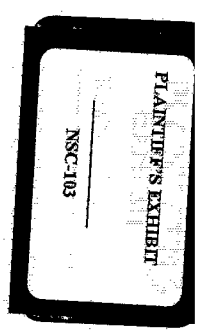
GENERAL SESSIONS



Transactions of the

45th National Safety Congress

(October 21-25, 1957, Chicago, Ill.)

NATIONAL SAFETY COUNCIL

425 N. MICHIGAN AVENUE, CHICAGO 11, ILLINOIS

CONTENTS

Officers, Trustees, and Board of Directors 5

ANNUAL COUNCIL MEETING

Minutes 12

Invocation ..... Dr. Paul Minnich Robinson 15

The President's Report ..... Ned H. Dearborn 16

1958 National Safety Good Turn ..... Warren Meland 19

Women in Industry ..... Mrs. Gertrude H. Frese 20

Keynote Address ..... Major General B. K. Young 25

ANNUAL BANQUET

Banquet Address ..... Honorable William G. Stratton 29

Award Presentation ..... Paul G. Hoffman 33

WOMEN'S ACTIVITIES

Our Role in Safety Leadership ..... Mrs. Raymond Sayre 37

Time for Decision ..... William G. Johnson 38

The Traffic Problem ..... James D. Hill 41

Fundamentals of Home Safety Activities ..... Miss Eunice Heywood 51

The Philosophy of the Beaded Shoes ..... Charles W. Ferguson 52

Officers 54

Safety Exposition Exhibitors 55

Index to all Current Safety Topics volumes 65

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

National Safety Council

OFFICERS

Chairman, Board of Directors—WALTER F. CAREY, Automobile Carriers Inc., Flint, Mich.

Vice Chairman, Board of Directors—DR. LOWELL B. FISHER, President, North Central Association of Colleges and Secondary Schools, University of Illinois, Urbana, Ill.

President—NED H. DEARBORN, President, National Safety Council, Chicago, Ill.

Vice-President for Farms—KIRK FOX, Editor, *Successful Farming*, Meredith Publishing Co., Des Moines, Iowa.

Vice-President for Finance, and Treasurer—WILLIAM H. LOWE, Treasurer, Inland Steel Co., Chicago, Ill.

Vice-President for Homes—DR. GEORGE M. WHEATLEY, Third Vice President, Metropolitan Life Insurance Co., New York, N. Y.

Vice-President for Industry—GERARD O. GRIFFIN, Director of Safety, Dravo Corp., Neville Island, Pittsburgh, Pa.

Vice-President for Labor—P. L. SHEMELLER, General Vice President International Association of Machinists, Chicago, Ill.

Vice-President for Local Safety Organizations—WALTER K. KOCH, President, Mountain States Telephone and Telegraph Co., Denver, Colo.

Vice-President for Membership—EDWARD C. MYERS, Vice-President, United States Steel Corp., Pittsburgh, Pa.

Vice-President for Public Information—CHARLES W. FERGUSON, Senior Editor, *The Reader's Digest*, Pleasantville, N. Y.

Vice-President for Schools and Colleges—DR. LOWELL B. FISHER (Also Vice-Chairman of Board; see above).

Vice-President for Traffic and Transportation—E. J. BUHNER, Chairman of the Board, Silver Fleet Motor Express, Inc., Louisville, Ky.

Vice-President for Women's Activities—MISS MARION E. MARTIN, Commissioner of Labor and Industry, State of Maine, Augusta, Me.

Executive Vice-President—G. C. STEWART, Executive Vice-President, National Safety Council, Chicago, Ill.

Secretary—R. L. FORNEY, Secretary, National Safety Council, Chicago, Ill.

Assistant Treasurers—BUFORD B. MCCULLOCH, President, Bureau of Safety, Inc., Chicago, Ill.

J. D. FULFORD, Director, Treasury Bureau, National Safety Council, Chicago, Ill.

National Safety Council

TRUSTEES

Chairman of the Trustees—W. S. S. Rogers, Former Chairman, The Texas Company, New York, N. Y.

Vice-Chairman of the Trustees—John Stilwell, Yonkers, N. Y.

Secretary of the Trustees—Ned H. Dearborn, President, National Safety Council, Chicago, Ill.

Members

Melvin H. Baker, Chairman, Board of Directors, National Gypsum Company, Buffalo, N. Y.

James B. Black, Chairman, Board of Directors, Pacific Gas and Electric Co., San Francisco, Calif.

S. Bruce Black, Chairman, Liberty Mutual Insurance Company, Boston, Mass.

Walter F. Carey, President, Automobile Carriers Inc., Flint, Mich. (Ex-Officio).

Cason J. Callaway, Blue Springs Farms, Hamilton, Ga.

William G. Chandler, President, Scripps-Howard Supply Co., New York, N. Y.

Charles R. Cox, President, Kennecott Copper Corp., New York, N. Y.

Cleo F. Craig, Member, Executive Committee, American Telephone & Telegraph Co., New York, N. Y.

Walter J. Cummings, Chairman, Board of Directors, Continental Illinois National Bank and Trust Co., Chicago, Ill.

Harlow H. Curtice, President, General Motors Corp., General Motors Bldg., Detroit, Mich.

Ned H. Dearborn, President, National Safety Council, Chicago, Ill. (Ex-Officio).

Richard R. Deupree, Chairman, Board of Directors, Procter and Gamble Co., Cincinnati, Ohio.

J. Doyle DeWitt, President, The Travelers, Hartford, Conn.

Morse G. Dial, President, Union Carbide Corp., New York, N. Y.

E. F. du Pont, Director, Employee Relations Dept., E. I. du Pont de Nemours & Co., Inc., Wilmington, Del.

National Safety Council

(Trustees, continued)

Frederic W. Ecker, President, Metropolitan Life Insurance Co., New York, N. Y.

Benjamin F. Fairless, President, American Iron & Steel Institute, New York, N. Y.

Calvin Fentress, Jr., Chairman, Allstate Insurance Co., Skokie, Ill.

Francis J. Gavin, Chairman, Board of Directors, Great Northern Railway Co., St. Paul, Minn.

E. Roland Harriman, Brown Brothers Harriman & Co., New York, N. Y.

Clifford F. Hood, President, United States Steel Corp., Pittsburgh, Pa.

Joseph L. Lanier, President, West Point Manufacturing Co., West Point, Ga.

George E. Leighty, Chairman, Board of Directors, Railway Labor Executives' Assn., Washington, D. C.

Ray D. Murphy, Chairman, The Equitable Life Assurance Society of the United States, New York, N. Y.

T. S. Petersen, President, Standard Oil Co. of California, San Francisco, Calif.

Gwilym A. Price, President and Chairman, Westinghouse Electric Corp., Pittsburgh, Pa.

Walter P. Reuther, Vice President, American Federation of Labor-Congress of Industrial Organizations, Detroit, Mich.

W. S. S. Rodgers, Former Chairman, The Texas Co., New York, N. Y.

Edward L. Shea, Chairman, Ethyl Corp., New York, N. Y.

Herbert E. Smith, Former Chairman, United States Rubber Co., New York, N. Y.

John Stilwell, Yonkers, N. Y.

Arthur E. Stoddard, President, Union Pacific Railroad Co., Omaha, Nebr.

Dr. John F. Thompson, Chairman, The International Nickel Co., Inc., New York, N. Y.

Kenneth C. Towe, Chairman, American Cyanamid Co., New York, N. Y.

Juan T. Trippe, President, Pan-American World Airways System, New York, N. Y.

C. E. Wilson, Birmingham, Mich.

Robert W. Woodruff, Chairman, Finance Committee, The Coca-Cola Co., Atlanta, Ga.

National Safety Council

BOARD OF DIRECTORS

Chairman of the Board of Directors—WALTER F. CAREY, President, Automobile Carriers Inc., Flint, Mich.

Vice-Chairman of the Board of Directors—DR. LOWELL B. FISHER, President, North Central Association of Colleges and Secondary Schools, University of Illinois, Urbana, Ill.

Members

FRANK R. AHLGREN, Editor, The Commercial Appeal, Memphis, Tenn.

