state of mind, a "positive" state of mind. Without that "positive" state of mind, all the safety equipment, all the traffic controls and legislation can be without purpose.

This business of "positive thinking" was brought to my attention some years ago while having dinner in a restaurant. It was before the days of air conditioning and the restaurant was extremely warm. Customers were asking for extra ice water almost as fast as the girls could bring it. One tall, blonde, southern girl seemed to have twice as many people to serve as most of the other girls. She was extremely efficient and thoroughly courteous, running back and forth with water jugs, extra pats of butter and iced drinks of various kinds.

There was a woman sitting close to us who seemed to be unnecessarily demanding and bothered her incessantly. When it came time for the girl to serve our table, I could not help but remark her pleasant attitude, and I asked her how she maintained such an excellent measure of tolerance and cheerfulness when people were making so many unreasonable demands. Her reply was very significant. She said, "It sure is tough at times but, believe me, it pays big dividends."

EXPECT THE BEST

The Reverend Norman Vincent Peale in his great book, "The Power of Positive Thinking," mentions the magic of believing, and that when you set your sights low and expect the worst, you get the worst—whereas, when you expect the best results and work positively to that end, you will get the best possible results.

We all have good examples of that negative type of thinking with the men in our own staff. You know the type—the driver who is beset by imaginary fears. Before he even starts out of the terminal yard with his rig, he wonders if the police will be weighing on the road today—will the fog be bad in the valley—will the traffic be heavy on that long hill into Centerville—will he be able to arrive at the terminal on time?

We call them "worry warts" and you know them well. They do a good job most of the time, but when the chips are down, things are tight and the traffic heavy on the highway because of the football game, or plugged with snow, you and I know which driver is going to blow his stack and possibly give up on the shoulder of the road somewhere until he settles down. Is it the driver who always measures his problems carefully and positively, and says, "Sure boss, I think we can do it," or is it going to be the "worry wart" who frustrates himself mentally and physically with negative, mental processes, which magnify and distort everyday problems out of proportion?

HELP WORRY WARTS

William James, the famous psychologist said, "Your belief at the beginning of any doubtful undertaking is the one thing that insures the successful outcome of your venture."

As supervisors and safety directors in our respective companies, I feel we can spend a little more time with these "worry warts" and try to improve their job. It is the success of those with whom we work that indicates our ability and our success, and the measurement of our ability and our success is what puts the groceries on the shelf at home in small packages or big packages.

Frequently the problem kid in our organization is, in a roundabout way, trying to keep in the spotlight and make us know indirectly that he is around. He is also telling us something that he doesn't know—that he needs us and our understanding. Some of them need a lot of understanding.

If you have a rugged individualist on your staff, do not cuss him for the problems he is causing you, much as you would like to,

because it would probably take more out of your old tummy than it would to dent the armour he has built up around himself over the years. Approach him in a friendly fashion, using his first name not his last, and give him the impression you are genuinely interested in getting his viewpoint on those habits and negative attitudes that give us the impression he is unco-operative.

To handle people—you have to be a good listener—and it doesn't have to be a task! A "positive" mental attitude attracts the "positive" attitude in people just as a magnet attracts steel.

If you can get him psychologically "unlocked," you may be able to solve his problems. Possibly, if you approached him with the same "positive" attitude that you would use to lower your golf score, the results would be just as gratifying.

We often allow the negative attitude of a few individuals to obscure the higher-than-average standard maintained by the majority of our personnel. We, as important parts of administration and supervision, should practice the policy of "positive" thinking and "positive" procedures as frequently as possible and in a manner most beneficial to these few. They are the ones that need our help the most.

Governments and firms spend millions in public relations. How much do we spend, not in money, but in time? It's worth thinking about!▲

BE POSITIVE IN DRIVER TESTING

by A. L. HAUCK

director of safety & public relations, Transportation Underwriters, Inc., Indianapolis, Ind.

I speak not as an industrial psychologist but as a layman discussing our attitude toward driver testing. I have spent many months talking to safety directors, supervisors and many administrative people sincerely interested in safety discussing current practices in testing.

There were many pros and cons as to its value. One fact did come out: those who did use testing were strong in their beliefs of the benefits derived. Most were using tests for training or indoctrination purposes.

Testing, according to Webster's New Collegiate Dictionary, Copyright 1953, used in the educational sense says "Any series of questions or exercises or other means of measuring the skill, knowledge, intelligence, capacity, or aptitudes of an individual or group."

The interpretation of that definition has varied among the people I have talked to. It has varied from "taking a small sample and from the test of the sample predict the whole" to "an exact measurement of the whole by analyzing the sample."

Tests for driver selection include:—

1. Road test in traffic.
2. Yard or skill tests.
3. Psychophysical tests.
4. Knowledge tests.
5. Vision tests.
6. Psychological tests.

Disregarding entirely the discussion of who believes and who does not, I would like to talk about some of the positive attitudes I have seen in psychophysical testing. You know the depth perception, reaction, peripheral or tunnel vision. The greatest success encountered was in the attitude of the safety director or supervisor giving the psychophysical test.

I asked as of its value as to screening and physical check as to reaction. The answers were of this pattern:

Value?—"Do you realize that for each test given I have the undivided attention of our prospective driver and with each test I tell him of its relation to actual driving and how important it will be to his success as a safe driver." With reaction we study the evils of tailgating.

I may never again have his undivided attention but for that time I do. This is not a contest between the applicant and the testor, but a case where the applicant is encouraged to do his best. "This is positive thinking. These safety people knew what they wanted to get across and did it."

USE POSITIVE THINKING

The next point is the positive thinking in vision tests. The successful and enthusiastic people held forth the idea that the vision test was given to assist the prospective employee and in many cases the vision tests were given regular employees in all departments. The results of the test indicated that he or she should or should not see their oculist or optometrist. Here is an example of this idea.

In Louisville, Kentucky, my home town, we had planned vision tests for all employees. The "scoop" got around as it normally does that the safety department was checking eyes. The maintenance manager came to the safety office and informed us the mechanics were discussing the point of whether to submit to the examination and informed him that nothing in their contract said they had to take the test and some said furthermore we were not doctors.

Both points were absolutely true. To combat this attitude we posted a small notice on the garage bulletin board to the effect that as an employee they too were entitled to receive the free vision test which would indicate if there was a need for further eye examination and to please see the garage foreman to arrange an appointment to avoid the crowd.

Before we were through they coined an expression for us "You can't set points if you can't see points." Positive thinking.

I am sure many of you have conducted road tests in traffic or yard or skill tests. Again while giving and immediately after, the student gives you his undivided attention. Sometimes the errors point towards what should be stressed in further training. These items are placed in our hands for action.

Knowledge tests afford us the same opportunity of assisting our people. With the proper attitude on our part it tells us what should be stressed in training and retraining programs.

Of these tests or testing devices some may ask—"Where do I find them?" or "Who could help me?" Without fear of plugging but with pride—your National Safety Council can help you.

These tests are meant for practical supervisors. Training and knowledge are necessary, of course, but the training and knowledge needed is readily acquired.

On the last point I tread lightly and with just a little advice. I refer to psychological tests—intelligence, personality, etc. If you contemplate this type consult an industrial psychologist or with state universities. They are a great help in putting each one of us on the right track. Consult them, they are a world of help in this field.

Testing has as many facets as the most beautiful diamond, but the brilliance of any one only reflects your attitude or thinking. If testing is but a sample, the prospective employee is also getting a sample of what the company thinks and does. Can he judge the whole company accurately from the sample you gave him?▲

BE POSITIVE IN USING INCENTIVES

by JOHN H. WASPI
director, Safety & Driver Personnel, Allied Van Lines, Inc., Broadview, Ill.

The title of this talk "Be Positive in Using Incentives" may cause some people to wonder exactly what do we mean by that subject. According to Mr. Webster, *incentive* is that which incites or has a tendency to incite, to determination or actions; motives; spur, as money and pride are incentives to action.

In other words, when you give someone an incentive, you give them a reason to act as you want them to. Mr. Webster used the word *spur*. This does not mean that you put spurs on your safety director, although spurs might help under certain circumstances.

What do we mean by positive? There are many ways to explain positive, however, in this case I refer to a plus not a minus. In other words, we add, we do not take away. That gets back to the word *incentive*. By giving, you incite someone to act as you wish.

Now what types of incentives are there? Money can be used as an incentive to an employee. The payment is an incentive for them to do their work. Certainly they would not do the work without the money. Money can also be an incentive by giving an employee additional money to perfrom an exceptionally good job.

BOOST THE EGO

There is also "ego." By publicizing the good work of an employee to his fellow employees, you boost his ego and make him proud of himself. Merchandise awards are also incentives designed to bring in the family of the employee. In many cases, the merchandise prize is the best incentive to offer, since the employee who brings home a merchandise prize also benefits his family and at the same time, boosts his ego because his family appreciates what he has done.

Now that we have gone into "positive" and "incentive," let us determine when we should use them. Since we are primarily concerned with drivers and safety, we shall put the *positive* incentive plan for drivers into effect. The most common argument against incentive plans is "why should we give a driver an incentive to do a good job when we are already paying him enough to do a good job." This is a very good argument until you reach a certain point. Our job is to know when we reach that certain point.

Certainly management is not going to give you authority to set up an incentive plan until you hove proven to them that you have done everything that you can to reduce your accident rate through the normal and more economical means. You reach the need for an incentive plan when all else has failed. What type of an incentive plan should you put into effect in your own fleet?

Chances are that you already have some sort of an incentive plan in effect. Every time you issue a safe driver award, you issue an incentive. This is the ego type of incentive. You give the driver a badge telling him that he has operated his vehicle over a period of time without having a preventable accident. You may have a driver of the month program or a driver of the year program in which you honor a specific driver for doing something better than the other drivers. Such a program is a positive incentive on the ego of the drivers.

Now comes the decision. Shall we go into a cash or merchandise plan? If you asked your drivers, they would probably say, "let's have cash." There is a good argument against cash awards. Cash is easily spent and we know that a good percentage of the drivers would spend it on themselves and it will never reach home. Cash in many respects, will do you no good, since it becomes an addition to his salary. He begins to expect it and takes it for granted. Then too, it does not get into the house where the wife and family can take advantage of it. The cash award therefore is not desired in most cases, so let us look at the merchandise award.

The common practice here is to award the driver prize points that are redeemable in merchandise. These prize points are earned by the driver for operating a given number of miles without an accident. He can also be given prize points for operating over a period of time or a specific number of miles without being arrested for violating speed limits or other traffic violations. He can be given prize points for the number of years he has been in service in addition to his accident record or arrest record.

If you have a road patrol system, then he can be given prize points for each satisfactory report he receives. Please note here that we do not take points away from a driver for having a violation charged against his record or an accident charged against his record. It is not recommended that you issue points to a driver and then take them away from him when he has an accident or when he is arrested or when he has an unsatisfactory report of some type or another. That is being negative.

Let us assume that you have set up a merchandise award plan based on the positive issuance of prize points. What is going to be the basis of this program? What will its rules be? It is recommended that you set up your program in such a way that all awards are based upon improvement, either improvement in the driver's record or improvement in the company's record.

POINTS FOR NO ACCIDENTS

Since your company is paying your salary, your first interest should be improving the company record. One thing that you want to improve for your company is your accident rate. Therefore, you can set up your incentive plan based upon accident rate improvement or the reduction of accidents. Prize points can be issued to drivers who have no accidents during a given month. Suppose that you had 10 accidents during July last year and five accidents this year. This is a reduction of five accidents assuming that mileage remained the same or increased.

You can figure the average cost of an accident, multiply it by five, and you have the approximate amount of money saved for the company. Naturally, you do not want to give all of this as incentive prize points to the drivers who had no accidents. Certainly it is worth 50 per cent of the money saved for the company. This amount can be given to the drivers in incentive prize points.

In such a plan, you want to inform your drivers of the company's past record. Keep them aware on a weekly basis of how they are doing in reducing the accident record for that month over the same month for the preceding year. You will note that this is almost a no cost plan since you are saving money for the company over previous experience. You pay out nothing until you have saved for the company.

PROMOTE COMPANY RECORD

At the same time that you issue prize points for reduction of accidents, you want to award those drivers who continually do a good job in accident prevention. You give the men only 50 per cent of what is saved for the company. This leaves you a little room for a bonus. You can give the drivers who go an entire year without an accident, a bonus for their good performance. The amount of bonus may be determined by the company.

The bonus arrangement is a method of taking care of the good driver regardless of what the bad drivers do to your accident record. In other words, it gives the good man an incentive to continue to be a good man even though other drivers have cut him out of participating in the monthly awards due to increased accident ratio for that particular month.

When setting up a merchandise award plan, you must carry your message to the driver's family. This is often done by presenting the prize catalogue to the family as a group. The driver's wife and children immediately become interested in obtaining the many merchandise prizes shown in the catalogue.

FAMILIES HELP PROGRAM

Families then have a tendency to get on the bread winner's back and encourage him to drive safely and perform in such a manner as to earn merchandise awards for them. Experience indicates that as soon as the prize catalogue reaches the home, that it becomes marked showing the awards that will be ordered first.

This should be followed up by constantly reminding the family of the merchandise award plan and that all they have to do to win, is to encourage the bread winner, the driver, to drive safely and follow company rules and good safety practices. You have

in effect, added another safety supervisor to your staff. The wife and the children have a lot at stake, not only the merchandise awards but the life of the husband and father.

This is a positive incentive plan. It can and will work. These ideas and methods are not necessarily the ones that you will want in your own fleet. The idea is to think positive and set up a plan that will improve your safety record and at the same time, improve your drivers.

BE POSITIVE IN USING SAFE DRIVER AWARDS

by JOHN L. HUGHES

director of safety, Southern California Freight Lines, Los Angeles

One of man's most powerful motivations is the desire for recognition. We want everyone to know we excel in our field and this desire frequently forces us to exert a real effort to excel.

As children in school we took great pride in seeing our paper exhibited as an example of neatness, ability or proficiency. When one paper was exhibited we increased our efforts because having once tasted the sweetness of recognition we were determined to taste it again.

As we advanced in years, another motivation began to affect us. This was the desire to belong or be a part of some group or effort. If we were athletically inclined we tried to make the team, or perhaps we joined a debating or theatrical society.

The recognition motivation was temporarily replaced by a strong determination to support the common effort. Soon we realized that we could best help the group by developing ourselves and again the recognition motivation assumed its proper place in our advance to maturity.

EVERYONE DESIRES RECOGNITION

To satisfy both motivations our school made use of an age old idea. Bestowed on us was a device, an insignia or a letter which proclaimed that here is a person who has achieved the right to belong by his ability, skill, knowledge and perseverance. Throughout history men wore signs or devices, perhaps unaware of the underlying urge for recognition.

On leaving school and entering the business world we found the same motivations charting our courses. Perhaps they had now assumed different degrees of relative importance, but we still had them and one of the most important was the desire for recognition.

In our complex modern civilization we find a need for the rapid, safe and efficient transportation of persons and goods. The mule trains and stage coaches of yesterday have given place to rails, planes, trucks and busses. The trucks and busses use the same streets and highways as the public and must cooperate with the public to get the maximum safe and efficient use of these facilities.

AWARD SAFE DRIVERS

A wise employer of commercial vehicle drivers will call upon the basic human urges to help him develop his organization. Aside from the humanitarian consideration, it is economically unwise to have an unsafe operation. One effective means to encourage safe operation of trucks or busses is to recognize the driver who has a record of safety. This recognition will be a challenge to him to continue the safe record, and to other drivers to gain such recognition.

Some persons rely on monetary recognition of a safe driving record. I believe a sign or insignia is more effective. Money may be obtained in many ways but the sign or insignia sets the driver apart and gives him the recognition he values so highly. Such a device is the Safe Driver Award of the National Safety Council, the nation's highest award to the professional safe driver.

No award is effective unless it is bestowed with appropriate ceremony. Such ceremony re-impresses the recipient. But just as important it impresses others with the value and desirability of the award. I have known employers who mailed awards to their drivers or who passed them out like prizes out of a box of cereal. Such awards lost their meaning and value to the safe drivers and were no incentive to others.

In my experiences in the use of the National Safety Award, I found it is imperative to comply with the rules governing qualification. The award must be hard to get. That makes it more valuable. What a man fights for or works hard for, he values more. The award must be known as the sign of a man who knows how to do a good job and has done it.

Each year we have a series of Safe Driver Award dinners. These are regional dinners given at the times and places most convenient to the greatest number of award recipients. We select one of the better hotels or restaurants and choose the menu carefully to insure an attractive, interesting and satisfying meal. We avoid repetition of both menu and location so the drivers can look forward to a new experience each year.

COMMEND DRIVERS' SERVICE

With great care we avoid preaching to these men the benefits of safe driving. After all, these men know how to drive safely. They have proved it. We do, however, impress them with the value of the service they have rendered their community by the manner in which they have operated their trucks. This interpretation of their achievement is clearly illustrated by the speaker or speakers selected for the occasion. We always have as speaker someone prominent in the community. We have had a police chief, a mayor, a highway patrol commissioner, a judge and a senator. The fact that such persons will give up an evening to honor the safe drivers adds to the prestige of the driver and the award.

We publicize the award and the award dinners by newspaper and magazine articles. These articles are clipped and posted on our bulletin boards. Later they are reproduced in our company newspaper. Although this may appear to be repetitious, it is effective in keeping the occasion in our employees' mind for a long time. Sometimes we take pictures of the dinner and put these on the bulletin boards or in the company newspaper.

Our positive approach in building up the value and meaning of the Safe Driver Award has returned to us manifold the cost of the effort. The cost can not be evaluated in dollars nor can the returns. The returns in employee moral and in employee relations, although intangible, can nevertheless be recognized and cherished. Here are some examples of our drivers' feelings for the award which have been engendered by the sincere esteem our management has for it.

PRIDE IN DRIVER AWARD

One of our drivers had become ill and I visited him in his home. He expressed apprehension that his absence might prevent him from earning another Safe Driver Award. I assured him that it would just delay it a bit. A short time later I visited him in the hospital and this time his major worry was that he would miss his three year dinner.

It was apparent that he had little time left him and yet he had time to dwell upon this phase of his obligation to his fellow citizen—the obligation to drive safely. At the funeral the minister related this man's ideals and his pride in having won a National Safety Council Safe Driver Award. One of his last requests was that the award lapel pin be on his coat as he was returned to the earth.

The minister said that long after the physical part of this man was gone there would remain an indestructible monument—his service to his fellow man. This man's effort to drive his truck safely was encouraged and nourished by his knowledge that his achievement would be recognized.

Once while visiting the home of one of our drivers, I saw the 15 Year Expert Driver Certificate on the wall right behind the TV set in the living room. I suspect the TV lamp was placed exactly so it would illuminate the certificate. The driver told me he expected to replace the 15 year certificate with the 20 year certificate immediately after our next Safe Driver Award dinner.

When men take these things home with them and give them a place of such prominence, you know that pride in accomplishment and pride in recognition are supported by an intention to keep up the good effort.

The other powerful motivation is the urge to belong. This urge made its appearance among our drivers in an interesting manner. As it was directly associated with the Safe Driver Award, it is a reaction which will be duplicated whenever management has the same positive esteem for the award. Our president had just bestowed the last award and after a sincere message of thanks, returned the meeting to me for adjournment.

Before I had time to act, a driver stood up and asked for a few minutes. He stated that a number of them had been thinking about the fact that they had something of value in common—the Safe Driver Award, and that they felt that their combined know-how and combined efforts would be of benefit not only to our company but to the community as a whole.

EVERYONE WANTS TO BELONG

The enthusiastic response of the drivers present was matched by the enthusiasm of management and public officials present. Plans were made for organizational meetings and a new traffic safety group was born—Safe Drivers of America.

This is their resolution:

A. We, a group of Professional Commercial Vehicle Drivers, residing in California, who have proved that it is possible to drive such vehicles without accidents, observe that:

B. Whereas, our National Health and Safety depend upon the unrestricted and uninterrupted use of highways in the transportation of goods and persons, and;

C. Whereas much of these goods and many of these persons never reach their intended destinations because of traffic accidents, and;

D. Whereas these accidents take a toll of American life and wealth greater than that taken by war, and;

E. Whereas almost all of these accidents result from the personal failure of one or more drivers, and;

F. Whereas many of these failures stem from improper attitude, from lack of skill, or from ignorance, now therefore,

G. BE IT RESOLVED that, we shall create an organization of drivers of proved skill and ability to drive defensively and so to avoid traffic accidents.

To that end we pledge ourselves: 1. To continue to set a good example. 2. To discourage unsafe acts by other motorists. 3. To join with other Safe Drivers of America in the community for the prevention of automotive accidents.

I believe the individual and group reactions to the National Safety Council Safe Driver Award clearly illustrate what can be expected if we try to develop the position of the award in our safety program.

If we neglect the award, it is just another gadget. If we give it its proper place and make it a positive factor, it can be made to be our most important and effective tool.

THE POSITIVE APPROACH TO DRIVER PHYSICAL REQUIREMENTS

PHYSICAL FACTORS

by DR. EUGENE P. OWEN
president, Northwest Association of Occupational Physicians, Portland, Ore.

Prevention of motor vehicle accidents is a universal concern, accidents in general representing the major public health problem in the nation.

The public should be conditioned to accept more stringent qualifications for driving vehicles, such as those now accepted for flying planes or carrying a gun. Finding poor drivers and removing them from the highways is a major need.

In January 1956 the nation was shocked; headlines flared. A Santa Fe passenger train, on a curve, had left the track at 70 mph. The tragic results were 30 dead and 117 severely injured. The Interstate Commerce Commission reported the engineer was 61 years old and in the opinion of the examining physician, had suffered an epileptic seizure and was not conscious of his actions at the time.

In Johnstown, Pennsylvania in 1953, a truck and trailer loaded with steel bars collided head-on with a passenger bus that was just discharging its passengers. The truck was on the wrong side of the highway. The findings were that the truck driver was a diabetic and in insulin shock at the time of the accident.

PHYSICAL HAZARDS

These are just two of a number of serious accidents that have occurred in the transportation field and have resulted from a physical condition affecting the driver. They have this in common: an individual was relied upon to control a moving vehicle, but because of a physical condition he was rendered unfit for the task, thus the vehicle, weighing many tons, was released from conscious control and of course was capable of great destruction.

I am in no way criticizing the industry. I know the progressive steps that have been made in accident prevention. At Consolidated Freightways in 1948, the accident rate was 1.49 per 100,000 miles; in 1956 it was .51 per 100,000 miles. This has meant saving in life, a saving of many painful hours of suffering, also many dollars. In 1948 the cost at this company was one cent per mile and in 1956 it had dropped to .03 cent per mile.

I also realize that companies have devoted a greater part of their research to develop mechanical safety devices. By that I mean the size of wheels, the skidability of tires, and the braking surface of the brake-drums. All of these, of course, have been great accident reducing factors. But quoting Ernest Cox of the Interstate Commerce Commission:

"In truck accidents during the past year only about 14 per cent were due to mechanical failures and about 86 per cent to human failures."

NO SUBSTITUTE FOR DRIVERS

Our economy is geared to trucks. They are our life blood. They move over congested roads at high rates of speed, carrying 20,000 to 40,000 pounds of cargo day and night, in all kinds of weather. The operation of these vehicles requires a more alert and physically qualified man back of the wheel than in any other type of transportation. The railroad has a dead-man switch, and is operating upon a restricted right-of-way. The airplane pilot has dual controls with a co-pilot.

But the truck driver is alone, all by himself. He must then be in top physical condition at all times. In addition he has a great economic value to his employer. The cost of selecting and training of a driver is estimated at $4,925.00 at Consolidated Freightways.

In an attempt to control the drivers in interstate commerce, the Commission has formulated minimum regulations, they are

1. There must be no loss of foot, leg, hand or arm.
2. No mental, nervous, organic or functional disease can interfere with safe driving.
3. No loss of fingers, impairment of the foot, leg, fingers, hand or arm or other structural defects or limitations can interfere with safe driving.
4. There must be a visual acuity of at least 20/40 (Snellen) in each eye, either without glasses or corrected with glasses; the form field of vision in a horizontal meridian shall be not less than a total of 140 degrees; there shall be an ability to distinguish red, green and yellow colors.
5. The hearing shall not be less than 10-20 in the better ear without hearing aid.
6. There shall be no addiction to the use of narcotics or habit forming drugs, or the excessive use of alcoholic beverages.

Dr. Payne is to discuss the visual factors and Dr. Turrel the emotional or psychological factors. I will concentrate on the regulation: no mental, nervous, organic or functional disease that may affect safe driving. These are the physical factors affecting safe driving.

DANGEROUS PHYSICAL CONDITIONS

Now what are some of these? One of the most vital is vascular and by vascular I mean heart or circulatory diseases. Can or should a man be issued a certificate to drive who has had a heart attack or a coronary occlusion? These are often immediately fatal and if not, the occurrence of the next occlusion cannot be predicted. The United States Air Force, commercial and passenger airlines ground permanently all pilots who have had an occlusion.

At the Consolidated Freightways there has never been an accident due to a coronary occlusion. There have been some heart attacks but fortunately the driver realized he was ill and had pulled off the highway before death occurred. The margin of safety, however, far too close and in my opinion a certificate should never be issued to an individual with a history of a previous attack.

There are many other types of heart conditions that are dangerous because they will cause a sudden loss of consciousness; but if an adequate physical examination is done, they most certainly would be recognized for their danger.

BEWARE HIGH BLOOD PRESSURE

Another vascular condition is high blood pressure which may precipitate a stroke. Prior to the time a stroke occurs there have been many small hemorrhages in the brain. This has been demonstrated at autopsy, when many scars have been found in the brain tissue. I am wondering if some of the accidents reported in which a driver states that he blacked out could not have been due to one of these tiny hemorrhages that caused a momentary loss of consciousness, which, in turn, has been due to high blood pressure.

We realize that truck driving is a sedentary job and that obesity in truck drivers is perhaps higher than in other types of workers. Obesity often is accompained by an increase in blood pressure. This, then frequently leads to premature disability of the driver.

Now, believe it or not, the Interstate Commerce Commission regulations concerning blood pressure states merely "An individual having a blood pressure over 150 mm of mercury, systolic, shall have a urine test."

Another large group of diseases that are potentially dangerous are neurological conditions. Our interest in this group is because these conditions may produce abnormal muscular reaction.

About two months ago a driver, four miles from his terminal, and just at the beginning of his run, crashed into a bridge abutment. Apparently there were no known causes of the accident. The driver could not explain what had happened. However, electroencephalographic tracings showed an abnormal tracing consistent with epilepsy. Therefore, it is most likely this driver must have been having an epileptic seizure at the time of the accident.

The sclerosing diseases affecting the brain and spinal cord are almost uniformly disabling. Some of these are, Lou Gehrig's disease, multiple sclerosis and Parkinson's disease. These diseases are easily diagnosable and should be easily detected on examination. Because they may cause a lack of coordination, slowing of reflex action, momentary blindness and sudden loss of consciousness, anyone with one of these diseases should not be issued a certificate to drive.

Another group are the metabolic conditions, such as diabetes and its disturbances. In the Johnstown, Pennsylvania accident the taking of insulin by a diabetic precipitated a loss of consciousness. But a diabetic without insulin is apt to have major problems. Diabetics soon lose depth perception and will go into a coma if their diabetis is not controlled.

As Dr. Melvin Newquist, medical director, Texas Company, in a recent article concerning drivers, said: "At first it would seem desirable for the physician to individualize each case of the diabetic driver; this however, is not advisable inasmuch as the physician, the diabetic, or the employer, does not always have control of conditions which would safeguard the diabetic driver against either drowsiness or coma, or insulin shock. Long hours, irregular meals, emergencies, or breakdowns, wherein food or insulin may not be obtained, are some of the complicating factors beyond control of the certifying physician."

DANGEROUS DRUG EFFECTS

Another group of conditions that should be discussed are those due to drugs. The sleep-resisting drugs called amphetamines are by far the most dangerous. They have a two-fold use, that of keeping one awake and to dull the appetite. Their use by truck drivers is common. These drugs often produce hallucination, visions of on-coming vehicles, animals in the road, strange objects or peculiar twists in the highway. Accidents from the use of these drugs are assuming serious proportions.

Tranquilizing drugs! Two hundred million dollars worth were sold during the last year. They are sleep producers. The sheriff of Imperial County, California, cited the fact that seven fatal accidents during 1956 could be traced to these two types of drugs.

Other physiological conditions are malignancies, anemias, and the leukemias. A case in point: Driver C had had most of his stomach removed because of cancer. Six months later he was recertified to drive. One night on the highway between Portland and Spokane, Washington, his rig was seen weaving from one side of the highway to the other. A driver supervisor who fortunately happened to be following him was able to stop the rig.

The driver was in a partial coma. The coma was due to complete debility from the lack of proper digestive function and the assimilation of food. Of course this driver is now on another type of job, but it does illustrate that more thorough and detailed study should be given to these men prior to the time a certificate is issued.

AMPUTEES—BAD RISK

With relation to amputations, there should be no necessity to discuss these conditions as it is evident that one with an amputated extremity should not be issued a driver's certificate. At a meeting in Portland, Oregon of an amputation clinic a rehabilitated amputee, his leg having been removed at the hip, was on his first job since his injury, and to my amazement his job was to "drive a ten-ton truck." This had been arranged for him by the rehabilitation department of the State Industrial Accident Commission.

The best example of the loss of function of an extremity or a portion thereof is the end result of poliomyelitis. Many of these persons have a real impairment and in most cases should not be allowed to drive.

In an attempt to track down the causes of driver accidents we at the Consolidated Freightways have compiled the results of the last 155 accidents; 27 per cent of these accidents were caused by the less-than-five-year driver. The larger percentage of accidents in all ages occurred in the first four hours of driving, regardless of the time of day or of traffic hazards. We are in the process now of reviewing the medical histories of these drivers, and one of the salient facts worth mentioning is a possible relationship to diet.

I am sure that this type of careful scrutiny of accidents by the Medical Department has been a primary factor in savings .07 cent per mile at Consolidated Freightways.

Here are some positive approaches you should take to see that drivers are in the best physical condition at all times and that the physical factors affecting safe driving are safeguarded.

ORGANIZE MEDICAL PROGRAM

● Some medical program should be started by your company. Many companies are now large enough to have full time medical directors, heading a medical section. Through this department pre-employment physical examinations should be evaluated to determine whether the drivers are meeting adequate standards for safe driving.

Re-examination records should be kept and evaluated over the years, as we now know that many drivers are getting into the upper-age level in which degenerative processes may rapidly develop. These re-examinations should be thoroughly scanned for disease trends and corrective measures instituted.

Again quoting Ernest Cox, "No one would inspect a vehicle for the sole purpose of determining whether or not it was roadworthy and upon the first unfavorable finding, junk the entire rig. Rather, such an inspection is expected to detect unusual wear, defects, and cracks in their early stages, so that corrective measures may be taken."

Just recently the safety director of a major motor carrier of the mid-west presented himself for examination to 11 local physicians who were retained by his company for driver examinations. He was sadly disappointed by the results of five of his examinations. As he said: "Particularly were the physicians uniformed as to I.C.C. regulations and were not aware of their vital importance in this commercial field." A medical department should assist in the selection and education of physicians doing these examinations.

DOCTOR ON BOARDS

● On every accident board there should be a well-trained physician, and a thorough study should be made of the driver who has had the accident to determine the possibility of human failure. A case in illustration. About two years ago one of our drivers applied for a transfer from Portland, and he was assigned to a run out of Chicago. In two months he was back on the coast, and presented himself at my office complaining of severe stomach distress.

Adequate examination disclosed no disease. A few days later he rolled a truck and trailer on a curve. At the accident hearing he maintained he had blanked out. The real cause of this human failure was a psychotic wife, who threatened to kill herself and their baby. The answer in this case was simple, and we placed the wife under psychiatric care. Happily the matter was straightened out and he is now an adequate driver.

The Interstate Commerce Commission requires that a driver shall be examined once every 36 months, but many conditions may develop the day following an examination.

RE-EXAMINE DRIVERS

● I suggest that all drivers should be re-examined after any illness requiring ten days away from duty, or following any major accident. The results of this examination should be kept in his medical file, not the personnel file, by your medical section, and from these files adequate statistical information can be developed of the relationship of disease to accidents.

The Industrial Medical Association and the Industrial Council of the American Medical Association have an active committee now at work on driver requirements and it has been surprising how little information has been obtained from companies concerning the effects of disease and accidents. Their report will be released in the near future.

The I.C.C. is attempting to enforce its driver regulations but because companies have failed to evaluate accident records in the light of human failure, they have little or no basis upon which to suggest that additional recommendations be included in their driver requirements.

Until physicians have more detailed positive regulations, in which disqualifying defects and diseases are listed, the Commission's regulations will be subject to individual interpretations, and because of these interpretations, we are very likely to have drivers on our highways with physical impairments that are apt to cause accidents.▲

VISUAL FACTORS

by DR. BRITTAIN F. PAYNE
clinical professor of Ophthalmology, New York University Post-Graduate Medical School, New York City

Poor eyesight may be the basic cause of the awful carnage from automobile accidents occurring every day in our country. Far too many automobile drivers with defective vision are endangering the lives of others and themselves on the roads at the present time. Many drivers see well enough, but they fail to use judgement or act in accordance with what they perceive. This is a psycho-physical problem and not related to eyesight.

It matters not, whether one is an experienced commercial driver in a deluxe bus or an old-individualist farmer with a model "T" car, visual requirements should be definite and fixed. At present, there is a tendency to require better vision in commercial drivers. The day will come when driver requirements will be the same for the individual as for the commercial drivers. The people will demand this equalization to spare the lives of their families and themselves. It is just as important for the average driver to have good vision as the special operator of highly specialized machines.

CONGRESS BILL

Automobile fatalities have created such a problem that Senate Majority leader, Lyndon Johnson of Texas, introduced a bill in Congress to investigate and report on necessary measures for correction. The bill, S.1292, which would establish an Automobile and Highway Safety Division within the Department of Health, Education, and Welfare is as follows:

"(1) collect from public and private sources information on the causes of automobile accidents and possible preventative measures to eliminate such accidents and to reduce the seriousness of injuries caused by such accidents (including the design of automobiles and highways) and support and aid research to determine such information.

(2) evaluate and disseminate such information in such manner as may best promote safety on the highways and the reduction of the automobile accident death toll; and

(3) prepare and establish, on the basis of such information and in cooperation with other Federal agencies, with state and local governments, and with industries involved, programs to promote safety on the highways and to reduce the automobile accident death toll."

This measure was referred to the Committee on Labor and Public Welfare, without action being taken. Such an investigation would undoubtedly call for a visual evaluation of operators of motor vehicles. Perhaps some correlation of vision and accidents could be determined. At the present time, there are no adequate figures but Dr. DuPont Guerry III, a medical authority, has stated that between three and five per cent of the accidents are caused by faulty vision. He further reports that visual acuity requirements range from 20/70 to 20/30 in 46 states and no tests are required in two states.

My thoughts on the importance of vision in driving were stated most ably by Mr. S. E. Nelson, Supt. of Safety, Burlington Truck Lines, Galesburg, Ill., in his excellent argument "Against Road Patrolling" at the 44th Annual Safety Congress, October 1956, in Chicago. His statement in the 1952 Transactions, Vol. 18, p. 12 were as follows:

PORTABLE CLINIC TESTS VISION

"We are currently engaged in a program of testing drivers in our fleet on a portable clinic, which tests color vision, visual acuity, depth perception, field of vision and reaction time. During the first week of this testing we found a driver who had not had a physical since July 11, 1955, and, therefore, was not due for another one under I.C.C. rules until July of 1958. This man's eyes had failed during the past few months to the extent that he could not see well enough to drive safely. When we con-

fronted him with the results of our tests, he readily admitted that he could not get around to spending the amount of money required for a pair of glasses. He agreed to have his eyes tested by a doctor and received a new pair of glasses.

"Today that man is a safe and happier employee, and no doubt is probably grateful for the testing job that we did. I might add that we could have followed this man on the highway for miles and probably wouldn't have the faintest idea that his vision was poor. Yet, he could have been involved in an accident because of his failure to see a hazard or danger. My point is this: The money spent in testing this man was a better investment than the same amount of money spent to buy an observation report of his activities."

Mr. Nelson's experience with this employee is fairly common with those of us who examine eyes day after day.

Unfortunately, the vision of some operators cannot be improved by glasses alone.

Recently, a trusted personal chauffeur of an official of a great corporation was sent to me for relief of failing eyesight. The examination showed beginning blindness from extensive retinal hemorrhages. Further tests showed that he had unsuspected diabetes mellitus and his sight was so affected that it could not be restored. The employer had not insisted on a pre-employment examination of his personal driver, when his company insisted on annual medical examinations of all employees, including the official himself.

RECOMMENDS 20/30 VISION

The ability to see is recognized as the most important factor in driving an automobile of any type. Responsible bus line and trucking firms insist on strict visual requirements. Dr. Hedwig Kuhn, a recognized authority on vision in industry said that some firms follow Air Force regulations for pilots closely when selecting driving personnel for commercial purposes. Such requirements exceed those suggested by the XIII International Congress of Ophthalmology and the recommendation made at a meeting sponsored by the American Medical Association at New York University Medical College, May 23, 1956.

Although I participated in this meeting with Doctors Kuhn, Berens and others and was in agreement with the suggested recommendation of correctable vision in each eye of 20/30, (if glasses required for 20/30 they should be unbreakable or an extra pair should be available) it is my feeling now that better correctable vision of 20/20 for each eye should be required. Just what disposition is to be made of vision in relation to motion and moving objects will have to be evaluated in the laboratory and on the highways themselves.

The above is concerned with vision for distance. The ability to shift the focus from the road to the instrument panel is the effort of accommodation. It is taken for granted that human engineering has taken care of the visibility of the instrument panel. Older farsighted operators frequently used weak bifocal lenses to see the speedometer, oil gauge, and other instruments. Although, not continuously required for drivers licenses, it should be noted on employment and reexaminations. Some embarrassment might follow if the driver could not see the indicator for "engine heating." Eye glasses might help the lack of accommodation.

DOUBLE VISION DANGEROUS

"Seeing double" or diplopia is a serious condition which may cause an automobile crash, head-on collision and side-swiping. Double vision indicates lack of muscular coordination, either from fatigue, injury or disease, and should disqualify a person from any type of driving. A test for double vision should be included in the examination.

A satisfactory test for depth perception, or the ability to locate still and moving objects in space, in daylight and partial darkness should be devised and used. It might be well to investigate road hypnosis and the effect of twilight on this faculty or vice versa. Misjudging distance in passing may be the direct result of poor depth perception. A test for stereoscopic vision will give some information at least.

Color vision or the ability to recognize colored traffic lights, in dazzling sun, fog and at night is necessary. At least one out of every 10 males and one out of 1,000 females have some deficiency in color appreciation. A simple lantern-type test for red, yellow and green would be satisfactory for practical testing. My own experience with 25 per cent color deficiency while driving into the sun makes it almost impossible

to tell when the lights turn green. A heavy fog confuses my color appreciation quite seriously. Therefore, total "colorblindness," whether congenital or acquired from tobacco and alcohol or disease, should be a disqualifying factor.

Dark adaptation and recovery of vision from glaring headlights are important factors in safe driving. The tests are rather complicated, but give considerable information of value. Ingestion of vitamin A will help dark adaptation which tends to diminish with age and is definitely lowered by alcohol, tobacco, and carbon monoxide fumes.

REQUIRE 140 DEGREE SIDE VISION

Peripheral vision or side vision is a necessary faculty in safe driving. Such diseases as pigmentation or separation of the retina, increased pressure within the eyeball, scarring and hemorrhages will cause serious loss of side vision. If the driver is progressing through a narrow tunnel of vision, it is impossible to see many objects overtaking him or approaching from either side. A crash may result because the affected driver may not see the object in time.

The normal field of vision for the two eyes in the horizontal plane is at least 180 degrees and less than 140 degrees should disqualify for driving. When the eyes are tested separately the horizontal extent of the field should not be less than 70 degrees and if any meridian shows contraction to 20 degrees the applicant should be disqualified. He should be limited to daylight driving because he is actually driving through a narrow tunnel of sight.

Dr. Harold Brandaleone, Medical Director of the Third Avenue Transit System and the United Parcel Service of New York City, uses a profile classification system similar to that of the United States Air Force. Class 1 represents the highest and class 4 the lowest division in this evaluation. The use of narcotics, sedatives, antihistamines, dexedrine and other stimulants in excess as well as chronic use of alcohol will place the applicant in the fourth group. The visual standards are similar to the above discussion.

The recommendations of the Committee on Visual Standards from the meeting on Medical Aspects of Motor Vehicle Accident Prevention at the New York University-Bellevue Medical Center 23 May 1956 are worthwhile. Although minimal in many aspects, adoption of these recommendations may save many lives on our highways. They are as follows:

"We recommend that the usual three main categories of public transportation, interstate commerce, and private care operators be changed so as to combine public transportation and interstate commerce personnel into one group.

"I. The following are our recommendation for the minimal visual standards for the first group (public transportation and commercial operators):

A. A correctable visual acuity to 20/30 Snellen in each eye. If corrective glasses are required for obtaining visual acuity of 20/30, unbreakable glasses or an extra pair of glasses should be mandatory.

B. Form fields of 70 degrees in the horizontal meridian with each eye and 140 degrees in the horizontal meridian with both eyes.

C. No requirements for color vision indicated. However, it is recommended that the shape, size, position, and color of traffic lights be standardized.

D. No requirement for stereopsis (depth perception) indicated or recommended.

E. No test for light sense recommended but the presence of night blindness should be excluded by direct question.

F. Mandatory yearly examinations under the supervision of a qualified eye examiner.

FOR NON-COMMERCIAL DRIVERS

II. The following are recommended as the minimal requirements for private car operators:

A. A correctable visual acuity to 20/40 Snellen in one (the better) eye.

B. Form field of 70 degrees in the horizontal meridian in each eye or 140 degrees in the horizontal meridian in one eye.

C. Re-examination of eyes every three years.

III. The following recommendations are considered pertinent to the board role of vision in safe motor vehicle operation:

A. There is need for greater recogni-

tion and correction of present inequalities in related state laws.

B. Further consideration must be given to such mechanical factors as the following:

1. Vehicle design (windshield bars, wipers, blind spots, etc.).
2. Lowered visibility in use of tinted windshield and/or use of tinted glasses for night driving.
3. Reflections inside the car (chrome, etc.).
4. Rear window and mirrors.
5. Visibility of moving objects on road or roadside.

C. Consideration should be given to the advisability of requiring parties involved in a serious accident to undergo more extensive medical (including visual) and mental examinations under duly qualified examiners to evaluate their fitness to continue to drive.

D. No specific recommendations are made at the present time in regard to color vision, stereopsis, and light-sense because of the lack of uniformly acceptable tests.

E. Consideration should be given to further research concerning the relation between the causes of accidents and depth perception (stereoscopic vision), muscle balance, and particularly visual and mental reaction time.

F. It is recommended that every commissioner of motor vehicles have available qualified eye consultants for consideration of all visual problems, including limited license and hardship cases.

G. It is recommended that the licenses of all individuals receiving aid for the blind be revoked.

Great emphasis must be placed on further evaluation of total environmental factors in accidents and on scientific determination of the perception and proficiency of drivers."

My personal feeling is that far too many automobile drivers with defective vision, are endangering the lives of others and themselves on the roads and highways today. Persons with one eye or defective vision in one eye should be given limited driving licenses.

Drivers with poor color appreciation should be examined carefully and if they are unable to distinguish red and green lights their licenses should be limited to daylight driving only. If the fields of vision are diminished to less than 20 degrees in any meridian, the applicant should be limited to daylight driving.

Applicants with poor depth perception, the inability to locate objects in space, should receive special attention and perhaps be disqualified for night driving.

EMOTIONAL FACTORS

by DR. EUGENE S. TURRELL

director, Psychiatric Div., Denver General Hospital, Denver, Colo.

Injuries and deaths due to accidents constitute one of the major health problems of this country. As in the case of any health hazard, a knowledge of etiology is of paramount importance in developing adequate preventive and treatment measures.

The task of investigating a phenomenon as inherently complex and as multi-determined as motor vehicle accidents demands a many-sided approach. Among the types of accident research currently in progress, they are:

1. Studies of factors of automotive design and safety features
2. Investigations of the relation of highway design and traffic characteristics to accident frequency
3. Research on safety regulations and law enforcement
4. Studies of the relation of physical health and physiological functioning to accident susceptibility

Added to these, are studies of emotional factors in relation to accident frequency and

investigation of the effects of psychotherapy on driver behavior. Though this paper will focus on emotional factors, it must be emphasized that these influences operate within the previously noted framework of multiple causality.

EMOTIONAL CAUSES OF ACCIDENTS

Interest in emotional factors in accidents gained its impetus when Marbe, in 1926, proved statistically that the person who has one accident is more likely to have another than the person who never had one. In 1934, Alexander Adler suggested that an unknown factor in human personality was responsible for repetition of injuries in these persons prone to accidents.

Additional work of Dunbar, Menninger, Tilman, McFarland, and others further demonstrated this relationship between personality factors and accidents. However, what might be considered a single influence in causality, turns out to have multiple facets. In other words, there is not a single, isolated emotional influence related to accidents but rather a multiple of interrelated emotional factors—thus further complicating our already complex system of multiple causality.

Perhaps I could illustrate this by brief case histories:

● One young man in his early twenties had five accidents during a three-year period. During this time, his father had been ill and our patient had to do all of father's work around the farm. The patient had resented this, and the five accidents had all occurred while driving the father's car, with damage only to the car.

● Another patient had an accident, when he ignored a stop sign and a truck ran into the right side of his car. His wife was sitting on the right side holding their baby. Fortunately, no one was injured. However, a careful history revealed that this accident had occurred following an argument between the patient and his wife—an argument which the patient felt that he had lost.

● Another patient had six accidents in a two-year period. In all of these, the patient had been run into and complained that he was not at fault. He made it appear as though he had been victimized in each circumstance and was thus able to seek sympathy in his role as the victim. However, the number of accidents of this nature would indicate that he had had something to do with setting the stage. Further evaluation revealed underlying suicidal drives.

Though the settings were superficially different in each of these cases, each involved hostile and aggressive impulses. The difference appears in the handling of these impulses. In other cases, sexual impulses or guilt reactions to sexual impulses may be involved. Menninger, in his book "Man Against Himself," classifies the accident motives as follows:

1. As a means of atonement of guilt
2. As a permission for further indulgence
3. As a result of rage

But this leads us a little nearer the solution of the accident problem, since much of human behavior is motivated by sexual and aggressive impulses.

ACCIDENTS REVEAL HOSTILITY

During our studies at the University of Colorado, we had the impression that a measure of hostile, angry feelings would give some indication of accident susceptibility. Such feelings generally arise from frustration of normal aggressive drives and, psychodynamically, are found to stem from early frustrations. We used the Rorschach test as an indicator of these impulses, or derivatives of impulses, and intensively studied a group of accident and non-accident subjects.

These tests were then interpreted by skilled psychologists who did not know into which group each of the subjects belonged. The subjects were divided into two groups on the basis of the degree of exhibition of such impulses, with the startling result that each group was composed of half accident and half non-accident subjects. We could not have come closer to a chance phenomenon had we tried.

HANDLING AGGRESSION

On the basis of this study, we concluded that accident potential is not related to the degree to which individuals have such impulses, but rather to the methods by which they handle or cope with these impulses. Incomplete results on further analysis of our data continues to support this conclusion. The question then becomes: having experi-

enced such feelings or impulses, how does the individual control his behavior?

This view agrees with other findings of our study—that accident and non-accident drivers are best differentiated by a particular test, the Allport-Vernon scale of values.

This is a test which rates individuals as to how well they agree or disagree with different value systems. Those dealing with aesthetic, theoretical, and religious concerns proved highly discriminatory on both the original and cross validation samples in our study. The remaining scales (economic, political and social) did not.

The non-accident subjects were more oriented toward religious values and less toward aesthetic and theoretical values than the high accident subjects. The mean scores of a middle accident group fell in a middle range between the high and non-accident subjects.

DRIVING REFLECTS LIVING

Such a differentiation would further indicate the importance of controls over impulses, since value systems are probably a reflection of behavior in response to varying impulses. These findings are in agreement with Tilman's studies and his classic statement that "a man drives as he lives."

Dunbar in her studies of accident proneness also emphasizes the behavioral aspects of the accident subjects. She describes the accident-susceptible person as a decisive, psuedo-impulsive person with unresolved conflicts with authority; and makes the interesting observation that accident proneness seems to occur when delinquent behavior is no longer a successful mechanism for handling such conflicts.

Each of these studies would indicate, then, that social adaptation and value systems of the individual will give some clues about his safety as a driver. If these findings are valid, we are then confronted with the question: What components of social adaptation and of value systems will best discriminate between the accident susceptible and the non-accident driver?

Our findings with the Allport-Vernon scale of values need to be validated on a larger sample and it is hoped that commercial firms might use this test and compare the results with the accident records of their drivers. In addition, both Tillman's and Dunbar's studies give some clues concerning features of the social adaptation which might be utilized and compared with accident records of the drivers.

A history of conflict with authority and delinquent or psychopathic behavior, especially if these behavior patterns have changed, may be good indicators of accident susceptibility. It should be emphasized, however, that the use of such indicators should be approached as research studies, since the validity of these observations requires further confirmation.

In the practical problem of selection of commercial drivers, there is an additional complicating factor—the motivation for this particular type of employment. The motivation should also be evaluated to determine whether or not this contributes to or subtracts from the personality features associated with accident susceptibility.

At this point, I should like to digress for a moment and discuss the relationship of psychoses and neuroses to accident susceptibility. I have never seen any valid studies which would indicate that neurotic or psychotic patients are more prone to accidents than other groups.

In addition, my own clinical experience would indicate that patients with certain types of illnesses, who come to the attention of psychiatrists, may have less than average susceptibility to accidents. Therefore, I would caution against considering a person accident prone because of manifest psychiatric symptomatology.

INTELLIGENCE INFLUENCES

The level of intelligence is another factor frequently implicated in accident behavior. Though I do not have specific references, there are indications that, in routine jobs of driving, highly intelligent individuals have more accidents. It has been implied that the discrepancy between intellectual capabilities and the demands of the job leads to boredom which in turn leads to accidents.

However, it is equally valid to assume that such accidents are the result of frustrated ambitions, which could reasonably have been achieved, had such highly intelligent individuals been able to properly channelize their aggressive drives.

It seems reasonable to assume that, at the other end of the scale, low intelligence would interfere with ability to master the complexities of driving and would therefore be associated with increased frequency of accidents. This is undoubtedly a factor at some level of intellectual deficiency but further data is needed to determine the level at which this becomes a factor.

To this point, our discussion may have led to the impression that personality problems are static and are amenable to single analysis from which we can predict driving behavior. This may be the case in a small group of frequent repeaters, but it is far from the fact in the majority of individuals who have accidents. As in the case of the young man who had five accidents with his father's car, he ceased to have accidents when his father got well and he, the subject of our study, was no longer required to carry on all of father's duties.

CAN PREDICT POTENTIALS

Probably most accidents are experienced by individuals during periods of stress with accident susceptibility subsiding as the stress is alleviated. However, basic value systems and behavioral mechanisms for handling such conflicts may be subjected to evaluation: thus indicating the potentiality of accidents if the individual does meet particular stressful situations.

Now, assume for a moment that we could be completely successful in the selection of drivers who would not have accidents. Dunbar reports on one commercial firm who transferred susceptible accident drivers to other jobs within the company, only to find that they continued their accident behavior by having other types of industrial accidents.

If all industries could select accident-free personnel, manpower resources would not be adequate from which to choose. Therefore, in addition to evaluation procedures, we will need to develop preventive measures to help certain individuals overcome their accident susceptibility. We need further research in education, counseling, incentives, and psychotherapy as useful measures in the field of accident prevention.

HELP SUSCEPTIBLE WORKERS

It might also be of value to explore the possibility of substitute aggressions. The noted physiologist, Dr. Walter B. Cannon, pointed out that the physiological mechanisms for our aggressive behavior stem from the time that man lived a more primitive existence and needed such defenses. Though modern society does not require such primitive aggressions, the mechanisms still exist and still react.

Dr. Cannon proposed a program of substitutes, such as competitive sports, as a means of discharge of these aggressions. I recognize that many industries have programs of sports and recreation but do not know that such programs involve a large percentage of employees, nor that the effects of such programs upon accident rates have been evaluated.

I should like to emphasize the need for additional research regarding factors in causality as well as in prevention of accidents. Much of this can be done with properly controlled studies in the field of commercial driving and I would encourage the increased development of such programs of investigation.

PANEL FORUM ON POSITIVE DRIVER TESTING

by A. E. NICHOLS
safety director, Consolidated Freightways, Inc., Portland, Ore.

Medical Panel: DR. EUGENE P. OWEN, DR. BRITTAIN F. PAYNE, DR. EUGENE S. TURRELL

Group Interviewers: DR. HAROLD BRANDALEONE, medical director, United Parcel Service; assistant clinical professor of medicine, New York University, College of Medicine, New York city; E. G. COX, chief, section of Motor Carrier Safety, Bureau of Motors Carriers, Interstate Commerce Commission, Washington, D. C.; J. P. HIGHTOWER, director, transportation and safety, The Greyhound corp., Chicago, Ill.

Nichols: Starting with the interviewers at my left. Mr. Cox, do you have a question?

Cox: Dr. Payne, you advanced the theory that far too many automobile drivers are driving with defective vision and are endangering their lives as well as the lives of other users of the road. Do you know this to be so or do you assume it?

Payne: I assume it.

Cox: How are we ever going to approach the problem if we are going to have to rest at this point without ever running down a positive finding in the situation and is such an eventuality possible in your judgment?

Payne: Yes, I think it's possible. All you have to do is to refer to the eye examination record. If these requirements are stated and duly recorded they may be associated with the accident. If a driver should see double, as he might through the curved windshield or if his vision is such that his eyes do not focus properly and he sees double it is reasonable to assume that that accident was caused by trouble with his vision. Frankly, I do not know, it's up to the safety engineers to figure out how they would associate this visual difficulty with the accident. Things happen so rapidly, with the emphasis on speed and power that you hardly have time to associate one cause with another, but it is only reasonable to suspect that some accidents do occur from blackouts or from poor vision.

Brandaleone: Mr. Chairman, I would like to explain that the problem of motor vehicle accidents requires an educational program not only for the public but for physicians. National medical committees are trying to educate the physician about his important role in motor vehicle accident prevention. There is a committee on standards for motor vehicle drivers of the Industrial Medical Association and a committee on medical aspects of motor vehicle injuries and deaths of the American Medical Association.

EDUCATING PHYSICIANS

There is also a Committee of Congress that is investigating motor vehicle accidents. The committees are working almost full time to establish medical criteria that can be presented to the physician and everyone else interested in this problem. These criteria will assist in determining who should be granted a license to drive.

The industrial physician can supervise the drivers under his jurisdiction and observe and study them. The Committee of the Industrial Medical Association is trying to collect data, through questionnaires on the relationship of various physical or organic diseases associated with accidents. As soon as this data is collected the results will be published.

The American Medical Association Committee is working on a booklet that will be sent to physicians who will make it available to his patients. This committee is also preparing two other books. One book will contain the criteria for licensing and will be available to all police and motor vehicle licensing bureaus. The other will be written for doctors to assist them in deciding who is capable of driving. This is a tremendous project and requires a great deal of time.

The Interstate Commerce Commission requires assistance in establishing further criteria. At the present time their criteria are general. Their present standards state that if a person is not qualified to drive, he shouldn't. But they do not state specifically what that means. It is felt that more specific standards should be required.

Three papers give specific criteria for motor vehicle drivers. One paper is called "The Physical Standards for Vehicle Operators" it was published in *Industrial Medicine and Surgery*, in January, 1956. Another paper "Recommendations for Medical Standards for Motor Vehicle Drivers" was published in *Industrial Medicine and Surgery* in January, 1957, by the Committee of the Industrial Medical Association. The third paper presents results of the symposium at New York University called "The Medical Aspects of Motor Vehicle Safety" which was published in the *New York State Journal of Medicine*, December, 1956.

Basically, everyone agrees that rigid rules are necessary to stop the tremendous loss of life that occurs on the highway. At the present time the rules are not rigid enough. The Industrial Medical Association Committee is studying the results of a questionnaire to determine in industry the relationship between coronary occlusion and accidents.

HYPERTENSION HAZARDS

Someone asked about hypertension. At what level is it dangerous to drive? This depends on individual evaluation—and the answer depends on the complications of hypertension and the condition of the heart and blood vessels. I would disqualify a driver for hypertension when it reached somewhere between 180 and 190 systolic and 100 diastolic. Some doctors may have different ideas. They may be more lenient or more rigid.

Dr. Owen mentioned something about drivers being obese and having more coronary disease. Recently I had the privilege of spending two days with Dr. Leslie Norman in New York. He is the medical director of the London Transport. He has 40,000 drivers under his jurisdiction. He studied bus drivers and found that there was a much higher percentage of drivers as compared to conductors who were overweight and had coronary disease.

I believe we are all aware of the importance of neurological problems. Persons with convulsive disorders should not be allowed to drive.

We will allow a driver in our company to drive if he has diabetes but does not take insulin, provided he checks with us frequently. However, there is always a possibility that he may be taking insulin without our knowledge. If the person is taking insulin we do not want him to drive under any circumstances. There is a new drug in the treatment of diabetes, orinase, a tablet, which is taken by mouth. This drug is effective in mild older diabetics. Persons taking orinase do not develop the same type of hypoglycemia that occurs with insulin. Recently in a discussion with a physician from the Joslin Clinic in Boston, I learned of a case where after two days of orinase medication the patient went into a coma and died. So you see, even with orinase, unconsciousness occurs in some patients.

The effect of drugs on driving is another important problem for discussion. Everyone must remember that the drugs sold at the drug stores for the common cold contain antihistamines. There is nothing that makes some people sleepier than antihistamines. There is no question that the amphetamines are stimulating and will keep people awake. Many people expect these drugs to work in spite of overwhelming fatigue and when they don't an accident occurs.

Tranquilizers are wonderful drugs but I think that everyone should try them out before they drive. Some people become very sleepy after taking some tranquilizers. Other are not affected by these drugs.

COLOR TESTING

Hightower: I have heard the repeated reference to the three colors associated with traffic signals and I would like to ask Dr. Payne whether the minimum requirement for commercial drivers is sufficient.

Payne: I'm not too sure it is sufficient. From the viewpoint of the aviation it is not.

You have to pass at least 75 per cent of the test plates for color appreciation or the equivalent thereof. I have difficulty with colors especially if it's foggy or raining or if I'm driving into the sun. With the sun striking the traffic signals one may have trouble distinguishing whether they were red, green or yellow. If the traffic movement gives no indication that the lights have changed a person might run through the lights innocently.

Nichols: Then, Dr. Payne, you would change your opinion from the symposium in New York and you think that the color *tests are very essential to driver* requirements?

Payne: I have changed my mind.

Owen: May I discuss that just a second? We find that there are more than just the traffic signals that have to be discussed in color vision. Many drivers, especially over the road drivers who travel through many cities, are liable to find signals with the red where the green belongs and vice versa. It would be impossible for him to memorize all the signals that he meets. Another thing when he is approaching curves, especially into an area where there is shade, he uses the shading and the different colors of green foliage as a tip-off such as a ditch, a ravine or to distinguish the different levels in the ground, etc. Therefore, color association at curves is important.

One thing that we find is that most people who see orange generally call it red. The railroads, as you know, have a big orange light for a caution light. We have found that accidents have occurred when the individual seeing the light thinks it's red and has stopped and the person *following him crashes into the rear end* of his vehicle. We therefore feel that color vision has been an extremely important part of driver requirements and we are not accepting drivers who are color blind.

Hightower: The Greyhound Corporation has been using the Ishara Test and your comments strengthen my own belief in its importance.

Cox: Dr. Owen, you and Dr. Brandaleone both made reference to the fact that the ICC standard, or requirements on which commercial drivers are either certified to drive or are not, use generalized terms, "likely to interfere with safe driving." Now I would like to learn from you and the other doctors here whether it is a practical thing for those regulations to be worded to define specifically conditions which would disqualify.

MAKE STANDARDS SPECIFIC

You have no idea of the controversial problems presented to us constantly because the driver's own family physician says that he's all right to drive. Maybe he has diabetes but he's under good control or he has *epilepsy* but it is petit-mal. Besides that he hasn't had a seizure for two years. If we are to reduce to a government regulation (unless there is some special waiver arrangement such as the Civil Aeronautics uses) the regulations could, and should, be worded to exclude conditions such as diabetes, epilepsy and so on?

Owen: This is one of the most important things we want to do today and that is putting the positives and the specifics in this regulation. Let me illustrate that I review all of the physical examinations of drivers for Consolidated Freightways such as placement and annual physical tests.

I find that a certain per cent of those drivers should not be issued certificates by the physicians, even our own physicians. We find that a greater percentage of non-qualified drivers come to me with a certificate from their own physician.

As an illustration, we have the famous Green case in which the man has diabetes and is taking insulin and has certificates issued by five physicians. He is on 40 units of insulin a day. If we place ourselves in the position of this man's family physician this driver must have a means of livelihood. The physician knows the family and their dependency upon him to earn a living. He has a job to take care of that family and he is going to see that the man maintains his job. Of course, he's going to certify that driver regardless of whether he's a diabetic, or not.

In fact, there is a lack of appreciation of the situation among many doctors. We have one man that has a Jacksonian epilepsy following an injury and goes into a seizure at times. The head of the neurological department of *our own* medical school wrote a letter to this driver's union and said certainly he's able to drive a truck. We must have this whole problem spelled out in ABC's. A diabetic taking insulin shall not drive! An epileptic whether he be on control or not, shall not drive! Everything else must be spelled out so that we do not have these individual interpretations and the arbitrations that go with them following that particular type of a thing.

Brandaleone: I would like to emphasize the remarks of Dr. Owen. We, who see these things know and understand the seriousness of the whole situation. We must realize that the private physician is in a difficult position. He must protect his patient and help him as much as possible. There are some physicians who perform 60 I.C.C. examinations in an hour. He just has time to fill out the forms and does not do the examination at all. We have compared our own reports with such examinations and frequently find gross errors. Examinations done improperly are of no value and may permit an unqualified person to drive.

Dr. Turrell in his remarks said it was not necessary for a neurotic or a psychotic to be more accident prone than anyone else. I don't agree with that at all. It is almost an individual problem. There may be neurotics or psychotics that may not be accident prone, but many of them may be dangerous drivers. He said earlier in his presentation that the most important aspects of the psychological problem is the hostile or sexual reactions of a person. Does not the neurotic have a distorted picture of his hostile and sexual responses?

NEUROTIC OPERATIONS

Turrell: I can only answer from the standpoint of having examined and evaluated 200 servicemen that fit into the two categories of accident and non-accident people. There were none of the accident people who had serious overt emotional illness. Primarily the neurotic problems fell into the group of people who had no accidents. With some exceptions and as I pointed out, there are certain obvious psychoses during which it may be dangerous for the person to be at large. I would assume that some accident susceptible persons come in this category and should be put into a hospital with or without his consent. Now one other interesting thing. I don't know what it means but, in a study of patients in psychiatric hospitals, there were more members of families of psychiatric patients who had been killed through accidents than there were in a similar group of control patients. But these were members of the families and not the patient.

Brandaleone: I think then that there is great need for further investigation as *you have indicated, but my own feeling* is that I would not like to have a child of mine riding on a bus that was being driven by either a compulsive neurotic or a manic depressive psychotic in a manic stage.

Owen: May I interrupt to ask a question? Is there any particular type of test that we can use that the ordinary interviewing officer can use to tell which are the safe and the non-safe compulsive neurotic or psychotic individual?

Turrell: I think that such tests can be developed. It can be done in one of two ways with a psychological test or an interview. A skilled person as a psychiatrist, physician or doctor of psychology can learn much about a person's accident susceptibility. Perhaps we should make a study in industrial driving using the Allport-Vernon Scale of Values. If results of this test continue to indicate those persons who had accidents or did not have accidents, then I think this is the type of screening we need and for which we are looking. But my own personal opinion is that there would be no correlation between the accident and non-accident groups and psychoses and neuroses. I believe that persons are often victimized because they carry a psychiatric label.

Hightower: I believe that Dr. Brandaleone must be talking about something other than intercity buses. His children would certainly be safe on that type of travel. I'm inclined to agree with Dr. Turrell. We have used a very extensive plan for the last 10 or 12 years delving into temperament and personality and frankly I don't think there is any correlation between the two, the psychotic or neurotic

person—and certainly we haven't observed it in our experience. I strongly concur with Dr. Owen in his remarks about concrete standards toward driver physicals. We go far beyond the I.C.C. requirements, as you well know, and we run into this situation you speak of frequently and it would be most helpful if we had it spelled out in black and white.

DEPTH PERCEPTION

Cox: Dr. Payne, you said that a satisfactory test for depth perception should be devised and used. You emphasized the importance of depth perception especially in the field of commercial vehicles. Do you imply that there are no such tests or equipment available now?

Payne: There are three or four tests being used at present. One is still acceptable to the Air Force which is the so-called Howard-Dohlman test. It has been used satisfactorily since World War I. It seems to me, for the purpose of driving cars, you wouldn't have to use it, the Verhoeff test or the Orthorater. You could use a simple steroscope and determine whether or not the person knows where things are located in space. There are arguments as to whether depth is determined.

The test would show whether the two eyes are used together in unity. If they are, the chances are that fusion is fairly good, and third dimension is present. You can do this with an inexpensive steroscope which costs about $3.00, with one simple slide, containing an F on one side and an L on the other. You look through that steroscope with both eyes and if the F and L come together and form an E you have fusion. However, if you see the F and L as separate images more elaborate tests will be needed.

Cox: This also concerns the I.C.C. safety requirements which now require a driver to have at least 20-40 Snellen rating in each eye. People who are critical of that standard have told me that drivers who can satisfy the requirements of 20-40, still may not have adequate vision for commercial driving. Let me put it another way. I've been informed by persons who have had experience in the field, that the standard will let some people drive who have much less satisfactory vision than other people who will be kept out because they cannot measure up to 20-40 in each eye separately. Will you comment on that please, Dr. Payne?

Payne: It my feeling that the driver should have better than 20-40 vision. He should have single vision with two eyes with depth perception. The eye standards should be outlined arbitrarily, perhaps somewhat less than those that are used in the Air Force. If the applicant didn't come up to requirements he should be disqualified.

Owen: I will agree with you on that. The thing that I wanted to bring out is about fusion and phoria. I don't believe that 20-20 or 20-40 will tell us whether both eyes are looking in the same direction as Dr. Payne has said. The American Optical company's Keystone Telebinocular or the Bausch and Lomb's Orthorater give us a pretty good testing mechanism and I think that an individual should be rejected who has elements of phoria quicker than a person who hasn't the aquity test of 20-40 because he is apt to see double. I think he should be rejected.

Nichols: Then, doctors, you agree that eye examinations should be spelled out more definitely in the regulations?

Owen and Payne: Agreed.

USE OF PSYCH TESTS

Brandaleone: I would like to emphasize the things that have been said about the use of psychological tests and of the interview. We published a paper a few years ago showing the results of three psychological tests. The people who took these tests and passed them had a better accident record than a control group who did not take them. These results were obtained in a small group. It was not conclusive evidence nor did we feel that the tests that we used were the ideal ones. I hope that Dr. Turrell might give us the opportunity to study the Allport-Vernon test that he has been using. I think that we could use it in some of our groups.

I think that there is one thing that has not been brought out, of interest to nonphysicians. A person may have perfectly normal vision, but he may have weak eye muscles and not be able to converge to get fusion of both eyes. I think that the I.C.C. visual standards should be made

very rigid and include rigid criteria for fused vision. I think we should all do everything we can to assist the I.C.C. in establishing more rigid physical requirements.

Owen: The thing that I would like to see us do is to bring out some specific things. Might I suggest that all six of us go on record stating that I.C.C. should have these specific recommendations so that the National Safety Council can work on some specifics.

Turrell: I would like to second that. However, I think that rules and regulations from the standpoint of specific requirements for driving sometimes are inclined to go too far. Especially, since public or non-commercial driving and licensing may follow the recommendations of a group like this. I should like to put in a plea for the study of the engineering features which would help out so that one wouldn't have to have 20-20 vision in order to drive a car. There are a lot of people who depend upon an automobile for a living.

Driving down wide boulevards with stop signs on each side and one every block that are not synchronized, you don't quite know which one you're looking at. Furthermore, this is complicated by advertising signs in various colors of red, white, green and blue. It makes it difficult to pick out the stop signs. I would think that pressure from groups like this should call for designing certain sections of towns and highways to help the person who perhaps does not have 20-20 vision to negotiate them safely.

I think we also have to approach the psychological problems from the standpoint of therapeutic intervention. I would like to ask Dr. Owen to comment on this in terms of some therapeutic approaches to particular stressful situations.

THERAPEUTIC INTERVIEWS

Owen: The thing that we have found is that many of these men who are compulsive drivers or who have a problem at home disturbing them have to get it out of their system. If you can have an impartial medical discussion with impartial physicians and you can make them realize that you are not going to take back to their boss what they tell you they can get the particular irritation out of their system. I'm sure that by this method we are actually preventing accidents. If we encourage the people to come to us rather than having to pay for it they will come to us and let their hair down. We believe it will save a lot of money for your company.

Hightower: My question is directed to both Drs. Owen and Payne and I believe will be of interest to the audience. With the growing popularity of contact lenses do either or both of you feel that the wearing of contact lens by commercial vehicle drivers, when that lens has corrected his vision to meet our requirements, is safe?

Payne: This would be a most dangerous situation for an individual to drive any type of vehicle. You never know when you will scratch your eye with them or the eyeball becomes swollen and irritated. Contact lenses have a reasonable use. I was one of the first ones in New York to fit contact lenses and have had a lot of experience with them and I'll tell you this, they're not safe for automobile drivers. The people who can wear them and wear them successfully are usually the type who have eyes which cannot be corrected by regular lenses. The person who wants contact lenses, ordinarily wears thick glasses, uses them a few times and discards them later. Eventually they may be developed for practical use, but they are contraindicated at present.

Hightower: My own personal reactions concur with that but, unfortunately, the doctor recommended that a driver be kept in service as the driver's vision was corrected to 20-20 and the regulatory body through the Public Health's doctors approved it.

Owen: This is just another indication that we need more evidence and spelling out of the possibility of individual interpretations.

Cox: Dr. Turrell, you heard Dr. Owen in his paper refer to the driver who had the psychotic wife. I can think of any number of tragic accidents that have been traced to people with what I would call "preoccupation." There isn't time for me to use examples but I am sure that this involves a condition which you wouldn't

normally classify as psychosis or a neurotic.

The first time I heard Dr. Brandaleone, roughtly five years ago, he referred to a driver on the Third avenue transit system who had had an excellent record. Within a short space of time the man had three accidents, all preventable. They called him in for counseling. They found that the man was recently married, his wife wanted to go to California to live and she had no use for New York. Upon counseling they sent him out there, guaranteeing him his job if it didn't work out. When they got there his wife wanted to return to New York. They came back and he's had a good record since. Now, does it take a physician to handle that type of counseling?

Turrell: I don't think it necessarily requires a physician. Each company should have enough counselors who knew the men well enough that, when they ran into problems of this nature, they would have someone to whom they could come for counseling.

HOME EMOTIONAL PROBLEMS

Brandaleone: In our own experience we have found that drivers with emotional difficulties either at home or on the job are materially benefited when they come to the physician in the company medical department. The well trained doctor must give a patient a great deal of time and complete confidence must be maintained, but the results are gratifying. Sometimes it means a temporary change of job. In some cases even that is not enough. For example, in one case a man was terribly worried over an ill child and his job was changed from a driver to a cleaner-shifter. Unfortunately within a few days he killed one of the men in the garage. He was just not able to think about what he was doing at all. Taking the man away from the wheel of his vehicle apparently didn't help.

In response to another comment you made, Dr. Turrell, I can understand, as a practicing physician myself, how you feel toward rigid regulations. We must realize, however, that 40,000 deaths a year is an impressive number. We may in establishing certain rigid criteria be unfair to some persons, but it is a necessary step and after a trial and error period our criteria may be more fair.

The Massachusetts Licensing Bureau grants certain epileptics and diabetics on insulin a temporary license. This method seems to work well. Every three months these persons must be examined by an objective physician, not their own, who is a qualified specialist in his field, to determine whether the driver is able to continue. This may be a solution to the problem.

Hightower: As you know, the I.C.C. requires a physical examination once every three years which is an improvement over its former rules. The question is whether or not you think that this is adequate for a commercial vehicle driver and whether or not you feel they should be examined oftener?

Owen: We are examining yearly. I'm inclined to think that in some cases we are doing it too often in the 25 to 40 year level. However, an examination is not to disqualify, but rather it is to find any defects and to correct them before we have to disqualify the driver. Now if we examine a man once every three years we are going to have disease trends already established before we get to the individual. I believe your medical department should have the right to determine when and how they want a man examined and it should never be less than two years on a commerical driver and in certain cases be as often as every six months.

Brandaleone: I so agree with Dr. Owen. In talking about cancer detection and diabetes detection these examinations are detection for everything and more preventive medicine than anything else. We feel that civilian drivers up to the age of 45 should be examined every three years and after 45 every two years and as far as industrial drivers are concerned, up to the age of 45 every two years and annually thereafter.

Nichols: I think you're right. I would like to make a comment about drivers within Consolidated Freightways, that I'm experienced with in the older or upper age levels. Incidentally the closer I got to 50 the younger 60 seems to be. These older drivers 60, 62, 63 years old, because they have been on a good medical program, are

in good condition and are our best drivers. It's keeping them on this strict medical program and taking care of them the way they should be taken care of and advising them properly, I believe, that has done much to keep these men on the job.

(At this point the moderator asked if there were questions from the floor. The following question was posed—I would like to have the doctors say a little more about the tranquilizer drugs particularly amphetamine.)

TRANQUILIZER DRUGS

Owen: The tranquilizers and antihistamines are sleep producers. I don't believe we are in a position to state that the I.C.C. should put in its regulation that these cold remedy drugs should not be used but I think that any dispatcher who knows that the driver is on a tranquilizing drug should be a little hesitant about letting that driver go out until he has thoroughly checked his reactions.

Brandaleone: Dexedrine is just the direct opposite of the antihistamines and tranquilizers. Dexedrine is a stimulant. The transquilizer and antihistamine are relaxing drugs. These two are entirely different. Benzedrine is taken to keep persons awake. They may do that for a short period of time but so frequently people take them and they expect them to work far beyond their capacities and fatigue and sleep will overcome the use of any benezedrine or similar drugs. Tranquilizers are useful drugs which may cause some people to get sleepy and others may not be affected at all. It must be remembered too that different tranquilizers react differently. The important point is that anyone who drives should not take medication which might make him sleepy.

(Another question from the audience. I would like to ask Dr. Owen. Someone mentioned the connection between obesity and heart cases. I'm wondering if you found any connection in accident proneness in any types of underweight as well as overweight or for any types of size or stature?)

Owen: We haven't made any particular study on the anthropological size of the person as it affects accident prevention. Abnormally little or abnormally big have to be questioned as to whether they actually can drive. I'm positive that some of our truck drivers that weigh 250 pounds and five foot six inches tall have difficulty reaching the levers on their control panels. We have to study them from the standpoint of whether they can or can not actually handle a machine and it is something that probably should be done.

Hightower: I've had information from doctors that drivers should not be permitted to drive the day after they have taken the Asiatic flu shot.

Owen: I don't feel that we have had quite enough experience in the giving of the Asiatic flu shot to determine whether or not it is dangerous. Within my own practice we have given about 1,000 inoculations for the Asiatic flu. I only had three people sick and they all were sick in the same family. I am sure there was a great deal of psychosis mixed up with this whole picture. The Asatic flu vaccine may make you feel a little dopey the next day. I took it myself and I felt that I could have driven all right. We use the intradermal method with two shots, rather than take a chance.

Brandaleone: That's what we are doing and I see no reason why a "flu" injection should make them sleepy. It may give them muscle aches or malaise, but nothing more.

ACCIDENTS CAN BE STOPPED AT THE HIRING LINE

(A Symposium)

SAFETY STARTS WITH YOUR EMPLOYMENT APPLICATION FORM

by D. J. MOFFIE

vice president, Hanes Hosiery Mills co., Winston-Salem, N. C.

A study of the development of personnel procedures over the past 50 years shows that these have progressed from the subjective to the objective. Systematic and analytic methods have replaced "intuition" and "hunches." The psychologist, the safety and personnel people have been largely responsible for this.

Notable advances have been made in the interview, tests, reference checks, accident analysis, criterion development, training, and supervision. More recently, emphasis has been placed on the application blank. Safety experts now realize that accidents are caused by many human factors, and that no one test or technique will be the panacea for selecting safe drivers.

The application blank can play a real part in effective selection. Insurance companies, through weighted application blanks, place heavy reliance on this technique. Colleges have used it in their selection of freshman students. Industries are now beginning to develop weighted application blanks as a selective tool.

This report illustrates one situation where the application blank has been studied for the selection of safe drivers. This study was conducted through the North Carolina State College Department of Psychology for the McLean Trucking company. It was part of a larger research project conducted at N. C. State College for quite a number of years, originally beginning with Carlton Alexander, then safety director for the company, now directed by Howard Walton. The study consisted of two groups—an accident free and an accident group.

The accident free group consisted of drivers who worked a minimum of 12 months, were accident free, and were charged with no more than three violations or complaints. The accident drivers worked a minimum of 12 months, had incurred two or more accidents in which the driver was responsible and may have had any number of complaints or violations. Sixty-five accident free drivers and 36 accident drivers comprised the two groups.

The types of items and their weights are ascertained by determining what personal history or biographical responses are most frequently given by desirable employees and are given less frequently by undesirable employees. A large number of statistical techniques can be used to determine whether or not these differences are significant.

Chi Square has been one, or the significance of difference between percentages may be used. In every case, however, the techniques will determine whether or not the differences between the two groups in their responses to the items are statistically significant and not due to chance.

SIGNIFICANT QUESTIONS

In this particular study, the application blanks of these accident free and accident drivers were studied in relationship to such factors as height, marital status, number of children, average age of children and level of education. The items on the application blank which were statistically significant between the two groups were as follows: Height, marital status, number of children, average age of children, association with social or civic groups, hobbies, reading materials, kind of car owned, age of car, license of individual, level of education, and average length of employment on last three jobs.

To establish the significance of an item, it had to differentiate the accident from the

accident free in terms of weight, and in normalcy of distribution. For example, the first item height, a weight of two was established for those drivers who were from five feet four inches to five feet seven inches.

A weight of one for those drivers five feet eight inches to five feet eleven inches and statistically from six feet up a weight of zero was assigned. This would mean that the safer driver based on this study ranges from five feet four inches to five feet seven inches. On marital status, a single driver received a weight of one, a married driver a weight of one.

MARITAL STATUS RATES

If a driver were divorced or separated he received a weight of zero. For number of children, no children gave a driver a weight of two, one child, a weight of one, two children, a weight of zero, three and up, a rate of one. For membership in social or civic groups he received a weight of two; owning a higher priced car received a weight of two. The age of the car, if the car were one to five years, gave a man a weight of two.

From an educational standpoint, the grades nine to ten were most indicative of accident free drivers. This educational level received a weight of two. As we increased the education level, or decreased it below nine, we find that the weight assignments are significantly less. Average length of employment of last three jobs showed somewhat of a descrepancy, nevertheless, one year or less received a weight of two; two years, one; three years, zero; four years and up, one.

The items which were found insignificant between the accident and accident free drivers were as follows: weight, bank account, previous accidents. Those which were questionable because of distribution were time at present address, arrest, duties of last job, and reason for leaving last job.

Based on these weights, the original 65 application blanks for the accident free drivers and the accident drivers were studied. Weights were assigned and the total score was computed. The larger percentage of the scores fall below the optimum cutting score for the accident group and a normal distribution is seen for the accident free group. The average weighted score for the accident group is 12.2, for the accident free group 9.1. Incidentally, these differences were significant.

Slicing the data from another standpoint indicates the percentage of accident free drivers we would have hired above the cutting score of 12 and the percentage of accident drivers who would have been rejected. If the optimum cutting score had been available and used at the time of hiring, 81 per cent of the accident group would have been rejected. Likewise, 40 per cent of the accident free would also have been rejected under these conditions.

Conversely, 60 per cent of the accident free would have been hired, but only 19 per cent of the accident drivers would have passed the initial screening device. Incidentally, this study is now going on and will be cross-validated with the additional groups at the company. Normally this would be the routine procedure in the validation of an application blank under the conditions of this study.

Our conclusions from this study show that the weighted application blank has promise of being a good selective device for drivers. But the weights and cut-off scores found in this study should be considered preliminary and characteristic of this company only. The sample of undesirable drivers should be extended to include a larger number of terminators.

An application blank must also be used in collecting standard information identifying the individual, his education, marital status, previous employment and residence. Items which are extraneous to the selection of the the individual for a particular job should be eliminated, such as one's religion or the number of previous jobs.

TAILOR MADE BLANKS

The application blank is only one of many devices that can be used. Your employment procedure should supplement the application blank with selective tests for knowledge, character, abilities, and aptitude. And many tests have been found to be worthwhile in these particular areas. Steps should be taken to tailormake the application blank to fix your own needs.

The portion of the driver application blank that should be tailormade or standardized can only be determined through statistical

study such as we have completed here. I should also like to point out that in order to conduct such studies there is need for clear cut and reliable criteria, and in many industries the criteria of an accident or an accident free driver is still one to be desired.

The bulk of evidence in the field of driver selection seems to point towards personality as the dominant factor in accident causation. This view has been supported by studies at N. Y. U., studies at the University of Colorado, in the far west in California, N. C. State College and other universities too. Since this appears to be true, the weighted application blank approach might prove a worthwhile selection procedure.▲

SAFETY GROWS WITH YOUR INTERVIEW

by WALLACE C. TAYLOR

director, Personnel & Safety, Ringsby Truck Lines, Inc., Denver, Colo.

Until comparatively recent times the Interview was the accepted entire employment program. An applicant said, "I want a job" —if you needed someone, say a truck driver at the moment, you pointed to the vehicle to be operated and said, "Get going."

We have learned though—we've learned "the hard way"—that the pre-employment interview if properly conducted, can save many headaches, and a lot of money; in fact, may help to prevent a business from going on the rocks.

Some employers rely solely on the interview—others discount it entirely. However, most do find great value in the initial contact with an applicant.

Some use a patterned interview form, such as published by White Motor company —or several publishers, which lists stock questions and even gives you clues on what kind of answers are most desirable or undesirable.

We'll discuss a man—truck or bus driver applicant:

APPROACH:

1. Hands out of pockets.
2. Walking or standing straight-leaning on wall or desk.
3. Clothes clean and neat.
4. Pleasant facial expressions. (He's a potential representative of your company.)
   He doesn't have to be handsome but better that he doesn't look too much on the rough side.
5. Self introduction or just "I want a job."
6. Handshake (firm or dead-fish). Hands and finger nails clean?
7. Look you in the eyes.
   There're all kinds of sayings and proverbs about people who won't look you in the eye.
8. Nervous-trembling speech, hands, smoking hard, chewing hard.
9. Offensive breath or body odors not good in customer contacts, working with others indoors or on a sleeper cab truck.

BEGINNING:

1. Try to put him at ease by your talking just enough about the weather or your company to acknowledge his stated desire for work and get him started talking about himself, his qualifications and ambitions.
2. Why do you think you'd like to work for this company?
   That question is a good way to test his sincerity—whether he's just "looking for a job" or has a genuine interest in your company.
3. Review the application with the applicant.
   (a) Discuss in detail his former jobs —details of the work and reasons for leaving.
   Work conditions at your company. Maybe the same as those he gave as reasons for dissatisfaction or leaving another company—"Not enough money"—"Wanted to get off sleeper rigs" or, "Wanted to take line job."
   (b) Double check age; marital status, state of current health. How long a resident? Own home, etc.
   (c) Review specifically "no accidents."
   (d) Review specifically any accidents noted and "is that all you have ever had?"
   (e) Review "Personal injuries" the same way. How caused? Does it bother him anymore? There is always danger of employment with you "aggravating the former injury"—Habitual compensation user?
   (f) Does your wife approve of your doing this type of work? is a question sometimes the acid test of whether or not he will stay long.
   (g) Education may be a factor—you may wish to get verbal details of that—but particularly note—can he write legibly.
   (h) Thorough—did he obviously read what the application asks and then answer completely.
4. Conclude the interview with a definite statement so the applicant will know "how he stands," i.e., "Sorry, we cannot use you now;" "Call me tomorrow," or "Step over here for some of our tests."▲

SAFETY IS IMPROVED BY YOUR INVESTIGATION

by JOHN A. DE PEW

director, Safety & Personnel, Dohm Transfer co., Rock Island, Ill.

I made up a questionnaire and sent it to 105 carriers throughout the country. These were sent to all types, such as, regular line haul common carrier, private carrier, automobile transporters, petroleum haulers, and bus companies. The number of drivers represented in those replying ranged from 25 to 1750.

The following is a summary of replies received representing 75 employers and 45,000 drivers:—

1. Which Department in your company does the applicant screening?
   Answer: personnel and safety 32, safety only 11, and personnel only 11.