J. T. BLALOCK, Vice President, Pacific Indemnity Co., Los Angeles, Calif.

T. N. BOATE, Manager, Accident Prevention Dept., Association of Casualty and Surety Cos., New York, N. Y.

NORMAN E. BORGERSON, Deputy Superintendent, State Dept. of Public Instruction, Lansing, Mich.

AL. E. BROWN, Vice-President and Regional Director for the West Coast, United Papermakers and Paperworkers, Portland, Ore.

E. J. BUHNER, Chairman of the Board, Silver Fleet Motor Express, Inc., Louisville, Ky.

ROBERT R. BURTON, Vice-President, Kenyon & Eckhardt, Inc., Chicago, Ill.

ALFRED W. CANTWELL, National Director Safety Services, The American National Red Cross, Washington, D. C.

WALTER F. CAREY, President, Automobile Carriers Inc., Flint, Mich.

DR. A. L. CHAPMAN, Chief, Division of Special Health Services, U. S. Public Health Service, Washington, D. C.

DR. ZENAS R. CLARK, Administrative Assistant, Wilmington Public Schools, Wilmington, Del.

JOHN M. CONVERY, Employee Relations Division, National Association of Manufacturers, New York, N. Y.

M. R. DARLINGTON, JR., Managing Director, Inter-Industry Highway Safety Committee, Washington, D. C.

J. B. DAVIES, Assistant Vice-President, Industrial Products Group, Mine Safety Appliances Co., Pittsburgh, Pa.

National Safety Council *(Board of Directors, continued)*

NED H. DEARBORN, President, National Safety Council, Chicago, Ill.

HENRY B. DUFFUS, Administrator, Accident Prevention, Westinghouse Electric Corp., Pittsburgh, Pa.

E. F. DU PONT, Director, Employee Relations Dept., E. I. du Pont de Nemours & Co., Inc., Wilmington, Del.

WALLACE FALVEY, President, Massachusetts Bonding and Insurance Co., Boston, Mass.

C. M. FERGUSON, Administrator, Federal Extension Service, U. S. Dept. of Agriculture, Washington, D. C.

CHARLES W. FERGUSON, Senior Editor, The Readers Digest, Pleasantville, N. Y.

R. H. FERGUSON, Assistant Director of Industrial Relations, Republic Steel Corp., Cleveland, Ohio.

DR. LOWELL B. FISHER, President, North Central Association of Colleges and Secondary Schools, University of Illinois, Urbana, Ill.

KIRK FOX, Editor, "Successful Farming," Meredith Publishing Co., Des Moines, Ia.

MRS. GERTRUDE H. FRESE, Assistant to Vice President and General Manager, New York Telephone Co., Brooklyn, N. Y.

GERARD O. GRIFFIN, Director of Safety, Dravo Corp., Neville Island, Pittsburgh, Pa.

S. W. GRIMES, Managing Director, Pacific Coast Association of Pulp and Paper Manufacturers, Portland, Ore.

PAUL E. GURSKE, Pompano Beach, Fla.

R. P. HAMILTON, Superintendent of Safety, St. Louis-San Francisco Railway Co., St. Louis, Mo.

J. P. HIGHTOWER, Director, Transportation and Safety, The Greyhound Corp., Chicago, Ill.

STANLEY C. HOPE, President, Esso Standard Oil Co., New York, N. Y.

GEORGE A. JACOBY, Director of Personnel Relations, General Motors Corp., Detroit, Mich.

NEWELL R. JOHNSON, General Manager, American Mutual Insurance Alliance, Chicago, Ill.

WALTER K. KOCH, President, Mountain States Telephone and Telegraph Co., Denver, Colo.

National Safety Council

(Board of Directors, continued)

DALIBOR W. KRALOVEC, Assistant Director in Charge of Safety, The Board of Education, Philadelphia, Pa.

FRANKLIN M. KREML, Director, Transportation Center, Northwestern University, Evanston, Ill.

EDMOND H. LEAVEY, President, International Telephone and Telegraph Corp., New York, N. Y.

E. W. LEHMANN, Prof. Emeritus, Urbana, Ill.

WILLIAM H. LOWE, Treasurer, Inland Steel Co., Chicago, Ill.

E. C. MCFADDEN, Vice President, Texas Employers' Insurance Assn., Dallas, Texas.

HAROLD G. MANGELSDORF, Standard Oil Co. (N. J.) New York, N. Y.

MISS MARION E. MARTIN, Commissioner of Labor and Industry, State of Maine, Augusta, Maine.

I. W. MILLARD, Chairman of the Board, Industrial Gloves Co., Danville, Ill.

EDWARD C. MYERS, Assistant Vice President, U. S. Steel Corp., Pittsburgh, Pa.

GUY L. NOBLE, Managing Director, National Committee on Boys and Girls Club Work, Chicago, Ill.

HENRY E. NORTH, Vice-President, Metropolitan Life Insurance Co., San Francisco, Calif.

CLIFTON W. PHALEN, Executive Vice-President, American Telephone and Telegraph, New York, N. Y.

MRS. IVY BAKER PRIEST, Treasurer of the United States, Treasury Dept., Washington, D. C.

A. V. ROHWEDER, Superintendent of Safety and Welfare, Duluth, Missabe and Iron Range Railway Co., Duluth, Minn.

ROBERT T. ROSS, Manager, Employee Service; Industrial Relations, Ford Motor Co., Dearborn, Mich.

MRS. RAYMOND SAYRE, Ackworth, Iowa.

A. J. SCHWANTES, Head of Dept. of Agricultural Engineering, University of Minnesota, St. Paul, Minn.

HARRY SEE, National Legislative Representative, Brotherhood of Railroad Trainmen, Washington, D. C.

National Safety Council

(Board of Directors, continued)

LOUIS B. SELTZER, Editor, The Cleveland Press, Cleveland, Ohio.

P. L. SIEMILLER, General Vice-President, International Association of Machinists, Chicago, Ill.

REUBEN D. SIVERSON, Manager, Dept. of Manufacture and Industrial Development, Chamber of Commerce of the United States, Washington, D. C.

J. L. S. SNEAD, JR., President, Consolidated Freightways, Inc., Menlo Park, Calif.

LESLIE J. SORENSON, City Traffic Engineer, City of Chicago, Chicago, Ill.

HERMAN J. SPOERER, Vice-President, Industrial Relations, The Youngstown Sheet and Tube Co., Youngstown, Ohio.

A. E. SPOTTKE, Vice-President, Allstate Insurance Co., Skokie, Ill.

G. C. STEWART, Executive Vice President, National Safety Council, Chicago, Ill.

WALTER A. STEWART, Trustee and former President, American Optical Co., Southbridge, Mass.

ARTHUR E. STODDARD, President, Union Pacific Railroad Co., Omaha, Nebr.

COL. W. L. TURRS, Assistant for Ground Safety, DCS/Personnel, Hq., U. S. Air Force, Washington, D. C.

LLOYD UTTER, Director, Industrial Health and Safety Division, United Automobile Workers, Detroit, Mich.

DONALD G. VAUGHAN, Secretary, Aetna Casualty and Surety Co., Hartford, Conn.

MRS. GEORGE WELLES, JR., Duluth, Minn.

DR. GEORGE M. WHEATLEY, Third Vice-President, Metropolitan Life Insurance Co., New York, N. Y.

R. S. WILSON, Executive Vice-President, Goodyear Tire and Rubber Co., Akron, Ohio.

W. O. WILSON, Manager of Safety, Standard Oil Co. (Ind.), Chicago, Ill.

DR. WILLIAM P. YANT, Director of Research, Mine Safety Appliances Co., John T. Ryan Memorial Laboratory, Pittsburgh, Pa.

ANNUAL COUNCIL MEETING

MINUTES

The 1957 Annual Council Meeting of the National Safety Council was held in the Grand Ballroom of the Conrad Hilton Hotel, Chicago, on October 21, with Ned H. Dearborn, President, presiding.

The meeting opened with a Presentation of the Colors by Explorer Post 2022, Chicago Council of the Boy Scouts of America. The Invocation was offered by Dr. Paul Minnich Robinson, President of the Church Federation of Greater Chicago.

Mr. Dearborn then proceeded with the business of the meeting by announcing a quorum present, in person or by proxy. It was voted to dispense with the calling of the roll; also to dispense with the reading of the minutes of the previous Annual Meeting, as the minutes had been printed and circulated to the membership.

Mr. Dearborn called for the report of the Nominating Committee, which consisted of the following members: George A. Jacoby, Chairman; E. J. Buhner, Franklin M. Kreml, Miss Marion E. Martin, Guy L. Noble, H. J. Spoerer, A. E. Spottke.

Mr. Jacoby reported in behalf of the Nominating Committee, pointing out that the Constitution authorizes the Committee to name candidates for election to the Board of Directors and to all offices except the offices of Executive Vice President and General Manager, and to place in nomination at the Annual Council Meeting said candidates, as well as the candidates for election to the Trustees named by the Trustees. The selections of the Committee, Mr. Jacoby stated, were reported to the Secretary of the Council more than 75 days before this meeting, and were announced to all members of the Council on September 6, 1957.

Mr. Jacoby then presented as nominees for Trustees of the Council, to be elected for a three-year term: Melvin H. Baker, Cason J. Callaway, Cleo F. Craig, Richard R. Deupree, Dr. John F. Thompson, C. E. Wilson. (Secretary's Note: A complete list of the Trustees, including those nominated and elected at this meeting, as well as those continuing in office from previous elections, is given on pages 6 and 7 of this volume.)

Mr. Jacoby presented nominations for Directors, to be elected for a term of one year. (Secretary's Note: A list of the new Board of Directors, as nominated and elected at this meeting, will be found on pages 8 to 11 of this volume.)

Dr. Yant presented nominations for Officers of the Council, to be elected for a term of one year. (Secretary's Note: A list of the Officers nominated and elected at this meeting will be found on page 5 of this volume.)

There were no nominations except those presented by Mr. Jacoby. Mr. Dearborn announced that there were 28,885 votes favoring the slate presented by the Nominating Committee, and no votes opposed. Those attending the meeting voted without dissent in favor of the nominations, and Mr. Dearborn declared the nominees elected.

Mr. Jacoby paid special tribute to the following Council Officers who, after valuable service to the Council, are giving up their positions this year: Walter A. Stewart, Chairman of the Board of Directors; R. H. Ferguson, Vice President for Industry; Boyd Lewis, Vice President for Public Information. Mr. Stewart and Mr. Ferguson, although giving up their offices, will remain on the Board of Directors. Mr. Walter Carey, who has served as Vice President for Traffic and Transportation, is named Chairman of the Board for the new year. Mr. Dearborn introduced various Officers of the Council who were seated on the speakers' platform.

Mr. Dearborn said that two years ago the Board of Directors had approved a plan for inviting a selected list of influential business leaders and government officials from other countries to be our guests at this Congress. Invitation lists were compiled with the assistance of several departments of the federal government and of industrial leaders with world-wide connections. Growing out of this plan, Mr. Dearborn said, 22 special guests are in attendance at the Congress, coming from 19 different countries and representing a great variety of industrial and governmental leadership. The special guests were invited to stand and were greeted with a round of applause.

Mr. Dearborn also expressed warm greetings to all other delegates from foreign countries, many of whom are in attendance year after year, and made particular reference to the many Canadian delegates who attend the Congress.

A large number of young people who were attending the Farm Youth Sessions at the Congress were also asked to stand and were greeted with a round of applause.

Mr. Dearborn then introduced Executive Vice President G. C. Stewart, who called attention to the Council's new annual report, "Report to the Nation, 1957." General Stewart emphasized several highlights of the report and urged careful reading of it by all Council members.

Mr. Dearborn announced that the 1958 National Safety Congress will be held in Chicago, October 20-24.

The remainder of the program consisted of four addresses—by Warren Meland, Mr. Dearborn, Mrs. Gertrude H. Frese, and Major-General B. K. Young. These addresses, as well as the Invocation by Dr. Robinson, are included as a part of these transactions, on the pages immediately following.

In introducing Boy Scout Warren Meland, Mr. Dearborn took occasion to express the great significance which the National Safety Council attaches to the National Safety Good Turn Project of the Boy Scouts of America for 1958. He emphasized the tremendous accident prevention potential that is inherent in this organized effort of four and one-half million Scouts and their adult leaders, all working in cooperation with families, neighbors, businessmen, and public officials.

In introducing General Young, Director-General and chief executive officer of the Royal Society for the Prevention of Accidents, London, England, Mr. Dearborn expressed his great appreciation to General Young for his willingness to make the long journey from London, and also took occasion to thank the General and the Royal Society for the invitation tendered him to address the opening meeting of the Royal Society's National Safety Congress last year. The courtesy shown him at that time and the interest exhibited in his address, Mr. Dearborn said, left him forever grateful.

R. L. Forney
Secretary

THE INVOCATION

By DR. PAUL MINNICH ROBINSON

President of the Church Federation of Greater Chicago

Oh, Lord, our God, who has been a help in ages past and who art our hope for years to come, Thy glory is set above the Heavens and yet Thou dwelleth in the humble hearts of those who love Thee.

We thank Thee for the beauty of the world around us, for all Thy work, declare Thy praise, and the firmament show of Thy handiwork and most of all, now we thank Thee that Thou hast created man in Thy image and has endowed him with the mind and spirit to respond to fellowship to Thy own infinite spirit.

We pray Thou wilt give us such reverence for human life we shall oppose the sign of any act that will endanger or destroy it.

Awaken us all to a sense of responsibility to protect and preserve the safety of all of our citizens in every community across this broad land. Let not the powerful machines men's inventive genius has placed on the highways to bless our lives, because of our careless use of them, become to us a curse.

Grant to them the grace and courtesy and restraint of fast-control, that we shall regard the well-being of our neighbor as important to us as our own.

We pray Thy blessing upon the work of the National Safety Council and those whose concern for the common good of our society has brought them to this place.

May their efforts bring an increased measure of safety to our streets and our highways, to our homes, our families, and our places of daily toil. Unite us all in a deeper dedication to alertness and care which will preserve ourselves and others the life we owe to Thee.

Let Thy Kingdom come and Thy Will be done on earth as it is in Heaven. In Thy name and for the sake of Thy mercy and love, we pray; amen.

THE PRESIDENT'S REPORT

HAVE WE FAILED?

by NED H. DEARBORN
president, National Safety Council, Chicago

You have just elected me as your president for the ensuing year. I pledge you my best efforts. By action of our Board of Directors I shall thereafter be associated with the Council as President Emeritus, and shall, I hope and believe, be able to perform certain services for the Council and its members as desired.

But I do feel that this is the appropriate occasion for me to talk with you frankly and sincerely about a number of things that have been very much in my thoughts over the years.

First, I want you to know that it has been a rare privilege and distinct honor to serve you, and I am profoundly grateful for your confidence, encouragement, and support.

Have we failed? That is the title of this short talk. To begin with, I am mindful of the many gains we have made together during the last 15 years. I am mindful of the vastly increased cooperation of hundreds, even thousands of organizations enlisted in the great crusade for safety.

I am mindful of the active participation of thousands of influential individuals—civilians and public officials—in our great social and economic movement to prevent accidents and thus to save countless lives, reduce serious non-fatal injuries, and to protect property. I am mindful of the enlistment of women and women's organizations in this mighty cause. I am mindful of enlisting labor support. I am mindful of the growing interest of schools and colleges in safety.

AGENCY SUPPORT

I am mindful of increased appreciation of governmental agencies—federal, state and local—in the importance of accident prevention.

I am mindful of the steady gains in home and farm safety.

I am mindful of the constant support of business and industry in safety through their own improved safety records, a growing membership in the Council, and through financial and other contributions.

I am mindful of the slow but steady acceptance of moral and social responsibility in addition to individual responsibility for safe practices.

I am mindful of the growing cooperation from medical and public health agencies.

I am mindful of the recent encouragement by the clergy of all denominations.

I am mindful of the important backing of our Trustees.

I am mindful of the dedicated services of our Boards of Directors.

I am mindful of the space and time contributed by all media of public information.

I am mindful of the consecrated efforts of our staff to the cause which in turn is consecrated to the social and economic welfare of our beloved country.