	Yes	No	No Ans.
2. Do you require a 10 year work history?	29	45	1
3. If not 10 years, how many in years? *Answer:* Less than 10 years 56, and others varied from last 3 employers to 5 years.			
4. Do you bond all employees?	41	31	3
5. Do you check previous employers?	75	0	0
6. Is this done by Telephone? telephone 6, letter 7, both 56, on answer 6.			
7. Do you check with state motor vehicle departments?	37	38	0
8. Do you have an outside agency check made?	45	28	2
9. Is this done by a detective agency?	10	39	26
10. Is this done by a credit bureau?	34	17	24
11. Do you have a credit check made?	40	29	6
12. Do you believe such a check is necessary?	52	21	2
13. Do you fingerprint all applicants?	22	53	0
14. Do you ask for past arrest records from employee?	66	8	1

15. Do you check on this information?	54	19	2
16. If an employee has had other than traffic arrests, is he eligible for employment in your company?	13	48	14
17. Do you find the Local Police co-operative in giving out past arrest information?	48	19	6
18. Do you have a single agency or association check prospective employees for your company?	27	44	4
19. Do you use the same method in all your locations in checking on past employment and arrest records?	59	13	3
20. Do you check on previous record of moral or social misconduct?	53	17	4
21. Do you have neighborhood check made?	36	37	2
22. Do you use a driver testing clinic? If the answer is "yes" please give the name and town of the Clinic:-	21	52	1
Some answered. The Associated Highway Carriers, Kansas City, Missouri; Los Angeles Driver Testing Bureau, and the Nebraska Safety Engineering Service, Omaha are the ones that were listed in the reply to the question above.			
23. Do you have any other method of investigation not mentioned above?	17	44	14

DETECTIVE AGENCY CHECKS

Now the second part to this question, if the answer is "yes" please explain briefly:—

One carrier claimed he put their employees through a polygraph examination; others mentioned a detective agency, such as, Thompson Dectective Service, in Indianapolis; the Brown Detective Agency, in Chicago, the Civilian Fingerprint Agency, in St Louis. Atlantic Greyhound have their own driver testing clinic, and I am sure the other Carriers included in the survey have their own Clinic, but failed to mention in the particular spot in the questionnaire.

This survey in my opinion points to one of the reasons why some carriers are having difficulty with their employees.

Please bear in mind these questionnaires were mailed out to carriers who in my opinion had a better than average selection procedure. I am sure that you can realize how many undesirables must be in this industry as a whole.

INVESTIGATE EVERYONE

Let me give you an example. Shortly after starting to work for our company, I received permission from the owners to investigate all employees, and the word all included the owners and myself. This is checking back on their past police records on employees.

In one of our locations we had a man working for us more than 10 years. Prior to coming to work for us had served two year in a Federal Penitentiary for theft from Interstate Freight while working for another carrier. This man was such a good employee his terminal manager and those in our general office couldn't believe that this was possible.

He did admit the complete story to me and I told him he had nothing to worry about as far as his future was concerned so long as he remained the good employee that he had been in the recent past. Many other things came to light, some of them amusing and some of them just the opposite. Since that time we have investigated all new employees and checked back in their police records.

In addition we have the prospective sign, which we call a "Record File." We read one paragraph over carefully, and ask them to be sure they remember everything and tell us the complete story. If this person has deliberately tried to hide the facts of his past after signing such a statement there isn't any recourse but to dismiss him at once.

As soon as word gets around to the other carriers and through the industry that your company has a thorough and strict screening process so that just everybody can't get a job, you will find that many undesirables will not even apply for work and waste your time trying to get employment with your company.

We are dealing with human beings, and regardless of your screening process one may creep into your organization who later turns out to be undesirable. For example, one could turn into an agitator or suddenly become involved in accidents—both vehicular and personal injury.

The more you can learn about an employee and his past, the better your relationship will be during his employment—if he knows that you know. You can inform him the only persons in your employ are those you yourself would like to invite into your parlor. This is when I am sure you would be able to improve your safety performance by improving your investigation during the probationary period of each and every employee.

INFORMATION FROM POLICE

Some of the methods used in obtaining this information will take a little time to set up, but it can be done. Sometimes this information can be gleaned from the police department direct if you contact the Chief or his designated substitute, explain your problem and show them how you would like to have this information.

You must do most of the work getting this request to them, and then in most cases furnish a stamped addressed envelope. A number of departments in medium-sized towns at the present time are giving us this information without cost. Most states will furnish the driving history on an individual, for a fee. For example, the State of Illinois charges $1.00 per individual check. Starting January 1st, 1958 they will furnish a form for this request to be sent to them on an individual or a group of individuals.

They will return this form with the information inserted giving you the history they have on their records whatever it may be. May I suggest if you have a mail clerk in your office—have this information sent to your home. It may save a great deal of embarrassment.

The safety performance of your drivers and all your personnel can be improved by a good and thorough investigation of all your employees including the office force.▲

SAFETY IS INFLUENCED BY YOUR DECISION

by J. WYLIE LUMPKIN

manager, Safety Division, Railway Express Agency, Inc., New York city

The fourth and final step and undoubtedly the most important in the procedure of positive driver selection is that of making a "decision"—a decision to hire or not to hire.

Immediately after the three preceding steps, those of taking the application, having the interview and completing the investigation, you must decide whether or not the applicant is to be hired. Careful selection of driver personnel is important in a safety program.

The task of assembling a group of drivers to operate the equipment efficiently, courteously and without accidents, starts with the initial selection of each driver. Safety in your company is influenced by your decision and, of course, your decision is the controlling factor of stopping accidents at the hiring line.

The ability to act safely is perhaps nowhere more important than in the operation of a motor vehicle where a driver, by a single lapse of mental alertness may cause an accident resulting in great loss of human life and damage to property.

Summing up the initial three phases of the employment cycle—how do you cross reference the application, the interview and the investigation?

The completed application form contains details of past data as submitted by applicant. This is the applicant's statement of his past record and history. All information should be carefully scrutinized and discrepancies brought to light by the personal interview

or the investigation should be given due consideration before making a decision to hire.

The personal interview is perhaps the most important single employment technique in the driver selection procedure. The overall perspective gained during the interview is often the determining factor in employment. A properly conducted interview should reveal additional facts about the applicant's past employment experience, knowledge of traffic regulations, attitude, personality, appearance, family life and general background.

INTERVIEWS CAN REVEAL

Following the interview the application should be reviewed again to determine whether the information coincides with that developed during the interview. Again, any discrepancies discovered should be carefully considered before a decision is made. In fact, your decision should not be made until all references provided on the application form are carefully checked.

Sometimes you may have difficulty in obtaining reliable information from previous employers. Some hesitate to put their frank *opinions in writing. Therefore, you should* analyze the information obtained from this source and compare it with that developed in the interview—as well as that detailed in the application form—before making a decision to hire.

You may obtain additional information from the local credit bureau, police department and state highway patrol records that will be helpful to you in reaching a sound decision.

Don't rely too much on what the applicant says he knows and the experience he says he has had. Check his past record carefully.

FACTORS FOR DECISION

In determining standards of selection the personnel or employing officer should first make a careful study of what the job entails and what qualifications the driver should possess to perform the job satisfactorily.

An example of an inventory of essential qualifications is that established by the American Transit Association for prospective transit employees. This lists nine basic qualities as follows:

Moral character
Mental ability
Motor ability
Health
Motivation
Stability
Maturity
Sociability
Manner & appearance

With minor changes this inventory should be applicable to all driver jobs. Relative stress to be placed on any of these qualifications would depend on the type of motor transportation.

An experienced personnel officer will detect all obvious and many subtle reasons why some applicants should and others should not be hired. These reasons will be matters of personal judgment based on experience and education. While the most important objective of a driver selection procedure is to screen out accident-prone applicants, you should not lose sight of the fact that many traits not related to accident-proneness must also be considered during the selection process.

Certain traits are considered important in deciding upon the general suitability of applicants for driving jobs, such as age, physical fitness, driving experience, intelligence, education, attitude and financial habits. These are some of the factors that will affect your decision.

AGE, PHYSICAL FITNESS

Generally, the minimum and maximum age limits for new drivers are between 21 and 40 years of age. The ideal age is between 25 and 30. Some firms are reluctant to hire a man over 30 unless he is a sound physical specimen and measures up well to all other requirements.

Youthful drivers are inclined to have more accidents than older drivers. This is attributed to their immaturity. Men under 25 years and especially those under 21 are not considered good accident risks. Fleet operators should take special pains in analyzing the qualifications of applicants under 25 years of age and accept only those who evidence a mature, stable personality.

Generally there should be limitations on the stature of a driver. Very short drivers have difficulty in reaching and manipulating

driving controls and devices. Short drivers and the overly fat drivers are not as dexterous in turning or backing a vehicle and the added effort necessary for them to perform contributes to a general state of fatigue.

Nervousness and clumsiness in an applicant are thought to be indications and causes of accident-proneness. A record of epilepsy or dizzy spells should be sufficient cause for rejection.

Blood pressure should be within reasonable limits. Applicants with bad hearts, poor eyes, inadequate hearing, are not likely to make good drivers.

DRIVING EXPERIENCE REQUIRED

What a man has done in the past is a good indication of what he can do in the future. Type of previous driving experience is important. You should try to obtain drivers with experience in handling vehicles of the type he will drive.

Individuals who have a record of repeated accidents should not be hired. They are likely to continue having accidents at the old rate.

While it is important, skill alone does not insure safety in driving. Actual driving skill can not be successfully measured by a laboratory test. Ample time should be allowed for road tests. How an individual responds in a tight situation is far more important than speed of reaction time in application of the brake.

Two general types of road tests can be used to measure driver skills. The driving range or obstacle course test is best for training purposes, especially for beginner drivers. The range provides normal roadway features but without the hazards of public traffic.

A standard road test permits observing and rating the driver under actual driving conditions. The test is used to measure his ability to drive in traffic, determine his general attitude, and detect his unsafe driving habits.

However, even road tests have certain limitations. They do not measure the driver in complex traffic conditions or dangerous road situations. They make no allowance for the emotional state of the applicant who may be excited and may not perform in a normal manner. They test driver performance only at the time of the test, not his potential ability.

Formal education is thought to have little bearing on an applicant's potential ability as a driver. Most firms, however, have minimum educational requirements. As with intelligence, middle ranges of educational qualifications are most desirable. Highly educated employees do not always make good drivers.

On the other hand, knowledge of driving principles and practices are important to the safe operation of a motor vehicle. However, the mere knowledge of traffic rules and regulations is no guarantee that they will be faithfully observed. Observance of regulations depends primarily upon the attitudes with which they are regarded.

Proper attitudes are essential to safe driving. A driver may possess the necessary skills and knowledge for safe driving and yet be involved in accidents. If he fails to appreciate the relationship between his behavior and the safety of others, if he drives in a mental state of disregard, selfishness and indifference, he can readily become involved in situations that are dangerous.

Dissatisfied, timid, naturally troublesome or otherwise temperamentally unstable individuals usually do not make good drivers. The irresponsible type of worker who seeks a job without the desire to render his best services, should not be employed.

MARITAL STATUS-MATURITY

Some firms will not hire single men. Experience has shown that married men are more settled and dependable as drivers. Married men have responsibilities and are therefore less inclined to drift from job to job. However, domestic troubles can make the married man a bad risk.

A man's financial habits may be an important index to his suitability as a driver. A man continually in financial hot water may be accident-prone because of constant preoccupation with personal worries.

Home ownership is an important indication of stability. The applicant who has, or is, buying a home will work more regularly and with more care than one who has no investment to protect.

All the factors mentioned, as well as others, should be carefully considered before a decision to hire is made.

Do such factors as labor market, pay standards and work standards in a highly competitive market determine the type of applicant reached initially? Do such factors affect the drivers' desire to be hired or to stay on the job once he learns the ropes?

Labor turnover is an outstanding cause of inefficiency and high accident frequency and its avoidance deserves much attention.

COMPETITIVE LABOR MARKET

There are two main causes of labor turnover. One consists of personal reasons, the other is based on dissatisfaction with the job. The following are among the personal reasons and they generally are difficult to cope with: more attractive offers, job with more pay; better hours and a better future, family conditions such as sickness at home and financial difficulties and living conditions such as distance from work, transportation difficulties and inability to find living quarters are other factors.

The company or the supervisor generally can do something about the causes of turnover in the other group based on dissatisfaction with the job. Dissatisfaction with wages or some related factor, and working conditions, including condition of facilities and surroundings are causes for turnover.

The most elaborate selection procedure will still yield a poor type of employee if only applicants of a generally low caliber are attracted to apply for work and you choose the "best of the lot" even though sub-standard.

Effort should be made to attract an adequate number of well-qualified persons to apply for employment. Advertisements in local newspapers stressing the advantages of employment as a driver have attracted more desirable candidates in some areas.

How is local organized labor tied in to the hiring decision? How can such factors be used in a positive direction?

Most of the labor union agreements contain a validating rule which states that the applications of new employees shall be approved or disapproved within a certain period of time. Generally, after the validating period expires, whether it be for 30, 60 or 90 days, you will need good and sufficient cause and formal investigation to dismiss a new employee found unsatisfactory after being put on the payroll.

Employing officers should take advantage of the validating rule, if it is in their agreement, and dismiss from service within the time allowed those who do not measure up to minimum requirements. This is a very important factor in the procedure of positive driver selection.

I have covered only briefly some of the factors that should be given careful consideration by you or the employing officer before a decision is made to hire.

The importance of proper selection of driver personnel at the hiring line cannot be over-emphasized. Undesirable results are bound to follow if a good job is not done.

It doesn't take long to invest a great deal of time and money in training driver personnel and then find that some of the new men can't absorb what you are trying to teach them. It is better to avoid the expense and problem of replacement by deciding in advance what kind of a man you want—and then make the right decision before accepting an applicant.

Safety in your company is influenced by your decision—and your decision is the controlling factor of stopping accidents at the hiring line.

EFFECTIVE SUPERVISION IS POSITIVE

ORIENTATION—THE BEGINNING OF DRIVER SUPERVISION

by WILLIAM W. CARTER
director, Safety & Personnel, Johnson Motor Lines, Charlotte, N. C.

Every employee some time or other has been new in an organization. In all probability there was a period embracing a few moments or a few hours between the time we were hired and the moment of introduction to our immediate supervisor.

It is this period of time I want to discuss . . . this short lapse of time that is so important to the new employee and the company. Since my topic concerns drivers, only that classification will be referred to . . . although many comments that follow could apply to every new employee.

Orientation of a new driver is the initial adjustment or conditioning interval of supervision. As such, and comparable to other undertakings, there must be objectives and procedures for effective accomplishment.

To insure a new driver getting off to the right start (a) he must be properly conditioned toward the company, and (b) a sound basis established by the supervisor for a truly friendly relationship.

Everyone is generally ill at ease in new organizations. So it is with new drivers. They want to do a good job and need proper guidance. At no time during employment will we find the driver more receptive to courtesy and kindly treatment than his first day.

SUPERVISOR MUST GUIDE

Should the supervisor fail to help and guide him, or disregard the importance of a friendly and sympathetic welcome from his fellow drivers and others, don't be surprised or cast blame on the new driver should he go to the union steward for advice and help. He needs help, he knows he needs it and he's going to get it from someone. The good supervisor knows this and takes full advantage of this time to insure proper conditioning toward the company.

There are certain "wants" existing in the mind of every new driver that the competent supervisor is well aware of . . . "wants" that can not be minimized or ignored to secure the most from orientation. He knows the new driver wants to be recognized as a human being, wants fair treatment and a square deal, to be accepted in the company family, have a feeling that his job is secure, good working conditions, a competent boss, to know what is going on, someone to hear his grievances, complaints and suggestions, to feel useful and know the value of his work, and an opportunity to show or demonstrate his ability.

TEACH 3W'S OF ACCIDENTS

Likewise the good supervisor knows the "wants" of his company. He is aware that a profitable operation necessitates a high level of productivity from every driver. His company desires daily performance where freedom from absenteeism, accidents, injuries, labor turn-over, and incompatibility prevails. Of these loss factors, vehicular accidents and injuries usually show the longest row of red figures in the accounting books . . . and the supervisor knows it. Particular emphasis is placed on accident prevention.

Laying the ground work for accident prevention during the adjustment period calls for knowledge of the subject. The good supervisor knows, by virtue of responsibilities inherent to his position, that drivers must be taught why, where, and when accidents occur . . . and how they can be avoided. He knows drivers must be indoctrinated with the philosophy of safe driving and kept alert to the need of practical application.

He is well aware that a productive driver understands and has adopted a scientific approach to accident prevention. It is within

practically every driver's capacity to operate equipment guided by principles which confine to a minimum the possibilities of collisions, upsets, jack-knifes and other loss producing incidents. He knows also that safe driving does not require a talent comparable to the arts, science, or athletics because ordinary driving ability is sufficient. He knows accidents are not caused or prevented by any particular human characteristic, for the reason it is usually too late to avoid a collision whenever any particular characteristic becomes necessary to influence the result of such possibility. He knows lightning action is necessary only after a faulty approach to the scene. He is appraised that the talent to drive equipment is the same talent which can serve to make driving safe.

EMPHASIZE PREVENTION PRINCIPLES

It can be readily understood the good supervisor has a wealth of background information on his company, the driver, and the principles considered with accident prevention. Being so equipped is of little value unless it is properly aimed at the target with enough force to hit the bull's eye.

Form a mental picture of an office (possibly your own) with good lighting, adequate ventilation, orderly arrangement of fixtures, without outside interference. You have the new driver in your presence. Now, what are you going to do? No doubt you will put him in the right frame of mind . . . condition him so you can "get through" to him. This entails creating a desire to learn the things you want him to learn. No faster method is known to create this desire than to show him the goal to be reached and its value to him . . . to him not only as an employee but a human being.

Most drivers know what it means to be a good citizen or a good neighbor, and most assuredly recognize the meaning of a good brother or a good son. Attitude and judgment have the same relationship to the art of driving that personality and character have to the art of living . . . in both cases, these things are the end objectives or goals. Seeming rational and logical, the goal to implant then would be that of living as a good citizen, and a good neighbor.

After this goal has been firmly planted in his mind, he must still be encouraged, encouraged, and encouraged. All of this can and must be enhanced by the earnest and fervent feeling shown by the supervisor.

Orientation is an attitude-changing affair . . . a setting to "sell" the new driver on accident prevention. As in other lines of selling, some can be sold quite easily while others pose a most difficult problem. Not all drivers will admit to any deficiency behind the wheel thereby denoting an unwillingness to change their driving habits. This amounts to nothing more than an elevated level of evaluation with respect to their own driving ability.

Several years of operation without an accident, for example, accounts for a lofty sense of confidence which is usually without foundation. Admittedly, this type of individual is a "hard nut to crack," but with a goal established, accompanied by desire, plus the supervisor's enthusiasm and perseverance, he too can be sold.

"Selling" the new driver on accident prevention is equivalent to showing him where he is going to profit . . . not necessarily in dollars and cents, but by satisfying his desires and "wants."

We have been told that attitudes are "caught" and attitudes are "taught." In this particular phase of driver supervision both methods should be used. Reverse the mental picture referred to a moment ago and place yourself in the new driver's position.

The supervisor has made you feel at ease by a cordial greeting and told you he is glad to have you in the company. A friendly atmosphere has been created. He has told you he is interested in you as a person. Said with sincerity and enthusiasm, he automatically put the softening-up process "in gear." He proceeds to give you a brief description of the company's history, the extent of operations, amount and type of equipment, number of employees with emphasis on number of drivers like yourself and gross annual business.

MAKE HIM FEEL IMPORTANT

You have discovered a new friend, he's making you feel "at home" and, in so many words, has said you are a mighty important person. Yes, he's recognized you as a human being, treating you fairly, accepted you in the company family and letting you know what the score is. In this short span

of time, you have "caught" the attitude pitched your way because the supervisor has commanded your respect. The desire to go out and do a job is beginning to grow on you . . . you have become inspired to a degree, and a goal is beginning to form.

You are asked the question, "What would you do if a money bag containing $20,000 was placed on your lap and entrusted to your care?" In all probability you'd say every reasonable effort would be made to protect it. Then you are told $20,000 is the approximate amount of the money the company is entrusting to you when assigned to a tractor-trailer unit . . . saying nothing of the thousands of dollars worth of property carried as cargo.

Now you realize you are recognized as a trustworthy person . . . a person entitled to confidence. This approval, this trust, "rings a bell" with you and that desire to go out and do a good job is continuing to grow on you.

A sheet of paper is laid before you disclosing the names of drivers holding safe-driver awards, and the number of safe driving years credited to each. You are shown a record which compares driving records of top performers with drivers who haven't been able to hurdle the three-year qualifying period. You note those holding five, eight, and 10 years of safe driving have few or no traffic infraction and reprimands from management. You also notice the non-qualifiers show innumerable instances of undesirable behavior.

Your attention is directed to the fact that so-and-so terminal manager, dispatcher, safety supervisor, and executive with the company began as drivers and attained their position by operating equipment safely in conjunction with other elements of high productivity. You are also told there is a constant need for competent supervisors and the gateway to those positions is always open.

CHALLENGE THE AVERAGE

These few thoughts are turning over in your mind, when you're told it's the so-called "average" driver that has accidents . . . not the above-average performer. This seems to "ring another bell" . . . that of a challenge. You ask yourself the question "do I want to be an average driver or above-average?" The immediate impulse, obviously, is to be an above-average driver.

At this point the new driver has set his goal . . . that of an above-average performer. He wants to belong to that winning team of men who are recognized for their achievements. The supervisor's inspiration has "rubbed off" on him. He has a goal, and from this point on he needs encouragement . . . lots of encouragement to inspire doing the job he wants to do and the job management wants him to do.

Citing examples concerning trust, what it takes to belong to a winning team, the regards of top performance, and opportunities with the company all tend to create a favorable attitude. These are a few examples of "taught" attitude . . . there are many more.

It appears axiomatic that greater emphasis on orientation of new employees is a "must." Fleets without such a period in employment should initiate one, and fleets with this conditioning phase of supervision should evaluate it with the objective of improvement . . . if we are to cope effectively with the ever-present factors of economy, public relations, and overall smooth functioning of the individual truck, bus, or taxi organization.

EMPLOYEE RELATIONS

Success in our complex business and industrial world appears equivalent to successful relationship or dealing with other people. Successful prevention of vehicular accidents likewise appears closely allied to successful dealings with drivers. This should be more thoroughly understood by everyone on the management team . . . and become so imbued as to command first attention for solving fleet operations problems of any nature involving drivers.

Many of you are associated with fleets that can display evidence of outstanding accident prevention programs, which would indicate your belief in, and practice of, sound techniques of driver supervision . . . and these reliable details of procedure most assuredly are headed up by the conditioning period, the "selling" period, the attitude-changing period . . . that phase of driver supervision we call orientation.

The ensuing days, weeks, and months should find every alert supervisor seeking and probing deeper in the search for methods

conducive to accident freedom. We must first realize we are dealing with people, . . . clearly understand the wants of the individual up and above money . . . . learn more about the ways and means of changing attitude . . . and faithfully practice the golden rule from the beginning of driver supervision.

EDUCATION—THE FOUNDATION OF DRIVER SUPERVISION

by F. S. LAKE

director of safety, Interstate Motor Freight System, Inc., Grand Rapids, Mich.

In the prevention of accidents, the education of people is basic to perform their respective duties in a prescribed manner whether they are workers or supervisors. It makes no difference whether we are referring to industrial accidents and injuries, or to vehicle accidents—we still find that most of these accidents result from some form of human failure, and that failure usually resulted from job performance contrary to the proper procedure as set forth in our manuals or other instructional material.

While such an introduction may appear apart from the topic assigned to me, we still must set our sights on our ultimate goal, which is the prevention of accidents, and injuries. To obtain this goal we must tie in all factors in our program, not just part of them.

Without being considered presumptuous, I would like to present this question—"Are we not too prone to direct our efforts to the selection, training and education of the driver himself, rather than to include all of the other people in our organization who have much of the responsibility for the manner in which the driver performs his duty and the results obtained from that driver?"

If our program is so conceived, then it is my opinion that it is incomplete.

EMPHASIZE ONLY DRIVER

Many discussions relate to programs for positive driver selection, his physical, visual, and emotional factors, and the relative merits of incentives and discipline. With the exception of the latter two items, all of these deal with the new employee, and all that we have accomplished is to determine that we have potentially employed the right man for the job he is to do. But if we leave the matter at this point what assurance do we have that he will continue to function and develop as we wish or expect him to?

We need supervision to accomplish this. Incentives and discipline are two elements of our continuing program. The purpose of these is to develop our driver, encourage him to perform in the manner desired to obtain our objective or speak him if he fails to do so.

GREATER SUPERVISION PROBLEMS

This raises a second question—"Are we, as safety people, willing to allow a driver —employed on the basis of his ability, attitude, knowledge and physical factors, and instructed or trained in accident prevention —to be supervised by one who has not been similarly trained and developed?" There is a large void between the employment, indoctrination and training of a driver and the finished product of the accomplished driver.

That void must be filled by supervision—and it is supervision of the right sort which will mold the new driver from the potentially good employee we hired into the finished or accomplished driver for our fleets. Therefore is education not only the foundation of driver supervision, but also is not education of the supervisor the keystone in our accident prevention program?

To borrow again from our counterparts in the manufacturing industry—Heinrich, in his book on *Industrial Accident Prevention*, gives a basic philosophy for accident prevention in which a large portion of the responsibility for such prevention of accidents is placed on the foreman or line supervisor. It must be conceded that our problems and methods of supervision are much different than those in manufacturing industry, and if anything, our problems are greater. For example, the supervisor in a plant can observe those under his supervision when they are performing their duties and can immediately correct any faults.

We, on the other hand, cannot do so as our drivers are alone and actually on their own, performing their duties away from direct supervision. We must therefore have a supervisor who can convey his instructions to the driver so that they will be remembered during the driver's tour of duty —so that, through supervisory efforts, the desire or will to comply with those instructions is instilled in the driver. While the principle is still the same, the problems differ and we must therefore compensate for them.

In our industry we actually have two types of driver supervision—the road supervisor and the terminal supervisor. The area of control over the driver is somewhat diverse, but the ultimate purpose is identical, namely to maintain the efficiency of the operation at the highest level which, of course, includes the prevention of accidents.

HIRING A SUPERVISOR

Let us start with our supervisor in the same manner as we do with the driver—that is his employment. We must naturally set certain standards for employment, but these standards must be higher than those for a driver, because we are now selecting someone who will be a part of management. Certain of these standards are set by our operating department to meet their requirements, and we as safety people would have little actual interest in those. However there are those standards in which both operations and safety must jointly concur.

The basic qualifications of a supervisor should cover such areas as knowledge, attitude, ability and action. Certain of these must be present before employment, but like our driver, we will find it important to teach others.

Knowledge of his overall job duties would be a prerequisite. But just as he would have to be trained in the procedures and routine of his duties, so he must be taught the company policies and educated in the manner in which they are to be enforced. He must be educated in those regulations by which our industry must abide, whether they are local, state or federal, because all phases of his responsibilities are circumscribed by these regulations.

Attitude—this we might call an intangible because it is something in us that is in the process of development throughout our entire life. However, any individual who has the responsibility for directing the activities of others should have a proper supervisory attitude if he is going to meet with success.

DEVELOPING ATTITUDES

We should therefore include in our educational program methods to develop this supervisory attitude which embrace his relationship with those whom he is directing —his feeling of responsibility to management of which he is a part—to promote their interests and carry out their policies, his sense of honesty and fair play to those workers under him, and as the go-between for management and employees, his responsibility to the latter to make his orders fair and to see they are carried out. This is essential to successful supervision.

One condition frequently encountered when an individual is given a position of responsibility and the authority, is a change in his attitude and the resulting improper use of that authority. Education in the proper use of authority is one important area which will assist materially in preventing the loss of respect for the supervisor by those whom he is directing.

Ability—this also might be considered an intangible. Some people are natural leaders and have the ability to direct others easily. But many, while able to perform tasks themselves, have difficulty conveying their desires and directing others. They lack the ability to organize either their own work or the group of workers they are supervising. They are slow to make decisions. Therefore, our education of the supervisor should be directed toward overcoming such faults—to analyze a situation quickly and take the necessary steps to counteract those adverse happenings and changing conditions.

A smooth operating supervisor will have a smooth operating organization, but one

who cannot organize his efforts will only pass this lack on to the workers with inefficiency the result.

Action is the fourth area and the one which finally gets the job done. This is the application of the other three areas of knowledge, attitude and ability. Without being able to apply these three requisites he is not going to be able to accomplish his own duties and responsibilities. Knowing what is to be done—having the desire and will to do it properly and the ability to organize to get it done will result in the finished product.

I have previously referred to two separate types of supervision in our industry—the road supervisor and the terminal supervisor. What can we gain from their efforts?

The road supervisor in a measure takes over after the unit has been dispatched and he functions when the driver is actually performing his work. In different companies this supervisor might be known under various titles such as safety engineer, safety supervisor or road foreman. Regardless of his title, his duties are similar. He checks the operation of the equipment on the highway to see that drivers complete their runs according to operational schedules, that principles of good driving are adhered to, and that all safety regulations are complied with.

Since the efforts of the road supervisor actually will tie in closely with the accident prevention program, his education as a supervisor has been usually formulated and directed by safety people within the organization.

EXPANDING FIRST REQUISITES

We are therefore in an excellent position to see that those policies we have established for the employment of new drivers are followed up and will actually be the continuation of our structure to build our group of accomplished drivers from the foundation which we have already established.

The education of the road supervisor should cover his thorough knowledge of what is to be done and how to do it and how to impart that knowledge to others. One major area of his education should be his ability to stimulate others to want to do the job properly without the whip of direct supervision to see that it is done.

With this I believe that we can leave the matter of educating road supervisors. To me the matter of educating our terminal supervisors—particularly those having relations with our drivers is of primary importance. In most companies this supervisor carries the title of dispatcher, because he actually directs the activities of the drivers

It is the dispatcher who instructs the driver as to what he is to do, when he is to do it and usually how he wants it done. Perhaps the only thing that he does not do directly, insofar as his supervision of the driver is concerned, is to instruct the driver in the actual physical operation of the vehicle.

DISPATCHER'S DIRECT CONTACT

The key man in a terminal operation is the dispatcher as he controls the pickup and delivery of freight and the cost to do it. He also is responsible to dispatch the equipment properly over the road or to receive it at the destination terminal. He is the one who has the greatest contact with the driver; is the last to talk with him before his departure on his run and the first to greet him on his arrival. In fact to many a driver the dispatcher is the company and is his only contact with management.

Since the basic philosophy of accident prevention places a large portion of the responsibility for such prevention on the supervisor, we must recognize him in this capacity as a key man in our accident prevention program. If we take a positive approach to supervision in the development of our driver, we cannot lose sight of the importance of the dispatcher to us and our continuing program. Accordingly, we should be vitally interested in the education of our dispatch personnel, and any failure to do so means that we, as safety people, are overlooking a major tool in our safety activities.

Supervision is the chain between the raw material and the finished product. If we must go to great lengths to insure that the drivers we employ are properly selected, and through our continuing program are educated to conduct themselves to perform efficiently and without accidents, it follows that just as much care should be taken to insure that the supervisor who is directing the activities of the driver is as carefully chosen, and likewise he must be as carefully and completely educated in the arts of supervision.

STIMULATION—THE FRAMEWORK OF DRIVER SUPERVISION

by S. E. NELSON

superintendent of safety, Burlington Truck Lines, Galesburg, Ill.

Our company was failing to stimulate our drivers to perform along the lines we wanted them to. We wanted to get our message across to drivers. Most of our drivers have never had a serious accident. Most of them never will have. Every organization wants to find ways and means of helping these drivers avoid having that serious accident. We improve our performance by taking a look at past performances and by picking out the flaws and defects and mistakes that we've made.

We have a series of colored slides taken at the scene of some of our most serious accidents. We made a detailed study of more than 150 million mi . of highways operations and we use slides from some of the accidents that occurred during that operation.

DRIVERS VIEW SLIDES

We have started talking to our drivers along the lines of asking them to try to recognize what has taken place at the scene of a serious accident. We do not draw conclusions; we ask them to look over the slide. We give them the facts, the evidence collected at the scene and they figure it out for themselves.

One slide shows an accident that occurred on a straight highway of dry road, ideal weather conditions and in the daytime. The driver failed to recognize a hazard—a soft mound of earth graded up on both shoulders preparatory to having it rolled out and sodded. He moved along at the permissible speed, in this case at 45 mph, but did not recognize the hazard of this soft earth. He lost control and was forced to leave the highway.

We have a closeup shot that impresses our drivers. They tell us that every time they step into the cab of a tractor they are reminded that their cab can end up looking like this.

We thought that it was physically impossible for a unit that weighed 20,000 pounds and had 26,000 pounds of freight on it, a total of 46,000 pounds to be lifted completely into mid-air without a collision. We found from our investigation that this unit left the road, hit this soft sod and traveled completely in mid-air and turned over and came down on the roof of the trailer.

EXPLAIN LOSS OF BUSINESS

Another slide shows a tractor and trailer taken out of service for a long time for repairs, while another tractor and trailer and driver are at the scene of this accident who would normally be delivering freight and performing service for our customers. A wrecker, the state police and cars moving past the scene are included which adds up to poor public relations.

One shot shows an automobile that struck one of our units which was legally parked. Many of our drivers have gotten into the habit of wheeling into their favorite coffee stop and jumping out of the cab and dashing in for a cup of coffee and a little conversation with the waitress without due regard to being legally and properly parked.

In this case we were not liable. We show these slides to impress upon our drivers the importance of parking legally and safely. The man who was driving this car was drunk. He was thrown from the car and killed.

But we had to prove, of course, that we were legally parked or we would have ended up paying out thousands of dollars as a result of this death.

CUT SPEED ON CURVES

Others show units that ended up off the highway because the drivers failed to recognize the need for reducing speed on a curve . . . a tractor taken out of service, a trailer taken out of service. Our customers are not getting the goods they want in time and we lose business as a result of this.

We can point out here that if a vehicle had been coming from the other direction

we would have had a head-on collision and probably fatalities. As it was it was a non-collision, the unit overturned.

This driver failed to recognize the highway signs preceding this curve. He had gone over this route so often that he thought he knew it by heart and he tried to negotiate a 30 mph. curve at 45 mph., which under these conditions was physically impossible.

One accident was photographed to help us sell our drivers on the use of the tachographs. We have a tachograph on every highway tractor. Some drivers complain about them as many of you know. In this case the driver of this automobile was late for work. Our driver had made a complete stop at a four-way stop sign. He shifted down after stopping, started to across the intersection and was struck by this car just at the landing gear of the trailer.

TACHOGRAPHS PROTECT

There was a clear view from all directions before approaching this intersection. The first thing that the state police and the sheriff wanted to know was whether or not our driver had stopped. They assumed that he might have slid through the stop sign and therefore would have been equally liable for the resultant injury.

The driver removed the tachograph chart and gave it to the state police and sheriff. They saw then that he had definitely come to a complete stop. This one set of slides has done more than anything else to sell our drivers on the fact that the tachograph can protect them and it stimulates their acceptance of it.

Another shot helps stress the importance of getting the load safely to our customers. The drivers realize when they see this that we pay out a lot of money as a result of damage to our shipments resulting from accidents.

CAUSED POOR RELATIONS

This accident also occurred on a curve with a frozen shoulder. The driver came around the curve at too high a rate of speed. He was not hurt, but he tore down the telephone line serving the area which caused a lot of criticism. Naturally it was a reflection on him as well as the company. We again took a tractor and trailer out of service and delayed a shipment.

Most of our drivers have told us that when they look at this slide they visualize themselves sitting there between that steering wheel and the rear of the cab. There isn't enough room for anyone of them no matter what their size is.

This accident and another one illustrates two of our men would have lost their lives if they had been strapped down with safety belts. You may say that that's purely an act of God and well it may be. But the fact remains that this man was thrown from behind the steering wheel into the right front seat and as a result jumped out of that tractor and walked away.

This picture impresses the drivers with the fact that it might have been their chest behind that wheel, between it and the rear glass.

One series of pictures shows another tractor accident—the only fatality in the service of our company. The driver left the highway during a snowstorm. He failed to recognize that decrease in visibility was a driving hazard. He continued to operate at 45 mph. when he should have either stopped or reduced his speed to possibly 15 or 20 mph.

VISIBILITY HAZARDS

He left the road, travelled 309 feet in a straight line on the shoulder and we think that he was still under power when he struck the tree. He struck it with such force that the trailer came in on the cab, the engine was shoved back in the cab and he was pinned against the back. The steering wheel pinned his hands to the dash board, crushed it against his feet and pinned them to the floor boards.

The man was alive following this accident and was coherent. He was concerned about his family and rightly so because he had a wife and five little kiddies whom he just left a few hours before this and they were expecting him back the next day. Most of our drivers give this picture serious thought when we show it to them.

Another shot shows the distance the tree penetrated into the tractor. It penetrated clear up to the fire wall. Most men don't realize the amount of force and energy that they have behind them when they cruise along at 40 or 50 mph. down the highway.

Needless to say we pick the worst accidents that we possibly can find. They're the most impressive.

One accident shown does not involve our equipment. It involved an over-the-road bus. We show it because many of our drivers travel over the route where this accident occurred. This occurred at a blind rural intersection. The driver of a farm truck failed to stop for the stop sign.

The bus driver was travelling leisurely but he failed to recognize the hazard that existed in the intersection. He did not reduce his speed, he was not prepared for what happened when he hit this truck. The front motor of the bus shot back past the front axle. The driver was killed and several people injured.

We have used these slides to good advantage. There are many people who think that this is a negative rather than a positive approach. We consider it positive because we get positive results. Our men have stayed around our safety meeting for an hour or two talking about these accidents. They never did that before.

CONSIDERING VISUAL AIDS

When we prepared the visual type of accident scene presentation we asked ourselves the following questions:

—Do drivers resent this sort of presentation?

—Is this a negative rather than a positive approach to accident prevention?

—Does this give drivers an impression that will encourage them to be more cautious?

—If there are any good results, could these same results be attained in any other manner?

—Does this tend to embarrass the individual who actually had the accident?

—Can the company benefit from this sort of detailed on-the-scene investigation?

—Is it practical to spend the time and money required for this type of investigation?

—Does the fact that you are self-insured or not have any bearing on this type of investigation?

—Will a detailed investigation pay off in accident prevention and a reduction in claims?

—Are there any other reasons to justify the time and expense involved in detailed investigations?

—Does a detailed investigation ever bring out facts about the equipment that would remain unknown otherwise?

—Is this kind of investigation given any consideration by the Interstate Commerce Commission?

—Should drivers be spared the discomfort of looking upon the serious accidents their buddies have experienced?

—Does this help to convince the drivers who think that it can't happen to them that it might happen to them? Most of your drivers have never had a serious accident and most serious accidents were a first time experience for those who have had them.

—Is a visual presentation the best for maximum effects? If so, what subject matter would be more effective than past accidents?▲

HUMAN RELATIONS—THE KEY TO DRIVER SUPERVISION

by DR. GEORGE D. HEATON
Minister, Myers Park Baptist Church, Charlotte, N. C.

While human relations is the key to all supervision, human relations bears the same relationship to supervision that pathology bears to the medical profession. Until the science of pathology developed, medicine was mere sorcery and magic. But then pathology gave the medical profession something sure and positive for making diagnosis and applying therapy.

Human relations is no gimmick. Human relations is no technique. It is the pathology from which all techniques develop. When one understands the real meaning of human relations, he sees that it has a definite bearing upon everything from the moment that an employee is being interviewed as a prospective employee on through his orientation, indoctrination, training throughout all of his supervisory experiences.

Human relations is the very foundation of communication, of discipline, of handling complaints, of obtaining the participation of people. It is the pathology of supervision. If the pathology isn't right, the techniques are mere guess work.

DEVELOPING TECHNIQUES

If human relations are not right, our techniques are only, at best, haphazard. But with right human relationships, men can find where the techniques that will not only cure some of the things that disturb us, but that will prevent *these things from* ever happening. So I would present to you just a few elements in this human relations which is the key to driver supervision as though I were presenting some elements of pathology to the medical profession.

These are elements that we know are true of human beings. When you accept these basic principles, you can upon that foundation develop adequate and satisfactory techniques not only for the supervision of drivers but for the supervision of all personnel, not only to eliminate accidents, but to reduce costs and improve service.

The first basic principle of all human behavior is this: every attitude that a human being has is his learned way of meeting his needs. You will never get anywhere in the long pull of making your drivers safety conscious unless you recognize that the attitudes of human beings are *our learned* ways of meeting our needs.

CHANGING ATTITUDES

Now there are only two sets of conditions on which my attitudes will ever be changed. One is when I discover that my attitudes which I had learned in childhood and adolescence will no longer meet my needs in an adult world. The moment that I find that any attitude that I have will no longer meet my needs I will change that attitude; nobody can change it for me.

The second *set of conditions is when I* discover that I have new needs for which I do not have attitudes. I have a son who lives in California. He married a year ago and my wife and I read the letters that his wife writes to us and since he's in that Hollywood section of California, we really wondered if it's our son that she's living with. The man that she writes about is not the one we lived with. I'd get up every morning at four at home. That's when he was coming to bed.

We shared the same bath and he'd always be with me and say, "Boy, I'd never work that hard for a living." I preached to him; I lectured to him but he was allergic to hammers, saws, lawn mowers and was sensitive to anything that involved work. But now our daughter-in-law writes about a man that she's living with who's made all the living room furniture, who gets up at four o'clock every morning and goes to work.

She says he's my son. But you see he didn't have any needs that required those attitudes as long as I was feeding him. But when he got her and became a husband, he found that he had some needs for which he didn't have attitudes, therefore, he changed.

Now this is the underlined principle to change the attitudes of people, and attitudes can be changed. You have to build on a sound pathology, you can't go around with any crack patent medicine remedies. You have to understand how people do change their attitudes by the statements that have been made to you.

RESOURCE FOR THINKING

That's the first part of the pathology. The second thing is this: every human being has only one resource for thinking, just one. That resource is the accumulation of all his past memories of his experiences. There is no such thing as a bolt out of the blue. There is no such thing as an idea that's unrelated to a man's past experiences. The only way that you can think and the only way that anyone else can think is by marshalling the memories of his past experiences to bear up on a problem.

If you will understand that all human behavior in its thinking process is but the use of the memory of past experiences, then you can make sure that your people will have experiences out of which they will be able to think, and to think in a pattern of safety. But, if they are denied the experiences which can be used as memories in thinking they will be unable to think as they move along a highway.

Now, this is the pathology of supervision and the third principle is that every human being is a unique. Every human being is a unique individual. God has gone to great pains to make you and every driver different from every other human being. Out of the sexual process of reproduction in which two microscopic cells unite in one cell and then it divides and divides, billions of people have been born and no two of them ever looked identical. A very profound thing.

EVERYONE CAN CONTRIBUTE

But what is more profound is that no two human beings have ever had the same experiences; no two human beings have ever acquired the same attitudes, the same habits, the same preferences. If you forget everything else, remember, that every human being who works for your company can make a contribution to the solution of a problem which no other person in your company can make.

For his memories are different from the memories of everyone else and there isn't any problem of safety, there isn't any problem of reduction of cost, there isn't any problem for improvement of service but that this individual regardless of his academic background can make a unique contribution to the solution of that problem which no other human being can make.

This is the real dignity of man and the pathology of supervision dictates that if you want the cooperation of people, you must give meaning and purpose to what they do in work by recognizing that uniqueness in their dignity, that uniqueness whereby they can make a contribution to the solution of problems which no one else can make.

REMEMBER—EVERYONE'S UNIQUE

If you don't do it you can't pay them high enough wages, you can't give them enough fringe benefits, you can't give them enough security that they will ever be anything other than sullen and antagonist and non-cooperative. You have violated that basic element in the pathology of human relationships that God made me unique and I can do something and think thoughts which no other human being can do.

Now that which seems to destroy this pathology more than anything else, that which seems to destroy good human relationships more than anything else is that which is described in this brief passage from the Bible:

"Bend your ear to this knowledge that caution may be your safeguard and prudence may take care of you. Keep hold of caution and sound sense that they may save you from the loose woman. Her lips drop honeyed words, her talk is smoother than oil itself but the end with her is bitter as poison, sharp as a sword with double edge, her feet go down to death, her steps leads straight to the grave. The high road of life is not for her, shifting and slippery are her tracks."

Who is this loose woman? I'll give you her names for she has many aliases. She is misunderstanding, she is misjudgment, she is miscalculation, she is misinterpretation, she is misteaching, she is mistake.

Whatever her name, she's a dangerous woman.

She destroys the relationships among men that enable men in full dignity to grapple with their mutual problems and if you will but recognize the basic elements in the pathology of supervision you will be able to build your own techniques which founded upon the truths about people will enable you to accomplish what is the goal of all management-to get an important job done with the help of other people.

It's not only hard to do it without their help, often it is impossible. Good human relationships is the way that you get the help of other people to do an important job. ▲

DO WE DRIVE AS WE LIVE?

by DR. PRESTON BRADLEY

Pastor, The Peoples Church of Chicago, Chicago

When talking about safety you only have one theme and all you can possibly do is a variation upon that theme. The effectiveness of what you're saying will depend entirely upon your capacity to create the variation.

I'm chairman of the Library Commission of the City of Chicago and chairman of the Mayor's Commission on Human Relations and a member of the Illinois Prison Investigation Commission. I've given a great deal of my life to enterprises with a civic circumference. But, I get a little tired about the constant undignified references to Chicago. If they would only tell all the truth it wouldn't be so bad.

We are in an era where accidents, murders, immorality, corruption and sin are news. Goodness and truth and achievement are not yet news. They do not possess the dramatic quality of news and that happens in this matter called publicity. Let me tell you what I mean. I could lecture giving the best of my mind, the best of my thinking, the best of my energy.

I could project my ideas to the best of my limitations which are many and nobody would pay much attention. Every editor in the city of Chicago is my friend. But the probabilities are that no matter what I'd say while I have this opportunity, it won't make any headlines. Nobody will care much about it, nobody.

THIS MAKES NEWS

But, I can put my name in one inch letters on the front page before eight o'clock tonight of every newspaper published in the city of Chicago with no trouble at all. All I have to do is artfully get my fingers in your pocket and get your wallet and put it in mine and then go around and visit some more and get in and get another wallet and get four or five of your wallets and start out of here.

The house detective gets me going out the door on La Salle Street and says, "Doctor can you step into the office a minute." He finds your pocketbooks in my pocket. There isn't a newspaper in the city of Chicago that won't have a headline "Doctor Bradley Arrested As A Thief." That's news.

Until we can bring sufficient pressure on those who have the power of creating public opinion in your field and in mine and in every other area which affects the human personality this is going to be an uphill battle.

PUBLIC OPINION BRINGS ACTION

The greatest force and power in a democratic society are the newspaper, the lecturer, the educator, the person who has the responsibility of creating public opinion. For public opinion leads to action and action leads to destiny and destiny is where we are all involved.

You can have a technical appreciation and technological education of the whole problem of safety. You can exchange ideas at national Congresses; you can discuss the by paths; you can do all that. But you and I must find the way in which we can touch that intangible power in a democratic society in which every problem is involved in the creation of public opinion.

Just as the present cold war of the world —a war of missiles and satellites—is not a cold war in which the national boundary lines of unimportant nations are involved or little inarticulate people. It's not merely a cold war in which the representatives of the free world argue and meet and discuss in the United Nations. Fundamentally, it's deeper than that.

This cold war is a war for the human mind. When we come out into the area in which the most valuable thing in the world in involved—a human life—we've got to become more basic and more fundamental than I sometimes think we are. It isn't enough to have a technological understanding of the problem; it isn't enough to have a machine made with honesty and integrity in your control.

Have you ever thought that there never was a perfect machine yet that could not be destroyed and wrecked by an imperfect machinist? The integrity of the machine

today is beyond question. Never were the manufacturers more honest; never was there less cheating in the actual product of transportation.

All of the great industrial equipment of the nation in the creation of the wheel, which is the symbol of the whole problem, were never more integrated with the basic honesty than they are today. I am familiar with a great many of them, a great many of the manufacturers, a great many of the techniques that are used. As an outsider who knows nothing about the technical aspect of safety I want to suggest to you something deeper; something more fundamental.

PURE ACCIDENTS DON'T OCCUR

I don't think that there has ever been a pure accident. I am not one of those who accept the philosophy of fatalism. I am not a fatalist in my theology and I am not a fatalist in my philosophy. And I have lived a long time in the heart of a population of three and a half to five million people and I'm face to face with this problem every day.

Perhaps I should tell you I never drove an automobile. I've been guilty of many things in my life but I've never been behind the wheel of an automobile. I've had an automobile every since there have been any and I have one today. But I have never driven an automobile in my life. Right now I imagine some of you are thinking, "What in thunder does he know about safety?"

Now don't be too sure. As one who doesn't drive, my opportunity to observe my chauffeur and the other fellows on the highway is pretty acute. Don't you discount the authority of that observation.

SAFETY DEPENDS ON PERSONALITY

I think that many times we've been a little wrong in our emphasis about some aspects of safety. When you resolved it all down to its final point it is a matter of personality. It's just as simple as that! It's a matter of personality! I submit this observation to your consideration for you are most deeply concerned.

Something happens to very man who gets behind the wheel of an automobile. Something happens to him, psychologically, and 99 per cent of the accidents both fatal and of little consequence can be traced to a personality defect, a fundamental personality defect.

I have written eight books, two of them on the human personality and I think in this field I speak with some element of authority. I'm dealing all the time with the human element—the element of personality. I have never yet seen a situation which could not be traced to some defect in the personality.

That means that over the long pull with the ever increasing opportunity of speed on the highways of America, and with the application of the scientific aspect of transportation which the experts are giving to us in the creation of the great freeways of the nation, we still have much work to do in the matter of driver's personality.

Last week I was speaking in Los Angeles and a friend of mine who was interested in this very subject took me out on the highways and freeways around Los Angeles. It was a never to be forgotten experience and in a matter of just two or three hours, I saw three tragic accidents in which the lives of eight people were involved.

. . . BECAUSE OF HUMAN FAILURE

When we followed through the investigations that came later, it was not alcohol or the like, it was human failure—lack appreciation of the rights of the other driver.

Obviously, no man should ever take the responsibility of all of his faculties. And, those faculties should not either be depressed or encouraged by an artificial condition. When a brain is befogged with alcohol, even a microscopic presence of alcohol that you could hardly detect on the breath, there is a psychological reaction in the person's will and judgment.

The idea that a person has to be so drunk that he staggers or that he weaves in traffic in order to come under the classification of intoxication is ridiculous. You can't take a spoon full of alcohol in a position of responsibility like that and not have a direct affect upon your will and your judgment. I think that there is an area of education in that field that sooner or later we've got to do something about. It isn't enough to treat it as objectively as it is being treated today.

If the job is really going to be done in the presence of the trend to create more power in an engine, it will take more regulation in the state legislatures and assemblies of our country. The paradoxical situation of most state legislatures talking about 65 daylight and 60 night time and putting increased limitations on speed and in the meantime the manufacturer providing more horsepower is creating serious situations.

I'm not so sure but what it's dangerous to put into the highway an instrument in the hands of a man who depends upon something called quick pick-up knowing that under him is 200 or 300 horsepower, that he can take a chance in any spot because he knows it's there.

I don't think we're beginning early enough to teach safety. This is a power age. Every kid is smitten by the power bug. I've got a nephew that's already talking about space flight. He explained to me the other day how to make a platform in the moon where they can land. He's got it all figured out.

Of course, I don't get as excited about those things as a lot of people. This little piece of tin running around the globe in an orbit doesn't bother me. I don't know why anybody bothers the poor old moon or Mars or any of the rest of it. I think we ought to be doing something about this earth first.

TRAIN PEOPLE EARLY

If we could have saved this money, half of the billions the taxpayers of America pay, to begin this problem of psychological training for the individual at the time we should be at it and not wait to do the job, we'd get the job done. We should be getting at this problem in the earliest grades of school.

We need to study the human personality; we need to develop the whole philosophy of one's reactions and reflexes and responses which are involved in any moment of emergency. What's the test of a man's character anyway? If we should have at this moment some great catastrophe; if there should be an explosion; if this roof would start falling in—we would all be experiencing some great emergency.

Let me see you in the first minute of that emergency and I'll read your character. Let some tragedy come into your life in the next 30 minutes. Let something happen and let me see how you handle that and I'll tell your character.

Most of us can be honest most of the time. Most of us can be true to one woman most of the time. Most of us can pay our debts most of the time. Most of us are pretty decent most of the time. Most of the time doesn't matter, it's what we are the rest of the time that matters, not most of the time.

EMERGENCIES REVEAL CHARACTER

A person is fundamentally what he does and how he responds and how he reacts in an emergency. If you can shape the human personality early enough to build a fortification for the emergencies of life you've done something to transform the whole area of our modern world.

This is a battle for personality and that's why I think that there are psychological tests that are now so definite in their character and so unimpeachable in their authenticity that I should think we would require a psychological analysis of each driver's personality.

There are people who have most of the major requirements but are so sufficiently defective in fundamental requirements that they go to pieces and you wonder why a sudden flare up in the highway happens, when sudden anger arises.

If my chauffeur who's been with me for many years ever told me I had the right of way, I'd fire him. There isn't any right of way, fundamentally. There is only a right way and yet there are those on these highways whose character becomes suddenly transformed and anger comes quickly. That's part of his personal character.

POWER AGE GROWING

It hasn't anything to do with his ability to drive or the principle of safety. It's a psychological factor in that person's life and I think we're wasting a whole lot of time and a great deal of our emphasis: first, by not beginning early enough. This is a power age and it's going to increase in power as the days go by; we haven't even started yet.

The automobile itself will undergo such a great transformance in the next 25 years that none of you would hardly recognize it today. Safety problems are going to increase not decrease. Let us, in the great area of the mind and in the psychological

aspect of it, recognize how important that phase is, too.

You let me see a person in traffic with responsibility and let me sit along side of him and analyze his reactions and I will grade that person's basic responsibility and understanding of safety to an uncanny degree of perfection. Let me see his reflexes and his responses and I will ascertain the quality of his understanding of safety. If pride and self-importance and right of way and all such factors are predominant, he's dangerous. And sooner or later he'll have trouble.

Of the awards that we have made in the city of Chicago for safety, and I've been making them to the Police Department and the Fire Department and to other institutions in our city, the recipients have been the most highly integrated characters in the departments.

A man for safety is an integrated personality. He's a man who is completely in control—first of his mind, next of his emotions, next of his body, so that he is in control of every given circumstance. That man knows and practices safety. Let us have more of those kind of men.▲

REPORT OF THE NATIONAL FLEET SAFETY CONTEST COMMITTEE

by E. G. COX

chief, Section of Safety, Bureau of Motor Carriers,
Interstate Commerce Commission, Washington, D. C.

Each year we report the current National Fleet Safety Contest, bigger and better than the year before. To some, this might sound repetitious and uninteresting. We know, however, that the situation indicates progress both in volume of accident data and in the accident frequency rate of reporting fleets. The mileage of participating fleets increased 215 million miles in 1957 compared to the previous year, yet, accidents dropped 200. The result was a decrease in frequency rate of five per cent.

The average frequency rate of 1.51 accidents per 100,000 miles operated is the second lowest frequency rate in the history of the contest. It is only exceeded by the 1954-1955 contest rate of 1.44.

Records of winning fleets were verified by personal audit for the seventh year. The largest number of contestants were checked by audit than ever before. The 325 audits represent over 93 per cent completion despite the difficulty of obtaining representatives of the contest committee in each state, Canada and the Territorial Hawaii.

From the audit work sheets reviewed by members of the contest committee, it was found that 70 per cent of the contestants were certified exactly as they reported to the contest. Twenty-one per cent of the audits resulted in some change up or down in mileage or accidents and in nine per cent of the audits, the contestant dropped out of the running.

250 AWARDS PRESENTED

More than 250 awards are being presented to contestants in the 1956-57 National Fleet Safety contest.

These consist of first, second and third place awards, as well as perfect record certificates.

To each of the winners, we extend our heartiest congratulations and to the runners-up our hope for improvement during the coming year. To every contestant who participated in the contest, we offer our thanks.

Needless to say every contestant cannot be a winner. Yet, every fleet that improves its record in each succeeding year is a winner by virtue of savings to the company in dollars and lives.▲

OFFICERS OF THE

COMMERCIAL VEHICLE SECTION

NATIONAL SAFETY COUNCIL 1957-58

General Chairman—F. S. LAKE, director of safety, Interstate Motor Freight System, Inc., Grand Rapids, Mich.

Vice Chairman—KARL SCHULZE, senior safety engineer, Standard Oil co. of California, Western Operations, Inc., San Francisco, Calif.

Secretary—L. F. PURVES, superintendent, Toronto Star, Ltd., Toronto, Ontario, Canada

Immediate Past General Chairman—K. N. BEADLE, director of safety, Pacific Intermountain Express, Oakland, Calif.

Standing Committee Chairmen:

Program—S. E. NELSON, superintendent of safety, Burlington Truck Lines, Inc., Galesburg, Ill.

Contest—J. A. DePEW, director of safety and personnel, Dohrn Transfer co., Rock Island, Ill.

Driver Award—N. J. BLEAU, safety director, Automobile Shippers, Inc., Detroit, Mich.

Membership—J. W. JACOBSON, director, accident control div., F. J. Boutell Driveaway co., Inc., Flint, Mich.

Regional Chairmen:

Central—J. H. WASPI, director of safety and driver personnel, Allied Van Lines, Inc., Broadview, Ill.

Eastern—B. A. RENNOLDS, safety director, Virginia Stage Lines, Inc., Charlottesville, Va.

Southern—W. L. FRIGON, director of industrial relations, Hennis Freight Lines, Inc., Winston-Salem, N. C.

Western—A. S. LOMBARDI, safety and personnel director, Western Truck Lines, Ltd., Los Angeles, Calif.

Members-at-large:

Central: E. M. BARBER, director of safety and personnel, Scherer Freight Lines, Inc., Ottawa, Ill.; J. L. CANTRELL, safety manager, Miller Brewing co., Milwaukee, Wis.; E. A. HATFIELD, safety director, Coca Cola Bottling co., St. Louis, Mo.; R. L. MOSIMAN, director of safety and personnel, Riss & co., Inc., Kansas City, Mo.; G. K. ROSS, director of safety and compliance, Frozen Food Express, Dallas, Texas.

Eastern: T. J. BIDDLE, administrator, motor vehicle safety, U. S. Post Office Dept., Washington, D. C.; W. A. DUFFY, director of safety and personnel, The Davidson Transfer & Storage co., Baltimore, Md.; C. E. EHRENBERGER, manager, operating dept., Standard Brands, Inc., New York, N. Y.; J. W. LUMPKIN, manager, safety, Railway Express Agency, Inc., New York, N. Y.; G. L. SMITH, assistant vice president, Motor Cargo, Inc., Akron, Ohio.

Southern: W. W. CARTER, director, safety and personnel, Johnson Motor Lines, Inc., Charlotte, N. C.; H. R. GRANT, JR., safety director, Deaton Truck Lines, Birmingham, Ala.; J. E. REID, director of safety and personnel, Central Motor Lines, Inc., Charlotte, N. C.; E. J. STEVENS, transportation manager, Atlanta Newspapers, Inc., Atlanta, Ga.; H. T. WALTON, director, dept. of safety, McLean Trucking co., Winston-Salem, N. C.

Western: J. L. HUGHES, director of safety, Southern California Freight Lines, Los Angeles, Calif.; H. B. LOWDEN, plant safety supervisor, Pacific Telephone & Telegraph co., San Francisco, Calif.; B. E. McENTEE, general safety manager, Denver Chicago Trucking co., Inc., Denver, Colo.; R. O. OLSON, safety director, Dan Dugan Oil & Transport co., Sioux Falls, S. Dak.; W. C. TAYLOR, director, personnel and safety, Ringsby Truck Lines, Inc., Denver, Colo.

Counselors: W. M. AICHER, employee relations, U. S. Brewers Foundation, Inc., New York, N. Y.; N. E. AIKIN, director of industrial relations, Commercial Motor Freight, Inc., Columbus, Ohio; C. D. CALKINS, director of safety, Pacific Motor Trucking co., San Francisco, Calif.; E. G. COX, chief, section of motor carrier safety, Interstate Commerce Commission, Washington, D. C.; E. J. EMOND, director, automotive safety, Armour and co., Chicago, Ill.; W. T. GOWENS, director, safety and personnel, Pilot Freight Carriers, Inc., Winston-Salem, N. C.; H. K. HALBROOKS, director, accident prevention div., National Automobile Transporters Assn., Detroit, Mich.; A. L. HAUCK, director, safety and public relations, Transportation Underwriters, Inc., Indianapolis, Ind.; J. P. HIGHTOWER, director of transportation and safety, The Greyhound Corp., Chicago, Ill.; H. R. HOSEA, director of research, National Assn. of Motor Bus Operators, Washington, D. C.; M. R. JENSEN, vice president, Consolidated Freightways, Inc., Indianapolis, Ind.; E. B. KELLOGG, secretary, Milk Industry Foundation, Washington, D. C.; W. G. MACINTOSH, manager, engineering dept., Hartford Accident and Indemnity co., New York, N. Y.; A. E. NEYHART, administrative head, The Pennsylvania State University, University Park, Pa.; R. N. PAPICH, safety consultant, American Gas Assn., New York, N. Y.; F. J. WIRKEN, director, safety and personnel, Interstate Bakeries Corp., Kansas City, Mo.

Staff Representative: AL FINCH, National Safety Council, Chicago, Ill.

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the [illegible] page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts, with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

THE OCCUPATIONAL HEALTH NURSING SECTION

This volume is a record of the sessions held at the 1957 National Safety Congress by the Occupational Health Nursing Section. The conduct of these Congress sessions each year is only one of the many cooperative activities which the Occupational Health Nursing Section carries on in behalf of its members, and for the benefit of accident prevention work in industrial nursing generally. The Section gives guidance in the preparation of a great variety of technical and educational material useful in the day-to-day safety programs of industrial nurses. The activities of the Section are under the direction of its executive committee, the members of which are listed at the close of this volume.

INTRODUCTORY REMARKS

by VERNA PASKUNA, R.N., General Chairman
Owens-Illinois Glass co., Streator, Ill.

There has been a session for nurses at the Congress since and including the third congress in 1915. This is proof that the National Safety Council recognized early the importance of the nurses' part in the accident prevention program. The fact that the nurses petitioned for a Section indicates that they wanted to take an active part in the overall objective of the Council, namely accident prevention.

This year a call has been sent to the nation to "Back the attack on traffic accidents" and we as nurses have a big responsibility in this endeavor.

The drive will be successful if we never overlook an opportunity to speak a word of caution, educating the impulsive to take care, guarding against the hazards so well known to all of us but so frequently ignored. To us accident prevention should be an ever present activity. Like religion it should be practiced every day and in every act we perform.

So team work again becomes the important factor. Each and everyone of us in the safety movement should join forces to help eliminate these tragic accidents on the highway that bring grief, pain, reduce man's earning power. All these factors affect production in industry.

As occupational health nurses we are in a strategic position to promote health and safety off the job as well as on the job. May you return with new ideas and zeal to help carry out this program in your own areas after attending this 45th Annual Safety Congress, and the 43rd in which the nurses have met in special sessions.

These meetings are set up primarily that those in attendance may derive some benefit from them and help you do a better job.

I want to express my heartfelt thanks to each and everyone on our committee for the time, interest and ideas they have contributed for the good of the Section. We are grateful to the staff of the National Safety Council for the moral support given us and especially to David Arm and his industrial staff and Miss Jane S. Weir, R.N., our Section staff representative, for their fine help and guidance.

EMERGENCY FIRST AID PROGRAMS IN INDUSTRY

by EARL H. BREON
director, First Aid Service, American National Red Cross, Washington, D. C.

Most people are satisfied that the definition of First Aid states the issue. This is far from true. A history of more than a half century of experience keeps insisting that the remedial values of First Aid education are about 10 per cent of the total and that preventive values are 90 per cent of the total.

Good safety education programs are concerned with CAUSE—EFFECT—and PREVENTION of accidents. First Aid education is concerned with these three and adds the all important fourth—CARE.

Because we deal with humans, we must face the fact that preventive measures can only reduce accidents to a certain unspecified minimum and then only under controlled circumstances. The uncontrolled situations create enough injuries to warrant training people in simple remedial measures. *PREVENTION* then is a *primary* goal of First Aid education.

In addition there are certain emergencies such as severe hemorrhage, suspension of breathing and ingestion of poisonous substances when immediate action is imperative.

Teaching lifesaving skills is a *secondary* goal of First Aid education.

When an accident happens, the victim suddenly has new problems and needs. Events seem unreal or remote and his mind is dull. The emotional reaction associated with a serious accident subsides only gradually. The first aider is taught to deal with the *whole* situation, the person, and the injury. He knows that handling injured parts should be avoided if possible and movement of the injured person should be attempted only if surrounding hazards pose a threat to life. The third goal of First Aid training then is *PROTECTION OF THE INJURED.*

REMEDIAL VALUES FIRST AID TRAINING

Emergency care cannot be confined to the health room or First Aid posts throughout the plant. A severed brachial or femoral artery will not wait for the nurse or doctor to come from a remote part of the plant before it starts to bleed. Paralysis of the respiratory center, accidents excluding air from the lungs, or inhaled gases that displace oxygen in the blood stream are examples of the need for action on the part of those at the accident scene.

How much time do you have after breathing stops, before brain damage occurs, and loss of life is imminent—not much time—a few precious minutes. The same is true of accidental oral poisoning and chemical burns, especially those burns involving the face. Industrial emergency First Aid programs must teach *all* personnel what to do in these emergencies.

The industrial nurse can and does play a vital role in planning good programs by (1) conversational teaching, (2) lectures, and (3) posting visual aids. But one additional step is necessary. The employee must practice safety skills (including First Aid skills) if retention is to be good. Studies in other areas confirm the fact that participation is essential if the learner is expected to remember motor skills for even short periods of time.

If we can agree that simple First Aid procedures for use in dire emergencies are a basic requirement for each employee, the next step involves areas of team work to handle skeletal injuries properly. If your plant is one where injuries to the long bones of the body, the back, and the head are high, your emergency care program should include training groups to transport the injured. When movement of a victim with a skeletal injury is attempted by a group of three or four even with some previous training, lack of team work often may bring disastrous results.

It is not an easy task to keep the body joints locked while moving a victim to a supporting frame or litter for transfer to the health room or dispensary. Those involved in the task must know the principles involved *and* be able to work well together. A competent leader for the team is essential. Selected, identified groups should function as units when accident victims must be transferred from any section of the plant to the health room.

The third step extends benefits beyond the four walls of the plant—to the employee's home and family, to his community, and to his own off-the-job activities. The same remedial values apply here. The lifesaving skills learned in the plant are brought to the home to be used, not only by the employee, but members of his family too.

The remedial aspect of First Aid training in industry should add up to these three things:

1. Training every employee in lifesaving skills.
2. Group training to provide essential teamwork for handling transportation of the severely injured.
3. Extension of the program to the family and community.

One final word about remedial First Aid. Advise changes frequently and sometimes drastically. Keep up to date.

PREVENTIVE VALUES OF FIRST AID TRAINING

The primary objective of First Aid training is prevention of accidents. The accident prevention impetus comes from active participation *in*, not passive acceptance *of* a program.

When the learner associates falls with fractures and practices immobilizing these hypothetical fractures on friends and coworkers, the association becomes deep-rooted and awareness of consequences of falls become something tangible. A motion picture or a lecture is a weak substitute. Safety awareness generated by participation in first aid skill activities is a lasting thing. It is "portable"—it goes with the owner. It has wide range of application on-the-job and off-the-job.

First aid cannot cure *all* the ills, but it can cure *some* of them. The whole plant safety program is made up of many ingredients. Emergency care is one of these and emergency first aid programs play an important role. Those who say First Aid is an "after the fact" activity just haven't had experience with it. First Aid training sharpens the desire for safety.

Safety doesn't stop when the accident occurs. Minor accidents do not become major ones and major ones fatal when basic principles of caring for injuries are understood and applied. Since 1882 when the Red Cross first became interested in this activity, these preventive values have been a by-product of First Aid training whether by intent or not.

The following equation is not for thermonuclear explosions but for simple human engineering.

MAN + MOTION = ACCIDENT

MAN + MOTION + JUDGMENT = ACCIDENT

MAN + MOTION + JUDGMENT + TRAINING = ACCIDENT

MAN + MOTION + JUDGMENT + TRAINING + DESIRE = ACCIDENT

With each addition the accident is postponed, made smaller and less vicious, but the accident never leaves the equation as long as MAN AND MOTION are involved.

Good "Emergency First Aid Programs in Industry" are:

- tailored to fit the plant needs
- part of the safety program
- part of the health program and in small industries they may be the total program
- programs with carry over value to the employee's family
- contributing to better community life
- creating large groups of self reliant people who should act better in emergencies such as disasters, man made or otherwise.

Building programs that do these things requires complete understanding at the operating level and complete support of management.

The physician, the nurse, the safety director and the employee must cooperate for the good of all.

To the industrial nurse—participate in formal and conversational teaching of employees, and each time you do this, have the man's family in mind. Show him how his training and skills can be adapted to his home life—help him to become more interested in first aid and safety. There isn't a higher dividend obtainable in any other company project.

Handling Problems of

ASPHYXIA IN INDUSTRY

by JOHN B. DUNNE

sales manager, medical and hospital dept., Globe Industries Inc., Dayton, Ohio

In a popular radio commercial, a voice on the phone asks a harrassed J.B., "Are you immune?" In a startled voice he asks, "Immune to what?" The answer comes back, "Immune to odor causing bacteria on the skin."

We're not interested in bacteria, whether they cause odor on the skin, but whether you are immune in your plant. Immune to what? Immune to accidents causing asphyxia.

During the last war, a plant manufacturing delicate instruments must have thought they were surely immune to such cases. One

night, however, a maintenance man set about repairing a test bench of one woman employee. His shoulder touched an electrical grid, his leg was touching a metal bench leg. The result was, according to the coroner's report, "Death caused by asphyxia due to electric shock." Then they knew their plant was not immune.

Several weeks ago, the manufacturers of a popular brand of coffee awakened to the fact that they weren't immune when sixty workers were overcome by inhalation of trichlorethylene escaping from a tank. Eighteen were hospitalized; fortunately none died. These purveyors of pleasant aromas of coffee may have thought they were immune to asphyxia.

Management can take positive steps to render plants as free from this type of accident as possible.

In order to do this we fall back again upon the "Triad of Safety." This three pronged attack on asphyxiating accidents we plan to use is composed of three parts:

Detection; Protection; Treatment.

DETECTION

The ideal way to prevent respiratory emergencies is to detect the causes at the source. Instruments now available permit the safety engineer or industrial hygienist to detect carbon monoxide, hydrogen sulphide and other harmful gases down to three or four parts per million. This equipment is portable and its use is only common sense. Routine checks with these instruments will determine the presence of most potential killers. The men can be alerted to the danger and protective measures can be taken.

In the case of the presence of carbon monoxide the instrument will give warning of the need to ventilate the garage or other area where internal combustion engines are used or where carbon monoxide from any source might be present.

Of course these instruments are most useful to determine leaks and give early warning of the presence of toxic atmospheres. They scarcely can be expected to predict a fulminating escape of gas. It is safe to assume usually where there are traces of gases there is the chance that larger amounts may be present later. Detection therefore, is of utmost importance in every industry. It should be part of every far reaching safety or industrial hygiene program.

Great advances have been made in this department of the "Triad of Safety" in the past 10 years. Workers used to depend on the dubious protection of filter type masks. They now can rely on air supplied, self-contained air or oxygen masks and work in safety. Since these units are independent of the surrounding atmosphere a man can go into a very toxic environment or one completely devoid of oxygen and perform his duties with complete confidence.

PROTECTION

The use of these masks also makes possible the immediate rescue of victims who have been overcome by gas or fumes of any sort. While much work has been done to educate the men to use this equipment, a lot more can be done. If there is any doubt in the mind of a foreman about the presence of gas he must be educated to insist on the men donning protective equipment to do a job.

Selecting the proper type breathing apparatus for various jobs will make teaching the use of this equipment easier. Using a half hour apparatus which weighs over 30 pounds is not justified for a short inspection job. By the same token where he has to work in a toxic atmosphere for several hours the worker needs more than a half hour apparatus but he should not have to carry a heavy load on his back to get his supply of fresh air or oxygen. There are other jobs which can be done ideally with the traditional half hour demand apparatus.

It is incumbent on the supervisors and safety personnel in the plant to analyze the jobs to fit the mask to the work it is best suited. It is incumbent on the mask manufacturer to put a variety of masks at the disposal of industry best suited to specific jobs.

These manufacturers must give thought to comfort of the mask, proper distribution of weight, greater safety for the mask wearer and on continuing development program for improvement of this equipment. Thus the safety men in industry and the manufacturers can jointly contribute to a better mask program. Education and development can go hand in hand to prevent accidents and aid production.

TREATMENT

In considering treatment of cases of asphyxia, it would be well to list the most likely causes. Industry today is faced with many more respiratory hazards than were present 25 years ago. Complex chemicals used in manufacture of plastics, development of synthetic substitutes, production of components of atomic energy, are just a few of the situations now integrated into our manufacturing picture which make the atmosphere more hazardous. Many plants have increased their electrification a hundredfold in this period, and thus hazards from electricity have multiplied.

Another element in the over-all picture is the introduction of thousands of new workers into new jobs where they are not acquainted with the hazards that are present. Production in heavy industries is being pushed to capacity with fatigue from equipment a very real threat. Small industry and commercial establishments are faced with an aging employee population, and cardiac cases are more prevalent.

Therefore, the most likely causes of asphyxia in industry are:

1—Carbon monoxide
2—Electric shock
3—Cardiac cases
4—Inhalation of hydrocarbons
5—Toxic chemical inhalation, including chlorine, hydrogen sulphide, ammonia, higher oxides of nitrogen, hydrofluoric acid gas and others
6—Exposure to oxygen deficiency.

There are over one hundred toxic agents. Here we'll discuss the five causes of asphyxia in industry according to their relative importance.

CARBON MONOXIDE INHALATION

Probably the most insidious gas known is carbon monoxide. It is colorless, odorless and tasteless. It can be generated almost anywhere without warning and unless special detecting instruments are employed, its presence may not be realized until someone collapses. It is generated wherever carbon products are burned without sufficient oxygen. Common generators of carbon monoxide are automobile engines, gas hot water heaters, unvented space heaters, coke ovens, coal furnaces with faulty flues and others.

Carbon monoxide has a combining power 250 times greater than oxygen with the hemoglobin in the red blood cells. These are the cells which normally carry the oxygen to the tissues. Even with a small percentage of carbon monoxide in the inspired air (a few parts per million) it is possible to displace the oxygen in the blood and saturate it with this other gas. With one per cent carbon monoxide in the surrounding atmosphere a person can become unconscious in a matter of three or four minutes.

SYMPTOMS

The victim usually experiences extreme feeling of fatigue with an overpowering tendency to yawn. A headache quite severe and rapid in onset may strike the front of the head. Dizziness and nausea may be present. Unconsciousness follows and then the stoppage of breathing. The color of the victim of carbon monoxide may be cherry red due to the change in hemoglobin. This often misleads the onlookers into thinking he is well oxygenated. Death will follow if the victim is not soon given artificial respiration.

TREATMENT

The patient should be removed from the gaseous atmosphere but *not exposed to cold*. So doing may cause death from acute cardiac dilatation. Artificial respiration should be started at once. Oxygen should be administered during artificial respiration and for several hours after normal breathing starts.

It is difficult to disassociate the carbon monoxide from the bloodstream once it has replaced the oxygen in the hemoglobin. The patient should not be allowed to get up after restoration of breathing, but should be kept lying down to protect his already overtaxed heart. He should be kept under medical care for as long as deemed necessary.

ELECTRIC SHOCK

Shock from electricity may be brought on by contact with a manufactured electricity source or by being struck by lightning. Voltage, amperage, duration of contact and type of ground all have their part to play in the seriousness of the case. The damage may be due to current passing through the brain, or through the heart, or it may be that the convulsive effect of the shock paralyzes the muscles of respiration.

SYMPTOMS

Victim is usually unconscious and not breathing. Burns are often apparent or may be present under the flesh. The body is often rigid, and the color of the patient is blue.

Immediate removal from the electric current is necessary, and should be done so as not to endanger the rescuer. A dry board, heavy rubber gloves, or dry woolen blanket can be used to pull the patient away.

A common symptom of electric shock which cannot be detected by the nurse, first aider, or rescue worker is ventricular fibrillation. This means that the muscle fibres in the ventricles of the heart are not working in unison, and thus the heart is rendered incapable of pumping blood. Much work has been done by medical investigators to develop a defibrillating device which can be applied to the outside of the patient to get the heart back to its normal function. Encouraging results have been obtained in this field of research.

TREATMENT

Artificial respiration is often difficult to administer manually because of the body rigidity. It must begin at once, however. A reliable resuscitator should be used if available, as this will ventilate the patient through a mask and not rely on movement of the chest wall. Maintain the patient's body temperature at normal.

CARDIAC CASES

Some heart attacks are accompanied by extremely distressed or depressed breathing. In many cases breathing may cease entirely. These cases require artificial respiration. If a reliable resuscitator can be procured, it should be used dispensing 100 per cent oxygen. The victim of such an attack should be kept absolutely quiet. Even when breathing and consciousness have returned, he must not be allowed to sit or stand. He must be transported on a stretcher.

There are heart cases which do not involve stoppage of breathing, but which need oxygen and must be handled with extreme care. These must be kept lying down and extremely quiet. The person should be kept from getting chilled and a doctor should be summoned. Oxygen should be administered continually.

INHALATION OF HYDROCARBONS

There is a long list of solvents which will cause asphyxia very readily. Among these are: gasoline, naphtha, benzine and carbon tetrachloride. When working in a confined space with these the victim may at first experience many of the feelings of intoxication from alcohol. These solvents being highly volatile can be breathed into the lungs, where they are rapidly transmitted through the lung cells to the bloodstream. Loss of ability to focus, staggering gait, thick speech are all part of the picture. Continued exposure will result in unconsciousness and asphyxia.

The patient should be removed to fresh air and artificial respiration begun at once. Severe headache and nausea will probably follow recovery of consciousness. Administration of oxygen over a three or four hour period will alleviate these symptoms.

INHALATION OF TOXIC CHEMICALS

There are any number of chemical irritants which may be encountered in industry today. Chlorine, hydrogen sulphide, ammonia, hydrofluoric acid gas, phosgene, the higher oxides of nitrogen, aldehydes, benzene, benzol, and many, many others. These share in common the ability to irritate the respiratory organs and even do permanent damage to the bronchial tree and lung cells.

When we consider that our lungs are made up of 5½ million alveoli, each a little individual cell capable of transferring oxygen through its wall into the bloodstream and removing carbon dioxide through the wall to be exhaled, we have some idea of the delicacy of these tissues. It is common knowledge to all of us what happens when we scald our hand or some other part of our body. A blister forms quickly as plasma is released into the traumatized area. How much more readily would this occur if a searing, burning gas is taken into our lungs where tissues are so much more delicate!

Fluid perfuses through the wall of the affected lung cells and soon we have a full blown pulmonary edema. If enough fluid fills up the cells, little room is left for air, and as one doctor aptly put it, "We drown in our own juice." Pulmonary edema, then, is a real threat in any of these irritant gas cases.

Still another threat is that when the victim starts to inhale the irritant he may get laryngospasm. If this occurs, he will get less gas in his lungs, but he may promptly suffocate, so his case is equally serious.

TREATMENT

The victim of inhalation of an irritant gas should be removed to fresh air immediately. If he is not breathing he should be given artificial respiration either manually or by means of a resuscitator which can give intermittent positive pressure. *Negative pressure should not be used in these cases.* If laryngospasm is present, it will be apparent that no exchange of air is occurring. The head should be pulled back, hyperextending the neck, and every attempt made to establish an open airway.

If the patient is still breathing he can be assisted with intermittent positive pressure oxygen. He can usually tolerate 4 to 8 mm of mercury pressure. This assists him on inhalation and will gradually overcome his apprehension. There is a slight positive pressure left in the lungs which exceeds the partial pressure of the fluid, which should prevent further perfusion into the cells. This treatment should be continued until he is transported to a hospital or until other treatment is designated by a physician.

Remember, these cases are tricky and the onset of pulmonary edema may be delayed. Thus, sending an employee home prematurely after exposure to an irritant gas may be dangerous. He may require periodic sessions of intermittent positive pressure oxygen for twenty-four hours or more. Much can be done towards preventing permanent lung damage by adequate emergency treatment.

EXPOSURE TO OXYGEN DEFICIENT ATMOSPHERE

We have pointed out previously that 16 per cent oxygen must be present to sustain human lives. Asphyxia brought on by being exposed to atmospheres deficient in oxygen is especially serious. The reason for this is that often the victim of oxygen starvation may not only stop breathing, but may also undergo acute cardiac dilatation. This means the heart expands rapidly and death ensues. Since it is not probable that the lay person can differentiate between asphyxia and death, he should perform artificial respiration until a physician has made his tests for death or until breathing is restored.

Oxygen deficient atmospheres are encountered often in cisterns, old wells, abandoned mines, chemical or oil tanks, vats or in any place where ventilation is poor. Tank cleaning is especially dangerous because the sludge may contain sufficient fumes to exclude the oxygen. No rescue should ever be attempted in these cases without an air or oxygen supplied mask. Filter masks are of no use in such cases.

SYMPTOMS

It is fairly easy to ascertain one's exposure to an oxygen deficient atmosphere. Of course, if the oxygen content is extremely low, the onset of unconsciousness and even death may be immediate. But if the percentage below 16 is not great he will be able to recognize his danger and get out. He will experience a feeling of apprehension. He will find his breathing will become rapid and labored and he may break out in perspiration. If such symptoms are experienced, he should walk or crawl slowly out of the atmosphere, taking care not to hurry unduly. This precaution may save his life.

It seems that it would be timely to say a word about establishing and maintaining a good airway. The finest artificial respiration, manual or automatic, is doomed to failure if the air passage to the lungs is not kept open. It is so important that some anesthesiologists have advocated teaching the technique of intubating to all nurses and first aiders. They have arrived at the decision that many lives are lost each year because air does not get beyond the throat, and the efforts at resuscitation are fruitless.

Inserting a metal or plastic airway will help to some extent. Also the tongue roots should be elevated from under the chin and the head pulled well back. Sometimes even these efforts are to no avail. Nevertheless, *do not neglect this detail.*

No plant, no matter how small, is immune to the hazard of asphyxia. Since this is true, industry should employ the "Triad of Safety"—*Detection, Protection* and *Treatment* to cope with this danger. Because the nurse is concerned mostly with the treatment aspect of the Triad, more attention

was given to this. In maintaining a safe plant, however, all three must be given equal importance.

Since asphyxia has become an increasing threat in our more complex industrial world, it behooves us all to do our utmost to combat it. As industrial nurses you can do your part by learning more about the hazards in your own plant, and then by being ever ready to act immediately. By applying your knowledge and skills you may be able to restore breathing and save human life.

NEW TRENDS IN OCCUPATIONAL HEALTH PROGRAMS

by DR. H. GLENN GARDINER
medical director, Indiana Harbor Works, Inland Steel co., East Chicago, Ind.

The inclusion of the words "trends" and "new" necessitate establishing a base from which to launch.

To identify the subject matter, I avoid the highly technical changes in the complex field of chemistry generally and the atomic energy area particularly. The more technical phases of these special fields seldom concern the nurse and few physicians. Yet, the impact of these developments is felt throughout the industry.

Going back to the beginning trends in occupational health in 1937 we will first discuss the field of patient care. Few important medications used then are still in use today. Of course, the principles of good, clean, basic surgical care have not changed. Some antiseptics today were then new and still to prove themselves. Tetanus antitoxin was widely used, but their problem of serum sickness and various other potential allergic phenomena attendant to its use are still with us today. Immunization of large groups with booster shot follow-ups was not yet practiced.

None of our present battery of chemotherapeutic and antibiotics were then available. There were such things as antitoxins, specific antisera, vaccines of general and specific types, the mysterious bacteriophages and immunogens being used with hope, but the effectiveness never approached the success we now routinely anticipate with our medicines.

Many adjuncts of yesteryear are little used or unknown today. Similarly, the diseases they were calculated to control are little known or rarely seen today: functional knowledge of fluid and electrolyte balance, early postoperative ambulation, internal fixation materials (metal alloys) used in bone surgery such as intramedullary pins and plates better tolerated by the tissues. Plastic and metal suture materials producing little or no tissue reaction are further examples of technical progress in traumatic surgery. Amphetamines and antihistamines have come into their own.

WORKMEN'S COMPENSATION LAWS

Secondly, 1937 was the year of legal awareness of occupational disease. For the first time industry and the business firms concerned with Workmen's Compensation were forced to take cognizance of liability for certain occupational diseases.

The big bad monster was silicosis. How well I remember the fear and consternation in Industry and Casualty Insurance Carriers of Workmen's Compensation when legislation enforced these responsibilities. So little was known about the disease at that time. The widespread industrial exposure to free silica was fantastic. Some people predicted total bankruptcy for industry and the allied insurance people. Time and reason have taken the place of fear.

Silicosis is known, but completely controllable in our modern industry by better housekeeping, improved handling techniques, substitution of safer, yet suitable materials and where necessary, the use of personal protective equipment. Management has been compelled to change its attitude or be refined by legal action. Desirable working conditions as contrasted to minimal legally allowable conditions have many favorable aspects which pay off in the long run, both directly and indirectly.

Now occupational disease must embrace many things: the pneumoconioses, the dermatoses and the many toxic exposures. The hazard of uncontrolled exposure of lead fumes, benzol, carbon tetrachloride, beryllium, cadmium, trichlorethylene, insecticides, and now more recently radioactive materials have opened a new field for exploration.

INDUSTRY FOLLOWED LEGISLATION

With the coming of O.D. acts, people realized the need for promoting occupational health programs in industry. The existing units in city, county and state health departments were expanded—new departments were established where none existed before. Large industry found it economic to seek their help. Where the problems were great and the demand exceeded the existing facilities, some of the more foresighted industries developed their own programs.

Large casualty insurance carriers responsible for the smaller industries pursued the course of enlightened preventive medicine beyond the field of simple mechanical principles of safety. Other allied groups, dedicated to saving life and limb created or expanded such programs, notably, the National Safety Council, the American Medical Association and the Industrial Hygiene Foundation. Pre-employment physical examinations, including chest x-rays, were desirable in most industries and a must in others. Selective placement became a reality to employ certain people without liability risks to employers.

Occupational health was influenced by the effects of World War II. Even before the United States became an active participant, industry moved into high gear production-wise. The resultant attendant hazards were apparent and often resulted from constant demands for increasing quality, as well as quantity. With active war declared, governmental agencies were concerned both directly and indirectly in all plants handling war or defense contracts.

Their concern was not limited to sabotage alone, but included development of new products and processes. Industry produced large quantities of high quality products both old and new, and as expeditiously as possible with due regard to health and safety of the people producing. With the wartime economy, programs previously considered too expensive suddenly began. The cost plus war contracts allowed the introduction of things long wanted and considered worthwhile. In the health field particularly these programs were favored.

WAR EXPANDED INDUSTRY SAFETY

With the O.D. acts and World War II, occupational health came of age and gathered momentum. The unprecedented post war prosperity has been a potent factor. The creation of new groups and expansion of old groups represented physicians, nurses, hygienists, dentists and physicians. A board of occupational health as a subspecialty of preventive medicine with public health and aviation medicine has come into being. Special training at postgraduate level is now available in a number of medical schools for special degrees certifying training and proficiency in this field.

Competition exists between the various organizations representing the interests of the professional people but it is a healthy, cooperative competition, adding to the accomplishments of each other and the ultimate goals of all.

In the field of occupational health, safety and health are inseparable. Industry has learned that it is economic to give formal attention to matters pertaining to health and safety. Large industries provide their own, small industries buy from or though insurance carriers or groups providing medical, dental, nursing, hygiene, engineering or other applicable services. More professional people are devoting part or all their time to problems related to occupational health than ever before.

Permanent impairment, time lost from work and the mortality and morbidity of occupational origin is at an all time low per unit produced. Our old problems are largely controlled, and new problems anticipated and minimized. Those escaping temporarily are soon identified, classified and dealt with. More and more the expert is called during the planning stage. By this means the recognizable hazard in the new product or process

is considered and often with great economic advantage. The delay in marketing a product after discovering an unsafe process can be disastrous. Materials or procedures can be altered when anticipating a toxic hazard of intolerable scope will occur.

CONTROL ENVIRONMENT FOR HEALTH

Environmental controls by the engineering and occupational hygiene approach in the better organized plants give attention to minute details. Not only hazards, but nuisance problems receive attention. Dust, gas, smoke, fumes and vapors which may be a community, as well as a plant problem, are seen. The very presence of these things in some manufacturing processes may indicate an inefficient or uneconomic operation, and correction would serve a multiple benefit. Also, under this general program are food available to workers, its preparation, handling and disposition in a safe, clean, appetizing manner, a place to eat, and garbage and sewage disposal in a safe and acceptable fashion.

Water pollution is often a greater problem than air pollution. The sportsman and the nature conservationist, backed up by laws, keep us alert to the dangers and damages of polluting lakes and streams. Sanitary facilities, bath water, drinking water, salinized as a convenience if general plant area is hot and pest control, should not be overlooked in the area of environmental control.

The rapid developments in chemistry and physics are almost beyond comprehension. Competition brings almost a daily announcement of an improved product, something that will do more for less and easier. With this comes the problems of employees' danger in toxicity of products, its basic components, its by-products, its production techniques, and also the hazard to the community, the ultimate consumer, the consumer's neighbor and customers. Here we are talking about the present day insecticides, the solvents, i.e., hydrocarbon derivatives such as in the rubber and synthetic rubber industry, and the radioactive materials. Geiger counters are now as commonplace to the hygienists as was the impinger a few years ago.

More pre-employment physical examinations are being carried out. Fewer injuries per unit produced are encountered. Earlier treatment and new techniques with present medications hastens healing with less production time loss and less permanent impairment residual. Union Health Centers are daily assuming a more important role in the health matters of the worker, his family and the community.

Far more nurses are employed in industry and their presence and proper functions are better understood and supported by management. The need for their collaboration with the physician responsible for the plant health program is soundly established, but not practiced as closely as desired in many instances.

EDUCATION AIDS O.D.

With the advent of visual aids in training and safety programs, we have the most advanced media for health education purposes, for on-the-job and off-the-job activities. These messages relate not only to the employee, but the various members of his family. Perhaps more familiar are the health messages presented through payroll envelope inserts, bulletin board and various magazines, newspaper and other media. The trend is increasing utilization of services through effective application of expert knowledge in a broadening and growing field of specialization.

TWENTY YEARS INCREASED PROBLEMS

Are all of our problems solved? Not by a long way. Automation and industrial research and progress generally will see that this does not occur. The effects and affects upon emotions and morale may create problems not easily solved. This has increased the need for nurses, psychologists, physicians and other specially trained personnel. The newer drugs termed "tranquilizers" have proven helpful when used judiciously.

Now 20 years after the O.D. furor of 1937 are we facing a problem of similar size and similar concern? Strangely and coincidentally we are. Noise and occupational deafness right now is a very major concern of many industries, businesses and casualty insurance companies, similar to the near-panic from the early version of silicosis.

Recently we learned a great deal about noise and its harmful effects on human hearing. There is still a great deal to be learned. Some of the early hysteria is abating. Representatives of joint committees of medical specialists and others are releasing conclusions on the basis of our present knowledge for guidance. We can not yet say with reasonable certainty some of the things that must be said and sustained before legislation amends the Workmen's Compensation Laws.

Workmen's Compensation is a means of providing a cost of living during periods of disability due to occupational illness or injury and to offset the loss of future earning capacity (based on past experience of the individual) of a person permanently impaired by occupational illness or injury. Some states still provide little or no remedy under the law for the employee, and there is a great disparity between benefits provided in the states. Due to the lag in our legislative system, no state provides adequately and probably never will unless a more practical, flexible, realistic, applicable formula is legislated to follow the constantly changing cost of living.

Amendments to Workmen's Compensation acts in recent years have done little to improve the situation. In addition, the interpretation of the existing acts by politically qualified, but otherwise unqualified representatives, have led to widespread abuses which embrace the creeping socialism so despised in principle by many of us. There is no doubt that there are many people deserving of help from public funds, yet this scarcely constitutes reason for calling upon Workmen's Compensation benefits at the immediate expense of industry to pay compensation for conditions not even remotely related to the man's job, simply because there is presently no other place wherein money can be made available to him. Industry has been and continues to be the whipping boy of our inadequate social system as it exists today in the legal sense.

We must say something to discourage complacency, carelessness and the indiscriminate use of wonder drugs, including tetanus antitoxin, the sulfas, penicillin and its derivatives and all the other chemical and antibiotic preparations. They are two-edged swords. There are definite indications for their use and definite contra-indications, and also a broad area of uncertainty where good judgment and experience must be relied on. To date we have no reasonable substitute for experience. The indiscriminate use of these drugs is reprehensible and at times approaches criminal. The potential of mishap, sensitivity, etc., is great and must not be taken lightly. As a rule when in doubt, don't. Make your mistakes on the safe side.▲

SOME CURRENT ASPECTS OF MEDICAL QUACKERY

by OLIVER FIELD

director, Bureau of Investigation, American Medical Assn., Chicago

In discussing the subject of "Some Current Aspects of Medical Quackery," it is perhaps advisable to consider the present status of pretension to medical skill in the light of what has gone before, particularly during the past half-century.

The Bureau of Investigation has been functioning for more than 50 years as a clearing-house of information on matters in this category. The Bureau was started as a department of the *Journal of the American Medical Association*, partly because of the zeal of the young physician who, soon after graduation from medical school, came to work as an editorial assistant. But his own personal experience caused him to begin a crusade of exposure of the evils of quackery and the venality of a large segment of the "patent medicine" industry.

At about the time this physician arrived as an employee of the American Medical Association, the Congress passed the first Pure Food and Drugs Act. The examples that we have of "cures" and products and their labeling in those days illustrate the

changes that have come about, particularly by the passage of the 1938 Federal Food, Drug and Cosmetic Act.

NO INFORMATION SOURCE

Before the passage of that Act, which, among other things, requires the revelation of the active ingredients on the retail label, there was no source except perhaps the Bureau of Investigation to furnish the medical profession and the public the information. Books, pamphlets, and reports in the *Journal* itself constituted the media whereby Dr. Arthur Cramp did his very effective work.

Before the discovery of insulin by Banting and Best of Toronto, there were a good many diabetic quacks. Their principal products were diuretics. Their claims were broad, their performance woefully inadequate.

Today, however, it is in the field of cancer that the particular interest of both the public and the medical profession lies. In a period of 10 months we counted, in a little more than 4,000 inquiries, more than 1,000 on the subject of cancer "cures" and treatments.

The example that we have here, particularly the Hoxsey cancer treatment, and examples of the methods of promotion, make it evident that over the years the quack has learned by experience that he is ever so much more effective when he hides behind religion and when he sells the public on the claim that he is a martyr to medical persecution.

FEDERAL GOVERNMENT HELPS

The federal government, in the agency of the Food and Drug Administration, has sought for several years to stop not only Mr. Hoxsey, but others, one of whom is particularly known in Vancouver, namely Dr. William F. Koch, who began his promotion from Detroit in 1919.

Although Dr. Koch has been ordered by the Federal Trade Commission to cease advertising that any of his preparations has any value in any disease category, his successors, the Christian Medical Research League of Detroit, continue to sell "Glyoxylide" for $25.00 for a 2 cc. ampule. Glyoxylide is labeled to be a *one to a trillion aqueous* dilution of several alleged ingredients. It is not at all surprising that no chemist has been able to find anything in the ampule but water.

In other fields the quack capitalizes on the advancements of science. We have, for example, the products alleged to be radioactive, which originated in the United States, at least, in the mid 1920's. These were sold as rejuvenators and "cure-alls." Some had no radioactivity whatsoever, others were dangerously radioactive. The modern-day application is the uranium-mine promotion. This has had the benefit of publicity and large patronage in Montana, California, and several other states.

The same is true of the radio. When radio became popular in the 1920's, a California physician, Dr. Albert Abrams, announced his "E.R.A."—Electronic Reactions of Abrams—claiming that he could diagnose from a drop of the blood, and that all disease had "vibratory" rates. Abrams had many imitators, among whom was a chiropractor in Los Angeles named Ruth Drown. Dr. Drown claimed, also, that she could diagnose from a drop of the blood, but failed miserably when put to a test before a committee of scientists at the University of Chicago.

There are many other categories in which the quack flourishes—in the field of reducing preparations, arthritis and rheumatism cures, rejuvenators, the special dietary foods, and the cure-all gadgets. It was Voltaire who said that the quack was born when the first knave met the first fool. The Bureau of Investigation has never accepted that as an adequate definition, feeling that if the person had some knowledge, it would be more difficult for the quack to fool him. That is the premise upon which the Bureau has operated, and hopes to operate in the future.

OFFICERS OF THE
OCCUPATIONAL HEALTH NURSING SECTION
NATIONAL SAFETY COUNCIL 1957-58

General Chairman—VERNA PASKUNA, R.N., Owens Illinois, Glass Container Div., Streator, Ill.

Vice Chairman—DOROTHY ARMSTRONG, R.N., Peoples Gas, Light & Coke Co., Chicago, Ill.

Vice Chairman & Membership Chairman—BARBARA BOREN, R.N., Ansul Chemical Co., Marinette, Wis.

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

THE PETROLEUM SECTION

This volume is a record of the sessions held at the 1957 National Safety Congress by the Petroleum Section. The conduct of these Congress sessions each year is only one of the many cooperative activities which the Petroleum Section carries on in behalf of its members, and for the benefit of accident prevention work in the petroleum industry generally. The section gives guidance in the preparation of a great variety of technical and educational material useful in the day-to-day safety programs of petroleum companies.

The activities of the section are under the direction of its executive committee, the members of which are listed at the close of this volume.

A MANAGEMENT LOOK AT PETROLEUM INDUSTRY SAFETY

by H. W. FERGUSON
vice president, Humble Oil & Refining co., Houston, Tex.

At first glance, of course, there is little new or novel about this subject. Ever since our industry came into being 98 years ago back in Pennsylvania, men in the petroleum business have been confronted with a multitude of safety problems. As was the case in many other industries, safety practices and principles evolved slowly.

Accident prevention had to travel the painful road of trial and error. It had to move through numerous stages of development. But today, throughout the industry, safety is recognized by all levels of management as an indispensable engineering skill. It has become an indispensable factor in keeping America abundantly supplied with oil.

That is the story of petroleum industry safety in a nutshell, but it is far from being complete. For we are living today in an era of great and far-reaching changes which are having, and will continue to have, an impact upon almost every aspect of our social, economic, and technological environment.

These changes may be observed, for example, in the size and make-up of our population, in our automobiles and our homes, in our jobs and the tools we use. This climate of change must inevitably have an effect upon the operations of the petroleum industry and, at the same time, upon the extent and variety of the industry's safety problems.

For a few moments, then, let's explore the changing future of petroleum industry safety. Let's consider some of the factors, both old and new, that will probably influence our accident prevention work and examine some of the problems we may encounter. Finally, let's look at our prospects for solving these problems and review the role that management can and should play in this overall safety effort.

One important factor—one facet of change—will undoubtedly be a substantial growth in all branches of the industry's operations. Such growth may be hard to visualize in these days of over-supply, but the economists assure us that it is very much in the cards. By 1965, for example, it is estimated that America's domestic consumption of oil and liquid hydrocarbons will be in the neighborhood of 13 million barrels a day—an increase of more than 40 per cent of today.

EXPECT INDUSTRY GROWTH

To keep pace with this anticipated growth, some 600,000 wells will have to be drilled over the next 10 years. The industry will have to make tremendous investments—not only in the exploration, drilling, and producing phases of the business—but also in transportation, refining, and marketing facilities.

Growth on this order, as it materializes over the years, can hardly escape multiplying the incidence of safety problems in the industry. It will pose a sharp and continuing challenge to our ingenuity in the field of accident prevention.

TECHNOLOGICAL CHANGE

Another aspect of this challenge—another factor with an important bearing upon our safety achievements of the future—is the industry's changing technology. If the old saying is true—that the future is but the past entered through another door—then we must look forward to new equipment, new methods, and new techniques.

Such changes have always gone hand-in-hand with our industry's growth and progress, and they have usually brought with them new or slightly altered problems in safety. As in the past, we must be prepared to adapt to the changing situation in every phase of our operations.

In exploration, for example, new electronic devices for detonating the explosives used in seismic work seem to be emerging from our research centers almost every month. Seismic techniques are also becom-

ing more complicated, the pattern shooting of recent years being a case in point. Where once we had to worry about shooting only one hole at a time, we now find as many as 36 holes hooked up in a single shooting sequence. Offshore, we are having to deal with large quantities of explosives, often several tons in just one small vessel.

Exploration, then, will continue to pose tough safety problems, especially as we move more and more into isolated areas—offshore, into the swamps and marshes and deserts, and into Alaska and other far-flung places. In offshore work, for instance, close operating quarters have a way of magnifying our safety problems.

Falls, fires, and other accidents are usually more severe and more dangerous there than they are elsewhere. In many locations, weather must also be reckoned with as a great potential hazard—not only in exploration, of course, but in all our operations. Hurricanes Audrey and Bertha drove that point home with considerable force.

DRILLING DANGERS

Drilling operations offer another fertile field for the safety work of today and tomorrow. As deep drilling increases, which it shows every sign of doing, we may encounter some tremendously high and exceedingly dangerous pressures. Just last month, for example, in Louisiana's Lake Washington field, a well in the 19,000-foot class—the second deepest producing well in the world—registered a surface pressure of 11,400 pounds per square inch. This was the highest pressure ever recorded in the history of the industry.

New drilling techniques may also be expected to add certain hazards around the rigs. Already, oil emulsion muds are contributing to more slippery working surfaces and to a greater danger of fire. Jet bit drilling, with pump compounding, puts more dangerous pressures on the hydraulic systems of our rigs. The use of air and natural gas as circulating media has created new possibilities for severe fires and explosions. As drilling equipment becomes heavier and more complex, there will be an increased need for better engineering, more safety devices, and better safety practices.

Those, of course, are only a few of the aspects of drilling safety which will require our best efforts in the years ahead. Gun perforating, formation fracturing, drill stem testing, acidizing, cementing — these and many other specialized tasks will continue, then as now, to call for careful job planning and close safety coordination among all personnel concerned.

ATOMIC ENERGY EXPANDING

In refining, to give you still a third example of our changing safety picture, there will probably be an increasing use of atomic energy in petroleum processing. That means we shall not only have to worry about fire prevention, but we shall also have to cope with the additional hazard of radiation. At the same time, expansion of the petrochemical business will be bringing in new processing techniques—operations that are often quite different from the usual refining processes. Moreover, at certain stages, some of the new petrochemicals are toxic.

Other safety problems in the refinery will arise out of increased mechanization and automation. It is getting to a point, in fact, where a man almost needs a college training to understand what some of the dials on a refinery instrument panel mean. There will undoubtedly be more built-in safety devices, but as our refinery processes become more complex, the men who operate the equipment will have to be better trained than ever and safety conscious to a very high degree.

These three fields—exploration, drilling, and refining—are enough to indicate the variety and extent of our safety problems of the future. We could go on, of course, with other examples—in transportation, with its growing number of super-tankers on sea and its high pressure pipelines on land; in research, with its Van de Graaff accelerators and its other futuristic scientific tools; in marketing, where the problems range from the handling of jet fuels to keeping people from smoking on service station driveways. But I have gone into enough detail to show that accident prevention will be just as demanding a job in the years ahead as it has been in the past.

TRAFFIC SAFETY

The most difficult problem of all, however, I have saved to the last: traffic safety. More Americans, as you probably know, have been killed in automobile accidents than in all of our wars put together. In the petroleum industry, automobiles used in getting to and from jobs have proved far more lethal than any other industrial hazard.

Traffic safety is a broad, encompassing problem—a community problem—but it is also one in which industry and its people have a tremendous amount at stake. A reduction of the senseless toll of life, limb, and property on our nation's streets and highways must, therefore, rank as our No. 1 goal.

Currently under way, of course, is a project that many people think will help brighten the traffic safety picture—the 13-year road building program which will add 41,000 miles of new interstate superhighways to our country's road system. But as every safety engineer knows, it will take more than improved highways to minimize the present carnage. Let me give you an example.

Down in Texas, there was until just recently a 17-mile stretch of brick highway between the towns of Temple and Belton. It was narrow and had many curves, but for five straight years there was not a fatal accident on this road. Early this year, this road was straightened out and otherwise improved. Within a period of six weeks, traffic accidents on the improved highway took four lives.

CREATE SAFE ATTITUDES

So traffic saftey is more than just engineering, education, and enforcement. The answer probably lies in the word attitude, and it is there—through the creation of safe-driving attitudes in all of its employees —that the petroleum industry can make its greatest contribution to a solution of the traffic problem.

I have listed some of the safety problems of the future. How successful will we be in meeting these problems? Can we measure up to the challenge? A backward look over the history of accident prevention in our industry offers every indication that we can. For we have come a long way from the time when accidents were looked upon as acts of God, when the petroleum industry was thought to be an inherently dangerous business where accidents were bound to happen.

Good safety engineering has provided guard devices for exposed operating equipment. Safety rules and safe practices have been established for every phase of the industry. Safety equipment—hard hats, breathing apparatus and goggles—now provide almost every conceivable type of protection. Safety meetings and training of supervisors and employees have become standard operating procedure. Good housekeeping has come into its own as a safety measure.

None of these factors has, by itself, been the whole answer to our safety problem, but collectively they have all led to the development o. the most important factor in accident prevention—the development of the proper attitude, the development of safety consciousness, on the part of employees, supervisors, and management.

LOW FREQUENCY RECORDED

This attitude and all of the industry's other safety measures have enabled us to greatly improve our safety record. Last year, as reported in the API's "annual Summary of Injuries in the Petroleum Industry," 255 leading oil companies with slightly more than half a million workers (539,651) accounted for more than one billion hours of work (1,132,586,195).

They had 8,219 disabling injuries and 109 deaths and permanent total disabilities, but their accident frequency rate was the lowest in the history of the petroleum industry—7.2 disabling injuries per million hours worked. The average days lost per injury was 119.

Compare these figures with the API's safety statistics of 1928, the first year the API made an aggregate recording of statistics for the petroleum industry, and you can see the progress we have made. In 1928, the API recorded the safety experience of 108,000 workers who worked a quarter of a billion hours (248,962,652). They had 6,800 disabling injuries and 77 deaths and permanent total disabilities. Their accident frequency rate was 27.3.

In 28 years, then, we have reduced our accident frequency rate from 27.3 to 7.2—a 73 per cent reduction.

INDIVIDUAL GROUPS' SUCCESSES

Nor do these figures, impressive as they are, tell the whole story. There are drilling rigs, for instance, now working in their eighth year without a disabling injury. Single refineries have worked more than seven million hours without a disabling injury. In our larger refineries, a million hours of safe work has become common-

place. Two research and laboratory groups I know of have worked more than 10 years and 10 million hours without a disabling injury. A gas plant in one company is in its fifth million hours of work without a disabling injury. A marketing organization has passed the four-million-hour mark.

And so it goes. You need only consult the annual summary of the National Safety Council and American Petroleum Institute awards to find many other examples of outstanding achievements. Where the future is concerned, they point to a steady increment in our safety knowledge and to increased effectiveness in our accident prevention work.

In other words, as excellent as our safety record has been in recent years, there seems to be every reason why we should make further gains in the years ahead. Our safety engineering is better today than it has ever been. Our industry's personnel is more highly trained. Great strides are being made in the field of safety devices and protective equipment. There is more automation and less physical effort in all phases of the industry. And, not least of all, there seems to be a greater and more widespread effort on the part of management to bring safety to the highest possible level of development.

MANAGEMENT AIDED

Management's contribution, I think we all realize, can have an important bearing on future results, for as management goes, it has often been said, so goes safety. If our safety record is to be further improved, management must continue to provide safe working conditions and safe equipment. It must set up safety rules and see that they are carried out. It must try to stimulate job interests and job satisfactions, since disgruntled employees are more accident-prone. Management must do everything possible to build up safety consciousness on the part of each employee.

Most important of all, however, management must render active service to the cause of safety. It must personally participate in the program. Lip service won't do. For as all of you must know by now, you can't sell safety through the backdoor. A sound and successful safety program demands the wholehearted and unstinting support of all echelons of management—from the top right down to the bottom-rung supervisor.

In my own company, we are trying to practice what we preach. Just recently, for example, one of our electrical foremen in New Mexico used artificial respiration to save the life of a farmer who had come into contact with a high-voltage wire. When our foreman was awarded the National Safety Council's President's Medal, our company arranged for a presentation of the medal at a family barbecue in the foreman's hometown. And our company president took time out from a busy schedule to travel more than 600 miles to present the medal.

Participation such as this on the part of top management does more to build safety awareness, we believe, than several reams of impersonal statements.

I am exceedingly optimistic as to our safety accomplishments of the future. The main danger is that of our slipping into the attitude of a certain farmer I heard of down the way. A brand-new agricultural agent, fresh out of college and eager to make a good impression, called upon this gentleman. The young county agent offered to provide the farmer with all sorts of pamphlets on terracing, crop rotation, and all the other essentials of modern agriculture. He volunteered to get the farmer's soil analyzed and to help him in many other ways.

"Well, much obliged," the farmer drawled, "but I don't believe I need all that stuff. I'm not farming as good now as I know how."

Those of us interested in the safety movement, I think you will agree, are quite familiar with the potential dangers of that attitude. Our industry has sown seeds of safety information for many years now. We have harvested a large amount of good results. If there are any shortcomings in our future efforts, these shortcomings can hardly be attributed to deficiencies of safety techniques or equipment or to a lack of knowledge. It seems more likely that we'll just not be farming as good as we know how.

It is the responsibility of all of us in the petroleum industry to see that this doesn't happen—to see that we farm the best we know how—and thus help insure a safe present and an even safer future for all of our people.

SAFETY—A NATIONAL NECESSITY

by MIKE McCARTHY

industrial safety consultant, Columbus McKinnon Chain corp., Detroit

The prevention of accidents has been uppermost in the minds of industrial management for many years. Industry has toiled long and hard with this problem and has been successful to a great degree. However, accident prevention is a problem of national scope.

Through the medium of safety conferences throughout the 48 states rapid strides have been made in stressing to all citizens the need for further effort in the field of safety. Many of us do not recognize the enormity and seriousness of the problem and the toll taken each year.

All schemes for prosperity include what we have to do in the international field, what is necessary to improve our domestic economy, to increase employment so more and more of people can be gainfully employed.

Practically all of these ideas are based on some arbitrary plan for managing money. Others are based on some manner of settling accounts, all based on currency values. Each and every discussion omits the one basic fundamental necessary to keep our country in the forefront.

The thing to count on, the only thing to use for sound and enduring prosperity, is real wealth. The only real wealth in any country is natural resources and above all, *human resources. . . .*

Great as America may be, we are not big enough or smart enough to kill 100,000 people each year, maim 10,000,000 and still maintain our position with the nations of the world.

EDUCATION—PROGRESS

I have been asked many times to what I attributed the greatness of our country. My answer is the compulsory education system in this country. When realizing we have 40,000,000 people in educational institutions, and another 3,000,000 doing the educational work required, you can understand that education has played a large part in the development of our country.

You may wonder whether this education has been carried far enough when you realize that, previous to the war, for every accidental fatality in Germany, we had two fatal accidents in America. For every accidental fatality in Japan, we had three in America. Year after year we maim or kill the equivalent of every man, woman and child in the state of Kansas, Nebraska and Iowa. With all our ingenuity and know-how to build a higher standard of living, we fail in preserving the greatest wealth in our country—the men and women of America.

In the last 180 years mankind has really begun to experience equality, justice, freedom, and opportunity. Before the Declaration of Independence, people were tortured because of religion; slavery was accepted; a shoemaker's son could only be a shoemaker, and a king by the nod of his head, could send a man to his doom.

Within the last 60 years, mankind invented telephones, electric lights, refrigerators and automobiles. Is all that progress going to stop short today? I don't think so. We may not be able to see where we are going, but we are still going ahead!

Safety is a national problem as indicated by the fact that practically all states now hold safety conferences. This is a good indication of their recognition of the need for accident prevention.

SAFETY IS NATIONAL

The safety movement has been national, the only difference being in the amount of support given, first by industry, and then by state and federal government. Finally insurance carriers took a hand, until today captains of industry march arm in arm with governors, professors, teachers and scientists, all working with one purpose in mind—the preservation of human life. To make safety a part of our everyday way of life requires the active participation of all people.

The progress of the safety movement was slow until 1913 when a small gathering of

men, known as the Association of Iron and Steel Engineers held a national conference of safety engineers at Milwaukee, Wisconsin. From that meeting was organized the National Safety Council, first called the National Council for Industrial Safety.

Today this great humanitarian organization is made up of more than 6,000 industrial organizations, other associations, and influential individuals. They comprise a cross section of our national life, dedicated to the preservation of life and limb.

CAN'T FORCE SAFETY

The general conception of safety and industry was that all employers and employees could be forced to adopt safe standards of work. Employers' liability and various legislation was placed on the statute books, state inspectors attempted to enforce rigid machine guarding measures, and then employers themselves drafted some drastic measures for their own employees.

It didn't take long for everyone to realize you can not regulate a man's thinking. Management tried to reach the man on the bench by appeal, persuasion, through instructions, bulletins, and various educational media. Many industrial establishments now have a program aimed at off-the-job accidents, realizing that an accident on the highway, or at home incapacitates an employee just as much as one occurring in the plant.

Being closer to the men in the plant, management understood their problem and carried safety activities beyond any official regulations. Accident prevention was economically sound, and many industries, particularly the larger ones, observed a noticeable decrease in accidents.

Manufacturing methods and factory measures were altered for better conditions, and industry played a large part in bringing to the attention of the manufacturers the need for building safety into the product to eliminate hazards and to lighten the burden for our workers.

Much has been acomplished in this direction—hand trucks have been replaced by motor driven trucks, automatic screw machines, oil burners in power houses, conveyors, line shafts and belting eliminated on machines, automatic stokers, all devised to remove hazards and back-breaking labor of these occupations.

Industry has continued to maintain its interest at a high standard and will continue, not only in plants but in the communities and every other field of accident prevention.

One of the most outstanding examples of industry's continued interest in safety occurred about 10 years ago when the automobile industry set up a $500,000 foundation, controlled by the National Safety Council for research work in highway and traffic accidents.

Considering the increased activity, in all but two of the 40 years since the advent of organized safety, the industrial death rate has been lower than it was in 1913. This result speaks well for the industrial effort. But one result transcends all others—people in all walks of life are becoming safety-minded.

In industrial plants, among the majority of thinking people, there is now a serious and definite attitude toward safety. There is a better understanding of the cost of accidents, and a realization of the tragedy which travels hand-in-hand with injuries of all kinds.

There is a growing feeling of the personal responsibility for safety losses in traffic and highway accidents as well as industrial injuries.

The cause of greatest concern in the field of accidents is motor vehicles and home accidents. The state and highway problem lacks the control we have in industry. We must first make the public understand the enormity and seriousness of the situation, and then organize effective leadership.

We should promote safety in the following channels:

PUBLIC SAFETY

Lend every effort toward a solution of the automobile accident problem. Prohibit from the highways unfit and reckless motor vehicle operators. Adopt strict driver's license laws, uniform traffic laws for every city, and standard traffic signs and signals.

Accident reporting systems, should be standardized, necessary street and highway improvements made, strict enforcement and observance of traffic laws and a recognition of the rights of others whether motorists or pedestrians should be stressed. Observe the principle of the golden rule.

INDUSTRIAL SAFETY

Regular and complete inspection and research should be done in all industries, large and small, followed by prompt application of approved remedial measures. Safeguard all dangerous mechanical equipment and use all such devices. Revise hazardous manufacturing processes, continue safety education throughout all plants and enforce full cooperation with all state, municipal agencies and safety councils in carrying on the safety program.

EDUCATION

Let education be the keynote of the coming year so that the lessons and well-defined principles of safety can be firmly implanted in every home and school throughout the state. Let youth be given an opportunity for a full understanding and appreciation of the real meaning of safety so the citizens of tomorrow may enjoy the blessings that safe conditions bestow.

Finally, remember that you stand today in much the same position that our safety pioneers did 40 years ago, when they organized, made new plans, and mutually resolved to do everything possible to save men, women and children from the tragedy of useless accidents.

Every citizen should lead the way recognizing at all times the safety of our people is more than ever a national necessity.

SAFING OF STORAGE TANKS BY THE ABSORPTION METHOD

by W. W. COLKET

coordination engineer, Sun Oil co., Marcus Hook, Pa.

Tanks are necessary for any industry that produces or uses liquids and in the petroleum industry, tanks for storage or processing purposes represent a major capital investment.

Eventually, all tanks must be cleaned for a change of service, for maintenance and repair or eventually, to dismantle and scrap the vessel. To clean those with flammable products, it is mandatory that they be made safe before personnel are permitted in the vessel.

Over the period of years, many accidents have occurred in the industry, primarily because of a lack of a tank safing procedure. In some cases, the only result was damaged equipment; others have resulted in injury to personnel. A great effort should be made to eliminate accidents, since human life is invaluable. Furthermore, they will undermine the confidence of the plant personnel, and create adverse publicity; even minor accidents are costly.

The Sun Oil company has developed a safing procedure through the combined efforts of the operating, mechanical, safety and laboratory personnel. After this plan was perfected, it was strictly adhered to. This procedure has been developed primarily for the protection of our personnel, and secondly, as a safeguard for the equipment. Because of this safing procedure, the tank cleaning operation, which is mostly hand labor, is more efficient due to the increased confidence of the workers.

CATEGORIES OF TANKS

For Sun's safing procedures, tanks are classified according to the products stored:

1. Products having a flash point higher than 125° Closed Cup Flash (Flash Pensky Martin).
2. Products having a flash point of 125° Closed Cup Flash (Flash Pensky Martin) or less.
3. Products containing tetraethyl lead.

Tanks that have been in leaded service are considered contaminated until cleaned, no matter what product stored thereafter.

The tanks in service having a product with a flash point well above 125° F. are comparatively easy to safe for any part of the cleaning operation. They are pumped down, stripped as low as possible and then the vapor space tested with a combustible gas indicator to determine if the vapor space is flammable. In most cases, the indicator shows the vapor is below the flammable range and the tank is safe.

All oil and gas lines are blanked on the tank side of the valves. Up to this point, no manheads have been removed from the tank. Next, the shell and roof manheads are removed and one or more air movers are installed on the roof manways, depending on the size of the vessel. From this point, personnel may enter the tank and cleaning is a routine affair by any method desired.

The tanks in which the products have a flash point of 125° F. or less, are the ones that concern us most. When such a vessel is safed, it must be pumped down and stripped as close to the bottom as possible. The bottom is then covered with an absorption oil (gas oil or fuel oil, having a minimum flash of 150° F.). This is done by pumping in, through a suction, discharge or stripping line, approximately two feet of absorption oil at ambient temperature, letting it soak for approximately 24 hours and then pumping it out, following the original stripping process.

USE ABSORPTION OIL

The tank, if it has a cone roof, is then filled close to the top angle with an absorption oil, and if a floater, it is filled to the point where the roof is floating. Depending upon the amount of bottom sediment and water, (b.s.&w.) that is estimated from gauge measurements to be on the bottom of the tank, it stays dormant for as long as a week. This part of the procedure permits the oil to absorb the hydrocarbon vapors in the vapor space, most of the light ends trapped in the b.s.&w. and behind the scale on the shell. After the soaking period, the tank is again pumped down and stripped.

A vapor space test with a gas indicator is then made from the bottom to the top, through a gauging device, under which there is no stand pipe. If it shows the tank is still within the flammable range, the filling procedure is repeated. When the vapor is below the flammable range, all oil and gas lines are blanked on the tank side of the valves. Then all shell and roof manheads are immediately removed and air movers installed on the roof manways and placed in continous operation until the tank has been cleaned. Personnel may enter when the air movers are in service.

Tanks that have been contaminated by tetraethyl lead are, with one exception, treated in exactly the same manner. This one exception is the mandatory order that no one enters the vessel without complete tetraethyl lead equipment, until such time as the tank has been declared lead free.

INCREASE OIL HEAT

There are many variations in the procedure for tanks in which the products have a 125° F. flash point or less, depending mostly upon the quantity and consisitency of the b.s.&w. on the floor of the tank, the viscosity of the material stored and the amount of scale and dirt deposited on the floor, roof columns and shell. It is sometimes desirable to use several floor washes before filling the tank. If the material on the floor is heavy after the initial wash, warmer (150° to 180° F.) absorption oil may be injected to insure penetration of the heavier b.s.&w.

It has been our experience on several extremely difficult tank safings, that after the second filling, it is necessary to fill the tank for the third time with absorption oil at approximately 180° F. One tank in particular, in which there were 15 feet of b.s.&w., was put into hot gas oil service (180° to 200° F.) for several months until the level of the b.s.&w. was reduced to two feet innage.

Many times after a tank has been made safe to open, the material left on the floor still has light ends mixed with it so that when stirred, it will release sufficient hydrocarbon vapors to make the vapor space flammable or explosive. This condition is eliminated by the use of air movers and by stirring the material on the floor with a high pressure water stream, using a grounded nozzle, (150#, using a 2½" fire hose and a ½" or ¾" nozzle).

The water and the material that is being slurried, are constantly pumped from the tank during the washing process. In one or two cases, when the b.s.&w. was extremely viscous, a high pressure, high flash, gas oil stream was used in the same equipment, to break up the b.s.&w. and to absorb the light ends it contained.

No personnel is allowed in any tank until the vapor space tests below flammable limits. A gas tester is in constant attendance when cleaning a tank which had contained liquids of 125° F. F.P.M. or less, staying inside the tank with the cleaning personnel, continually taking gas tests. If the vapors approach the flammable range at approximately 18 inches from the floor, all personnel are instructed to leave the tank until the vapor space is again safe. In the case of higher flash products, gas tests are made every morning and noon while the cleaning operations are in progress.

No part of the procedure is by-passed at any time, and regardless of the time consumed, no one is permitted to enter a tank or remain in one, if the vapor space reaches flammable limits.

RULES FOR EQUIPMENT

There are certain basic rules governing the types of equipment used and the location of the equipment at the tank site. Air movers used on tanks must be the induction type with a capacity of 4,000 CFM. No automotive equipment, such as engine-driven pumps or compressors is allowed within 100 feet of any open manway. All equipment used in or on the tanks, such as air movers, hoses, must be properly bonded to the tanks. All tools that are used on or within tanks must be fabricated from non-sparking materials.

The air movers are kept in service 24 hours a day, until the tank has been declared gas and/or lead free. At Sun Oil, the air movers are often used until the tank repairs are finished.

An alternate procedure has been developed to handle tanks with a flash point of 125° F. or less, that are located in areas where the use of an absorption oil is not practical or where the disposal problems of the oil and contaminated material becomes difficult or uneconomical. This method may be used where there is a possibility that tetraethyl lead from the recovery of the absorption oil could affect certain catalysts, for use in marketing division tanks, or at outlying tank farms.

PROCEDURES DIFFER

The pumping down and stripping operation remain the same but the balance of the procedure is radically different. After the tank has been stripped, all oil and gas lines are blanked off, and then it is filled with water. While filling, a sufficient quantity of absorption oil is injected with the water to cover the surface of the water with a ½" to 1" film of oil.

The quantity of oil is injected before the tank is ¼ full. When safing a cone roof tank, it is filled to above the top shell angle. When safing a floating roof tank, sufficient water is pumped to raise the roof approximately one foot off the supports. This places the liquid level in close proximity to a roof manhole for skimming operations.

Speaking only of the cone roof tank procedure, after filling with water, a vapor space test with a gas indicater is made above the oil and water level. If it is in the explosive range, an inert gas, such as nitrogen or CO_2 is slowly injected into the vapor space, forcing the hydrocarbon vapors through the roof vents to the atmosphere.

As soon as the gas tests show the vapor space to be inert or below the explosive range, all roof manheads are removed and all other roof connections opened if possible. One or more air movers, depending on the size of the tank, are installed on the manways or roof connections. These air movers stay in service 24 hours a day until the tank has been declared safe and/or lead free.

GAS INDICATOR TEST

The vapor space is again tested and if still below the explosive range, the oil skimming operation is started. This operation consists of the installation of a skimming pan (fabricated from non-sparking material) through a roof manway. The pan elevation is adjusted to skim the oil off the water. The oil and water accumulation in the pan is pumped into tank trucks, using bonded rubber hose and an air driven reciprocating pump. It is possible to skim the oil to a film thickness of approximately ¼".

When the skimming is finished, the water is drained and a gas indicator test is taken

through the open roof manway, to check the quantity of hydrocarbon vapors in the tank. If the test is below the explosive limits, the shell manheads are removed. The cleaning operation is not started until the gas indicator tests show the vapor space to be below the flammable limits.

If the tests indicate an explosive mixture, the filling process, using water and absorption oil, is repeated. Inert gas is not used since the air movers are kept in constant service.

After following the above procedure, the actual cleaning is done in the manner as previously described. All rules and regulations pertaining to safety of personnel are unchanged.

The procedure for floating roof tanks is somewhat different from that for cone roof tanks. After the roof has been floated, the primary seal is loosened at two points so that two bonded air movers may be connected to the annulus between the bulkhead and the shell at locations 180 degrees apart. A third bonded air mover is connected to some roof opening other than the center manway. All air movers are located above the top of the shell and connected to the roof openings by Snorkel Tubing. This is done to avoid collecting gases above the roof level inside the tank shell.

One air mover, connected to the annulus, is put into service sucking air through the mover, thereby sweeping all fumes from the annulus. After the sweeping process has been started, the center roof manhead is removed and the draining of water is started. This draining continues until the roof comes to rest on the roof supports and the water level is one to two inches below the lowest point of the underside of the roof. At this time, both air movers, taking suction at the annulus, are put in service.

AIR MOVER PREVENTS EXPLOSION

After the start of the draining process, the third air mover is put into service as soon as the liquid level is an inch or two below the bottom of the open manway. This air mover prevents the vapor space that is being created under the roof by the water draining from becoming explosive.

After the partial draining is finished, the skimming operation, such as described for cone roof tanks, is started. When the skimming is finished, the water is drained out of the tank and when empty, the vapor space is tested with a gas indicator.

If the test is below the explosive limits, the shell man heads are moved. The cleaning operation is not started until the gas indicator tests again show the vapor space to be below the flammable limits.

If the tests indicate an explosive mixture, the process is repeated, with two exceptions: first, the air movers are kept in service, and two, the roof is not floated, the liquid level after filling is 1" to 2" below the underside of the roof.

We prefer the procedure using the larger quantity of absorption oil. The alternate procedure should only be used where there is a shortage of oil or where the disposal of the oil is a problem. The relaxation of the hydrocarbon vapor limits that are allowed by the alternate procedure when removing the manheads permit a hazard that we recognize, but such a procedure is better than one that permits tanks to be opened while explosive.

EVOLUTION OF SEISMIC EXPLOSIVES

by J. W. COCHRAN

seismograph industry manager, Atlas Powder co., Joplin, Mo.

This may be the atomic age, but conventional explosives—dynamite and its many variations—are still our demolition workhorses. In 1956, more than 900 million pounds of commercial explosives were manufactured in this country. More is expected to be produced this year.

Explosives are truly one of the key materials used by man. They are a basic material to some of our primary industries. Without them many—if not most—of the raw materials we take from the ground would be virtually unavailable to us. They are equally as vital to the construction industry—for the excavation of rock for building stone and concrete and for cutting through natural rock obstacles.

The use of explosives in seismic exploration is a relatively recent development—only some 30 years old—but it is not the *most* recent. Today high explosives are even breaking into the guided missiles field, not just as a destructive force, but as a component of guidance systems. Controlled quantities of explosives are used to power fast acting electronic switches and similar devices. So although explosives are one of the oldest materials known to man, new uses for them are constantly being discovered.

HISTORY OF EXPLOSIVES

In order to discuss the development and use of explosives in seismic exploration perhaps we should disgress to take a look at the history of explosives. As we do this one thing will become evident: that the desire for greater safety has probably been the greatest single continuous force in their development. Greater control to provide greater confidence, has been and still is the goal of nearly every new development in the explosives industry.

Many people, the Chinese, Hindus, Greeks, Arabs, English and Germans, claim credit for the discovery of black powder—the world's first commercial explosive. Credit is generally given to England's Roger Bacon as the inventor, and to Berthold Schwarz as the first to put it to practical use. The first authenticated use of Schwarz's guns was in England in 1314. They signalled the death knell of the knight in armor, the Feudal system, and the Dark Ages.

More than 300 years passed before gun powder was put to the service of man. Crude blasting techniques—techniques that would send shivers down the spine of any blaster today and would probably give a safety engineer apoplexy—were introduced in the mines of Hungary in 1627. It is not surprising that it took a long time to persuade workers to accept the new tool. It apparently replaced crude hand and fire methods in the mines of England in about 1672.

The first use of black powder for blasting rock in a construction enterprise was in widening the Albula Road in Switzerland in 1696. Throughout these early developments the lack of effective boring machines and the high cost of black powder slowed industrial application.

SAME FORMULA TODAY

Despite the crude, virtually uncontrolled methods of testing and manufacture, the formula prescribed by the first powder makers for black powder was essentially the same as it is today. It was, and still is, an intimate mixture of finely ground solids: approximately 75 per cent potassium nitrate, 15 per cent carbon and 10 per cent sulphur. The potassium nitrate was obtained from saltpeter either in its natural state or as a product of decomposed organic matter. The carbon was wood charcoal and sulphur was obtained from volcanic sources.

In the New World the colonists manufactured their own powder from saltpeter obtained by wetting refuse piles and leaching the piles with water. Evaporation of the resulting liquor provided saltpeter crystals. Despite the fact that several powder mills were erected in Massachusetts in the 1600's, the Colonies were still inadequately supplied at the time of the Revolution.

Some claim that we could not have won the Revolution without powder imported

from France. Then in 1800, E. I. du Pont de Nemours migrated from France and established a powder mill on the banks of the Brandywine—the forerunner of three of today's leading explosives manufacturers.

Some of the construction jobs that were dependent upon black powder in the early 19th century were the National Highway joining the Potomac and Ohio rivers, the Erie Canal, the Baltimore & Ohio Railroad, and the Croton Aqueduct in New York.

POWDER'S DISADVANTAGES

Black powder had serious limitations. Charges were commonly ignited by an unpredictable train of fine powder—sometimes crudely enclosed in do-it-yourself tubes of goose quills, straw, rushes, paper or wood. The interval between fuse ignition and the blast was a matter of speculation, and accidents from premature ignition were common. "Miner's Safety Fuse," introduced in England in 1831, made initiation much safer. In its first application, the safety fuse reduced fatalities and blasting accidents in the West Cornwall coal mines by more than 90 per cent.

However, other factors still limited the utility of black powder. Since its explosion is a deflagrating reaction requiring ignition by flame, black powder can't be used in wet areas—a real limitation in most work. In addition, it is bulky, and detonates with low velocity. Even modern improvements haven't been able to overcome these drawbacks which severely limit its efficient use in the field.

Most modern high explosives are based upon the explosive properties of nitroglycerine. When these properties were discovered in 1846 by an Italian chemistry professor, the compound was considered too dangerous for commercial use and manufacture. For years nitroglycerine was primarily a scientific curiosity with only one practical use, as a heart stimulant. As an explosive, it was impossible to handle, ship or detonate precisely or safely.

BENEFICIAL "MISTAKE"

Then in 1866 Alfred Nobel mixed—some say by mistake—nitroglycerine with kieselguhr, a porous earth, to form a pasty substance which could be handled relatively safely, detonated easily and precisely—the first dynamite. The first "Nobel" nitroglycerine dynamite manufactured in the U. S. was made by the Giant Powder Co. of California, which became a part of Atlas Powder Co. about 45 years ago.

Since Nobel's discovery many other materials have been used to mix with the "oil," as nitroglycerine is called in the trade. Today, these materials, called "dope," include ammonium nitrate, coal dust, ground walnut shells, almond hulls, olive and apricot pits, and others.

Continuing research has resulted in the manufacture today of dynamites and other commercial explosives which are much safer to handle and use than the first Nobel dynamite which—despite its vast superiority to straight nitroglycerine—was touchy and finicky at best.

One development which might bear mentioning is the use of ethylene glycol—the basic ingredient of automobile permanent-type anti-freeze. It is added to dynamite—which normally has a relatively high freezing point—for the same purpose. Thus, frozen dynamite, once a potential hazard because of its unpredictable nature, is no longer a problem.

ELECTRICAL BLASTING

The development of electrical initiation with the electric blasting cap has probably been the most significant development in the industry since Nobel discovered dynamite. Safety fuse—though a vast improvement over older methods—still has an unpredictable nature. In addition, once the fuse is lit the action is inexorably begun and the blaster is dependent upon the fuse to give him time to reach safety, and upon his own ability to reach safety in that time.

Electrical blasting enables the blaster to fire the charge from a safe distance or from a protected location. It also permits safety checks right up to the time of firing and the firing of many charges simultaneously. These features are recognized in the mining laws of many states.

The purpose for which explosives are used in seismic exploration is different than in its more common application as an agent of purposeful and constructive destruction. Here explosives are used to start a shockwave in the earth. These waves are reflected and refracted as they travel in the earth and by recording them, underground formations can be located.

The first recorded use of explosives for this purpose—to measure the velocity of a shockwave in the earth—was in Ireland about 100 years ago. During World War I the Germans used seismographs to locate artillery pieces. But, it has been only since about 1925 that the seismograph has been teamed with commercial explosives for the seismic exploration of oil. Today the quantities used for this purpose are a sizable percentage of all commercial high explosives manufactured in the United States.

EXPLOSIONS UNDER GROUND

At first, seismic exploration parties had to use conventional explosives and blasting supplies. In those days, charges were often detonated on the surface or in shallow holes. Almost any type of explosive was satisfactory. However, refinements in technique called for the use of smaller charges exploded deep within the ground, usually well below the water table, where the superimposed pressures of water and drilling mud limited the type of explosive which could be used to the water-resistant gelatin dynamites.

As the needs of the seismic market increased, explosives' manufacturers began the development of special explosives and blasting supplies for seismic exploration. As drill holes became deeper, ordinary gelatin dynamite sometimes became desensitized by high pressure. Apparently, these high pressures compressed the explosives. Therefore, high velocity gelatin dynamites were formulated containing relatively incompressible substances to resist compression. A few of these materials were balsa wood, cane pitch, corn flakes, and corn cobs.

The decrease in density occasioned by the use of these materials created another problem. The density of the dynamite sometimes was so low that it would not sink in water. Therefore, explosives with greater density to enable them to sink were developed.

INDEFINITE PRESSURES

It cannot be stated definitely under what pressure any given seismic explosive will fail nor how long it can withstand a given pressure and still fire. High velocity gelatins, if detonated immediately after loading, should withstand all pressures encountered in ordinary prospecting. If the charges are left to "sleep"—under pressure in a deep wet hole for any length of time, the chance of failure increases as the pressure and the "sleeping" time increases.

Of course, not all seismic exploration is performed under adverse water conditions. Less expensive gelatin dynamites can be used where the water heads are less than 100 feet, but they are not recommended[4] for "sleeper" charges.

Even more recently, nitrocarbonitrate blasting agents have come into use in seismic prospecting. The increasing use of these blasting agents, many of which are little more than fertilizer grade ammonium nitrate, can be traced to their low cost and their insensitivity. They are not cap sensitive—that is, they require a charge of high explosive to detonate them—and they are so insensitive to detonation by shock or friction that they need not be shipped or handled as a high explosive.

On the other hand they do require the presence of high explosives—which must be cap sensitive, of course—to initiate and maintain detonation. As a result, once joined with these high explosive primers and boosters the entire charge must be treated as a high explosive.

WATERPROOF BLASTING AGENTS

Most blasting agents deteriorate in contact with water. The problem of shooting seismic blasting agents in wet holes has been solved by packaging them in special waterproof cans. The cans are threaded so as to be easily assembled into continuous rigid columns for deep loading in small diameter boreholes. The high explosive boosters, which contain cap wells for the insertion of an electric blasting cap, are packaged in similar cans for assembly into the column.

These are but a few of the developments inspired by the special needs of the seismograph industry. Because of the very conditions under which seismograph parties work and because of their peculiar requirements (compared to the more normal industrial requirements of explosives) many other improvements have been made in a seismic explosives especially within the last decade. A few of these are: special cartridge sleeves for the assembly of explosives sticks into rigid columns; special static resistant electric blasting caps to minimize the hazard of accidental detonation by static electricity; and, special packaging of blasting agents for offshore work.

Other innovations and improvements have made modern commercial explosives much more reliable and much safer to use. But, nevertheless, dynamite and other commercial explosives are dangerous, both to manufacture and use; and it's doubtful that they will ever be anything but dangerous because their very utility lies in the controlled release of huge concentrations of energy.

DANGER HARNESSED

Each pound of dynamite is said to have the power to lift a 3,000 pound automobile 300 feet into the air. The energy to do this work is released with a violent, potentially dangerous suddenness. It is a tribute to the ingenuity of man—to the explosive manufacturer, but even more to the explosives' user that this concentrated energy has been harnessed for use with such comparative safety.

Commerical high explosives have been built to explode, and unless they do, they have no utility. The trick is to make them explode upon command, after insuring that their detonation will do the job required without causing injury or damage.

Actually, the use of dynamite is much less dangerous than its manufacture. This is indeed fortunate because the conditions under which dynamite is made can be closely controlled, whereas the field conditions under which it must be used cannot be controlled beyond a certain degree.

SAFE MANUFACTURE

One would expect that the manufacture of commercial explosives would be an accident prone business. This is not the case. Actually, it is one of the safer industries. In 1956 American industry had 6.38 lost-time accidents for every million hours worked; the high explosives industry had 1.59—one-fourth of the overall average. For each hour on the job, workers in the explosives industry have only a sixth as many accidents as bakers, and only one-thirteenth as many as workers engaged in manufacturing dairy products.

Perhaps the inherent danger of the process, the daily exposure to violence is one reason for this astonishing safety record. Certainly no one engaged in this business would tolerate carelessness.

The safety problem facing the user may not be as acute, but, we must remember it is faced under much more adverse conditions and usually by people, who—although they are experienced—lack the many years of experience of the producing companies.

The manufacturers of explosives are aware of this fact. And although the explosives industry is a highly competitive one, there is one point at which nearly all the manufacturers cooperate. This is in the promotion of good practice in the use and handling of explosives. Through the industry association, the Institute of Makers of Explosives, they report to each other and investigate every accident and near accident to determine causes and corrective precautionary measures.

ISSUE SAFETY MATERIAL

This same body formulates the safety literature which is distributed by the explosives industry. Chief among these instructions is the "Do's and Don'ts," the pamphlet which is entitled "Prevention of Accidents in the Use of Explosives." This pamphlet is found in each case of explosives. Of course this little pamphlet can't hope to cover every possible hazardous situation. But, neither could an encyclopedia, and these are as comprehensive as the combined experience of the country's leading powder manufacturers can make them at this time.

Of particular interest in the seismic industry is another Institute pamphlet entitled "Radio Frequency Energy—A Potential Hazard in Electric Blasting." This little booklet details the results of years of study of this problem—which seems to have been vastly over-rated in recent years, probably out of ignorance more than anything—and describes specific precautions to be taken when blasting in the vicinity of radio transmitters, including two comprehensive tables of recommended safe minimum distances.

Last, but certainly not least—if I may say so without appearing immodest—we, at Atlas, have recently completed a short safety movie entitled "How to Handle Women and Explosives." As you might guess from the title it is a humorous treatment of a serious subject. It's not a technical film, and intellectual managers of the business may not be impressed by it. But, our experience is that it is well received in the field by the members of the shooting parties.

It doesn't go into detail about safety procedures; it's designed to stress the importance of handling explosives with care and respect. It won't teach any of the finer points but we think it is useful for kicking off a safety program which can delve into the subject after the movie has stimulated a little interest.

Seismic exploration is an unusual industry as far as the use of explosives is concerned. Probably no other industry using explosives requires its crews to handle such large quantities of powder so often, so fast. Quarrymen and miners may fire larger shots, but they seldom load so much powder in so many holes in such short periods, so constantly.

Seismic shooting is a day in day out proposition, not a once a day once a week or even once a month proposition as it is in so many other industries. This speed and constancy of operation is a constant invitation to carelessness.

Handling high explosives and even less sensitive blasting agents—after all, they require high explosive boosters—must always be classed as a potentially dangerous occupation. Powder men can't afford to be careless. There just "ain't no" such thing as good odds on a human life—especially your own. Any odds less than a sure thing are in favor of the house.

USEFUL AND USEABLE SAFETY MEETING TECHNIQUES

(A Demonstration—5 minutes)

by EARLE S. HANNAFORD

safety engineer, Long Lines Dept., American Telephone & Telegraph co., New York city

PRESENTING THE DEMONSTRATION

Purpose

The demonstration is designed to illustrate by actual discussion the practical methods and steps in conducting on-the-job safety meetings. It requires 35-40 minutes for presentation.

Participants

In so far as is possible, participants should be selected with their particular parts in mind as this tends toward a more natural presentation. However, a little coaching and assistance during practice sessions will work wonders in adjustment of participants to their parts. Spontaneity can be developed even though the nature of the demonstration requires close adherence to the script.

Practice Sessions

Advance practice is vital to a smooth, natural presentation. The first step should be a purely "reading through" session with each participant merely reading his part with no attempt at dramatization since the purpose is to gain familiarity with the script and cue phrases. Following the "read through" session an average of six to eight actual practice sessions will give sufficient "carry" to the demonstration without attempting to memorize the parts. After the third or fourth practice, attention can be given to developing spontaneity, naturalness and dramatization.

An important point is to make certain that participants speak at a level and volume so as to be heard and understood by the listening group.. This is of particular importance in small groups where a public address system is not used. Also of importance is using a rate of speech that is neither too fast for the audience to follow nor too slow to maintain interest.

Setting and Arrangements

The participants should be seated at the table with the open or unoccupied end facing the audience and the demonstration

leader at the end of the table farthest from the audience. This permits a view of the faces of all participants. Where possible it is suggested that two small tables be used to form an open "V" with the opening facing the audience, with a small reading table for the demonstration leader at the point of the V. This permits a better audience view than with a single table. A lectern can be provided to one side for the use of the leader while he is presenting the material which is not actual group discussion, as this aids in separating the two in the minds of the audience.

Each participant should have an individual "flip over" ring type binder approximately 7½"x4" in size, with the rings at the narrow end. All of the script should appear in each binder; however, the binder for each participant should have his own part typed in capital letters and underlined in red. Since the other parts are typed in lower case each participant can identify his part quickly and at a glance. Only one side of each page should be used and typing should be double spaced for each participant's part.

Display cards should be prepared as required in the text, with lettering large enough so that the cards can be easily read by the audience. An easel and newsprint, together with crayons should be available for the leader. However, the diagrams and items which he refers to in the lecture part of the demonstration should be prepared in advance so that it is merely necessary to turn to required sheet.

It is best to have two assistants, one who displays the cards in accordance with the directions of the other who is equipped with a script and signals for each card by number. The numbers are placed on the back of the cards in accordance with the numbers placed on the script used by the leading assistant. The leading assistant can use hand signals to indicate the length of time each card is to be displayed. These two assistants should participate in the practice sessions in order to insure proper coordination.

For large audiences or unusual room arrangements, two sets of display cards and three assistants may be necessary. In addition, individual table microphones should be supplied for the participants with a harness or lapel microphone for the leader.

Alternates

In order to avoid difficulty due to sickness or unavoidable absence of a participant, it is recommended that the leading assistant in displaying the cards be trained as a replacement. This can be done by selecting the assistant with it in mind and having the assistant actually act as a participant in a couple of practice sessions. In addition, the alternate should read all parts thoroughly since it is best to have regular participants take only their own parts, leaving all "fill in" duties to the alternate including substitution for the demonstration leader.

INTRODUCTION

Safety meetings are a time honored way of selling safety to individual employees. In recent years many people have been saying, are they worthwhile?—Do we really sell safety?—What are the things that make safety meetings click?

All too often safety meetings develop into a "telling them" with the group playing a passive rather than an active part in the meeting. We who hold the meetings are talking when we should be listening. Once the problem has been clearly stated there must be participation by those in the meeting. Without it there isn't much chance of convincing anyone. And yet, time is of the essence also. On-the-job safety meetings just shouldn't take forever.

This morning we will demonstrate for you some of the useful and useable safety meeting techniques. These techniques have been developed and learned the hard way through actual experience. We are not going to smother you with a lot of words and technicalities. We are going to tell you briefly what we are going to demonstrate and then do it right here before you.

Only the most important key ideas necessary to a good safety meeting will be demonstrated. There will be two 10-minute demonstrations with a few supplementary items being shown between the two demonstrations. Before each one we will tell you briefly just what techniques are being demonstrated and the subject which will be discussed while demonstrating them.

During each discussion large placards will be displayed, pointing out just what technique is being demonstrated at the moment. (HOLD UP A PLACARD.) In addition, on the easel to the left of the platform, a large card will show the subject under discussion during the duration of each discussion.

In all of our demonstrations we will assume that the necessary preparation has been made by the leader—which I assure you is the case. Thus, the safety meeting techniques we will demonstrate deal solely with the conduct of the meeting itself. I would like to introduce those who will participate. (Each group member will rise as his name is called.)

Our first demonstration is designed to show the following things:

1. The value of group participation and how to get it—in other words, getting the gang in on the act.
2. The use of illustrative personal experiences of the group members—helping them sell themselves.
3. Getting reasoned voluntary group acceptance—checking to make sure they have bought the bill of goods.

The subject which will be discussed as a means of demonstrating these three things is —"Are On-the-Job Safety Meetings by the Supervisor Worthwhile." (Card with subject on it should be set up on easel at this time.)

The demonstration will be in two parts: First we will discuss the subject without using any of the three items to be demonstrated. Then we will discuss the subject again using them. During the course of the second discussion, placards will be displayed as each of the three items: group participation, group acceptance, and illustrative personal experiences, is used.

We will now proceed with the first part of Demonstration No. 1. The three items necessary to good meeting techniques will not be used and the subject under discussion is (pointing at the card) "Are On-the-Job Safety Meetings by the Supervisor Worthwhile." This part of Demonstration No. 1 will last approximately three minutes.

DEMONSTRATION NO. 1

(3 minute demonstration without using the three techniques mentioned; display card saying "WITHOUT.")

LEADER: Fellas, I'd like to find out what you think about these on-the-job safety meetings. Are they worthwhile? We've been holding them every week for a long time now; personally I think they are pretty good. It gives us a chance to have things lined up about safety. What do you think about it, Ed?

DALTON: Yeah, boss, it certainly lines things up all right.

LEADER: None of us wants to get hurt. I know that and I know you fellas are all with me when it comes to safety. It's important that we talk over new safety rules and get them straight before we start using them. Don't you find these meetings OK, Bill?

HRDLICKA: Swell, boss, just swell. Ken asked me about a new safety rule just the other day. I told him—"Take it easy, boy, the boss will explain the new safety rule when we have our next safety meeting. For now, just watch how I do it." Yep, these meetings are OK all right; just couldn't get along without them.

MALLE: Being a new man on the gang is sort of tough. Now about that new safety rule—just how do I use . . .

LEADER: I'll get to that in a while, Ken—let's decide about these meetings, whether they are good or not.

MALLE: Well, this is my first one. Guess they must be good or you wouldn't be holding them.

LEADER: Earle, we haven't heard from you yet, how about it?

CADWELL: Er er, what! How about what?

LEADER: What we are talking about, safety meetings.

CADWELL: Sure, they are fine. Just as you spoke I was wondering whether I had turned off the electric furnace before I came over here. Maybe I better go look just to make sure.

LEADER: Gone this long, might as well let it run another minute or two. We'll be through soon.

LEADER: I guess we are all agreed that these safety meetings on the job are pretty good for us—how about it?

EVERYBODY IN CHORUS: They sure are, they are just fine.

LEADER: OK boys, let's get back on the job. I will let you know when we will get together again.

We will now discuss the same subject: "Are On-the-Job Safety Meetings by the Supervisor Worthwhile" using group participation, illustrative personal experiences of the group members and voluntary reasoned group acceptance. (Have assistants show placard using the three techniques.) (During the course of this demonstration the assistants will hold up card on each side of the stage with the appropriate item on it as that item is being demonstrated in the discussion.)

LEADER: I've just been making out the time schedule for the next month. Since we've been holding these weekly safety get-togethers on the job for quite a while now, I want to get your ideas about them. Should we keep on with them or lay off of them for *a while? What do you think?*

HRDLICKA: You mean you want us to tell you, boss—that's a switch.

GROUP PARTICIPATES

LEADER: Yeah, Bill, I'd like to find out what you fellas really think about these safety meetings. Are they doing you any good?

(Group Participation card displayed.)

DALTON: Doing us any good? What do you mean GOOD?

CADWELL: Aw, Ed, I know what the boss means and you do too. He means, does it help us to work safely to kick these things around now and then.

LEADER: Yeah, that's it, Earl, that's just what I mean. Work at it fellas.

MALLE: Of course, I'm new around here and can only say how it looks to a young sprout, but I think it has helped me a lot.

LEADER: Just why do you think that, Ken?

HRDLICKA: Yeah, Ken, what's so hot about it? Right now I've got that rush service order waiting for me to get at it.

LEADER: Ease off a bit, Bill, let's give Ken a chance to have his say.

MALLE: Well now, let me see.

(Illustrative Personal Experience card displayed.)

LEADER: Ken, have you got anything particular in mind where it helps you. Tell us about it.

TELLS PERSONAL EXPERIENCE

MALLE: Yeah, I remember something. You probably don't remember it yourself but we had one of these safety get togethers just after I came on the job. I was helping Ed here. You remember it, Ed?

DALTON: Yeah, I remember your helping me, but what are you talking about?

MALLE: You remember Ed. At that meeting we discussed wearing safety goggles when soldering. Seeing as how I don't wear glasses I thought it would look kind of silly. I left them off one day and the gang jumped me about it, and just a short time after I put them on there was a little flash of hot metal and it lit on the goggles instead of my eye.

HRDLICKA: Yeah, but it wasn't the meeting that did it. We jumped *you about it.* We always jump a guy who breaks a safety rule.

CADWELL AND DALTON TOGETHER: Now wait a minute, Bill, wait a minute.

CADWELL TO DALTON: You tell him Ed, I think we both are going to say the same thing anyway.

DALTON: Maybe we'd jump him and maybe we wouldn't. Having these safety get-togethers sort of refreshes our mind and keeps us on the ball.

(Gross; Participation card displayed.)

LEADER: Anything you want to add to that, Earle?

CADWELL: Sure, just this. At these meetings we've been making it our plan to talk about the safety angles of the job at hand. I've been around here a long time; sometimes I think too long, but I've never seen the day when taking time to talk over the safety angles of the job didn't help me.

HRDLICKA: Yeah, in the meantime I still got that service order staring me in the face.

LEADER: That's right, Bill, but let's go on and make sure about how we feel about these safety meetings.

DALTON: Wait a minute fellas, I've been thinking maybe Bill has something there about our not needing these safety meetings.

LEADER: What do you mean by that, Ed?

DALTON: Well, just figure it out. After all we are a pretty small crew and we work together all the time and you are right here with us most of *the time.* Why do we need special meetings anyway? We can keep up with what is going on.

(Illustrative Personal Experience card displayed.)

MALLE: Maybe you old hands can, but I sure can't.

MORE PERSONAL EXPERIENCES

CADWELL: Well, Ed, there may be something to what you say but I was just thinking about the times when getting the job done seems so important we forget some of the safety angles. It gets to be a habit with us, so much so that the wrong way seems like the right way. If we discuss the safety angles now and then it gets us back on the track.

HRDLICKA: You are right, Earle, about the job being important. Now I got that service order—

LEADER: Wait a minute, Bill, wait a minute. Let's see just what Earle has in mind. Have you any particular cases in mind, Earle?

CADWELL: Well now, yes. I remember one and you were mixed up in it too, Bill.

HRDLICKA: Yeah, that so, what was it?

CADWELL: You remember when we had that emergency call about the exchange cable being out and tests showed it was in the manhole at the corner of Washington and Lincoln streets.

HRDLICKA: Yeah, I remember it. It was about six months ago. The boss had been called into the office. You, Ed and me rushed out there.

CADWELL: Yeah, that's right.

DALTON: Yeah, I remember it, Earle, now that you mention it.

CADWELL: Remember, Bill, you rushed out and we got the cover off and in our hurry we sort of forgot to make tests for gas before entering the manhole?

DALTON: Bill should remember it. We sure had to get him out fast. Lucky he wasn't done in.

HRDLICKA: Yeah, I guess you fellas sort of got me. We did forget to make those tests.

(Reasoned Voluntary Acceptance card.)

LEADER: Well, we can all be glad that it worked out OK. What about these safety meetings though—do we want to continue them or not?

VOLUNTARY ACCEPTANCE

DALTON: Well, I guess we do all right. I take back my crack about being together on the job every day taking the place of these meetings.

CADWELL: Yeah, that's the way I feel about it, too. Having been around here a long time I have seen these things come and go and we have always done a better job when we had these safety meetings.

LEADER: Ken, how do you feel about it?

MALLE: Well, there's no question that I'm new and need all the help I can get, and I'm aiming to be around here a long time like Earle.

LEADER: Well, Bill, you got anything to say?

HRDLICKA: Yes. I'll go along with these meetings, I guess. Maybe we do *need to* stand off and look at what we are doing now and then, just to make sure we are doing it safely. But I still got that service order staring me in the face.

LEADER: Well, fellas, are we all pretty much agreed now that we want to continue with these safety meetings on the job each week?

CADWELL: Yeah, let's go ahead with them.

DALTON: I'm for it.

MALLE: I sure want them.

HRDLICKA: OK, OK, count me in.

LEADER: All right, next week let's talk about wiping joints the safe way. Ed, supposing you be ready to talk about it and show us some of the angles and have Ken help you.

DALTON: All right, we'll be ready, won't we, Ken?

MALLE: Sure will.

LEADER: Well, I guess that just about wraps it up for the day. Maybe we better let Bill get at that service order.

HRDLICKA: OK, boss, I'm on my way now.

I doubt if anyone in the audience missed the way the group participation made the safety meeting really click, as compared to the first discussion in which the leader tried to carry the ball himself; also obtaining reasoned voluntary group acceptance really sells the ideas under discussion. People like

to "get in on the act" and the selling power of being in on it yourself is tremendous when compared to just listening to someone else's logical presentation.

In our second discussion use was also made of illustrative personal experiences told by the group members. I guess we are all built about the same when it comes to hearing the sound of our own voices. From the standpoint of getting safety ideas across, it is certainly a powerful tool.

DISCUSSION TECHNIQUES

Before we present our second demonstration we would like to cover three practical work-a-day discussion techniques which were used in the first presentation and will also appear in the second one. These are:

1. The use of the question
2. Shaped or controlled discussion
3. Overhead or uncontrolled discussion

It is hard to believe that such a simple thing as a spoken question is one of the keys to influencing human conduct. With it we can obtain an expression of the thoughts and reactions of other people setting up channels for mutual exchange of ideas and getting reasoned voluntary acceptance. The power of the question lies in its requirement of an answer. It should be phrased in such a manner as to require more than a mere *yes*, or *no*, for we must know the *why's* and *wherefore's* if we are to influence people's decisions or help them form their conclusions. Questions are the main operating device of the discussion leader.

There are four basic types of questions:

1. Overhead, in which the leader asks the question without indicating a particular person to reply.
2. Directed, in which the leader asks the question and then names the individual who is to reply.
3. Reverse, in which the individual asking the question had a question directed back to him by the leader in order to have him develop the answer himself or to gain more information.
4. Relay, in which the leader relays the question to someone else or to the group at large to get group participation.

CONTROLLED DISCUSSION

Every discussion or meeting is made up of one or both of the two basic operating procedures. The first is the shaped or controlled discussion, in which the leader keeps direct control by asking the questions, designating specific individuals to reply without permitting uncontrolled discussion between the group members themselves.

Overhead or uncontrolled discussions take place between the group members with each participating at will after the leader presents the item for discussion.

Actually, all discussions are composed of both types of operation. However, the nature of the discussion is determined by that which predominates. Each type has its place depending upon whether the leader is trying to sell his idea or to allow the group to develop its own ideas. I would like to demonstrate the types of questions and the shaped and overhead discussions before undertaking the second safety meeting demonstration.

As each of the types of question is being demonstrated a display card will be shown, showing its name. The same will be done while the brief demonstrations of shaped and overhead discussions are in progress. The subject material which we will use will center around this item—"How Can We Slow Down the 5 O'clock Stampede," even though we will not pursue it to its final conclusion.

(Display Overhead Discussion card.)

LEADER: We've been having quite a few accidents as a result of the 5 o'clock rush to get off the job. Isn't there something we can do about it?

HRDLICKA: Sure, we can let them all out at 4:30.

LEADER: That's one answer, Bill, but people would miss that last half hour's pay. Any other good ideas?

DALTON: I think we've got a problem. Maybe we could stagger the time for different departments, so we wouldn't gang up.

(Display Directed Discussion card.)

LEADER: Are there any other things we can do, Earle?

CADWELL: There must be but they don't occur to me right now.

LEADER: Any ideas on this, Ken?

MALLE: Yes, one thing I think we can do is to get people educated as to the dangers of rushing out.

LEADER: That's good. You got any other ideas, Bill?

HRDLICKA: Couldn't we put this up to the safety committee and let them worry about it?

(Display Reverse Discussion card.)

LEADER: Well, just what would you do, Bill, if you were on the safety committee?

HRDLICKA: Well, I'd get off the committee.

LEADER: No, we wouldn't let you off that easily, Bill. Seriously, what would you do if you were on the committee?

HRDLICKA: Well, I guess I'd find out just where the worst accident spots were and work on them.

LEADER: That sounds good.

CADWELL: Sounds OK, but just how would we do it?

(Display Relay Discussion card.)

LEADER: Ed, you've been on the safety committee. Got any suggestions?

DALTON: Let's look over all our accidents and find out from the record just where they are happening.

MALLE: That sounds like a good approach, Ed. Who's going to do it? Where will we get the information?

LEADER: Well, I'll get the information from the industrial relations group and see what we can do about it.

SHAPED OR CONTROLLED DISCUSSIONS

(Shaped Discussion card displayed.)

LEADER: In the 5 o'clock rush last night one of the fellows was jostled, lost his footing and fell, breaking his ankle. Isn't there something we can do about this? What do you think, Ed?

DALTON: Yes, we could get these folks educated about the dangers and quiet them down a bit.

LEADER: How would you go about it, Earle?

CADWELL: We could use some posters.

LEADER: Have you got any suggestions, Bill?

HRDLICKA: Well, we could put in a public address system and have some nice sounding gals talk over it to caution people.

LEADER: Aw, guess we'll pass that one up, Bill. Got any ideas, Ken?

MALLE: Seems to me we should just talk it over in our on-the-job safety meetings.

UNCONTROLLED DISCUSSION

(Display card.)

LEADER: We are having too many injuries in this 5 o'clock stampede. Isn't there some way we can control it?

HRDLICKA: Sure, let everyone out at 4:30.

DALTON: Aw, pipe down, Bill. This is a serious matter. If we go over the records maybe we can find out just what is happening and where it is happening.

CADWELL: Yes, that's a good idea, Ed. Isn't there something we can do right away in the meantime?

MALLE: Well, it seems to me that we could make it a subject for discussion in all our on-the-job safety meetings.

DALTON AND CADWELL: That sounds like a good approach, Ken.

LEADER: I think that's swell and I will pass it on up the line.

To summarize, so far we have demonstrated for you the following things:

—The value of group participation
—The use of illustrative personal experiences by group members
—The need for voluntary group acceptance.
—The four types of questions and their uses
—Shaped or controlled discussion
—Overhead or uncontrolled discussion

For our final demonstration, we will put on a discussion in which the four steps in a successful safety meeting will be portrayed. The four steps are:

1. Subject definition
2. Getting everyone's ideas and reactions
3. Voluntary group acceptance
4. Developing a plan of action

For those familiar with conference leadership and the five step conference leadership process, I would like to point out that these four safety meeting steps are based upon and tie in directly with those of the

conference process. The fundamental principles to all meetings underlie both procedures.

SUBJECT DEFINITION

Step 1, Subject Definition, is where we present the subject for discussion to the group, making sure that they understand it. This would include such things as presenting a planned program or anything else that you want the group to accept.

In the second step everyone in the group should have a chance to express his ideas and reactions so that the magic of group participation will lay the groundwork for the third step, voluntary group acceptance. In the fourth step we develop a plan of action wherever it is indicated and then summarize what we have worked out in the meeting.

In our demonstration we will use and apply all of the techniques which we have just demonstrated for you—watch for them, see if you can identify them and be sure to check on their effectiveness. If you have any questions we will be glad to discuss them following this demonstration.

We will now proceed with our second demonstration. It will portray for you the four steps in a safety meeting and we will use as our subject "How Can We Sell Taking Safety Home."
(Display Subject Definition card.)

LEADER: It surprised me, personally, to find out that we are having almost eight times as many lost time accidents off the job as on the job in our company. It looks as though we are not doing too well in getting people to take safety home with them. Just how can we get people to be as safe off the job as on the job?

CADWELL: Would you say that again, boss. Did you say, eight times as many lost time cases off the job as on the job?

LEADER: That's right, Earle, pretty close to eight times as many.

CADWELL: I didn't think it was that bad.

MALLE: Neither did I.

DALTON: Seems to me we should do something about it.
(Ideas and Reactions card held up.)

LEADER: That's just the point. How can we get people to take safety home with them? What do you think, Bill?

HRDLICKA: I'll tell you what I think—I think what I do off the job is my business. The company can tell me what to do on the job but after 5 o'clock, oh no! that's something else.

LEADER: How do the rest of you fellows feel about this?

MALLE: 'course I'm new around here, but just the same eight times as many accidents off the job is something to think about all right.

LEADER: Earle, you've been through the mill—how does it strike you? Do you think we should do something about it?

CADWELL: Yes, I do.

LEADER: Well why, Earle?

CADWELL: Well OK, it's this way. Some years ago I thought like Bill here, but when the Misses fell over that bucket I left on the cellar stairs and broke her leg, something happened to my viewpoint. You know, if I had been on the job I would never have left that bucket there in the first place.

DALTON: That brings to mind something that happened to me once. It sure convinced me.

HRDLICKA: Yes, that's all OK, but nevertheless—

LEADER: Wait a minute, Bill, wait a minute. Let's see what Ed has on his mind. What was it that convinced you, Ed?

DALTON: It's a near miss I had a couple of years ago when I was putting up the storm windows. It seemed pretty far to go clear around the house to get the ladder and the wheelbarrow was right there so I used it. When it tilted I dropped the window and busted it, but luckily I was able to hop clear and didn't get hurt. If I had sprained my ankle I wouldn't have been able to have gone on that hunting trip I enjoyed so much.

MALLE: What you fellows say sort of has me sold, but just how are we going to get it across to other folks if everyone feels the way Bill does, that the company can't tell him what to do after 5 o'clock?

HRDLICKA: You got me right, kid, that's just what I mean.
(Display Voluntary Acceptance card.)

LEADER: I just wonder, does everybody feel the way Bill does about it?

CADWELL: I certainly don't and I doubt if those who say it really believe it.

LEADER: How does it strike you, Ed?

DALTON: Oh, I'll go along with Earle—I don't care how it's done just so long as I don't get hurt or my folks don't get hurt. If it works for me on the job, it should work off the job, too.

MALLE: As far as I'm concerned, I don't think a hospital bed would be any softer just because it happened off the job.

LEADER: I have heard it said that if you really believe in safety and work at it on the job it doesn't take too much effort to make it work off the job, if you try. What do you think about that, Bill?

HRDLICKA: As I said, no one's going to tell me—

LEADER: No one's trying to tell you, Bill. Just suppose you had a ladder with a broken rung on the job, would you use it?

HRDLICKA: No, it's up to the company to furnish me with good tools.

DALTON: You mean, Bill, that the company should furnish you with the stuff you use at home.

HRDLICKA: No, I didn't say any such thing.

CADWELL: Would you use a ladder with a busted rung at home, Bill? Deliberately that is. Don't you think as much of your own neck as the company does?

HRDLICKA: Of course I do, it's my neck.

LEADER: Just a minute fellas, I think Bill doesn't want to get hurt off the job any more than he does on the job, do you?

HRDLICKA: You're darn tooten I don't.

LEADER: I guess we can all agree on that point. No one wants to get hurt off the job.

ALL AT ONCE: That's right.
(Action and Summary card displayed.)

LEADER: Well let's look at some of the things that we can do to keep from getting hurt off the job; in other words, some of the things that sell people on taking safety home with them. Got any ideas fellas?

MALLE: It's done me a lot of good just to talk about it here. Why not make it a subject for discussion in on-the-job safety meetings?

DALTON: I'll go along with that, Ken.

CADWELL: So will I, because we can think out the problems better that way and line up things to do.

LEADER: Bill—

HRDLICKA: Uh, Uh!

LEADER: I'm going to put some of these things down, fellas. (Writes on easel—"How Can We Sell Taking Safety Home.")
(1. Discuss off-the-job safety in on-the-job safety meetings.)

LEADER: Some companies mail stuff home. What do you think about that?

CADWELL: Yeah, my brother's company does that. I have read some of the stuff, it's pretty good on off-the-job safety. What do you think about it, Ken?

MALLE: I think it would help.

DALTON: Yeah, if it didn't get in the waste basket too soon.

CADWELL: Aw, I don't think many people would throw it away without reading it.

LEADER: Well, let's add it to our list anyway as one of the things we can do.
(Adds this item to list on easel—Mail off-the-job safety material to home.)

LEADER: Any other ideas?

DALTON: Boss, you said at the beginning of this meeting that off-the-job accidents are eight times the number of on-the-job accidents and it impressed me. I think we should keep good records on off-the-job cases and make comparisons of them with on-the-job accidents from time to time. It may sell other people, too.

LEADER: What do the rest of you think about it?

MALLE: I think that's right.

CADWELL: So do I.

LEADER: Well, Bill, what do you think?

HRDLICKA: Ya, ya, it's OK.

LEADER: Bill, you remember a few years ago you spent a couple of weeks in the construction office to help make some hazard check lists for use on the job?

HRDLICKA: I sure do—that was a good list, even if I say so myself. In fact, I will say so.

LEADER: I agree with you, Bill—we've gotten a lot of use out of it all over the company. You know, Bill, you could do an awfully good job on this off-the-job hazard deal, too, if you would.

MALLE: If it's even half as good as that on-the-job hazard list I would take one home tonight.

LEADER: What do you think of the idea, Earle?

CADWELL: I like it. If I had looked at something like that once in a while and checked the hazards around the house, I would never have left that bucket on the stairs.

DALTON: I agree with that idea of a hazard check list. If I had something to keep safety on my mind at home, I would probably never have used that wheelbarrow as a ladder.

HRDLICKA: What I think these guys need is for someone to make up a list for them.

DALTON: It looks to me like more than a one man job.

MALLE: Well, we could all make our own lists, couldn't we?

LEADER: Earle, what's your reaction to this?

CADWELL: Listening to the gang here, it seems to me it would be a good idea if we all made a list and brought it in and discussed it in one of these on-the-job meetings where we talk about off-the-job safety.

LEADER: Now I think we've got something here. Let's do that. Let's each bring in a list, talk it over, and I'll send it in to the office and have some copies made. Let me put it down here with the other things. (Adds this item to those on the easel.)

LEADER: It seems to me these four things we've come up with for selling safety at home are pretty good. I am going to write them up and send them into the office. Maybe the safety committee or the safety supervisor can work out something that will help everyone in the outfit.

CADWELL: Boss, why don't you wait until after we have discussed this ourselves?

HRDLICKA: I think Earle's right. When I was making that on-the-job hazard list, the other fellas and I kicked it around before we came out with one.

LEADER: OK, fellas, let's do it that way. Let's take a couple of weeks to make our lists and then we will discuss them. Does that suit everybody?

ALL IN CHORUS: Yeah, that's fine.

That concludes our second and final demonstration. I am sure that you were all able to discern the four steps in a successful safety meeting as the placards were displayed. In addition, an experienced group of safety people like yourselves were probably away ahead of us all the way with respect to the techniques we have been demonstrating.

SAFETY THROUGH THE EYES OF A CAMERA

by J. L. MUIR

personnel manager & chief safety supervisor, General Petroleum of Canada, Ltd., Calgary, Alb., Canada

How many times can you remember that you have had to describe in great detail some unsafe practice or condition to a person or a group of persons and wished that you had some other visual aid to help you? You knew that your full description was not going over, not being fully grasped because the necessary description was too big, too confusing, too mixed up for your listeners to grasp the whole landscape.

How many times have you addressed a group of workers on safety or a related matter, and even had as assistance, posters and the like? But you knew that you would not have the full interest of the group in front of you, and that a part of the group at least, was not absorbing your message. But, when you mentioned a matter that touched one of them personally, or an individual or crew of the same company, interest was immediately noticeable.

How many times have you heard and perhaps yourself said, that you wished you could take some of the reckless drivers we find on our highways to the scenes of vehicle accidents and thus, by seeing the picture or by visual aid, if you care to call it so, show them the damage, injury and death caused by careless, forgetful, or reckless driving?

I could go on for hours telling you of the various difficulties many others have had in trying to impress, educate, and teach, one or a group of persons some matter, or matters of safety. I have been in the same situation before this time.

PICTURES TELL STORY

But let us never forget a small but true saying, a saying that is not used enough, "every picture tells a story," and if the picture is, what I would like to call a "real" one, your story is told easily, quickly, and fully, and it is registered and recorded for a much longer time in your audience's mind, than by just talking.

How, therefore, can we achieve the goal we are striving for in this matter? I submit for your consideration that you gain that objective through the eyes of a camera, and so the heading of my talk to you, "Safety Through the Eyes of a Camera."

I have photographs in groups and will describe each as it is presented. All of them were not taken in connection with either my own company, my previous occupation before being with General Petroleum of Canada Limited, or even connected with myself. Several safety engineers from Canada provided me with certain photographs which went to complete my talk.

My first group of pictures covers problems that all safety directors have in connection with the transport phase of our work, that being the accidents that take place with our transport and drivers. In the first picture, we see an accident as a result of icy conditions of the highway, and you will readily agree that to try and describe those conditions without a picture would be nearly impossible. In the second is a close up of the vehicle in the same accident, which by the way, resulted in a fatality.