And I am mindful of the Council's privilege of serving in some measure the people of other countries.

It has been a memorable 15 years for me and I am proud to have been a part of the progress in safety in the time I have been with you.

HEALTHY DISSATISFACTION

One of my guiding principles has been to maintain a high degree of healthy dissatisfaction. This talk is in harmony with that principle.

We have failed thus far to achieve our ideals. All of us together have failed thus far to arouse the American people to the true importance of safety to the social and economic health of our society.

We have failed to stir the hearts of our fellow countrymen. There are scores of eminently worthy causes which arouse widespread support—hear ailments, cancer, tuberculosis, poliomyelitus, muscular distrophy, and, currently, Asian influenza, to mention only a few.

Why, oh why, in the name of humanity, don't the American people react to the terrible toll of accidents— 95,000 killed in 1956 alone, more than a million injured, many thousands of them permanently; and an estimated economic loss of $11,200,000,000.

The facts have been told over and over again. But Americans just don't react as they do to other worthy causes. You and I have failed to reach their hearts and minds.

Who are the "we" I seem to indict so vigorously?

It is all of us who are actively participating in the safety movement. That includes you and it includes me.

SUPPORT STILL WEAK

Business has only recently taken positive action against off-the-job accidents and even so their programs are far from universally applied. Business support of our public service program has grown steadily but slowly but I regret to say that it has been in hundreds of thousands of dollars where it should have been in millions. That is especially true of industries which profit most from accident prevention.

Labor is still a weak safety voice crying in the wilderness.

Women are nowhere near as active, so far, in our field as in other worthy welfare work.

The schools and colleges at best have made only a good beginning.

Government interest and action is growing, but many areas are still sadly neglected.

The U. S. Department of Health Education and Welfare, the natural national official home of safety, has no officer whose sole function is the promotion of safety, except among department employees.

The religious crusade is too recent in origin to assess beyond its potential worth.

All media of public information have earned our highest praise in emphasizing safety, but it apparently hasn't aroused public indignation against violators of safe practices.

Some agencies still show symptoms of apprehension of the National Safety Council's prestige, even though they are free to, and do, participate in the Council's conferences, sections, and committees.

Even the Council's own governing body and its own staff at times exhibit timidity and complacency.

PUBLIC UNIFORMED

Our public information program has enjoyed an incredible success with public information media as measured by time and space, but the Council is still most often mentioned by Mr. and Mrs. John Q. for its weekend holiday estimates of traffic fatalities—only a small fraction of our year-round public information program.

I have made suggestions from time to time related to program changes and additions which in some cases have met with passive opposition. But that can only mean that I personally failed to persuade a sufficient number of my colleagues and associates to a program of action that would set fire to the intelligence, imagination, and emotional reactions of the American public.

Some of my suggestions were either insufficient, inadequate or impractical. Whatever the reason, I repeat, you and I have failed to arouse the American people to the point where militant action against accidents is locally applauded and supported.

One example will typify local attitudes toward safety in contrast with those toward the dread diseases. The Titusville Herald, a first-rate daily newspaper in our recently adopted home of Titusville, Pennsylvania, had a special editorial in its issue of October 14, 1957, entitled "No Cause for Panic." I quote excerpts from it—not at all in criticism of the contents of the editorial or the praiseworthy reasons for publishing it, but to contrast community reaction to one of the dread diseases, in this case typhoid fever, with community reaction to accidents.

REACTION DIFFERS

In the last few days 16 cases of typhoid fever had been recorded in this beautiful city of some 10,000 souls in an even more beautiful setting in the foothills of the Allegheny Mountains. The editorial was as follows:

"The typhoid fever outbreak naturally has the community upset . . . The disease seems to be confined in general to one age group in one school . . . If the disease had struck in

several age groups in several localities, the situation would be far different than it is . . . Parents are now alert to watch for symptoms in their children . . . The medical profession in Titusville has been and is ready to strike back with every medical weapon in its vast pharmacy. The community is also fortunate to possess the fine facilities of the Titusville Hospital . . . Our health authorities will continue in a methodical and scientific way to track the beast to its lair . . ."

In the same issue of the Herald there were seventeen news stories of accidents over the weekend and all but one were about accidents in the immediate area. Eight deaths were reported, three of them in the vicinity of Titusville.

There have been no deaths from typhoid fever and yet the main "talk of the town" is this incipient epidemic. Even the Asiatic flu and good old sputnik have taken back seats to typhoid fever. The only place where accidents seem to be recognized as a primary problem is in the Herald, the police department (whose good work in traffic safety was properly editorialized earlier by the Herald), and a handful of local business concerns whose interest is primarily in plant safety.

NO COMMUNITY EFFORT

The fact remains that there is no organized community effort in Titusville to prevent accidents and no obvious interest in such an enterprise beyond those groups I have mentioned. There are thousands of communities throughout the nation of which similar comment could be made. This is no criticism of the good people of these communities.

It is, rather, a criticism of us in the safety field. I repeat again we have failed to arouse the American people sufficiently to a deadly and diabolic peril which they can control. We can have safety anywhere if a sufficient number of us want it.

What, you may properly ask, can be done about this unhappy situation?

In the first place, a new look at the program of the National Safety Council can be instituted by our Board of Directors.

The new look should be taken by people with scientific training outside our own staff—psychologists, psychiatrists, medical and health officers, sociologists, biologists, mathmaticians, and others who are competent objectively to study the problems and to make recommendations on how to prevent accidents.

You in this audience and other members not represented should welcome and support such an investigation. The report of such a study as I have, in a general way suggested, should be welcomed and supported by every agency, private and public, engaged in accident prevention in any field of safety.

We need to know the basic causes of accidents and how to circumvent them. It is not enough to know where, when and how the accidents occur. We must know why they occur and that is the reason for more and more scientific appraisal of the basic causes. This kind of an appraisal might very well revolutionize our programs of accident prevention. At the very least it would have a very sobering and salutary effect on all of us.

RECHANNEL FUNDS

American business spends enormous sums on research to keep pace with the times. Safety deserves the same kind of support. We lack sufficient finances to conduct adequate research for the things we are doing to say nothing of the research financing needed for the additional things we should do. That just does not make sense.

I am glad to know that this type of traffic safety study now is being undertaken by the Northwestern University Traffic Institute and by the Bureau of Public Roads in the U. S. Department of Commerce.

Evangelism is needed, too. But so far it isn't fiery enough or it has fallen short in methodology. Not all of us are Billy Grahams in the safety movement, but each of us in his own limited way is an evangelist. The net result so far is too few who have made the great decision for safety.

Finally, let each of us in safety work examine and re-examine our own efforts to prevent accidents with a critical eye and a receptive mind to changes in safety education and practices.

Let us each be a more consecrated apostle of safety and win disciples, far and wide, who will spread our sacred gospel to the ends of the earth. This is no less than our solemn duty.▲

1958 NATIONAL SAFETY GOOD TURN

by WARREN MELAND
Explorer Post 2912, Boy Scouts of America, Chicago

You can imagine what a thrill it is for me to appear before the greatest gathering of safety leaders held anywhere, any time, in the United States—and announce that in 1958 the Boy Scouts of America will devote their good turn to safety!

This links the Boy Scouts and the National Safety Council together in what I am sure every one of us agrees is one of the greatest crusades in history—and I can tell you that the Boy Scouts are proud and honored to be part of this safety movement.

OPERATION—SAFETY

I'd like to take just a minute to tell you how the Boy Scouts intend to conduct this safety program, one which all of us—young and old—must make a success.

The Safety Good Turn is a major campaign—within our own Boy Scout movement—and also in the way we will affect the general public. To do it right—and that is the only way the Scouts like to do things—we will break it into bite-sized pieces we can really get our teeth into.

The plan of operation for the 1958 Boy Scout Safety Good Turn will be divided into these three groups: first, traffic safety; second, outdoor safety and lastly, home safety.

Our first phase, traffic safety, will be emphasized during the months of March, April and May of 1958. At this time each Cub Pack, Boy Scout Troop and Explorer Post will take part in a safety project in the automotive, bicycle, pedestrian, railroad or farm equipment field.

During the months of June, July and August the emphasis will be on outdoor safety. Hereby each unit will take part in either a water, fire, firearms or farm safety project.

ALERT THE FAMILIES

The third group to be completed during September, October and November stresses Home Safety. Here, particularly, all units will participate in projects designed to alert the entire family on being prepared to make safety a personal and fundamental part of everyday living.

If the Safety Good Turn does nothing more than alert the Scouts and their immediate families, we can bring safety to 18-million people directly, more than one-tenth of the population of this country.

The 1958 Safety Good Turn then becomes a challenge to every Scout and Scouter in the nation. We know we must promote the proper attitudes toward safety practices in traffic, outdoors and in the home and give everyone the opportunity to put into action the motto "Be Prepared."

We know that national programs are fine—but they must be carried to the individual. In Scouting we like to say, "Learning by Doing" and through your help that is how this safety program will be carried out. Think of what it will mean to have safety played up big by 100,000 Scout units in our country.

SAFETY—DAILY HABIT

These projects must include interesting the youth and the public of our country in safety, making it apparent to everyone the urgent need for reducing the tragic toll of accidents. But, even more important, to stimulate a public concern in the prevention of accidents, the Boy Scouts of America will co-operate with all safety organizations in individual, group, and community safety projects. We will make safety a part of our daily living; almost as much a part as eating, which I am sure no one forgets to do.

The Scouts are proud to have been called upon by the President of the United States to enlist in this campaign. It gives youth the opportunity to serve our community and our nation—in a significant manner—in a way we can be sure of accomplishing something. To have a part in the conservation of human life, to help influence other youth and their families, to reduce injuries and prevent accidents—all of this we will do. But even though I, myself, and my four-

and-one-half-million fellow Scouts are eager to carry this message—we want to carry the right message.

Therefore, we turn to you at this time. In your group is the experience in safety which we must look to.

Here, then, is my message to you. The Boy Scouts are counting on your aid. Thousands of "sign up" cards will be made available to you during this week. Fill out this card indicating your interest in helping the Scouts to do this good turn. Please sign up! We'll try our level best to do our part —but we need your expert safety help.

Every Scout takes the Scout Oath. It starts "On my honor, I will do my best to do my duty to God and my country."

With your interest and aid, Gentlemen, four-and-one-half-million Scouts can and will do their best.

WOMEN IN INDUSTRY

by MRS. GERTRUDE H. FRESE

assistant to vice president and general manager, New York Telephone co., Brooklyn, N. Y.

Are people always going to read the mounting statistics of accidents—fatal and mutilating—and stand by complacently, thinking, I'm immune to all this—I'm different? Or are they going to face up to it and get in and do something about it? Can't we make safety as much a part of daily living as food, clothing, relaxation and spiritual refreshment?

Dr. Norman Vincent Peale in his book *How to Stay Alive All Your Life*—which incidentally would be an appropriate title for a safety campaign—reminds us that "The body is a temple given to us by God." To keep it, we must feed it, cleanse it, use it in moderation. Most of us do this automatically without thinking about it as a temple. That is, we care for ourselves as far as we can through good nutrition, sleep, shelter and clothing. But the Bible says "Know ye not that the body is the temple of the soul." If we could fully comprehend this statement, would we not seek to protect our body, this temple of the soul, from accident in every way possible." That's a big "if."

If we did—wouldn't we be cautious in the home, careful on the street, and alert on the highway?

If we did—knowing that attitudes are formed early in childhood, wouldn't we train our children in safety as a way of life?

If we did—a mother would not look at me in questioning fashion when *I* asked what the local P.T.A. is doing to teach safety to small fry. She wouldn't say blankly—"Safety! I don't think we are doing anything. Why?"

If safety were part of our daily living, children wouldn't be riding bicycles pell-mell down a highway in suburbia on the wrong side of the road, or riding in—"look ma, no hands" style.

THE BIG "IFS"

If—parents wouldn't be rushing to the railroad station with only seconds to spare, the wife in curlers, a coat thrown over her pajamas. Nor would the husband try to drive and drink a cup of coffee at the same time, not only missing his train, but dying in the attempt to make it.

If—a pilot wouldn't be able to say that we lose many more men driving home than we do flying planes.

If—a taxi driver wouldn't drive through a crowded street with one finger on the wheel, his right arm over the seat, turning his head to talk to his passenger.

If safety were part of our daily life, girls wouldn't clip-clop along in toeless, backless, shoeless shoes endangering life and limb with every teetering step down a stairway; nor wear the thin, thin spike heels that sink in every crack and cranny tripping the wearer.

If—teenagers wouldn't drive with one arm out the window as their dads do—or, worse, ride with baby shoes, dice, scarves and feathers dangling on the rear view mirror.

If safety thinking and protection of our body were part of our daily living, a father wouldn't race down the platform and try to board a train as it picks up speed pulling out of the station. If—If—If!

How can we eliminate these big "ifs?" How can we get people to believe the body is the temple of the soul? How can we get them to "stay alive all their lives?"

STATE OF MIND

The remedy, of course, is a properly conditioned state of mind within the individual. The individual must be impressed with the advantages of safeguarding himself against accident and then be given no opportunity to forget these advantages.

In trying to save people from themselves—an accident, an injury, a tragedy that they themselves could prevent or avoid—every idea, every device, every school of thought possible is needed and should be used. But ideas, devices and schools of thought are not of themselves sufficient—we need to enlist people—millions of people—if we are to make safety-consciousness a way of life in our country.

This brings me to my theme—the power of women as a force for safety. This is not a new subject. Women and the power of women we have had with us always! In fact, I can't even claim credit for resurrecting it. General Stewart asked me to go into this. He knows I'm a business woman, and a club woman, as well as a housewife. He further knows that the Women's Activities conference of the National Safety Council this year adopted as its goal, alerting all women to the fact that they are the "guardians of safety" for themselves and their families.

WOMEN'S BASIC INSTINCTS

The power of women which can and must be applied in the safety field is acknowledged by all—men and women alike. It derives naturally from the status of American women, developed down through the years to our present position in society today. Women possess natural basic instincts that tend toward caution, security, absence of violence, love, family stability and protection of the young. We have qualities of intuition frequently not possessed by men. We are the mothers, the teachers of the young, the homemakers of the nation. We are more social than men and set the standards of social conduct and morals.

Women can be a tremendous force for good when they are aroused. Haven't you seen a group of mothers prove to the town fathers that a street light is needed at an intersection? Pretty soon a traffic light is installed. They won their point through united action.

Women can be terrible in their wrath, as every husband present knows. The newspapers recently carried a bit about a man in Albuquerque, New Mexico, who learned the hard way. His car was blocked by a line of traffic. He got out and threatened the woman of the car in front of his. She reached down, picked up a hammer, and hit *him on the head. This rather violent reaction* to masculine criticism is not recommended, of course.

What is our responsibility if we women are to do something in the field of safety? The problem is immense and intricate. There are sociological, physiological, economic and political aspects all wrapped up together. And the American woman can effectively tackle all aspects at once. But how?

OBLIGATIONS OF WOMEN

First, let us consider our obligations and responsibilities in the home.

Are mothers devoting care and thought to safety training for their children? Have some lost the respect of their children and abandoned all effort to guide and control them? The home is the heart of our lives and the wife and mother should be the heart of the home. Here, through courtesy, kindness, consideration, tact and untiring diligence we have our best opportunity to develop safety-minded citizens. Safety by example and training is needed here.

The housewife, however, is the hardest person to reach. If she is a joiner and belongs to a club, she can be approached and taught the meaning of safety. If not, it's more difficult. However, many wives and

mothers are married to men in industry, and industry is beginning to reach out to them. The Bell Telephone company of Pennsylvania, which is part of the Bell System to which I belong, has started a series of evening meetings for the family. Safety skits, motion pictures and talks are part of the program. The children, the husbands and the wives attend. Home and traffic safety are discussed, even to teaching the youngsters how to roller skate safely.

My own company, the New York Telephone company, is about to launch a safety essay contest for children between the ages of nine and 13. The subject is what my mother or father, or both, are doing to prevent accidents. This is another means of reaching into the home—another way to get the wife and mother thinking about safety.