The tracks show the power of a vehicle when the driver or the vehicle goes out of control. The next group of four pictures resulted in a fatality, which I am sorry to say, took place within my own company, when the driver, without reason ran off the highway. Without pictures, to try and describe the results of just running off the edge and rolling over, again would be nearly impossible.

SAFETY BELT—LIFESAVER

In another picture, we firmly believe that had the driver had a safety belt on, it might not have resulted in a fatality. In the picture, I can point out the cab, the condition of which makes us say that. In the next two pictures, the first one resulted in a railroad crossing fatality. At the far side of the railroad tracks, you can clearly see the skid marks of the car, plus the 100 per cent visibility of the railroad crossing on the highway. Again that picture tells a story, which could not be easily described.

In the second, which again resulted in a highway fatality, the skid marks of the vehicle are plainly seen and definitely, without having to explain by word of mouth, will show everyone who sees the picture, the result of extensive speed on a curve. The last of this whole group was the result of a head-on collision, cause being a center line accident. Here again to try to describe would be nearly impossible. To visualize the point of impact we must show the debris by the right front wheel.

Another set of pictures was the result of a wild well in the far northern part of British Columbia, when gas escaped through the blow-out preventor and caused an explosion resulting in a fire. As to the arguments about how the fire started or otherwise, we will not discuss, but the point I would like to make is that it would be impossible to describe the conflagration and damage done, the danger to workmen when such a catastrophe takes place, and the need for education, training and supervisory control if something should go wrong during drilling—impossible without pictures.

In the next group of three pictures again I would ask you, how would you describe the results of this accident? This was a derrick being raised in the northern part of Alberta, with the temperature around 40 below zero. When the derrick reached about half way up, it literally fell apart. What would have happened had the men on the rig not been taught to stay clear when the derrick is being raised, and how many times do we find just that situation existing? But, again try and describe why they should be clear. I think you will agree with me that the pictures educate.

SHOW RIG EQUIPMENT

The next group of pictures are "good" pictures, but they show clearly and definitely without much description how our rig equipment should be at all times if rigging up, and until tearing out. The first picture shows the closed hook on the tong evener and the second picture shows the electric wiring clear of the ground and all machinery.

No short or spark can take place when wire is kept in that condition. The next shows a rotary table with the guard properly installed; the next, derrick cages in proper order and, by preventing the derrickman or other crewman running up and down the ladder without pausing to get his breath, eliminating the danger of a falling accident. The next illustrates a place for everything and everything in its place, no tripping; the next, a cathead and cathead guard, and catline in safe condition; the next, cleanliness, cleanliness is next to godliness, and no accidents can happen when cleanliness is practised; the next, an educational picture—the proper way to place tongs on the pipe when making up or braking out. Try and describe that without a picture.

Next, how many men have been clobbered by pieces of fingers falling from the monkey board? One picture shows it can be prevented. Next is the proper way to fasten a tong safety line. Isn't it much better than trying to describe it? However, there are other ties besides the three clamps, as for example, my company uses the nesco clamp, which we find just as effective, if not more so, than the three clamps.

Another set of pictures show crew men at work. Some of them show faulty, unsafe practise, while others show a good safe crew carrying out work safely.

It is tough, but let us go to another catastrophe, the first picture of the group, although not connected with the remaining six, could be the cause of the catastrophe.

WILD GAS WELL SCENE

Picture #1 was a gas well being brought in and the crew, although they had two flare pits, failed to stop and think for a few minutes, with the result that they fed the gas into the pit into the wind and this picture shows this situation. The set of six pictures are of a wild well in the northern part of our province in the middle of the winter, with the temperature well below zero. The pictures tell their own story.

The next six pictures show bad rig up, and again to describe the unsafe conditions without visual aid would be a considerable chore, if not entirely impossible. There are several faults to be found in each picture, which, if you were using them, you would naturally point out. In the first picture, the blow out remote control unit being placed as it is, is as useless as a snowball in hades to protect the operator if the rig caught fire; there is also a suicide ladder.

We also have a number of 35 milometer slides which show accident picture. The first and second is a derrick being raised, and let us recall the accidents we saw previously with derricks.

Three slides are photos taken from a helicopter going into one of our rigs in the far northern part of Alberta and show the terrain that we have to work in on many occasions. I might point out that for miles around, this is nothing but muskeg. The drinking water and supplies had to be hauled in by stone boat and caterpillar and took one day on each trip.

Three other slides cover a railroad accident caused by an unsafe condition. Five slides show the skidding of one of our rigs in the Saskatchewan area. A successful skid job can only be carried out when all operations are made safe before the job is commenced. Indeed, in this actual incident, the mud conditions were so bad that the two wheels on each of the buggies were hub deep, and it took considerable mobile power to carry out the operation. Remember the tight, heavily strained cables being used in this operation.

GOOD PUBLIC RELATIONS

A safe crew is a happy crew. One picture of one of our crews shows the smiles on their faces. Such a picture goes a long way towards good public relations, good employee-employer relations, and a good no accident record.

Now—what type, style and make of camera will give the best results? Today, there are many, many makes and styles of cameras on the market and in my years of travels, I have used several styles, sizes and makes, but have now settled for three styles of still cameras, namely a 35 milometer, a

polaroid, and a minox. However, to the safety men who are traveling at all times with their car, I would suggest that they have a 35 milometer, so that they might take colored pictures, and a polaroid, so that when an incident takes place, the safety man can be sure that he has a picture before leaving the scene.

There is also one other camera that can be useful, but not to the same extent as a still camera. That is the movie. One can get good results with a movie camera of a crew in operation. But owing to the speed that a movie flashes past an audience, many important points are missed. Although a movie film can be used on several occasions, I, myself do not think that the top results can be obtained by the use of a movie. However, please do not think that I am pushing the use of movie film completely aside. It can be useful.

As to the price of the cameras, we know that they vary from a cheap type box camera to an expensive, all equipped unit. However, I find that the medium priced cameras do a perfect job and therefore, I will not go into that subject.

I hope that I have been able to give you some guidance in the matter of direct visual aid in this matter of safety.

RESTRICTIVE REGULATIONS AT SERVICE STATIONS

by M. E. WOODWORTH

Flammable Liquids engineer, National Fire Protection association, Boston

All regulations are restrictive to some degree. However, there is a major difference between regulations based on reasonable safe standards of good practice and regulations based on securing economic advantages.

There is no more reason—from a fire protection point of view—to limit service station locations within 750 feet or any other distance of each other, than to limit barber shops, restaurants, hotels, food stores and similar occupancies. Neither is there any good reason for limiting the size of tanks or quantity of gasoline stored at service stations.

On the other hand there is every reason to insist that the storage and handling of flammable liquids be in accordance with nationally recognized standards of fire protection. The most widely adopted standards are those of the National Fire Protection Association which have been in existence since 1913. They have been changed many times to recognize new developments and particularly to recognize the first experience of service stations.

Examples of changes to keep abreast of new methods of gasoline delivery can be exemplified by a complete new section added this year on remote pumping systems. The advent of automatic nozzles with latch open devices also required a performance requirement addition to the standards.

UNDERGROUND TANK EXPLOSIONS

To expand on restrictive legislation, let's analyze the problems of storing and dispensing gasoline at service stations.

In 1913 when the standards on flammable liquids were first developed and the storage of gasoline in underground tanks was comparatively new, there was concern over the hazard of an explosion in an underground tank. However, after many years of experience with all types of conditions, it was found that except for a few unusual cases, explosions did not occur in underground tanks. Nevertheless there are still many people who have an inherent fear of an underground tank's exploding.

The real problem and hazard is the removal or abandonment of underground gasoline tanks.

The second phase of the problem of underground tank storage is the hazard cre-

ated by a leaking tank. This problem has not been solved as yet, although a NFPA committee has been working on it for four years. Underground tank leakage is becoming more common and in my opinion is the number one public relations problem for the oil industry and particularly for service stations.

HAZARD OF LEAKS

To answer the potential hazard of an explosion and to minimize the hazard of leaking tanks, for many years the rule was to relate the size of the tank to the distance permitted to a building or property line. But after a study of dozens of cases of underground tank leakage, spacing was not the answer.

For example, once some gasoline from a leaking 1,000 gallon tank showed up in the basement of a multi-storied building over one mile and a half away. Since there wasn't any relationship between the size of the tank and its location to the building, NFPA Standards were changed.

The only distance limitation for underground tanks now is a three foot distance to property lines that can be built upon and a one foot distance to buildings on the same property. These distances are predicated to protect building foundations and to protect the tanks from pressures from the building foundations.

However, for many years to come there will probably be people who will insist there should be a limitation on tank size and a distance factor to buildings based upon tank size. This thinking, of course, is based upon previous NFPA Standards which influenced many laws. The only answer to this problem is for industry and enforcement officials to understand the reasons for these changes.

As stated previously, the problem of underground tank leakage is becoming an increasing one and is of major concern to many people. The NFPA committee studying this problem is convinced that at least a major portion of leaking underground tanks is caused by the failure to install tanks in clean earth or sand as required by the standards. In addition, the committee is confident that failure to install the piping and the tank carefully serves as a contributing factor.

FAULTY INSTALLATION HAZARD

An example of careless installation is the practice of rolling tanks into a hole and possibly damaging the protective coating causing corrosion at the break in the coating. Tanks should be carefully lowered into the hole. Piping not made up tight or broken by heavy trucks when paving a service station yard is a principal cause of gasoline leakage underground.

Unfortunately service station operators are notorious in failing to maintain an inventory control or to suspect leakage when a discrepancy does occur. As a result the industry will be faced with more restrictions. The public has the right to be protected from gasoline leaking into their homes and buildings. Since steps have not been taken by the industry to prevent such incidents, *enforcement officials will be forced to take* preventive steps.

To answer the statement that filling stations are a fire hazard, let's look at the fire record. The NFPA Fire record department estimates there are approximately 4,000 filling station fires a year involving an annual loss of more than $5,000,000. These fires are considerable in number when taken by themselves. In comparison, however, with other occupancies this record is good.

For example, churches and schools are not considered a fire hazard. Yet, there are twice as many fires in schools per hundred schools than in filling stations. There are only 10 per cent less fires per hundred churches than per hundred filling stations. Despite this excellent comparative fire record, people still maintain that service stations should be limited in number.

Probably one of the reasons for the excellent fire record is that all major cities have excellent observance of proper installation which includes tanks, piping, vents, pumps, heating and all electrical installations. Add to this the knowledge and training in fire prevention which service station personnel receive and you can appreciate why filling stations have comparatively few fires.

MUST OBSERVE RULES

The NFPA has published an Occupancy Fire Record on Service Stations. This is one of many such occupancy fire records including such occupancies as supermarkets, farm property, food canneries, restaurants, motor boats and many others. In the analysis of

100 service station fires the failure to observe simple rules of fire prevention results in fires.

Why anyone working at a service station would clean floors with gasoline is incomprehensible. Still the fact remains that such cleaning practice is the number one cause of service station fires. Careless handling of gasoline during vehicle repair and while fueling a vehicle also rank high in the causes of service station fires. Eleven out of the 100 fires analyzed were caused by leaking underground tanks.

Improper sized vents on underground tanks as well as overfilling the underground tank are major contributors to the fire record of service stations. This analysis of service station fires shows the need for a continuing educational program with service station personnel as well as the need for strict adherence to service station design and maintenance.

The fire record of service stations is excellent in comparison with other businesses; but there are still service station fires which could be prevented. A study of the fire record of service stations discloses nothing which could substantiate the need for restricting their location in respect to other service stations or any other occupancy including places of public assembly.

However, the fire record does disclose the need for the continued awareness that service stations should be designed in strict accordance with nationally recognized standards, and that service station personnel should be continually alert to the potential dangers of gasoline.▲

TRAFFIC PATTERNS AND SAFETY PROBLEMS AT SERVICE STATIONS

by W. E. SPLAIN
assistant division engineer, Socony Mobile Oil co., Detroit, Mich.

Each year in the United States, about 40,000 people lose their lives in motor-vehicle accidents and two million receive injuries ranging from minor to totally disabling. These traffic accidents are undoubtedly the major problem that confronts the National Safety Council. Untold hours of study are devoted to determine basic causes and seek methods to reduce this human slaughter. Progress has been made but the problem is far from being solved.

The problem is a huge one. Data must be accumulated from all sources by competent traffic and safety engineers. The basic problem is motorist behavior. Better highways, more rigid law enforcement and better motor cars will reduce accidents. But accidents will still occur until ways are found to improve the driver's skill and his willingness to control his car.

Changing the behavior habits of a motorist is difficult. If this were not so, drunken driving and speeding would have been eliminated by the constant barrage of publicity that has urged drivers to drive at safe speed and to stay away from a steering wheel after drinking.

The petroleum industry, supplying gasoline and essential services to the motorist, is vitally concerned with the problem of traffic safety. Of special concern are the movement of our product trucks over the public highways, and the movement of millions of vehicles into and out of gasoline service stations.

The petroleum industry has spent a lot of money and time to determine how motorists behave when entering and leaving gasoline stations and to determine if these traffic movements contribute to the national traffic problem.

In the mind of most of the people, a gasoline service station is a dangerous traffic hazard. Vehicles crossing sidewalks to enter and leave a station are regarded as a serious threat to the life and limb of pedestrians. Cars entering and leaving the main flow of highway traffic are regarded as important

causes of vehicle-to-vehicle accidents. These beliefs result in ever increasing restrictions being placed on the design and operation of stations. If these beliefs are true, the industry should accept in good grace any code limitation that is practical and that will reduce accidents. If they are not true, the industry is being unduly penalized. It is the purpose of this paper to present factual data obtained in Ohio and Michigan in an attempt to evaluate the traffic hazards that are found at service stations.

Behavior habits of the motoring public are directly related to traffic accidents. A study of driver conduct when entering and leaving stations will therefore be discussed first.

STUDIED OHIO, MICH., GAS STATIONS

Several years ago, the technical subcommittee of the Petroleum Industries committee of Ohio with the Ohio State Highway Department made tests on motorist behavior. The tests were made at service stations selling various brands of products in Ohio and Michigan to resolve differences of opinion between the highway department and the Oil Industry of Ohio. Both were trying to work out a satisfactory code for ingress and egress.

Accurate traffic counts were made, paths of cars entering and leaving the stations were recorded, and accident records investigated. When the data was tabulated, placed on slides for group viewing, and analyzed, it was found that both groups were in error. The data was accepted as fact and a state code was written. Three simple findings in the tests formed the basis for agreement:

1. "The percentage of motorists entering a gasoline station that will "buck" across oncoming traffic to enter a station is much higher than commonly believed."

   Any vehicle that crosses the flow of oncoming traffic to enter a service station is construed to be "bucking" traffic. Experience in Ohio and Michigan shows that an average of 38 per cent of the cars entering a service station "buck" traffic to enter.

   DRIVER SELECTS SAFE PATH

2. The motoring public will unconsciously regiment themselves to the safest possible pattern when leaving a station."

Regardless of how approaches are arranged in the stations, the motorist leaves on the easiest and safest path. We recently checked a four approach station, built at a heavy traffic intersection, and found that six and one-half per cent of the cars in the station, left by the same approach as they entered. In general, the traffic pattern governs the safest exit path and the motorist will select that path.

3. "Pedestrian safety reached its highest order at a gasoline station built at an intersection of two streets. This is probably due to the excellent visibility that is inherent with station design."

Our safety investigations were conducted jointly with the Accident Prevention Bureau of Detroit. Records for the first seven months of 1947 showed that of 32,121 highway accidents in Detroit, six were on approaches and sidewalks at service stations. The record looked so good that we were accused of selecting an ideal time to make the test.

We made another investigation in 1950. During the year, 71,618 accidents occurred —nine on service station approaches and sidewalks none fatal; nine minor accidents at 2,091 service stations and one minor accident on approaches and sidewalks in each 232 years of station operation.

Mr. Fred McLean, who heads our division safety, Insurance & Claims department continued these investigations. His later investigations reveal that our earlier investigations are on the conservative side.

Bucking Traffic

More cars "buck" traffic to enter a station than is commonly believed. Our studies show about 38 per cent of cars entering stations cross the flow of oncoming traffic to do so.

Why do motorists buck traffic? When a traffic light turns there is an open space in the oncoming lane. If a motorist intends to turn at the corner, the easy, safe path is through the station and the motorist takes this path. Bucking traffic is directly related to the second general principle namely, that the motorist will select the easiest and safest path.

Pedestrian Safety

All of the data assembled indicates that a high order of safety exists for pedestrians at service stations. Four accidents—none fatal—out of 75,500 reported accidents are a record that can make the industry justly proud. The belief of some councils and legislative bodies that it is necessary for reasons of safety to impose further restrictions on service station approach design is unrealistic and not supported by fact.

Vehicle-to-Vehicle Accidents

If, in a city where driving conditions are quite difficult, where traffic volume is high and moves quite rapidly, a vehicle-to-vehicle accident occurs only once in 8.4 years of station operation and a vehicle-to-vehicle accident that causes personal injury occurs only once in 119 years of average station operation, the finger of guilt can not be pointed at the gasoline service station.

We believe our findings will be supported by research conducted elsewhere, and hope that our studies will contribute in some small measure to a better understanding of the traffic safety problem that exists at gasoline stations.

THE PETROLEUM INDUSTRY'S STAKE IN THE PUBLIC SUPPORT EFFORT

by A. ROSS ROMMEL

chief safety engineer, Humble Oil & Refining co., Houston, Tex.

To initiate a discussion pertinent to public support, it would probably be well to define and consider what we mean by public support and in what specific endeavor or in what phase of our way of life do we refer to public support on this program. As you might imagine, the public support reference in this discussion is applicable to the broad subject of traffic safety—a problem of magnitude and sometimes seemingly unsolvable facets.

First, I want to say that I feel strongly in my identity as a professional safety engineer and as a citizen. The traffic safety challenge is becoming larger by the day, more demanding in the answers needed for a solution, and more exasperating with its increasing complexity.

Hence, the need for this matter of public support—whatever you and I might do or attempt to accomplish with our good intentions, we can expect little without full public support. Leading law enforcement personnel, representatives of municipal, county, state, and federal governments, traffic engineers, and safety engineers try to develop answers to this problem but they realize that little can be done unless we generate the needed community attack on traffic accidents throughout the nation.

So, public support to me by definition means nothing other than the marshalling of all phases of community life and activity toward the solution of this malignant, cancerous problem about which we talk so much and concern ourselves.

INDUSTRY IDENTITY

We find ourselves in this particular production group of the Petroleum Section—safety engineers, supervisors, staff people, and management personnel—identified, individually and corporately, with traffic safety. As the operator of a piece of motor vehicle equipment which may belong to your company—and which is one of your biggest company safety problems—or which may belong to you, your identity goes even further.

Do you stop to consider that your corporate affiliation may put you even closer to the problem? You are different from the public utilities employee, the supervisor in the air craft industry, the safety engineer of the pulp and paper industry, or any others because that the industry you represent is irrevocably identified with the power end of motor vehicles in the form of gasoline and its allied products.

So isn't it logical to feel we have a responsibility as individuals because of our industrial association to serve well in community safety activity which may be devoted to the battle against traffic accidents? I feel strongly that we do and that because of this identity and association, we have a particular responsibility in the generation of public support.

It would be helpful to review some areas in which public support must be developed to a maximum if we are to realize improved traffic safety conditions in all phases of community activity. First, let's look at who needs public support. Let's consider law enforcement agencies.

LAW-ENFORCEMENT SUPPORT

The program of any law-enforcement agency depends upon the public for its effectiveness. Irrespective of how dedicated, how competent or qualified a law enforcement organization may be, it cannot function effectively without the support of all community representation—namely, public support. In our democracy and way of life the people have the final say-so regarding any governmental activity through the jury service, the ballot system, the referendum and other means of expressing public preferences.

With the avenue of enforcement being recognized as a strong control factor in traffic safety, the agencies which provide this control can only be effective in number, competence and program with the full participating support and encouragement of the public. In the legislative area, we find an equal need for public support.

The public elects our city councils, our legislatures and our commissions. Can our ordinance-making and law-making groups be expected to realize and appreciate all the facets of a community, county, state or even national problems without hearing the voice of the people and without their support?

The public official finds himself in an almost untenable position in the pursuit of good government and in the expression of his convictions without the support and voice of the public. In reference to the public official and the traffic safety, we cannot expect him to take the initiative and provide the leadership in the battle against traffic accidents without the will, support, and energy of the public.

ACTION PROGRAM

The pattern for traffic accident control has been established within the past 10 years through the Action Program of the President's Highway Safety Conferences pertinent to laws and ordinances, public information, accident records, enforcement, education, motor vehicle administration, and engineering. This program states that there is no royal road to highway safety and that only through a balanced program supported by the public can we produce the desired result in the control of traffic accidents.

The entire Action Program is dedicated toward the development of a complete understanding of the traffic safety problem, its requisites, necessary programs, and how these programs can be applied. The Action Program cannot possibly be successful unless every phase of it is utilized in every community.

It is not my intention at this time to review the Action Program. If you are other than a safety engineer, I suggest that you approach your company's safety engineer, your public officials, or your safety council to procure a copy of this program. It represents the best thinking of competent law enforcement public officials, safety people, highway engineers, educators, and a complete cross section of specialists throughout our nation.

There is no phase of the traffic safety problem which is not covered by the Action Program. There is only one thing from which it suffers, and that is lack of understanding on the part of the public—and just plain apathy.

CAN SOLVE PROBLEM

I do not consider myself a sage or one who, because of his years on this earth, is in the position to have such infinite wisdom that he can say through experience and trial and error that he knows the answers to the traffic safety problem, or any other for that matter. But I do set this out as a conscientious wholehearted belief that the American people can solve any program placed before them, that is, if first, they know what the problem is, and secondly, if the problem needs a solution.

You and I in our concern over the safety problem recognize it for what it is, devote our efforts to it, and are frequently critical of the inertia, the passiveness, the apathy

which surround even the groups immediately identified with the problem who actually need the public support. But primarily we feel that we observe these failings on the part of the public itself.

Who is in a better position to tell the public the story and to serve as a spearhead for public support than the safety people of American industry and the safety and management people of the petroleum industry. These people are so closely identified with the energy which coupled with the mechanical device known as the automobile motivates and powers this equipment which in the hands of the careless, the naive, the untrained or the apathetic can make a untrained or the apathetic can turn a mechanical servant of man into a ruthless master and destroyer of man.

"What Is the Petroleum Industry's Stake in the Public Support Effort?" The stake is high—like that of any other fundamental segment of our way of life. The solution to this problem is up to the petroleum industry and to every industry. It is up to every business, every organization, every citizen, every law enforcement agency, and every public official; up to every educator, to every mother, every housewife, and to every child because the problem represents a community, a state, and a national problem.

NEED PUBLIC SUPPORT

And how is such a problem solved? It is solved by the public mindedness of industry and business and the cooperation of citizens in every phase of community life. You and I have seen great community undertakings in the form of fund appeals to operate agencies which are vital to our communities, which help the indigent, and help develop a better society in which we and our children can live. Traffic safety needs the same support, but in all too few communities does it have the cohesive community backing and public support as do many other community problems.

Traffic safety like industrial safety depends upon the fostering and developing of attitudes. In my thinking there is little difference between the two. The average individual driving a modern-day vehicle, who may be a housewife with a loaded station wagon of children or a businessman driving home, hardly realizes that he or she is a potential killer.

These fine American people whom you and I would dare not address as a criminal, a murderess, or a menace to society, but who through their actions behind the wheels of American automobiles killed 40,200 people last year and contributed to the mayhem, bloodshed, tragedy, heartbreak, and excruciating expense which marks this terrible problem confronting every citizen of this nation.

In answer to this question, "What Is the Petroleum Industry's Stake in the Public Support Effort?" you and I represent this great industry and we are tremendously proud of it and our employers. We should appreciate the traffic safety problem and raise our voices in the form of public support. Let us join together with the informed in our communities and let our public know that there is a problem, that it can be solved but that it cannot be solved without a complete and solid community effort toward the preservation of human life which is today being cheapened by the accident by-product of a vital phase of our way of life.

THE USE OF CHECKLISTS IN SAFETY INSPECTIONS

by S. V. ASBURY
accident prevention representative, Gulf Oil corp., Harvey, La.

When making a visual inspection a man too often looks and sees the most obvious points of interest, while other points of equal importance go unnoticed. This natural reaction takes place when an "on the job" inspection is made. When inspecting a drilling rig, the safety engineer may observe an acetylene hose scattered on the derrick floor and call this hazard to the driller's attention.

Yet, he will fail to notice whether the dead line of the traveling block was anchored properly. This inspector saw the most prominent hazard on the job scene, but because his inspection was casual and not scientifically planned, many other important hazards were not noticed.

An individual making an inspection must use a checklist previously designed for the task.

To illustrate this point further, let's look at a blowout preventer hookup on a barge type drilling rig located in south Louisiana. A safety inspection of this location was made to determine hazards on this job scene.

After viewing this work area the most obvious hazards were:

- The coating of drilling mud on the blowout preventers.
- The height at which employees must work without proper scaffolding.
- Poor housekeeping.

There are additional points, though not as obvious, but equally important. For example:

- Are rams in good condition?
- Do blowout preventers operate properly?
- Do blowout preventer connections meet with company specifications?
- Do drilling crews know how to operate blowout preventers?
- Are closing wheels installed a proper distance from blowout preventers?

Specifically and scientifically designed checklists can guide the inspector. Casual inspections without a checklist, with the findings mentally recorded are a poor excuse for the real thing. Many accidents, some fatal, could have been prevented had a planned checklist inspection been made and action taken as a result of these findings.

DETERMINING THE NEED FOR CHECKLIST

Whenever specific information is needed —information best obtained by personal observations such as the condition of field equipment—the inspection should be systematically planned and a checklist developed afterward.

Some inspections are conducted to cite a specific problem, for example, the condition of working surfaces that have caused numerous accidents. Other inspections are general, planned to detect unsafe acts and conditions. In any case, the reason for the inspection should be firmly fixed, the manner it will be conducted decided upon, and serious thinking done before the inspection begins. After this, developing a checklist is a natural followup to make the inspection complete.

The possibilities for using inspection checklists are unlimited. They are used for simple inspections, such as determining the condition of first aid kits and for more complex inspections of checking an offshore drilling platform for both unsafe practices and unsafe conditions.

SELLING A CHECKLIST PROJECT

Management refers to supervisory personnel, from the top level of the president to the lower level of the roustabout foreman. Line management refers to supervisors of the operating departments, and operating personnel refers to all employees in the line organization.

When the need arises for a checklist, the safety engineer must decide which management should develop the needed checklist. The safety engineer should act only in an advisory capacity to management, lending guidance and assistance. Only in rare cases should the safety engineer develop and use the safety checklist solely on his own.

To decide what level of management should develop the checklist depends on its purpose. A checklist for inspecting a field for a local safety meeting report, should be developed by the field foreman. The specific selling tactics would take the same course as any other recommendations made by the safety engineer.

If the problem is more extensive, for example, if a number of drilling rigs are involved or the problem covers many phases of a company's operation, it might be necessary to make a recommendation to the top level supervisor of the concerned department. A simple rule is to do the selling job at the lowest level of supervision that has the authority to take action.

The problem of who develops the checklist depends on the purpose for which it is intended. The ideal situation is for members of the line organization to develop it with the assistance and guidance of the safety department. In some rare cases, the safety department might develop a checklist to assist them on an accident prevention problem. However, a checklist designed exclusively by the safety department and used to check conditions and practices of the line organization is going to die a slow, but sure death, because it will be looked upon as a brainchild of the safety department and a stepchild of the line organization.

Therefore, the safety department should suggest, guide and advise, but the actual checklist should come from the line organization.

USING THE CHECKLIST MOST EFFECTIVELY

The checklist should not only be developed by operating people, but it can be most effectively used by operating people. The safety record of a company is not the responsibility of the safety department, but a responsibility of management. By the same token, safety inspections should be made by qualified operating people, assisted by the safety engineer. It is sheer folly if the safety engineer thinks he is an expert in every phase of the operations.

No safety engineer has a first hand working knowledge of pilot and temperature controls of gas regulators, weight lever valves on separators, christmas tree valves, heater treaters, pop-over regulators, or many of the other complex pieces of equipment operating in the oil patch. A safety inspection should be a cooperative effort with the safety engineer assuming his rightful position of advisor. When he oversteps these bounds, then he is assuming responsibilities delegated to operating personnel.

One of the major problems confronting the safety engineer is to get management to assume the accident prevention responsibilities which are rightfully its. Unfortunately, too many employers think when they hire a safety engineer they can relinquish their accident prevention responsibilities.

For a successful accident prevention program, management must assume its rightful safety responsibilities. To illustrate how a checklist can be either a useful accident prevention tool, or a crutch, let's review the personal experience of "John Doe," safety engineer.

Mr. Doe used to inspect drilling rigs by observing the most obvious hazards. Had he been asked about the rams or turnbuckles on the blowout preventers, he could not have reported their condition there.

Realizing that little could be gained by this method, Mr. Doe gave birth to his first checklist. It helped but at the same time it created resentment among the field people and soon died. The cause of death was as follows:

- Management had not been shown the need for such inspections.
- Management was not shown the need of a checklist for making these inspections.
- Line management should have made the inspections with the assistance of the safety engineer.

Mr. Doe's initial checklist inspections were not completely successful. But now he has a drilling rig checklist based on his original brainchild that his company is using successfully. Why did the company's checklist work? Simply because the safety department only originated the idea and rendered advice. The actual development work was done by the line organization. The checklist inspection is actually made by qualified operating personnel. Mr. Doe's checklist failed because he assumed responsibilities which rightfully belonged to line management.

Here's how a checklist works in actual practice. Assume that the Spindletop Oil

Company contracts all its drilling. Company employees such as tool pushers, engineers and field foreman perform supervisory duties on this rig. The company is concerned with accidents that might injure these employees or delay production. Therefore, it is the company's policy to inspect all contract rigs to insure that equipment and practices meet Spindletop's requirements.

At irregular intervals the company drilling engineer or drilling supervisor inspects the rig. Inspections are made at irregular intervals because a truer picture is obtained than if the crews are anticipating the inspection. Another reason for irregular inspections is that it is virtually impossible to make an inspection such as this when running a string of casing or when a well is kicking.

In any event, the inspection is made by the company drilling engineer and usually with a representative of the contractor.

After the inspection, the findings are discussed with the contract tool pusher, and corrections and changes within authority of the tool pusher are agreed upon. If changes recommended are beyond his authority, the top level drilling supervisor of the company must discuss the matter with the top level supervisor of the contractor.

This plan of action works smoothly. The contractor benefits as much from the inspection as the operator. On these inspections the Spindletop safety engineer occasionally accompanies the company drilling engineer and renders advice as needed.

The reason this plan works successfully can be illustrated by the comment of the drilling engineer, when asked his opinion of the checklist: "We think that the mechanics are fine and the checklist plan works good. *After all, we helped develop it.*"

Safety inspections should be systematically planned, and a checklist used to guide the inspector on a complete coverage of the equipment or practices. Unless this is done, the inspection may not be of any real value.

The possibilities for using checklists when making inspections are unlimited. They can be used for the simplest inspections or the most complex ones in the oil field.

Selling the checklist to management is an important matter. The safety engineer, after determining the need for the checklist, should make his recommendation to the lowest level of supervision with the authority to take action. The actual proposal should not be any different than any other recommendation made by the safety engineer to management.

Who develops the checklist depends upon the purpose for which it is intended. The ideal situation is for members of the line organization to develop it with the assistance and guidance of the safety department. Only in rare cases is the safety department justified in developing the inspection checklist.

The checklist can be most effectively used by line management and not the safety department. This thinking is based on actual experience with checklists and is in keeping with progressive thinking regarding accident prevention responsibilities.

If "on the job" inspections are to be successful, the safety department should plan the plays, but the line organization should lead the interference, and carry the ball. If this is done, all concerned should achieve their goal of valuable safety inspections. This in turn will lead to safer working conditions, safer working practices and, without a doubt, fewer accidents and injuries.

BETTER SAFETY MEETINGS THROUGH TRAINING COURSES FOR CHAIRMEN AND SECRETARIES

by W. A. MALLOY

safety engineer, The Texas co., Chicago

Meetings occupy a very important place in our present day business world. Meetings are also an important part of our community life. In fact, they aid in conducting much of the world's business.

If meetings are so important to our way of life, then it is necessary to spend whatever time, effort and man-power it takes to make these meetings successful.

Training, in the matter of handling meetings, is the logical approach toward more successful meetings. Meeting leaders of all stations of life and endeavour, should have basic training in the fundamentals of conducting meetings. This type of effort will produce better and more fruitful meetings.

TRAINING CHAIRMEN AND SECRETARIES

Safety meetings are to a safety program, what church services are to religion. Safety meetings are a "shot in the arm" of faith and education in safety. These meetings are held for the purpose of better acquainting those in attendance with the comprehensive safety program.

Safety meetings provide for an exchange of ideas, acquaint the men with the hazards of the job they are doing, familiarize them with personal protective equipment, offer a place for discussion of safe working practices, a place for impressing the importance of the use of safeguards, promote safety consciousness and certainly prevent accidents. The value of safety meetings cannot be over emphasized.

In my company, approximately 7,000 safety meetings are held each year. Minutes of these meetings are prepared and submitted to the safety division. The chairman and the secretary are the key figures in a meeting, therefore a training program for these keys was needed so they could perform their tasks with the greatest possible results.

The safety division developed a program for training safety meeting chairmen and secretaries. The safety division also developed and prepared a manual of basic, fundamental training material for chairmen and secretaries called "Manual for Safety Meeting Chairmen."

In the early stages, monthly safety material was prepared by the safety division and distributed to safety meeting chairmen. Although use of this material was not mandatory, many chairmen took advantage of this aid.

The zone safety engineers were charged with the responsibility of conducting these chairmen schools. In conducting these schools, the engineer uses the safety chairmen manual as a text book. He ad libs and illustrates each phase of the manual to be certain the group understands the points presented.

Next, a cooperative management within my company's producing department, accepted the program and provided the initial personnel for the first safety meeting chairmen school. Men were selected from each safety meeting group and sent to a central location for a full day's attendance.

Since that first school, the manual has been revised several times and is still used as a text for the present chairmen school. Success of this program was instantaneous. Word soon spread to other departments and today each department has the chairmen school as part of its safety program. The zone safety engineer conducts the safety meeting chairmen schools held in his zone.

DISCUSS PUBLIC SPEAKING

During this eight hour course, we cover the most basic fundamentals of public speaking. The chapter on public speaking explains some of our fears in speaking to a group and we explain why these fears are a natural thing. Can any of you say you have never experienced the quaking of the knees, the moist perspiring of the forehead, the dryness of the throat before you address an audience?

A discussion includes voice modulation, vocabulary, gestures, enthusiasm, personality and the preparation of the speech itself. A finished public speaker is not expected to emerge from this short discussion, but the *open, frank, down to earth approach* of what makes a good public speaker helps each man understand how he can become a better public speaker.

The planning of a meeting is fully covered. The zone engineer modifies his discussion to suit the group requirements using his intimate knowledge of those problems represented to present useful assistance for arrangement of the meeting place, discussing ventilation, lighting and seating.

Hints are given on where and how to obtain guest speakers and seeking the participation of fellow employees so they will present papers and talks. Suggestions for the placement of the secretary and chairman for maximum results are also discussed.

Conducting the safety meeting is another chapter. In this chapter the step by step conducting of a safety meeting is outlined, complete with suggestions on how to conduct this meeting. The zone safety engineer illustrates this chapter drawing on his experience, to inform the group on the proper method to conduct safety meetings.

Another chapter is on safety meeting procedure. Suggestions are incorporated to make a business-like attitude at the meetings. Procedure of the meeting is discussed step by step. Gimmicks and ideas to stimulate group participation are presented and explained.

For example—accident analysis can be made a group discussion by these steps. Read all the facts available concerning an accident or injury to the group. Have the group give you the causes—you list the causes on a blackboard. Then ask for preventive measures, and the group has analyzed an injury or accident. This successfully stimulates group discussion.

AIDS TO SECRETARIES

Suggestions to the secretary is still another chapter of the manual. In this, we point out the value and importance of good safety meeting minutes. We offer suggestions on how to accomplish this and how to arrange and caption the proceedings.

We don't try to make a polished chairman in the time allocated. We try to reduce the fears for the job, to install confidence in him, give him the basic fundamentals he needs for the job and encourage his participation in community function so more experience in the task of chairmanship can be gained.

We explain the aid and assistance available from the safety division in the form of Monthly Safety Material, use of Safety Digest (Co. Safety Magazine) and of course, reference to the Manual which becomes the permanent possession of the chairman. A pocket sized card is also presented to the chairman to refer to if he wishes.

The safety division has done a good selling job on the importance of safety as well as safety training and education. Persistent effort was required. The glaring failures in some of our safety meetings were again and again pointed up to management and finally the need for chairmanship training was recognized by departmental management.

Results are always demanded to justify the expenditure of effort and manpower, to say nothing of money.

Pointing out results from this type of program is relatively simple. Attendance, especially if voluntary will be increased. The quality of material presented at meetings will be improved, with corresponding improvement in the attitude and safety consciousness of the employee.

Safety meeting minutes will become more than just a note indicating that the meeting was held. The minutes will become interesting reading matter for all safety personnel and impart many hazards to investigate and correct which will help prevent accidents. These are some of the benefits derived.

If you wish to improve the calibre of your safety meetings I recommend the development and institution of a chairmanship training program for your organization. Personalize the program to fit your needs and favorable results are inevitable.

SOHIO SERIOUS INJURY INDEX

by O. C. HAIER

manager of safety, Standard Oil co., Cleveland, Ohio

For many years our company paid attention to disabling injuries. To be sure, we asked our employees to report all injuries, no matter how slight—but we really never gave much thought to cases if they didn't become disabling. There is a good reason for this type of thinking.

1. The American Standard Method of Recording and Measuring Work Injury Experience, Code Z16.1, has emphasized disabling injury frequency rates for years.

2. *National Safety Council Sectional* Safety Contests and Awards are based on disabling injury frequency rate, as are most other contests.

3. A.P.I. members' records of Accident Statistics are compiled on the basis of disabling injuries.

4. There is something dramatic and real about disabling injuries which everyone can understand and feel. Therefore, they become logical things upon which to base all-out efforts for accident prevention activities. In addition, for many years the number of disabling injuries was large enough to warrant spending most of our time on them.

We have watched the frequency rate of Sohio's manufacturing department go down year after year. From a high rate of about 14.00 in 1945 it decreased to 3.25 in 1953. The number of disabling cases dropped *from 65 in 1945 to 13 in 1953.*

We had reasons to be happy with such performances. Our largest refinery, working about one and a half million man hours per year, operated two years without a disabling injury. This was a remarkable performance for a plant which only seven years before had 27 disabling cases in one year.

In 1946 we instituted our Safest Sohio refinery contest in which the refinery with the lowest frequency rate for each six-month period is named Sohio's Safest. This honor entitled them to fly the Safest Sohio refinery flag, display plaques, and participate in ceremonies and celebrations which often include a dinner or a buffet lunch and presentation of awards and congratulatory speeches by the manufacturing department vice president.

When more than one refinery had a perfect record for the six-month period, each shared the honor. To date, there have been 22 contest periods and 37 winners. In only two or three instances has a refinery received the Safest Refinery Honor without having a perfect record for that period!

FREQUENCY RATE ROSE

In spite of performances like these, we safety engineers were not satisfied with the job we were doing. There was a constant battle to beat down feelings of complacency and smugness. We couldn't do any valid predicting on a long-term or short-term basis. As a result, we used the same tools *on the premise they were still doing* an effective job, when in reality they had begun to lose their effectiveness.

Late in 1953, after our frequency rate increased about 15 per cent, the first such increase in several years, I prepared a review of plant safety performance for the vice president of manufacturing, his refinery managers, and staff. The chart indicated we would wait until a disabling injury or a series of them occurring in a short interval of time showed us that something had to be done—that our methods needed revision.

At about this same time, the operations research group looked into the problem of injury occurrence, and the predictability of disabling injuries.

The statisticians, applying control chart techniques to annual frequency rates for 1949 to 1953, concluded that the small number of injuries did not lend to short term predictability. Some more sensitive measure than disabling injuries would have to be used to measure safety program effectiveness.

In searching for this more sensitive measure we first considered using all injuries. This would give us sufficient numbers to work with and would be easy to compile

from current dispensary reports. But several objections seemed inherent. Employees might not feel free to report minor injuries if all first-aid cases were used. In addition, certain minor injuries were bound to occur, and it was not economically sound to employ all the preventives necessary to avoid them.

Take a pump mechanic, for instance, who cannot wear gloves and do his job properly. Even the most careful man may receive small scratches, abrasions, or even punctures on his hands while handling materials and tools.

CAN'T USE ALL INJURIES

The removal of wind-borne bodies in the eye comprises a large percentage of first-aid cases. The number of cases depend on many variables such as location of the plant, operating conditions in surrounding plants and wind. Under these conditions comparisons between plants or even between periods in one plant are not true reflections of accident prevention effectiveness. For these reasons, we discarded the "all injury" method and selected certain injury types stipulating that the injuries should be:

1. Easily identified.
2. Free from individual judgment or personal bias in determining ones to use.
3. A type that employees cannot fail to report.
4. Occurring often enough to give us sufficient numbers to work with.

The following types of injuries were selected to comprise the Sohio Serious Injury Index:

1. All disabling injuries.
2. All non-disabling eye injuries from work-produced objects or corrosive liquids, requiring treatment by a physician. (Wind-blown objects are not included).
3. All non-disabling lacerations requiring sutures.
4. All non-disabling fractures.
5. All other non-disabling injuries for which the physician prescribes work restrictions or motion limitations.

They were selected also because they fitted into a pattern of easily recognizable types with no differences of opinion on reportability.

For example, in eye injuries our medical director's orders to plant nurses (each refinery has a nurse) states if a foreign object in the eye cannot be removed with two or three passes of a sterile swab, the injured employee must be referred to an eye specialist. Thus, all such cases will be reported.

There will be no particular questions about non-disabling fractures since these are usually determined by X-rays as ordered by the attending physician. Since only attending physicians suture lacerations, the only problem is a nurse deciding which cases should be referred to the physician. This is a very minor problem since there are frequent visits to the dispensary by the doctors.

Admittedly, there may be some discrepancies in determining that motion limitations or work restrictions are necessary. Doctors' attitudes and knowledge of the injured man's work vary, and influence their decisions. However, these injuries include many sprains, strains and back injuries, which are rather universally recognized as requiring such measures. Disabling injuries are, of course, judged according to the nationally accepted American Standard Method of Recording and Measuring Work Injury Experience, Z16.1. The number of these injuries, expressed on a "per million employee-hour" basis, gives us our Index number.

CONTROL CHART TECHNIQUE

Our research operations group, working with the safety group, had fresh ideas and techniques to interpret and evaluate our statistics in a scientific manner. The statisticians suggested that we too, apply "control chart" techniques and the concepts of random or chance variations to make the Index or frequency rate of serious injuries a more meaningful measure.

The control chart is based on the concept that any measure of performance will be subject to random or chance variation with no easily discernible cause. When some specific influence, either very effective or very ineffective, is brought to bear on the problem, the variation will no longer be due to chance. The influence will show up as very low or very high levels of performance.

In our case, the number of serious injuries per million employee-hours is plotted monthly on a control chart for each individual refinery. A mean or average monthly figure calculated from the previous three-year period is shown as a solid horizontal line on the chart. Control limits also are calculated. These are shown on the chart as horizontal dotted or dashed lines above and below the mean. These control limits are the estimated amount of random variation expected to occur without any change in the kind or intensity of injury prevention activities.

As with any quality control chart, when our Serious Injury Index stays within these control limits, it is under control.

Another way to look at the index variations within the control limits is that the effectiveness of injury prevention is about the same if the index is within the control limits. If the index, however, goes above the upper control limit something has probably gone wrong in our prevention activities, and we should find out so corrective measures can be instituted.

Likewise, if the index goes below the lower control limit something special took place to give us such a good performance and we should find out what it was to continue and expand its use.

Through these control charts then, we should be able to detect when effective or ineffective accident prevention activities are in use. We could not detect this with a disabling injury frequency rate alone. When plants operate with one or two disabling injuries in a year, the statistics are just too meager to interpret.

In actual practice, the refinery managers recognizing that elimination of all injuries is the ultimate objective, have chosen to regard the mean as their upper control limit. When their index exceeds this average, they show concern that is passed on to the supervisors.

Has the use of the index been effective—is a natural question. It has now been in use for two years. The refinery managers have discussed its continued use and have decided that it is a more complete measure of effectiveness. We have shown a 14 per cent reduction in the number of injuries included in the index. One refinery has reduced the number by 33 per cent in this two-year period.

Other departments are using the index also. The pipe line department uses it as the basis for its divisional safety contest. The marketing department is reporting weekly to the vice president the number of such injuries.

Our operation research involves thinking, reflection and analysis. They think about the problem of injuries, how they occur and what might influence them.

INJURIED EMPLOYEES INTERVIEWED

Injuries, they thought, involved people, work and hazards, either physical or personal. If a man recognized a hazard he might avoid it or overcome it. To find out if people are able to recognize hazards and take actions to avoid or overcome them, an interviewing program was set up. Approximately 100 employees at one refinery were interviewed after they were injured. Among the questions asked were these:

1. Did you actually give safety any conscious thought before or during the job?
2. Did you do any specific thing (not habit) to eliminate a hazard or make job safer?
3. Did you think about the hazard that caused your injury?
4. Did you do something specific about the hazard that actually caused the injury?

Of the answers, 82 per cent said they gave conscious thought to safety before or during the job. This could be overwhelming proof that our safety promotional program was very effective.

54 per cent said they took some specific action to make the job safer.

30 per cent said they thought about the hazard that caused their injury.

And, 11 per cent said they took some action to overcome it but still were injured.

Thus, we have several very important points to consider:

1. Most people interviewed seem to think about safety on the job.
2. Relatively few analyzed the job completely.
3. Very few took action to overcome or avoid the specific hazard involved.

Does this mean supervisors must improve employees' ability to analyze jobs for possible hazards or must we build up their real-

ization of the necessity to analyze more completely?

Does this mean that employees don't take specific action because they don't analyze properly or because their evaluation of the hazard leads them to believe that nothing much serious can happen to them or because they think they might be censured for being too cautious or taking too long to do a job?

These are some of the questions for which we are now seeking some answers. We don't have them yet, but we are working on them.

In conclusion, we feel that our serious injury index is a step forward in accident prevention activities. It has helped us reset our sights on the goal of preventing injuries rather than solely on the prevention of loss of time from work. It may not be the ultimate solution to the injury prevention problem, but it is a step in the right direction. In addition, the use of the Operations Research group adding its time, efforts and talents to the safety problem has been productive and will be more so in the future. ▲

OFF-THE-JOB ACCIDENTS

Statistics are such boresome things
And figures rather dull.
It's hundreds, millions, billions, trillions,
Over which we mull.

But facts are facts where 'er we go
Regardless of amounts,
So here's some facts on accidents,
And that's what really counts.

It isn't always big machines
With blades of sharpened steel
That rob a man of arm or leg
And make his senses reel.

Nor is it always "on the job"
Most accidents take place,
But just the opposite is true
And figures prove our case.

It's carelessness in little things
At home and on the street
Neglect in moving objects small
Away from running feet.

A makeshift ladder, sliding rugs,
Electric cords that spark
A disregard for cellar stairs
And stumbling in the dark.

Crossing where no crossings are
While looking at the sky,
Driving on a slippery road
With milestones whizzing by.

These are the things that take a toll
We all should frown upon
So watch for them when off the job,
As well as when you're on.

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council

THE PRINTING & PUBLISHING SECTION

This volume is a record of the sessions held at the 1957 National Safety Congress by the Printing and Publishing Section. The conduct of these Congress sessions each year is only one of the many cooperative activities which the Printing and Publishing Section carries on in behalf of its members, and for the benefit of accident prevention work in the printing and publishing industry generally. The Section gives guidance in the preparation of a great variety of technical and educational material useful in the day-to-day safety programs of printing and publishing companies.

The activities of the Section are under the direction of its executive committee, the members of which are listed at the close of this volume.

OPENING REMARKS BY RETIRING GENERAL CHAIRMAN—

EUGENE P. ERNEST
safety officer, U. S. Government Printing Office, Washington, D. C.

This is incidently the 10th anniversary of the birth of the Printing and Publishing Section. We have accomplished much, and yet so little, in these 10 years and there remains much to be done before we can claim a job well done.

Ours is a giant industry of small businesses and our major problem, seemingly an impossible one, is finding means to reach the many thousands of small printing plants in which organized accident prevention effort just does not exist. The section has for many years recognized this as its major problem, and its efforts have been directed primarily towards finding and developing means to reach these people.

We have been particularly fortunate in having the full co-operation of the Printing Industry of America, the Education Council of the Graphic Arts Industries, the Lithographic Technical Foundation and other associations in this effort.

ACCIDENT RATE DOWN

National Safety Council's statistics indicate that the frequency rate for the printing and publishing industry is considerably less than it was for the year of the founding of this section, and the severity rate shows a greater reduction; however these reductions are no greater than those shown for all industry. Considering the fact that these are statistics furnished by safety-conscious printing plants that are members of the National Safety Council and actively participating in the safety movement, the record is not too good.

The personal satisfaction derived from a job is considerably affected by the extent to which accomplishment can be measured. The engineer who designs or builds a bridge has a lifetime reminder of the results of his efforts; the salesman is constantly reminded of the extent of his success by the size of his commission checks; the printer, the platemaker, the pressman, and the bookbinder has the end product of his labor in a permanent form that can be used as a measure of his skills.

The safety engineer has to deal in intangibles; the only record of his success available to him is the accident frequency and severity rates which are essentially measurements of what didn't happen. On the other hand the accidents that do happen furnish the indication of his failures.

FATAL INJURY AVERTED

Once in a great while positive indication of success happens along. About three weeks ago one of our employees was injured while hand-feeding a Seibold continuous trimmer. This employee was hand-feeding 24-page pamphlets that had been saddle-stitched on a web press. The employee's left thumb, first and second fingers were caught in the clamp and the employee struck at the shut-off pedal with his right foot and missed it.

His head and shoulders were pulled into the shield of the safety device and the machine was automatically shut off with the cutting blade approximately ½ inch above his wrist.

We have five of these trimmers in the Government Printing Office and in the last 10 years we have had approximately six similar accidents. Although all of these accidents resulted in injuries to fleshy tissue only, we have nevertheless considered this exposure as unusually serious.

Several years ago we saw in operation in another printing plant an electric safety device manufactured by Seibold to use on these trimmers. The units were purchased and arrangements were made to install these devices at such time as the machines were down for major overhaul. Two of the devices still have not been installed. In this particular case, the operator noticed earlier that the brake was not properly adjusted and a mechanic was called to correct this condition. Fifteen minutes after the brake was adjusted the accident occurred.

It is highly probable that the operator would not have noticed the poorly adjusted brake had it not been for the electric safety which is normally used in stopping the machine. And, had it not been for the electric safety the employee would have been unable to strike the old mechanical safety release in time to stop the knife stroke.

This accident has provided us with a positive indication of both failure and success. Unfortunately, the employee lost the terminal phalanx of his left thumb and some bone repair was necessary for the first and second fingers. However there is absolutely no doubt but that the employee would have lost his left hand at the wrist had the trimmer not been equipped with the electric device. Needless to say the two remaining safety devices will be promptly installed on the machines not so equipped.

As a further result of this accident our planning and production people have made arrangements to trim this type of pamphlet on other equipment and it is hoped that we will never again have such an accident.▲

NEW IDEAS IN SAFETY SWITCHES

by FRANK N. BURT

manager, Trip Control Dept., Micro-Switch div., Minneapolis-Honeywell Regulator co., Freeport, Ill.

Micro Switch once made three switches. Customers asked for different actuators, different enclosures, different seals, different capacities, different characteristics—both electrical and mechanical, and Micro's policy was always "If we don't have what you need, we'll make it." The result is that we now make more than 9,000 switch products and a line of electric controls for dangerous machines like punch presses, brakes, and guillotine cutters.

Many different requirements were needed by engineers and safety men for electric systems to prevent damage to machines or injury to the operators. We're grateful for the opportunity to participate in these contributions to safety. The Micro Switch trip control was developed from our need for a safer way to protect our punch press operators.

The most common use of electric switches for safeguarding machines and operators is as an interlock. Interlocks tie one action to another, such as the interlock on a new car which prevents starting the motor unless the transmission is in neutral. Another common interlock is a switch which prevents a machine from damaging itself. Interlocks can feel position, sense the reading of a pressure gauge, or a temperature measuring device, or prevent our forgetting something more accurately than we ourselves can do these things.

HIGH VOLTAGE SWITCH

One of the new interlocks that Micro Switch developed is for use on high voltage electronic equipment enclosures. An electronic register control is a good example in the printing and publishing industry. When someone not qualified opens a high voltage electric cabinet, he could be electrocuted. This door interlock switch shuts off the high voltage power whenever the door is opened. The door must be closed securely before the circuit is re-established.

However, this kind of equipment occasionally requires servicing while the circuit is live. The common way to do this is to tape or wedge the interlock switch so that it does not interrupt the power. Unfortunately, the service man could finish his job, close the door, and go away leaving the interlock taped or plugged. When the door was next opened, the power stayed on and someone could be exposed to the high voltage hazard. By the use of this door interlock, the service man can work on a live circuit by pulling the plunger which the door usually pushed. Closing the door automatically resets the door interlock. When the door is next opened, it is sure to kill the circuit and afford protection.

LIGHTED PUSHBUTTON SWITCHES

Another new line of Micro Switch products are the colorful lighted pushbuttons. This is a brand new idea in safety switches. Lighted pushbuttons were developed to save panel space by eliminating the need for a pushbutton and also a light. The early ones had momentary action, and later a choice of momentary or alternate action was made available. Then, two-level buttons were introduced so the operator could see that a button stayed depressed until it was actuated again.

From here the development led to putting a "feel" into the button so that the operator would know if he had pushed it or even if he had pushed it sufficiently to do the job. Then a control for the light from somewhere else was developed so that an operator would push a lighted pushbutton but would never push an unlighted one.

A still newer idea in lighted pushbuttons is to have several colors show on the same pushbutton denoting several conditions which can be either locally or remotely controlled. The color of the light could be changed by another condition anywhere else; for example, at the other end of a huge printing press, and not until the color of the light changed would anyone push the master starter button. This second color could be an intermediate condition, and the third and possibly even the fourth color would have to appear before the operator started the press. These lighted pushbuttons offer many combinations.

The newest development is a magnetically held pushbutton. When the pushbutton is depressed, a circuit is not only closed but held closed electrically. It remains closed until it is broken electrically, either by the same pushbutton or elsewhere. This "bailing" action can be either manual or electrical, and arranged so all hazard points must indicate an all-clear signal before a master starting switch receives the proper all-clear light, or even is able to start the machine.

Micro Switch field engineers and design engineers are already working to incorporate these new lighted pushbutton systems to prevent accidents on large presses.

OUT-THINK CARELESS EMPLOYEES

To out-think careless workers, or to prevent accidents by eliminating the breeding place of accidents, management can incorporate the new science of human engineering into the everyday operation of machines. Micro Switch has developed new products, including the trip control system, which are *"human engineered." They are designed so* their use is in the safest, most logical manner, so that the desired action or sequence of action is followed quite naturally by the worker.

In the development of pushbuttons, the human engineering principles have been followed when the choice of colors was made. The operators are not forced to watch a hypnotic color for long periods of time, and the stimulating colors provoke fast action when an emergency arises. In the case of *the tri-lighted pushbutton, there is never a* choice to be made as to whether a bulb is burned out, because one light should always be lighted. If no light appears, it is time to call the maintenance department.

Another new product is the Honeywell proximity switch . . . our name for a static switch. A static switch is a switchless switch—one that permits current to flow or prevents current from flowing without the use of contacts or any moving parts. In fact, it is actuated by any magnetic material passing within a short distance of a sensing head. This device enables counting rotations of rollers without contacting the roller, working with metal plates, specifically tin plates as used in the printing industry, and counting and registering many other devices which are impossible to contact physically. Needless to say, the long life of such a device without moving parts will some day make this new system more common than mechanical-type switching devices.

TRIP CONTROLS FOR GUILLOTINE CUTTERS

Of the new Micro Switch products for the printing and publishing industry's safety, the Micro Switch trip control for guillotine cutters is probably the most directly adaptable. The use of Micro Switch trip control for guillotine cutters was an accidental but fortunate adaptation to paper cutters of a control originally designed for the metal working industry. Micro Switch trip con-

trols have worked out very nicely on flatbed cutters, affording an uncheatable control that is easier to operate and because of its electric flexibility, allows the operators to safely hold labels, tickets, or other narrow work.

Micro Switch is now offering a special Micro Switch trip control designed especially for use on paper cutters. This control differs from its metal-working machine counterpart in that it does not have a "Single Stroke" and "Repeat" selector. Other trip controls have either "Single Stroke" or "Repeat," although this selector is tightly locked in the control box, its presence was distasteful to safety men in the printing and publishing industry because a repeat operation is entirely unnecessary on a paper cutter.

LIMIT SWITCHES GIVE AUTOMATIC UPSTROKE

Micro Switch trip control offers automatic upstroke, that is, the operator could release his hand switches once the knife had hit the stick and took over and caused the machine to go back to the top of the cycle, automatically, and stop there automatically. This automatic portion of the cycle and the automatic stopping was accomplished by means of limit switches actuated by the drive-shaft of the machine.

When a knife was changed, it was possible to "inch" the machine to stop it holding one of the limit switches actuated. To start the machine again it was necessary to change the setting on the control from "Single Stroke" to "Repeat." For this reason it required considerable research to eliminate the "Repeat" selector and proceed if the machine should stop holding one of the switches actuated.

The new trip control for paper cutters does all of these things. When used in conjunction with an angle bracket it either requires the operator to hold both hands on switches safely located beneath the front table of the cutter or allows him to hold labels, tickets, or other narrow stock with the angle bracket and control the machine by a two-hand control with one switch located on the angle bracket and the other in the normal under-the-front-table location.

Any time either of the switches on a Micro Switch trip control is released during the downstroke, the cutter stops immediately. Any attempt to cheat the control, or any failure of the control, such as a short circuit or power failure, or an airline failure or a damaged component, will not endanger the operator because the machine can not run until the damaged or cheated components are restored to normal.

These more recent developments by Micro Switch are the results of normal progress and constant cooperation by our engineering department to meet progressive requirements of safety engineers engaged in a continuous effort to out-think the unthinking worker.

SAFETY 'ROUND THE CLOCK—AN EXTENDED HEALTH AND SAFETY PROGRAM FOR INDUSTRY

by DAVID T. SHUTE

assistant vice-president, Loss Prevention Dept., Liberty Mutual Insurance co., Boston, Mass.

Why should industry establish a health and safety program that extends beyond the work place? From the public health point of view, health services offered by industry benefit a large segment of the population. From management's point of view, when the influences on an employee outside the plant are good, the results of lower cost and higher, better quality production likewise are good. The more a company provides for employees the more it is regarded as a good company for which to work and one which exerts a favorable influence on the entire community.

There is a definite need for home accident control since accidents are the number one

cause of death among children and young people up to 24 years of age. The chief reason is that the accident problem has been stressed sufficiently for parents to realize that preventing injuries to their children is just as important as preventing the communicable diseases of childhood. However, there is no reason why the laissez faire attitude toward accident prevention within the family group can not be changed. There could be increasing awareness with correspondingly beneficial results if everyone in a position to do something about the situation joins in the crusade.

MORE WORKERS HURT AT HOME

Initial attempts at controlling home accidents were made by local health departments. Results of surveys, statistical studies and early preventive measures revealed that a severe problem existed, but in a short time serious efforts might bring results.

In addition to the high accident rate among children, more employees have been injured at home than on the job. Many states are placing more financial responsibility for off-the-job accidents on employers, which is a good reason why industry can and should get into the picture.

Illness and injury mean suffering, sorrow, and added burdens—mental, physical, financial—for the employee and his family. Illness and injury mean absenteeism for management. Establishing a health and safety program that extends into the home should help to control these conditions by:

1. Reducing employee absenteeism from injuries due to home, highway and recreational accidents and employee and dependent injuries and illnesses.
2. Increasing employee efficiency and improving morale through the prevention of illnesses and injuries and improved employer-employee relations.
3. Reducing group disability insurance costs through better accident and illness experience.
4. Increasing community acceptance of the industry as a good place to work.

Any industry with an effective on-the-job accident prevention program can achieve satisfactory results by including activities aimed at preventing non-occupational injuries and illnesses. It must be acknowledged at the start that this is a more difficult goal since the home atmosphere, unlike the industrial environment, is not controlled. However, most companies that have off-the-job or home safety activities believe it is well worth the time, effort and money expended, if only from the aspect of employer-employee relations.

A group of industrialists meeting in New York city in 1955 to discuss home accident prevention agreed that a workable program for reducing home accidents would win employees, their families and community good will. This group concluded that "heads of families and school teachers, like industrial plant supervisors can be taught responsibility for safety of individuals. But safety principles and attitudes rather than safety specifics must be taught to employee families and then to entire communities."

To help a family live with better health and greater safety is a matter of education —developing in the worker and his family a safety-consciousness that will apply regardless of where they are or what they are doing. This family safety program should be a broad, long-term venture, carefully planned from year to year.

FAMILY SAFETY PROGRAM

It should cover not only home, highway and recreational safety but any situation which may adversely influence the health of a family, and it must be adapted to the specific plant. In some cases home safety activities should be a separate project. But they are usually more successful as an extension of an effective on-the-job program.

Primary efforts are usually concerned with getting information into the home. There are various ways of doing this:

1. Provision of wall racks in the medical department, first-aid room or other accessible location to display pamphlets for employees to take.
2. Distribution of health and safety pamphlets to the health service for the nurse to give employees when they come for care or counseling.
3. Periodic distribution of health and safety information in an envelope with the pay check.
4. A health and safety column in the employee publication.

5. Monthly, bi-monthly or quarterly mailings to the home.

Every possible effort should be made to stimulate interest. Whenever possible an introductory letter should be sent to the home of each employee, emphasizing the value of health and safety activities in a family and encouraging their participation.

USE HOUSE ORGANS

If the plant has a house organ, an introductory article could announce the initiation of the program, with suitable follow-ups in succeeding issues outlining the progress and success of the project. From time to time, appropriate posters on plant bulletin boards could tie in with the particular phase of health or safety being stressed at that time.

When the company is the main industry in a community the program might be launched with an open house, at which time off-the-job, family safety, and on-the-job safety features would be stressed. Stimulation of and cooperation with community organizations, use of local health facilities and resources, educational programs in the schools, demonstrations and exhibits for PTA meetings and other activities might be developed as the program progresses.

Either a committee or an individual may head up the program. Ideally a special committee or the health committee might be responsible for activities. Few plants have organized health committees to carry out family safety activities. However, many plants have safety committees and since the activities of the employee both on and off the job are interrelated in health and safety, the safety committee or a sub-committee could extend its efforts to include family health and safety. This also gives employees some part in program planning. If there is no safety committee or it is not feasible for the committee to handle activities, the personnel director, safety director or some other person with a keen interest in employee welfare might be appointed to head up the program.

Liberty Mutual's extended health and safety program for industry provides group disability policyholders with a service directed toward controlling injuries and illnesses of employees and their families. There are various ways of approaching the situation. The method we presently emphasize is the home mailing program, which enlists the aid and support of the woman in the home.

She is a force in her family and is an extremely important person in preventing injuries and illnesses to the whole family. Given the knowledge, she can also reach into the plant to protect the man of the house from work injuries.

HOME MAILING PROGRAM

The mailing program starts out with an introductory letter from management sent to each employee's home. The letter is addressed to the wife, mother or homemaker and explains the nature of the program, why it is being undertaken, how it will be handled, what it will accomplish for her and her family, and her part in the program. Along with this letter is a postcard to be signed and returned if she and her family wish to receive the health and safety material monthly.

After replies are in, a second letter is sent to all families consisting of two pamphlets—one on health and one on safety. Appropriate material is sent monthly thereafter.

It is the responsibility of our health consultants to help management individualize its program and work out other methods of distribution when a plant can not handle the mechanics of a mailing program.

With the coming of automation and less work for more people, an increasing number of employees will spend less time on the job and more time at home, on the highway or in recreational pursuits with their families. It has been said that "The individual effort of an informed person will do more for his health and that of his family than all the things which can be done for them."

Industry can set its sights on no higher goal for the future than to create in the worker an awareness of his health needs and a willingness to cooperate in all measures designed to promote and protect his health and that of his family.

PRACTICAL SAFETY DEVICES INCLUDED IN HARRIS-SEYBOLD PRODUCTS

by JOSEPH McCONNAUGHEY, JR.

Western District Manager, Harris-Seybold Co., Division of Harris Intertype Corp., Chicago

We at Harris-Seybold have always been safety minded in design and manufacture of printing machinery—presses and cutters. These machines require close operator contact and by their nature, though well guarded, can, through a mishap, cause a severe injury.

Safety consciousness in cutter design was demonstrated as far back as 1899 when a two hand throw-in (operating control) was put on the old Seybold Holyoke model paper cutter, and in 1913, the two hand safety device was supplemented by a positive locking steel safety bolt, making a dreaded uncontrolled repeat cycle impossible.

PRESS SAFETY FEATURES

Since those early days, many improvements in printing machine safety have been made by Harris-Seybold engineers. Several years ago, our engineers were invited to assist in writing a Graphic Arts Safety Manual. The information supplied to our group by the committee, plus some additional studies on their part, forcibly proved facts about safety requirements which had always been supposed to be true. This created an even greater desire on our part to build increased safety into our machine. Let's consider briefly presses—Harris and Cottrell presses today incorporate such standard design *safety* features as:

1. *The "Two-finger Start" safety push buttons.* This is now being furnished as standard equipment at no extra charge on new presses. This new safety device has won astounding acceptance by both operators and owners and is now considered a standard of the industry. This feature was introduced two years ago at the National Safety Congress.

2. Also safe-lock control station buttons are supplied on all presses: plus limit switches on load raising and lowering power lifts with fail safe brake and warning devices, being standard on multicolor presses.

3. As much and as comprehensive safety guarding as possible to guard critical mechanisms is supplied which will still allow efficient operation of the machine with maximum operator safety. In areas where a man must work on dangerous mechanisms, guards are electrically triggered so as to make the machine inoperative when guard is removed.

4. Safety hand rails, grips and cat walks with grip treads are also furnished to assist in operator safety, when moving around on the press.

LIGHT REFLECTING PAINT

5. And something new—experiments are also being conducted through cooperation of Western Printing & Lithographing Company in using an off-white light reflecting paint on presses. A paint developed cooperatively by Harris-Seybold and Pittsburg Plate Glass engineers. Western Printing safety engineers and press operators are quite enthusiastic and this change to lighter colors for printing machinery for improved visibility and safety purposes may presage a new trend.

6. Operator Manuals are furnished in the belief the more the operator knows about the machine, the safer he will be. Safety was one of our prerequisites in the original concept of the design of our Seybold "Saber" cutters and of the Full Hydraulic large size commercial and mill trimmers. Safer "Saber" meets safety requirements for all six major hazards as outlined in National Safety Council Data Sheet #D-298 titled "Power Guillotine Cutters."

a. Danger of operator getting hand under descending knife.

b. Fingers being crushed under pressure clamp.

c. Contact by hand with cutting edge of knife when at rest.

d. Injuries from handling and changing cutting knife.

e. Accidents due to repeat cycle of knife.

f. Injuries due to contacting moving parts of the machine.

Examples of how the Saber meets N.S.C. requirements are:

REQUIRED HAND-POSITIONS

1. A positive approach to safety is demonstrated by establishing a required safe position for the operator's hands during the cutting cycle—in other words, both hands are necessary to operate the two hand start, two hand hold cycling control. This approach can be compared to the negative approach of attempting to stop the machine during a cycle after the operator's hands or arms are in the danger area. An example of this would be the light beam—electric eye safety device such as furnished on imported cutting machines.

2. Again, a positive approach has been used in safety design by use of the highly reflective off-white color on knife bar, coupled with adequate flood lighting—a feature which reduces operator eye fatigue and insures safer operation throughout the shift.

3. The present day Seybold hydraulic paper cutter clamp is capable of producing eight tons or more of pressure which can do as much damage to the operator's hands or arms as the knife. Harris-Seybold pioneered the necessity of making the operator unlatch the clamp before it can be lowered by the foot treadle, thus preventing the possibility of the operator (or some buddy) accidentally stepping on the foot treadle and bringing down the clamp while his hands or arms are in the danger area.

4. The dreaded repeat cycle of a paper cutter has been met head on by our engineers—the result is "The Double Safety Bolt." This can be described as a safety to protect safety to protect safety. In other words, the sequence of operation, in case required, would be: if the electric fail safe brake fails, if the #1 safety bolt fails, the #2 safety bolt will stop the machine—and prevent further operation until cause of these failures is corrected.

5. The knife changing operation on cutters—always a procedure requiring extreme caution—has been made much safer by the introduction of knife changing knobs. And through cooperation with Eastman Kodak safety engineers an electrical circuit that interlocks the knife changing knobs is incorporated so that when knobs are removed from their storage position—as is the case when the knife is being changed—the machine can not be cycled. This prevents any possibility of an unexpected cycle while the operator is working in the danger area.

6. There are numerous safety features designed into our Safer "Saber" paper cutting machines—features not as dramatic perhaps as those already mentioned but important. They are:

a. Strength and stability of basic machine.

b. Thorough guarding of all points such as pulley, flywheel, gears, belts, and levers.

c. Correct table height so that operator is not off balance when placing heavy lifts of stock. Also air film available on larger machines lessening possibility of operator strain in positioning lifts of stock.

d. Electrical voltage reduced to 110 volts from line operating voltage in control panel, reducing danger of severe shocks.

e. In event of power failure, everything on cutting machine stops instantly and is either electrically or hydraulically locked in position.

f. Knife in rest or non-cutting position guarded so operator cannot come in contact with cutting edge.▲

SAFETY AND SEMANTICS

by KARL F. SIMPSON, JR.

director, safety & industrial relations, Folding Paper Box Assn., Chicago

An institution is "collective action in control of individual action." Following this train of thought, institutional economics is the study of business ethics which deals with the rules of conduct arising from a conflict of interest. These rules are enforced by the *moral* sanctions of collective opinion. At times this concept of an institution seems analogous to a building, a sort of framework of laws and regulations, within which individuals act as inmates. It seems to mean the "behavior" of the inmates in our social organizations which results from the conflict of interest.

The application of "institutionalism" to industrial safety can be appreciated if we apply the "conflict of interest" concept to the conflicting attitudes of the general public. On one side, we have the pressure of competition which stems from the public's desire for more production and higher quality at lower cost. On the other side, we have a "moral" pressure from the same general public who feel the greater production and higher quality should not be achieved at the price of an unduly high cost in industrial injuries.

In this "conflict of interest" the "moral conscience" of the public has been translated into economic pressure on industry in the form of workmen's compensation. This shifts the burden of administering this moral sanction to the business community. By altering basic rules of the business community and taking full advantage of a basic characteristic of human nature, the altered flow of business activity should decrease injury rates.

Thus, workmen's compensation is based on the idea that the "institutional" or persistent behavior patterns of the businessman will reduce and eliminate cost items (injuries) which are subject to his control. That portion of the injury "cost" which cannot be eliminated should be part of the product cost and reflected in the purchase price.

In this definition of institutional economics we find a significant contribution to understanding industrial safety. In a safety program there are two problems which must be considered: (1) effectively presenting the program to get management's full cooperation and (2) presenting the program to employees to secure their acceptance. Lack of understanding on the part of management prevents effective action, while a lack of rapport with the employees reduces the program to a sterile exercise in theory with no effective use.

TWO PROBLEMS OF SAFETY PROGRAMS

The way to present a safety program to top management, is not the same as presenting it to employees. The facts are the same for both groups. The problem is selecting pertinent information which will be understood and appreciated by each group. Since the conditioning and training of the businessman differ from that of the employee, he will be responsive to different arguments.

For a safety program to be really effective it must be "sold" to top management, so they are induced to put their full weight behind the project and drive it through to completion as they would in marketing a new product or installing new machines and techniques. The reason top management supports a new product is because if the program is successful, the organization will profit. The reason management supports installing new machines is because it will lower cost, increase production and, in the end, should mean greater profit.

One basic mental institutional characteristic of the businessman is his unbounded optimism and faith in the future. One valuable instrument for measuring his activity and his estimates of the future, is the "profit and loss" statement. He thinks, eats, breathes and lives "profit and loss." We must recognize this characteristic. However, there is a great difference between recognizing this characteristic and effectively using it to activate a safety program.

You can tell a businessman that a good safety program will alleviate suffering, be good for his employees, be good publicity (this may have some monetary significance to him), is needed to keep the union quiet, will get him into Heaven, or stress all the humanitarian and revival arguments, and if lucky, you will get an indifferent acquiescence to your program. You might as well bury and forget about the activity right there because you will never really get the program off the ground. The only thing you are sure of is the disaffection of your co-workers and laryngitis from shouting into closed ears.

GIVE MANAGEMENT FACTS

This complete indifference is the situation faced by many practitioners in industrial safety. They are fighting a one man battle for a program which requires the complete support of the whole organization.

Many industrial safety men are not taking full advantage of their power. This power or force consists of an aroused management or business organization in search of profit. The catalytic agent necessary to activate this element is proof of decreased costs through the reduction of accidents. This proof must be more than a pious affirmation of faith that a cost reduction will result. The monetary nerve of the businessman is quite well developed and extremely sensitive, therefore it is logical to present arguments to activate this sensitive sensory organ. If you want to see top management sit up and act, just tell them a good safety program will save them money. *Be prepared to back up this statement with a factual presentation worthy of their consideration.*

Does this mean that businessmen are heartless monsters to whom welfare arguments mean nothing? No, but it means by telling them a safety program saves money, you have said something their analytical mind understands. You are getting through to them; you are talking in a language they appreciate and evaluate.

To approach this task of "cost" analysis intelligently, reduce the problem to its basic elements. Webster defines the word *accident* as "an event that takes place without one's foresight or expectation, especially one of an afflictive or unfortunate character . . ." On the other hand, Webster defines an *injury* as "damage or hurt done or suffered . . ." If we assume that an injured person was not trying to maim himself, then every injury is an accident, but every accident will not result in a personal injury. We reduce these classifications into sub-groups on the basis of damage to plant, machinery or equipment:

1. Accident—no injury to an employee and no damage to plant, machinery or equipment.
2. Accident—no injury to an employee but the destruction or damage to plant, machinery or equipment.
3. Accident—an injury to an employee but no appreciable damage to plant, machinery or equipment.
4. Accident—an injury to an employee, as well as the destruction or damage to plant, machinery or equipment.

Since all injuries result from accidents, the fertile field for exploration involves the area of accident reduction. Because of the controversial nature of the data on the "total" cost of injuries, let us ignore this aspect of the problem and explore the other economically significant area of "cost," replacing or repairing of plant, machinery or equipment damaged or destroyed by an accident. Webster defines the word *maintenance* as "the upkeep of property, equipment, etc." This upkeep is necessary by normal wear and tear on equipment.

CHECK MAINTENANCE COSTS

This idea has become somewhat adulterated and *maintenance* in many instances now means all outlay to maintain plant and equipment, including the cost of restoration or replacement after an accident. When this new definition is followed, the maintenance budget often is so large that top management reduces the size of the maintenance crew or delays expenditures for needed repairs. Seldom is an effort made to determine *why* maintenance costs have become unduly high.

If your maintenance costs are too high, you should investigate to determine why each expenditure was made. Ask these questions:

1. Was the expenditure from the actual wear and tear normally expected?
2. If not, was it due to an accident?
3. If it was, why did the accident occur?

Separating out these "accident" expenditures is not as easy as it seems. People who have *wasted* the company's money are seldom willing to admit it. Despite the difficulties inherent in such a project one company in the paper industry has made a preliminary investigation of the subject and unearthed the following facts:

1. 15 per cent of the maintenance work was unquestionably made necessary by circumstances which could be classified as "accidents."
2. An additional 15 per cent of the work was made necessary through employee negligence — (some people, however, might question the use of the word "accident" in these cases.)
3. There is another area beyond this basic 30 per cent which could not properly be classified as "fair wear and tear"—damages which might have been prevented by the type of systematic job analysis which is called for in an effective program of accident prevention.

These results are based on an analysis of 1,251 work orders. If "accidents" and "negligence" had been eliminated the total would have been reduced by 375.

If your operation is anything like the organization which made this study, you might apply this 30 per cent figure to your maintenance expenditure for last year and see if you can stimulate any interest in your top management in a program which offers the reasonable expectation of this dollar saving.

This obviously is not a complete picture of the benefits of good safety program. However, if our thesis is correct—that you must translate the value of a safety program into terms top management can evaluate and appreciate—then it offers a fruitful area for exploration and possible exploitation. Turn your safety plan into a program designed to eliminate the basic ingredient in each personal injury—the accident—and use factual material to back up your assertions that accidents and injuries cost money.

Although you may not be able to determine the "total cost" of injuries, you should be able to substantiate your offer of savings in maintenance expenditures which by itself should be sufficient to "sell" any top management on your program.

Behind the Scenes—

THE INSURANCE COMPANY'S ROLE IN INDUSTRIAL SAFETY

by FREDERICK J. DODSON, JR.
assistant manager, Loss Prevention Dept., Liberty Mutual Insurance co., Boston, Mass.

Cooperation between representatives of the insurance company and the policyholder, which may sound like an obvious necessity, deserves to be examined.

This is an area of the accident prevention scene in industry where there is substantial room for improvement—the zone of inter-relationship between the insurance carrier loss prevention representative and those in industry responsible for the administration of the in-plant safety program.

Real misunderstanding exists in only a small percentage of cases, but there is room for improvement in the vast majority. Admitting that we must always live with the personality conflicts existing in any human contact, let us see if there is any other basic reason for difficulty.

The plant safety director is engaged as a management representative charged with the prevention of accidents or production interruptions in the broad sense and he generally

acts with the delegated authority of top management. He is trained and experienced in the problems of his organization, and he knows its limitations and economic restrictions. He can draw on the skills of his own organization's staff and he can consult with numerous agencies for advice.

ENGINEERS AID POLICYHOLDERS

The insurance company safety engineer although engaged by a different employer is expected to contribute a service to the policyholder which will achieve the same goal as that of the plant safety man—an improved accident experience. Every insurance company safety engineer is not a top-flight operator and the same observation could be made of industry's safety engineers.

In the early years when industrial safety was in its infancy we probably had many cases where the insurance company safety man's activity was too greatly concerned with "replacing rungs in ladders," or "patching holes in the floor." However, a lot of water has gone over the dam and the broad exposure of information and education now available to insurance company safety engineers has changed the picture greatly,—yet I feel that in many places industry doesn't really understand this.

The insurance engineer is trained in the same basic principles as the plant man. He has, however, access to a vast experience accumulated by his employer which far exceeds that of the individual plant. He has close contact with specialists in the more technical fields of engineering and can draw on such help as he needs it. In our rapidly advancing technological system these skills, in depth, are essential to keeping our loss prevention activity in tune with the times.

I can see no basic reason for misunderstanding between the carrier and the insured. There is unity of purpose. Safety representatives of both are members of the same profession working toward the same objective.

INSURANCE MAN IS CONSULTANT

In the ideal situation the plant safety man accepts the fact that the insurance man cannot know all of his and his plant's problems and that he must acquaint the insurance man with background information so he can make a maximum contribution to their joint undertakings. The plant safety man must also recognize that the insurance representative is not in competition with him but is, in effect, a consultant for his assistance.

The insurance safety engineer, in the ideal situation, recognizes that the plant man must live with his plant problems every day of the year. When the insurance engineer visits the plant he must carefully evaluate any examine the plant's activities before attempting to offer advice or suggestions. When he encounters new situations not within the scope of his own experience he must take time for necessary research and study of the industry's experience as compiled and documented by his own company. He may need to call upon specialists for further assistance.

I believe it is the accumulated experience of the insurance carriers, many of whom have acquired and developed special knowledge of particular industries, that puts the insurance engineer in a position to be of maximum aid to the plant man. Various insurance companies, over the years, have acquired extensive coverage in certain geographical areas where particular industries tend to center, making it possible to develop special services for such industries. Such services can frequently be extended to other less concentrated areas through the carrier's training and supervision of its field representatives.

CARRIERS EDUCATE PLANTS

The carriers are also called upon by trade associations and organizations such as the graphic arts industry to assist in the development of educational material and the research of special problems. Through these contacts the carrier can often bring to the individual plant knowledge of new developments that have not yet filtered down to the operating levels.

The plant safety man has much to gain from the insurance carrier by learning to make use of its safety services to best advantage. He can do this by endeavoring to establish the best possible personal relationship with the carrier's servicing engineer so that there will be a constant free exchange of problems and information. Through this local contact he has access to the full facilities of the insurance company.

assuming that sufficient rapport or understanding has been established between plant and insurance safety men let's examine some of the specific activities to which the carrier services can contribute.

ACCIDENT PREVENTION

As industrial organizations grow large, two significant factors emerge that seriously affect the accident prevention effort—one helps, the other sometimes hinders.

First, the larger organization recognizes and accepts a broader responsibility for its human and community relationships. This leads to more vital interest in the loss prevention effort and a demand for positive results. I know of no large, successful business concern that does not face up to this obligation and acknowledges its importance from both legal, social and economic points of view.

This recognition also leads logically to management's demand that the insurance carrier be equipped and staffed to render every practical consultative aid on loss control. This imposes a powerful incentive on the carrier to develop a service geared to the changing requirements of industry.

The second significant factor to arise from the growth of the industrial organization is the development of the staff function and the delegation of authority. In dealing with the smaller policyholder we usually achieve results more quickly by establishing effective contacts with the owner-manager or the shop superintendent. In the case of the larger organization we, as relative outsiders, frequently encounter impassable channels of authority, delegation and decentralization.

It is not unusual to discover in the course of attempting to render effective service that we must deal with an insurance manager, a safety director, an industrial relations manager, a standards department, an engineering department, a medical director, a factory superintendent, an architect, a chemist or process engineer, a purchasing agent and a government security officer—to mention a few.

To get decisions, to activate necessary changes and to organize necessary follow-up under these circumstances pose no simple problem. In many cases we achive simple, effective communications with the proper authority. In others, we find ourselves dealing with ineffective subordinates and fail in our purpose.

Therefore, it seems appropriate to conclude that the insurance buyer can assist the carrier to render effective service by establishing good lines of communications with appropriate management representatives.

NEW SKILLS NEEDED

Since World War II the technological developments of industry have advanced so rapidly that a whole series of specialized fields of science invaded the scene. This new complexity extended to the field of accident prevention. New skills were needed, research into new hazards was urgently required, new training was necessary and new techniques had to be developed. Obviously, no single firm could assume or afford the full responsibility for these new problems—but, the insurance carriers have been able to bridge much of the gap.

We believe the insurance company loss prevention specialist makes an important contribution in this situation because successful accident prevention activities in today's complex industrial atmosphere are no longer simple ABC's. A truly comprehensive loss control program must draw on many skills and no manufacturer, merchant or contractor can afford to staff his organization with all the professional know-how that may be required to do a total job. Through the insurance company, however, it is possible for the policyholder to avail himself of many skills because they can be made available to so many policyholders that the expense can be justified by the carrier.

LOSS PREVENTION DEPT.

I think you may be surprised to learn the multitude of the specialties that it has been necessary to develop in order to make available a complete modern loss prevention service. Here are the talents that we employ in our Loss Prevention Department and some of the services these people render. (Note that these are in addition to the field servicing engineers and elevator inspectors who make regularly scheduled visits).

INDUSTRIAL MEDICAL CONSULTANTS

Planning in-plant medical facilities
Assisting in selection of personnel

Establishing health counselling programs
Setting up job placement programs
Investigating special health problems.

INDUSTRIAL HYGIENISTS

Field instrument testing—air sampling
Design of ventilation systems
Developing control measures—dusts and gases
Evaluation of waste disposal problems
Determination and control of explosion and fire hazards.

ACOUSTICAL ENGINEERS

Measuring sound levels
Designing noise control devices
Setting up audiometric programs.

TRANSPORTATION ENGINEERS

Designing industrial power truck programs
Analyzing parking lot and traffic systems
Controlling peak traffic hazards
Laying out shipping and receiving traffic patterns.

CONSTRUCTION ENGINEERS

Analyzing floor loading and building design problems
Measuring and correcting building vibrations
Studying and controlling blasting operations
Analyzing strength of temporary structures.

ELECTRICAL ENGINEERS

Controlling hazards of power generation and distribution
Study of high and low voltage exposures.

HEALTH PHYSICISTS

Measurement of radiation exposures
Analysis of radioactive material handling
Establishing radiation health control programs.

INDUSTRIAL ENGINEERS

Designing effective machine safeguards
Reviewing and assisting in plant lay-out
Analysis of material handling programs
Preparation of job and operation studies.

PUBLIC LIABILITY SPECIALISTS

Analysis of catastrophe possibilities
Study and control of public assemblies
Application of building codes and standards
Evaluation and control of product liability exposures
Design of controls to provide legal defenses.

FLEET ENGINEERS

Establishing driver selection and training programs
Developing vehicle maintenance programs
Training of fleet supervisors and driver trainers.