TEACHERS' INFLUENCE

After the home, the next great training field for youth is, of course, the school. Women as teachers can exert great influence for safety in our schools. Furthermore, through our participation in Parent-Teacher and other civic organizations, we can provide assistance in the schools for appropriate safety education.

In Phoenix, Arizona, there is an effective program which I understand, is spreading elsewhere in our country. Children in elementary school are taught how to drive. The schoolyard is marked off to simulate a city street or highway. Small pedal cars are used for instruction purposes. The boys and girls learn to recognize and observe universal signals and signs. This is most effective: for not only does it reach the child, but many parents attend these training meetings. This type of training is invaluable and women could be instrumental in making it available all over the country.

What about the slaughter on our highways? If we have any desire to protect our loved ones and any compassion for pain and suffering, women should act here! And we have plenty of tools—tact, charm, ingenuity and authority to force our friends and loved ones to protect themselves. In this field club women have contributed a great deal.

An example—my own club, the Altrusa International's public affairs program is directed to four major areas of concern. Traffic safety is first in order, with emphasis on three individual goals—to be a safe driver, to promote safe driving and to be a law-abiding pedestrian. The last item is of particular importance. Did you know that another word has been added to our vocabulary in recent years—"Pedestricide?"

TRAFFIC SAFETY MONTH

As a result of Altrusa's forward-looking public affairs program, many of our clubs over the country have been contributing toward safety in the community. In Oregon, the month of February was designated as traffic safety month and the Portland Altrusa club promoted safety on a state-wide basis.

One interesting event was a fashion show which featured such items for traffic safety as: white umbrellas, white overshoes and white raincoats for pedestrians. Another organization, "The American Council of Railroad Women," has a code called "Good manners are good business," and item three is a rule as to how a women should act as a pedestrian and a driver.

I have attended many club board meetings, the purpose of which was to find a project for the club year. Women in every town and hamlet, every city and village, searching for a worthwhile endeavor for the club to work for. Safety programs of all types promoted by women's clubs everywhere in the United States could have a powerful effect in helping to reduce accidents, particularly if the clubs banded together in the community for a common purpose.

FOR WOMEN ONLY

In a New York Safety Conference, a general of the United States Army was quoted as saying "I can keep the boys safe while they are at camp—our safety record is good—but I can't keep them safe when they leave home too late, to drive too far, too fast. It's the mothers of America, the fathers of America, the homes of America that are murdering American boys." Well, a number of telephone women working in the safety field heard that quotation, and it added fuel to the fire.

They had been concerned about the increasing number of off-duty automobile accidents. Too many of our girls are injured while riding as passengers. This seemed to be the time to launch a crusade for safety on the road; a program of "women only," for the working women, of the New York Telephone company.

We needed first of all a plan, and we called that plan "You Are Important as a Woman in Traffic." This was really a clever title since it was directed to telephone operators who work in what is known in our company as the traffic department. Telephone calls are known as traffic in my business.

The crusade was an entirely new thing for us really because it called upon every female talent known to man—charm, tact, ingenuity and love. All these distinctive characteristics were to be concentrated on just one thing—keeping the family together—alive, together— particularly when dad and the son took over the wheel.

LEISURE TIME SAFETY

We in the Bell System have done, and are doing, quite a bit along the lines of leisure time safety. We have published informative and interesting material on the subject of safe vacations because we believe that summer vacation was instituted to refresh and renew, not to exhaust and maim. We cover such subjects as over-exhaustion, poison ivy, sunburn, and other bothers and hurdles in the obstacle course of today's summer living. Furthermore, we have every reason to believe that our people share this information with their families and friends.

But this safe driving crusade is unique in the sense that it changes a potential back seat driver into a convincing safety influence —in other words, a co-pilot. There are more than 31,000 women in the traffic department of the New York Telephone company and that's a powerful lot of influence when properly directed—either in the back seat or the front.

SOME SAFETY DON'TS

Listen for a moment to a bit from the Crusade Leader's Guide. After pointing out to the girl the many roles that she can play to promote safe driving, the Guide notes "Avoid tensions, irritations—these can be translated into an accident behind the wheel of a car. Don't start a discussion at the breakfast table which you know may become heated. Let your husband drive off to work in a happy frame of mind and hold the fire for some other time.

"Don't get your family all fidgety and nervous by always being late to get started for church, the movies or shopping. Don't keep your boy friend waiting 'just for effect;' he may become annoyed, rather than impressed, and if he takes his anger out on the car almost anything can happen."

There's more to our crusade. A series of 12 safety posters were developed. Leaflets associated with these posters are distributed by safety committees to employees on-the-job. One and all are urged to plug safe driving at picnics, ball games, dances, bridge parties, and in their civic organizations, churches and clubs.

We are sure that we are going to get as much safe-driving mileage out of our fathers and sons, nephews and uncles and, incidentally, ourselves, as courtesy and friendly persuasion will allow.

This brings me to a sizable and accessible group of women—the women who work. There are more than 22 million women employed full-time in the United States today holding one-third of all the jobs in the country.

WORKING WOMEN POTENTIAL

The growing importance of women in industry is indicated by the fact that the number of working women has increased about 57 per cent since 1940 while, during the same period, the male working population increased only about 12 per cent. The days when the song, "Heaven will Protect the Working Girl" really meant something are over.

Numerically the working woman is becoming a dominant factor in industry, an important man-power reserve, and a necessary economic participant. I think, therefore, that we must conceive that in the area of industrial safety, women are today an important factor. Are we taking full advantage of this kind of safety interest and safety motivation?

There are probably many people who believe that the type of work women do is not hazardous, therefore, women do not require the same degree of safety education as men. In the Bell System a few years ago, we were rudely jolted by the discovery that lost time on-duty accidents among our women employees were running at twice the frequency of male mishaps. A plan of

co-education was instituted with no lessening of emphasis in its application to women, and, today, there is no such disparity in the accident frequency records of our men and women.

We have found our telephone women to be receptive to fundamental safety suggestions such as, care on stairs, closing file drawers, opening doors carefully, and the like. We believe that specific suggestions on how to be safe on the job are much more effective than slogans and exhortations on the overall subject of safety.

COMPANY SAFETY PRIDE

The average woman in industry is not terribly concerned over office or department safety records in which she is nothing but a statistic. She may experience a vague sort of pride to learn that her company has earned a safety award. She is not likely to be too conscious of her part in winning such an award. The American working girl is a pretty realistic sort of person, a far cry from her ancestors of the smelling salts era.

She responds best to a safety approach that subordinates company banners and records and brings the matter right to her as an individual. I think the average working woman will react readily to the type of safety education which touches upon the unpleasant consequences of carelessness on-the-job or at home. Safety takes on a new meaning when its absence is associated with discomfort, loss of earning power, possibility of disability—yes—even the possible loss of dignity.

One of my own girls asked me with eyes flashing if I'd forgotten what the gals in my own department are doing, and I quote—"Monthly safety meetings, films, posters, pamphlets, discussions of ways and means to keep everyone alerted to the danger and harm that could affect us. The appointment of a 'safety observer' to act for a month at a time to watch and prevent accidents in the office. The final result—the development of a 'safety-eye' for hazards." End of quote. That girl has religion. She believes in the program. She practices it on-the-job and at home. There are 22 million like her that can be reached in industry today.

Her use of the term "safety-eye" struck me forcibly. With a "safety-eye" all women would indeed become the "guardian of safety" for themselves and their families. They'd see the rubbish in the cellar, the toys and packages left on the staircase, the flammable cleaning fluids in the kitchen.

They'd see the danger of a hurried breakfast and a dash to the railroad station. They'd try to control the driving of foolish teenagers. They'd see the danger of the thin spike heel, the backless shoe and the long pointed toe. They'd train their families to keep a "safety-eye" open in the "do-it-yourself" projects, in highway travel, in sports—in all daily living.

I firmly believe that we women can do a tremendous job in public and family safety education. We have the motivation in our basic instincts. We have the numbers to reach millions of people.

I have a firm belief that there is a force that can be put to work for safety. Its effects are scattered now but could be drawn together in one great movement. Women have the time, and the talent, and the cause is of transcending importance. It's up to the men to realize this, to understand that we can work side by side with them. It's up to them to mobilize this force and to call upon us really to do a job, a united job, in the safety field.▲

KEYNOTE ADDRESS

by MAJOR GENERAL B. K. YOUNG

director-general, The Royal Society for the Prevention of Accidents, London, England

The toll of death, injury and suffering—quite apart from economic loss—caused by accidents, can only be reduced by constant and continuous attack. That is our experience in Great Britain, and it is, of course, only from that point of view that I can talk to you.

Personally I think the word "accident" is both overworked and wrongly used. Close investigation of these incidents, be they road, home or industrial accidents, discloses that the main cause has so often been the failure of the human element; failure through ignorance, thoughtlessness, lack of consideration for others, breaking of rules or the disregard of the law.

Putting it bluntly, incidents, or accidents as we all call them, of this kind should never have happened and are totally unnecessary—yet with us they amount to no less than 80 per cent of all accidents.

I believe that most accidents are preventable; the arch enemy of prevention is that attitude of mind that says "it couldn't happen to me." People who think like that are really going about with their eyes shut deceiving themselves into thinking that it is always the other fellow who meets trouble and they themselves need not worry.

The safety worker's weapons are those of education, enforcement and engineering. There are no short cuts to any safety programs. Steady and persistent persuasion, allied to the enthusiasm and energy of the safety worker, will produce results despite the minor set-backs and apathy which he so often meets.

THREE E'S OF PREVENTION

There is no doubt about what the three E's of accident prevention can accomplish if given a chance, but though each of the three can individually accomplish a great deal, they can do far more if they are working continually and in the closest possible co-operation. At home, my Society, generally speaking, confines itself to education and all that that implies, but it doesn't believe in working in a watertight compartment so it maintains close liaison and co-operation with those responsible for enforcement and engineering. May I add that we also believe in a fourth E—Enthusiasm—and a good supply of that is essential.

Reduced to its simplest terms, we believe that the actual implementation of a safety program in any field must be undertaken locally. The local safety worker knows best the local conditions and can add the necessary local color to a national safety program. My Society, in conjunction with the appropriate Government departments, selects the campaign theme and produces and makes available for the local workers the necessary material, posters and leaflets. Special national campaigns are imposed, as thought fit, on top of the steady, all-the-year-round work. These may be of anything from a week to three months' duration.

We have found that by this method central planning goes far to ensure that at the appropriate and same time, all over the country, a simultaneous attack is launched locally using the same material and all directed to one particular and identical aspect of accident prevention. By this means we consider that we have achieved maximum penetration of the public mind. In this we get great help from the press and radio.

MORE MONEY REQUIRED

Before I get tied up with figures and statistics, I want to deal briefly with that other ever-present problem—finance. May I say at once that we never seem to have enough! I think it is really true to a considerable extent that safety can be bought—and it is just because we feel we would like some more safety that we wish we had more money with which to buy it.

In financial matters my Society does work in watertight compartments; each activity, road, home, industrial, agricultural safety is financially separate and funds obtained for one activity or branch of our work are not

available for another. We rely on subscriptions for our income. These come from a variety of sources: local authorities, industrial firms, transport organizations, insurance interests etc. It is only in the field of road safety that we receive a government grant.

To give you some idea of our task we have in Great Britain a population of just 50 million who own some seven million vehicles which they use on about 200,000 miles of roads which were not built for them. Of our population of 50 million there are on the average 11 million employed in those industries which come under our Factories Act and with which my Society is concerned.

FATAL ACCIDENT STATISTICS

On an average in Great Britain 80 people die as a result of some accident every day

(17 in some form of transit)
- 15 on the roads
- 1 on railways
- 1 in air & water transport

(5 in place of work)
- 2 in factories
- 1 in coalmines
- 2 in farms & quarries

- 7 miscellaneous, e.g. drownings, sports, falls
- 21 in the home

The annual toll of accidents averages 700 killed, and injuries to between 180,000 and 190,000. Machinery accidents are much in the minority, only about 16 per cent; the remainder are human failure or error accidents and include falling, handling of materials, being struck by a falling object or tripping over things.

Poor housekeeping is certainly a contributory factor. There is at present an annual increase in transportation accidents within the factory perimeter due to the fact that in many cases the internal traffic system was not designed for power trucks, fork lift trucks or mobile cranes.

Safety standards in industry are fixed by Parliament by means of the Factories Act which is implemented by the Factory Inspectorate. We regard this official standard as the bare minimum and use it as the base from which springs the voluntary accident prevention work sponsored by my Society.

We believe that safety in industry must be the concern of all from top management all the way down the line to the man on the shop floor. A good safety record should be the concern and pride of employer and employee alike. The safety officer is not an executive; his duties are advisory. He should be brought into the first planning stages of the design of a new factory or the expansion or alteration of an existing one.

Safety should be an integral part of any training program for new entry. There is no sense in spending money on a new machine and only training the operator how to use it; it is equally essential to train the operator how to use it safely, if only because an accident to the operator may well cost the employer more than the cost of any damage done to the machine.

SOCIETY'S SAFETY COURSES

My Society holds residential 14 day courses for safety officers and has taken great pride in fathering the birth of the new sturdy institution of industrial safety officers. To retain contact and encourage the vital interchange of safety ideas and experience we have now industrial safety groups operating in all the main industrial areas. The Society produces a technical safety journal *(The British Journal of Industrial Safety)* and an Industrial Accident Prevention Bulletin, together with a series of safety codes and propaganda material.

We plan and initiate an annual campaign, obtaining locally the cooperation of our industrial members and their safety officers, of local civic heads and of chambers of trade and commerce. These campaigns are usually for a week or 10 days; we completed our 1957 special campaign just before I left home, with the theme "Guard Your Hands."

Our annual road fatalities are about 5,250 and the injuries 250,000. I must add that according to the International Road Federation we have a vehicle per road mile density of nearly 21 against your 17, and that does not include the large number of motorcycles (more than 1,250,000).

We take pride that the continuous campaign (1) is holding these figures despite more vehicles on our roads and on increasing population at risk; (2) has reduced the annual fatalities from 7,000 at which figure they were running 25 years ago; and (3) has over the same period reduced child deaths from five a day to less than two.

HUMAN FAILURE

As in industry, an examination of road accidents shows that some 80 per cent should never have happened. They are due to a human breakdown such as ignorance, showing off, breaking the law, drink and lack of courtesy to others. It is a strange reflection on the human character that everyone always claims to be a good driver

If I asked whoever was driving me if he was really competent, that individual would be most insulted! On the other hand, if I asked someone, a stranger, to play golf he would most likely say he probably wouldn't be good enough, in fact he would not claim to be a plus player—but he thinks himself plus in the driving seat

We believe most sincerely in road safety education from the moment the child goes to school at about five years old. A start is made with the Kerb Drill (how to cross a road) and progresses to cycle training and a proficiency test. Through motorcycle clubs we are trying to teach and train the young motor cyclist. In all this we have the most excellent help of police and teachers.

I believe the child cyclist and the young motorcyclist are greater problems with us than with you. We are most anxious to carry on this progressive training so that the young teenager can be properly taught how to drive. If the next generation is properly trained in road sense, and taught to be defensive drivers, surely they will be better and safer road users than our own generation which did not have such good start.

PLANS CAMPAIGNS

Campaign planning and the production and provision of the necessary material is my Society's job. The actual campaign is carried out locally by the Road Safety committee of local authorities who in many cases employ a road safety officer who comes to our training courses. The government subsidizes approved road safety programs of local authorities to the extent of 50 per cent. I must emphasize that I am referring to the educational aspect, training and propaganda.

The Society, in collaboration with the Ministry of Transport, selects an annual campaign theme. This we break down into quarterly periods for which we issue an appropriate planning guide containing sample materials and suggested plans for local campaigns. On top of this we produce a special Christmas pack and material for the bank holidays at Easter, Whitsun and in August. It is a sad commentary on our civilization that holidays should mean more accidents and that Christmas Eve should be our worst day of the year.

At RoSPA House, in the center of London, we maintain our permanent Road Safety Training Center and Exhibition. With its staff of instructors, this center, by the use of all the visual aids, gives instruction which can be modified to interest children and experts.