In addition to these skills we have also found it necessary to develop facilities to examine new or previously unsolved technical problems. Various companies have approached this situation in different ways. Our company has built a Research Center at Hopkinton, Massachusetts, dedicated and devoted exclusively to the solution of real or potential accident problems arising from the activities of our policyholders.

This is not a profitable operation if measured in terms of direct gain to Liberty Mutual. In terms of future profit to American workmen, it has already given promise of justifying itself. We believe that ours is a service organization and must contribute to the general welfare to justify confidence in its purpose and to this end we are proud to have pioneered in this phase of loss prevention activity.

TECHNICAL SERVICES

Now these special services are delivered by home office and staff people—available to support and assist the field servicing engineers responsible for first line contacts with the policyholders. Clearly, these skills are too numerous and too highly developed to fall within the scope of even the most versatile safety engineer.

In listing the special consultative technical services I do not mean to detract, in any way, from the ability or importance of the servicing engineer. His is the basic responsibility for the carrier's Loss Prevention Service. Most field representatives are graduate engineers, who have completed an intensive training program. They are capable of dealing effectively with 95 per cent of the problems they encounter but of major importance is their ability to recognize and evaluate the unusual situations and to obtain the assistance of specialists when required.

My second recommendation is that the policyholder acquaint himself with the specialized insurance services available to him and that he make known his need to his carrier's local loss prevention representative. This is a problem of timing. It is common for us to detect new problems in the plants of our policyholders that we might have earlier resolved at less cost and inconvenience if we have been consulted. In fact, in the designing stage of new processes we have often submitted proposals that were easily adopted but which might have been prohibitive after the operation was started.

NOTIFY SAFETY MEN

This situation leads logically to my third recommendation. The policyholder should alert his engineering and construction departments to notify the safety department and his carrier's loss prevention representative of new plans, new layout, new machinery, new materials, new processes, new products and extensive alterations while these changes are in the planning stage. In this way we can frequently forestall hazardous situations and avoid expensive changes that might result if the conditions are detected "after the fact."

I have made several inquiries of industrial safety directors and personnel managers to determine their view of an insurance company's role in industrial safety. I certainly got a mixed reaction. Replies ran all the way from "an unnecessary evil" through "too little and too late" up to the complimentary "principal force behind our program" and the one I like best—"They (the insurance company representatives) are like a staff of experts on our own payroll."

We all know that no two insurance companies are alike and the extent and calibre of loss prevention service rendered by these companies cover a broad gamut. These services are geared to reflect three forces—(1) the demands of the policyholders, (2) the cost of such services and (3) the insurer's philosophy or belief in the effectiveness of the loss prevention effort.

ACCIDENT PREVENTION BENEFITS

Modern industrial management knows the economic advantage of effective loss prevention but, in addition, has accepted more and more a broader responsibility for its human and community relationships. The desire to develop a solid community reputation for providing a safe and healthy working environment, to attract the highest calibre employees, to reduce turnover and absenteeism and to establish general goodwill has motivated industrial management to re-examine its accident prevention activities.

This examination sometimes indicates that there is much more that can and should be done. On many such occasions the insurance carrier is called upon to supply additional special services in keeping with the broader concept of managements' responsibility—and this demand motivates the insurance carrier to improve the scope and calibre of its services to meet the challenge.

Loss prevention service is exactly that—a service—and what the policyholder gets out of it will be in direct proportion to his willingness to make use of it. Many companies seem interested only in the immediate direct cost of insurance, failing to realize that in the final analysis the cost of losses is the greatest single factor in the determination of rates. In the long run, an individual concern will do well or poorly in direct ratio to its ability to reduce losses.

The cost of loss prevention service is about the same in any company—the important thing is what the company does with this expense money and what use the policyholder makes of the service. Since the indirect or uninsured cost of industrial accidents far exceed the direct or insured loss, the policyholder stands to gain much more than the carrier from effective loss control activities.

HIGHER CLAIMS COSTS

In today's expanding economy we are confronted with much higher claims costs because of liberalization of benefits and higher medical expense. It is a credit to the efforts of both policyholders and carriers that there has been no severe increase in Workmen's Compensation insurance costs. As a result of improved experience in industry the higher cost of cases has been partially offset by a reduced frequency and basic rates have increased only slightly in comparison to the cost of cases.

The attitude of the insurance carrier itself is an important factor. My company has been dedicated, since its founding, to the belief that it must contribute substantially to the prevention of loss and suffering so that our American insurance system will be more than a system of reimbursement for damages done.

The important points that I have tried to make are:

- There is room for improved understanding between insurance loss prevention engineers and industrial safety men in the policyholder's plants. Much can be gained by a re-examination of the two points of view because such an examination will reveal that there is a common objective which can be best achieved by close cooperation.
- Good communications between the insurance carriers and the policyholder are essential at management level. The policyholder can do much to be sure that proper working contacts are maintained.
- The insurance buyer should acquaint himself with the special services his carrier is equipped to render and should call upon these services when needed rather than waiting for the carrier to discover the need.
- The policyholder should promptly notify the insurance carrier of intended process, product or plant changes so that recommendations can be considered in the planning stage of such developments.

I am confident that the principles and suggestions I have made will have universal endorsement. If you are not well acquainted with your insurance carriers representatives, invite them to talk things over. You may be surprised to find that their thinking is little different from yours.▲

BUILDING SAFETY INTO THE PRINTING PRESS

The Latest Ideas

by ALBERT T. KUEHN

sales service engineer, Miehle Printing Press & Manufacturing co., Div. of Miehle-Goss-Dexter, Inc., Chicago

The latest ideas of safety built into printing presses are found in the presses designed and built after the last war. These are high speed Rotary Sheet Fed Presses. They are designed to print in one to five colors by both the letterpress and the offset lithograph process. They print anything from the size of a postage stamp to the size of a bed sheet (52"x76") at speeds up to 500 feet per minute.

Many safety devices are built into the presses, but the most important of all is the completely new design of the press itself. It is engineered for safe operation.

In the letterpress process we find that the design of large presses has changed from a flat bed reciprocating press to a streamlined Rotary Press.

In the offset lithograph process we find that the presses have changed from high, slow speed, cumbersome presses to low, high speed streamlined presses.

To appreciate fully the safety engineered into the new presses, let us take a backward look at one of the prewar presses. Here we see cams, gears and a maze of moving parts dangerously exposed on both sides of the press.

These hazardous areas are eliminated on the new presses. All cams, gears, and moving parts are enclosed in streamlined housings. Some of the parts operate in a bath of oil, others are automatically lubricated.

Now, it is perfectly safe to walk up to one of these presses, running at high speed, and pat the side of the press with your hand.

SAFETY IN PRESS OPERATION

The most amazing change in safety on the new presses is the simplicity of the press operation.

Just picture a flimsy sheet of paper, the size of a bed sheet (52"x76"), being printed.

First the sheet is separated from a pile in the feeder and is moved on tapes to a position where it is registered. It is then accelerated to the speed of the press and transferred to the printing cylinder. The sheet is then printed in one to four colors while it travels from 300 to 500 feet per minute. Next, it is decelerated, stopped and placed on a pile in the delivery. This goes on for hours with very little attention by the pressman.

The press is automatically tripped off, when damaged sheets are fed to the press, or when they are not accurately registered.

It is now possible to print the finest quality on the large sheets, at the fastest speeds, with complete safety to the operator. This is the most amazing change on the new presses.

SAFETY IN PRESS MAKEREADY

Press makeready includes placing ink, water, paper and printing plates on the press. Next, sheets are printed and adjustments are made to register colors on the printed sheet. After completing the press run, the printing plates and the ink are removed. The press is then "washed up" for the next printing job.

During the makeready operation one to four men work on different parts of the press at the same time. To prevent accidents, many safety devices and means are built into the presses. Electrical push-button safety stations and emergency stop stations are located at many convenient places on the press.

A safety bar is located where printing cylinders come together. It prevents the operator from placing his hand between printing cylinders. The slightest movement of this guard brings the press to an emergency stop.

Other safety measures include ink roller guards and perforated guards at the printing cylinders and at the delivery end of the press. Wide platforms and hand rails are other safety measures.

SAFETY IN PRESSROOMS

- How effective are the safety measures built into the latest presses?
- How do many accidents occur on presses?
- How can they be prevented?

To find the answer to these questions we visited a large Chicago printing plant, operating about 50 printing units. The pressrooms foreman told us that accidents occur on the presses at the rate of one per month. The causes are immediately investigated. In most cases, the causes are carelessness and disobeying orders pertaining to safety practices.

The foreman said that the number of accidents on the presses today are only a fraction of what they were previously. He could offer no suggestions for additional safety measures.

This brings out the fact that the latest ideas in safety are effective.

Our engineers are constantly on the alert for safety suggestions. They cooperate with safety committees.

The latest ideas in building safety into printing presses are:

Safety in the design of the press

The presses are lower, all outer gears, cams, and moving parts are enclosed in oil tight housings and streamlined guards.

Automatic lubrication eliminates the need to work in hazardous areas.

Safety in the operation of the press

Little attention to the press is required after printing production starts. Automatic detectors check the register and the transfer of each sheet.

The press is tripped automatically when a damaged sheet is fed to the press.

All operating controls are located in non-hazardous areas.

Safety during press makeready

Safety switches, tripping devices and emergency stop switches are located in convenient locations on the press.

Safety guards are placed over ink rollers, printing cylinders and at the delivery of the press.

Pressroom foremen experience few accidents on the Advanced Design Rotary Presses. This is truly a sign of progress in building safety into the printing press.▲

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

THE PULP AND PAPER SECTION

This volume is a record of the sessions held at the 1957 National Safety Congress by the Pulp and Paper Section. The conduct of these Congress sessions each year is only one of the many cooperative activities which the Pulp and Paper Section carries on in behalf of its members, and for the benefit of accident prevention work in the pulp and paper industry generally. The Section gives guidance in the preparation of a great variety of technical and educational material useful in the day-to-day safety programs of pulp and paper plants. The activities of the Section are under the direction of its executive committee, the members of which are listed at the close of this volume.

SAFETY IS A STATE OF MIND

by REX PAXTON

director, public relations, Sutherland Paper co., Kalamazoo, Mich.

In Public Relations we try to produce a state of mind for a product, an idea or a person. In the case of safety it's an idea. When we accomplish this the end result is agreement and acceptance of our safety programs. When our ideas are accepted our publics are "with us". And when people are with you they follow you because they understand and believe that their best interests are safe with you.

When untrained men are suddenly committed to full combat, this unskilled unit will lose approximately one-third of its men —*rapidly*. But, the remaining two-thirds will not only live—but will survive combat after combat.

Why? Because of a *state of mind*. Because of an attitude of mind that influences these men and convinces them beyond every possible doubt that they *must* do certain things—and avoid doing other things—so they may *stay alive* in combat.

Instinctively they conduct themselves to avoid becoming involved in any harmful situation. They survive because they no not panic when the unexpected occurs. They survive because they think *think safety*.

Someday in your own plant, you will go a full 365 days without a single disabling injury. This will occur when everyone in your employ lives up to what we know will create this ideal situation. This will happen when we get our people really *safety-conditioned*.

COMMUNICATIONS—ANSWER FOR SAFETY

Public relations is simply communicating *deserved respect*. All that we do and say is dedicated to the preservation and perpetuation of human life. What could possibly deserve more respect than this great humanitarian endeavor?

We do not necessarily have to work harder in our safety programs. But we must work smarter, more skillfully, and more professionally to communicate this state of mind toward safety. Here in the United States, we have the most efficient elaborate machinery in the world for communication. Yet, communication remains our greatest problem and the world's greatest problem.

We must deliver our impressions daily, like newspapers, to the mental doorsteps of our people. We can never accomplish this until our employees are on our *safety team*. This team-spirit is the answer to our safety problems.

Our problem is communicating the right ideas at the right time. You know the right thing at the wrong time becomes the wrong thing. Timing is just as important in our work as it is to a humorous speaker, or a television comedian. In our study and brilliant march of progress in America we have passed through four ages of communications:

1. The age of silence.
2. The age of half-way communication.
3. The age of one-way communication.
4. The age of two-way communication.

In the first age, business said absolutely nothing to its publics or its employees. Its business was its business and not the public's. In the second age they began to speak softly and to undertake a token, or half-way communication: Businessmen found that it paid handsome dividends to tell people a little something about its affairs.

Next, it tried the one-way communication. Business then found that the more people knew about its company, its employees, its products, and its policies, the more they wanted to do business with it.

Today we are in the fourth age—the two-way communication stage, when we not only speak but listen. If you want to know what your public is thinking it pays to listen. This two-way communication is not necessarily a new dimension for safety experts. But it is an area we can use to far greater advantage.

When we speak, is anybody listening? Are we getting through? Here is the *key to our success in safety work*. Our people

must not only hear what we say, they must *accept* what we say and *agree* with us.

What's the secret of influencing people? I believe it is from the standpoint of *what interests them.*

In 1956, 95,000 persons died *accidentally* in this country, and another 9,500,000 were injured. Total casualties? 9,595,000! The *state of mind* toward accidents in this country must change.

STATE OF MIND IS CHANGING

It is changing. There's positive proof in the steel mills, which have done a magnificent job. But conditions weren't always as safe in the steel industry. In the early days, the injury and death rates were appalling until Stewart Holbrook wrote that the best location for an undertaker's establishment was near the exit of the steel mill properties in Gary, Indiana. The steel industry then took safety to heart and *did something about it.* Now, steel enjoys a rate of only 3.83. This is most convincing compared with other industries. The fluid milk plant for example is six times more dangerous than a steel mill.

Perhaps the little lad from the south was thinking about safety when he got his first job in a big defense plant where hazards were numerous. He was quite confused and had to do something, so he painted a sign and pinned it to his shirt. The sign read "In case of accident dis *vas* Johnny Jones."

Accidents never just happen. *They are caused.* An accident not only affects the individuals involved, but the company, and many others involved in reclaiming merchandise.

In creating and perfecting our safety programs we can never operate a "closed mind" shop—anything we do now can and will be improved. There is always a better way. Our greatest need is *new ideas for safety.* Nothing is as powerful as an idea whose time has come. *Safety-consciousness* must be invested with sovereignty.

You recall when Caeser landed in North Africa, he ordered his troops to burn their ships. Then he told his warriors if they ever expected to return home and see their wives and children again it would be in the enemies ships. He created a *state of mind* so intense, so dynamic that the safety of their very lives depended upon accomplishing certain things, without failure. His communications were direct and his audience *listened* and were *determined* to do what he asked.

The airlines have taught all of us an impressive lesson in safety work. In the beginning their No. 1 problem was to overcome *fear* in passengers. Their job was to *communicate safety.* Fortunately, they recognized that this was their No. 1 problem. And they have solved it through the channel of communication. Good public relations and the science of communication intelligently applied by the airlines have solved this fear and created a state of mind in their passengers giving them a sense of security and safety.

"GET THROUGH" TO PEOPLE

We are striving toward a vital goal—influencing a state of mind—for SAFETY. We accomplish this only as we "get through" to our people. You know it doesn't matter how good our safety programs are if people do not think they are good. It is what people think that counts.

No company can survive without a good safety program and a capable safety executive. The people now expect this. Safety is a vital part of our code of ethics—a *must* in our obligation to our way of life here in America.

Management must be sold on the need for safety, to encourage employees to participate in sound safety practices. This is a continuing job. It cannot be turned on and off like water. Our job is to convince every individual in our employ that it is to *his best interest* to be careful, to think safety.

The time to *duck an accident* is before it happens. A good safety program goes to work *before* accidents happen. I don't know of a more effective highway safety sign for example than the one on the side of a Police Patrol Car. The state of mind produced by the patrol car is one of caution and alertness that makes one think and act *before* an accident happens. He slows down his speed and becomes thoughtfully cautious. I believe the day is nearer than we think when public sentiment itself will be so powerful that accidents on the highways, in the homes, and in the factories, will grow less and less. I came to this conclusion when I read the Safety Council's prediction that the second million would be killed in traffic accidents in about 12 years at the present rate.

Most accidents are caused by pre-occupation, wrong general attitudes, or ignorance of the basic safety rules

Often a man's mind is not on what he is doing. He's preoccupied by home troubles or other things and becomes careless. We cannot go into the homes of every one of our employees and see that peace and tranquility prevails. We can't hang on every wall the beautiful sentiment "Home Sweet Home." But we can and must conceive *new ways* of changing the thinking of our careless employees. And when you change the thinking of an individual you change everything. This can be done. It is being done.

Last year General Motors enjoyed its best safety record. Fully 99.8 per cent of its 500,000 employees in the United States and Canada lost not a single day—not a single hour—because of occupational illness or on the job injury. Accepting the award Harlow H. Curtice, President of General Motors said his organization spent $30,000,000 a year on accident prevention and health insurance.

Curtice said "the outstanding performance of G.M. in 1956 is a real tribute to the cooperative efforts of all G.M. employees, and the members of supervision who guide them in applying safe working habits in their daily jobs."

Top management is the *golden key* to the whole safety structure. Oddly enough they often have been the most difficult to convince of the need for *positive action* in safety work. Top management must not only finance but actively give their moral and oral support to this important segment of industries' responsibility.

A NEW DAY IN SAFETY IS DAWNING

Man's ambition to improve himself is the basic force which established our highly satisfactory way of life. This is the place where almost everyone in the world would come if he could. Here in America our freedom of thought and action has brought to light many useful wonders in this age of miracles. We must match these miracles of modern times with miracles of safety habits.

Think of the miracles in the engineering and construction field. One of the most dramatic buildings in America is the new Prudential building in Chicago. The Prudential had to purchase air rights from Illinois Central Railroad to build this modern structure.

The marvels of Univac and other ingenious creations of man stagger the imagination. These—and thousands of other reasons explain why we cannot be satisfied with safety standards, precautions and records that are outmoded. What is good enough today is not good enough for tomorrow.

You, as key men in safety programming, are the "radar." You must see what *could happen,* and then see that it *doesn't happen.* You guide the men under your command. You are the top echelon of safety in America. You are the leaders. And the hardest part of being a leader is to keep on being a leader. But as leaders you know that the price of safety—like the price of peace—is *eternal vigilance.*

A new day is dawning. There is much to encourage us that the state of mind for safety is changing. I was riding on a train one day to Detroit. It was broad daylight, the weather was perfect, but a man driving his car didn't see the engine and hit it squarely in the middle. Fortunately he was not killed. You say what's strange about this? There were about 200 to 300 people *on this train and no one felt sorry for that man.* Rather the feeling was one of impatience and even disgust.

I heard these remarks "I have no sympathy for anyone who will do this in broad daylight." Another person said "I can't feel sorry for him." This man through his carelessness had interrupted the plans of all of *these* people and *they didn't like it.* What he did was unnecessary. That's the key. There is the awakening attitude.

There is indeed power in this state of mind. Safety executives who really get things done know when they change the thinking, the attitude toward safety, they accomplish amazing results, like the steel industry.

Here's proof that a new day in safety is dawning. The accident rate in 1956 was nearly 40 per cent lower than the five year

period of 1908—1912—or 60,000 fewer persons died in 1956 than would have been killed at the old rate in the period just mentioned. *And the National Safety Council is responsible for this great contribution to the saving of human life.*

Once the whole known world was ruled by Caesar. Man lived but to please Caesar. Then came a light out of the East. A man came out of Galilee preaching the philosophy "do unto others."

When we can, in our safety crusade create this philosophy, this state of mind "do unto others as ye would that they should do unto you," we shall have reached that exalted state of mind when we think, not in terms of accident reduction, but in terms of NO ACCIDENTS AT ALL.▲

ACCIDENT INVESTIGATION

by HAROLD A. SEWARD

secretary-treasurer, Lehigh Valley safety council, Bethlehem, Pa.

In the safety movement there are people who know how to investigate accidents and those who don't. In fact, there are four classes of people in the safety movement as far as accident investigation is concerned:

1—Those who know how and who know that they know how—they generally use accident investigation to good advantage.

2—Those who do not know how and know that they do not know how—they are generally eager to learn, do learn, and do something about it.

3—Those who know how and do not know that they know how—they generally are not in a position to follow through with their knowledge.

4—Those who do not know how and do not even know that they don't know how—this is the group that is referred to as hopeless, although they still can be shown and can profit from the explanation.

Accident investigation can be used as a marvelous tool in the safety program—a real tool to help in the prevention of accidents. There are five parts to a complete accident investigation: the Facts (the investigation itself), the Report, the Analysis, the Recommendation, and the Follow-Through.

In the general safety program, before we can do anything, we must first find out what our problem is, then go on to solve it. We first find the Facts. Then we add the Analyses, then we make our Plans, then we put our plans into Execution. We should then get what we are trying to achieve: Accident Prevention. Here we have a formula:

Facts plus Analyses plus Plans plus

Execution equals Accident Prevention.

Sometimes we do not get true Accident Prevention. Sometimes we have done something wrong and the result does not reduce our accidents, does not cut down on the number of accidents, does not bring us true Accident Prevention. Then we must go back and start over, review our efforts, re-plan and execute again—then, we should get real accident prevention. Since the safety program is no good unless it is continuous, this must be done continuously; we must constantly check the results of our program.

We might say this is costly. But in an accident prevention program, if it really *does* prevent accidents, there is no cost, for *safety is an investment, not a cost. The safety program is insurance.* We never consider insurance a cost, but an investment which returns us handsome dividends.

The five parts of accident investigation agree with the main parts of the general safety program. Good accident investigation can aid the safety program and can help to produce accident prevention in a number of ways.

First, consider how we get the facts in the investigation: we must find the Who, What, When, Where, Why, and How. Then, we make the Report and here we find out the Scope and Degree of the accident.

Next we analyze the report. In the Analysis we should find the Remedy for this kind of accident. This leads us to set up ways and means of preventing the recurrence of this accident. Then we are doing Prevention work. Now, we come to the fourth part of our total accident investigation action: the Recommendations.

Recommendations come in the three well known E's of safety: Engineering, Education, Enforcement. The Recommendations may be just in Engineering, or just in one of the other two. They may be in a combination of any two, or they may be in all three. But, the important thing is to make the proper Recommendations to cover the possibility of recurrence.

Since safety has only one goal, our Recommendations must aim at accident prevention. Accident prevention is the one goal of any safety program. *Safety has only this one goal.*

Up to now everything is fine. We are making a very fine accident investigation and we have carried it through the report, analysis, and the recommendations. Everything should work out all right now. However, in actual practice, it will never work out unless the fifth and vitally important step is taken. This is the Follow-Through step. Without this we have nothing but a paper record, nothing but good investigation but we have no insurance against that accident's being caused again, no real accident prevention.

It is of utmost importance that top management be completely sold on this Follow-Through and that each echelon of management right on down to the last worker does Follow Through to insure real accident prevention. There is no point whatsoever in investigating accidents if we do not want to achieve accident prevention.

To investigate for its own sake is ridiculous. To accumulate a lot of information that we are not going to use is bad and costly business. If we want our safety program to be an investment and not a cost we will use our accident investigation procedures to bring about accident prevention and thus bring in the dividends which the investment should show.

There is no use in taking the four steps in the accident investigation procedure if we are not going to give the Follow-Through every ounce of energy it should get in order to carry out the Recommendations so that through good Engineering, Education, and Enforcement we arrive at good Accident Prevention.

If we go about our Accident Investigation in this manner, all the effort and money we put into it will not be a COST, but truly an INVESTMENT that will pay us handsome dividends and lead us to real ACCIDENT PREVENTION.▲

ACCIDENT INVESTIGATION

by PATRICK J. REILLY

labor relations representative, St. Regis Paper co., Pittsburgh, Pa.

I hope that what I have to say in this paper will contribute toward the solutions of the problems in accident prevention—solutions which involve the individual and the group which in effect includes all of us whether we be hourly or salaried, laborer or top management, union or non-union—for fundamentally accidents have no discrimination. They draw no boundary lines and hence they become the responsibility of all of us.

Your superiors and mine know that their investment in the National Safety Congress will in some way bring dividends to it and its employees by way of furthering the campaign of accident prevention. We must all realize that this is but another tool in the field of safety—granted, however, an important tool. For here we proclaim in spirit and in numbers the importance of collective participation in and the recognition of active safety programs and continued research in the field of accident prevention.

The Congress should be the culmination of our endeavors in the field of accident prevention, not the beginning but rather the

highlight of them. For the groundwork of safety should have been laid back in our individual plants. Just what is that groundwork and how is it put into effect? How is it motivated?

To answer these questions I feel that we must explore the meaning of a plant safety program—its, origination, its elements and its final objectives.

OBJECT OF SAFETY PROGRAM

The final objective of a good safety program is obviously the easiest to answer—to reach the point where we are free not only from immediate accidents but free in spirit that we have done all we can to prevent future accidents.

Probably the most important but yet the most difficult area to explore is the area of the elements of a good safety program. I think that the following elements are the most reasonably accepted:

1. Top management recognition and leadership.
2. Assignment of and acceptance of responsibility by the officials directly given the task of putting that program into effect.
3. Acceptance of individual, collective, and union responsibility for accident prevention.
4. Concentrated job training in so far as safety practices are concerned.
5. Maintenance of safe working conditions.
6. Adequate first-aid and medical conveniences.
7. Accident record systems.

These elements are certainly not all-inclusive but they comprise the hard core of any safety program whether it be in a plant of 100 or 1,000 employees.

TOP MANAGEMENT'S JOB

First and foremost—top management recognition and leadership; secondly, the assignment of and acceptance of responsibility by the officials directly responsible for putting a program into effect; and thirdly, the acceptance of individual, collective, and union responsibility.

A short time ago the quiet serenity of a small town paper mill community was disrupted tragically by the shocking news to its workers, their wives and children, that a death had occurred in the mill—an accidental death—but nevertheless, a death.

Jim Jones, a relatively new employee, was the victim. Upon investigation we find out the following:

Top management was shocked. Its chief official stated that only two months prior to the accident he had given permission for two hours a week to be spent on covering accident prevention. He added that he always suspected it was a waste of time and money and that he was talked into it against his better judgment.

The personnel manager admitted that Jim Jones had not been given the usual indoctrination which includes the safety checklist and that there had been no follow-up with the employee and his foreman due to the pressure of other activities. Safety had been postponed. The foreman didn't have any time to give job instruction to Jim Jones.

After all, he said, when the boys in the front office are putting production pressure on me, I just can't take time for job instruction—that has to wait until I can fit it in. If Jim Jones could give his excuse, he might say that he didn't realize the danger to which he exposed himself. This was the first time he had ever been around heavy machinery. He thought his particular action was a safe one.

In most of the foregoing comments we have indicative evidence of the lack of at least some of the major elements of a good safety program.

NO JOB INSTRUCTION

The foreman under whom Jim Jones worked hadn't given him job instruction which included safety instruction due to the pressure of production. He presumed that this could wait. This foreman, knowingly or not, violated the principle that instruction in the field of job knowledge and accident prevention must be a major part of the indoctrination of all new employees. He violated the principle that his was both an individual and collective responsibility in behalf of accident prevention.

The absence of this responsibility immediately ruled out any chance of success for the safety program existing in this mill for its success rests in the hands of those on the firing line. The most elaborate organization, the finest equipment, the best laid safety campaigns in the world, go down to ruin if supervision is unaware of its immediate responsibility in safeguarding those under its jurisdiction.

The acceptance of responsibility is elevated to an even higher position if your plant happens to be unionized. Through organized labor we can find a medium which is not in the least reluctant to help spearhead a good accident prevention program provided all of the other elements of that program are faithfully met—and those other elements rest in the hands of management whether it likes it or not.

You cannot blame organized labor in certain plants for its cynical attitude toward a safety program if that attitude is, as is so unfortunately true, based upon the indifference and lack of initiative of management. Don't let us necessarily take pride in the fact that we may reward our unions or our individual employees either monetarily or otherwise for good safety records. Do we offer a reward to an individual for protecting his own life? Rewards are gimmicks and gimmicks are sometimes necessary to keep the spark alive—but let us keep them in their own perspective.

BELIEVE IN PREVENTION

Top management told us upon our investigation that, in effect, it had allotted two hours a week toward safety conferences. It told us that it had the best, insofar as the elements of medical care, accident record systems and accident maintenance programs were concerned. It also told us that much of this had been done against its better judgment. Need I say that top management, by making that statement, failed where failure is worst of all—failed because it gave cognizance to, but apparently did not believe in, did not have faith in, the very thing it was endorsing.

It might have been better if management had remained silent on the whole subject of accident prevention because then those in lesser roles of top management, namely those directly responsible for the activation of the safety program, those responsible for training, job instruction, and employee participation might have done their jobs more conscientiously, if they were ignorant of the indifferent attitude on the part of their top superiors.

By giving piecemeal acceptance to the elements which we have outlined and thus to the whole system of accident prevention, the thinking of top management permeated through the logical channels usually followed. Indifference, voluntarily or involuntarily, was assumed right down the line, rightfully or wrongfully.

SAFETY PRODUCES EFFICIENCY

Is this a castigation of management insofar as the organization and effectiveness of a good safety program is concerned? Certainly not! Most of our companies in the Paper Industry are well aware of the sincere faith which they must put into the creation of a corps of specialists to deal with accident prevention and not merely to let it rest on pious wishes. Top management, as a whole, realizes that a good safety program not only produces efficiency, but also that that efficiency must include the safety program.

It realizes that unnecessary harm to human life can be of itself morally evil and that any indifference to that conception can only be accepted as moral guilt. I work for a company which has recognized its moral and practical responsibility for safeguarding its employees. And you, too, represent companies which uphold the same philosophy in respect to accident prevention. We cannot emphasize enough the importance of having this philosophy impregnated in the mind of the rank and file employees at our individual plants.

The three important spheres in our local plant safety program are its honest initiation by top management, its activation and organization by secondary management and its acceptance and workability by the rank and file. It is in this latter sphere of the rank and file that we may be committing sins of omission by not utilizing one of the greatest weapons we have to combat accidents—namely, our labor unions.

The unions want to participate actively because they, too, have the safety of their members sincerely at heart. We might go so far as to say that if management is content to rest on its laurels, the day may not be too far off when unionism, through its research and efforts, in the field of acci-

dent prevention, may well be the larger contributor to the cause. Both management and labor working hand in hand, reaching for the same objectives, can scale any pinnacles in the march toward an accidentless existence.

I feel certain that at best I have given you a rather vague conception of what exactly are the elements of a good safety program. In short, they include all of those things which go toward the initiation of, the administration of and the acceptance of the program itself. I have tried to emphasize the salient points, top management recognition and leadership, the responsibility of the individuals directly charged with carrying out the program, employee acceptance and responsibility, both individual and collective, and job instruction.

If we succeed, and succeed we will, in the field of accident prevention, let us thank God for it and compliment our own human resourcefulness. But if we fail, let us blame no one but ourselves.

THE ROLE OF THE TRADE ASSOCIATION IN INDUSTRIAL SAFETY

by THOMAS CLELAND
director of industrial relations, Fibre Box Assn. & Fibre Board Assn., Chicago

During the past 30 years the science, the economics, the culture of this country have been undergoing changes. These changes are coming so rapidly that we have become accustomed to change. Such rapid changes of necessity bring problems. Our methods of living, of producing, of distributing, our social and political lives are changing so rapidly that it becomes obvious to the individual that he can't handle all of this alone.

This is especially true of the manufacturers and business men. These men do not have the time nor the resources to cope with the problems brought about by these spinning forces that are bringing these changes and so a new function or entity comes into being. This function is the trade association. It's an attempt to stay alive to the problems, to find solutions for them. Trade associations come into existence to do the things for the group which the group cannot do properly or effectively as individuals.

SINGLE PURPOSE ASSOCIATION

Today, for the purpose of this discussion I would like to divide associations into two general areas. We have the single purpose association and the multi-purpose association.

In the single purpose association as the name implies, a group of men, manufacturers, companies, units, get together to effect one purpose—to develop action along one line. We have an outstanding example of this in the kraft paper industry in the South—a safety association.

Here a group of companies, represented by their safety men, is carrying along a program devoted to improving the safety record of their industry. They are doing an outstanding job, represent the function and achievement of associations as well as any that ever existed.

There is always a reason for an association. Some people get together to do group buying for the obvious advantage of volume purchase. Some groups are organized to bargain out a labor agreement with a union. Some groups form to do research on a project sharing the cost and the results equally. But there is always a reason, a purpose which can be better served by group action.

In the kraft paper mills safety association there was a problem of safety. Two or three safety men were alarmed about it. State and federal authorities were not happy. So these few had a meeting, agreed to meet again and an association was born. All that was a long time ago and today that association's work stands out as one of the finest contributions one group of men can make to another.

These single purpose associations are not strictly trade associations in the true sense of the word. The typical trade association is concerned with many things and safety might or might not be one of these activities.

SAFETY IN TRADE ASSOCIATIONS

Let's talk about what one of these typical trade associations might do if the directors of that association should decide to take on safety. This puts us into the every day problem of Al Baltzer who heads the small business and trade association department of the National Safety Council.

As safety men know most of industry's accidents occur in small companies. It is an obviously valuable notion to reach these small plants with a message on safety, through the medium of their trade association. Here these companies have a mutual problem. They have identical equipment and operations, they have the same hazards and most important there is in existence a whole mine, a large mountain of experience locked up in the mind of the members of that association.

This experience can be good, bad, or indifferent, but it can be exploited by the association which can bring it all together and focus it on the single problem of safety —the safety of that industry. The association can become the rallying place, the unitizer; these members are association minded, they are accustomed to the association. So there is the potential. Now, how best to exploit it?

WHAT ASSOCIATIONS DO

You gentlemen are safety directors and safety engineers interested in achieving a perfect safety record for the companies that employ you. And there is a most remarkable similarity between what you do for your companies and what an association man does for an industry. There is an even more remarkable similarity between how you do what you do for your company and how that association man does what he does for his industry. Let's look at that.

For all of you there was once a day when you were called in and asked to take over the safety work of your company. In the natural course of events you had to know how much there was to it. For all you knew, your firm might have been the safest place to work in the whole world. You didn't think so, but you couldn't prove it so you set out to discover the situation.

You surveyed the problems. You dug into the records, the reports to the insurance companies and the accident reports. You tried to find out the scope of the problem. You wanted to find a path to follow. So as you did for one plant or one company so does the association man. When he takes the job he wants to know what size, what obstacle to progress, what record in the past. And he finds this out by investigation, by survey. He doesn't know but what he might have the safest industry in the world. He would take odds that it wasn't but he doesn't know and so he finds out.

He does this for 200 or 300 companies. Not that his job is any bigger because of the number but because he has to know about an industry what you have to know about your company. Where is it good? Where is it weak? Where can we improve? What are the problems which need immediate attention? What kind of a program can we begin? What form shall that program take? All of this based on what he has learned about the industry.

RECORD KEEPING

First part of any successful safety program is keeping records. This is true in individual companies as well as associations. You have to know where you're been so you can go ahead in the future and see what progress you're making and avoid repeating mistakes. So after we have surveyed we start a program of keeping the record.

You do it by departments in your plants. We do it by plant in our association. You start competitions between departments based on the record. Associations start competition between plants in the industry. You give awards to the departments. We give awards to members.

So the association uses records in something of the same way that you do. Yours are a lot more particular and more valuable to you as a company but we use them to

get impetus, to get attention, to isolate the danger spots, to get the history of safety, to give it the kind of clinical attention a doctor gives a problem.

Another area where associations do about the same as you do is in safety meetings. You have safety meetings in your departments, in your plants—your committees, your five-minute, stand-up meetings conducted by your foremen, your meetings with your foremen. Why these safety meetings?

You say meetings engender interest in safety. They maintain a consciousness of safety. They develop the interest in safety that's necessary. They develop an atmosphere of safety, sharpen the instinct for safety. They show the employee that you're interested in safety. They give an opportunity to assess blame, to investigate suggestions, make improvements. It can be said that safety meetings are the best possible demonstration of an active safety program.

What you say about safety meetings in your plant I say about safety meetings in association work. We want to engender interest. You have had supervisors or superintendents who didn't care about safety. Who might even have said, "All that safety guy wants to do is build up his job." They have a negative attitude and somebody has to make a Christian of them before a savage accident teaches them the hard way.

So in a safety meeting this reluctant one gets a chance to talk to his own kind of people. Other superintendents or foremen and he hears from them. He gets their opinion based on their experience and the others help you make him a convert.

ASSOCIATION SAFETY GROUPS

So it is with association safety meetings. We have members who don't wish to be bothered, who are sure the safety man is trying to build up a large job for himself. But in a meeting he meets his own kind, he talks to them and soon he is coming round. Without meetings this is not going to happen. Meetings held at regularly spaced intervals on the part of the association engender the interest in safety in an industry as they do in a plant.

Here members are discussing how to improve their records, what programs are followed with regard to safety shoes, eye protection, responsibility and investigation. everyone speaks up. This shows the members that the association is interested in the problem and is willing to help. Just as safety meetings are the best possible demonstration of your interest in safety to your employees, so our safety meetings perform the same function for us as far as our members are concerned.

There is one angle of these safety meetings where you men holding meetings in your plants have something of an edge on the safety man who works for an association. Yours are usually fairly willing audiences. They work there and they've been in the habit for some time. And there is an obligation to go which can be backed up by authority if that becomes necessary.

DIFFICULTY PROMOTING INTEREST

Association meetings are not like this. We get the meeting set up, the agenda as interesting as we can make it. We call on volunteers until they are ready to hide when they see us coming; we get out notices for the meetings; we follow the notices with reminders; we plead and cajole and get as near to the line of being pests as we can and too often we don't get the size crowd we like. Size is not important. It's just that it is used as a measure of interest.

When you have an industry made up of a great number of small employers, they don't have full-time safety men. The safety man wears many hats. He's labor, personnel, purchasing, expediting, safety. For this man to leave that plant for a day or two devoted entirely to safety is sometimes a little bit of a problem. And it's one that contributes to the frustration of being a safety man for an association.

To this time I have mentioned the many areas where our jobs seem to be similar. We have surveys, records, and meetings. I mentioned earlier the gimmicks that safety men use to increase or retain safety consciousness on the part of the employees in a plant and, of course, we are always seeking the same thing.

In this area we are presently working on a program which we hope will accomplish this end—to improve the safety consciousness of the particular plants we serve and also to identify the association with the effort being put forth on behalf of safety in our particular industry. We hope to accomplish this with safety posters. Now everyone knows that posters are only a small part of an overall safety program. Someone once said about five per cent.

IDENTIFICATION IN POSTERS

But there is an area here for association activity that first can help accomplish that five per cent and second can show the members of the association that something is being done. Again we depend upon identification. We have series of posters which carry a general safety message backed up by pictures of our machinery. If we have a poster on falls we have the guy falling over something that you find in one of our plants.

On safety shoes we have his foot being injured by something which might injure his foot in our plants. On specific hazards we have our specific machinery. We also include on these posters some statistical information concerning our industry.

We tell how many accidents we have had of a particular type. We want the safety people in our plants and the employees in those plants to identify themselves with the effort we are making in the direction of industrial safety. We want their ideas for posters. There's another point about these posters.

We have many small employers who pay small attention to safety and we like the idea of this type of plant using posters. When they put a poster up on their wall they are declaring themselves as in favor of safety and their action had better suit the words or someone will be pointing a finger at the posters. Advertising is usually followed by action and action is what we are seeking.

ENCOURAGING SAFE ATMOSPHERE

We have hopes that these posters will bring about an identification. One of the wonders of human nature is this instinct for identification. The men in your plants identify you with safety efforts. You are the constant reminder to them of safety. You seek to engender an atmosphere of safety. And the efforts you put forth along this line are in the direction of getting the employees, the foremen, the superintendents to identify themselves with your efforts.

That's what we are trying to do with this poster program. It shows the safety men in our industry that we are trying to do a job and hope that they will identify themselves with our efforts and all to the end of achieving a safer industry.

There is another area of effort where we are both concerned. As safety men we know how hopeless our job is unless we have the interest and support of top management. And we have this job in common. Just as the top management of your company is your employer so this same top management is our employer.

NEED MANAGEMENT'S SUPPORT

There is a large difference in the actual employer—employee relationship. And this difference enables you to help the trade association safety man and it also enables the trade association man to be of assistance to you. You want his interest in the plant or company and we want it as a member of an association, as a dues-paying member of an association. If your top management is interested in seeing the trade associations have a safety program then the association will have a safety program and if the top management has no interest then the association safety program will never get off the ground.

The safety men of an industry have an obligation to tell their top management about the value of the association program, the ways in which this program enables you to do your job better. And if you think, or sincerely feel that you don't need an association activity then you should tell him that. No use having an association working away at something like safety if the safety men in the industry don't feel it has any value.

The "how" of getting top management's interest is a most fascinating topic. How is it done? As many top managements as there are, so there are ways of getting their interest. It is an individual thing. As an association we are using costs. This is not to imply that top management is a group of heartless inhuman people. But only that we are absolutely sure that they are interested in costs.

In these past two years many industries have been caught in something called the cost-price squeeze. Stated simply, the costs

of doing business have skyrocketed and the prices have staggered. And when this unhappy circumstance prevails for any length of time you have this squeeze.

COST-PRICE SQUEEZE

Since industry is operating in a sharply competitive atmosphere, not much is expected in the way of price relief and so eyes turn to costs, how to reduce costs. You know the savings possible in accident prevention. And so at this time, perhaps as at no other time we have a wonderful opportunity to pitch our message on behalf of safety.

Too many times leaders of industry are absolutely sure that they have gone as far as they could with cost reduction, that there are no more corners to be cut, that the reasons for these increasing costs are to be found in forces far removed from the everyday business life and that they can do little except shield themselves from the blows and buffets that are coming upon them from all directions.

CUT ACCIDENTS—CUT COSTS

There are many leaders of industry who overlook obvious matters when it comes to matters of cost. One of these is the money to be saved by a program of accident prevention. The tasks of an association man are to tell top management this story—to get them to look into their own operations with more scrutiny, to assess blame for these costs and to indict managers and superintendents where this is necessary. This placing the blame is a function of top management.

One of our company presidents had an idea for assessing blame. He had his safety man draw a bar chart showing on the right-hand side the location of the plants and then a line made of dollar signs going out to the right-hand side. There on the chart he had the cost of accidents assigned to each plant.

On the bottom of each chart there was a little note from the company president. "Isn't this an interesting chart." It was so interesting that in two years that company had the best safety record in our industry. Now that company president wasn't interested in achieving the best safety record in our industry. He was interested in dollars and cents of cost.

This is what a trade association can do for the safety men in his industry to keep this message before the top management. How well we do it depends on opportunity and timing, because if the boss is interested in safety, we're on our way to the ultimate goal we all seek. That goal is safety; factories, mines and plants where people are not hurt, where there are no accidents.

DO THE "IMPOSSIBLE"

This takes the imagination and challenges belief. Imagine a country where there are no industrial accidents! This is an age where the impossible things are being done. You could get a lot of people who would absolutely swear that no one would ever climb Mt. Everest. But some fellows didn't believe those people. They climbed it.

For those industries where the record has been good, where it started way up high in frequency rates and has come way down there is a worry. They are concerned with the thought that perhaps they can't get any safer, that the ultimate has been reached. For those industries I would leave this message.

The name Whirlaway is familiar to all of us, that wonderfully game thoroughbred that thrilled the racing fans of our nation some years ago. You remember his incredible runs in the stretch, how his jockey would take him way outside on the outer rail, and then head him for the wire. With his long golden tail flying out behind him he would pass the other horses as though they were standing still.

So when you think you are as safe as you're likely to be—as safe as possible—remember Whirlaway with his golden tail flying in the afternoon sun as he headed for home. This magnificent horse always ran that—long—last—quarter mile of the race faster than he ran the first.

CHEMICAL HAZARDS OF ALKALINE PULP LIQUOR MAKING

by BOOKER P. BUNCH

technical assistant to the Production manager, Chillicothe div., The Mead corp., Chillicothe, Ohio

Compared to many industries, the chemical industry has a most commendable safety record. It is not because of the inherent nature of the industry, for the manufacture of chemicals presents hazards comparable to any manufacturing process. Rather it is because, as an industry, the chemical group is extremely safety minded and goes to great lengths to acquaint its employees with the nature of the product they are processing and of the potential dangers involved in improper handling of materials.

Alkaline pulping is sort of a first cousin to the chemical industry, for it involves the processing and handling of a variety of chemicals. And the success of our industry, like that of the chemical industry, is certainly dependent on the awareness of our employees to the nature of the materials with which they are dealing.

The major chemical operation in any alkaline pulp mill is the preparation of the cooking chemical. This paper will deal only with the hazards in the re-causticizing area, and will not encompass the entire liquor cycle.

CAUSTIC SODA HAZARDS

In the liquor making plant we are reacting calcined lime with soda ash to produce caustic soda, known chemically as sodium hydroxide. Sodium hydroxide is a strong alkali and active chemically. The principal hazard that exists is contact of the skin or eyes with caustic soda. Other chemical hazards are lime burns due to lime dust slaking in perspiration on the skin, and dermatitis due to handling lime and/or soda ash.

Before we talk of safety precautions, protective clothing, and equipment in the re-causticizing area, let's take a closer look at the product we are making and become familiar with a few facts about it. In most re-causticizing plants, a solution of caustic soda has an amber color, a smooth soapy feeling, and a bitter taste. In all phases of the operation the temperature of the solution is close to the boiling point. In contact with the skin it can produce serious burns which usually heal slowly unless given prompt attention.

Caustic soda does not, however, give any warning by a burning or stinging sensation at the onset as one might expect. The portion of the skin in contact with caustic can be severely damaged or literally "eaten away" before one is aware of it. Caustic is particularly damaging to the eyes. The use of safety goggles, therefore, cannot be stressed too strongly when handling caustic.

Let's go over a little fundamental first aid for caustic burns:

1. Immediate attention is necessary. Even the smallest delay increases the severity of the burn.
2. The effected area should be flushed with large quantities of fresh water. This action is of prime importance—in case of eye injury it should be continued for 15 minutes. Due to the heat liberated when caustic solutions are diluted slightly, sponging or blotting the area with damp cloths or the like may actually increase the seriousness of the burn.
3. Never attempt to remove or pull away the injured tissue, especially around the eyes.
4. Report to the plant hospital—any burn can become serious.

USE OF NEUTRALIZERS

Many companies recommend the use of chemical neutralizing agents, which, in the case of alkalies, would be weak acid solutions, such as, acetic acid, vinegar or boric acid. At our plant we leave this phase of treatment to the discretion of the plant nurse or physician and perscribe that first aid in

the field be limited to irrigating the effected area with large amounts of water only.

All areas where caustic is handled should be equipped with safety showers. These showers should be fitted with a quick opening valve operated by a pull chain or foot pedal. The shower should be operated from time to time to make sure it is in working condition. At our plant at Chillicothe we have two such safety showers, one in the re-causticizing area near the slaker, the other on the charging floor of the digester room. Signs should designate the location of the safety shower, for while the operator certainly knows its location and purpose, newcomers in the area, such as maintenance and clean-up men, may not.

Lime is one of the raw materials used in producing caustic soda. It is usually fed into the reaction tank, called the slaker, in pebble form; however, dust to some degree is always present. The presence of lime dust can be discomforting and dangerous in several ways to the mill workers. When lime slakes in water it is an exothermic reaction, which is to say, the reaction creates heat as it progresses.

BEWARE LIME DUST

When lime dust comes in contact with those parts of the skin that are moist from perspiration or other causes, the slaking action occurs here just as it does in the reaction tank with water. Workers should thus wear tight fitting clothes, long sleeve shirts, gloves and a cap. Most lime unloaders at our plant wear the old fashioned red handkerchief around their neck for protection against the dust. A dust respirator is also standard equipment at our mill.

In the slaker, where the dissolved smelt from the recovery furnace is reacted with calcined lime to produce caustic soda, the temperature is maintained close to the boiling point. As mentioned before, considerable heat is liberated when the lime slakes in the green liquor solution, and almost simultaneously heat is generated when the reaction occurs between the green liquor (sodium carbonate) and the slaked lime (calcium hydroxide).

In chemical terms we refer to this as heat reaction. The temperature in the slaker is usually controlled by regulating the temperature of the green liquor solution going to the slaker. The slaker will boil over from anyone of the following:

1. Unbalanced lime and/or green liquor flow
2. Green liquor temperature too high, and a remote possibility is:
3. Having the slaker agitator stop and thus having a localized concentration of lime.

INTERLOCK TO STOP BOIL-OVERS

Because any unbalance between the green liquor flow and the lime feed can cause a serious boil-over of the slaker, it is important that these two be interlocked. We experienced a serious situation because this was not done at Chillicothe. The green liquor pump kicked out, but the lime feeder continued to pour lime into the slaker until the slaking action became so violent the mixture blew back up the feed slot spraying the surrounding area with hot calcium hydroxide.

Because the possibility of the slaker boiling over is ever present, the area around and under it should be posted to indicate the hazard. I consider this the most hazardous area in the re-causticizing plant.

From the slaker the mixture flows into causticizers, which are relatively small tanks that provide retention time for the causticizing reaction to reach equilibrium. Because of the scale forming tendency of the mixture at this point of the operation in closed pipe lines, open troughs or slotted pipes are usually used to convey the material from one causticizer to the other. Here the danger of spills or splatter is also ever present and guards and appropriate signs are recommended.

PROTECTION AGAINST CAUSTIC SODA

From the causticizers the chemical mixture is pumped into a clarifier, which is a large tank that separates the caustic solution from the calcium carbonate precipitate that is settled, concentrated, and pumped from the bottom of the unit. Operation of this unit is usually trouble free, with the major hazard being drips from leaks in the piping and tank connections.

Operators in the causticizing area soon become aware of the fact that caustic soda attacks wool and leather rather seriously. The recommended apparel is therefore rubber shoes and cotton clothing. A wide brim hat is also recommended to protect the neck and face from overhead leaks. Safety goggles and gloves are a must and should be worn by repairmen who work on equipment in the area.

Before repairmen start work in the causticizing area, the supervisor should make sure that all persons involved are aware of the hazard that caustic liquor presents. The foreman should never assume that everyone knows the danger involved. Tanks should be thoroughly flushed before workmen enter, and pipe connections should be broken with considerable caution, even though the lines have been drained.

When work has to be done in a tank, the main control device for any agitator should be tagged or locked out and tagged; and any employees going into the tank should wear a life line or rescue harness. Workers should be instructed to check their clothing for signs of caustic attack after they have completed their work. All extension cords used in tanks should have rubber insulation or some other material not subject to caustic attack.

LIQUOR SAMPLING HAZARD

The securing of liquor samples by the operator may present a constant hazard. Lines can become plugged and thus splash and spurt when they are purged. We have overcome this hazard to a large degree by piping all liquid sample lines into the control room and allowing them to run continuously. Green liquor, white liquor and weak liquor are each piped through insulated three-fourth inch lines into the control room.

The drain from the sample sink into which these lines discharge goes into the third causticizer and the flow is small enough that no measurable difference in the product liquor can be detected by returning the sample liquor to the system at this point. The sample sink is hooded, or rather enclosed, by a removable metal box affair with a small four inch by twelve inch opening in the front for securing a sample.

As all caustic plant operators know, it is a struggle to maintain a neat appearing plant. Caustic liquor, at most any measurable concentration, will attack paint. However unless some painting program is undertaken, new leaks cannot be told from old leaks that have been repaired. For that reason we have been most insistent that the caustic plant be kept well painted.

Causticizing plants should be surrounded by a concrete floor with an ample amount of drains. Caustic is extremely slippery and should be immediately hosed away when leaks occur. Good housekeeping in this area should receive top priority.

There is an old saying that states "familiarity breeds contempt"—I would like to recommend, however, that we all become familiar with caustic, with the hope that in this case familiarity will breed respect.

CHEMICAL HAZARDS OF PULP BLEACHING

by Chester Matzenger, Jr.
safety supvr., International Paper Co., Southern Kraft Div., Mobile, Ala.

Probably the most widely used and best known chemical in a paper mill bleach plant is chlorine. To say that this chemical alone creates numerous hazards is, I believe, a most factual statement. People in bleach plants will agree, I am sure.

In recent years our industry has added to this chemical hazard of bleach plants the ever increasing use of a chemical, chlorine dioxide, which brings on new problems. We shall discuss the chemical dangers of chlorine and chlorine dioxide bleaching. Since the dangers of each do create some problems that are different and some that are common, we shall endeavor to discuss them separately and then together.

Our most prevalent danger in the chlorine bleaching system is probably from the fumes of chlorine. This, predominently, comes from leaks in the lines. The gas is most irritating to the respiratory system, hence someone in it will generally start coughing

and leave if the concentration does not become too strong too fast. Watering eyes are also a warning sign.

These effects can be a blessing in that the man will leave the area before the concentration becomes too strong. One part per million has been suggested as an acceptable concentration for continuous exposure. An acid type gas mask can be secured to provide protection for concentrations of about two per cent. However, long periods at this concentration can cause serious irritation.

FINDING CHLORINE LEAKS

Bad leaks can be quickly found in any liquid line by the formation of a greenish yellow frost that forms around the leak. Smaller leaks (the most common) can be quickly found by shutting off the chlorine line, clearing the air in the building and then testing it, a section at a time by putting ammonia hydroxide on a rag and passing it over the section to be tested. When a leak is crossed by the rag a white smoke will develop.

Another precaution in working with chlorine lines is never to shut off both ends of a line carrying liquid chlorine at the same time. This will, at times, cause an expansion sufficient to rupture the line. Most modern plants have expansion chambers in the lines for just such emergencies.

When our liquid chlorine enters the mixing tank and caustic soda is added we then increase our problems. Caustic soda should never be handled without proper personal protective equipment, such as face shields, chemical goggles, gloves, aprons and boots. With proper ventilation no respiratory protection is necessary. However, in most cases this is hard to secure and a respirator is desirable.

Water alone will help remove caustic soda, but two per cent to five per cent solutions of acetic acid should be kept readily available for use should anyone get caustic soda on his skin or clothing. This solution should not be put in the eyes, however. Use only water without medical approval. There is a good article on precautions in handling caustic soda in the September issue of "Occupational Hazards."

At our plant the bleach plant foreman of 15 years claims he can tell what part of the system has developed a leak by the smell of the chlorine. Most of the time he is right, but I would not recommend that this be used as the safest method for locating chlorine leaks. Our foreman himself will not rely on his nose alone.

We now come to our chlorine dioxide system where we are faced with sodium chlorine, sulphuric acid, sulphur dioxide and air. Of these, the most dangerous is probably sodium chlorate. Most of our men will respect the other chemicals, but the delayed action of sodium chlorate creates a severe hazard.

This chemical in a liquid state is not as dangerous on a man's shoes or pants as it would be an hour or so later after it dries. The slightest spark, or, under most favorable conditions, extreme heat will set off a fire. Persons handling this material should wear rubber clothing that can be thoroughly washed after each use.

We have, for demonstration purposes, dripped, not soaked, a pair of pants and shoes in this solution and let them dry for two hours. A cigarette touched to them caused them to burn so fast it almost caused an explosion. They were gone without any ashes faster than we could time them with a stop watch.

DANGERS OF SODIUM CHLORATE

A pump used to pump this liquid was shut down for a couple of days. The packing had a slight leak and enough sodium chlorate dried on the outside to cause the pump practically to explode after starting it. This was from the heat generated by the shaft turning the stuffing box.

The most probable danger of sulphur dioxide is the inhaling of the fumes. However, its action is generally limited to the upper respiratory system, and if its concentrations are kept low enough there is no irritation of the nose or throat. Fortunately, for us, it is more toxic to vegetable than to animal life.

The most probable danger of sulphuric acid would be face and body burns. However, it is irritating to the mucus membranes and skin as a liquid, or its fumes, and proper protective equipment must be worn. If water or moisture get to this chemical that is in an iron drum, hydrogen gas is formed and a fire hazard develops. Proper ventilation is a must.

CHLORINE DIOXIDE—FLAMMABLE

Before being dissolved in water, chlorine dioxide is most flammable. A piece of wood or a wad of grease in it will cause a fire. Chlorine dioxide is most corrosive (much worse than chlorine) and the possibility of leaks because of this must be engineered for and watched for.

All chlorine dioxide generators must have a large hood and suitable exhaust fan, particularly if they are inside a building. All generators I know will let some gas escape at times.

In either type of chemical bleaching we have the danger of chemical burns to the skin or irritations to the respiratory system. Both types of bleaching create numerous chances for fire hazards.

We should all remember that chemicals *will not* always react the same way nine out of 10 times, in that the container in which they are handled or the other chemicals with which they may be mixed, on numerous occasions will create dangers entirely foreign to the dangers created by the chemical itself.

HAVE GAS MASKS AVAILABLE

Regardless of the type of system used in your plant, there should be a good distribution of gas masks that are checked at least once a month, and the canisters replaced after each use or at least once a year. A written report of these inspections is most desirable.

A self-contained air mask such as the Scott Air Pack will allow a person to enter certain areas at times that the best gas mask will now allow. Thought should be given in using these self-contained air masks that the gas or liquid in the area will not be dangerous to the skin.

At the danger points emergency showers that turn themselves on when you walk in are a must. At some points an eye wash station may be desirable.

Planned periodic drills for the possible dangers in your plant should be held so that each member of your bleach plant is familiar with the dangers of his particular operation and knows what precautions to take.

FIRST AID SUGGESTIONS

I would like to mention First Aid treatment that is generally known but often forgotten when we are dealing with chemicals in pulp bleaching. In gassings always remove the man from the gassy atmosphere. If you have oxygen breathing equipment, and all plants that have bleach plants should have one, then the equipment should be started at once. Remember it is always better to move the equipment to the man rather than to move the man to the equipment.

In chemical sprays you would, naturally, immediately put the man under a shower, but remember if the water is ice cold the shower should be brief and then hustle the man to some other place where he may continue his shower with warm water. While the man is under the shower he should have all his clothing removed even if it is necessary to cut it off. Chemicals stay in clothing long after they have been washed off the skin.

We must train our bleach plant operators to keep their eyes and mind on the operation of chemically bleaching pulp.

INSPECTIONS—RESPONSIBILITY—TRAINING

by SHERMAN T. MARKER

safety engineer, Marsh & McLennan, Inc., New York city

"One of the weaknesses in the accident prevention program of many industries is the feeling of management, or even the director of the accident prevention program, that the inspection as conducted by the insurance engineer or inspector, or the safety committee suffices. Nothing could be farther from the truth.

Basically, what I hope to cover in this paper is really nothing more than a part of

our overall philosophy that the key people *in our accident prevention work are the* supervisors and that we do everything that possibly can be done to direct our help to that level of people.

Before we get into that part of the discussion, let us first revert to some academics as respects accident prevention.

SOUND BASIC PHILOSOPHY

I would presume that all organizations have developed a policy statement issued by management of the need and importance of accident prevention as it effects the profitable operation of the company. The policy statement or the program itself, somewhere includes in so many words, the fundamental principles of accident prevention.

The first of these principles is of course management's interest and participation; second, determination of accident facts—the causes of accidents (unsafe personal performances and unsafe physical conditions) and third and last the necessary corrective action.

These three fundamental principles are *the backbone of our accident prevention* philosophy. Surprisingly, it is really remarkable how so few people in accident prevention work have that knowledge and, of course, are not familar with their existence and naturally, therefore, do not apply them.

ONLY INVESTIGATES ACCIDENTS

What we are concerned with in this discussion, however, applies to that second fundamental principle—determination of accident facts.

In too many cases we have found that in the application of this principle the safety man confines his activities to accident investigation. Actually, if you read the many text books on the subject you will find that the second principle implies that investigation is the way we determine accident facts. Right here and now, let us be frank and state that accident investigation, accident reporting and a lot of other details created because of accidents, are not accident prevention in itself.

Prevention is what we do before an accident occurs. Accident prevention could *be defined as a process of recognizing* causes, accidents in the making, unsafe conditions or unsafe practices and taking action to eliminate these conditions and practices before the accident occurs.

Again I repeat, this all important activity should not be limited to the inspection of an insurance safety engineer or inspector or the safety committee or other group. It should be a vital part of the activity of all persons in a supervisory capacity—plant management, department heads, superintendents, as well as other supervisors and foremen.

If a person knows what to look for and where to look, it should not be difficult to do an effective job. Past accident history has given to us a wealth of material that helps to focus attention on important items Let us take a few minutes to consider the general subject of inspection for the purpose of detecting probable accident causes.

WHAT INSPECTION MEANS

Universally it is recommended that the responsibility for making inspections should be delegated by the plant superintendent to responsible people especially safety committees or members. But this does not mean that the plant superintendent should not make inspections or that the department head and other supervisory personnel should not make inspections.

When responsibility is delegated, the manager should exercise control over the actions taken under the responsibility so delegated. This means that checking on the manager's part to assure satisfactory results is essential.

The art of inspection can be divided into four different phases:

1. The detection of what might be called obvious hazards—the actual unsafe conditions which have been created either by the action of people or physical deterioration. These are the conditions, such as a wet floor or hose on floor which because of their existence, will cause an accident.
2. The detection of conditions which of themselves might not be the direct cause of an accident but which would be a contributory factor. For example, cleaning sky lights, soapy water spilled on floor, not mopped up, created an unsafe condition on the floor.

3. The detection of employee performances which are deviations from standard practices or established policy and therefore, in themselves wrong and unsafe.
4. The detection of employee performances which of themselves are not hazardous but which create hazrads either directly or in a contributory manner.

Our past accident history will give us a great amount of information as to what to look for. But we do not necessarily have to rely on a history of accidents at a plant or department before doing a good job of inspection.

TYPES OF ACCIDENT

All accidents involving people can be classified by type into a relatively small number. There are 10 such classifications and by considering each one separately, we can do an effective job of anticipating probable accident causes.

As you review each area of activity or the performance on individuals, consider each type of accident and ask yourself, "Is there anything about the building, machinery, equipment, tools, or other things that would cause a person to fall, or is there anything that a person might do unless properly warned that would cause him to fall?"

If each type of accident is considered in this fashion, the majority of probable accident causes can be readily anticipated. The 10 accident types and typical examples for each are:

- Falls (same level)—covers all cases where a person actually slips or falls on floor, ramp or ground. Probable causes:
  - Slipped and fell on wet floor.
  - Tripped over hose to spray tank.
  - Stepped on broken floor board in truck and fell.
  - Cleaning skylights, stepped on soapy water and fell hitting mouth against wall.
  - Rope broke while lowering overhead door. Employee lost balance and fell.
  - Walking along railroad track and tripped on a railroad tie.
- Falls (different level)—covers all cases where a person falls to a lower level. Probable causes:
  - Fell from step ladder.
  - Heel caught on a backless step which was well covered with snow.
  - Fell off dock when he stepped back after closing box car door.
  - Standing on 42 inch platform ladder, over-reached and ladder overturned.
  - Fell into an open trench.
  - Working on a scaffold 10 feet high. Plank in scaffold broke and employee fell.
- Struck by—covers impact cases where the motion is primarily that of the object rather than that of the person. Probable causes:
  - Bundle fell off end of conveyor and struck him on right knee.
  - Was placing an empty pallet into position. It slipped from his grasp and fell on his foot.
  - Replacing rope and weights on fire door. Weight fell on right foot.
  - Hit on top of head by bucket which slipped from co-workers hands.
  - Glass from safety award frame came loose and fell hitting back of neck.
  - Using portable saw and it struck him on left leg.
  - Using rope block and tackle to move car. Rope broke and block struck him on right leg.
- Struck Against— covers impact cases when the motion is primarily that of the person rather than the object. Probable causes:
  - While cleaning machine struck head on vacuum line.
  - Struck elbow against door frame.
  - Hurrying out of office and collided with another employee.
  - Reached into locker and struck head against a new axe.
  - Used a 12 inch length of pipe as a lever. Pipe slipped and right hand struck slitter knife.
- Caught in or between—covers non-impact cases as squeezing, pinching or crushing between a moving and a stationary object. Probable causes:
  - Thumb was pinched between trip hammer and frame of bundling machine when thumb slipped.
  - Operator attempted to take a shingle off V belts on cutter. Thumb was caught between V belt and pulley.
  - Left hand caught in inking roll nip.

Removing scrap from doctor blade and thumb got caught between conveyor and blade.
Hand caught between roller and looper bar while guiding sheet into looper.

- Bodily reaction of person—covers only non-impact casts where sprains, strains, and ruptures result from over-exertion, unsafe posture, sudden noise, fright and efforts to recover from slips and loss of balance. Probable causes:
  Bending cartons on the scored line, a strained muscle in side.
  Stepped on a pipe laying on the floor and sprained knee.
  Lifting a 100 pound bag of fibre and strained side. (Hernia)
  Wrenched back cleaning fire boxes.
  Attempted to lift a heavy sump pump alone and strained back.
  Helping push a tow motor which was stuck in soft area and strained back.
- Rubbed, abraded and penetrated—covers non-impact cases from handling materials, stepping or kneeling on sharp objects, foreign matter in eyes, over a period of time. Probable causes:
  Stepped on a roofing nail that had been dropped on the floor.
  While moving a pallet a splinter entered palm of hand.
  Scraped arm against cut edge of bracing strap in box car.
  While walking down stairway with hand on wooden rail, received a large splinter under thumbnail.
  Feeding rags from bale and a needle stuck in finger.
- Contact with electric current—covers non-impact cases where shock or burn results from contact with live wires or conductors. Probable causes:
  Unplugging cable to electric welder. Plug shorted out, burns on both hands.
  Welding with wiring type goggles, received flash burn of eyes.
  Helping welders and did not wear welding goggles. Flash burn of eyes.
- Contact with extreme temperatures—covers non-impact cases where injury is due to contact with hot or cold surfaces, or liquids. Probable causes:
  Taking a plug out of screw conveyor to check for presence of asphalt, asphalt which was in conveyor splashed out on hand.
  Mixing bucket with steam, hose came loose causing burn.
  Helping unstrip #2 defibrator, steam backed up and blew out of #1 defibrator scalding left lower leg and foot.
  Cutting a piece of angle iron with a torch and a piece of hot metal went into his glove.
- Contact with caustics or toxic substances—covers non-impact cases where injury is due to inhalation, ingestion or absorption of substances. Probable causes:
  Mixing boiler compound. Solution boiled up into his face and eyes when steam was turned on.
  Filling tank with boiler water compound and a drop of caustic soda splashed into eye.
  Pulling paper through soda roll, paper tore causing soda to splash into eyes.

PAST ACCIDENT CAUSES

In addition to using accident types as a guide, we have the invaluable data that has been assembled from the investigation of past accidents in our plants. In this case there is no question of probability. These have been the causes of many past accidents of varying degrees of severity and will continue to produce accidents unless a more concerted effort is made to prevent their occurrence.

In such cases, therefore, when a potentially serious situation is involved, we must check sufficiently to satisfy ourselves that the instructions are being lived up to.

In all of our inspection work, there are certain causes that we consider more important than others. The liability potential is greater and, therefore, they deserve preferred attention. Such cases should get the benefit of many random observations. When specific items are selected, it requires little effort during the course of a visit to a plant to make numerous spontaneous checks on these special items.

A consideration of the past experience of your department or the experience of an individual operation will tell you which items are most important. If they can be controlled, the effect on the over-all picture will be substantial.

Making inspections and observations is important but unless we follow through on the results of inspections, we have gained very little. Our objective is to prevent accidents and to do this we must correct the conditions or eliminate the performances that are accidents in the making.

FOLLOW UP ACTION

It is not sufficient to correct the individual when a deviation from standard practice is observed. We want to prevent others from doing the same things. Observations and inspections at the best can be made only periodically and we must, therefore, try to cultivate safe working habits for every one.

Why do they do things wrong? An answer to that question may often give a clue as to what must be done from other angles. Insufficient instruction, or failure to correct the individual on many other occasions or failing to appreciate the seriousness of what is being done are some of the most common reasons given for taking unnecessary chances.

SPOT HAZARDS BEFORE ACCIDENTS

This we know is practical because of the truth in the axiom that accident causes, unsafe conditions and unsafe performances can be observed many times on the average before an accident actually occurs. It is practical, therefore, to integrate inspections for accident causes into our normal work of checking our operations.

This is not an unreasonable or impractical suggestion because the causes of accidents or the reasons for their existence are the same as the reasons for our operation difficulties. Primarily it is failure to control employee performance. Accidents mean waste, inefficiency and interference with planned operation. They breed complaints, dissatisfaction, poor morale and generally poor employer-employee relations.

In the process of considering each area of our plant from the gate, through plant, to our yards and back again we can check for existence of these unwanted conditions.

A single observation is not necessarily sufficient in all cases to be assured that unsafe practices have not developed. Evidence of deterioration, physical defects and many unsafe conditions can be determined each time an inspection is made. But as respects the performance of people, single observations are usually not sufficient.

NEED FOR MULTIPLE OBSERVATIONS

It is not safe to assume that instructions are being followed or that an established policy is being adhered to unless we actually witness the performance involved.

A single check is not always sufficient. In many cases, individuals deviate from standard practices only occasionally. Most of the time their performance is satisfactory but every once in a while they take chances and do the things that cause trouble.

If physical hazards are observed, the department head should have no difficulty getting the condition corrected. But why was the condition allowed to exist? Would such cases not be a clue as to the effectiveness of the job being done by the plant superintendent and/or the department head? In fact, if the plant superintendent, department head, foreman and employees are doing the job, the inspections made by outside engineers should not disclose many violations.

Check inspections and the follow through to correct the unsatisfactory situations constitute the heart of effective accident prevention. The plant superintendent, department heads and foremen are in the best position to achieve success because the methods of most value in getting results in accident prevention are analagous with the methods required for the control of all other phases of plant operation.

GUIDE FOR PLANT INSPECTIONS

ASPHALT ROOFING DEPARTMENT

1. Loose nails on floor.
2. Wet floor.
3. Failure to provide clearance for hands.
4. Poor grip on object.
5. Pipe railing used as a catwalk.
6. Not wearing proper clothing.
7. Carrying sharp knife in pocket.
8. Unnecessary haste.
9. Sharp edges on catch pans.
10. Defective ladder.
11. Wearing wrong type of safety glasses.
12. In running nip not guarded.

13. Using hand tool improperly.
14. Poor hose connection.
15. Putting belt on while machine was in motion.
16. Nails in old board not clinched.
17. Rolls not stacked properly.
18. Not looking where stepping.
19. Attempted to clean moving machinery.
20. Wearing ring while working.

ASBESTOS MANUFACTURING

1. Using inexperienced help.
2. Lack of attention.
3. Did not watch where walking.
4. Poor teamwork.
5. Moving a heavy object without help.
6. Hose lines on floor.
7. Guard missing from ink wells.
8. Inadequate guard over nip.
9. Using hand instead of wooden stick.
10. Poor judgment.
11. Not wearing protective equipment.

FELT MILL

1. Reached through guard.
2. Defective equipment.
3. Poor teamwork.
4. Did not have proper footing.
5. Unnecessary haste.
6. Poor grip on material.
7. Failure to use proper equipment.

MAINTENANCE

1. Not wearing welding goggles.
2. Improper position when lifting.
3. Improper type of goggles used.
4. Improper position on ladder.
5. Not wearing protective equipment.
6. Using lift truck for a working platform.
7. Over-reaching while on ladder.
8. Oil and grease spilled on floor.
9. Defective plug on welder.
10. Did not shut off power while working on switch.
11. Truck wheels not properly blocked.
12. Failure to watch where stepping.
13. Failure to provide clearance for fingers.
14. Using hammer with defective head.
15. Scaffold planking defective.
16. Rope sling not properly used.
17. Failure to use proper equipment.
18. Poor judgment.

SHIPPING AND WAREHOUSE

1. Skid standing on end.
2. Unnecessary haste.
3. Stacking too high and insecurely.
4. Failure to use proper equipment.
5. Poor housekeeping.
6. Not watching when driving lift truck.
7. Trailer not parked properly.
8. Improper position when lifting.
9. Defective flooring in trailer.
10. Failure to sand icy surface.

RECEIVING

1. Material not stacked properly.
2. Using improper equipment.
3. Adjusting rope while car puller was in motion.
4. Defective wooden rail on stairway.

MOTOR FREIGHT

1. Improper positions when lifting.
2. Not wearing protective equipment.
3. Not using available equipment.
4. Unnecessary haste.
5. Pouring gasoline into carburetor to start motor.▲

SAFETY AND THE FOREMAN

by ALEX Y. WILSON

general foreman, The Ruberoid co., Joliet, Ill.

The foreman is the key man in safety in any operating establishment, as he is in an important position to attain results in any accident prevention program. Therefore, the most important phases of safety the foreman has to deal with are PROCEDURES, HOUSEKEEPING and the INVESTIGATION OF ACCIDENTS.

The program at The Ruberoid co. Joliet plant under the direction of the plant safety director consists of participation of equal members of rank and file workers and foremen. These people rotate every two months to give everyone the opportunity to serve and participate in the safety program.

PROCEDURES AND ORGANIZATION

The number of people on the safety committee of each department is governed by the size of the department: ours being small, (less than one hundred people) has only four members, two rank and file people and two foremen. The union appoints its people and the safety director appoints the foremen.

This four man committee functions as the safety committee of the department for two months. The safety committees have a co-chairmen of foreman and workers who rotate each month, and are responsible for holding the meetings and keeping the minutes. In other words a worker will act as chairman one month and a foreman the following month.

This committee holds a safety meeting once a month to discuss and recommend the correction of 1. Housekeeping 2. Hazards 3. Unsafe Acts.

During the month at least two members of the committee (one worker and one foreman) make two complete inspections of the department to observe housekeeping, hazards and unsafe acts. If the inspection finds a guard is needed, or someone is doing something in an unsafe manner the situation is remedied immediately if possible.

This type of program is a great help to the foreman. All personnel are participating in the effort to prevent accidents, and the foreman is relieved to give more time to the productive functions of his group.

Setting up definite safety procedures as well as operating procedures is very helpful. As an illustration, we have posted at each machine the operating and safe procedures to be followed at all times. Doing the job the safe way is just as important as operating the equipment in a manner to produce the most material.

All foremen are interested in having their personnel follow safe procedures, as it is important in attaining production efficiency. This was brought to my attention two years ago when I made a tour through a large paper mill.

This mill was working to achieve three million man hours without a lost time accident, and was well on its way, having passed the two million man hour mark. The foreman who guided me through the plant was proud of the safety record, and pointed out various factors contributing to the prevention of accidents in the mill.

In the machine room posted above each machine was the production record of that machine. In each instance the record was very high. My guide explained that the high production record was made during this campaign to achieve the three million man hour goal. Incidently, that plant worked 723 days, or 3,280,000 man hours without a lost time accident which definitely proves ADHERING TO SAFE PROCEDURES REALLY PAYS OFF.

HOUSEKEEPING

Housekeeping is an important phase of accident prevention that requires continuous attention by the foreman. When demand for production increases there is a constant temptation to relax housekeeping rules. This was the case in our plant this past summer. We became very busy, and were breaking in new help since many people were on vacation.

The old alibi used by our supervisors was that they did not have the help to keep the place clean and orderly. However, that was not the reason for the poor housekeeping. The main reason was that the foremen were giving all their attention to production problems and not enough to planned housekeeping methods.

Planned housekeeping methods work well when closely supervised. On some of our operations the operators are not busy continually so we set up as part of their job the task of keeping their area clean. At one of our combining machines the Back-Tenders at each end of the machine, who put large rolls of saturated felt on the machine to keep it running continuously, are not always busy.

Therefore, these men have time and are assigned the task of keeping the machine room floor clean, and accumulated scrap picked up and placed in containers. In this way we keep our work area fairly clean and orderly, as everyone cooperates and does his part. However, when the foreman relaxes his attention to housekeeping prob-

lems the work areas quickly become dirty and disorderly.

Orderliness and good housekeeping are fundamentals of good supervision. The foreman who insists that all his people cooperate in keeping work areas clean and orderly will have a low injury rate and also good production efficiency.

INVESTIGATIONS

The other phase of accident prevention the investigation of every accident should be done promptly by the foreman of the group where the accident occurred. He should personnally investigate every accident occuring to workmen under his supervision to improve his own supervisory performance and aid in preventing other accidents, or the re-occurrence of the same accident. The knowledge gained by the thorough investigation of all accidents should be very helpful in the accident prevention program, inasmuch as many safe operating procedures can be set up from the information thus gathered.

Thoroughness should characterize the investigation of accidents. Every person who might have information bearing on the accident should be interviewed to gather all the facts so a complete record can be made The investigation should be made immediately following the accident to obtain all the facts first hand, while they are still fresh in the mind of the witnesses. After the investigation is completed and the cause determined immediate steps must be taken to eliminate the cause. If it was an unsafe condition, it should be corrected immediately. If it was an unsafe act preventive measures should be set up in the procedures in order to prevent re-occurence.

We foremen have to know our men as we personally instruct and train them. And we have the best opportunity in the world to correct improper practices before they can cause trouble. Research proves that 98 per cent of all accidents are preventable, and that 88 per cent are due to unsafe acts within the control of the foreman.▲

EYE SCREENING PROGRAMS IN INDUSTRY

by DR. DON MARSHALL
Kalamazoo, Mich.

I will endeavor concisely to answer six questions:

1. What does an industrial eye screening program consist of?
2. How is it established in an industry?
3. To what industries can it apply?
4. Why have one; who benefits?
5. What are the results in general?
6. What are the results in the printing industry?

I must acknowledge at the outset that this paper is based on the experience of many vision experts in industry and medicine, more than on my own experiences.

We could define an industrial eye screening program as a well-organized plan for testing every employee for his visual capabilities, studying the visual requirements of every job in the factory, and the assigning each employee to a task for which he possesses at least the minimum visual ability.

It is a program for visually sorting man and job and seeing to it that a square peg does not get into a round hole. A total vision program for a factory includes measures for accident prevention and safety, a division of the field that will not be considered in this paper.

EYE SCREENING PROGRAM

An eye screening program consists of the obtaining, compiling and application of considerable information, outlined as follows:

1. An Ophthalmologist serving as "visual engineer" with necessary assistants, procures a job classification list for the plant, and the qualifications for each job as established by labor and management. He then visits the plant and makes a survey of the visual requirements and peculiarities of each type of job, going from machine to machine.

   Does the particular job demand good near vision, good far vision, good color vision, good depth perception? How will bifocals work on an older employee? How is the illumination; what are the hazards? If a man will move, to what job does he go? What are the capabilities of workers on the job who have been fully successful at it? From this are set up visual minimum standards for each job; no employee should be assigned or changed to a job for which he lacks the minimum visual ability.

TEST ALL NEW EMPLOYEES

2. Now all new employees must be tested for their visual ability as a pre-employment or pre-assignment study. This is done by trained technicians and a machine specially designed to screen the good from the poor in many different visual characteristics. Individual records are kept, and consulted in original placement, in transfer of assignment, and if the man fails to meet production standards, or is accident prone.
3. Decision must be made whether to test all present employees, or only the dangerous or vitally important sections. One must be practical, but ideally each employee will be examined.
4. Special attention is given to screening and placing candidates for special training, those considered for promotion and transfer, those working in hazardous positions, those doing precision jobs and important inspecting.
5. After a program is well organized and in full effect, periodic surveys are needed to pick up changes in visual ability that may appear as a result of aging, disease or injury. In the interests of safety, fairness and efficiency, standards may need revising for certain jobs, either up or down.
6. In the screening tests, all individuals who are discovered to have visual ability below minimum standards, should be sent for complete professional examination and help, and nearly all of them, with that aid, will be found then to meet requirements. Nearly every worker can be salvaged, often for the job he or the employer has in mind, but at least for something. Often with professional medical aid, a square peg can be reshaped to fit a round hole.

PROGRAM SELLING

That, briefly, is what the program consists of. To establish it is not that simple. To get it going requires advertising throughout the plant, and publicity to sell the proposals to the workers, the supervisors and management. The boss must be sold on its value, and must be given reports of progress and results. The workers, by continuous publicity, must be convinced that the program is to help each of them and to fire none.

It must start, at least, on a voluntary basis. There must be a capable medical or professional consultant supervising the program, with enough well trained technicians to do the actual testing and record keeping accurately, quickly and in good spirit. There must be careful planning, with all details settled in advance.

Screening must be done on the job. It will take three to five minutes per worker. Division of cost of glasses between employer and worker must be decided. Employees must understand that the plant testing, by use of a screening machine, does not supply a prescription for glasses.

APPLIES TO ALL INDUSTRIES

To what industries can such a program apply? The answer is-*all*. Experience generally has been that almost any type of industry will benefit from an eye program. Maybe only part of the plan will apply, or all of it, but there are hardly any exceptions to the possible benefits. Any industry will profit by analyzing the ocular demands of its work, and the ability of its employees to meet those demands.

Aviation discovered this fact first. Flying was a life or death matter. They were the first industry to test for more than just visual acuity. Today no company has failed to get ample reward from such a program; no industry can claim exemption.

Now that we know, at least in principle, what we are talking about, maybe we should go back to the beginning again and ask what is the need for such a program, and what is its broad purpose? Any owner in-

terested in profit, any worker interested in security, may well be skeptical of the need for such a program and of the results. Who benefits from it?

In the words of the medical director of the New Jersey Telephone Company, L. H. Whitney, M.D., a visual program benefits management, employees and the community. Many other equally observant, objective and authoritative men have agreed, and said so in print. What is their reasoning and proof?

LABOR IS COSTLY

Of all the commodities that a manufacturer buys, labor is the most expensive, and the most variable in quality. Yet far too seldom is labor subjected to anything like the analysis and checking that is rigidly applied to other purchases. Labor is expensive and hard to get; it should and can be carefully studied, classified, improved, and utilized. A vision testing program deals with that.

In such matters as machine design, time studies, and setting up a production line, manufacturers have shown great progress. In safety measures they are learning fast, though the plant where goggles are required is still the exception. But the tools that each worker is constantly using, his hands and eyes and brain, have been neglected.

There are many characteristics to consider in classifying and placing an employee, and which determine his success at a task, —such things as motivation, dexterity, intelligence, temperament, hearing, vision and others. There are tests for all of these, and now-a-days some firms even take a long look at an executive's wife before he is hired.

But nearly all of a worker's impressions come to him through his eyes, and thus visual performance is important in every job, and the most important function of all to *test in many jobs. The visual ability of* the employee, and the visual requirements of the job can each be determined.

LABOR FORCE IS HUMAN

Better than thinking of labor as a costly and variable commodity, it should be dealt with as a group of human beings. These humans, managements' greatest asset, deserve maintenance and upkeep far more than machines. These humans deserve, more than machines, to be used intelligently, each in accordance with his own abilities and limitations.

If management does that, each worker can function with greatest ease and effectiveness and productivity. To do that, management must know each worker. Whatever helps the worker helps his contentment and his production. An employer is under *obligation to use each worker effectively.* In that spirit, both employer and employee should support a health program that endeavors to keep each employee in his best health and on the job.

The worker should be fitted to his job visually just as well as in other characteristics. Twenty per cent of job failures in some industries are due to inadequate visual skill. You would not give a blind man a truck to drive, but during the war Lockheed had 300 totally blind persons on highly skilled work, who kept up production and had a lower than average accident rate. You would not knowingly put a one-eyed man on a crane, but he might be able at color discrimination.

GOOD VISION REDUCES ACCIDENTS

Management must be convinced of the value of the program, or the medical director will be without funds. Management must be shown the fact that fitting a man visually to his job will reduce accidents, *reduce spoilage, increase production,* improve morale and reduce labor turnover and training time.

Employees must be convinced the program will benefit them, and will not ease them out of a job, or there will be no one to test. The workers worry about being substandard, and as a consequence losing pay or job. The IBM Corporation has convinced them that the company will not do anything to them, but will do something for them; that the program is not a means to speed up work, but rather to help the employee to work more comfortably and safely at his job, at home, driving and elsewhere.

No IBM worker is ever told that his visual performance is not up to a required standard, but rather he is told he can be benefitted by further examination and help, which he becomes motivated to seek for his own welfare. The employee must learn that scientific visual placement increases job

performance eight to 40 per cent, so it improves individual production and piecework pay, that it helps avoid accidents and hazards due to poor visual ability, that it reduces fatigue and job failures, irritation and absenteeism, that it promotes contentment in his mind and puts money in his pocket.

It helps to keep older people at work by finding a job they can do, and by guiding those who need it to seek professional aid for their visual disabilities. A man may be unemployable on one job while excellent at another.

Having convinced you, I hope, that everyone benefits from an eye screening program in some form, let us make this point certain by reviewing the general results in various industries of such a program.

POOR EYES—ACCIDENT PRONENESS

A multitude of reports show that management and worker have been sold on the value of an industrial vision program. Many reports stress the reduction in accidents, and the savings in lost eyes, something an accountant can easily translate into dollars. Surveys show that workers prone to accidents have generally worse visual function than the accident free.

We mention that aspect of a safety and goggles program only in passing. For one example, Shell Pipe Line corporation of Houston reduced the cost of eye injuries by 90 per cent in five years, from $5,000 annually to $500. But aside from accidents avoided, a vision program pays off to management and worker alike. IBM at Bingham reports greater production and better work, with corresponding reduction in production costs, material costs, accident costs and general overhead expenses.

Since IBM has no time studies or piece work, exact figures cannot be given. Sperry Gyroscope company at Lake Success, N. Y., found in some departments as high as 45 per cent of the workers had vision inadequate for performing their jobs comfortably and efficiently. As a result of a plant wide program of vision correction, spoilage and waste have been reduced and production increased. In one year, vision testing of applicants revealed 21 per cent failed to meet standards, until, for 90 per cent of these, glasses were obtained.

For Sperry management, the eye service program has produced results well beyond original expectations. Among 15,000 employees voluntarily screened by New Jersey Telephone company, 10 per cent were found to need a complete eye examination, to meet standards that were *not* unusually high. Timken Roller Bearing company began a visual screening program in the roller inspecting department in 1948.

PRODUCTION INCREASED

In three years the number of rollers inspected per inspector increased 28.7 per cent and the number of final rejects decreased 44 per cent. They concluded "it can be definitely stated that the increase in production and decrease in defective rollers found in final inspection is due to the visual inspection performance program." The Owensburg, Kentucky Tube Works of G.E., found in various departments from 29 to 60 per cent of their employees not up to good visual standards, the plant average being 39 per cent.

Those on piece work who met standards were averaging four to nine cents more per hour than the others. They found a direct relationship between visual performance and earnings. When a worker who failed the screening test got his eyes corrected, he increased his pay nine cents per hour. The foreman's rating of these workers who get needed help went up 36 per cent.

So much for specific experiences in specific instances of varied industries. Some companies with new vision screening programs laboriously determined the dollar value of the program. Many others were as certain of the benefits but could not or did not translate them into numbers.

OTHERS ADOPT VISION PROGRAM

IBM for example, aims to help each worker to his top potential visual efficiency, considers him as an individual, does not use predetermined visual job requirements, never tells a worker his visual performance is not up to standard, and believes that there is a place in industry for workers with physical handicaps so long as the employer is aware of them.

The Delco-Remy Division of General Motors at Anderson, Indiana found that their plant vision and safety program was so effective and beneficial that it soon spread to the local high school driver's training

courses, and later throughout the entire school system. Other local Anderson industries were forced by employees' pressure to follow the example of Delco-Remy. All reports tell of the satisfaction that both management and worker have from a properly working, carefully organized visual screening program.

What results from such a program in a printing department or firm? One excellent report, at least, is available on this, by the medical director of R. R. Donnelly and Sons, and I will extract freely from his printed results.

The program was begun in one critical department made up of composition, linotype operators, monotype operators, lockupmen and proofreaders. All voluntarily were screened. Efficiency went up and spoilage went down so much, from corrective action, that the program was authorized for the entire plant, and completed in two years.

PROOFREADERS MORE ACCURATE

The program and its results showed that proofreaders who meet visual standards are 37 per cent more accurate than those who fail; they have 7.9 points higher efficiency and produce 12 cents more value per man hour than those visually below standard. Similarly compositors visually up to standard have 5.5 points higher efficiency, and monotype keyboard operators 19.1 points higher, and produce 71 cents per man per hour more.

As in most industries, it was found that 90 per cent of those who did not meet standards, could readily do so after getting professional aid or glasses. Considering the cost of spoilage to consist of paper, inks, time and customer satisfaction, Donnelly's figured that in this one department of 336 employees (in a plant of 2,000), the savings that resulted from the vision correction program were more than $6,000 per month.

What does an eye program in industry cost? There are figures more readily available concerning accident prevention than in increased efficiency. I have already noted the experience of Shell Pipe Line corporation of Houston: cost of eye protection plus eye injuries dropped 90 per cent in five years, from $5,000 a year to $500.

In a 10 year period Sperry Gyroscope company spent $400,000 for setting up and maintaining its in-plant eye program, or an average of $40,000 per year. Employees varied between 7,000 and 18,000. At least 82 eyes were saved from loss, attested to by smashed goggles. At $5,120 each in New York State, these saved eyes saved $419,840 alone, or more than the total cost of the program.

Figuring four dollars of indirect cost for each dollar of direct accident cost, a total of $1,679, 360 was saved by not losing the 82 eyes. In 10 years there was a 90 per cent drop in first aid eye cases, an approximate saving of $200,000.

The cost of a screening program aside from safety I do not know, and it would vary a good deal, depending on how much the company and the worker contributed toward special examinations and needed glasses.

Nevertheless, one company after another has adopted and continued these programs, convinced that they are worthwhile when properly adapted and run, either on a dollar and cents basis, or on the basis of those less calculable items of efficiency, contentment, morale and productivity.

May I suggest that for those of you who may be interested, the National Society for the Prevention of Blindness has a number of short pamphlets written by a variety of experts, detailing their experience with eye screening programs in industry. These may be obtained at cost from their N. Y. office (1790 Broadway, N. Y. 19).

WHAT GOOD VISION CAN MEAN TO INDUSTRY

by KARL F. SIMPSON, JR.
director, Safety & Industrial Relations, Folding Paper Box Assn., Chicago

The Folding Paper Box Association of America is a service organization. The service we provide is concerned with the buying, selling, and producing functions which each member performs, and is specifically designed to meet their individual and collective needs. In other words, we help our members with activities directly or indirectly related to the making of a profit.

Our interest in profit is dictated by the cold fact that this symbol represents the nucleus of their thinking. This preoccupation with monetary matters is not peculiar to folding box manufacturers, but is a characteristic common to all members of top management.

Since "profit" is the symbol to which top management responds, we present programs and projects which can be reduced to monetary terms. This is necessary because management, with their analytical minds, are constantly measuring and evaluating each activity in terms of the profit symbol to determine its ultimate effect on the profit and loss statement of the organization. If we present projects which cannot be related to this one overriding preoccupation (profit), then we risk not having our program accepted, regardless of its merit.

In line with this thinking, we at the Folding Paper Box Association are actively supporting a program of vision testing and we urge our members to invest time and money in this activity. We are convinced that if they do not make this necessary investment, they risk wasting substantial sums of money and thereby place themselves at a competitive disadvantage in a most highly competitive industry.

ALL VISION FIELDS

With the credo of "service to our members" as their philosophy, the Industrial Relations committee of our Association in 1956 authorized the staff to explore the area of vision testing. From a general survey of the literature, we found that Industrial Ophthalmology is a special field of the visual sciences. It is more than just prescribing glasses. There are also the related fields of vision and the job, color, depth of field, illumination, and many other problems of a medical, production, and a human relations nature. There are three basic phases connected with the installation of a vision testing program:

1. *A Vision Survey of the Plant.* This includes a determination of vision standards for different jobs. This involves a determination of whether or not an employee is required to do close work, the importance of distant vision for each job and the significance of depth of field or color perception in relation to each particular operation.
2. *A Program of Selection and Placement of Employees Through Pre-employment Tests.* The purpose of this phase of the program is to place employees in jobs which will utilize their specific qualifications. This is necessary to insure high quality and safety of operation.
3. *Periodic Re-checks Throughout the Plant in Areas Where Good Vision is an Important Factor.* Men, like machines, need to be checked to be sure they remain in good working order so that they will be capable of continued operation at top efficiency.

RESULTS OF STUDY

Other facts uncovered in our non-technical survey indictated that the accuracy of work is directly related to good vision. This is to be expected. We also found that the visual skills for the greatest accuracy may not be the same as those required for the greatest degree of speed. The explanation of this is that those with good vision detect and correct their own errors. To keep within the tolerances specified for the job, they work at a reduced speed. On the other hand, those with poor vision are unable to see the flaws in their work and as a result they work more rapidly.

To substantiate the close relationship between quality of production and the level of visual efficiency, the Bausch and Lomb

Optical company has released the following results of a study conducted among a group of lathe operators.

EMPLOYEES RATED AS HIGH QUALITY PERFORMERS:

13 per cent of these employees did not pass the visual performance test for their job.

87 per cent of these employees did pass the visual performance test for their job.

EMPLOYEES RATED AS AVERAGE OR MIDDLE QUALITY PERFORMERS:

28 per cent of these employees did not pass the visual performance test for their job.

72 per cent of these employees did pass the visual performance test for their job.

EMPLOYEES RATED AS LOW QUALITY PERFORMERS:

68 per cent of these employees did not pass the visual performance test for their job.

32 per cent of these employees did pass the visual performance test for their job.

Information of this type has meaning to top management because it can be converted into monetary terms. As proof of this statement, I wish to cite the case of one of the pioneer companies in the field of industrial vision testing. The medical director of this organization indicates that their preliminary vision testing program cost approximately $10,000.

As a direct result of this pilot project in one area of their operation, the company realized a savings of between $5,000 and $6,000 each month from reduced spoilage alone. If we take the lower figure, this would indicate a 600 per cent return on their investment. If we assume that this is an unusual case and cut the benefit in half, we have a return of 300 per cent on the original investment.

GOOD VISION DECREASES ACCIDENTS

Aside from the benefit of reduced cost (higher quality), studies indicate a direct relationship between safety and visual ability. This, again, is not unusual or unexpected. One of these studies reported that only 23 per cent of those employees who met the minimum visual standards for their specific jobs had serious accidents, while 88 per cent of those who did not meet these minimum visual standards for their jobs suffered serious mishaps. Another report concluded that 65 per cent of those with adequate vision were accident free, while only 45 per cent of those with substandard vision were accident free.

Another aspect of the problem which has an important bearing on industrial vision but is often overlooked is the question of adequate illumination. We might ask ourselves, what good is 20/20 vision if the work area is so dark that the employee is unable to see? Studies indicate that there is a direct relationship between adequate light and the quality and quantity of production. These reports conclude that by reducing illumination below the most satisfactory level, total production declines and the number of errors are easily doubled.

This is but a brief glimpse into the storehouse of material available to those interested in the field of Industrial Ophthalmology. However, on the basis of this brief preliminary study, the Industrial Relations committee of the Folding Paper Box Association authorized the staff to set up a pilot study among a group of our member companies in the Chicago area.

PILOT STUDY

The purpose of the test, as set forth by the Industrial Relations committee, was to determine the prevalence of eye deficiencies among the members of our own work force, and to prepare a foundation for the possible establishment of vision standards for various critical job classifications within the industry. Dr. Hedwig Kuhn, an outstanding authority on industrial vision, acted as technical consultant to the pilot group which consisted of the following companies:

Container Corporation of America, 35th Street Carton Plant.

Container Corporation of America, Lake Shore Plant.

Continental Can Company, Inc., Robert Gair Paper Products Group, Chicago Plant.

Klearwrap, Incorporated

Four critical areas were chosen for a sample check of 265 employees. There areas

embraced the following departments in each of the four plants:

Press room
Cutting room
Ink room
Die and Plate department

Of all the employees tested, a minimum of 37 per cent had a vision deficiency sufficiently pronounced so as to place them outside the acceptable range of normal vision for the particular job they were performing. In the press room, 31 per cent of the pressmen needed an eye examination to secure glasses or have glasses corrected to their present need. We also found that 28 per cent of these pressmen had a noticeable deviation in depth perception, and 15 per cent of them had a color perception that was not up to par.

Of the feeders, 55 per cent in the press room and 54 per cent in the cutting room had deficiencies in their depth perception. In addition, 30 per cent of the feeders in the press room, 25 per cent of the feeders in the cutting room, and 18 per cent of the ink room employees lacked satisfactory color perception. There were also 34 per cent of the die and plate department workers who needed an eye examination to secure glasses or have glasses corrected to their present need.

VISION PROGRAM UPS PROFIT

There are but a few of the alarming highlights which pointed up the need for a full scale vision testing program. To us the significance of these findings were obvious. We did not feel that it was necessary to convert this material into specific monetary terms, since our study corroborated previous reports on the prevalence of eye deficiencies among members of the work force.

On the basis of similar studies in closely related fields, we felt the savings they had experienced would apply equally well to our own group and industry. Therefore, on the basis of this material it was decided that our Association would support a vision testing program among all of our members.

The next step concerned the development of a presentation which would "sell" member companies on the idea of installing a vision testing program in thir own plants. It is true that we had some rather startling results of our pilot survey to present. We could also point out that there was a bright side to this otherwise dismal picture since once these vision deficiencies had been uncovered, approximately 90 per cent of them could be corrected.

However, after serious study we came to the conclusion that there were two basic points of emphasis which might be stressed. Our problem was to determine which of these two arguments would best serve as the cornerstone for our presentation. One of the basic points of attack involved the safety question and concerned the argument that employees with deficient vision are not only a hazard to themselves, but they also make accident prevention much more difficult.

This argument involved an analysis of how improved vision might reduce injuries and consequently reduce human suffering as well as insurance, compensation, and medical costs. The other area for possible exploitation was the financial hazard and expenses resulting from the production of scrap and low quality work, which could be directly traced to deficient vision.

PRODUCTION QUALITY INCREASED

In presenting our program for the first time we stressed both aspects of the problem. From the beginning, however, it was obvious that the key to top management's interest and support came not through the safety argument but rather through a factual presentation of potential savings from the reduction of scrap and low quality work. Being pragmatic in our thinking we pursued the course which seemed to offer the greatest possible return.

Our presentation is now primarily based on the problem of quality control, with safety thrown in as an *added* benefit. On the basis of this approach, we feel we have achieved an appreciable degree of success as measured by the number of vision testing programs which have been installed by our member companies.

For a company to reap the full benefit from this project, a vision testing program cannot be thought of as a one shot cure-all. The simple phase of the operation consists of finding the employees with sub-standard vision. The difficult task consists of the follow-up required to be sure these employees get the medical attention they need.

Once the present work force has been raised to top efficiency in terms of vision, the program still has a function to perform. This consists of maintaining a constant check on all new employees to be sure they meet the vision standards for their specific operations. There is also the need for a periodic re-check of the whole work force in areas where good vision is an important factor. This is necessary to maintain top vision efficiency.

From our vantage point, we are firmly convinced that the case for a vision testing program is adequately supported by the facts. There appears to be sufficient monetary benefit in the areas of both quality control and accident prevention to warrant the expense of installing and maintaining the program. The big problem is "selling" the activity to top management. This hurdle is not insurmountable if you remember that "profit" is the most dynamic characteristic of our free-enterprise economy and is the catalytic force which activates our whole industrial machine.

If you evaluate a vision testing program in terms of the "profit" which can be expected from an investment of time and money, neither you nor your top management will question the worth of this activity.

HAZARDS OF 110 AND 220 VOLTAGE IN INDUSTRIAL OPERATIONS

by HOWARD A. BROWN

Rochester Gas & Electric corp., Rochester, N. Y.

Before venturing into the discussion of hazards of 110 and 220 voltage in industrial operations, we should review the factors and conditions under which these low voltages may be hazardous. There are many people who are not aware that low voltages may be hazardous either because they have never had the conditions pointed out to them, they have failed to comprehend them fully and have forgotten the details.

This presentation will review research and the authoritative opinions of people in the fields of electrical engineering, medicine and physiology. Especially I will use material by W. R. Smith which was presented before the Public Utility session of the 19th Annual Safety Convention and Exposition of the Greater New York safety council, March 31, 1949.

Dr. Cecil K. Drinker, professor of physiology, Harvard school of Public Health, states, "Teaching should be based upon the principle that no electric shock is without danger, and users of electricity must employ every means to avoid accidental contacts."

Dr. H. B. Williams, formerly Dalton Professor of Physiology, Columbia university, is an authority in the fields of medicine, physiology and electrical science. He has for many years called attention to the possible hazard of low voltage electric shock, saying, "The nature of the necessary precautions is so extremely simple that a young child may comprehend it."

Statistically, the annual number of fatalities caused by low voltage electric shock throughout the country is not large. The National Safety Council statistics show approximately 800 deaths caused by electricity, which is less than one per cent of all deaths. Of these probably not more than 200 were due to low voltage, but this small number is important because:

1. These were 200 human beings—industrial workers, wives, mothers and children.
2. These deaths were in many cases the consequence of a condition of which the victim was unaware.
3. Many of these deaths evidence the fact that, in the mind of many people, there is not yet a clear understanding as to why such deaths occur in one instance and not in another, where apparently there was a similar condition.

A large percentage of these fatalities can be prevented by a proper application of understanding and knowledge:

- Understanding the effects of electric current on body physiology
- Understanding why low voltage can be hazardous and under what conditions
- Knowledge of proper procedures and practices that will prevent conditions that are hazardous and fit us to avoid their harmful influence

PHYSIOLOGICAL EFFECTS OF SHOCKS

The first factor involved in electric shock is the type of current encountered. Generally speaking, this discussion is limited to two types of current, direct current and alternating current. The principal effect of direct current is that it will produce a very serious burn. The heat generated by the direct current is the factor which produces the injury.

Many fatalities that occur from direct current are caused by the effects of the heat when the current passed through the body tissues. A direct current passing through the body from head to foot generates heat in the blood cells causing them to expand and explode. Deaths have occurred due to direct current shocks from internal hemorrhages rather than from extensive burns on their person.

Alternating current is the most common exposure in most industries. Arcs from either direct or alternating current can produce external burns. Alternating current has several other effects in addition to burns. This current, particularly at low voltage and low frequency, can cause a paralysis of the muscular tissues. The stimulation of the alternating current, in flowing through the muscles paralyzes them.

Respiration can stop from a contraction of muscles. If this is the only effect, natural respiration will begin as soon as the contact is broken (provided the time interval has not been too long). Violent muscular contractions can also cause falls with serious consequences. Lesser currents may not affect respiration directly, but if muscular contractions prevent the victim from releasing himself, death can result from exhaustion and consequent respiratory failure and asphyxia.

The next effect of alternating current is caused when the current flows through the nerves that control breathing. Breathing is controlled by the phrenic nerves which come down the sides of the neck, through the trunk and attach to the diaphragm.

BREATHING PROCESS

The impulse of the breathing center at the base of the skull goes through these nerves and causes the diaphragm to rise and fall and control breathing. If the current passes through the nerve center, it destroys the ability of the nerve center to send the impulses down the nerves; or, if the current goes through the nerves, the effect is transmitted to the nerve center and breathing is not possible.

When this happens, we say a person dies of shock; he suffocates because he cannot breathe due to the paralysis of the nerves. Artificial respiration is an attempt to keep the victim breathing until the paralysis of these nerves and the breathing center has been reduced or eliminated and breathing is again normal by itself.

The third effect of alternating current is one upon the heart itself. The heart normally beats as a pump, in perfect coordination, 72 times a minute. An abnormal stimulation such as the impressing of a 60 cycle electric current, may cause the heart muscles to go out of step and flutter in a completely uncoordinated manner.

VENTRICULAR FIBRILLATION

There does not necessarily have to be any unusual damage to the heart. The heart quivers rather than beats, the pumping action ceases, the blood becomes contaminated very quickly from failure to circulate, nerve centers and the brain are deprived of oxygen and the person dies in a few minutes—an asphyxial death. As far as is known, there is no practical way to get a heart out of this uncoordinated flutter—known as ventricular fibrillation. Research indicates that an immediately applied counter shock will restore the heart to its regular rhythm.

These effects—the paralysis of the muscles, the effect on the nervous system con-

trolling breathing and the fibrillation of the heart are effects peculiar to alternating current. In an emergency either shut off the electric circuit or get the person off the circuit so the current no longer runs through him. The paralysis will disappear shortly.

Artificial respiration is applied for paralysis of the breathing. In fibrillation nothing can be done since it can not be determined if the heart is in fibrillation. Therefore, the only advice in the case of an electric shock is to get the person off the circuit or break the current as quickly as possible, and secondly, apply artificial respiration if he is unable to breathe.

The effect of an electric shock will depend upon:

1. The nature and intensity of the current
2. The parts of the body affected
3. The duration of the current flow

The intensity of the current depends upon the voltage and body resistance.

$$\text{Current in Amperes} = \frac{\text{Voltage (volts)}}{\text{Resistance (ohms)}}$$

BODY RESISTANCE

The body resistance is a combination of the skin contact resistance and the actual body resistance which is low because body fluids are a good electrical conductor. Skin contact resistance varies greatly from a normal dry of 40,000 to 50,000 ohms per square centimeter to a moist value of 1,000 to 2,000 ohms per square centimeter. The total resistance may vary from 100,000 to 300,000 ohms or more, or in conditions of wet hands from perspiration, a low value of from 300 to 500 ohms total resistance may be obtained.

Therefore, if the total resistance should be 500 ohms, the current would be as follows for the indicated voltages:

Volts	Current in Milliamperes (1/1000 Ampere)
100	200
50	100
12.5	25

Thus, we see the values of current that can be obtained at very low voltages.

Let us now consider what these current values mean.

Charles F. Dalziel, professor of Electrical Engineering, University of California, conducted tests on 120 male subjects and determined the following results:

1. Threshold of perception—1 to 1.2 milliamperes
2. Surprise but no discomfort—8 to 13.9 milliamperes
3. Paralysis preventing voluntary control—15 milliamperes
4. "Let-go" values painful—9.7 to 21.6 milliamperes
5. Reasonably safe values to handle continuous or uninterrupted—8 to 9 milliamperes

Note: Values for women are about 70 per cent of the above values, and for children, in general, less.

MUSCULAR CONTRACTION OCCURRANCES

Frequency affects the "let-go" value very little in the range from 10 - 180 cycles. At lower, or higher, frequencies the "let-go" currents are somewhat higher than those above.

Muscular contraction with alternating current is steady and continuous. Muscular contraction with direct current occurs when the circuit is closed and again when broken. Direct current is safer at somewhat higher values and is preferred by many for welding operations.

If currents exceed the "let-go" values, severe muscular contractions will result with consequent effects on breathing organs and eventual exhaustion. The duration of such shocks will determine the seriousness of the consequences. The above conditions will generally not affect the heart immediately.

There is no exact information on what is the lowest value of current that will stop normal respiration and produce unconsciousness, but it is believed to be between the above "let-go" values and that which produces fibrillation.

Extending the above tabulation would give the following picture:

6. Great pain—breathing difficult—20 to 50 milliamperes
7. Respiration stopped—40 milliamperes (estimate)
8. Ventricular fibrillation—100 milliamperes to 25 amperes plus duration
9. Heart action stopped by shock (result of severe muscular contraction) —200 milliamperes and above

In the relationship of currents of different values and their physiological effects, the values of currents are very small. We have only tabulated currents up to 200 milliamperes; that is only two-tenths (0.2) of an ampere. We have talked of one to 1.2 milliamperes as the threshold of perception; that is only one one-thousandths (0.001) of an ampere.

These are extremely small quantities of electricity and account for the fact that in many accidents the fuses were not blown. It was hard to believe the party was electrocuted when the power had not been interrupted.

The current that flows is directly proportional to the voltage and inversely proportional to the resistance. An increase in voltage generally results in a worse shock. Likewise, a decrease in resistance results in a worse shock. With a given voltage, the variable is the resistance. The resistance of the contact is most important.

The larger the area contacted, the lower the resistance. The more the pressure of the contact, the lower the resistance. A contact can be a tap, or brush, or a grasp which may start as a light grasp but the flow of current contracts the muscles and the pressure of the grasp tightens, and the tighter the grasp, the lower the resistance and the more current will flow.

MOISTURE INCREASES SHOCK

Moisture is also a factor involved in contact resistance. Moisture improves the contact, making it better, so that the flow of current is increased. The peak of fatal electrical shocks occurs each year during May, June, July and August. This reflects the effect of the perspiration of the men who are involved in contacts.

There is a difference in the susceptibility to shock of individuals which is an important factor. Some people are more sensitive to electricity than others. Some people can stand repeated shocks; they have experienced it before; they know what it feels like and nothing much happens to them.

On the other hand, other people are very sensitive to electricity and their heart and mental adjustment may be in such a state that they are frightened to death. Fright kills them rather than any burns or serious injury due to the effects of the current passing through the body.

I have pointed out a sufficient number of factors involved in electrical shocks. We have covered enough of the fundamentals to indicate that it is not only the voltage that kills, and not only the total resistance, but rather a combination of them that creates the condition.

You must be in the circuit across some voltage (which is usually to ground), to cause current to flow, the magnitude of which is determined by the resistance of the circuit. We have seen that it only takes a very small current flow to cause an effect which may be fatal.

INSULATION RAISES RESISTANCE

Insulation is used to keep the resistance value high, either above ground or between wires. All insulation passes current under some condition. The insulation has to be chosen to minimize the current flow at the voltage being used. Insulation may be defective or deteriorated and therefore should not be too much depended upon.

To prevent electric shock, whether it be low or high voltage, should be simple, at least in principle, for it means simply:

- Keeping clear of contact in any way with energized circuits and grounded surfaces or objects when handling electrical tools or making connections, and
- Grounding any external metal parts of portable tools or stationary electrical equipment.

The message of low voltage electric shock for the shop electrician and maintenance man is to use suitable electrical tools and devices and to clear power and lighting circuits before working on them. There are two ways of working on a circuit—"dead" or "alive." That applies to the workman as well as to the circuit. The safest way is to work only on "dead" circuits.

Probably it is a tribute to the electrical industry that we can point to evidence of complete ignorance of essential precautions in using safety with electrical appliances, tools, and devices operating on 110 volts. It is a consequence of the practical every-

day safety of the commodity we supply. We *must recognize the facts that have been presented* and what, on one day, may be an insignificant tingle, on another day may cause a fatality.

Let us summarize the essential precautions we have been talking about:

- All voltages of electric energy should be respected and treated properly. Chances should not be taken. For those who must work on or near an energized electrical connection, they should stand on dry boards or other non-conducting materials and when practical use only one hand. At all times keep the body clear of grounded surfaces, equipment and pipes.
- The normal high value of the skin resistance when dry usually safeguards those who receive shocks from any serious consequences. Extra precautions should be taken when hands or body are wet from water, perspiration or chemicals.
- Proper devices and equipment should be used with cords of high grade rubber insulation suited to the conditions. Good maintenance is imperative. All permanent sockets, especially brass shell, should have connections *polarized so that the screw contact is* at ground potential.
- Low voltages (6-32) are recommended for supplying extension cords for lights which have to be taken into tanks, boilers, *or places that are extremely damp*, or where conducting chemicals are present. Brass shell sockets should never be used for extension cords, nor in any locations for which they are not approved in the National Electrical Code.
- Portable electric tools should be properly grounded, preferably by a third conductor in a connecting cable using polarized plugs and receptacles or by a positive third wire connection to nearby electrically grounded steel, water pipe, or electrical ground bus.

If the grounded side of the supply circuit is used to ground the frame, an open circuit at any point in the grounded wire of the cord or at the plug receptacle will result in the frame becoming energized, thus creating the condition which the ground connection was supposed to prevent.

TRAINING TO CONTROL UNSAFE ACTS

by NEIL NELSON

district engineer, The American Mutual Liability Insurance co., Manchester, N. H.

Three years ago I investigated a fatal accident reported from a local paper mill. While reviewing the facts the superintendent was quite sure that the unfortunate accident was the result of carelessness. I had to agree, however, while the superintendent was sure that it was the man's carelessness, I was equally sure that most of the responsibility for the accident lay at the superintendent's door.

A young man recently employed was attempting to remove a small piece of paper from the dryer roll on the paper machine using a broom handle. In some way the handle was caught in the nip point of the turning roll and in attempting to remove it, the man's hand and arm were caught which resulted in such serious burns and shock that he died shortly after being admitted to the hospital.

Investigation of the accident established this: the young man, 18 years old, had been employed in the mill for approximately three months and was learning to be a back tender. It takes many months of constant training and experience before one can qualify as a back tender. So I asked several questions.

1. Why was the man using a broom handle when it is contrary to all good practice in attempting to remove a piece of paper from the dryer roll?
2. Why was a young man with such limited experience permitted to attempt to remove paper in the first place?

NOT PROPERLY TRAINED

It was quite evident that proper *training* had not been provided. He was permitted to remove paper when he was not trained to do it and furthermore, he was permitted to use a wrong practice. In this case it was vigorously claimed that the more experienced back tenders did use a wood spear and the right practice. However, the reason for the young man using the wrong method was not explained. It is hard for me to understand why a young inexperienced person knowing practically nothing about the operation of a paper machine, should deliberately pick up a broom handle if he had never seen that done before.

It was finally established that some of the more experienced men did use a broom if the broom was handy. Therefore, we had an unsafe practice by an inexperienced man causing his death. There is no doubt in my mind that the cause of this man's death, was, he was not trained to do the job to which he was assigned.

What do we mean by training? The desired end result is, of course, to have every person work efficiently and safely. But how do we get this? Certainly not through casual remarks about safety to a workman by his supervisor, particularly if the supervisor has not been trained in the same subject. How much training remains as an indelible stamp in the minds of supervisors when management is only mildly interested or worse, has no interest at all? There is a large number of small mills where training programs are conspicuous by their absence.

INVESTIGATE NEW WORKERS

It would be most unusual for management to buy any equipment, either new or used—sight unseen. As a matter of fact, careful investigation is made to be sure that the investment will be proper and profitable. Unfortunately, this practice is not always followed in the investment in man power. The larger mills undoubtedly do have programs, some adequate and some not.

The smaller mills make little or no attempt to secure their investment when hiring employees. There are reasons given for this, some justifiable, others are not. For instance, a small mill in a rural area may find a tight labor market, the wage scale may be lower than neighboring plants in other lines, the working conditions may be inferior to other plants, so that when a man wanders in looking for a job, if he looks normal and healthy, he is usually hired. If good luck holds, the man may be properly placed.

On the other hand if he is physically unable to do the work or is otherwise unsuited, he is soon involved in accidents and injuries. The pre-placement examination is the only way to match *the man* to the job. The job analysis is the only way to know how and where a man's abilities and aptitudes can be utilized safely and profitably.

There is no reason why a satisfactory *placing program* could not be undertaken in even the smallest mill. The mill owner or manager certainly knows the job and the physical and emotional qualities necessary for the man to do the job. There is usually a local doctor who will take an interest in the project and work with the manager. Only in this way can training people to control unsafe practices get off on the right foot.

HOW—WHERE—WHY

All of us are familiar with the practice of investigating accidents and many types of forms have been designed to record the necessary information. But all point to three important questions—How, Where and Why. Examinations of hundreds of reports indicate in a great many cases, that the investigation is superficial and does not get to the root of the problem. It is amazing to note the repetition of two statements by *supervisors*—"I thought the man knew better" and "I told him time and time again."

Now, if we agree that most men want to work safely and will carry out instructions to do the job right, there is something *wrong* when *he* makes an error and becomes involved in an accident. One reason he makes the mistake is because he does not understand what he is supposed to do, even if his foreman had instructed him. A man can be instructed only if the instructor knows how and will take the time to do it.

If you want to find out how well or how poorly your men are instructed, ask your supervisors to write up a job description showing the operation with the attendant

hazards. Believe me, you will be surprised at the omissions. This is not because the foreman or supervisor does not know. He knows the machine, job or operation as well as any man but without training he does not know how to transfer his information to another man and make it stick. Usually, the instruction consists of the supervisor telling a man a few times how to do something and when the man nods vaguely that he understands, it is assumed that he does.

This procedure, then apparently justifies the statement I referred to on the investigation report, "I told him time and time again" or "I thought he knew better." Now, if accidents are to be controlled, there can be no guess work or no assumption. A supervisor has to know that the man understands. He will know when the man can tell him and show him what he has learned. How long will it take? No one can forecast that. It depends upon the job and the ability of the man to absorb instructions.

FOLLOW-UP INSTRUCTIONS

The best of instructions need close follow up. Many supervisors lose out on all their good work by letting go too soon. If a well trained man is to continue along these lines, he needs supervision. There are many practices that creep into a man's activity that gradually undermine the whole training program. He will shortcut to save time.

He will change from the accepted procedure because he thinks he has found a better way to do the job, fail to use the personal protective equipment, ignore the presence of machine guards, get sloppy in his personal habits and aggravate the housekeeping program. If accidents from unsafe practices are to be controlled, the supervisor has to supervise. One of the problems is that an accident cause or an accident itself is not recognized or acknowledged until some injury or damage results.

Too much reliance is placed on the record of lost time accidents and entirely too little on the story told by the first aid treatment record. When a fatal or serious injury is reported or severe damage to property or equipment occurs, the entire organization corrects the cause. But day in and day out, practices are indulged in that could cause the loss of eyes, loss of fingers, hands and arms, hernias, back strains and many other injuries.

Many of these probably could have been prevented if sufficient supervision corrected the problem when first observed. I mentioned the lost time injury record and its effect on supervisors. Many times at safety meetings I have found much complacency because departments have operated for a month or longer without a lost time injury. In checking first aid reports, it was not assuring to see the trend of minor back strains, lacerations, foreign bodies in eye and so on.

PRACTICES CAUSING ACCIDENTS

My survey showed the practices responsible for these trends, men lifting improperly, cluttered storage areas where materials have to be handled and re-handled, use of make shift tools, wrong size wrenches, screw drivers for chisels, using grinding wheels without shields or goggles. Not a lost time injury reported but the ground so fertile, just waiting for a change of luck. While the investigation of a serious accident is necessary, the control of an unsafe act before the serious accident results, is even more necessary.

While we look to the supervisor to assume the leadership in his department, there are other influences affecting behavior over which the supervisor has little or no control. I always remember an accident in which a man lost a hand doing a simple routine job which he did every day safely. One morning he forgot and his hand was caught in the machine. After a while when he returned to work, I asked him how it happened.

It appears that he had just bought a new home and while he was physically doing his job, mentally he was planning the changes he was going to make in his home. There are many other problems which affect a man's stability and his judgment, worry over home problems, illness, disagreements, financial matters, rumors that business is not good and the thought of impending layoff. These are difficult problems that cause accidents.

While a supervisor cannot interfere or pry into a man's personal affairs, he can through friendly approach gain the confidence of his men that they will seek his

advice and help when they need it. Supervision means more than just running paper through a machine or pulp from digesters. It implies leadership and guidance. Most of us need both.

GAIN WORKERS' CONFIDENCE

I refer again to a statement that often appears on a supervisor's report of accident investigation. "I have told him time and time again." This means that accidents occur in spite of instruction from supervisors. It was pointed out that one reason is that the man does not understand the instructions. There is another reason, perhaps equally important. Sometimes there is a dual set of plant rules, one for production and one for safety.

I have yet to visit the mill where production rules are not observed without question. I wish the same could be said about the safety rules. It makes one wonder when we see an intelligent man accept wholeheartedly instruction on production problems and ignore or at least accept halfheartedly the program on personal safety. Men are quick to sense authority and sincerity and unless a supervisor issues his safety orders with the same degree of importance as production orders, they are not going to be carried out.

CONTROLLING UNSAFE ACTS

It is even more discouraging to hear a manager or his safety representative deplore the fact that supervisors do not take the proper interest in carrying out the safety policy. It is the same story. When the manager means what he says, it is carried out. Double talk is largely responsible for a negative reaction.

We will all agree that there are many factors which influence the control of unsafe acts. I selected for this discussion five which appear to me to be the key factors and briefly summarized they are:

1. *Job Placing*—Selection of the man according to physical abilities and emotional stability. Proper matching of the man to the job and the job to the man.

2. *Job Training*—Make sure the man fully understands the mechanics and operation of the job to which he is assigned. This can be done only if the supervisor himself fully understands all phases of the operation, the hazards attendant to the operation and the controls that should be established.

3. *Supervision*—Close checking on men for observance of safe acts taught during the training period. In the case of older employees, close supervision to maintain these practices which the supervisor has developed for safe work and operation. In this case, review of first aid injury reports, supplies many clues for the establishing of unsafe acts.

4. *Outside Influences*—Varying factors including home environment, economic problems and health problems all add to the factors responsible for the unsafe acts.

5. *Discipline*—Proper discipline to enforce the safety policy of the plant will remove the all too frequent statement, "I have told him time and time again." Unfortunately, there seems to be two sets of operating procedures where rules are concerned. Plant rules for production and process problems are observed without question. Safety rules and regulations many times are ignored or merely tolerated without too much cooperation.

INSULATING & ROOFING

(Round Table Discussion)

Presiding: Hugh M. Jackson, manager, Industrial Health program, Johns-Manville Corp., New York city

Recorder: Raymond J. Preston, safety supervisor, The Philip Carey Mfg. company, Cincinnati, Ohio

1. *Would like to hear what kind of housekeeping program plants have and methods plants use for reporting to main office?*

   a. Insurance companies have housekeeping inspection reports that could be used.

b. One plant uses a demerit system with percentage rating. Safety committee makes inspection with safety supervisor and foreman. Committee evaluates and makes ratings. A copy is sent to each supervisor giving conditions. Low rating plants receive a letter.

c. Housekeeping standards should be set. Determine how often scrap should be cleaned up. Should keep scrap and debris off floor entirely where possible. Have to set up schedules to do major cleaning jobs such as dust removal. Assign men to clean up work when there is downtime on machines.

d. Use photographs on house keeping inspections to pinpoint bad conditions.

2. How is dust removed from beams?

a. Efforts should be made to eliminate dust by collecting at the source with effective exhaust system.

b. Vacuum clean.

c. Periodic blow down, then vacuum off floor.

d. One company uses a portable vacuum cleaner with plug-in stations for vacuum at various locations along the line to eliminate the use of an excessive amount of hose.

3. Have employees been given any type of formal training in the use of liquified petroleum gas?

a. In some states the code calls for very stringent safety precautions in the handling and use of liquified petroleum gas.

b In one plant the general engineering group developed a manual which is used in a training program for all persons using or handling this gas. Articles are also printed in the plant publication to educate people further in the safe use of this type of gas.

c. Written instructions for people filling gas tanks.

4 What type of training program is used for all in-plant truck drivers?

a Only one company has formal training program which includes an obstacle course. Annual physical examinations are given with emphasis on vision and heart.

5. Have plants experienced eye inflammation from dust particles?

a. Generally only irritation was experienced.

6. What has been the experience with correction of pallets dropping on toes?

a. This seems to be a fairly general problem. One company makes it mandatory that employees wear foot guards on jobs such as take-off on roofing machines where pallets have to be dropped into position.

b. Use metal straps to cradle shingles which eliminates pallets.

c. Use jig instead of pallet. Pick up shingles from jig with fork truck and place in storage.

7. How do you get unsafe pallets out of service?

a. Supervision's job to check this and see that they are taken out.

b. Pallets to be taken out of service marked in warehouse with dab of red paint.

8 How do you create safety awareness on part of employees?

a. Personal contact with employee by supervisor is best way. Have 15-minute-a-day program with at least three men per day. This program can be audited by asking men if supervisor has talked to them.

b. Silver dollar approach. Ask employees how many days since last disabling injury or certain safety rule in their department. If they can give the correct answer, give them a silver dollar.

c. If an employee has too many injuries send a letter to his supervisor.

d. Create enthusiasm through departmental safety meetings.

e. Use Safetygraphs from the National Safety Council.

f. Make sure employees get the proper instructions.

g. Safety awareness comes through training.

h. More engineering is needed before we can say that lack of safety consciousness is to blame. Example: New shingle mill machine installed. Take-off man had to reach about head high to catch shingles. He pulled a pallet up and stood on it to make working position less tiresome. Several days later as he stepped down off pallet he turned his ankle. Report showed that employee was careless. But wasn't lack of proper engineering the real cause?

i. Need better communication between engineering, safety and production departments. Plans for all new installations to be approved by all concerned.

j. Use industrial engineers to make sure proper methods are set up and audit periodically to see that safe methods are still being followed.

9. How do you prevent the two inside men on shingle take-off from tripping over rollers or striking head?

a. No one else seemed to have this problem. Most take-off's are designed so that all take-off positions are on the outside.

10. What is the policy on use of and providing eye protection?

a. No company represented makes wearing of eye protection mandatory over the entire plant. Most plants define hazardous areas such as machine shop, saturator area, take-off, etc. and makes wearing of eye protection mandatory in these areas. One company makes wearing of eye protection mandatory for employees with one eye and maintenance employees.

b. Most companies provide other than prescription safety glasses and goggles to employees. Some companies secure prescription safety glasses for employees at company cost if employee provides the prescription. Other companies stand the full cost of providing prescription safety glasses for their employees.

c. Use of a mild soap solution to wash glasses will help to prevent fogging.

d. Bifocals on the top of the lens of glasses for welders, electricians or other employees required to read gauges overhead have proved to be very satisfactory.

11. Is wearing of safety shoes mandatory?

a. Most companies do not make wearing of safety shoes mandatory.

b. In one company operation where toe protection is mandatory the company provides over-the-toe metal guards. If employees wear safety shoes, the guards are not required.

c. Most companies provide shoes at cost.

12. Is anybody checking operating efficiency other than by accident frequency?

a. Check by accident costs.

13. Does anyone have mandatory rule of not wearing rings on the job?

a. Most companies do not have such a rule.

b. One company has a mandatory rule after having a serious finger injury.

c. One representative reported that just before coming to Chicago to the meeting he had to cut a wedding band off the finger of one of the employees in his plant.

14 What has been the experience with back X-rays on pre-employment physicals?

a. Only one company reported having experience with back X-rays. The cost is about $15.00. Reveal about 65 per cent have some back problem. Not all are rejected, but rejects run high in some cases. Back cases have been reduced since prorgam was initiated. Plan to extend program to other plants within the company.

REHABILITATION IN ONTARIO, CANADA

by DR. BRUCE H. YOUNG
superintendent, Hospital & Rehabilitation Center, Malton, Ont., Canada

The aim of our program of treating the injured workman is to prevent accidents and subsequent disability and loss of skill to industry. To accomplish this, the united effort of legislators, management, labor and medicine is required.

The immensity of the problem is seen in the statistics of Ontario, where more than 120,000 work accidents occurred resulting in more than 70,000 persons being off work for more than five days. The answer to this problem is sought through the combined effort of the legislators, management, labor and medicine, with legislation interpreted by the Workmen's Compensation Board, consisting of three members. It is within this framework that we can accomplish some success in rehabilitation.

I shall discuss our work in cases where an accident has occurred and injured the workman. Our program considers the injured person as its key.

AIM OF PROGRAM

A definition of rehabilitation is "the process of returning an injured workman to a normal and healthy position in his community." The basis of our process is rehabilitation, and to be successful it must be continuous from the first aid station to the return of the injured workman to suitable and gainful employment. In the majority of injuries the patient's own community is where this program should be carried out. Consequently, we strive to utilize the community's resources in medicine to their maximum.

There is a point in the injury when more than the supervision of a doctor, physical therapist or any other single person is necessary. There is also a point in the process of the patient's recovery when the patient's belief in himself begins to wane. To deal with this set of circumstances the Ontario Workmen's Compensation Board provides a Hospital and Rehabilitation Center.

At this Center are the various skills to accomplish our objective, and to superimpose leadership towards recovery for the man by a team. The needs of any given individual vary. Consequently the services offered by the various representatives of this team will vary, depending upon the individual patient requirements. Thus, we provide a program that may be fitted adequately and suitably to an individual's needs.

LADIES GUIDE MEN

We do no active surgical care at our Center. Ours is the care of the patient after the initial medical and surgical therapy. The members of our team are staff doctors, occupational therapists, physical therapists, remedial gymnasts, rehabilitation officers, psychologists, nurses, recreational officer, part time teacher and an administrative staff to see that the overall unit functions smoothly and without delay. In addition, we have the various elements of a maintenance staff, such as cleaners, kitchen and dietary personnel, making a total of 225.

Only male patients are treated at our Center. Therefore, we choose a good percentage of female therapists, since it is my firm belief that we are all notoriously lazy and selfish, and have a natural instinct to exhibit our talents in front of members of the opposite sex.

In this way we have an atmosphere which is void of any militant routine and one in which the necessary element of patient cooperation is stimulated. The young ladies on our staff are particularly skilled in the approach to our workmen, and in obtaining a maximum performance under a given set of conditions.

Our program is basically to gain the maximum physical performance which a man will do. Any program under any circumstances, is only an observation what a man will do, not what he can do, for none of us really know what we can do in terms of physical output, but we all are aware of what we will do. We will do best only what we want to do (the selfish side of our nature), and in our own time (the lazy side of our being).

Certainly the old adage that "you can lead a horse to water, but you can't make him drink" applies in our work. It must be remembered that the sum total of this program is the assessment of the individual from start to finish, and this assessment is only on the basis of what a man will do, not what he can do. In ascertaining the physical capacity of an individual, we must have the patient's full co-operation. This can only be achieved by gaining his confidence.

GAIN MEN'S CONFIDENCE

At the outset we attempt to gain the patient's confidence by a thorough discussion of his problems with a staff doctor. This discussion is then followed by a complete examination of the injured part. We must remember we are treating an individual, not merely an injured part.

Therefore, during this interview and examination we relate the man to his injury. Our patients frequently remark this is the first time they have had an opportunity to discuss their problems thoroughly with a doctor. This initial period also gives the doctor an opportunity to understand the patient's problem, and from this a program of active treatment, based on physical function, is assigned.

There is a saying at our Center that if the man remains with us for four days he will remain willingly until his treatment is completed, because he observes the staff's personal interest as well as his own opportunities for improvement. He also talks with fellow patients and they impart to him knowledge that we try to assist him in getting better.

PHYSICAL THERAPY

Just as it is essential to have the patient's co-operation, it is equally important for the patient to see the actual benefit from his treatment. Most of our patients feel the only form of treatment which benefits them is physical therapy. This is the application of heat to a given part to ease discomfort, the use of massage for relaxation and to ease discomfort, the applications of electrical therapy, or the use of the full length water bath for relaxation.

Any one or all of these methods are interpreted by the patient as being active and useful treatment. These various forms of therapy by easing discomfort, facilitate the next step of the rehabilitative treatment—functional treatment.

In this treatment various occupations offer the necessary use of muscle co-ordination to increase strength so the patient will gain confidence in his own ability and make progress. The use of these methods prepares the man for the work he has to do. I try to explain this to my staff by using the analogy of taking a quinine capsule. None of us would take a spoonful of quinine and drink it down with water, even though we knew the results would be beneficial, because of the extreme bitter taste of quinine.

However, in a capsule it is easy to take and we obtain the same beneficial results. So, with the passive forms of treatment, these act as a capsule around the next step—obtaining proper muscle action individually and in a group manner, thereby increasing strength, as well as re-establishing patterns of movement. It is in this particular field that our Center has made its unique contribution.

PATIENT SELECTS ACTIVITY

We use occupational therapy to develop and re-establish muscle patterns, adapting a craft or activity to a production function. In choosing an activity for the patient, we find if a patient chooses to make a product he or his wife or mother might be interested in, then we have the first evidence of good co-operation. We follow this, with direction by the occupational therapist, into that activity which will produce the most benefit for his injured part.

The activities which we use of a lighter nature are arts and crafts, of a moderate nature we use carpentry, handling projects made from wood, and in our heavy program we use gardening, or simulate or duplicate the man's activity. For example, if it were a hand case, we may want a fine movement such as a needle and thread activity.

However, we go over a list of projects with the patient to find out what he would like to make for himself, or others. His choice will be guided so that making the article will require proper functional use of his hand. It will have the interest necessary, because our patient is doing something he wishes to do, and he will also be exercising his hand properly, regaining its proper co-ordination with other parts of the body.

In this way we have rugged lumbermen, miners and construction workers accept light, unrelated activities with enthusiasm. Certainly a few patients are not interested in this project, so we must look further to find what will satisfy their desires and our requirements. It is necessary that the patient understand his activities.

CASE HISTORY

I like to mention the case of John, hospitalized at our Center after an amputation of his right arm above the elbow joint. On the first day of his hospitalization, he came to me in my office to say in a very belligerent manner, "I don't see any reason for staying here at all. That girl in green gave me, if you can imagine it, a ball to throw, and horseshoes to pitch with my left arm." He said, "I certainly see no reason why I should be required to do this, nor am I going to stay any longer to find out."

After discussing his problem for one hour, he was convinced that although we were going to fit him with a prosthesis and that the prosthesis would help him in holding and carrying activities, he would have to utilize his minor hand and arm to a greater degree than before. The principle behind having him throw a ball and play horseshoes was the first step in gaining co-ordination of this part into a new muscle pattern, and gradually finer skills could be introduced for this previously little used hand.

REMEDIAL GYMNASTS

This patient was the secretary of a local press plant union, and in a week he became one of our staunchest advocates. One's greatest support comes from the opposition who have been converted, because he has been converted by reason. By the same token, men with shoulder injuries work on looms, working at the level of the shoulder, which requires increasing range and muscle power to hold the arm in its new position, and all the time the arm is exercised in its proper manner.

In this stage, to gain muscle power we utilize resistance exercises through the guidance of male therapists. These therapists are called "remedial gymnasts." In this field we consider the male represents a better leader than the female. Under the remedial gymnasts we also have group exercise activities graded into classes. These classes are organized on an anatomical basis, for example, the back class, shoulder class, foot class, hip and knee class and special hand class. In these classes we have group morale development which stimulates the patient. Here the patient sees those about him who are much worse off physically. It is generally true that the more severely handicapped put forth a greater effort, and, in truth, shame those less severely handicapped into a greater degree of co-operation and performance. After a patient says he feels he can go back to work if so-and-so, who is much worse off than he, can perform the way he does. He sees no obvious reason why he should not be able to carry on at his former gainful occupation.

MEN, GARDEN, PAINT, PLASTER

In this group of classes we also have an obstacle course, which is a means of increasing physical exertion, as well as a lot of friendly competition among our more advanced patient groups. As the patient progresses with his program, we try to increase his activities so that he is putting forward an effort as near to the maximum as possible. To do this we utilize a variety of media.

We have 12 acres of grass to cut, and purposely do not have power motors. We have our patients with various types of injuries push the lawnmowers in groups, and thereby keep the lawns in shape. We have flower gardens prepared, planted and maintained by patients. We paint the insides of our buildings, not once, but many times by patients who are painters by trade, or require shoulder activity on their particular job. By graduating these activities the patient gains confidence in his ability to handle his own work.

WORK ON BOXCARS

We have the shortest railway in Canada, which is frequently raised and lowered by injured railway personnel. For the plasterer, we have an area of wall which is continually being plastered to test the man's skill in plastering; for the bricklayer we use the bricks of his trade and allow him to re-establish the fact that he can bend, if he is a back case, or lift and handle bricks, if he is an arm or shoulder case.

He may also carry the hod to gain confidence in ladder climbing. We also have provided a boxcar for those railway men who have to climb and walk, and otherwise handle a boxcar. All these activities are used on a graduated basis to regain the conditioning of the workman for his previous occupation.

If a medical or surgical consultant is required on case, we refer these men to specialists. In our particular area we utilize the staff of the University of Toronto to assist us in sorting out the difficult problems regarding treatment. One year ago we acquired the services of two highly skilled psychologists to evaluate a man's potential for work, to give aptitude tests to those who must change occupations, and assist us in counselling patients who are not responding to the program. We represent as large a psychological unit as there is in this type of work, because our program stimulates psychological health.

A question commonly asked us is, "Do you have out-patients at your Center?" The answer is, "We do not." We can better rehabilitate the patient if he remains for the entire treatment day. By doing this we can control his daily routine.

In addition, we provide him with recreational facilities during the off hours and evenings. A patient who takes our program is required to maintain a reasonable habit as far as work hours are concerned. He is up at 7:30 a.m. for breakfast at 8:00, and commences his daily six hour program by 8:30 p.m.

WALK 2-3 MILES DAILY

Every patient is required to walk a minimum of two to three miles a day. Actually most of our staff cover the same distance. This is true without any other treatment consideration—about five to 10 times the distance he would walk while at home. There are no places nearby to obtain food other than that provided at the Center.

Consequently, our patients are reasonably prompt at meal hours, and this keeps them in touch with the type of control most are accustomed to in industry. The program is on a timetable basis, which requires their attendance—and their attendance is checked. This, again, is supervision comparable to that in industry.

When the patient is sufficiently improved to return to employment, we arrange his discharge from the Center. Approximately 80 per cent of our patients return immediately on discharge. This is arranged through our industrial placement officers during the patient's stay at the Center. They contact the patient's employer and try to give him an idea when the man will be available for work. From the medical side, the original attending doctor is informed by a full medical report on his particular patient every two weeks.

No matter what type of program is set up, we cannot really duplicate all aspects of a man's occupation, and therefore, return to work represents the fourth stage in the man's recovery.

THE REAL TEST

The fourth stage means returning to old friends, to areas where his skill was used before, but where he tests his real ability in competition, and must not only co-operate, but co-operate and produce at the same time. This is an added factor which is most difficult to duplicate.

We, therefore, ask our employers to consider this fact, and many patients receive some form of work modification. The duration of the modification varies with the individual case.

The employers in our province assume a moral obligation in the vast majority of cases to take back their injured workmen. This is a purely moral obligation, because no employer is, by law, forced to accept a workman after injury. We feel that those who do not return to work represent the failure from the Center, even though they may have recovered sufficiently to become independent.

We like to feel that there is a place back in industry, since each of these men came from industry. We do not want to see a scrap pile of broken, unproductive bodies, which represents people whose whole aim in life has been shattered by an industrial accident. However, some end this way despite all our efforts.

The greatest contribution to lessening serious industrial disablement is preventing the accident which has caused the disablement. If it does occur, however, I have

described a program of activity led by a team of dedicated people, from the sweeper to the doctor, whose only interest is locating a solid road to recovery for the injured workman.

We do our utmost to abolish disability which can be abolished by treatment. But if this is impossible we then assist the patient in accepting his disability, and attempt to motivate him to come out with an accepted disability with which he will meet his future in the industrial world.▲

SAFETY TRAINING FOR FIRE PROTECTION FORESTERS

by JOHN F. SHANKLIN

staff assistant, U. S. Dept. of Interior, Washington, D. C.

An official report transmitted by the Bureau of Land Management to the Secretary said of the bad fire situation which existed in Alaska this past summer:

"As a result of a combination of factors, the Bureau of Land Management is experiencing a serious fire situation in Alaska. The driest year in the interior since 1906, coupled with the normal difficulties of vast areas, isolation and rough terrain has created a "bust" fire suppression condition. To combat this situation the Bureau has expended Emergency Fire Funds at a rate of 15 to 20 thousand dollars per day during the month of June. Such expenditures are continuing this current fiscal year and will probably continue through July unless normal rainfall occurs.

"Approximately 400 fire fighters have been mobilized and dispatched to going fires, 12 supervisory personnel were drawn from Area 1, Portland, for assistance in directing fire fighting during June, and 12 replacements have been obtained from Area 2 at Salt Lake and Area 3 at Denver for similar aid during July. Extra tools and equipment have been purchased through GSA at Seattle and flown to Fairbanks. In addition to the six BLM owned and operated aircraft, light planes and helicopters have been chartered from private sources. The military forces have provided excellent cooperation on an emergency basis by providing helicopters and manpower. In addition, the military has assisted the logistic situation by flying gasoline and other supplies into air strips being used as fire operations bases.

THREE FIRES DAILY

"An average of three or four new fires has been and is being reported daily. Most of the fires are lightning caused and appear to have started high on the ridges in spruce timber. During the initial period of the fire fighting season simultaneous lightning fires at great distances apart forced the Bureau immediately to commit its full fire fighting resource to its physical limit. Continued dry weather, increasing hours of daylight, and exhaustion of manpower soon created a lag in the number of fires reported and the number upon which initial action could be taken.

"To meet this continuing demand, the Area Fire Control Officer was forced to establish areas of priority within which initial action could be taken consistent with existing transportation and communication facilities. Manpower has not been the critical item. Once a fire crew was committed to action on any one fire, additional demand immediately developed for the air transportation of relief manpower, additional tools and supplies. The air transportation of these items thus became the limiting factor.

"Action on all new fires occurring outside of the limits of air service had to be postponed or ruled out. It is for this reason there has been an average of approximately 40 fires burning daily with about half of them being manned. Complete control action without rainfall on fires in excess of 40,000 acres appeared to be physically impossible. By July 1 an increasing smoke pall from the several large fires in excess of this acreage had made aerial reconnaissance and regular fire line service practically impossible in some areas."

During that period contact was lost with fire fighters for as long as three days at a time, due to the tremendous volume of smoke. Difficulty was experienced in dropping food supplies and additional fire fighting equipment. More than five million acres were burned over. The tremendous and hazardous operation to bring these fires under control has a direct relationship to the training in safety instituted by the Department of the Interior.

To understand the problems confronting the Department in its safety training program as related to the forest resources administered by the Department requires first, an understanding of our responsibilities.

EXTENT OF RESPONSIBILITY

The Department of the Interior has a total of approximately 57 million acres of forest and woodland in the continental United States. In Alaska it is responsible for some 125 million acres of forest and woodland, including 40 million acres covered by mature timber and 85 million acres of woodland most of which has been devastated by fire and in various stages of natural revegetation. There is an additional 225 million acres of range, marsh and timber requiring protection.

The annual utilization of timber from forests administered by the Department has been averaging approximately 1½ billion board feet in volume and with a value of nearly 25 million dollars. The average number of fires for the past 10 years has been slightly less than 2400 and our average fire loss for the past 10 years has been slightly more than one million acres.

Four Bureaus of this Department are concerned with land management and especially with forest administration; the Bureau of Land Management, the Bureau of Indian Affairs, the Bureau of Sport Fisheries and Wildlife and the National Park Service. Wide differences exist between these Bureaus as to their basic objectives.

The National Park Service administers approximately six million acres of forest lands in the States and approximately one-half million acres in the Territories of Alaska and Hawaii. The obectives of management are primarily to maintain the forests as nearly as possible in their natural undisturbed condition. These forests are cherished for their aesthetic and scientific values. Portions of them are heavily used for recreation.

CARES FOR WILD LIFE

The basic problem of management is to devise ways and means of handling the increased visitor load to the parks safely and at the same time conserve the forests in their natural state. A total of 55 million people visited our national parks and monuments in the calendar year 1956.

The Bureau of Sport Fisheries and Wildlife administers about ¼ million acres of forest lands of which ⅓ million acres are considered as commercial forests. The timber lands found on the national wildlife refuges are managed to demonstrate practical means of developing and maintaining optimum game populations, to produce removable surplus wildlife species for restoration projects undertaken by other Federal and state agencies, to determine the practicability of research findings in the management of forest habitat, to explore means of managing wildlife population, for removal of animal increment through regulated public hunting and, consistent with these objectives and in accordance with sound forest management practices, to obtain the maximum timber yield and return from the refuge forests.

OPERATED FOR INDIANS

The Indian forests, of which 6½ million acres are considered commercial, have the distinction of being managed under the first Federal legislation in the United States in which the practice of sustained yield management was definitely prescribed. The management of the Indian forests is directed towards the same objectives sought in the management of a public forest. However, there are certain

fundamental difficulties which give rise to radically different management problems.

Indian lands are private property held in trust for the Indians by the United States. As such, the timber resources must be managed for the best benefit of the Indian owners. Moreover, by reason of the fact that the Indian forest property is so closely interrelated with the welfare of the Indians themselves, forest management plans must recognize the general Indian problem and be coordinated with the whole program of social and economic betterment for the Indians. This necessitates a far greater flexibility in long-term forest management plans than is ordinarily required or considered ideal from a purely technical viewpoint.

Generally speaking, the first objective of Indian forest land management is to obtain high level timber production. The second is to obtain for the Indian owners the highest possible income not only through the sale of stumpage but also through the direct employment of Indians.

The forest lands administered by the Bureau of Land Management fall into three major categories. The first, the revested Oregon and California railroad grant lands and reconveyed Coos Bay Wagon Road grant lands in western Oregon, commonly referred to as the O & C lands. Second, the public domain forest lands in the continental United States, and third, the public domain forest lands in the Territory of Alaska.

TOP AMERICAN FORESTS

Forestry on the O & C lands presents one of the most challenging problems in American timber management. On these lands are some of the finest stands of original timber left in this country. Their economic and social importance both locally and nationally places them in the front rank of American forests. In accordance with basic legislation, it is the policy of the Department to restrict cutting timber on these lands to their sustained-yield capabilities.

It is the policy of the Department to direct all timber cutting operations under approved rules of forest practice. Moreover, it is the policy of the Department that these rules of forest practice shall be established only after full consultation with a local advisory board consisting of citizens of the State of Oregon who represent the lumber industry, the forestry college, conservation associations, labor unions, grazing mining and agriculture.

The management objectives for the approximately three million acres of commercial public domain timber in the West are much the same as for the O & C lands. However, these plans are subject to the establishment of policy determinations as to whether the lands should be retained under the jurisdiction of the Federal Government or should be disposed of to public agencies, private citizens or corporations.

In addition to these commercial timber lands there are 25 million acres of woodlands on the public domain. These are found chiefly within the grazing districts and are of considerable importance locally as a source of fence posts and related material for use by the range industry. The management of these lands is definitely keyed to the objectives sought in the management of the range lands.

FIRE SAFETY MAJOR PROBLEM

In the Territory of Alaska a major problem confronts the Department in determining proper management for the tremendous extensive areas of forest and woodlands. To date the objective has been to provide something approaching adequacy of protection from fire. This has not been entirely achieved, as reference to my opening statement in this paper will show. But the future appears to be much brighter due to a better understanding by the citizens of Alaska of the need to exclude fire from the Territory.

To relate safety training for fire fighters to the fire situation referred to in the opening paragraphs of this paper, let us look at exactly how the Bureau of Land Management provides safety training.

The Bureau at the present time does not have either a safety manual or any specific safety instructions issued solely for training in safety with respect to forest management. General instructions pertaining to the entire work of the Bureau have been prepared by several of their field offices. All field areas use safety material issued by other agencies, Federal, state and private.

The Bureau does not have a safety committee functioning at its national level, but each of its major regional offices has a functioning committee. None of these regional, or area offices as they are termed by that Bureau, nor any of its state offices have made any special safety studies in the field of timber management, and no analyses have been made of accidents occurring in the timber management field alone.

TRAINING SESSIONS

However, each year training sessions are held for fire control and timber cruising. Such programs always include training in first aid and safety.

The Bureau has approximately 300 permanent foresters and 60 temporary foresters. It operated during the past year 18 fire training schools at which approximately 250 employees were present. It also operated five timber cruising schools at which approximately 100 employees were present. Furthermore, 24 Bureau employees attended some six training schools supervised by other agencies.

All employees are required to follow certain safety practices including those employees concerned with forest management. These safety practices include:

1. Equipping all of the Government vehicles with fire extinguishers and first aid kits.
2. All fire fighters are being equipped with hard hats as rapidly as sufficient funds are made available.
3. On all project fires a first aid station is manned by qualified first aid attendants.
4. All employees are encouraged to take the essential courses in first aid.
5. It is general practice not to permit single persons to work in an isolated area. Two or more are always assigned.
6. Radio communications are being installed as a safety measure in fire control.

As examples of the exact safety program, two states will be described quite comprehensively.

IDAHO SAFETY PROGRAM

The Bureau's program in Idaho is fairly well organized. It so happens that the Area Fire Control Officer is also the chairman of the safety committee. Accordingly, he also handles the safety programs at the fire training schools. All Bureau vehicles in this state are equipped with a safety packet which includes a first aid kit and instructions for first aid treatment together with the necessary forms required for accident reporting.

All grazing districts in this state are equipped with a very high frequency radio communications network. A base station is located at strategic high points to insure communications to mobile units operating in other parts of the state. From a safety viewpoint, radio communications are very necessary.

Second, the Territory of Alaska. In Alaska, as we have already indicated, special problems confront the Bureau in safety training. In Alaska, two foresters serve on the Territorial Safety committee. All permanent and temporary foresters and temporary fire guards are required to take first aid training. This training includes instructions on survival in the Arctic. To insure the safety of employees working on fires, cruising timber or on routine inspection, it is mandatory that the crews consist of two or more.

USE CHECK-OFF LIST

In order to insure the safety of all employees involved in air operations in connection with the fire control and timber sale programs of the Bureau, the Civil Aeronautics regulations are followed explicitly. This includes the use of a printed check-off list before each takeoff.

The Bureau has developed picnic areas along the highways in Alaska especially at those points where the highways either cross streams or are close to lakes. This was done essentially as a fire hazard reduction measure. Campers, picnickers and travellers who stopped along the highways to cook a meal usually found heavy debris and deep organic material. To clear out a place for cooking or warming fire was quite discouraging. Many times fires were built on wet organic material that was in some cases mistaken for

mineral soil. Many fires have originated from such a situation. However, with the development of over 30 picnic areas by the Bureau, the incident of man-caused fires along the highways was measurably reduced.

Comparable training is given in the Bureau of Indian Affairs. However, there is a very interesting development in the field of fire safety training which involves the Indians under the administration of this Department. We have what is called the Red Hat Program in which several hundred Indians from the Southeastern states are annually trained. These Indians, it has been found, make the finest fire fighters of any personnel in the United States, and their services are utilized by all forest fire services both in this Department and in the Department of Agriculture as well as by state agencies.

LOW ACCIDENT RATE

This training program, initiated by the Bureau of Indian Affairs, includes training by the Forest Service and the National Park Service. The training afforded these Indians has certainly paid off well, not only in bringing fires under control but in taking care of themselves while on fire lines with the least possible record of accidents of any group of forest fire fighters commonly used in this program.

The isolated nature of the installations maintained by the Bureau of Indian Affairs on each large reservation presents serious problems in protection and safety training. Many of the reservation agencies are in close proximity to extensive areas of forested land.

The protection and training of thousands of Indian children who attend reservation schools in programs designed for their safety are of special concern.

Fire hazards are high because the agency buildings are generally old. Consequently the wiring and heating systems are often inadequate by present day standards. Occupational hazards are ever present in the numerous garages and other service shops where power tools are in use.

In recognition of its special problems the Bureau has a safety committee functioning at the national level. Similar committees function at the Area and Agency levels. In all, there are over 100 safety committees. A Safety Director has been appointed to head up the program. Two safety engineers were hired within the year to provide guidance and impetus to it.

NATIONAL SAFETY COMMITTEE

The enthusiasm created in all ranks of personnel by these developments in the safety field insures that this program will take its rightful place among all the others carried on by this Bureau. The safety training of fire control personnel should benefit under the skilled direction now available.

Finally, let us look at a problem in safety training which is allied with our management work. Recreation is considered one of the multiple uses within the over-all forest management programs of most land managing agencies. For example, more than 33 million visits were made to the national parks and monuments last year, and while these visitors are on Department lands every effort is made to insure that the visit includes a safe experience.

SAFETY FOR VISITORS

Here are some of the activities in health and accident prevention which are applied to visitor activities and also to employees in general by the National Park Service. In order to insure visitor health, many types of actions are required including:

a. Provision for potable water.
b. Provision for sanitary rest rooms.
c. Provision for adequate garbage disposal and camp ground cleanliness.
d. Provision for first aid facilities.
e. Provision for inspections of eating and lodging facilities in order to insure adequate sanitation.
f. Provision for hospitalization and medical care.
g. Periodic inspections of bathing and swimming facilities.
h. Elimination of noxious insects, plants and animals in public use areas.

Many things are done for the safety of vistors. Highway safety practices are included in the design, construction and maintenance of park roads. Hazardous trees such as leaning or dead trees are removed from the public use areas and road sides. Elevators, used principally in those parks with caves, are regularly inspected.

All structures within the National Park System are given regular periodic fire hazard inspections. Fire control facilities for all structures are available and building fire brigades trained in structural fire control. The Service maintains regulation and inspection of all mountain climbing activities. It maintains regulation and inspection of many water activities. It inspects ski lifts and tows and provides for safe practices for winter use activities. The Service trains and provides lifeguards, patrols and rescue teams.

It provides for safe walking surfaces, including hand rails and guard rails at hazardous points within the parks. It provides boardwalks in the thermal areas and enforces all visitor activities pertaining to enjoyment of bear and deer. The Service insists that safety features be followed in the designs of new public use structures. It also has regulations for the installation of automatic sprinklers in multiple story hotels.

EMPLOYEE PROCEDURES

As employee safety has a direct relation to visitor safety, the National Park Service has developed many specific general employee safety procedures. It has safety committees at all field and regional levels and follows the dictates of the Department requiring Government drivers' licenses.

It provides orientation training and on-the-job training for employees, including training in safe practices. All employees' quarters and working structures have regular periodic structural fire hazard inspections. First aid training is required of all protection personnel. It requires training of all personnel involved in structural fire control, water activity protection, and all mountain and winter sports personnel.

The Bureau of Sport Fisheries and Wildlife has an over-all safety program which applies to the management of its forest resources as well as all other activities. The program is based on the Bureau's safety policy which, in essence, states that safety is an integral part of every task. No job is so important or no service so urgent that sufficient time cannot be taken to perform them safely.

Each employee is directed to give safety the same serious thought and consideration that he gives other phases of his work. The rules for safe operation of motor vehicles and certain other equipment and tools as well as safety in construction work are set forth in a Safety Requirements Handbook and other instructions.

EQUIPMENT STANDARDS

The Branch of Engineering is responsible for the establishment of standards in respect to the acquisition, operation, maintenance and review of operating methods for all equipment from the standpoint of job adaptability and safety, industrial safety, fire prevention, public and employee safety and provides technical assistance to the regional safety committees in evaluating the causes of accidents and making recommendations for remedial actions.

Each Regional Office has a safety board and a fire board responsible to the Regional Director for program development, directed toward improving safety conditions and reducing fire losses. The fire board is specifically directed to assist the Regional Director in determining responsibilities, developing programs to prevent fire losses and in improving fire pre-suppression and suppression.

The National Wildlife Refuges and Fish Hatcheries hold monthly safety meetings and on-the-job training in their respective work activities, including timber management and fire suppression. Periodic fire inspections are made on all buildings and facilities. Over-all safety inspections are required of Regional Supervisors on each visit.

Public education and active participation in fire pre-suppression and suppression are sponsored in those areas of high

fire hazard and extensive public utilization. Radio communication facilities are used extensively in the National Wildlife Refuges to facilitate patrol and for directing fire fighting activities. Controlled burning is practiced as a means of wildlife management and to reduce fire hazards in certain areas. Slash disposal and other fire safety requirements are written into timber cropping contracts. Each National Wildlife Refuge and Fish Hatchery has a fire plan appropriate to its problems.

The Department provides for safe working conditions for employees and where functions are hazardous, provides the necessary training to alert employees how to handle themselves safely.

HOW TO SET UP AN INDUSTRY SAFETY TRAINING CONFERENCE

by W. C. CREEL
safety director, North Carolina Dept. of Labor, Raleigh, N. C.

Safety training is one of the greatest needs in accident prevention work. While this need is generally recognized, very little has been done on an industry basis to promote safety training. One idea used successfully by one section of the National Safety Council is to use the conference method to promote safety training.

The leaders of the fertilizer section of the National Safety Council promote safety training for the fertilizer industry. They believed that the need for safety training was so great that a special committee was set up to promote safety training.

The committee further felt the greatest need was on the supervisory level, and therefore, set up the Supervisory Training committee. This committee, with the full assistance of the entire fertilizer section has conducted two successful industry safety training conferences.

MUST TRAIN SUPERVISORS

The first objective in setting up an industry safety training conference, is to sell the industry on the idea. In the fertilizer section, the selling job started with the entire executive committee of the section. The proposals of the Supervisory Training committee were explained, and suggestions were received at a regular executive committee meeting. After complete plans were approved, the executive committee was asked to endorse the plans, and give full cooperation. Securing this cooperation was probably the most important step in assuring the success of the safety training conferences.

The great need for safety training in the fertilizer industry is on the supervisory level, as is true in the wood products section and the pulp and paper section. Once the level of the conference was established, emphasis was placed on making the conference as practicable as possible. With these ideas in mind, it was decided the conference should be in the form of a training course—more of a school than a social get-together.

The general idea for the meeting was to instruct fertilizer industry supervisors in the latest techniques of accident prevention and to train them in setting up their own plant safety programs. The importance of a supervisor in a plant safety program and the ways he could reach the worker was stressed throughout the program.

The topics on supervisory safety training included "Safety and the Foreman," "Know Your Accident Problem," "The Human Element," and "Safety Education and Training."

Besides the topic of supervisory training, basic subjects in a plant safety program were presented. These included "Safety Organization," "Materials Handling and Storage," and "Housekeeping."

A special session on "Practical Problems in Supervisory Safety Training" was held to allow all participants to take part in an open discussion.

The course was based on the needs of the industry and followed the suggestions in the National Safety Council's Supervisory Safety Training Manual. In fact, this was one of the two textbooks used for the course. The other was the Safety Subjects, revised 1956, U. S. Department of Labor.

The agenda for the meeting was planned so that a wide variety of methods of safety training could be used. The straight lecture was used only in combination with some other method.

DISCUSS MAJOR HAZARDS

A most important part of the two day program was a planned group discussion on major hazards in fertilizer plants.

Each student was asked to designate on a card the group discussion section he wished to attend. Assignments were made on the basis of these requests and each student attended one of the three group meetings where the leaders presented the problems and lead an open discussion. At the end of one hour the groups met together and a designated person reported for each of the groups.

The audience participation plan was used in the "The Accident Problem" presentation. Each student received a series of 12 questions to answer. At the end of the period the instructor gave the correct answers. The questions covered basic information on the accident problems in the fertilizer industry.

The audience participation method was also used in the presentation of the topic on "Plant Inspection." Each student was given a flow chart showing the steps in the operations of a dry mixing plant and asked to mention hazards with which they were familiar. The instructor then summarized likely hazards for the important fertilizer plant operations.

MOCK SAFETY MEETING

A mock safety meeting was used as one form of panel discussion. The instructors acting as members of a plant safety committee actually conducted a plant safety meeting. The instructor briefly gave the fundamental ideas of a safety committee before the mock demonstration, and summarized the safety committee's part in a plant safety program after the mock demonstration.

The instructors for the safety training course were selected to give variety to the sessions. A college professor presented the basic ideas of training, and an industrial safety engineer with teaching experience gave the basic ideas on accident prevention. Discussion leaders from the industry were selected to give prestige and guidance for the meeting. The idea of balance, as well as variety, was stressed throughout.

The accepted basic methods of presentation were used, including some from our visual aids. In every unit, one of the best received visual aids material was the new National Safety Council series of training films, "Safety and the Foreman." This series is recommended for any safety training course.

The committee went to great lengths to plan details for the meeting. Besides the usual name badges, banquet and local newspaper publicity, two or three different ideas were successfully used for instruction. At the mid-morning and mid-afternoon breaks, cokes were provided saving time and offering an opportunity for fellowship. In addition, all participants were given an opportunity to meet with one of the industrial leaders for an individual conference, on their specific problems.

The two conferences were attended by 94 people representing 56 plants. Each participant received the basic ideas of safety training and instructions and materials to set up a safety training program for their individual company or plant. Other regional conferences are being planned for the fertilizer committee. The executive committee of this section has completed a successful project and has done much on an industry wide basis for the cause of accident prevention.

I believe the following conclusions will be of interest and benefit to all engaged in industrial safety.

- There is a real need for supervisory safety training in the fertilizer industry as well as the wood products and pulp and paper industry.
- The industry recognizes the need for supervisory training and will send plant

representatives to a regional safety training conference.

- Full cooperation of the National Safety Council, state agencies, and safety leaders can be obtained for conducting supervisory safety programs.

The fertilizer section of the National Safety Council is comparatively new. The wood products section, and the pulp and paper section are not only much older, but are larger and more influential. It is a real challenge to you as individuals and representatives of your section to do something about the need for safety training in your industry. If you want to make a lasting contribution to the cause of accident prevention in your industry, urge the executive committee of your section to start immediate plans for safety training.

PROMOTING WOODS SAFETY

by J. KENNETH PEARCE
professor of Logging Engineering, College of Forestry, University of Washington, Seattle, Wash.

In considering what I, an amateur in safety, could say to you professional safety men who represent firms with excellent safety programs and award-winning safety records, my thoughts wandered back to my laboring days in the woods. Thirty-seven years ago I was hired as a third rigger on a Lidgerwood skidder out of Union Mills, Washington, now a ghost town. I had worked on ground lead and high-lead yarding crews but had no experience with skylines.

My first morning on the job the head rigger handed sledge hammers to me and another green young third rigger and told us to go knock the tail hold on the skyline loose. That was all the instruction we received. We proceeded to the back end where the one and one-half inch diameter wire rope skyline was wrapped around a stump and fastened with railroad spikes. One thousand feet of skyline was suspended 100 feet in the air between head tree and tail tree shoes.

SAFETY ORIENTATION

The surplus length of the skyline lay stretched out on the ground to one side of the stump. We started knocking out spikes, and soon the skyline started to run. The wraps sizzled and smoked around the stump and the loose end flailed around like a snake. How we got out of there alive I don't know.

That incident typifies the "let him learn the hard way like I did" attitude toward the green hand coming into a logging camp in those days. No one told him how to do the job safely. Great progress has been made in woods safety since those days. In the operations today safety goes hand-in-hand with production and safety-minded foremen keep a watchful eye on the training of the green hand. But are you doing all that could be done to promote safety at the time the worker is most receptive, most eager to learn? This time is when a young man first comes to work in the woods, or in your operation.

Many of my senior logging engineering students have worked one or more summers in logging labor jobs. Some have worked for companies with outstanding safety records. When I asked the students what orientation or safety training they received, all replied that they started right to work with the whistle the morning they reported. Any orientation they received came from their immediate supervisor.

They felt it was just luck if they started under a helpful, safety-minded supervisor. (Of course it was good management, but they did not realize it at the time, and no one told them this was part of the safety program.) The concensus of the students said that the weakest part of the safety and labor-relations program of the employer was how they were handled when they first went to work in the woods.

Some executives in the Pacific Northwest logging industry have felt concern that young men from communities which traditionally furnished woods labor are going instead to aircraft and other industries. One deterrent to recruiting the active, intelligent young men is the accident record of the logging industry, well known in woods communities.

ACCIDENTS DISCOURAGE WORKERS

Not so well known is the fact that logging accident statistics show the highest accident frequency rate among the youngest age class and the group with the least number of months experience. Efforts are being made through Junior Logging Congresses, vocational talks to high schools, and industry films, to attract young men to the logging industry. A good safety record could be a potent recruiting aid.

The book "Safety Subjects" published by the Bureau of Labor Standards, U. S. Department of Labor, used as a textbook in my class "Safety Practices in Forest Industries," makes a distinction between safety education and safety training. Education is defined as broadening of knowledge and understanding; training as the development of skill in performance. Safety training is usually competently handled by the safety-minded supervisor. But what about the safety education, particularly of the new employee? Is this a weak link in the chain of woods safety promotion?

University authorities have found it worth while to take the first one, two or even three days at the start of the new academic year for the orientation of the freshman and other new students. If college students need orientation, is the man in the same age group entering industry any less in the need of orientation?

SAFETY EDUCATION PROGRAM

The following program of orientation, and initiation of safety education, is suggested for groups of new employees of large operations. It embodies suggestions from students as to what they would have liked to have had when they first started to work in the woods, as well as my own ideas, as an ex-logger, foreman and superintendent.

1. *Orientation Session.* The first morning they reported the new men would be brought together for an orientation session. The Logging Superintendent would tell them of management's interest in safety and other company policies. An organization chart of the operation and authority might be shown.

Opportunities for advancement in jobs with the development of skills and learning by experience would be explained. The timekeeper would explain pay periods and procedure, deductions and insurance plans. The forester or fire warden would emphasize the importance of fire prevention and the organization for fire-fighting, since every man in the woods is a potential fire-fighter.

2. *Safety Education Session.* Following the orientation session, the safety supervisor would take over, and tell them of the safety program, first aid facilities and the training program. Safety training films are available from the various Loggers Associations, the American Pulpwood Association, State Safety Departments and the National Safety Council.

REPETITION VALUABLE

Booklets or cards covering job safety instructions would be issued and discussed. The value of repetition cannot be over-emphasized. Even college students can learn only by the repetition of reading the textbook, taking notes on the lecture, and writing the examination.

Ample opportunity and encouragement to ask questions should be given. Time for private talks with the personnel man should be made available for men who have a question or problem they do not want to voice in the group sessions.

3. *Observation.* Opinion among my students was divided as to how the first afternoon should be spent. Some thought that a tour of the whole operation, and observation of the various operations, such as yarding and loading, felling and bucking, road construction, and the shop to give the whole picture, would be helpful. Others thought that the afternoon might be better spent by observing the particular activity or job in which they

are to work, in company with their foreman, who would point out the safe and efficient way to do the job.

The foregoing orientation and safety education program is obviously not suggested for boomers or drifters who will hit the road with their first paycheck. Rather it is intended for the "home guards" who can be expected to stay on the job long enough to justify the time and money expended on them. It would be followed up at intervals with evening safety education sessions, using audio-visual aids.

Since the average 20 to 24 minute film teaches more lessons than can be absorbed, combining the running and re-running of short sections of a training film with the discussion-conference technique, is advocated. As an example, the Rarig Motion Picture Company of Seattle reproduces the sound-color film "Hauling Logs" which they made for the British Columbia, Pacific Northwest and Redwood Loggers Associations, in six four-minute sections. They publish a film guide of questions and answers for each section and a "Conference Leaders' Manual" to accompany the films.

The small operation, or the one to which new men come singly, presents more of a problem. However the same objectives of orientation and safety education, accomplished by individual discussion, rather than group sessions, would improve labor relations and promote woods safety. This is only a preliminary to the most important on-the-job safety training under a safety-minded supervisor.

OFFICERS OF THE

PULP AND PAPER SECTION

NATIONAL SAFETY COUNCIL 1957-58

General Chairman—EARL F. RIPSTRA, personnel manager, Container Corp. of America, Chicago, Ill.

Vice-Chairman and Program Chairman—R. G. BELKNAP, personnel manager, Bemis Bro. Bag Co., East Pepperell, Mass.

Newsletter Editor—GEORGE R. MERRIMAN, safety coordinator, International Paper Co., Southern Kraft Div., Mobile, Ala.

Secretary and Membership Chairman—D. V. HILL, safety director, The Mead Corp., Kingsport Div., Kingsport, Tenn.

REGIONAL MEMBERSHIP REPRESENTATIVES

Great Lakes—*ARTHUR CARLE, safety director, The Northwest Paper Co., Cloquet, Minn.; *East*—*H. P. HEUBNER, insurance manager, The Flintkote Co., New York, N.Y.; *South*—*DALLAS E. HENRY, safety coordinator, Southern Advance Bag Operation, Continental Can Co., Inc., Hodge, La.; *Canada*—*DOUGLAS B. CHANT, secretary-engineer, The Ontario Pulp & Paper Makers' Safety Assn., Toronto, Ont., Canada; *Midwest*—*FRANCIS H. WAGNER, director of safety, The Mead Corp., Chillicothe, Ohio; *West*—ROBERT M. GILMORE, general safety supervisor, Rayonier, Inc., Hoquiam, Wash.

Medical Advisor—DR. A. P. ASSELSTINE, medical director, Spruce Falls Power and Paper Co., Ltd., Kapuskasing, Ont., Canada.

Special Projects Committee: Chairman: GORDON B. LEMKE, research engineer, Employers Mutuals of Wausau, Wausau, Wis.; LAMBERT LOUY, safety director, Container Corp. of America, Chicago, Ill.; *A. E. MINOR, safety supervisor, The Ontario-Minnesota Pulp and Paper Co., Ltd., Kenora, Ont. Canada; D. L. EISENACH, safety director, Minnesota and Ontario Paper Co., International Falls, Minn.; RUSSELL E. BELL, safety director, The Crossett Co., Crossett, Ark.; ROSS E. SCOTT, assistant to the secretary-engineer, The Ontario Pulp & Paper Makers' Safety Assn., Toronto, Ont., Canada; FORREST E. KIMMELL, safety & medical director, Sutherland Paper Co., Kalamazoo, Mich.; HARRIS K. WILLIAMS, assistant coordinator of safety, Southern Kraft Div., International Paper Co.; Pine Bluff, Ark..

Contest Committee: Chairman: A. SCOTT DOWD, president, Fritz Publications, Inc., Chicago, Ill.; *J. FRED BERRY, general insurance manager, Alton Box Board Co.; Alton, Ill.; *HARLEY B. GOODRICH, maintenance engineer, Strathmore Paper Co., West Springfield, Mass.; JAMES N. CONAWAY, manager of safety & plant protection, Industrial Dept., Scott Paper Co., Chester, Pa.; *FRED O. SOUGHTON, services & safety supervisor, LongLac Pulp & Paper Co., Ltd., Terrace Bay, Ont., Canada; DAN ADAIR, coordinator of safety activities, Pacific Coast Assn. of Pulp and Paper Manufacturers, Portland, Ore.

PULPWOOD LOGGING DIVISION

Division Chairman: FRANKLIN LARRABEE, assistant director of personnel—Woodlands, St. Regis Paper Co., Bucksport, Maine

Publication Committee: Chairman: T. C. DONNAN, safety supervisor, Spruce Falls Power & Paper Co., Ltd., Woodlands, Kapuskasing, Ont., Canada; LEO ST. DENIS, woods employment supervisor, Abitibi Power & Paper Co., Ltd., Iroquois Falls, Ont., Canada; EDWARD C. CORDON, staff forester, Louisiana Forestry Commission, Baton Rouge, La.

Visual Aids Committee: Chairman: R. C. HAMMOND, safety engineer, Employers Mutuals of Wausau, Duluth, Minn.; H. GORDON BARRETT, safety inspector, The Ontario Paper Co., Ltd., Thorold, Ont., Canada; CARL G. STRICKLAND, assistant wood procurement manager, Gaylord Container Corp., Div. of Crown Zellerbach Corp., Bogalusa, La.; PAT REITEN, personnel manager, Simpson Logging Co., Portland, Ore.

PULP MANUFACTURING DIVISION

Division Chairman: HARRY J. HAHN, safety supervisor, Hammermill Paper Co., Erie, Pa.

Publication Committee: Chairman: W. B. BALLINGER, safety coordinator, Brunswick Pulp & Paper Co., Brunswick, Ga.; ROBERT W. WOOD, staff safety supervisor, Kimberly-Clark Corp., Neenah, Wis.; JAMES E. EMMERICH, safety director, Mosinee Paper Mills Co., Mosinee, Wis.

Visual Aids Committee: Chairman: CHARLES R. HAGAN, safety manager, Oxford Paper Co., Rumford, Maine; OTTO WAGERS, safety supervisor, The Champion Paper and Fibre Co., Pasadena, Tex.; PHILIP L. DANDRIGE, safety coordinator, Sonoco Products Co., Hartsville, S. C.; SAM BLACKWELL, safety supervisor, Olin Mathieson Chemical Corp., Forest Products Div., West Monroe, La.

PAPER MANUFACTURING DIVISION

Division Chairman: ROBERT J. GELL, staff assistant, Paper Mills Div., Eastman Kodak Co., Kodak Park Works, Rochester, N. Y.

Publication Committee: Chairman: MERLIN C. RACE, safety director, St. Regis Paper Co., New York, N. Y., M. C. M. POLLARD, director of safety, National Gypsum Co., Buffalo, N. Y.; A. E. TOPMILLER, safety supervisor, The Champion Paper and Fibre Co., Hamilton, Ohio; RALPH E. MYERS, safety supervisor, Chillicothe Div., The Mead Corp., Chillicothe, Ohio.

Visual Aids Committee: Chairman: GEORGE A. LAHUSEN, general safety supervisor, Crown Zellerbach Corp., Portland, Ore.; JAMES M. PINKSTON, JR., personnel & safety supervisor, Crossett Paper Mills, Crossett, Ark.; HARRISON J. DAYSH, secretary, Industrial Relations Committee, American Paper and Pulp Assn., New York, N. Y.; FRANK C. HARMON, employment manager, Hollingsworth & Vose Co., West Groton, Mass.

PAPER CONVERTING DIVISION

Division Chairman: V. P. COULON, safety director, The Sealright Co., Inc., Fulton, N. Y.

Bag Manufacturing Committee: Chairman: HAROLD HEWITT, assistant personnel manager, Bemis Bro. Bag Co., Peoria, Ill.; JOHN T. WARREN, director of training, St. Regis Paper Co., Pensacola, Fla.; CHARLES H. MASON, safety & training director, Robert Gair Co., Inc., New York, N. Y.; TOXIE R. TRIM, safety director, Gaylord Container Corp., Div. Crown Zellerbach Corp., Bogalusa, La.; ALBERTO CHIPCO, safety director, W. R. Grace & Co., Lima, Peru, S. A.

Box Manufacturing Committee: Chairman: CARL J. LAMBERTH, personnel manager & safety supervisor, Container Corp. of America, Chattanooga, Tenn.; DR. KARL F. SIMPSON, JR., director of industrial relations & safety, Folding Paper Box Assn. of America, Chicago, Ill.; JACK WALL, personnel manager, Grand Rapids Mills and Folding Box Plant, American Box Board Co., Grand Rapids, Mich.; HENRY KVINTUS, safety director, Cornell Paperboard Products Co., Milwaukee, Wis.

Roofing Manufacturing Committee: Chairman: H. R. MESLER, JR., safety director, The Ruberoid Co., New York, N. Y.; R. J. PRESTON, safety supervisor, The Philip Carey Manufacturing Co., Lockland, Cincinnati, Ohio; FRED INGHAM, assistant insurance manager, The Flintkote Co., New York, N. Y.

Insulation Manufacturing Committee: Chairman: BUDWIN J. LEE, safety director, Wood Conversion Co., Cloquet, Minn.; AMOS S. KEEN, manager of safety, Personnel Administration Dept., Armstrong Cork Co., Lancaster, Pa.; M. F. MATTSON, safety supervisor, Insulite Div., Minnesota and Ontario Paper Co., International Falls, Minn.

Specialties Manufacturing Committee: Chairman: HAROLD E. TEBO, personnel supervisor, Baryta Div., Kodak Park Works, Eastman Kodak Co., Rochester, N. Y.; JACK HARTLEROAD, safety director, The KVP Co., Kalamazoo, Mich.; WILLIAM A. STRACHAN, plant manager, Fibreboard Paper Products Corp., San Francisco, Calif.

OFF-THE-JOB SAFETY DIVISION

Division Chairman: LEO M. SHAW, manager, C & C Plant Services, Carton and Container Div., General Foods Corp., Battle Creek, Mich.; *KENNETH L. FAIST, coordinator of employment and safety, The Champion Paper and Fibre Co., Hamilton, Ohio; CARL W. BEHNKE, district engineer, Hartford Accident and Indemnity Co., Grand Rapids, Mich.

Staff Representative—ROBERT CURRIE, National Safety Council, Chicago, Ill.

*Past General Chairman.

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

THE RAILROAD SECTION

This volume is a record of the sessions held at the 1957 National Safety Congress by the Railroad Section. The conduct of these Congress sessions each year is only one of the many cooperative activities which the Railroad Section carries on in behalf of its members, and for the benefit of accident prevention work in the railroad industry generally. The section gives guidance in the preparation of a great variety of technical and educational material useful in the day-to-day safety programs of railroads.

The activities of the section are under the direction of its executive committee, the members of which are listed at the close of this volume.

TOGETHERNESS IN TRANSPORTATION

by J. T. URBAN

assistant to the vice president & general manager,
The Denver & Rio Grande Western Railroad co., Denver, Colo.

Our subject "Togetherness in Transportation"—*deals primarily with safety in that* field although, literally, it is applicable to every department of railroading since they are closely integrated. Functionally—to a greater extent—they involve personnel, from which are developed the foremen and supervisors of the organization; herein lies the basic alliance with the safety program. How much—how broad—and the proper ingredients—are difficult to estimate but the proof lies in the fact that members of the National Safety Council have provided the receipt—the policies and procedures to be followed:

"Togetherness" means from the start—not just ultimately. It is generally agreed that a majority of potential accident risks can be spotted during the pre-employment test period. Various methods of obtaining the initial information are employed—as you are no doubt aware. *Considering the data at* hand, indication of a spotty job history, frequent minor injuries, numerous hospitalization and evidence of law violations, arrests and convictions (through finger printing the applicant) all suggest instability and/or pre-disposition to have accidents.

Social and legal-aid agencies, credit agencies and banks listed may also yield valuable information. Tracing with all former employers as to the employment record and job experience of the individual are highly important. Not only does this preclude spending an endless amount of time and money testing an applicant who may later be disqualified because of his past record, but such a program provides some degree of assurance to the regular employee that management is attempting to secure the safest employee possible to work with them in their regularly assigned duties.

FINGER PRINTING APPLICANTS

To touch upon one phase of this program, approximately seven years ago the Rio Grande instituted finger printing the applicants. To date, slightly more than 13,500 individuals have been finger printed, out of which approximately 2,500 had a police or criminal record—although more than 50 per cent of these denied ever having been arrested, and 520 of the total with police or criminal records were not considered employable.

Coincident with this program some clues may turn up as to his personality traits and how well a worker adjusts to every day living is just as important as his ability to get along with other people. Further, it is possible to gain some measure as to what his future behavior will be. If he is a misfit he will develop a poor record, part of which will be his accident and injury rate. Hence with proper orientation and cooperation from foremen, supervisors and co-workers, we may prevent a new man from becoming a misfit or poor performer. Generally speaking, he wants to make good and the natural thing to do is to capitalize on *this feeling.*

Negative and hostile attitudes may be spotted during the first impressionable days of the employee on the property. Job satisfaction is a personal feeling a man has to his job. Morale is a group feeling, rather than personal—*both of which can, and do,* exert a tremendous influence on the potential accident and injury rate.

LACK CONSTANT SUPERVISION

A short step beyond the new employee is *the presently* employed worker—the "old timer" and the "in-betweener." Unlike the mechanical and maintenance of way worker, a transportation man is not under constant supervision by his foreman. Protective devices and engineering safeguards have about reached the point of diminishing returns in accident prevention.

The next approach must be to people. We are all susceptible to the malady of boredom and monotony. Younger men, through observation, may learn bad habits or practices in safety from older men who feel secure in the fact they have gotten away with their home-made short-cuts over a long period of time.

Supervision at the division or department level cannot ignore its safety responsibility *and assume, incorrectly, that it is the safety* department's duty alone—and vice versa. Their "togetherness" must be complete and harmonious—clearly understandable—through distinct communication so they may be compatible, complement one another and obtain the proper end results. In this connection, the division supervisors should endeavor to make a detail survey of all accidents or injuries to develop the real cause, uncovering therefrom potential or unsafe practices or conditions that might lead to, or result in, a more serious situation at a later date. This is the procedure when a claim is filed—and it can be just as efficacious without waiting for such an occurrence.

SELF-INTEREST UNIVERSAL

Strange, complex and "*mysterious*" as we human beings sometimes are, there is one trait we all have in common—the spark or urge to have something better out of this life—of which safety is not the least. This urge of self-interest is so strong some people even dwell on their "safety" or "welfare" in the hereafter.

Couple self-interest with participation among employees and supervisors as well and it makes quite a team to hitch to your safety wagon. Of course, this is what you, as safety supervisors, devote a life-time to selling. How well your product is accepted lies not so much in the safety record as it does in the day to day performance or application by the individual and his conscious awareness of its benefits to all concerned. The only price tag on safety is the price you are willing to pay for its neglect. It cannot be over-sold, over-preached or overstated. With human error being on the increase we must never lose sight of the worker's attitudes.

Even with the most ideal hiring procedures, training programs, supervision, and physical working conditions and with good morale and satisfied work force, accidents will happen. But there are some or many things we can do and are doing to improve the situation. In considering a worker's behavior or attitude, certain signs may predict an inclination towards trouble, such as:

—Excessive and/or chronic absences;
—Repeated visits to medical department;
—Series of superficial injuries;
—History of minor accidents;
—*Frequent complaints and grievances;*
—Poor worker performance;

Or evidence of—
—Poor safety training;
—Poor supervision;
—Weak selection procedures;
—Ineffective enforcement of safety procedures;
—Inadequate safety procedures.

Supervisors and foremen may observe his appearance—whether it is tense, altered or *troubled, anxious, strained, sad, pre-occupied.* Are his habits showing a loss of interest in activities previously enjoyed? Increased absenteeism? Alcohol and smoking increased? Does he display an attitude of loss of interest in his work, or more dissatisfaction? Lack of care about safe practices or unconcern over near accidents? Cool or evasive towards supervisors or others? Overly sensitive? A tendency to be edgy, irritable, excitable? Lack of confidence displayed in his feelings or emotions? Indecisive in his general behavior, showing a lack of interest and enthusiasm? More mistakes?

HELP EMPLOYEES WITH PROBLEMS

It would seem that these items when used in combination and not singly would be reasonably *predictive of accidents.* With empathic understanding—putting yourself in the other fellow's position—you should not pass up an opportunity to manifest some interest in the individual's behalf and indicate your willingness to assist in his problems. Remember that cooperation from the worker is not entirely his responsibility but depends to a large extent upon the effort put forth by management (or supervision) to secure and sustain that desire.

Achievement—safety-wise—by the individual is the only thing to help management or supervision because it pays inestimable dividends to both parties!

The very nature and scope of train and yard service operations makes the administration of safety to employees in this area of occupation most difficult from a practical standpoint. Supervision can only go so far. There inevitably comes a time when the employees are on their own. They must

be made aware that the best preventive medicine is alertness to the possibility of changing conditions or situations.

Complacency in itself can be a monster but when allied with reliance on past practices or experiences can be devastating to any safety program as well as fatal to the individual. "Togetherness" at this point—to be effective—should constitute the supervisor's personal contact, wherever or whenever possible with the trainmen, enginemen or yardmen. Making themselves available at terminals to discuss safety or operating problems and displaying a sincere interest in their human affairs, will promote confidence.

CONSIDER ALL SAFETY COMPLAINTS

Rather than taking an arbitrary attitude towards the questionable performance of an employee, we shall gain more in unblocking the human communication system by becoming an impartial listening post. Safety complaints and grievances that warrant consideration must be carried to the proper level for a fair hearing. To retain his confidence and respect, the employee must be assured this is being done with subsequent advice to him of the outcome—through corrective action, or reason for declination.

Even some observation by the supervisor, in yards particularly, that a standard practice of doing a certain job is awkward for a particular employee may lead to helpful assistance in his behalf. We have unlimited opportunities to manifest an interest in our people. When adversity strikes the family of an employee or supervisor do we always prove our close friendship by offering assistance? Do we feel we have been "spoiled" in the past by such so-called "paternalism?" I doubt it!

How long has it been since the "boss" has acknowledged to you personally his appreciation or gratitude for your own performance? How long has it been since you did likewise to those similar deserving individuals? Weeks? Months? Years? We do have to have—and insist upon—a positive attitude of safety education to all concerned and see that we obtain a positive response in return.

Encouragement is a valuable implement in our aptitude for improvement. How's your sense of humor? The humorous approach may be direct or subtle. Some of these little cards with just the word "think," "think before your louse something up," "think—it might be a new experience," "use your brains—it's the little things that count," can arouse a chuckle—and convey the message—without being offensive. There are many others.

Pooling our efforts with those of others and spreading our influence we can—and have—achieved worthwhile results. "Togetherness in Transportation" often helps to break the ice for the supervisor with the men under him. Most of them will respond if you are considerate and courteous.

Then with pride and humility perhaps some day we can say:

"We met the challenge for man's need—
By planting deep the safety seed.
God's help and spirit does the rest
Our privilege was to do our best."

Personal Contact with Road and Yard Train Service Employees is Essential to Safety

(A Symposium)

WHY IS PERSONAL CONTACT ESSENTIAL TO SAFETY?

by CHARLES A. THOMAS

switchman, Denver & Rio Grande Western Railroad co., Grand Junction, Colo.

Personal contact is essential mainly to make the employee safety conscious. We on the Rio Grande as all railroads have our safety rules which of course, are important —but safety rules do little good if the employees don't use them. Hardly a day of work passes when there isn't a safety rule broken, and in the most part the worker realizes that he is breaking a rule when he does it.

Of course, in the majority of these cases the worker's intentions are good—he's thinking that he is saving time or saving himself some steps. A great many times a worker responsible for an accident has the poor excuse of "I didn't think" or "I forgot."

On the Rio Grande the personal contact is made by a supervisor to the employee on the job. This is done to show the employee the advantage of the safety program to himself as well as to the company. It makes the employee feel that he is a part of the safety program. Also, it gives the employee an opportunity to give his own views and ideas which may improve the safety program—as well as a chance to report any unsafe conditions which he may have observed. As a whole this is a good means to improve the management—employee relationship.

Another method of personal contact used on the Rio Grande is our visual education program. This consists mainly of safety films and posters, and acquaints the employee with the hazards that exist—as well as the safe way to handle the work.

They also show films of accidents caused by neglect of the rules. These, to be sure, leave a vivid and lasting impression in the mind of those doing work. These things turn out a safe worker—which is a good worker—and makes a good safety record.

We of the Grand Junction division went seven months and 29 days without a reportable injury in any department. So we feel that personal contact really pays for the employee as well as management.

HOW IS PERSONAL CONTACT ESSENTIAL TO SAFETY?

by W. R. BREHM
safety supervisor, Union Railroad co., East Pittsburgh, Pa.

You can have weekly personal safety contacts with all road and yard service employees! How? . . . Utilize your first line supervisors. There is probably one major problem you will have to overcome to insure effectiveness. The average first line supervisor has certain deficiencies that deter from his effectiveness in this responsibility. First, he has had little experience leading meetings —especially—safety meetings. He lacks time to prepare and hold meetings. He lacks sufficient safety knowledge to direct and control his meetings.

He lacks a method of communication with the yard and road employees working with him. Last but not least he needs a common meeting ground for supervision and labor from which a free flow of safety discussion will come—keeping safety on the lips and mind of the workers at all times . . . these deficiencies seem insurmountable. However, they can be combated. We use a tool called the visual aid.

The visual aid is no invention. It's an application of the National Safety Council's safety graphs. It is portable, easy to present, makes a point concerning safety and is relatively inexpensive to make on a "white print machine." On one side is a picture for the crews to view and the other is a script for the supervisor to follow. The stand consists of two sheets of hinged plywood . . . to further explain the use of the visual aid in a crew room situation, let's do a little play acting. You be the crew members and I'll be the supervisor—while I present a visual by 35 m.m. slide film media.

VISUAL SLIDE PROGRAM

This visual is one of a series that was written and presented to reinforce the role the visual aid plays in our safety program.

2nd Slide—This is Vic the Visual Aid. His job is to tell you stories. He hopes each time he makes a point. Do you know what part he plays in the safety program?

3rd Slide—Since the railroad can be dangerous, there is a definite need for a safety program. Vic will help you define your safety program and you'll have his purpose in a nutshell.

4th Slide—He can't convince you of the dangers of your job. Only you can see them. Only you can hear of the injuries that are happening to other men on the union.

5th Slide—Can he tell you the right way to railroad? No.—You have learned to railroad through your own experience and what others have shown you.

6th Slide—Vic is only a reminder. Once a week he tries to call your attention to a problem. All he wants you to do is think about it.

7th Slide—If he can help start a discussion, you should get a better understanding of each other's safety views. Exchanging your own views will make you more interested in safety than Vic could.

8th Slide—He aims at your problems hoping he can be the basis of an understanding between yourself and the yardmaster.

9th Slide—He also wants to relate to you the happenings on other parts of the road so that you might benefit from them.

10th Slide—Vic hopes that safety can become a part of your basic way of living. His job is to be just as he is named—a visual aid to every man in making safety an active part of his life. Since Vic should be interesting and helpful, do you have any suggestions how he can do his job better? We would appreciate your ideas for future visual aid topics.

With the final question of the visual aid the supervisor leads discussion during the remainder of the meeting period. Meetings are held to a limit of 20 minutes of company time. We have been using visual aids weekly since the beginning of 1957. Evaluation has been taken in two methods. The results of a written evalution form showed 80 per cent acceptance on the part of working man in meetings when the visual aid was used.

Performance-wise we are appreciating approximately a 60 per cent reduction in the number of reportables this year as compared to last. From this evaluation one might say some success has resulted; however, the use of visual aids during this period has brought to light a new group of problems. Though a new subject has been used every week, a state of monotony has resulted. An intermittant change of pace is needed.

VISUAL REVEAL NEW HAZARDS

Even with the aid of a visual the supervisors are not doing an effective job. Part of the failure we find has resulted from our trying to tell our people to be safe. Since you cannot tell a man how he should work, measures must be taken so that he will come to his own conclusion about safe working habits.

We hope to eliminate the current problems by training our supervisors. Every yardmaster will have three full days of training pertaining to holding effective safety meetings. The training will cover effective meeting procedures and introduce the problem-solving technique for the yardmaster's use in the field. All our yardmasters will be trained by January 1st.

WEEKLY SAFETY MEETINGS

When's the payoff? Frankly, I don't know . . . looking ahead to 1958. There will be a prearranged schedule of topics to be covered in the weekly safety meetings. For change of pace the weekly topics will be covered by visual aids, movies, printed matter, and problem solving sessions.

In this manner we hope to arrive at certain planned results. A line of communications will have been established both up and down. We will have our employees and first line supervisors finding the group solutions to their safety problems.

We don't feel this is a panacea for everybody's accident prevention problems. It is only a method by which personal contacts can be made. We don't know how successful it is yet. However, the Union Railroad company appreciates the chance to review what we are doing to combat personal injury. We'll continue the fight—we feel sure you will too.

WHEN IS PERSONAL CONTACT ESSENTIAL TO SAFETY?

by E. F. WINTERROWD
assistant superintendent, Texas & New Orleans Railroad co., New Orleans, La.

The methods and techniques of safety have been developed by trial and error and proven by results achieved. It can be safely said that although continued improvement and refinement of methods is to be expected, the knowledge of how to reach and maintain top safety performance is sufficient for the job to be done; the problem is primarily one of securing adequate application of tried and proven methods.

Getting people to work safely is primarily a sales job. People can be ordered or even compelled to do things, up to a point, but compulsion cannot get really good performance in anything. Only interest—the desire to do good work—can bring about the results that all of us on the railroads are striving to obtain. Enforcement of safety rules may at times be necessary. When it is, however, it certainly means that the sales effort has failed with the person or persons involved and, therefore, it is necessary to use the substitute—enforcement, pending the time when the sale can be made.

Selling safety is a difficult job. It has been proven in this field that advertising, although helpful, is not sufficient. Here, close personal contact is essential. I think that those of us engaged in selling the product, safety, in most instances face more

difficulties than the sellers of some of the more tangible products.

The first essential in any sale is a good product. A product is good only if it yields the purchaser a profit, a profit in service, or pleasure or satisfaction, or some other value. Safety is definitely such a product. It brings to people and employees freedom from injury and suffering, loss of wages, and hardship for dependents. We, as salesmen of safety, should be very careful to make no exaggerated claims. The truth is enough.

A good supervisor, by personal contact, can make the sale and secure the necessary cooperation from operating employees by conducting himself in such a manner that he has the respect and confidence of the employees, understands their problems and is always ready and willing to administer those little preventives that keep both individuals and groups satisfied with and receptive to the established safety and operating rules under which they work.

When these rules are formulated in such a manner as to command the respect and conformance of the rank and file, they will observe them automatically and spontaneously, and will encourage others to do likewise. In other words a concept of citizenship will prevail. The term "citizenship" is used to mean that the individual recognizes that he owes an obligation to himself, his family, his community and to the company for which he performs service.

FEELING OF BELONGING

This feeling of obligation can only be made prevalent and deeply developed in any organization by affording the individual an opportunity to belong and contribute according to his means and talents.

A famous trainer of men, when asked the secret of his success, answered "First off you must know people." In order to know people, continuous personal contact is essential.

It has been proven that people can be motivated and, when they have a good working knowledge of the job they are performing, are aware of the hazards involved and understand the rules. Then it is comparatively easy by personal contact to insure success in your safety program by motivating them in the desired direction.

While it is necessary for a supervisor to maintain a close personal relationship with all employees to insure and maintain a high level of interest in safety matters, I think the most opportune time that personal contact will bring the best results is when a new and inexperienced man is first interviewed after his application for employment has been accepted. At that time he is entering a strange, new world and will be in close association with people he does not know.

EDUCATE NEW WORKER

A supervisor at this time has an opportunity that will never again be available to make a sale in safety. The individual will be alert and receptive to all suggestions and instructions. A pattern for his future performance can be laid out that will insure development of a safe, careful and conscientious employee.

I can best substantiate this statement by relating an actual experience. In the latter part of 1955, it was necessary to employ in the New Orleans Terminal 65 yardman and 32 firemen, in connection with the inauguration of the five-day work week on our railroad. These employees were scheduled to begin service on December 1, 1955, which is, so far as weather conditions are concerned, probably the worst month of the year in the New Orleans area. We were concerned over the possibility of some of these new employees sustaining personal injuries before they had obtained sufficient knowledge to cope with operating conditions they would encounter.

In an effort to alleviate this situation, each applicant was carefully screened and those accepted were assembled in groups of four for an informal discussion, at which time we obtained all information possible about the individual. The job for which they had been selected was fully explained with special emphasis being placed on the importance of safety.

TRAINING PERIOD INTERVIEW

Then began a 14-day training period after which each completed a written examination on the operating and safety rules of our railroad. They had then completed all requirements necessary to entering their railroad career. As an added precaution, however, each employee, before being permitted to mark up for duty, was again interviewed

by an operating officer who had been assigned to watch closely and supervise these employees during their break-in period. This association enabled him to be in a position to point out and correct some of the unsafe practices observed before they became a habit.

After two years and 10 months of service, not one in this group of new employees has sustained a disabling injury on the job. The positive attitude and interest displayed by these new employees was like the measles —contagious, infecting the older employees to the extent that they also began noticeably displaying more interest in safety. Today, the yield from the seeds of safety sewn in the fertile field of new employees has been very gratifying, since their accident ratio is among the best.

DAILY PERSONAL CONTACT

I do not mean to infer that after the initial discussions mentioned that the new employees were allowed to go about their daily tasks without help and supervision in the matter of safety. Almost daily personal contact with supervisors welded together a strong chain of communication and understanding, which is a must in any undertaking. This permitted the exchange of ideas and questions on a man-to-man basis —an understanding of the ideas, comments and feelings of the other fellow by looking at the situation from his point of view.

Keeping employees informed about their performance, as individuals, is the responsibility of a supervisor and a right due every employee. We should be informed as to how he stands and how he is doing. He deserves praise when he does a good job, and constructive criticism when he doesn't.

It is easy for a person in a supervisory capacity to fall into the habit of ignoring the positive values of giving praise, saying nothing as long as things go right, but raising the roof when they go wrong. This attitude in the majority of cases will cause employees to develop a negative attitude toward both their job and their supervisors.

Great strides have been made in past years in the field of safety. To insure continued progress, we, as people who must live and work together, must develop a greater sense of human values and responsibilities to one another. We, as supervisors on our respective railroads, are daily living examples for those who look to us for leadership. How we guide them, how we work with them will determine the degree of success obtained.

It is, therefore, necessary that nothing be left undone to improve ourselves so that we may inspire others to do likewise.

THE IMPORTANCE OF SAFETY IN MECHANIZATION

(A Symposium)

TRACK MAINTENANCE

by L. A. VILLELLA

safety inspector, The Pennsylvania Railroad, Philadelphia, Pa.

In considering the importance of safety in the mechanization of the maintenance of track and roadbed, it must necessarily be considered from a train accident standpoint, as well as from an employee personal injury standpoint, because both are closely related and both result in economic loss.

Since the earliest days, when what we now consider crude methods and inadequate tools were used, and on through to the present day with our improved methods, tools and better machinery, the prevention of accidents has been the greatest concern in the maintenance of track and roadbed. As a matter of fact that is one of the reasons for the progress to-date in the art of maintaining adequate track. It has never been enough for our engineers to maintain

a track and roadbed which will support the weight of our trains and to provide a constantly available facility upon which to run them.

It has always been their concern to maintain efficiently the safest track and roadbed so that it can, not only be utilized to get a ton of freight from here to there, but to make sure that it gets there safely. While it is partly true that there has been more talk than action in this direction, there has been enough action to establish an admirable record of safety in the transportation field—a record met by few and exceeded by none.

MANAGEMENT PROMOTES SAFETY

Particularly in the last 30 years we have seen a definite effort to integrate into our practices and work procedures the known reasonable precautions to prevent accidents, both to the operation of trains and to the activities of our employees, in maintaining the roadbed. The intense interest manifested by management in this connection, has resulted in a universal practice, followed by the men presently responsible for formulating and executing the policies in connection with track and roadbed maintenance, that all phases of safety must be foremost in their endeavors.

As a specific example of this, the chief engineer of The Pennsylvania Railroad has established a practice of soliciting the assistance of the safety department during field experimental work involving changes in methods or machinery. This policy has resulted in the further integration of the principles of safety with the principles of production methods. The manufacturers of equipment and materials used in the maintenance of track and roadbed have been for some time and are *now*, increasingly *concerned* in the matter of integrating safety with their design of equipment.

Fortunately for us in safety work, there is a happy natural union inherent in the mechanization of all phases of track maintenance work with safety and efficiency. There are certain basic characteristics of mechanized work in this field which automatically set up circumstances of safer conditions. For example, from an overall safety standpoint mechanization appears to afford a better opportunity for supervising and controlling the operation, and thereby resulting in fewer avoidable injuries and less economic loss.

With mechanization of operations there is every opportunity for specialization with the obvious result that men working in such mechanized gangs may become more proficient, with the natural result that within a reasonable length of time the transition from manual operations to mechanized operations will create an atmosphere wherein more effective measures can be taken for the avoidance of personal injury, the prevention of train accidents, and the elimination of production losses.

By the very nature of the mechanized work being done by large forces making a concerted effort to do a complete job in a concentrated area, the precautions necessary to make this an economically efficient operation provide protection for the men so employed. To get highly efficient production from a large mechanized gang, it is obviously necessary to take a track out of service for a period of time; and by so doing, automatic protection is afforded employees working in these gangs which was not always provided with the manual gangs.

So it appears from a safety standpoint, whether prompted by an accident prevention motive or not, mechanization by the very nature of economic necessity and practicability calls for safeguards which are assured for economic reasons.

LESS LABOR REQUIRED

To sum up some of the many advantages of mechanization in track and roadbed maintenance, we should point out of course the obvious advantage—reduction in the number of gangs. Machines reduce the number of manual operations and, therefore, personal injury exposures for a given amount of work. With mechanization men become specialists in their particular work, become more proficient themselves and are more easily supervised.

Many complex manual operations actually requiring a supervisor with "a thousand eyes" are now being changed to the simple operation of moving a single lever on a machine which can be readily observed. Readily supervised mechanical operations should result in practically no deviation from established procedures, and should lend themselves to prompt detection and correction of unsafe acts.

Further advantage is the increased practice of taking a track out of service when work is to be performed on it which greatly eliminates a train accident potential and eliminates the occasion for chance taking. This procedure also eliminates the possibility of employees being struck by trains while working on the track and provides a safe place for them to clear quickly and easily for the passage of trains on other tracks. The construction of some machines permits working without assistance from any person on the ground, without obstructing any other tracks, and without requiring gang watchman protection.

Further, there is reason to believe that in the foreseeable future machines will possibly become sufficiently automatic to permit proper spacing, moving and working by remote control without an operator on each machine. This will certainly eliminate or greatly reduce at least, the accident potential to employees.

On the other hand for every advantage gained, some price must be paid. One of the immediate results of mechanizing maintenance work, which we as safety men must seriously consider, is the immediate effect upon the morale of the employees. The morale of our men and the attitude they have toward their job have a serious effect upon their individual safety. For this reason we must recognize the age old tendency to feel that machine work interferes with their well-being as workmen.

In the development of plans for further mechanization of track and roadbed maintenance, there are several factors which must be taken into consideration. We must see to it that either the designers of the machines or our own people provide the necessary safety features on the machines. We must make sure there are sufficient in-operation checks so that we will know the condition of these machines, and that these checks are followed by repairs or adjustments to insure that the machines are well maintained and clean. Thirdly, we must select and train competent machine operators, and fit other employees into places for which the performance indicates they are best suited.

Fourthly, we must to a greater extent insist upon compliance with known practical safety precautions, as well as with the accepted machinery and work procedure instructions. And we must be sure that in our plans there is no letting down on safety precautions in order to obtain, what may be apparent but not actually real, production improvements. It is obvious from our past experience that by integrating the proper principles of safety, production performance does not suffer, but rather is increased.

Our experience with mechanization has been that with an efficient utilization of the machine, our overall good economic operation is obtained if strict safety precautions are followed and the rules for accident prevention are respected.

BRIDGES AND STRUCTURES

by E. P. HACKERT

division engineer, The Denver & Rio Grande Western Railroad co., Denver, Colo.

In speaking on any phase of safety, it is difficult to be original or to suggest original ideas. Those of us who have worked toward making our properties safer places to work are agreed upon the basic principles by which men can be lead to keep safe working habits always uppermost in their mind. Unfortunately, there are those of us who, in their zeal to get a job done quickly and economically, lose sight of the fact that violations of these basic principles are sometimes being condoned by supervisors and foremen.

They are too busy at the moment to take time out to correct an action or condition. Besides, that was a condition which was incidental to a unique phase of an operation and won't come up again, and nothing happened that time anyway! While possibly not thought in those exact words, I'll bet almost anyone here can recall an incident where his thinking was similar.

These few lapses in the practice of safety can be disastrous. Safety isn't something you sell at a big bargain sale, or a rummage sale, or a "going out of business sale" to sell your quota for the week and then relax. Safety must be sold—and I do mean sold—like popular cigarettes, or automobiles, by the constant, confident presentation of it until it becomes a household word, not by the high pressure type of salesmanship—until a man would not think of using a grinder without wearing goggles anymore than he would pick up a red hot piece of iron. The most successful salesman is the one who talks softly and confidently and knows his product.

SAFETY NEED SALESMANSHIP

The practice of safety in connection with increased mechanization of bridge and building crews is just such a problem. A man doesn't touch something hot because every man at one time or another has been burned with painful but usually not disastrous results. However, a man does not go a fast round with a runaway hand power saw and come off with just a painful blister—unless he is a lot more lucky than most people.

Yet, how many of us have taken the time to inquire of a foreman if a new man had been shown how properly to use such a handy surgical instrument? A 10 inch power hand saw does a good job rapidly on a three by 12— and it is equally efficient at shortening an arm or leg—but not as neat! That a man does not know he should not lift a running saw from a cut is understandable if he is a novice; but it is not understandable that any experienced person should let him use the tool without such instruction and further guidance until it is known he can use it safely.

Since much of the use of power tools depends on an electrical source for power, and since six of my seven gangs are road gangs, it follows that the electrical source must be furnished by a portable generator. No doubt many of you have a similar situation. The Underwriter's Laboratory has endorsed the use of a three-conductor cable for electrical power tools so that the body of the unit will be properly grounded and the operator saved from severe, if not fatal, shock should an insulation failure occur.

A portable generator unit of, say, 2,500 W can kill as well as can a commercial source. A man working under a bridge boring holes for sway brace bolts—just as an example—is usually himself pretty well grounded; much better, in fact, than a mechanic in a shop standing on a concrete floor.

I could go on great length along these lines, but since we are, I believe, agreed that we believe in safety, are willing to extend an effort to promote safety and sell it, these few examples may lead to further thought and the possible discovery of an obvious condition which has been overlooked.

Just remember, a man could get a nasty gash from a carelessly used handsaw; but he can lose an arm or a leg to a carelessly used power saw. He may get sore muscles wielding a ship auger, but he can come up with a broken arm from an improperly held power drill.

Properly used, power tools and other forms of mechanization make the work easier for our men, turn out more work better and faster—but only if properly used and cared for.

We are now precisely where we started; but, I hope, with some food for thought. You observe, but you observe all of the time; you teach, but you teach all of the time; you correct, but you correct all of the time. Now you have made safety a by word and the practice of safety a habit.

SIGNAL AND COMMUNICATIONS

by A. L. ESSMAN

chief signal engineer, Chicago, Burlington, & Quincy Railroad co., Chicago, Ill.

I don't know when safety has been so important in the performance of our duties than it is at the present time, particularly when a large share of our construction men have either just finished high school or have been released from a branch of the Armed Service, and in most all cases rarely have they ever had experience with any type of machinery other than an automobile.

No doubt, a large number of you have lived close to a street intersection where, because of its heavy traffic in one or more directions, arterial stop signs have been installed. Quite frequently you will hear the screeching of brakes, the sound of sliding tires, and the roar of an exhaust pipe, causing you to get out of your chair to see what has happened only to find a car driven by some teen-ager.

With such experiences, one can readily understand why, when we endeavor to insure our automobile, the question is asked if there is any one in the household under 25 years of age who would be driving the car. If there is, I think that most of you have learned your insurance rate is much higher. I make this point because to me it is one of the important things in assigning personnel to the handling of mechanized tools in both the signal and communications departments.

PROFIT FROM INSURANCE COMPANIES

Surely, the rate structure of insurance companies has been made only after a careful analysis of the age brackets in which a large number of accidents occur, and I think that we can profit by taking a page from the insurance company's book of experiences when we select personnel to handle mechanized equipment and every supervisor, foreman, or anyone delegating responsibility for the handling of this equipment, should keep this uppermost in his mind.

The adaptation of mechanized tools and equipment would not appear on the surface as being extensively used in signal and communications departments. There is, however, considerable mechanization, but only to the degree in which savings in labor can be brought about. Signaling, in particular, is more of a tailor-made job. Communications follows closely to this pattern.

However, in the construction and maintenance of pole lines for both signal and communications purposes, there has been the advent of the power augers for drilling holes for poles, winches and derricks for the erection of such poles, and equipment to facilitate the stringing of wires. Other mechanization has been made principally in shop procedures of these departments.

In viewing such operations from a safety standpoint, it is my opinion that too many and too often people have been misled by the word "safety." I refer more specifically to the safety belt used in climbing poles, safety shields on grinding machines, safety guards on trenching machines, safety hooks on ladders, and safety valves on pressure tanks.

CAN'T RELAX SAFETY

Of the various types of machines used, it is recognized that in their operation a greater hazard exists at one place more so than at another. As a result, someone tacks on a safety shield or safety something and the individual's attention is, in some cases, relaxed because of such mis-nomer devices. In my opinion, when the word "safety" is used, it is a need for using extra precaution over and above that which is normally used with tools of this kind.

I recall, just the other day, viewing a young lad climbing a power pole. He proceeded up the pole with his safety belt properly snapped on his tool belt. As he reached about mid-point of the pole, he fastened his safety belt around the pole so as to permit both hands to be free to hook a chain on the pole to permit it being lifted out by derrick. As he proceeded down the pole, he unsnapped one side of his safety belt, letting the loose end dangle from his tool belt. When he reached the bottom, the first foot reaching the ground stepped on

the safety belt, and as he started to step away from the pole with his free foot, he was pulled to the ground. There was a good chance of his receiving a serious injury from one of the gaffs on his leg, and this is usually the result.

I am reminded of another incident involving a safety belt where a young lad was on a pole, which had not as yet been equipped with crossarms, and was in the process of transferring wires from an old line across the top of the pole to another side. To perform this operation, it is necessary for the man to be sufficiently close to the top of the pole so that the wires could be laid over its top. The safety belt was fastened around the pole in the proper manner and presumably was fairly close to the top of the pole, and in an effort to become more comfortably situated he grabbed hold of the safety belt with both hands a short distance from the pole.

He shifted his weight forward to ease the tension on the belt and with such tension so relieved, would move the safety belt upward with both hands. In so doing, the belt moved too far so that there was not enough bearing of the belt on the top of the pole to hold his weight when he settled back into the belt, and the man fell to the ground. The purpose of this belt was for his safety while he was on the pole so as to permit him to use both hands, but yet the very thing that was to assure him safety was the very same thing that caused him injury.

MUST USE SAFETY DEVICES

When we view a man in the shop using a grinding wheel which is equipped with safety glass shields, again, the man is misled to the point where he feels that goggles are not necessary. He proceeds to grind the material without realizing that fragments of the material or the wheel could become dislodged and glanced from other surrounding objects, striking him in the eye.

Safety hooks on ladders will, at times, prevent the ladder from slipping away from a cable or messenger, but the mere fact that there is a safety hook provided does not mean that the man should not take the necessary precautions to see that there is proper footing for the ladder. In most cases, that is the principal reason for ladders slipping or tilting.

In some signal and communications departments, there is in use hundreds of miles of cable suspended airily from messenger attached to the pole. Some of this cable requires painting and inspection. When using cable buggies for riding the messenger, the operator should never relax from the requirements of knowing that the cable buggy is properly seated on the messenger. Where the cable is painted by paint guns, sprays or shuttles, even though the equipment provided is the best that can be secured, there is always the need for extra precautions to be taken in connection with its use.

SHUTTLE ACCIDENT

I am reminded of an accident that occurred recently where the shuttle type painting process was used. This process is where the long tube is placed over the cable with gaskets at both ends with provisions to either pull or push the shuttle from one pole to another. The paint completely envelops the cable, and because of the limited size to permit the shuttle to be pulled inside the messenger rings, it has to be filled with paint approximately over two poles; and to facilitate this filling process, pressure cans are employed.

In this particular instance, the man was pumping up the pressure in the can and only had performed two operations of the pump when the tank exploded, blowing out the bottom of the tank causing the pump on top to strike the man in the face. There was a flaw in the seam of the bottom of the tank which was not detected although this particular tank was used for three years for such operation. The principal reason the pressure in the tank was so great after only two operations of the pump was because of the fact that the tank had been sitting in the extremely hot sun for a considerable length of time. Other instances have also occurred where safety valves have not performed their function.

BE ALERT CONSTANTLY

I think it can be said that, in most cases, where there is a device employed on machines which a great many of us use and where the name is preceded by the word "safety," it is possible that such term has misled some in its use. Therefore, where there is some extra hazard, I think one of the important things which should be advocated in the use of mechanized equipment or machines, employing the word "safety," is that the individual should be alerted so that extra precautions can be taken.

The equipment should not be treated as an ordinary tool because, surely, there are extra hazards existing or the extra equipment would not have been applied. There is nothing more discouraging to a signal or communications officer than to receive a report that a man had fallen from a pole because of not having safety belt properly snapped to the ring, or where a man has lost his eye because of not wearing his goggles simply because the grinding machine had been equipped with a glass shield, or where a man had received a lacerated thumb or finger because of having caught his hand in a payout or take-out reel.

If there was some way of impressing upon all persons that have anything to do with mechanized equipment, regardless of the departments in which it is used, that if there is a machine that is powered by any means or if there is any automatic action to that machine, it should be considered as a hazard for which extra precautions must be taken.

SAFE TROLLEY MAINTENANCE

by T. B. KIRK

assistant engineer, Electrification Dept., Chicago, Milwaukee, St. Paul & Pacific Railroad co., Seattle, Wash.

The Milwaukee Road electrification over the western mountains, because of geographical location and type of power, has been somewhat isolated from the other main line electrification in this country. This has resulted in the development of a trolley maintenance system and organization relatively independent of the influence of other electric roads.

The Chicago, Milwaukee and St. Paul completed the westward extension of the rails to Seattle-Tacoma in 1909. Because of the severe profile, plans to electrify the mountain sections were initiated shortly after steam operation started. Electrification of the 436-mile Rocky Mountain division in Montana and Idaho was completed in 1918. The 226-mile Coast division in Washington was placed under electric operation in 1920.

This electrification was the pioneer 3,000-volt direct current installation, its nearest predecessor being the Butte, Anaconda & Pacific Railroad electrication at 2,400-volts D.C. in 1912. Today, the trolley voltage is 3,400 D.C., fed from motor-generator substations spaced at 35-mile intervals. A 100,000-volt transmission line parallels the railroad in the electrified sections and supplies power to the substations. All power is purchased and received through transmission line interconnections with several power companies.

The trolley system is primarily wood pole, bracket arm construction. Span wires are used where there are two or more tracks. Cross arms on the trolley poles carry one or two heavy trolley feeder cables and a 4,400-volt A.C. circuit supplying power to the block signals.

When electric operation was started, maintenance procedure was essentially copied from the numerous street railways and inter-urban lines, but with a few concessions to the higher and more dangerous trolley voltage.

TROLLEY TROUBLES

The trolley system is subject to the same structural and insulation troubles as a power company line, and the same trouble from wind, lightning, floods, fires and trees. In addition, there is the necessity of maintaining the contact wires in close vertical and horizontal alignment with the track. Any serious misalignment usually damages the engine pantograph collector, and frequently tears down overhead system.

Trolley maintenance from the start has been mechanized in varying degrees. During the first few years of electric operation,

maintenance was performed from insulated platforms built on top of box cars which were pulled with steam engines. The work trains also included living quarter cars for the line crews and train crews. Later, each work train was consolidated into a single, self-propelled, gas-electric car, converted from passenger service.

These cars had living quarters for the line and train crews, had storage space for considerable material, and an insulated working platform on the roof. The cars were equipped with air-operated tools which included winches, jack hammers, drills and wrenches; powered by the car air compressor. Each of the maintenance crews, so equipped, normally maintained a division of more than 200 miles.

During this period, construction work and scheduled heavy replacement was usually handled by extra line crews, working out of box car camps and using track cars for transportation.

With the trolley system aging and requiring heavier maintenance, the work train type equipment proved inefficient and too costly. About 10 years ago, a gradual change-over was made to crews working out of a home terminal. These crews replaced both the maintenance and construction crews and took over both types of work. Two or more crews are sometimes combined to handle large construction projects and major cases of trouble.

WORK CREWS' EQUIPMENT

The basic equipment for these crews is a highway-rail truck, equipped with hydraulically raised ladders. These trucks have track car type flanged wheels and axles, mounted fore and aft of the regular truck wheels. The truck is driven up onto the track and the tires lined up on the rails, usually at a road crossing, but may mount onto the rails at any point with the use of light wood frogs. The flanged wheels are then lowered to the rails and the steering gear locked.

Most of the truck weight is on, and all of the driving and braking is through, the tires. These trucks can change from rail to road operation in less than a minute. They can be moved off the rail at any point where there is sufficient shoulder on the right-of-way to allow clearance from the rails.

Heavier straight road trucks, equipped with pole derricks and power diggers, are used when possible on construction and transmission line work. Use is also made of track cars, small towers on push cars, and light duty road trucks. All road-rail trucks and the heavy road trucks are four-wheel drive and are equipped with power take-off driven winches. Electric tools are powered by portable generators. Electric and gas chain saws are used, particularly on tree clearing projects. Portable air compressors for occasional rock drilling work, and bulldozers, when needed, are usually furnished by the track department.

The complement of the trolley maintenance crews is made up of men trained through the railroad apprentice program and of experienced power lineman able to meet the railroad qualifications. An otherwise fully qualified power lineman requires considerable education on the job as to railroad operations.

NO MAINTENANCE SAFETY

Because of train movements, it is necessary to perform a major part of all maintenance work with the trolley and signal feeder circuits energized. As such work, particularly trouble shooting, must be done in all kinds of weather and frequently during darkness, there is, unless safe working practices are applied, a high degree of hazard involved.

As previously mentioned, original maintenance working procedures were mostly evolved from previous experiences with street railway and power companies. In common with power company methods of that day, safety rules and practices were very rudimentary. It was, in general, each man for himself. Rubber gloves and other protective equipment was available but seldom specified or used. As might be expected, accidents to lineman due to electrical shock and burns were frequent and serious.

In the electrified territories, during the period 1915-1931, eight linemen were electrocuted and many received serious injury. In the same period, 18 railroad employees on the electrified divisions died due to electrical shock and burns.

In 1931, a new code of safety rules and instructions for line crews was issued, and a policy of education and strict enforcement adopted. These rules prescribed a definite procedure to cover as many types of work as possible, and spelled out protective measures that must be taken. This new code was based on 15 years operating experience, plus a digest of power company rules applicable to trolley work. Also, a set of rules and instructions was issued to engine and train servicemen, and other employees on the electrified sections who performed work there was a possibility of contact with high-voltage circuits.

These safety rules, although amended at various times, still remain essentially unchanged and the results have been highly satisfactory. Beginning in 1932, there was a period of over 24 years without a fatal accident to electrification forces, including both line crews and substation men.

ATTITUDE CHANGE NEEDED

When the new rules were first placed in force, the most pressing problem was to reverse the thinking of the line forces and their supervisors. Rubber gloves are always uncomfortable, and the requirement that they use protective measures was considered by some lineman as a slur on their ability to take care of themselves; and some of the supervisors thought the rules would slow down the work.

Concurrent with the strict application of the rules was the insistence that the men work as a team; that warnings are to be given and be acknowledged, of any unsafe or unusual condition present or developing; and, also, that there must be complete and explicit understanding by all members of the crew of the work and of all intended moves.

Essentially, the rules define work that may or may not be done with the lines energized, protective measures required for hot work, and procedures for de-energizing and grounding.

Hot line work must be done in such a way that any potential circuit through a workman's body must be protected against by at least two insulators in series, so placed that not more than one can be accidentally bridged. An insulator in this rule is a porcelain insulator rated for the voltage involved, protective rubber hose and blankets, or 12 inches of the surface of a pole in good insulating condition.

When it is impracticable to provide double insulation otherwise, rubber gloves may be considered one of the insulations. However, rubber gloves must be worn always when working on or near live high-voltage circuits.

The transmission line must be de-energized when any projected work will bring men, material, or equipment to within five feet of the conductors. The trolley and signal circuits must be de-energized when the double insulation stipulation cannot be met; when installing or removing cable or fixtures which cannot be handled in complete safety; after accidents to the trolley system when the extent of the damage is not fully known; and when, because of emergency conditions, repairs are to be made by inexperienced men.

The rules are very explicit on handling work on de-energized circuits. The same care to prevent verbal misunderstanding must be used in handling circuit clearances as in handling train orders. Protection against locomotive pantographs bridging the insulation between live and dead sections of trolley is provided by train order and/or flagging.

All circuits de-energized must be short-circuited and grounded before they can be considered clear. Grounds are applied by the line crews at the location of work and are under their direct control.

Rubber gloves are vulernable to damage from sharp objects, and require regular checking by visual inspection, air tests and water tests. The gloves and all other rubber protective equipment receive a standard voltage test each 90 days. Tools and equipment are inspected regularly, with particular emphasis on the flanged wheels on the trucks and track cars.

Much heavy pole handling and setting must be done by the relatively small crews, and each rail truck and most straight road trucks are equipped with winches to furnish the power for this work. Considerable insistence has been placed on safe rigging for heavy pulls and lifts.

CODE REGULATES OUERATION

The operation of track cars and of the road-rail trucks is under the Consolidated Code for Track Car Operators, under which all qualified car operators must be examined each year. The road-rail trucks, in par-

ticular, require careful operation, so they can run long distances on the road out of sight of the track, and then return to rail operation at any convenient road crossing.

When there is a doubt as to the location of trains, portable phones are used to obtain the information, or the necessary flag protection is used. For the protection of other track cars, the intended working limits of the trucks is included in the track car line-ups each morning.

In general, while all basic safety concepts have been retained and improved on when possible, an attempt has been made to take advantage of all new developments in equipment and tools in line with the continuing modernization of the electrification in particular, and the railroad in general.▲

HIGHWAY — RAILROAD CROSSING SAFETY

REMARKS OF H. G. J. HAYES

executive secretary, Ohio State Safety Council, Cleveland, Ohio

If our program is in any way unique it may be because of one of two features. The executive committee of the Railroad division, which is the body that develops and administers this highway-rail crossing program, embraces not only representatives from each of the major railroads in our state having more than one mile of track in Ohio, but is rounded out by delegates from the Ohio Assn. of Chiefs of Police, Buckeye State Sheriffs' Assn., Ohio Highway Patrol, the Ohio Department of Highways, the Ohio Department of Education, Ohio Department of Highway Safety, the Ohio Federation of Women's Clubs, the Ohio Congress of Parents and Teachers, and several other organizations.

Another point which may be slightly unusual is that we depend almost solely upon the media of mass communication in the development of our program. In line with the directive of the executive committee, at the time this program was first undertaken, the highway-rail crossing incidents receive only that share of attention which is proportionate to their importance in total traffic incidents and casualties having gone from eight per cent to five per cent.

Newspaper and radio form the backbone of our public information program. The grade crossing problem is referred to perhaps a half dozen times a year in regular releases, which deal with the general accident problem for the period under discussion.

Special emphasis is confined to just one week in the year. Usually it is the week just preceding May first. In this period, while there are special releases devoted to the grade crossing situation, we have that problem featured in every regular information service.

GRADE CROSSINGS SAFETY WEEK

"Safety for my Family" and "So Help Me, It's the Truth" both are keyed to the crossing situation, or give it a large share of attention in that week.

I am sure that some of you may be acquainted with the details of our Highway-Rail Crossing Accident Prevention Week, perhaps you will not mind if I summarize quickly the elements that this week embraces.

We obtain a proclamation from the governor designating the period, calling attention to the crossing accident problem and to the progress that has been made in bringing that problem under control. The Department of Highway Safety produces a special crossing safety poster, printing in excess of 25,000, which are distributed throughout the department's normal channels of distribution. Several thousand are available to the Safety Council's members. About 4,000 are provided to the participating railroads for display in places of public access on railroad property.

Well in advance of the designated week, we make a tape recording using the voices of civic and safety leaders throughout the state and a number of railroad safety officers. This tape is edited and transferred to platters which are provided to 10 strategically located radio stations, who have agreed to use the message on the platter on a saturation basis during the week. Most of these stations use one of the messages at least every hour, so that in a week's time we have in excess of 1,000 short safety pitches made by radio.

CIVIC LEADER TAPE MESSAGE

In addition to this, all radio stations in the state receive brief messages which can be used by any station personality. Similar short items are provided to the newspapers. Both newspapers and radio receive a detailed story of the week's activities and a number of special items which may be used on the air, or in the column, at the discretion of the program director or editor.

Ordinarily crossings are observed by one railroad each month during the year, to discover the frequency with which drivers violate the proviso that they shall not drive on a crossing when an electrical or mechanical signal gives indication of the approach of a train. During the grade crossing accident prevention week, however, all railroads make observations at crossings which they select.

Since all roads are notified periodically of those counties in which crashes at crossings are most frequent, the railroads naturally tend to concentrate their observations in those counties along their rights of ways which have the poorest experience.

We will receive 50 to 60 reports of vehicles that have not complied with the law during that week. The owners of these vehicles are identified and the Council sends a letter to said owner telling of our program, asking that they caution all drivers of that vehicle to approach crossings cautiously. Sometimes we receive notice of a vehicle that observed the warning exceptionally well, and a complimentary letter is sent to its owner, much in the same fashion as we appeal to the owner of violating vehicles.

In 1948, which was the year just before the start of this program, there were 178 persons killed in crossing crashes, giving us a fatality rate of 0.723 deaths per hundred million vehicle miles. In 1956 we had 122 deaths and a fatality rate of 0.339. This was the second best year we ever had. However, a rash of multiple death crashes made 1956 the first year in six when we did not have a reduction in the number of persons killed. For the year 1957 to date, we are substantially below the experience of 1956, not only in deaths but in the number of incidents as well.

The railroad men who have been identified with the program are generous enough to say that the collaborative, concentrated, activity that has been our pattern from the beginning, is responsible for the results we have obtained. They seem to be good, but neither the railroads, nor the Ohio State Safety Council, will be satisfied until we get the deaths below the hundred mark for a year.

I admit quite willingly that we do not believe that this pattern is the only answer. It has produced reasonably satisfactory results in Ohio. Many non-railroad groups contributed to these results . . . and we are reducing accidents, injuries and deaths at grade crossings. Possibly some other state can do better in another way. If so, our railroad representatives will be sure that we consider it. We never will be satisfied until we reach that irreducible minimum, zero.▲

REMARKS OF E. G. KIESELE

superintendent of safety, Chicago, Milwaukee, St. Paul & Pacific Railroad co., Chicago

While the work of all committees of the Railroad section is directed primarily to service to our fellow man, it probably is more predominantly emphasized in the work carried out by your Highway-Railroad Grade Crossing committee.

First let us look at the record as given in the 1956 progress report on the Signs of Life Program. During the 12 year *period 1945 to and including 1956, there* was a total of 18,109 deaths in collisions at highway-railroad crossings which was 4.3 per cent of the total of all motor vehicle deaths.

There has been a rather consistent reduction in this ratio throughout the individual years, dropping from 6.1 per cent for the year 1945 to 3.3 per cent for the year 1956.

The actual number of deaths in highway-railroad grade crossing collisions declined from 1,703 in 1945 to 1,325 in 1956 or 22 per cent while those in all motor vehicle accidents increased from 28,076 to an estimated 40,000 in 1956 or 42 per cent.

DEATH RATE DECREASED

The total motor vehicle death rate, representing deaths per 100 million vehicle miles, decreased 43 per cent while the rate for highway-railroad crossing collision deaths decreased 71 per cent for those same comparative years 1945 and 1956. These are encouraging results and yet it should be obvious that there is still much to be done.

In what better manner can we serve our fellow human beings than to try to keep them alive? Alive to enjoy life itself, a full three score and ten and more if possible.

We cannot afford to conclude that our work has been finished because of the reductions made but rather this should serve as a challenge for all of us to find ways and means for greater and even greater accomplishment.

Just as long as one death occurs at a highway-railroad grade crossing, there is work to be done by this committee and by all railroad employees.

By the same token, we as safety-minded citizens should likewise realize that the same applies as long as one death takes place in a motor vehicle accident of any kind or at any place, and for that matter in any kind of an accident.

Service to mankind is never ending and has many ramifications as well as many avenues of approach. No one person in a *given lifetime can successfully attain the* ultimate in each phase of such service. However, we can dedicate our lives to that phase of service which concerns the safety of our fellow human beings and I believe this to be the overall purpose of the National Safety Council.

DEVOTE TIME, ENERGY

Let us pick just one phase of service that of devoting time and energy toward the elimination of all types of accidents which will include those at highway-railroad grade crossings. It should be a service extending far beyond the ordinary call of duty as we have come to regard it.

As railroad people I believe we can all understand this and those who have seen military service of any kind undoubtedly know what I am talking about.

To be of service in this most worthwhile endeavor we will have to extend ourselves. It may be necessary to make some sacrifices of time to attend meetings of Parent Teachers Associations, service clubs, community gatherings and the like—all for the purpose of bringing to those people the message of safety; the message of how lives and limbs may be saved.

SIGNS OF LIFE PROGRAM

An excellent approach in many instances is the Signs of Life Program. Here you have a story to tell which is ever new and thought provoking. The National Safety Council stands ready to supply you with the necessary materials and I urge you to use them at every opportunity.

In practically all phases of safety work, results are measured by the comparison of the number of accidents or injuries for any given period compared with a corresponding period of previous years.

However, certain safety activities are carried out which can be measured; not to such an extent as to be able to state definitely the number of accidents or injuries prevented but certainly to a degree to indicate the likelihood of such prevention. I refer to the programs known to be in effect on at least three railroads in the United States whereby violations of the laws covering the approach to and the crossing of railroad tracks which intersect streets or highways are reported to the owners of the motor vehicles for handling with the drivers.

Generally the owners have responded with a letter of appreciation and with assurance that appropriate action had been taken to avoid a repetition.

EMPLOYEES REPORT VIOLATIONS

It would be most helpful to have such activities carried out by all railroads. The plan is a simple one. Briefly, the motor vehicle laws pertaining to the crossing of railroad tracks at grade for the states through which the railroad operates are made known to its employees with request that they report to the division superintendent any violations of the laws as observed by them. The superintendent then writes a letter to the owner or operator of the vehicle calling attention to the violation requesting that the law be obeyed in the future in the interest of safety.

In a period of approximately two months on one railroad, letters were written on violations of the law by 200 tank trucks, eight school buses, six other buses, two trucks handling explosives and to the operators of three other trucks handling ordinary materials which trucks narrowly cleared trains.

It is a cooperative program as are most safety programs. The railroad employees *must cooperate in noticing the violations and* in gathering sufficient details for writing the letters. The operators of the vehicles on receiving the letters should handle not only with the offender but all their other drivers as well. Such cooperation on the part of all interested individuals is bound to bring results.

It is a plan which will be helpful in reducing the number of highway-railroad grade crossing accidents and is strongly recommended to all railroads.

I would like to ask that you consider seriously the suggestion that you resolve to be of greater service to your fellowman in this life saving program.

FINAL SESSION ADDRESS

by E. F. TUCK

chief mechanical officer, St. Louis-San Francisco Railway co., Springfield, Mo.

Supervisors have a leading role in safety. But safety is, in truth, a one-man job, and the man who is most responsible for an individual's safety is that man himself. All of the gadgets in the world will not keep a careless man from getting hurt—and a man is a careless man if he is thoughtless for only one fleeting second, because that moment may mean life or death to him.

If a person is careless for only an instant he is not keeping up his practice of safety long enough.

Safety is a challenge to all. We are constantly faced with hazards, whether at home, on the street, in the office, in stores, theaters, our own private cars, or public transportation systems. No matter where we are, as long as there is motion there is a challenge to safety.

One only has to read the paper to find a report of some kind of accident. But that accident which rates publication may only be one of the freaks or one of the more serious which, because of its nature, is classified as news. I wonder how many other accidents occur for that one "freak" which never make the papers? How many daily challenges to safety were not successfully met? Many, many more than reach the news caused discomfort and loss of time to the injured.

SAFETY IS A CHALLENGE

Safety is a constant challenge if we are to overcome the tremendous losses sustained by humanity every year in loss of time—in loss of income—in permanent impairment of faculties—in just plain discomfort. Safety is a constant challenge if we are to increase our longevity—if we are to better our chances of living a fuller life—better our chances of remaining whole, hale and hearty.

Who is challenged? Every man, woman and child on this earth, rich or poor, young or old—none escapes hazard, none is safe unless he thinks safety constantly. Even the home, that sanctuary to all, is full of challenges. No one is immune, no one is sheltered. The only remedy, the only chance for victory lies in thinking and practicing safety—it should be preached, policed and practiced by all.

You men in safety work occupy a most peculiar position. You have an unlimited quantity of a most valuable article to give away—data on safety—but, unfortunately, this is an intangible item.

I wonder what would happen if you were told that you had an infinite supply of cigarettes at your disposal and your company's only request was that you give them away—free—no strings attached—just give them to any and all who would accept—all you had to do was give, give, give. How much trouble do you think you would have? None—customers would return and return, time and again, and new ones would be added. But don't forget—*your supply is unlimited*—as long as folks will accept, you can give. Wouldn't that be an easy job to handle—and a pleasant one?

CAN'T GIVE AWAY SAFETY

Well, you have something of much more value—you have unlimited quantities to give away—but it is intangible. The peculiar situation about your position is the fact that with an unlimited supply of a most valuable item—safety—you can't give it to people—you can't get them to come after it—you have to sell it to them.

There's no charge—*it's absolutely free*—but you still have to sell it, and you have to be just as good a salesman as you would to sell any commodity on the market today. Your safety record is your order book—it is a daily challenge to your salesmanship.

It is most disheartening to try, try and try, and then see reports of accidents that should never have happened—accidents that could have been prevented if the victim had only accepted that free item which was available to him in unlimited quantities—that item you had to give him, and tried your best to sell to him.

We are all familiar with the hazards that beset one during each day of his existence, and we reiterate them pictorially

and statistically to those under our supervision with the hope that extra thought will be given to practicing safety.

Are we always getting our story across as we intended? My position is directly connected with safety because in the operation of a railroad many hazards exist. The men are fully aware of the risks involved in that sort of occupation—they are naturally more careful than they would be if engaged in some less hazardous task. However, we find it necessary to remind them constantly of oversights on their part—to remind them to practice safety every minute of every day.

As in other large industries, we on the railroad compile statements and statistics about our accidents. Through these statistics we arrive at a ratio—the number of accidents occurring per million man hours of work.

How much does this mean to you—men engaged primarily in safety? It means a great deal to you—but what does that ratio mean to the units that formulate it—those units are men, the workers. I'm afraid that a 5.1 ratio or a 95.1 ratio would indicate little to them.

MAN IS PRIMITIVE

Man is fundamentally primitive—he grasps quickly the simple things and flounders upon the complex. When he began his existence, he first noticed his fingers, and then his toes—and to record numbers, he began by using these. Five fingers on one hand, five on the other—that made it easy for him to comprehend up to 10. After he progressed a little farther, he included his toes—and then he could comprehend 20—10 fingers here, 10 toes there.

He is still primitive—he still subconsciously uses his fingers and his toes. When you go beyond, and beyond, and beyond that into the realm of astronomical figures —*million miles, million dollars, million light years*—and, yes, million man hours—he's hopelessly, irrecoverably lost—so far lost that he shrugs his shoulders and says "so what—a million, a billion, a trillion—I'm only one—that first finger on that right hand, that's me—and the millions, billions, *trillions are of no concern.*

Yes, I can think beyond me—that hand has five fingers on it; me, my wife and three kids—that's one hand, that's one family —my family. Now you are talking about something I can understand . . . but a million man-hours—and there goes the shrug again, and "so what."

Now, you are intelligent men and are familiar with statistics—you work with them all of the time—you should be most adept at understanding them. I am going to quote to you some figures about a particular railroad.

During a certain month, the total man hours worked on that road was 9,320,000. There were no fatalities during that period but 43 injuries did occur. The ratio of injuries per million man hours totaled sufficiently to make a ratio of 4.61.

DON'T COMPREHEND MILLIONS

Now, as I said before, you are exceptional men in this line of thinking—it is your work, your job . . . you do it all of the time. But I wonder how many of you could repeat the figures which I just quoted —a few, yes—the majority, no. How many workers, *the units you use to make your* statistics, your ratios—*men*—how many of them could comprehend what those figures mean? Very few, if any. How many would say "millions—billions—trillions—so what?" Very many?—Yes. Why?—Because the story has not been given to them in the *units they can understand readily*—10s and 20s—10 fingers here—10 toes there.

Now let's see if there is some way we can bring these figures down to earth—get them out of the skies so that a man without a telescope of higher learning and without the astronomer's mind can understand them. Let's see if we can't get them down to the units he understands.

The average man today works eight hours a day, five days a week—that's 40 hours a week or 2,080 hours a year. How many years would it take this one man—this "me" —*this man you are talking to*—to complete one million hours of work? Why, at the rate of 2,080 hours a year it would take him 480 years.

So, we're still way out of his realm—we are talking about a period approximately *seven times as long as he will live, if he* lives to reach 70. We are far—too far—away from his 10 fingers and 10 toes. We'll have to get closer than that.

Our ratio per million man hours was 4.61. That means that for every 480 years this "me" would, according to the law of averages, be injured about four and one-half times, or once every 106 years. Still too far away—but we're getting closer.

Let's say—and we won't be far wrong—that the average worker spends 35 years at his task. That means it takes the lifetime of three workers to make 106 work-years—and in that 106 years of work, our ratio shows one accident is due.

ONE OUT OF THREE HURT

Now we're getting down to the fingers. One worker out of three will have an accident—one out of three. Now, can this "me" we are trying to impress understand? You bet he can—he can look around him and see two other workers, and say to himself "one of us is going to be hurt in our lifetime, one of us three—will it be me?"

There, you've made the story click. He knows that unless he and his fellow workers do better practicing safety, his chances are one out of three to get hurt—and one out of three is pretty big. He doesn't have to use many fingers to count that—it's pretty close to home.

Now, safety is everybody's individual job and it is an everyday, around-the-clock business. It's our job to preach it and police it to see that it is practiced. It's our job to let the workers know where they stand and what their chances are—it's our job to bring the story home to them.

We want to make everybody safety-conscious all of the time, and bringing the story home will do a most fruitful job.

The illustration I have used can be applied to any form of accident we care to illustrate. It only takes a little trained thinking on our part to put it in language our hearers will understand—a language that will put the "me" in the picture for them. And when you have them thinking about their "me," you've got them thinking!

THE IMPORTANCE OF SAFETY IN MAINTENANCE OF EQUIPMENT AND STORES

(A Symposium)

LOCOMOTIVE MAINTENANCE

by C. H. GRAY

master mechanic, Chicago, Rock Island & Pacific Railway co., Chicago

Inasmuch as railroading is one of the oldest industries in the United States, the railroads have some of the oldest structures, the oldest methods, the oldest ideas, the oldest men, and in the case of safety, the oldest problems. In the case of the oldest problems, the oldest answers are not necessarily the best ones and new answers to old questions and problems are in demand, by the newer and aggressive managements.

There are innumerable problems that stand in the way of maintenance of equipment safety, but if we spend our energies toward curing the ailments, instead of listing the problems by numerical order, we find considerable headway has been made.

The responsibility for the safety of the men working in the maintenance of equipment department belongs to the boss. One can delegate authority to subordinates, but cannot delegate responsibility. The head of the department must formulate a plan to be followed to accomplish a safe working program. He must be able to sell his program for safety to his supervision, in such a manner that they in turn, will be able to put the program across to the people working in the shops.

ALL METHODS VARY

The same methods of obtaining results in safety, will not always work in different shops, or with different groups of people. Generally speaking, however, action that ends in results that can be seen, will go a long way toward putting safety program on its feet, and cause it to gain momentum.

When a fire department arrives to put out a fire and finds someone else has done so first, they don't go away mad. When the bridge and building department arrives to repair an unsafe stairway or ramp, and find someone else has done so first, there is sure to be a big fuss—but whoever said for certain, they would ever arrive in the first place?

Why should they complain if an unsafe condition has been repaired and a possible injury prevented? The responsibility of safeguarding of mechanical employees is with the mechanical officers, not with the bridge and building department.

Included in this responsibility to accomplish safe work, is the responsibility to provide a safe place to do it. The safe place is one with adequate room. It is sometimes surprising to find that floor space is increased 50 per cent when material is stocked in the storehouse, instead of the shop floor, and when the scrap is removed regularly by one man rather than periodically by a dozen men. When working in cleanliness instead of dust, a man not only does his work faster, but cleaner, better and safer. Good housekeeping is fundamental in a good safety program and a well organized and operated mechanical facility.

Sometimes, as strange as it may seem, safety first needs to be given respectability. I have had the misfortune to be transferred to a mechanical facility at which the officer in charge, only paid "lip service" to safety first. He walked through the shop day after day when it was in disorder and filthy dirty. He would continually walk by unsafe conditions and men performing their work using unsafe practices and do nothing to straighten the place up or stop the unsafe practices.

He would meet with the safety committee and promise anything and do nothing. Generally the safety meeting took the aspect of a labor committee, meeting to handle grievances. There were safety items that

had been reported for eleven years and no action taken.

My first action was to inquire who was respected by a majority of their fellow-employees and then dissolve the old safety committee. I formed a new committee and explained to them that certainly there was one problem that would not become an issue between the employees and shop management and that was *safety first*. In one year we had made tremendous strides in cutting down injuries; we wiped the 11 year old safety items off the books and were working currently on conditions that were reported. In 90 per cent of the items brought before the safety committee, the answers that solved the problems came from the employees themselves.

The shop management and the safety committee were respected. The rank and file knew that the officer in charge of the shop backed up safety, because every day he made some corrections of poor housekeeping or unsafe conditions in plain view of other employees. The safety record improved 75 per cent in 60 days. The supervision in the shop knew that safety first was first in their duties.

SAFETY IS TEAMWORK

Now the shop safety achievement doesn't happen by accident—it needs promotion and whose responsibility is it to promote shop safety? The same fellow who has all the rest of the responsibility. Only the men involved might know as much as they do about it, so let's let them do a little of the work themselves. This is team work; with team work use gimmicks, tools or any other means to attract attention to safety first, but avoid being ridiculous and thus cheapen the program.

At one of our facilities, we do the following things:

1. Fly the American flag and the safety flag over the premises.
2. A safety meeting committee made up of highly respected men meet twice monthly to discuss safety and solve safety problems.
3. White caps with the Green Cross, emblematic of *safety first*, is worn by each committeeman during their tour of duty. This allows employees easy access for handling safety first ideas. It is felt some employees will go to a fellow-employee rather than a boss.
4. Each craft foreman and departmental foreman has above his office door a light that flashes green and bears a number indicating the number of days without a reportable injury. Should a reportable occur, a red light flashes until the end of the month, when the count starts over.

Of the items mentioned above, each one was suggested by employees themselves and seeing their own devices and programs at work, they have a feeling of pride and a desire to see their own program succeed. Moreover, in the instance of the green or red flashing lights, the crafts are in competition with each other and none wish to walk through the doorway that bears a red flashing light.

PUT VARIETY INTO MEETING

One of the common complaints among employees is that the same people talk to them in safety meetings, saying the same things over and over. I have heard it said so many times—"Why don't we have new faces and hear new things."

About two years ago, in one of our large shops located in a community which included a large number of heavy industries, I obtained the names of several safety superintendents of such industries as John Deere Plow company, American Aluminum company of America, and International Harvester. Arrangements were made for these gentlemen to speak at our safety meetings held once a month in a mass meeting in the shop. Much to the surprise of all the employees, it was found that many of the same problems in *safety first* confront these other industries that confronted us. It seemed to me that our employees were more satisfied to buckle down to our problems and do a good job of *safety first*.

As safety suggestions are solicited, received and put into effect, a momentum is established which sometimes inspires more and better ideas. Any enthusiasm is a good thing and can be directed into a clean up campaign that winds things up even further.

We find that a good way to promote safety among our people is occasionally to have a *safety first* rally in our shops and invite the families of the employees.

We also realize how much influence the wife and family exert on the husband or father. If the families become acquainted with the supervision and the shop facilities in which their men work, we can enlist them on the side of *safety first*. After seeing these facilities, we believe they will help us instill this in the husband and father. We have held such safety parties as I have mentioned and know that such affairs are beneficial.

HOLD SAFETY PARTY

On November 1, we held a safety affair as I have outlined for the entire Chicago division of our railroad. Shop employees and their families attended and employees and their families from all of the other departments were present, approximately 2,000 people. *Safety first* was the theme of the party and a special train brought our people to the party. The shop was decorated by the various crafts and departments, door prizes were given—and, there was dancing and refreshments.

As part of the entertainment we had a safety film suitable for the family to see and a short *safety first* talk. Important too was the opportunity for the members of the employees' families to meet the officers and the supervision for whom their men work. Also the men had an opportunity to display their shop.

I have not attempted to discuss technical safety practices to be followed in the maintenance of equipment; the technical safety practices will come if the boss is sold on *safety first* to a degree that he can intelligently put his program across to his supervision and they in turn will sell it to their fellow workmen.

Good housekeeping, respectability, salesmanship, intelligent instructions, progressiveness, aggressiveness and team work—will lick any problem.

Therefore, if the boss accepts his responsibility and makes certain all of these ingredients are placed in the pie, there can only be a final result—*safety first*.▲

FREIGHT AND PASSENGER CAR MAINTENANCE

by D. L. CRONKHITE

master car builder, Chicago & Eastern Illinois Railroad co., Chicago, Ill.

It has been my responsibility and [illegible] to serve on safety committees and to foster and promote safety of operations in freight and passenger car maintenance for the [illegible] several years. During this period of time, I have seen the accidents involving personal injury accepted without much thought to the pain and unhappiness caused, and I have seen the gratifying reactions to an aggressive drive to eliminate this scourge of pain, suffering, and tragedy which affects our happiness and economical well-being. This change in attitude has not been achieved individually, but by the cooperation of management and employees in their endeavor to make everyone safety-conscious.

This drive to eliminate the old habit of accepting an accident as something that just happens occasionally, and to substitute the habit of trying to avoid or prevent an accident before it happens, has resulted in a much better accident rate on our railroad. The maintenance of equipment department last year achieved a record of working one million man hours without a reportable injury, and we had over 500,000 hours on the second million before an accident occurred which broke our record.

We received the Award of Merit from the National Safety Council for this achievement, and for this we are justly proud and happy. This did not just occur, but represented the cooperation and earnest endeavor of all our employees. Another department on our railroad, the maintenance of way department, previously received an Award of Merit also for one million man hours worked without a reportable injury, and spirited competition has developed between these departments to see which will receive the next award.

During my work and experience in the field of safety of operation, I have conducted many inquiries into the causes of

accidents involving personal injuries. Although hazards were involved which if eliminated would undoubtedly have improved the safety of operation, I feel the greatest cause for accidents is the lack of individual thinking on the part of supervisors and workmen. I believe that we must get the lazy thinker sufficiently interested in the subject of safety so he will recognize the hazards and take necessary precautions to protect himself and his fellow workmen from being involved in an accident.

In some cases, we have found individuals who showed sharp and alert thinking. But in the majority of instances we have found that there was just plain carelessness and negligence, and the thinking was after the accident had occurred. I do not wish to imply that this lack of thinking applied only to the party who was injured, but that supervisors, safety committees, and other individuals all failed in their responsibility of doing some constructive thinking and taking necessary precautions.

CAUSES OF ACCIDENTS

It must be recognized that in our work there are conditions which are dangerous and which are liable to cause accidents if proper precautions are not taken to work with them safely. This applies to the methods and practices which have been in effect for many years, and to the innovations in the field of mechanics, electronics, and chemistry, which present new hazards where they have been adapted to our field of operation.

In the past, most of our injuries were due to such causes as muscle strain in handling heavy materials, working with hand tools, flying rivets cut by hand tools, or being struck on the jaw with a jack lever. Today, we have injuries due to being struck by motorized equipment handling materials, flash burns to eyes exposed to electric welding, or exposure to gas fumes which may be irritating and in some cases toxic.

Therefore, if we are to enjoy the better things for performing our work, we must also avoid the hazards, and through education and constant and consistent thinking provide ourselves with a solution for living safely with these hazards.

We have technical experts to assist us in our programs of safety education, but we must always remember that getting each individual to think safety is most important in any program for eliminating accidents. And we should not be selfish with our knowledge of safety of operation. We should be ever on the alert for the new and inexperienced man, to see that he does not become lax in his thinking about the safe way to perform his work.

I can not tell you how to get a man to think correctly in the field of safety. I do know that we must have a program into which our safety activities must be channeled, and the better the program, the better benefits can be expected. We must have the intestinal fortitude to keep at it consistently, and not allow mistakes and frustration to discourage us to the point of interfering with the program. We must have a sincere desire for a better safety record, and we must instill that desire in our employees if we are to lead our organization to that goal.

STORES OPERATION

by F. F. FORBES
supervisor, scrap & reclamation, Erie Railroad co., Meadville, Pa.

It is the little things that annoy us. "You can sit on a mountain, but you can't sit on a tack." Paraphrastically, this old saying sums up our safety program for maintenance of equipment and stores operations. We have learned to respect the potential hazards in the many complicated problems of handling dangerous commodities, such as explosives, inflammables, etc., but in the simplicity of daily routine, we have had and will continue to have the problem of contending with the unpredictable behavior of the human element at work.

Little new can be written about safety that has not already been expressed in varied ways, somewhat similar to our religious inclinations, bolstered by repetitious reminders of shortcomings to keep us from backsliding. We continually strive to create interest in safety programs and many times feel we are getting nowhere with them. By the same token, we must not relax in our efforts to contact and teach employees to join hands in the all-out "Fight for Life."

Education is a major process through which accidents can be reduced. We can and we must make such provision for the education of the rising generation to make them safety conscious to the "nth" degree. The conditions under which they will work, play, and live, will be even more dangerous than present existing conditions, as we live in a world whose chief concern is more and more speed.

In this haste and speed we violate safety rules or laws which in turn build up sales resistance which is hard to overcome. It is this phase of our safety work to which we must devote our greatest effort. In the maintenance of equipment and stores, American railroads recognize this problem and spend untold time and money in educating employees in the matter of personal safety. By so doing, they keep pace with changing conditions through those now employed who must set the example for those who will follow. This educational endeavor is getting results and has contributed its part in the reduction of accidents.

An active safety committee, making routine inspection of properties, equipment and stores operations, ferretting out dangerous conditions, faulty equipment and improper tools is a medium that becomes a part of a positive approach in getting across to the individual the sincerity that must be the keynote of the program. The person who contributed the following was on the right track when he wrote:—

"No man will pay heed to anything he is not interested in. To capture his mind, you must first get full attention, and this can be accomplished by stirring his personal interest. Man is more interested in himself than anything else in the world. When you prove to him that you are interested in him and that you are sincere in your thoughts and actions, your task of developing him into a Safe Man has progressed greatly. Keep faith with your men; show them that you are interested in their welfare and they will respond. Establish the idea in the mind of your men that the result you are endeavoring to produce is the elimination of personal suffering, rather than an endeavor to build up a record of rule violation."

To me, it would seem the first requisite of a good safety committee, attempting to install a positive and active program of accident prevention, is the ability to gain the confidence and respect of all employees. The day of prohibitions and rules of *Don'ts* sponsored by safety workers is gone; their work now must be inspirational and educational, and their contact with employees pleasant experiences.

It might be of interest to you to know how a safety program is planned at one of our terminals to emphasize the logic that a safe-working employee is more contented and happier in his work and contributes to better relationship between management and himself by actively engaging in promoting safer working conditions.

This terminal is at Meadville, Pa., where I am chairman of the division superintendent's safety committee. (All such activity on the railroad comes within the jurisdiction of our superintendent of safety). There are 400 employees in 16 sub-departments that are contacted each month at 12 locations where they can be readily assembled. The committee is made up of the top departmental heads of the local operations.

PROGRAM SET-UP

The chairman sets dates for meetings and notifies the members, as well as sends notices to all departments for bulletin board posting. The notices carry the time for the meetings and the subject matter to be considered. Diversified material is used; however, only one subject is taken up each month, e.g.—

Review of preceding year's safety posters.

Checking on safety rule books and their usage.

Proper clothing and health protection.

Thanksgiving, Christmas, New Years, or any special holiday can provide suitable topics for safety talks, as well as the seasons of the year, vacation, school opening, etc.

Once a year a motion picture on safety is shown and the following month a discussion on the film creates interest.

Every possible angle that can be used to keep a fast-moving, 20-minute, safety meeting on the chosen subject is employed to create human interest.

Near the close of each sub-departmental meeting, a short discussion period is held for a status report on items brought forward from preceding month's meetings. Additional items requiring attention are solicited and only safety items that cannot get immediate correction are considered for the summary report given to the division superintendent. Handling in this manner, the list of items is kept to a minimum and include those requiring further study and in a few instances require appropriations which must be approved before corrections can be made.

DIVIDED INTO GROUPS

The functioning of the committee is simple. Ordinarily there are 12 members who make the rounds and this number is divided into three groups of four members each, referred to as Groups A, B, and C. All members present themselves at the first location. Immediately with the start of this meeting, or the subsequent meetings, Group A moves forward to the next location to assemble employees and introduce any preliminary feature or arrangement in anticipation of Group B.

The talk or message is handled by Group B as are the discussion periods. Instances where more time is required than the scheduled 20 minutes, Group C stays on to clear up safety items that become involved during the discussion period. The success of the meetings depends greatly on a functional and well-balanced schedule, and the dividing-up of the Committee into the three groups has been very effective.

The primary objective of the work of this committee is to encourage employees to actively participate in the safety program to correct the causes of accidents, and help correct unsafe practices and conditions regardless of department which becomes involved. In this safety promotional work, maintenance of equipment and stores operations are so involved with the safety of every department that it is felt greater benefits are obtained through a committee representing all operations. Possibly this procedure would be of value at other railroad terminals.

OFFICERS OF THE RAILROAD SECTION NATIONAL SAFETY COUNCIL 1957-58

General Chairman—J. LLOYD, Jersey Central Lines, Jersey City, N. J.

Vice Chairman—L. C. HAHNEY, Elgin, Joliet & Eastern Railway co., Joliet, Ill.

Secretary and News Letter Editor—F. C. LEWIS, The Pullman co., Chicago, Ill.

Associate News Letter Editors:

Southeast—H. C. DAULTON, The Louisville & Nashville Railroad co., Louisville, Ky.
West—P. H. JENNER, The Western Pacific R.R.co., San Francisco, Calif.
Central—J. E. SLAVEN, Chicago, Burlington & Quincy R. R. co., Chicago, Ill.
East—J. L. BABCOCK, Bangor & Aroostook R. R. co., Bangor, Maine
Southwest—G. R. KNIGHT, St. Louis Southwestern Railway Lines, Tyler, Texas
Canada—J. G. BELDHAM, Toronto, Hamilton & Buffalo Ry. co., Hamilton, Ontario

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

THE SCHOOL AND COLLEGE DIVISION

This volume is a record of the sessions held at the 1957 National Safety Congress by the School and College Division. The conduct of these Congress sessions each year is only one of the many cooperative activities which the School and College Division carries on in behalf of its members, and for the benefit of accident prevention work in the field of education generally. The Division gives guidance in the preparation of a great variety of technical and educational material useful in day-to-day school safety programs.

The activities of the Division are under the direction of the School and College Conference. The officers of the Conference as well as those of various School and College sections are listed at the close of this volume.

PREVIEW OF EVENING DIVISIONS

PLAN OF ROTARY GROUPS

by FRANK BENNETT

specialist, Safety Education, Public Schools, Baltimore, Md.

At the President's Highway Safety Conference at Atlantic City, N. J., in May, 1956, arrangements were made for a series of meetings that were repeated for rotating groups. The members had a choice of the meetings they wished to attend, so that it was possible to provide for delegates with wide interests and for those who wanted to be oriented on most of the facets in any one or more areas.

When I mentioned this type of arrangement to the program committee last year, there seemed to be considerable interest. The committee agreed to try this arrangement, and invited me to explain the procedure.

This afternoon you will meet the five Chairmen of the leadership teams. Each Chairman will have an opportunity to indicate the areas of interest, current problems, and perhaps some of the leading or promising practices or trends in his particular field. This evening, each of the Chairmen will have a team composed of consultants who have had wide experience in their respective fields. After the Chairman has introduced the consultants and "kicked off" the subject, there may be key statements from each consultant with respect to the discussion subject.

Then, the whole area will be opened up for questions and discussions by the members in attendance, with questions being directed to any one of the consultants either by the individual participant or through the Chairman who may turn the question over to any one of the consultants.

This evening, you will have an opportunity to attend three of these discussion sessions as each group will hold three one-half hour sessions. The five topics under discussion will be:

1. The Schools and Fire Safety
2. Safety for School Personnel
3. What the Boy Scouts' Safety Good Turn Means to Schools and Colleges
4. Safety Through Physical Education
5. Safety in the Practical Arts

You are invited to select the three meetings you wish to attend and go to one from 7:30 to 8 o'clock. At the sound of the gong you will be dismissed and are to go to the next meeting which will begin promptly at 8:10. At the sound of the second gong at 8:40, you are invited to go to the third meeting which will begin promptly at 8:50.

This procedure will give you an opportunity to get a general background in three areas. If you wish to gain further information, and or have direct questions you would like answered, raise these at this time in the discussion groups. If you wish more complete information and background you may remain in one of the discussion groups for an extra period.

In the event that you go to one of the discussion and find every seat taken, will you kindly go to the meeting of your second or third choice, and come back to the same meeting for the second session; or, if it should be filled a second time, make a switch and come back to this meeting for the third time.

In planning these sessions, it was the program committee's hope that this procedure would make it possible to gain a wider spread of interest and yet an opportunity for detail. We hope this plan will appeal to new Congress visitors and to veterans also.

SAFETY FOR SCHOOL PERSONNEL

by LESTER L. WASSERBURGER

supervisor, Employees' Safety Education & Accident Prevention,
Los Angeles City Board of Education, Los Angeles, Calif.

Your concern for the topic "Safety for School Personnel" will be influenced by your answers to the following questions:

1. Is your responsibility for safety concerned with a small, medium or large school district?

2. Do you have a formalized employee accident prevention program?

3. Do you have a token program with someone responsible on a part-time coordinator basis?

4. Do you know the premium paid for Workmen's Compensation Insurance by your school district?

5. Do you know the relationship of loss-experience to insurance premiums?

6. Do you make a monthly accident analysis of on-the-job accidents to all employees?

7. Do you have within your staff a trained person capable of investigating and analyzing accidents?

8. Do you make any attempt to convey to personnel in your district the information gathered from the investigation and analysis of employee accidents?

9. Do you know whether it is your teachers, custodians, clerks, maintenance crews, cafeteria workers, bus or truck drivers, or warehouse employees who are involved in the most on-the-job accidents?

10. Do you know what could be the expectant dividend you would receive of the total premium paid for Workmen's Compensation Insurance if you reduced your loss experience for on-the-job accidents?

If you know what you are paying for Compensation Insurance and what dividend can be expected by an active aggressive Employee Accident Prevention and Control Program you can classify yourself by the following formula. Forty per cent of the total premium paid can be returned if you have reduced your loss experience through a reduction of on-the-job accidents to employees.

Are you interested in saving $5,000, $15,000, $25,000, $55,000, $105,000, $155,000, $205,000 or $255,000, which is being poured down the proverbial "rat hole" with not even a remote chance of recovery of even a single penny?

WHY, WHAT, AND HOW?

A well planned Employee Accident Prevention and Control Program organized on the basic philosophy and fundamental principles of Industrial Accident Prevention is the start to recovery of this economic loss to school districts all over the United States. Perhaps this stimulates three important questions:

1. Why do school districts need an Employee Accident and Prevention Control Program?
2. What are the approaches used to organize a program?
3. How do we plan a program which will fit the needs of our school district—whether it be small, medium or large?

The answer to the Why! is basically that school districts have a legal and moral responsibility to their employees and the general public they represent.

Primarily, the legal concept of the statutory regulations, establishing a "degree of responsibility" for safety of employees as required by all school boards, superintendents, administrators, supervisors, and foremen, is generally misunderstood and misinterpreted.

Legally, school districts have a greater "degree of responsibility" as they operate under four specific codes: The Education Code, Workmen's Compensation Laws, Labor Code, and various types of safety orders issued by a division of industrial relations or some comparable agency.

The above codes all contain sections which place the "degree of responsibility" on school districts to provide a safe place of employment. Further, they shall include measures to acquaint employees with the hazards of their employment and instructions in safe practices and procedures in performing their work.

The power and statutory responsibility is vested in the school district governing body. They have a moral responsibility to employees and the public to prevent human suffering and waste. They have a civic responsibility to the public to reduce costs to a minimum without jeopardizing the educational program. They can fulfill all of these responsibilities by establishing an Employee Accident Prevention and Control Program.

MORAL, CIVIC RESPONSIBILITY

Endorsement of a program by a governing board or an administrative representative, delegated the "degree of responsibility" to organize the program, is imperative. This statement will assure the rightful status necessary to the success of your program.

The answer to the third question How! evolves around the basic principles and philosophy of industrial accident prevention.

In the organization and planning of your program, consideration should be given to the immediate and long range planning. The immediate approach should be towards direct control of personal performance and environment. The long range approach should encompass training and education.

Basically, the purpose of any accident prevention program is to assist all employees to *recognize*, *evaluate*, and *control* the hazards of the environment in which they *work*, *play*, or *live*. If we review this definition we see that such a purpose involves both on-the-job and off-the-job safety.

EMPLOYEE ACCIDENT REPORTS

You can recognize your hazards by requiring that all employee accident reports be sent to the office of the person delegated the responsibility for employee accident prevention and control.

That office can begin to *evaluate* hazards as to the agency which was the proximate cause of the accident. Analysis of reports will reveal the accident source and the nature of injuries.

The *recognition* of the hazards and the *evaluation* of resultant causes of your accidents will suggest *controls*, which must be established to prevent similar occurrences of the accident.

The above three criteria for the *evaluation* of your immediate program will pinpoint the occupations where you will need to place emphasis in your long range approach to a program of training and safety education.

Experience in accident prevention has shown that we can reduce on-the-job accidents to a fraction of what they were. As school districts why should we not profit and benefit by the experience of Industrial Accident Prevention?

SAFETY IN VOCATIONAL AND INDUSTRIAL ARTS EDUCATION

by J. F. INGRAM

state supervisor, Trade & Industrial Education,
Dept. of Education, Montgomery, Ala.

It was once a rather common thing among educators to ask any man who was a teacher and had a finger missing or a mutilated hand, "Where do you teach manual training?" This question had several implications: (1) that teachers themselves were not good examples of the matter of safety, (2) that the program was one of "training" the hands only, (3) that the program involved unavoidable accidents and (4) all manual training teachers sooner or later met with an accident.

Progress has been made in this respect. There are more better-prepared industrial arts teachers. Industrial arts is now recognized as an educational program which extends much beyond woodworking. More teachers with some industrial experiences are being used, and modern machines and equipment with standard safety attachments are more commonly used.

More emphasis is placed upon safe practices as an integral part of the curriculum as opposed to isolated "courses" in "safety." Industrial arts is recognized as an educational program through which pupils master and apply considerable knowledge while sampling the arts and skills of industry through safe practices.

TEACHING SAFETY WITH SKILLS

There is an important philosophy which must be basic to any functional safety program. In the first place it must be understood that no piece of equipment, process or machine is, itself, dangerous if properly installed, serviced, and/or used. Then one must believe that all accidents can be avoided and all hazards minimized with correct knowledge and practices. Fear of tools, machines, and equipment can and should be displaced with confidence based upon skill and applied knowledge in their use.

Safety must be considered the practice of using the correct tools, machines and equipment to perform work in a correct and safe manner. In other words, safety is "learned by doing" just as any other skills are learned. Safety is taught best with a positive approach—always stressing the safe ways of doing things, using proper tools, machines, equipment, and techniques.

There are many sources of teaching aids and helps in the matter of safety. For instance, the manufacturers of tools, equipment, machines and materials provide some excellent materials on safety which relate to their products. In many instances manufacturers will send safety engineers out to assist in the layout and color schemes which contribute to safety and will teach the instructor safe use of the product.

Modern textbooks for industrial arts now include more and better instructions in safe practices in the school shop. However, too much of it is still negative rather than positive instruction. In the hands of good instructors it can be made very effective.

CASE METHODS OF TEACHING

Teachers must be well-trained and educated in the principles and practices of safety based upon a thorough knowledge of the problems and of the best practices found in industry and business.

A technique which has been quite successful in reducing accidents in industrial school shops has to do with an accident reporting procedure. Immediately after each accident occurs the instructor is required to make a detailed report of all facts concerning it. Then a thorough analysis is made of the causes and detailed statements of how the accident could have been avoided.

These are used by all instructors as supplementary aids in teaching the safe use of machines, tools, or equipment. This is a case method of teaching and points up hazards at the same time showing how to minimize them.

Perhaps the National Safety Council working through its affiliated local councils has done more than any other one single group to make this country safety conscious.

WHAT THE BOY SCOUTS' SAFETY GOOD TURN MEANS TO SCHOOLS AND COLLEGES

DISCUSSION SESSION REPORT

Leadership Team:

Chairman—Donald M. Higgins, director, Health and Safety Service, Boy Scouts of America, New Brunswick, N. J.; Daniel DenUyl, associate professor of Forestry, Dept. of Forestry & Conservation, School of Agriculture, Purdue University, Lafayette, Ind.; Lonnie Gilliland, director, Safety Education, Public Schools, Oklahoma City, Okla.

The 1958 Safety Good Turn Program of the Boy Scouts of America is planned to follow this schedule:

February, 1958—Kickoff in Scout Week —February 7-13.

March, April, and May—Traffic Safety —Each Scout unit takes part in or puts on a project in automotive, bicycle, pedestrian, railroad, or farm equipment safety.

June, July, August—Outdoor Safety— Each unit takes part in or puts on a water, fire, firearms, or farm safety project.

September, October, November—Home Safety—Members of the Boy Scouts of America will deliver a message about family preparedness for emergencies to every home in America. Materials will be furnished and distributed to Scout councils by the Federal Civil Defense Administration. Units will also take part in or put on fire prevention and home safety projects.

February, 1959—National report as part of the Report to the Nation.

The National Council, Boy Scouts of America, has been given the support of many national organizations in planning and organizing the activities of the Good Turn Program. The National Safety Council, as part of its effort, supplied an enrollment card for all delegates to the 1957 National Safety Congress to report their availability to local Scout officials to help carry out the purposes of the Good Turn Program.

These cards, picked up from all sessions of the National Safety Congress, will be routed to the National Council, Boy Scouts of America, and in turn sent to the appropriate local Scout officials for their information in locating professional safety personnel in their communities.

School officials are urged to make personnel and other facilities available to the program whenever this is possible and support it through bulletins, announcements, and other methods consistent with the policies and programs of their schools systems.

Recognition of the Safety Good Turn project and cooperation in its various features can be the basis for activities of student councils, parent teacher organizations, safety councils, and other groups in or related to school affairs.

The cooperation of school faculties and students can be of value to the Good Turn Program in these ways:

1. arranging and conducting exhibits, demonstrations, and assemblies for the project.
2. preparing and disseminating information through various media .
3. assisting in recruiting, training, and selecting speakers who can publicize the Good Turn in the many meetings held daily by civic, social, and commercial organizations.
4. helping to establish the proper educational approach to the program as it is prepared for adults and the various other levels of interest and comprehension.
5. assisting Scout officials to uncover the adult leaders who will cooperate in making the program maximally effective.
6. evaluating and future planning of safety programs, publications, etc.

At the collegiate level, many of the foregoing services of public and private schools will also apply. In addition, there is in existence on many campuses local chapters of Alpha Phi Omega service fraternity which consists solely of former Boy Scouts, many of them of the Eagle or Life Scout class.

This fraternity and other men's and women's service groups cooperate both in campus projects and college community enterprises. Safety has been a project for them in the past. Many of them will undoubtedly welcome the opportunity to cooperate in every possible way with the Boy Scout Safety Good Turn Program in 1958.

I should like to emphasize the importance of making your safety skills and understanding of community service available to the local Scout officials who alone can make the Boy Scout Safety Good Turn program a vital force in American life today and in the future.▲

SAFETY THROUGH PHYSICAL EDUCATION

INTRODUCTION BY HOMER ALLEN

associate professor, Physical Education, Purdue University, Lafayette, Ind.

This subject means "Safety in other activities, now and later, as a result of having participated in a well conceived program of physical education." In other words, many of us who have been working in the whole area of physical education feel that a well balanced training program will be conducive to fewer accidents and injuries in *any* type of physical activity.

We know in the average school, either at the elementary or secondary level, about one third of the accidents and injuries occur in the gymnasium or on the playground. We accept this fact as almost inevitable, due to the physical activities involved in these areas.

On the other hand, at least one-half of these accidents are the result of:

A. Poor facilities and/or equipment

B. Overcrowded classes or groups

C. Poor supervision

The following questions might lead to some interesting and fruitful discussion:

1. What kinds of physical activities are suitable to children of various age groups? Can we specifically list certain activities in which an average child of a certain age may be expected to participate with a minimum risk of having an accident?

2. How strong, physically, should a child be to indulge in a specific activity?

3. Can we measure strength, or stamina, or a combination of the two, in an average school child?

4. Does strength, as such, determine ones fitness to participate in a physical activity?

5. Does the average person, (child or adult) consider his physical fitness in relation to: ability to participate or susceptability to an accident, in a specific activity?

6. Does physical fitness contribute to: coordination, skill, suppleness, awareness of ones physical limitations or personal safety?

I have from time to time composed what has laughingly been referred to as poetry. In the following verses I stress a few aspects of attaining safety through physical education.

To introduce my subject in a rythmic sort of way
Might add a little sparkle to the things I want to say.
For safety in the gym or on the playground or the pool
Can certainly be bettered in your home town public school.

We talk of training children in the skills of many sports.
We let them play on floors and fields and even tennis courts.
But do we give them training to develop strength of heart
And of all the other muscles which they need to do their part?

Small wonder that a youngster shies away from active stuff
If he knows he cannot take it when the going gets too rough.
For a bump upon the noggin, or a twisted leg or neck
Puts him on the shelf completely as an un-heroic wreck.

To those of us who've tried at times to practice what we preach,
Abolishment of accidents is not beyond our reach.
But it takes a lot of planning, and practice, every day
To make our children really safe and keep them fit for play!

An Analysis of Graduate Theses in School Safety In the United States from 1925 to 1950

by CHARLES PETER YOST

Ph.D., Thesis, University of Pittsburgh, Pittsburgh, Pa.

BACKGROUND OF THE PROBLEM

Numerous people have conducted research for the purpose of making our nation a safe place to live. Some research has been done by graduate students in partial fulfillment of an advanced degree, and has been concerned with presenting feasible plans of school safety. Very little has been done, however, to organize and classify the findings of graduate theses in school safety for functional use by school personnel. Rather than have the findings of these studies scattered throughout the United States it was believed that an accumulation of findings, located in one source, would provide a means by which school personnel could *better understand various facts, practices,* procedures, and policies regarding school safety, and hence initiate or conduct efficient programs in school safety.

The problem for study was to systematically identify and analyze masters' theses and doctoral dissertations in school safety as a *basis for identifying acceptable policies,* practices, procedures and instructional information in school safety for functional use by school personnel.

METHOD OF PROCEDURE

An examination of theses' titles in bibliographical references and in information received from leaders in the field of safety education revealed that 307 graduate theses had possible bearing upon school safety. Through inter-library loans 298 (97 per cent) of these studies were obtained for analysis purposes.

In analyzing the graduate theses, these questions were asked: (a) Was each study a graduate thesis or a "seminar report"? (b) *Did each study* have direct bearing upon school safety as *defined* for study purposes? and (c) Did each study meet the evaluative criteria developed for study purposes? The criteria were developed through the jury technique and were primarily concerned with ascertaining the scientific accuracy of each obtained graduate thesis. The above three steps were utilized in determining those these which could be used for purposes of the study. In applying these *steps to the obtained studies, it was found* that nine studies were not graduate theses (as indicated in bibliographical listings) but were "seminar reports"; ten did not have direct bearing upon school safety; and 13 failed to meet the evaluative criteria established for study purposes. This left a total of 266 graduate theses which could be used for study-purposes.

Further analysis of the useable studies involved noting various descriptive characteristics *including the years and institutions* when and where studies were completed, the degrees for which they were submitted, the research methods involved, the grade levels for which the studies were primarily concerned, the general topical emphasis, and the geographical areas where the studies were conducted.

Findings of the useable studies were analyzed and classified for functional use by school personnel by formulating various major topics and subtopics emerging from the graduate theses themselves. These major topics included "The General School Safety Program," "Safety in Athletics, Physical Education, and Recreation," "Safety in School Shops," and "Traffic Safety." For each major topic various policies, practices, and procedures were formulated. The conclusions are in outline forms as follows:

SELECTED CONCLUSIONS

1. *Identification and Descriptive Characteristics of Graduate Theses in School Safety.*
   a. No single source was available to identify graduate theses in school safety. Bibliographical listings were erroneous in some instances, and titles of graduate theses were sometimes misleading.
   b. The scholarly research effort reached its peak in 1940 and 1941 when almost one-fourth (24.8 per cent) of the studies were produced. The majority of the studies met recognized research standards.
   c. Sixty-three different colleges and universities produced a total of 266 graduate theses. Over three-fourths (78.5 per cent) satisfied requirements for a master's degree. Iowa State Teachers College produced the most masters' theses (17 or 7.9 per cent) while New York University produced the most doctoral dissertations (27 or 57.4 per cent). The single institution producing the most graduate theses was New York University (38 or 14.3 per cent). In regard to institutions producing the most graduate theses in various areas of school safety, New York University with 21 studies led in the area of "General School Safety Program"; New York University with ten studies also led in the area of "Safety in Athletics, Physical Education, and Recreation"; The Stout Institute with six studies led in the area of "Safety in School Shops"; and Purdue University with nine studies led in the area of "Traffic Safety."
   d. The normative-survey type of research has extensive use (used in 214 instances or 80.5 per cent). Of particular significance was the small number of experimental studies (32 or 12 per cent). The greatest percentage of experimental studies in any one area of school safety was in the area of "Traffic Safety."
   e. The most commonly used techniques for collecting data include "literature survey," "questionnaire," "group testing," "observation," and the study of "accident reports." The use of the questionnaire by writers of doctoral dissertations was generally accompanied by collaboration (jury).
   f. The majority of graduate theses dealt with safety at the secondary school level. School safety at the college level received major emphasis in 19 (7.1 per cent) studies.
   g. Graduate theses in school safety were concerned with safety in various areas. The topical emphasis of "General School Safety Program" received the greatest stress. "Farm Safety" received the least emphasis.
   h. The Midwest District of the American Association for Health, Physical Education, and Recreation was the geographical area where the most graduate theses (77 or 28.9 per cent) were produced.
   i. The topic of evaluation was given little emphasis.
   j. Graduate theses primarily listed as the cause of accidents the last acts of individuals involved. Personal factors were scarcely recognized as causes.
   k. From 1925 to 1941 courses of study were favorite topics for graduate theses. These studies followed the principles of general curriculum construction.
   l. The idea that "a program of safety education is essentially a local problem and must be dealt with accordingly" was quite pronounced in graduate theses which proposed safety programs for a specific school or community.

2. *History and Philosophy of School Safety.*
   a. No one time or place can be designated as the beginning of school safety. Limited evidence in the area of "Traffic Safety" indicates that driving instruction began in the early 1930's. Early safety instruction in the schools was received as relatively unimportant subject matter until the public realized the fact that accidents were taking the lives of numerous school-age children.
   b. Accidents have become the leading cause of death and disability in school-age boys and girls. However, this is not the primary cause for school safety. Safety is a fundamental life condition and therefore has a place in the school curriculum.
3. *Findings of Graduate Theses in School Safety in Various Areas.*
   a. *"GENERAL SCHOOL SAFETY PROGRAM."*
      (1) The organization and administration of school safety varied. Safety instruction through emphasis in established subjects, as a separate subject, through pupil safety organizations, through homeroom periods, or through "incidental" instruction were the methods used or advocated. There are many courses in the school curriculum in which safety can be correlated. No evidence could be found to indicate that safety education objectives could be achieved better by correlation than by offering safety as a separate subject.
      (2) Safety instruction lends itself to a variety of teaching methods. The choice of any one method is dependent upon available materials, the needs and interests of pupils, the time element, and local factors. Thus, no one method is best.
      (3) Although positive instruction has become popularized in safety instruction, no objective basis for the current interdict against negative forms exists. There is very limited evidence which suggests that negative language forms exists. There is very limited evidence which suggests that negative language forms are slightly more effective than positive forms.
      (4) Analysis of pupil activities, and the studying of where, when, how, and why accidents occur seem to offer the best means for selecting subject matter content. It is essential that all accidents be reported and that accident reports be used as constructive devices in improving the school safety program.
      (5) The widespread use of school safety patrols, particularly street safety patrols, is indicative that school authorities were receptive to modern educational philosophy which stresses "learning by doing," and "developing good citizenship qualities." Although non-school authorities sometimes had the responsibility of supervising patrol members it must be borne in mind that safety patrols should be under the direct supervision of school authorities.
      (6) A high degree of compatibility exists between the objectives of safety education and the objectives of general education.
      (7) Failure to assign major responsibility for the organization, direction, and supervision of the school safety program to one individual may handicap the program so severely that its success will be hampered. The title assigned to this individual may be supervisor, director, consultant, coordinator, or any other title which concurs with local administrative policies.
      (8) Schools can scarcely realize successful safety programs without enlisting the aid of outside organizations and agencies interested in promoting safety. It is highly essential that attention be given to coordinating the efforts of these organizations and agencies otherwise unnecessary and wasteful overlapping or duplication might occur thereby preventing maximum results. A careful check should be made to determine if services extended by such organizations or agencies are worthwhile and educationally sound.

      (9) An important phase of the school safety program is the provision and maintenance of a safe school environment. All school personnel must do their part in keeping the buildings and grounds in safe condition. This entails periodic inspections and good housekeeping.
      (10) Safety is a dominant factor that must be given the utmost consideration in the transportation program of any school. Essential safety features in pupil transportation include safe buses, competent bus drivers, safe transportation routes, legislation governing the actions of motorists who approach school buses stopped to load or discharge pupils, a safety education program regulating pupil conduct upon entering the bus while riding the bus, and when leaving the bus, and sound business practices.
      (11) Although fire safety is intensified during Fire Prevention Week, the nature of the school fire problem necessitates that year-round instruction be offered. A desirable program in school fire safety includes a safe school environment, standard rules and regulations, instruction in fire prevention and fire protection, fire drills, and cooperative community action.
      (12) Aside from the instructional program of first aid, first aid materials must be available in the school and a qualified person to administer first aid to injured persons.
      (13) Teacher education colleges have lagged far behind the needs of public school in the preparation of safety teachers. The development of college training programs had been retarded by the failure of state and local educational authorities to give deserving recognition to safety education. By 1940 only 23 states had direct or indirect statutory legislation requiring the teaching of safety, and few of these states designated the amount of time to be spent on safety instruction. Until school authorities demand that teachers be qualified, colleges and universities cannot be expected to offer safety courses, nor can teachers be expected to take available courses.
      (14) In the absence of a statute, the prevailing principle of law is that a school district or a school board is not subject to liability for pupil injuries. Individual school employees, however, are subject to liability for pupil injuries, if negligence can be shown. School employees should be familiar with the principles of liability as a means of protection for themselves and the school. Proper application of the knowledge concerning legal liability not only aids to avoid liability but helps to establish precautionary measures which safeguard the welfare of the pupils.
   b. *"SAFETY IN ATHLETICS, PHYSICAL EDUCATION, AND RECREATION."*
      (1) Many activities in the areas of athletics, physical education, and recreation are hazardous in nature, but the element of danger and adventure makes the activities intriguing and alluring. Many accidents which occur, however, are not due to the inherent dangers which are a part of the activities. Over 50 per cent of the accidents are due to improper facilities, equipment and poor leadership.
      (2) Football causes more deaths and injuries than any other interscholastic activity, but the dangers in football have been greatly exaggerated. "Tackling," "blocking," and "being tackled" were most often listed as actions producing injuries. Fewer football injuries occurred among teams who played opponents "in their own class."
      (3) Insurance companies were initially reluctant to enter into the athletic insurance movement. Many state high school athletic associations developed their own plans to meet the cost of athletic injuries. Limited evidence suggests that athletic injuries receive better care when insurance covers the cost of treatment.

(4) It is quite natural to expect injuries in those activities in which body contact is involved.

(5) Physical examinations are essential for pupils participating in physical activities.

(6) "Constant supervision and instruction" and "frequent inspection of all apparatus and equipment" are the chief essentials of playground safety.

(7) Camping and outing activities have become an integral part of the total school program. Increasingly, colleges and universities are requiring leadership courses for students majoring in recreation or physical education.

c. *"SAFETY IN SCHOOL SHOPS."*

(1) Industry aided school personnel in building programs of safety in school shops. Although industrial assistance provided for building safety programs it does not follow that strict industrial standards are wholly applicable in appraising local school shop conditions.

(2) Methods of safety instruction in shops vary, and no one best method has yet been developed. Highly regarded methods were demonstration in the proper use of tools and machines, and the use of safety rules.

(3) The grade or age level for use of different machines in school shops rises in accordance with the degree of danger associated with each machine. Basically a student should not be granted permission to use any machine until he is 100 per cent informed regarding its use.

(4) "Pupil carelessness" was most often listed as the leading cause of school shop accidents. It is essential that shop instructors closely observe students for signs indicating unsafe practices; undue haste on the part of students should particularly be observed.

(5) Machine guarding, inspection of tools and machines, provision of personal protective equipment, maintaining good housekeeping practices, administering physical examinations, and a program of safety instruction are essential features of a shop safety program.

(6) Teacher training institutions were deficient in setting good examples for prospective shop teachers.

d. *"TRAFFIC SAFETY."*

(1) Although early research studies emphasized the importance of faulty attitudes as a major underlying cause of traffic accidents, it was not until the 1940's that much needed research in measuring driver attitude was reported.

(2) It is difficult to attribute traffic accidents to one specific circumstance or cause. The human factor (the inability of individuals to exert self-control and follow safe practices) is undoubtedly the major cause of traffic accidents.

(3) Traffic courts which hand down punishment in the forms of fines or short-term confinements do very little to correct faulty driving attitudes. Of more importance are traffic violator schools which aim at the correction of faulty attitudes.

(4) In driver education courses, those items pertaining to the driver's attitude should receive the most emphasis that time and circumstances allow. Whenever possible, both classroom and practice driving instruction be offered in accordance with state department of education rulings.

(5) Programs of high school driver education have gained public support. In some states students completing a high school driver education course are excused from all or part of the state examination for an operator's license.

SELECTED RECOMMENDATIONS

1. All prospective teachers should receive a general course in safety education.
2. Each school system should appoint one individual who: (a) coordinates safety activities within the school; (b) coordinates the efforts of community organizations and agencies interested in promoting school safety.
3. Safety instruction should be part of all academic subjects in which there is evident relationship. Specific courses in driver education should be included in the curricula of all secondary schools.
4. Directors of educational research at our colleges and universities should encourage graduate students to do research in the field of school safety. Actually, one must consider this field as still in its infancy especially in comparison to the number of graduate theses produced in other fields. For example, from 1930 to 1946 over 3,000 masters' theses and 420 doctoral dissertations were produced in the field of Health, Physical Education, and Recreation.
5. In pursuing this study it appeared that further studies were needed in order to allow for more efficient school safety programs. Recommended for future study are the following topics:
   a. The ways and means through which home and farm safety education can be promoted.
   b. Present practices and methods used to insure safety in specific areas (school shops, athletics, traffic, etc.).
   c. The values of one particular method of safety instruction as compared to another method of safety instruction.
   d. Accident experiences in schools having accident insurance plans.
   e. Whether court rulings on school liability hinder or promote safety activities.
   f. Pupil safety organizations which function at the college level.
   g. Uses of various terms designated as causes of accidents.
   h. The extent to which community organizations and agencies cooperate with the school in developing and promoting safety education.
   i. The kind and amount of safety instruction for handicapped pupils.
   j. The effect of legislation for school safety.
   k. The status of teacher certification in safety education.
   l. Safety practices in college dormitories.
   m. The techniques used to solve pedestrian problems in specific cities.
   n. The practices regarding the employment of bus drivers in the various states.
   o. The development of criteria to evaluate the school program, or any part thereof.

EFFECTS OF DRIVER EDUCATION ON DRIVER KNOWLEDGE, ATTITUDES IN SECONDARY SCHOOLS

by BERNARD L. LOFT

associate prof. department of health & safety, School of Health, Physical Education & Recreation, Indiana University, Bloomington, Ind.

The purpose of this study was to consider the effects of a high school seniors' driver education course essentially to discover differences in driving knowledge and attitudes between students who completed a driver education course and students without training in driver education. A further analysis determined differences between the groups with regard to students' accidents and violations.

The 14 high schools investigated were selected from high schools in Indianapolis and Marion county, Indiana on the basis of their offering a two-part program—classroom and behind-the-wheel instruction.

A personal interview was conducted with faculty members of both classroom and behind-the-wheel instruction at each school to determine the school's status based on standards established by the National Com-

mission on Safety Education of the National Education Association. The collected data were then placed on a master chart for further analysis.

Selection of the two testing instruments was determined for their adaptability to the trained and untrained student drivers. The Siebrecht Attitude Scale was used to measure driver attitudes considered significant in the attitude scale: passing situations on curves and hills, the privilege of driving, traffic regulation, enforcement, condition of the vehicle, accident responsibility, speeding, cooperation, license examination for drivers, courtesy and consideration, condition of the driver, knowledge, and skills.

CHECKED DRIVING COMPREHENSION

The American Automobile Association's general test on Traffic and Driving Knowledge was used to determine the students' understanding of traffic and driving problems. This test consisted of 25 multiple response questions with emphasis on those elements of traffic safety that should be familiar to all drivers.

The two tests were administered to a total of 2,442 senior students. In addition, a personal data sheet was completed by each student giving sex, age, frequency of driving, and other pertinent information.

In administering the tests the investigator adhered to standardized procedures at each of the schools. Initially, all the students were told the purpose of the study and the value of their contribution in completing the Siebrecht Attitude Scale. Then the General Test on Traffic and Driving Knowledge was explained in detail. The investigator emphasized the necessity for all students to do their best.

In the final analysis, only those students with a valid driver's license were included in the study. Of the 2,442 who completed the two tests, 1,607 were subjects for the study.

Records of the 1,607 students in the Indiana Bureau of Motor Vehicles, gave data on the number of automobile accidents and traffic violations. This information, along with the results of the General Test and Siebrecht Attitude Scale was transferred to IBM punch cards.

A total of 4,884 punch cards was prepared, two cards for each student. The final sample was reduced to 3,214 cards for the 1,617 students with valid driver's licenses. There were 491 males with driver education and 316 untrained males. The female students totaled 560 with driver education and 240 without.

Mean scores and standard deviations were computed for the General Test of Traffic and Driving Knowledge and the Siebrecht Attitude Scale for each of the following categories:

Boys, driver education, non driver education, both combined; *Girls*, driver education, non driver education, both combined; *Boys and girls*, driver education, non driver education, both combined.

Using critical ratio as a statistical measure, differences between the means on the General Test and the Siebrecht Attitude Scale were analyzed at the five per cent level of confidence to determine if the populations of students displayed similarities or differences.

The variable factors were then compared in all possible combinations for related or unrelated tendencies by using the Chi Square technique at the five per cent level of confidence. A total of 40 Chi Square values was computed for boys and girls classified as driver education and non driver education in the following comparisons:

1. Frequency of driving and driving knowledge test scores
2. Frequency of driving and attitude scale scores
3. Frequency of driving and traffic violations
4. Frequency of driving and traffic accidents
5. Knowledge test scores and number of traffic violations
6. Knowledge test scores and attitude scale scores
7. Knowledge test scores and number of traffic accidents
8. Attitude scale scores and number of traffic violations
9. Attitude scale scores and number of traffic accidents
10. Number of traffic violations and number of traffic accidents

Frequency of responses by percentages on the Siebrecht Attitude Scale was included in the study to compare the driver education and non-driver education students on attitudes.

FINDINGS FROM THE STUDY

On the basis of this study the investigator makes the following findings:

1. Nine of the 14 schools scheduled driver education on the same basis as other subjects in the high school curriculum.

2. All the participating schools included classroom and behind-the-wheel instruction for students from 15½ to 16 years old.

3. Academic credit ranging from one-sixth to one credit was awarded upon satisfactory completion of the course in 11 schools.

4. With one exception, driver education instructors in the schools were certified in secondary education.

5. One or more instructors in each of the 14 schools completed professional preparation in driver education.

6. Classroom instruction ranged from 15 to 45 hours, with only four schools offering the recommended standard of 30 hours or more.

7. Behind-the-wheel instruction in the 14 schools ranged from two to 10 hours, with four schools offering eight to 10 hours of supervised road instruction.

8. Classroom instruction was established as a separate course for one semester in 10 of the schools.

9. Classroom enrollment at eight schools was comparable to the other academic areas.

10. Behind-the-wheel instruction of one period a week for a full semester was the practice at 10 schools.

11. All the schools used a driver education textbook and supplementary classroom study materials.

12. Dual control cars were obtained by the 14 schools on a loan agreement from local dealers.

13. A testing procedure for evaluating student progress was used in all 14 schools.

14. The mean score for 560 driver education girls on the knowledge test was 79.10 with a standard deviation of 12.64.

15. The mean score for 560 driver education girls on the attitude scale was 161.15 with a standard deviation of 14.86.

16. The mean score for 240 non-driver education girls on the knowledge test was 77.00 with a standard deviation of 12.24.

17. The mean score for 240 non-driver education girls on the attitude scale was 159.77 with a standard deviation of 16.67.

18. A comparision of the 560 trained and 240 untrained girls on the knowledge test and attitude scale produced differences in means of 2.10 and 1.38 respectively, in favor of the driver education girls.

19. Driver education boys, numbering 491, had a mean score of 77.55 and a standard deviation of 11.45 on the knowledge test.

20. The mean score for 316 non-driver education boys on the knowledge test was 76.70 with a standard deviation of 16.43.

21. Driver education boys, numbering 491, had a mean score of 154.94 with a standard deviation of 18.38 on the attitude scale.

22. The mean score for 316 non-driver education boys on the attitude scale was 154.07 with a standard deviation of 16.79.

23. A comparison of 491 trained and 316 untrained boys on the knowledge test and attitude scale yielded differences in the mean scores of .85 and .87 respectively.

GIRLS BETTER DRIVERS THAN BOYS

24. Trained and untrained girls combined were superior on the knowledge test when compared with the driver education and non-driver education boys. There was a mean score of 78.42 and a standard deviation of 12.56 for the girls in contrast to a mean score of 77.22 and a standard deviation of 13.63 for the boys.

25. A comparison of the non-driver education boys and non-driver education girls yielded a critical ratio of .2463. Thus, there was little difference between the groups on mean scores for the knowledge test.

26. A comparison of the means on the knowledge test scores for driver education and non-driver education girls favored the trained girls with a critical ratio of 2.1981 at the five per cent level of confidence.

27. At the five per cent level of confidence, an obtained critical ratio of 2.2470 for the difference between the means indicated

the superior driving knowledge of driver education girls as compared to non-driver education boys.

28. Driver education girls were superior in knowledge when compared with the driver education boys. This is revealed by a critical ratio of 2.0830 for the difference between the means on the knowledge test at the five per cent level of confidence.

TRAINING SHOWED RESULTS

29. The difference between the means on the attitude scale for the boys and girls with driver education and the untrained boys and girls yielded a critical ratio of 6.1123, indicating better driver attitudes for those who completed a driver education course.

30. There was no great difference in the means of the attitude scale scores of driver education and non-driver education girls. A critical ratio of 1.9303 was just slightly in favor of the trained girls.

31. The driver education girls had significantly better attitudes toward driving than the driver education boys. The difference between the means on attitude scale yielded a critical ratio of 5.9654 at the five per cent level of confidence.

32. The driving attitudes of non-driver education girls were significantly more desirable than those of non-driver education boys as was reflected by a critical ratio of 5.6716 at the five per cent level for the differences in the means of the two groups.

33. A critical ratio of 4.0596 indicated that non-driver education girls disclosed better attitudes toward driving in comparison with the combined group of non-driver education boys and girls.

34. Driver education and non-driver education girls with high driving frequencies scored high on the attitude scale.

35. Driver education girls with high driving frequencies were involved in the fewest traffic violations.

36. Non-driver education girls having high driving frequencies were involved more frequently in traffic violations.

37. Driver education and non-driver education girls with high driving frequencies were involved in the fewest traffic accidents.

38. Driver education and non-driver education girls with high scores on the driving knowledge test were charged with the fewest traffic violations.

39. Non-driver education girls with high scores on the driving knowledge test also produced similar scores on the attitude scale.

40. Driver education an non-driver education girls with high driving knowledge test scores were involved in the least traffic accidents.

41. Non-driver education girls having scored high on the attitude scale were involved in a smaller number of traffic violations.

42. Untrained girls with several traffic violations were also found to have the higher number of traffic accidents.

43. Driver education and non-driver education boys with high driving frequencies were involved in the fewest traffic accidents.

44. Driver education and non-driver education boys with high driving frequencies scored favorably on the driving knowledge test.

45. Non-driver education boys with high driving frequencies were involved in the least traffic violations.

46. Driver education and non-driver education boys with desirable scores on the driving knowledge test were involved in the least traffic violations.

47. The relationship between attitude scale scores and traffic violations revealed that the non-driver education boys with high attitude scale scores were involved in a relatively small number of traffic violations.

48. Driver education and non-driver education boys having scored on the attitude scale had only a few involvements in traffic accidents.

49. The frequency of responses for 1,607 driver education and non-driver education boys and girls on the Siebrecht Attitude Scale revealed that boys and girls with training in a two-part driver education course consistently responded in conformity with the established responses.

CONCLUSIONS OF STUDY

● Boys and girls having completed a two-part course in driver education possess desirable attitudes toward driving and adequate traffic and driving knowledge.

● Driver education is particularly advantageous to girls in their acquisition of traffic and driving knowledge.

● Boys and girls without training have a similar understanding of traffic and driving knowledge.

● Attitudes related to driving responsibility are not materially affected by a driver education course for girls.

● Girls without training have established a relatively safe driving record.

● Driver education courses should consist of specific learning experiences for boys so that attitudes and adequate knowledge be a realistic outcome of such a course.

● Driver education is influential in reducing accidents and traffic violations for teenage drivers.

● Students in driver education should be required to take a screening test at the beginning of the course to determine their needs.

AUTHOR'S RECOMMENDATIONS

Based on the findings, the investigator recommends that:

1. The administrator and a faculty committee periodically evaluate the driver education program to ascertain the quality of instruction in all phases of the program.
2. The evaluation be based on the objectives listed by the National Commission on Safety Education of the National Education Association.
3. Driver education instructors place more emphasis on the development of desirable attitudes through both the classroom and behind-the-wheel instruction.
4. High school students possessing a driver's license but who have not completed a driver education course be encouraged to enroll in such a course.
5. Greater emphasis be placed on proper reactions when confronted with an emergency driving situation.
6. Additional behind-the-wheel instruction periods be scheduled for the boys.
7. Instructors of driver education refer to this study for information concerning factors considered to be important in efficient automobile driving.
8. The findings in this investigation be used by the sample schools in Indianapolis and Marion county as a partial evaluation of their driver education programs.
9. Schools administrators and driver education instructors in Indiana familiarize themselves with these findings prior to a revision of their driver education programs.
10. The results of this investigation be compared with the reports of the American Automobile Association in Chapter I concerning the effectiveness of driver education in various locations throughout the United States.
11. The findings of this study be used in teacher preparation courses to familiarize prospective driver education instructors concerning the significance of traffic and driving knowledge and desirable attitudes as related to driving frequency, traffic violations, and traffic accidents.
12. The State Department of Public Instruction consider a follow-up study with a state-wide survey to determine the effectiveness of driver education for the state of Indiana.
13. A study be made to evaluate the quality of instruction as related to the number of hours for classroom and behind-the-wheel instruction.
14. A study be made to determine if driver education courses should have any different content and/or methodology for girls and/or boys.
15. A study be conducted to provide data as to course content and procedures for high school students who have previously mastered some of the driving fundamentals.
16. A study be made to show how driver education courses may be organized and presented to provide adequate attention to developing desirable attitudes.
17. The findings in this study along with further research be directed at deter-

mining the extent to which responses on attitude tests are deflected in actual driving practices.

18. A study be made to determine the extent to which undesirable attitudes may be the direct cause of automobile accidents.
19. A standardized knowledge test be constructed which would be consistent with the standards established by the National Commission on Safety Education of the National Education Association.
20. A study be made to determine the special problems of teen-age drivers as indicated by traffic violations and accidents.
21. A study be made to determine the effectiveness of driver education by means of a pre-test and post-test of driving attitudes and driving knowledge.

RELATIONSHIP BETWEEN DRIVING RECORDS, SELECTED PERSONALITY CHARACTERISTICS AND BIOGRAPHICAL DATA OF TRAFFIC OFFENDERS AND NON-OFFENDERS

by EARL DAVIS HEATH, Ph.D.
Division of General Education, Center for Safety Education,
New York University, New York City

In this, the concluding chapter, are presented:

1) a synopsis of methods employed in arriving at an answer to each of the four sub-problems posed in this study, along with a summary of the findings of each,

2) those conclusions which appear warranted on the basis of data revealed and statistical measures obtained, and

3) recommendations pertinent to the application of findings of this study, to the establishment and operation of driver improvement clinics, and to further research into driving performance.

The purpose of this investigation was to determine what personality characteristics and biographical data differentiate motor vehicle traffic offenders from non-offenders, and to relate any such differences to records of their driving performance. The solution to this problem was determined by answering the following four sub-problems:

1) What personality characteristics, as revealed by responses to the *Thurstone Temperament Schedule*, distinguish offenders from non-offenders;

2) What biographical data, as revealed by the subjects in planned interviews, distinguish offenders from non-offenders;

3) What personality characteristics and biographical data, individually and in combinations, are most significant for purposes of distinguishing offenders from non-offenders; and

4) How can these statistically significant scores of personality characteristics and biographical factors be related to the actual occurrence of accidents and violations?

TWO GROUPS STUDIED

The populations studied consisted of an Experimental Group of 763 traffic offenders who were resident motor vehicle operators of New Jersey and who had accumulated three or more traffic accidents and/or moving traffice violations since December 31, 1949. A Control Group of 195 resident motor vehicle operations of the same state whose driving records were free of accidents and violations during this same period was used.

The Control Group was equated to the Experimental Group in terms of estimated annual mileage driven, this item of information being obtained through a specially prepared questionnaire. These subjects appeared at the New Jersey Traffic Accident Prevention Clinic in Trenton over a 22-month period ending August 31, 1955.

In answer to the first sub-problem posed in this investigation; i.e., "What personality characteristics as revealed by responses to the *Thurstone Temperament Schedule*, distinguish offenders from non-offenders, statistically significant difference were found on three of the seven areas of this test device. Subjects of the Experimental Group were found to rate higher on the Impulsive and Sociable Scales, but lower on the Reflective Scale, then the Control subjects.

In analyzing biographical data obtained during the planned interview for purposes of the second sub-problem; i.e., "What biographical data, as revealed by the subjects in planned interviews, distinguish offenders from non-offenders," statistically significant differences were found on eight of the 13 categories investigated. The categories in which differences this great were obtained are: 1) age, 2) marital status, 3) education, 4) driver education indicated, 5) annual salary, 6) present occupation, 7) job turnover, and 8) reasons indicated for terminating employment.

EXPERIMENTAL GROUP TRAITS

The Experimental Group was characterized by younger, unmarried individuals. A greater proportion of this group had failed to complete high school or college and few were engaged in the professions or in managerial or official capacities. Moreover, they reported smaller earnings, higher job turnover, and termination of previous employment for reasons other than self improvement. More of the Experimental population indicated driver education; however, no investigation was made into the types or quality of this experience.

In determining the answer to the third sub-problem; i.e., "What personality characteristics and biographical data, individually and in combinations, are most significant for purposes of distinguishing offenders from non-offenders," the multiple cutoff method was employed. This technique necessitated the establishing of a critical score for each of the three statistically significant areas of the test device and for the sum of statistically significant biographical information.

Once these critical scores had been established, test and biographical data for each subject were assessed to determine the number in each group who would achieve a critical score on one or more of these areas. It was found that critical scores on the Impulsive Scale and on the Sociable Scale of the *Thurstone Temperament Schedule* in combination with a critical score on the sum of statistically significant biographical data provided maximum separation of the groups.

WELL-ADJUSTED—BETTER DRIVERS

The fourth sub-problem; i.e., "How can these statistically significant scores of personality characteristics and biographical factors be related to the actual occurrence of accidents and violations," was approached by selecting individuals of the Experimental Group who were likely to be representative of extremes of adjustment as indicated by test and biographical data. Subjects achieving a critical score on each of the four areas were considered as "well-adjusted," while subjects failing to achieve a critical score on any one of these areas were considered as "poorly-adjusted" for purposes of this phase of the investigation.

The "well-adjusted" group consisted of 24 subjects, each of whom achieved a critical score on each of the four areas. The "poorly-adjusted" group consisted of 112 subjects, each of whom had failed to achieve a critical score on any one of the four areas. Each of these two sub-groups then was compared with 1) the remaining members of the Experimental Group, and 2) with the other sub-group, in terms of their driving records as indicated by accident and violation experience.

The "well-adjusted" group was found to have a better overall driving record than either the "poorly-adjusted" group or the remaining members of the Experimental Group from which they were drawn. The "poorly-adjusted" group, conversely, exhibited a poorer driving record than either of the other two groups.

As an adjunct to the main portion of this investigation, 63 subjects, each of whom indicated a driving experience of 50,000 or more miles per year, were compared to the Experimental Group in terms of 1) test data, 2) biographical data, and 3) accident and violation data.

Members of this High Exposure Group were found to be more vigorous, more impulsive, more sociable, and less reflective than were members of the Experimental Group.

BIOGRAPHICAL INFORMATION

On items of biographical information, statistically significant differences were obtained between the groups on 1) job turnover, 2) present occupation, 3) annual salary, and 4) type(s) of vehicle(s) driven. Members of the High Exposure Group were found to have a higher rate of job turnover and higher annual earnings than members of the Experimental Group. Moreover, as might be expected, a large proportion of these high exposure subjects were professional chauffeurs or driver salesmen who drive various types of equipment in addition to passenger vehicles.

Inspection of driving records revealed the High Exposure Group to have a violation history considerably poorer than that of the Experimental Group; however, their accident experience actually was better than that of the Experimental Group.

On the basis of 1) data revealed during the planned interviews with each subject, 2) responses to each of the seven areas of the *Thurstone Temperament Schedule*, and 3) in the case of the Experimental and the High Exposure Group of offenders, traffic accident and violations records, the following conclusions seem warranted.

For purposes of distinguishing traffic offenders from non-offenders, impulsive, sociable, and reflective traits, as measured by the *Thurstone Temperament Schedule*, appear to provide for such differentiation, the offender group rated higher on impulsive and sociable, and lower on reflective than the non-offender group. However, the active, vigorous, dominant, and stable traits, as measured by the *Thurstone Temperament Schedule*, do not appear to be of value in distinguishing traffic offenders from non-offenders.

EIGHT VALUABLE ITEMS

The following items of biographical information appear to be of value for purposes of distinguishing traffic offenders from non-offenders: 1) age, 2) marital status, 3) education, 4) driver education indicated, 5) occupation, 6) number of positions held during the five-year period preceding examination, 7) reasons for terminating previous employment, and 8) annual salary.

The categories of biographical data which do not appear to be of value for purposes of distinguishing between traffic offenders and non-offenders are: 1) number of children, 2) languages written, 3) hospitalization, 4) types of vehicles driven, and 5) nature of driving experience.

The following combination of personality traits, as measured by the *Thurstone Temperament Schedule*, and biographical data appears to be of most value for purposes of distinguishing traffic offenders from non-offenders: Impulsive and sociable traits in combination with the biographical items of age, marital status, education, driver education indicated, occupation, number of positions held during the five-year period preceding examination, reasons for terminating previous employment, and annual salary.

The traffic accident and violation records of well-adjusted traffic offenders, as identified by a combination of test and biographical data, are likely to be superior to the records of poorly-adjusted traffic offenders as identified by the same criteria. Also, the driving records of these well-adjusted individuals are likely to be better than the records of traffic offenders who are considered neither well-adjusted nor poorly-adjusted. Driving records of poorly-adjusted traffic offenders, on the other hand, are likely to be worse than those of either of the other groups.

MILEAGE DOESN'T EFFECT ACCIDENTS

From a comparison of the driving records of traffic offenders whose driving experience was less than 50,000 miles per year with those whose driving experience was in excess of this amount, it appears that annual mileage has little effect on accident experience, but that violation experience seems to increase with driving exposure.

With the traffic problem as acute as it is, those active in traffic accident prevention

efforts may be interested in possible application of the findings of this investigation. Therefore, the following recommendations are presented for consideration:

- That those items of a biographical nature which were revealed to be statistically significant be among those items included on application forms for prospective drivers and license applicants. The purpose here would be, not that of selection, but the identification of individuals toward whom further investigation might be indicated. Likewise, it may be well to include these items on periodic inventories administered to driver personnel.
- That those areas of the *Thurstone Temperament Schedule* which were revealed to be statistically significant be included among the devices used in screening applicants for licenses or for positions as drivers with commercial, business, or industrial establishments. These areas of the test device may well prove of value with in-service drivers, and with traffic offenders as well, in assessing selected personality traits as an aid in establishing refresher and remedial activities.
- That the questionnaire on estimated driving experience, developed for purposes of this study, be used in an effort to obtain reliable estimates of driving experience among motoring populations.

IDEAS FOR DRIVER CLINICS

Since it is expected that several of the states will move in the direction of establishing clinics for driver improvement purposes, the following recommendations are advanced for the perusal of those individuals and groups interested in such activity. These recommendations, which are based upon 1) observations of clinic operation during the conduct of this study, and 2) a review of the literature on clinics, past and present, are:

1. That a thorough and effective accident reporting system, operating with equal effectiveness throughout the populations to be affected, be established if motorists truly representative of the offender population are to be reached. Ideally, reciprocity among the various states and the District of Columbia should be provided for the exchange of accident and violation information so that the driver's record may be as complete as possible.
2. That a point system be established for purposes of a) assessing the individual's driving performance, b) notifying him of this performance, and c) providing data to the Department of Motor Vehicles, the courts, and to persons associated with rehabilitative functions, including the clinic.
3. That the reported findings of other traffic clinic operations be perused and evaluated before deciding upon the procedure to be followed or the instruments to be used.

QUALITY PERSONNEL

4. That clinics be designed and evaluated by a group comprised of persons with preparation and experience in the fields of motor vehicle administration, law, education, sociology, psychology, psychiatry, and medicine. (The new clinic in New York State is being developed along these lines). Public or privately supported institutions of higher learning appear to be logical sources for obtaining such personnel and consultative services.
5. That personnel used to staff such clinics be of the highest quality and that they be thoroughly familiar with interviewing procedures and test administration.
6. That the keynote of the clinic as it operates in driver improvement situations should be experimentation. New devices, techniques, and processes should be introduced just as soon as practicable when research or rational grounds indicate their possible value.
7. That clinic findings (including those of other individuals and agencies to whom the subject might have been referred) be interpreted to the subject and that whenever possible specific suggestions be made as to how he might improve his driving performance.

8. That provision be made for follow-up study of subjects examined at the clinic, such a follow-up to evaluate, in some measure, the effectiveness of clinical procedure.

SUGGESTIONS FOR RESEARCH

In that considerable emphasis today is being directed toward the role of the driver in traffic accident causation, it is expected that additional research will be conducted in this general area. Accordingly, the following recommendations are presented for the assistance of those undertaking such investigation.

- That further research be conducted, using the *Thurstone Temperament Schedule*, on offender and non-offender populations where equating factors in addition to driving experience are considered.
- That further research be conducted on offender and non-offender populations, using devices which probe more deeply into those relatively stable personality traits of "Impulsive," "Sociable," and Reflective," as identified by the *Thurstone Temperament Schedule*.
- That data of offenders be probed further to establish the relationship between violations and accidents.
- That more extensive data of a biographical nature be obtained from subjects since this type of data proved more discriminating than any area of the test device used in this investigation.
- That test technicians, in cooperation with traffic safety specialists, develop test instruments which will probe more deeply into the impulsive, sociable, and reflective traits of personality as these relate to driving performance.

Through research such as that suggested and through the implementation of the recommendations advanced here, it is believed that those active in the field of traffic safety will improve their understanding of why drivers commit traffic offenses, and will be better able to initiate and evaluate driver improvement activities.▲

Submitted Paper

SIGNIFICANCE OF SAFETY ATTITUDES IN INDUSTRIAL ACCIDENT PREVENTION (Ph.D. Thesis, New York University, 1957)

by EARLE S. HANNAFORD

safety engineer, Long Lines Dept., American Telephone & Telegraph co., New York city

The purpose of this research was to investigate the readily assumed relationship between safety attitude of industrial workers and supervisors and actual accident experience of the workers on the job. There has been a lack of studies on the validation of such relationships.

An increasing number of industrial organizations include accident prevention attitude as observed on the job and actual accident experience as factors in the appraisal of employees and management proficiency. The full and confident use of measures for the formation and revision of industrial safety attitudes has awaited the proper validation of the significance of such attitudes as they are reflected in the workers' actual accident history on the job.

Previous industrial safety research has dealt primarily with the relationship between actual accident experience and environmental and personal factors other than that of industrial safety attitudes. Many studies have been concerned with accident-prone individuals or groups and accident repeaters, although there is good evidence that the majority of industrial injuries occur to workers with no previous accident history.

MUST KNOW ATTITUDES

It was important to know the significance of industrial safety attitudes for the employee group as a whole. Similarly, it was equally important to determine the relationship between safety attitudes of supervisors and workers under their direct supervision.

There were two stages in the study. The first concerned the development and validation of industrial safety attitude rating scales for male workers and for male supervisors. The study and, therefore, the industrial safety attitude scales, were limited to male industrial workers and supervisors. This was done because of the wide variations between work activities for men and women and the differences in pyschological approach to industrial work operations.

The second stage of the study was the determination of the significance of industrial safety attitudes of male workers and of male supervisors as these attitudes relate to the actual accident experience of the workers themselves.

The industrial safety attitude scales were developed according to the procedures used by L. L. Thurstone and E. J. Chave as described in the "Measurement of Attitude." This provided conformance with the Thurstone Attitude Toward the Law scale which was used as a control and to determine any possible relationship between industrial safety attitudes and the testees' attitude toward authority. Both the employee and supervisory scales are one-page, 20-item rating instruments.

TESTED 5,000 MEN

Approximately 5,000 male employees and supervisors in 450 selected industrial organizations furnished anonymous statements of their attitude toward safety which were used in the development of the safety attitude scales. These attitude statements were voluntary and sent directly to the researcher.

The industrial safety attitude scales for male employees were validated using 300 employees with one or more lost time injuries during the five-year period, 1948 to 1952. The male supervisors' industrial safety attitude scales were validated with 150 male supervisors whose employees had had lost time accidents during the five-year period.

Chart I "Validation of Attitude Scales" summarizes the results. The bi-serial correlation (r_{bis}) was .35 for the male employee attitude scale and the standard error was .026. For male supervisors, the bi-serial correlation (r_{bis}) was .20 and the standard error .036.

Chart I

VALIDATION OF ATTITUDE SCALES

Test Scores vs Accident Experience

Group	Bi-Serial Correlation r_{bis}	Standard Error S.E.
Male employees—1 or more lost time accidents	.35	.026
Male supervisors whose employees had lost time accidents	.20	.036

RELIABILITY

Product Moment Correlation R Method

	Test and Retest	Split Half	Equivalence of Forms
Employee Scale			.88
Form A	.88	.72	
Form B	.86	.77	
Supervisor Scale			.86
Form A	.86	.76	
Form B	.83	.76	

Reliabilities were found by the product-moment correlation. The reliability was determined by three methods: test and retest, split half and equivalence of forms. As noted, the reliabilities by test and retest are in the .88 to .83 range for the employees' and supervisors' scales.

By the split half method, the range was from .77 to .72 which difference is usual between the two methods. Equivalence of forms was .88 for the employees' scales and .86 for the supervisors' scales. These results are considered satisfactory for scales of this type.

There were 769 male employees and 481 male supervisors from 54 industrial organizations with good, fair and poor safety records over the five years who participated in the second stage of the study to determine the significance of safety attitudes as related to accident experience.

The character of the relationship between industrial safety attitudes and actual accident experience for male employees was also determined on another chart. This plotting gives the graphic relationship between male employees' safety attitudes and actual accident experience during the five years. The

ordinates are test scores and the absicissae the number of lost time injuries. All 769 male employees are plotted and the straight line joins the means.

ACCIDENTS, ATTITUDES CORRELATE

As was seen, as accident experience worsens so does safety attitude. Of particular interest is the range of test scores for those with one lost time injury. It covers a much wider range of scores than those with two, three, or four injuries. This may well indicate that an injury tends, in many cases, to "set home" safety attitudes based upon previous safety training. In addition, it seems evident that employees who have had one injury should receive special attention when the attitudes remain poor to offset the potential for accident repetition.

Chart II shows the bi-serial correlation between male employees' safety attitude and actual accident experience. For male employees with one or more lost time accidents in the five years the bi-serial correlation with accident experience was .32. For male employees with two or more lost time accidents the bi-serial correlation was .43. In other words, the correlation between safety attitude and accident experience is significantly higher for repeaters.

Chart II

Male Employee Safety Attitude vs Accident Experience

5 yr. period 1948-52 769 employees 47 companies

Groups	Bi-serial Correlation r_{bis}	Standard Error S.E.
One or more lost time accidents	.32	.029
Two or more lost time accidents	.43	.02

Significance of Difference in Means

	Critical Ratio C.R.	Standard Error S.E. of D.
Accident-free group vs group with 1 or more lost time accidents	6.5	.36
Accident-free group vs group with 2 or more lost time accidents	6.0	.49

Both differences in means are real and significant at .01 and .05 levels of significance.

The significance of the difference in means for the accident-free group versus the group with one or more lost time accidents is real and significant at both the .01 and .05 levels of significance and the critical ratio was 6.5. For the accident-free group versus those with two or more lost time accidents, the difference in means is also real and significant at both the .01 and the .05 levels of significance and the critical ratio was 6.0. Thus there is a real and significant relationship between the safety attitudes of male employees and the actual accident experience.

In the relationship between the industrial safety attitudes of male supervisors and the actual accident experience of male employees they supervised, the chart shows that the range of safety attitude test scores is more limited than that for male employees.

The bi-serial correlation, Chart III, is .18 where the employees supervised had less than .1 lost time accidents per employee and .21 where the employees supervised had .1 or more lost time accidents per employee. The significance of the differences in means for both groups is real and significant at the .01 and .05 levels of significance.

Chart III

Male Supervisor Safety Attitude vs Accident Experience of Male Employees Supervised

5 yr. period 1948-1952 481 supervisors 54 companies

Groups	Bi-serial Correlation r_{bis}	Standard Error S.E.
Less than .1 lost time accident per employee supervised	.18	.035
.1 or more lost time accidents per employee supervised	.21	.038

Significance of Difference in Means

	Critical Ratio C.R.	Standard Error S.E.
Accident-free group vs group with less than .1 lost time accidents per employee supervised	4.7	.28
Accident-free group vs group with .1 or more lost time accidents per employee supervised	3.6	.42

Both differences in means are real and significant at .01 and .05 levels of significance.

Since it was impossible to select supervisors whose employee groups had not changed during the five years, it was somewhat to be expected that the bi-serial correlations would be lower than for the male employee groups. However, the correlations were comparable with those obtained for the supervisory scale "How Supervise" (Remmers and File) which included safety items among others used in rating supervisors as to quality of supervision.

The attitude toward authority and actual accident experience were not sufficiently related to have appreciably affected the relationship between the safety attitudes of employees or supervisors and the accident experience of the employees. Bi-serial correlations between employee and supervisor attitudes towards authority in the means of accident-free and accident groups were not significant at the .01 and .05 levels.

SUPERVISORY ATTITUDE SIGNIFICANT

Thus the relationship between male employees' industrial safety attitudes and actual accident experience during the five years is significant. Also there is a positive and significant relationship between the industrial safety attitudes of male supervisors and accident experience of the male workers supervised.

Industrial concerns can feel assured that the time, money and effort spent in developing and maintaining good safety attitudes are amply justified. The use of safety results as a factor in appraising employees' and supervisory performance for purposes of advancement is sound.

Moreover, the industrial safety attitude scales for male employees and male supervisors are satisfactory tools for determining the industrial safety attitudes of individuals and groups so as to give safety education and training where and when needed. Furthermore, the scales, each of which has alternate forms, should be valuable in maintaining and stimulating interest in safety.

A TRIBUTE TO H. LOUISE COTTRELL, 1893-1957
A Pioneer in Research for Elementary School Safety

by DR. HERBERT J. STACK
program associate, Center for Safety Education, New York University, New York city

Louise Cottrell was one of the early leaders in the safety education movement. As a teacher in the Stockton School in East Orange, New Jersey, she was a frequent visitor to the Education division headquarters of the National Safety Council, then located in New York city. She was a friend of Albert W. Whitney and tended to follow and interpret his philosophy in the articles and books that she contributed, as well as in her Doctor's thesis. During a 10 year period, she prepared the elementary school lesson plans for the Council magazine, *Safety Education*.

She wrote a number of articles for professional journals and, in 1937, collaborated with Florence Nelson in a workbook, *Safety Through the Years*, published by McGraw-Hill.

In 1938, she was awarded a teaching fellowship at the Center for Safety Education, and was a member of the first class to be graduated. While working on the Doctor's degree, she taught courses at the Center and during the summer months lectured at midwestern colleges.

WROTE THESIS FROM EXPERIENCES

Returning to her teaching position in East Orange, she worked to complete her thesis, *The Selection and Preparation of Basic Material for the Teaching of Safety to Children*. This thesis was in part developed from actual teaching practices in the classrooms of her school. The classroom became her laboratory, and most of the materials she presented in her thesis grew out of classroom experiences.

A strong advocate of integration, she was one of the first to present a body of subject matter and methods for including safety on a broad front. To her, safety was not a narrow concept but a way of life. There are some important points in her 540 page thesis that should be stressed.

In her attack on the problem, she used the survey technique, making studies of textbooks, readers, and courses of study in various elementary school subjects. From this, she developed certain guiding principles and content material for a safety program. The first part of her thesis is one of the

best reviews of the safety education movement that has been written. She showed how safety could be included in studies of world geography, travel, children of foreign lands, industry, and agriculture.

"LEARNING BY DOING"

She also pointed out the need for grade placement of materials depending upon the psychological, physical, and mental development of the child. This was followed by the three major steps in the preparation of a course of study.

She advocated the "learning by doing" method expounded by Dewey. Urging the importance of integration, she wrote, "As safety is a way of living rather than a separate subject to be learned, it is entitled to a place in every phase of classroom activity that can make safety facts or behavior meaningful. To be of value, such relationship and points of contact must develop naturally."

Several years after her thesis was accepted, she converted some of the findings into a guidebook, *Safety Education in the Elementary Schools*, which is distributed by the Center for Safety Education.

Louise retired from teaching and, with her sister, operated a gift shop in the summer at Basin Harbor on Lake Champlain, and in the winter at Palm Beach, Florida.

Louise was a woman of fine character and sentiments. She had many friends in the teaching profession, and everyone who knew her loved her for her kindly disposition and good humor. She did much to lay the broad foundations of the child safety movement in her teaching and in her contributions to the literature. She will long be remembered as one of the pioneers in safety education.▲

A CRITIQUE OF SELECTED RESEARCH STUDIES IN SAFETY

by KARL W. BOOKWALTER

Professor of Physical Education, School of Health, Physical Education & Recreation, Indiana University, Bloomington, Ind.

Analysis and criticism of research from abstracts thereof are subject to a marked loss of reliability and validity. The present findings and suggestions are subject to this limitation. Since in most instances the authors abstracted their studies, it should be assumed, however, that the essentials would be given if they existed.

Several of the studies analyzed were in themselves *résumés* of the research literature on certain aspects of safety. Some good materials presented for consideration were strictly empirical essays and accordingly were omitted from this review.

LEVEL OF RESEARCH

For the purpose of comparison, the 55 studies were classified as master's theses (30), doctoral dissertations (10), and research projects (15). As a rule, the contributions of the studies seem to increase somewhat in that order. The research value of the average master's study leaves much to be desired for society and for the student.

These frequencies of master's, doctor's, and project studies are more artifacts of the process of collecting studies for this report and of availability.

Area of research. Seventeen studies were in the "safety education program" area. This, on the whole, was the most unscientific, illogical and inconclusive area. Oddly enough, most such studies were undertaken by the master's candidate. "Action research" might be more profitable in this area and the master's candidate might be guided into simple measurements, records, or documentary studies.

"Personal factors" involved in accidents ranked second and were somewhat evenly distributed over the research levels.

"Accident analysis" was third in frequency and these studies involved record analysis almost exclusively.

"Driver education," a rather well done area; "legality-liability," an area with marked agreement and similarity in the studies (usually done as private projects); "psychological and measurements" and "buildings and equipment" studies ranked about equally and lower in frequency.

SAFETY RESEARCH STUDIES BY AREA AND LEVEL

Areas	Levels: Master's	Doctor's	Professional	Totals
Safety Education Program	17	1	1	19
Personal Factors	3	2	4	9
Accident Analysis	4	2	1	7
Driver Education	3	1	2	6
Legality-Liability	0	1	4	5
Psychological-Measurements	1	3	1	5
Buildings and Equipment	2	0	2	4
Totals	30	10	15	55

Sponsorship. Similarly to "level" the frequency of sponsorship of the studies may well be opportunistic rather than social or statistical. However, of the over 38 sources, Indiana University (7), Iowa State College (6), safety organizations (6), New York University (5), and Yale University (3) lead in the contributions. Too much credence or importance should not be given to this ranking but these institutions are producing safety research somewhat outstandingly.

Techniques. The selection of the essential techniques for these studies indicated use of the criterion of "ease of application." While not of necessity related to the worth of the contribution, there is an almost complete relationship of ease of use to frequency of use. Witness: record analysis—18 studies, questionnaire or checklist—16, documentary analysis—13, philosophical—11, (It must be noted here that this category does not include the rigidly logical analyses. Quite the the contrary, it implies here the sloppy, sophomoric, disordered "term paper" approach.) measurement—9, and experimental —4.

EVALUATION OF THE RESEARCH

Findings. We have learned that motor vehicles are a high cause of accidents, that old age, adolescence, being a male, inattentiveness, the home, athletics, the physical education classes, the locker rooms, the playground, and crowded conditions are most frequently associated with accidents. We learned too that a *few* people incur far more than their share of accidents.

We have seen that wounds and bruises; injuries to the lower extremities, the head and the hands were most frequent. Falling, slipping, colliding, absence of guards, dirt surfaces, the giant stride, and being struck by thrown objects, such as balls, are the immediate causes.

Most of the activities surrounding the causes are essential and can not be eliminated. The immediate causes must be avoided. This requires better safety education programs. The preponderant group of research studies was aimed at this area but we sent children, so to speak, to do the job. Many or most of the research was inconclusive and unscientific.

Our best minds should be put at these administrative and curricular tasks. Apparently, the busy beginning research student is not the man for the job. The busy experienced and professionally mature workers, guided perhaps by the scientifically minded technician, should be a team to tackle these problems. The superior quality of the industrial and safety organization studies seem to lend credence to the concept.

Cooperative "action research" should at least be given a chance. The master's theses only consume time and energy and add confusion to the topic as a rule, if some of our samples are any criterion.

EIGHT GUIDES TO CRITICISM

Weaknesses observed. Lauer's eight tenents might serve as criteria to guide us as we launch with temerity into our criticism of the research in a field in which the author is a neophyte.

1. Problem defined. Many of the problems started with titles or purposes too expansive. In fact, there was a tendency of

"the smaller the research, the larger the topic."

One characteristic of the usual project type of study (non thesis) was its superior planning. Doctoral dissertations were also good in this regard.

2. Necessary assumptions made. The assumptions of randomness of sample, validity of measure, adequacy of the controls were innocently overlooked. A glaring and common weakness was failure to meet original purposes or hypotheses.

3. Sufficiency of data. Paucity of survey returns frequently injected biases into the findings which could have been far greater than criterion differences sought for. Some evidence was given that accidents were not fully reported or were incompletely filled out.

4. Appropriate research method. Particularly, in several safety program studies, no semblance of organization and analysis of data or planned attempt to close the gap between findings of accident causes to setting up the safety program could be seen. Exhortation replaced proof in several studies showing an ignorance of the nature of the research.

WAY TO CHECK DATA

5. Data statistically evaluated and tested. Frequencies were occasionally given without regard to the proportions in the sub classes in the sample. That is, *rates* (per 1,000 exposures, e.g.) rather than frequencies should have been used.

The statistical significance of the differences observed were rarely reported, if calculated. (Probably properly so, since samples were not randomly drawn or representative).

The percentages of response to questionnaires were not divulged occasionally. In one instance, a ridiculously low response was not tested (by follow-up) for its reliability.

6. Results presented in usable form. As represented by their abstracts, at least, several of the studies omitted the exposition of the techniques employed to arrive at their conclusions. There was a lack of definition of terms. At times, even the conclusions and recommendations were omitted. These omissions may be due in part to the exigencies of abstracting.

Particularly lacking in the abstracts were full bibliographical information.

A few studies *did* compare their findings with national norms or expectencies. The literature seems to be replete with normal expectencies, rates determined from large samples, *et cetera*.

7. Conclusions are limited to the data and properly qualified. A serious weakness was evidenced in starting conclusions unsupported by the evidence. This was more evident in the master's theses, again indicating naivete as to the nature of research.

8. The experiment so designed, described, and executed that it may be repeated and verified. In the first place, but few experiments are covered here, purposes were unsound in many studies, basic assumptions were unrecognized, randomness of samples was not assured. Statistical and other techniques were not revealed. Hence, many of these studies could not be repeated (nor should they).

SHOULD MEASURE VARIABLES

Needs. There appears to be a need for a better knowledge of sampling techniques.

Sharper, more discriminating personal factors and measures of known variables are needed for causal analysis and experimentation.

Better use of known variables in the control of experiments and record analyses is needed.

More universal uniform and complete accident reports and records are needed.

It appears that our health, physical education, recreation, and safety workers should become aware of the fairly complete information existing with regard to liability.

There is a need for personnel skilled in experimental and laboratory techniques.

This study has not touched the vital *"crash analysis" evidence from such sources* as Syracuse University. The retracted steering wheel hub, the safety belt, the safety door lock, and the padded front dash of the automobile have come out of these efforts.

MEASURE DRIVER EDUCATION

Values. There is evidence of vast stores of statistical, physical, and theoretical data in the traffic literature for use in safety education programs.

Studies are almost universally (albeit at times a bit optomistically) indicative of the values of driver education and of some of the mechanical substitutes for part of behind the wheel driving.

We are gradually accumulating tools of measurement of variables, psychological factors, and personality traits which can refine, and make more precise, our safety studies.

While there is some confusing disagreement in court decisions, in the main our legal status and liability with regard to accidents and nuisance is known and available.

There has been accumulated and documented a great deal, if not most of the important, research in the field of safety. This is due largely to the National Safety Council and is available through this organization.

MASTER'S THESES

Anderson, John W., *Safety Education in High School Machine Woodworking Shops*, M.S. Thesis. Colorado Agricultural and Mechanical College. No Date.

Replies of 83 checklists revealed most frequent machinery. Of these the table saw and joiner were the most dangerous. Lack of attention and non-use of guards were most frequent causes. More emphasis is needed upon safety program.

Baldwin, Josephine E., *Incidence of Accidental Injuries Occurring to Hospital Patients*, M. Ed., Marquette University, 1953.

Analysis of accident records for one year at a hospital. Older male patients, in daylight and in or near the bed, were more prone to accidents. Two per cent of the patients caused 67 accidents in six months.

Begnoud, Edward M., *A Recommended Safety Program for the Mabry Foundry and Machine Company and Iron Castings Incorporated of Beaumont, Texas*, M.S., Agricultural and Mechanical College of Texas, 1954.

A seven year study revealing 161 accidents. Dust is the most frequent agent and eyes the part of the body most frequently involved. Total bodily injuries were the most costly, however. No program was offered in the abstract.

Bowman, George W., *A Study to Determine the Areas in Safety Education that Require Emphasis in Secondary Schools*, M.A., University of Iowa, 1955.

One hundred students, randomly selected from driver education classes, were tested on three fields of safety: general safety, driver knowledge, and home safety with the results in decreasing order of knowledge.

Buse, August R., *A Survey of Procedures for Handling Student Cars Driven To or From High School Property in the State of Washington*, M. Ed., University of Washington, 1954.

Sixty-two Washington high schools were surveyed. Eleven per cent of the students drive cars; the trend is upward. There are no uniform practices of car control, but such are needed.

Carahan, James, *Cooperation Between Schools and the Colorado Patrol in the San Louis Valley*, M. Ed., Adams State College, 1957.

A survey was made to determine the wants, needs, and practices of selected schools. There was an intellectual jump from data to empirical suggestions as judged by the abstract.

Dettman, Ruth J., *Patterns of Health and Safety Education Programs in Connecticut Industries*, M.P.H., Yale University, 1956.

A questionnaire study of safety programs in 88 industries reveals similar practices regardless of type or size of industry. Safety programs, more numerous than health education programs, were the responsibility of the nurse. Departments are responsible to top management.

De Felice, Joseph, *The Trained Driver Versus the Untrained*, M. Ed., Buffalo State Teachers College, 1955.

Questionnaires to 600 former high school students obtained 100 trained and 100 untrained students. The former were superior *in accident records*, traffic violations, speed violations, and other records, such as injuries and property damage.

Derderian, William V., *Detroit Public Schools Driver Training*, M. Ed., Wayne State University, 1954.

Response of 30 per cent and 5.7 per cent to postal questionnaires to 300 high school graduates driver educated and 600 without revealed more untrained drivers had licenses

prior to driving. Half as many accidents occurred in the trained group. One hundred matched pairs revealed driver trained individuals were superior in accident records, traffic violations, injuries, and property damage.

Duckworth, Marian, *A Survey of Student Accidents in One Secondary School, 1949-1955*, M. Ed., College of the Pacific, 1956.

An analysis of 436 accidents over six years revealed that accident reporting was associated with better reporting under one responsible person. Accidents were associated with boys, shops and locker-rooms, unorganized activities, physical education activities, and crowded conditions.

Frey, Richard E., *Reaction Time Under Conditions of Preoccupation With and Without a Warning Signal*, M.C., Iowa State College, 1951.

An experiment in reaction time on 48 cases in which lighting, noise, length, and sequence were controlled and the instructions were standardized. Reaction time lengthened signficantly by preoccupation in 51 per cent of the cases. Proper control and statistical evidence seem to be available in the study.

Horton, Herbert D., *A Survey of the Safety Features of Expensive Items of Football Equipment Used in Texas High Schools*., M.A., Southwest Texas State Teachers College, No Date.

Questionnaires to 240 schools revealed that schools in higher classes spent more on equipment. Most was spent on protective equipment. Smaller budgets involved a higher percentage of shoulder injuries.

Kjerland, Reginald N., *Finger, Leg, Lip, and Voice Reaction, Time Under Two Experimental Conditions*, M.S., Iowa State College, 1953.

Forty subjects responded to foveal and peripheral stimuli with finger, leg, lips, and voice. Peripheral reactions were uniformally longer but foveal variability was greater except for vocal response.

Leo, Violette P., *A Survey of the Safety Education Program in the Secondary Schools of the United States from July, 1945, Through June, 1955, As Revealed By Periodical Literature*, M. Ed., Chicago Teachers College, 1957.

An analysis of a 10 year period of safety articles revealed that safety education should include all phases and teaching should be planned in advance. Pupil participation was emphasized and integration with other subjects preferred. Improved methods such as audio-visual aids and up-to-dateness were observed. There was a tendency to attibute common practices to exceptional instances in this study.

Long, Roy J., *Safety Measures for Woodworking Shops in Nebraska High Schools*, M.A., University of Nebraska, 1953.

Questionnaires sent to 78 shops revealed 323 injuries. All but one were caused by unsafe student practices. Sixty-seven accidents were caused by hand tools and 31 per cent were caused by power tools. No evidence was found in the abstract for the jump to recommendations based upon hortatory appeal to the emotions.

MacCollum, David V., *Reduction of Construction Costs by Use of Scaffolding*, M.S., Oregon State College, 1957.

Proper scaffolding saved production time and reduced accident risk. New savings were 3 to 12 cents per foot of panel surface. Techniques of the study were not revealed in the abstract.

McKeraham, D. Compton, *An Evaluation of Safety Training*, M.S., Oregon State College, No Date.

Twenty-four lost time injuries totalling 954 days five months prior to a safety program were analyzed. In five months following the safety program, three lost time injuries occurred involving 16 days. However, the following year, eight lost time injuries occurred involving 524 days. In general, safety education seems to reduce accidents.

Mangus, Glen V., *An Investigation of Safety Education in the Public Schools of Ten Mountain States*, M.S., University of Wyoming, 1953.

A questionnaire study of status and opinion in public schools in ten mountain states dealt with practices, fields, services, materials of instruction, agents, and responsibilities. There was some evidence of integrating safety in other subjects. There were rather inconclusive findings. There was a seeming lack of organization for safety education in the sample of data.

Meyering, John R., *Woodworking Safety —Needs, Values, Recommended Program for Medium Sized Plants*, M.S., Syracuse University, 1956.

The study deals with a reputed plan for accident prevention program based upon observation and published reports regarding woodworking plants. Suggestions are given for initiating building up and sustaining accident prevention programs. No evidence is given in the abstract for the conclusions reached.

Morrisy, William, *The Traffic Problem in America*, M. S., University of Wisconsin, 1955.

A source unit for introductory driver education covering the significance of the topic, topical outline, possible outcomes, possible activities, and suggestions for evaluation. Materials and recommendations conclude this philosophical curricular study.

Nicklas, George, *A Safety Education Program for the School Machine Shop*, M.S., Stout State College, 1951.

A documentary study by which features of a safety program were compiled. Accident record reporting was emphasized as was environment.

Recommendations involved what one might have expected from the present study.

Parrish, Henry M., *Causes of Death Among College Students*, M.P.H., Yale University, 1956.

Record analysis of 209 deaths at Yale University, 1920-1955. The leading causes of death were: motor accidents, suicide, heart, and circulatory system. The death rate was lower than expected except for suicide.

Pierce, Elwood P., *A Safety Program for the James Denman Junior High School*, M.S., San Francisco State College, 1955.

This is more a term paper than a research report. The title is misleading. The abstract gives little evidence of conclusions reached.

Rouse, Phillip, *A Study of Safety in the Oak Ridge Schools*, M.S., University of Tennessee, 1952.

Ten elementary and secondary schools in one system were surveyed for hazardous features. Abstract gives no conclusions regarding structural safety, fire resistance, fire protection, traffic safety, playground safety, and health factors.

Seker, Phillip D., *Survey of Student Accidents in Bowling Green University*, M.Ed., Bowling Green University, 1955.

A study was made of 725 accidents among 3,404 students in which 83.6 per cent had but one accident. The highest incidence was associated with Wednesday, 4-6 p.m., on campus, and among male athletes. The lower extremity was most frequently injured. Falls were the most frequent causes. Injuries were 6.1 per cent of the infirmary cases.

Steuck, Robert H., *Recommendations to Athletic Officials for Preventing Accidents in Certain High School Sports*, M.S., University of Illinois, 1954.

An analytical survey for determining means of preventing accidents in high school sports by officials indicates failure to fill out rating sheets on facilities and lack of planned program to improve safety by officials and administrators. Recommendable safe practices seem to be lacking.

Suhr, Virtus W., *Relationship of Personality Traits and Certain Psycho-sociological Factors to Driving Performance of Commercial Drivers*, M.A., Iowa State College, 1953.

A personality factor rating questionnaire, a driver performance inventory, and a background experience index were applied to 60 drivers paired by rating and accident records. Best scoring group had fewer doctors' visits, had consistency of opinion, had less Bohemianism, had fewer absences, and the individuals were born on a farm. Accident records showed similar results.

Susoeff, James S., *Recruitment, Training, and Retention of Student Safety Patrol Personnel*, M.A., San Francisco State College, 1953.

The abstract gives no findings of the 60 per cent response to questionnaires from 30 elementary schools in San Francisco.

Rosenblatt, Gerald, *A Critical Analysis of the Accident Proneness Concept*, M.P.H., Yale University, 1955.

This is essentially a philosophical résumé of literature on accident proneness as judged by the abstract.

Williams, Lloyd M., *A Study of the Extent and Importance of Safety Education in Selected Public Schools of Central Washington*, M.Ed., University of Washington, 1953.

The study deals with a 52 per cent response to questionnaires sent to 112 principals. Conclusions were quite general as to interests and need of instructors. Conclusions given seem not to be relevant to initial purposes and seem unsupported in the abstract.

DOCTOR'S DISSERATIONS

Freeberg, William H., *Law and Liability of Municipal, Charitable, and Private Corporations for Conducting Recreation Camps*, Re.D., Indiana University, 1949.

The author determines the liabilities of corporations responsible for camps. A documentary analysis and classification of statutory laws and court decisions concerning the many ramifications of recreation camps.

Hase, Gerald, *The Nature and Frequency of Accidents Among Elementary School Children in a Selected Sample of Schools in New York State*, H.S.D., Indiana University, 1956.

The study consists of record analysis in 92 elementary schools from 1954-1955. Accidents most associated with district schools, May and October, fifth and third grades, boys, eight-year-olds, wounds and bruises to head and hands. The last occurred most frequently on the playground and in the gymnasium. Free play and physical education activities were the chief source of injury; balls were the chief cause. Other pupils were involved most often. Class room teacher supervision had fewer accidents.

Heath, Earl D., *The Relationships Between Driving Records, Select Personality Characteristics, and Biographical Data of Traffic Offenders and Non-Offenders*, Ph.D., New York University, 1957.

Records and tests of 763 traffic offenders reveal that traffic offenders were signficantly higher in impulse and sociable scales and lower in reflective scales. Higher proportions of the group were in the 18-33 age group, unmarried, non-graduate, lower class jobs, earnings under $5,000.00 and indicated driver education.

Loft, Bernard I., *Effects of Driver Education in Driver Knowledge and Attitudes in Selected Public Secondary Schools of Indianapolis and Marion County*, H.S.D., Indiana University, 1950.

Driver attitudes and knowledge tests were given 2,442 students in 14 high schools. Driver trained girls were superior in both. Girls superior to boys in knowledge. Fewer accidents associated with trained boys with higher driving frequencies and better attitudes.

Mayshark, Cyrus, *A Health and Safety Attitude Scale for the Seventh Grade*, H.S.D., Indiana University, 1954.

Two 60-item forms of health and safety attitude test were validated by the interval consistency technique. Boys and girls were found to be significantly different in scores.

Myers, Frank H., *A Safety Attitude Scale for the Seventh Grade*, H.S.D., Indiana University, 1955.

Sixty items comprise forms A and B of a safety attitudes test for seventh grade students. The validity of the items was determined by the interval consistency technique.

Suhr, Virtus W., *Driving Efficiency Over a Six-Hour Period of Simulated Driving Performance*, Ph.D., Iowa State College, 1956.

Psychological, physiological, psychometric, and psycho-physical tests were given before and after six hours of simulated driving. No conclusions were given in the abstract.

Taylor, Harold T., *Administrative Implications of Health and Safety Records of Public School Children*, Ed.D., Indiana University, 1941.

Accident record analysis from 1938-1939 revealed that absence increased from September through March. White pupils had the most absences; girls more than boys and the fourth and eighth grades. Sickness caused 95 per cent of the absences; 40 per cent due to colds. Accidents occurred more frequently at the beginning of the school year and chiefly in the home. Boys incurred 67 per cent of the accidents.

Uhlaner, Julius E., *Relationship Between Two Dimensional and Three Dimensional Spatial Relations Aptitude*, Ph.D., New York University, 1946.

Standardized three dimensional performance scale was compared to the Minnesota Paper Form Board. The coefficient of correlation (r) was .27. The reliability of the former was found to be .80. The validity was not shown. The author advises the use of both tests jointly.

Yost, Charles P., *An Analysis of Graduate Theses in School Safety in the United States from 1925 to 1950*, University of Pittsburgh, 1956.

Identification and analysis of 307 master's and doctor's theses in school safety reveal no single source for identifying the studies. Errors were found in listing and many studies had misleading titles. The majority meeting research standards involved 63 different institutions, New York University being the highest. Techniques and topical emphasis were determined as well as the causes of accidents.

The findings are much like the present study in general.

PROJECTS

American Automobile Association, *Effectiveness of the Auto-Trainer*, Research report #62, June 20, 1957, 7 pp.

An experiment on 29 auto trainer and 21 non-auto trainer subjects resulted somewhat favorably to the auto trained subjects. Subjects favored auto trainer especially in shifting and starting.

American Automobile Association, *Seat Belts for Passenger Cars*, Traffic Engineering and Safety Department, American Automobile Association, Washington, No Date.

A national safety agency reports seat belts reduced seriousness of injury. Most fatalities in 130 auto accidents were caused by ejection through the door. Belts are more effective at a moderate rate of speed.

Ayers, Walter H., *A Survey of Automotive Seat Belts: Owner Experience and Non Owner Attitudes*, E. I. duPont de Nemours and Co., Wilmington, Del., July 18, 1956, 18 pp. plus 33 pp. in appendix.

A telephone survey revealed that more than three-fourths of the seat belt owners will buy again. Sixty-seven per cent of the non-owners and 90 per cent of the owners feel seat belts should be standard equipment. Nylon fabric is preferred.

Brody, Leon, *Personal Factors in Safe Operation of Motor Vehicles*, Center for Safety Education, New York University, 1947, 96 pp.

The related literature previous to the study was reviewed. Tests of various mental and physical traits were administered to each of 26 drivers who had been involved in at least three reported accidents between 1935 and 1940 and to 26 drivers whose records were unmarred. Systolic blood pressure, accuracy of reactions, side vision, and passing on the road were tests 92 per cent effective in separating repeaters and non-repeaters. Sixteen other factors proved inconclusive.

Cutler, William A., *Organization and Function of the Safety Department*, American Management Association, New York City, 1951, 31 pp.

Safety trained engineers were found to be superior to engineers supervised by a safety supervisor. Three-fourths of the safety personnel have had in-service safety education. Full time safety supervisors are in only 60 per cent of the firms.

Dyer, D. B. and J. G. Lichteg, *Liability in Public Recreation*, C. C. Nelson Pub. Co., New York City, 1945, 107 pp.

There is a review of technical terms, defenses against liability, proprietary and governmental functions, safe conditions and nuisances, and liabilities of municipalities, school districts, board members, and individuals.

Eno Foundation for Highway Traffic Control, *The Motor Vehicle Driver: His Nature and Improvement*, Eno Foundation, Saugatuck, Conn., 1949, 165 pp.

A synthesis of literature, not an original research. The study revealed 15-20 per cent of the motorists cause 80 per cent of the accidents. Factors studied included rural-urban, age, and attitude tests. Needs are cited for data on anxiety, fatigue, mental qualities, nature of roads, why drivers violate right of way, effects of diseases, and effects of habits on fitness to drive. Basic elements for needed higher licensing standards are not yet known.

Eno Foundation for Highway Traffic Control, *Personal Characteristics of Traffic Accident Repeaters*, Eno Foundation, Saugatuck, Conn., 1948, 64 pp.