OLD, YOUNG FATALITIES

Though faced with some 8,000 or more fatalities a year and an unknown number of injuries, this side of our work is the most backward and meets the greatest apathy, though I am glad to be able to add that it is really moving forward a little now. The victims are predominantly the old people and the under five's. The principal causes, so often due to carelessness, ignorance or thoughtlessness, are falls in the case of the old, and suffocation, burns and scalds in the case of the young.

Slowly but surely we are setting up local committees which will put in action what is really a major educational campaign. We enlist the help of medical officers of health, district nurses, health visitors, clinics and indeed, every kind of women's organization which we can interest.

My Society produces the educational and propaganda material for local committees to use and we are now issuing a regular quarterly planning guide.

Our own home provides us each with our own background. What happens in it affects our attitude and frame of mind, not only when going to and from our place of work but also when at work. If we could really get to the bottom of every accident we might well find that some minor accident at home

had set off a chain of reactions which became the primary cause of our accident on the road or at work.

NOT CLOSED SHOP

The moral is, I suggest, that accident prevention is not a closed shop and that there must be a real overlap when dealing with the different kinds of safety work.

From a close study of your Congress program, from the titles of the many interesting papers and addresses that will be given, even more so from noting just who your speakers are and what they do, I am convinced that our problems are similar to yours. I have come here to learn and to take new ideas back home with me. We are happy that in Great Britain we are assured of the closest possible contact and co-operation with your Air Force units stationed on our Island; we believe in an interchange of ideas and methods.

It was for that reason that we were so glad to have Mr. Ned Dearborn with us at our annual Congress. I am both proud and delighted to be here as the representative of my Society and would like to say here and now a most sincere thank you to you all and to wish you a most successful Congress.

ANNUAL BANQUET

BANQUET ADDRESS

by HONORABLE WILLIAM G. STRATTON
Governor of the State of Illinois

The opportunity to talk to this meeting tonight is one I have been anticipating for some weeks. It is good to be here in this atmosphere of dedication to a cause most important to every American—the cause of safety on our highways.

I am certain you know the intense interest the national Governors' conference has in this subject, and I bring you the greetings and best wishes of that conference, along with the welcome of the people of Illinois to your congress.

It would be encouraging if we could talk of nothing but progress in the drive to end the killings on our streets and highways. It would, however, be shortsighted indeed, even tragic, if we accepted what we have done with a complacent pat on the back, and said it is enough.

It is far from enough—remotely far from enough.

TOUGHER LAW, ENFORCEMENT

Here in Illinois in 1957 we took giant steps toward reducing the highway toll—through new and tougher laws, through heavy increases in our police force, through advanced planning for the education of younger drivers, and through better local enforcement.

It is true we did this, and it is true it seems to be having a salutary effect, but it is not enough.

In most of our other states the subject of traffic safety received close legislative and administrative scrutiny, and progress was made, to be sure—but it wasn't enough.

Truly, 1957 has been a year of action on the safety front, but our figures and our studies show it is still not enough.

Thus we must not talk of success, but of what must be done in the future. We must talk of the tremendous job ahead—the challenge facing all of us here and all people in this rapidly expanding, constantly motorized, economy.

I conducted a conference with department and agency heads who direct various phases of the traffic safety program here in Illinois. Representatives of the National Safety Council sat with us in the meeting. We discussed, analyzed, and dissected what we are doing to reduce traffic toll in human loss and economic cost.

We learned we are making progress, that things are moving ahead in this war for safety, that results to date have been good, as has been pointed out here tonight.

MUST INCREASE ATTACK

We learned something more important, however. We learned that what we have done is not enough, that much, much, remains to be done, that the attack must truly be stepped up. We left that meeting, I am convinced, with new drive and desire to accomplish our goal—the reduction of traffic toll to the irreducible minimum—and with the conviction that it can be done quickly.

Then a few days later we opened our newspapers to read the sickening news that five teen-age boys had died in one instant on a road in northern Illinois. We learned that they died in the shattering crash of a car which a second before had been going 100 miles an hour.

Any satisfaction we had experienced, those of us in that conference, was wiped out in that tragic instant. Some way, for some reason, this message of safety had not sifted through to the boy who was driving that car, or to his companions.

Certainly, we are making progress, but our new laws, our added police, our inven-

tories, our expensive advertising campaigns, missed the mark in that case, and five were dead.

We missed the mark. So it is that we should not talk of success, but of what is wrong. Where is our failure? Why are we not getting through to all the people this crucial message of traffic safety?

I note that your programs in this congress have sought some of the answers to that question, and I believe sincerely the solution to the problem lies among you here tonight. You are the persons who have the know-how for action.

Your firms daily call upon the boundless energy of American ingenuity to operate this nation's business and industry. If we can channel your knowledge, your experience, and your enthusiasm, into the field of traffic safety, the greatest killer and crippler in our time would be well down the road to defeat.

We need your help. Government and law can go only so far. Public support—(and the support we have received in Illinois is one of the most gratifying aspects of our safety program)—can do only so much. This emergency calls for skill, for adroit and effective appeal to the individual driver's conscience.

It is one of the most perplexing human behavior problems facing our states today. We can set speed limits, and we have done so in Illinois. We can enforce those limits, and we are doing so.

ILLINOIS' EFFORTS

We can enact stringent driver license requirements, with strong penalties, and enforce them—and we are doing that in Illinois. We can appeal through our media for support, cooperation, and caution, and we are doing that. We can exhibit the horror of auto tragedy, attempt to frighten dangerous people into sanity on the road. But it is not enough. The bitter fact is—it is not enough.

We need something further to produce a better driver, a more aware driver. We must make our drivers alert to the constant danger, the continual hazard they face when they sit behind the wheel. We must do this in the field of engineering, through the effective employment of the knowledge gained from our social scientists.

We must divert to our use the skill and techniques of modern marketing, to sell our product—safe driving.

Much attention has been given of late to the powers of persuasion which marks modern advertising techniques in creating expanding markets. The key to the effort, in many keen advertising minds, is to obtain the knowledge of what motivates people, and how their behavior can be changed by changing the motivational forces working upon them. The use of this mass psychoanalysis to guide campaigns of persuasion has become the basis of a multi-million dollar industry.

NEED MOTIVATIONAL RESEARCH

What these advertising people are learning about us could be useful in the field of traffic safety. Perhaps our answer is to have the motivational research specialists turn their attention to our problem.

A basic theory advanced by these subconscious salesmen in their work is the building of images that should arise before a person's inner eye at the mere mention of a product's name. The images the experts attempt to build into these products resemble something in the person's general make-up—a quality or trait to be admired—an expression of one's achievements.

Perhaps one of the most spectacularly successful image building performances has been that of the automobile industry.

The automobile has become more than only a method of transportation. It now tells people who we are, or who we want to be. One man said, "It is a portable symbol of our personality and our position." One research report even went so far as to place certain brands and colors of cars in buyer personality groups.

If this research is effective in telling manufacturers who are buying their cars, and why, it is quite possible that the same kind of research might tell us what quirks among the purchasers of automobiles lead to traffic violation and accident. Certainly there is potentiality of this modern advertising technique developing into an important tool for our purpose.

Like the hucksters, to be successful we must sell safety much the same way they sell soap, toothpaste, and automobiles. We are competing for the attention of the American public in a busy world. Even though we have finally sold the idea that a license to drive is a privilege and not a right, much remains to be done to create an improved climate for traffic safety through improved salesmanship.

We must search again to create in the mind of the public the proper image or symbol to associate accident prevention and traffic safety with all that is good and necessary. We must probe to find what the symbol is, and we need scientific knowledge and help to do it.

Some of your discussions here have posed this same possibility in the field of home safety, but accident proneness is not limited to step ladders.

We know now that constant hammering at the fact a person might be killed or maimed in an automobile accident is not a powerful enough deterrent to irresponsible driving. We must revamp our approach. We must find or create a more meaningful symbol than death to drive our point home.

Loneliness, scientists tell us, is perhaps the most unbearable of human emotions. Perhaps this is the peg for traffic safety in our advertising and educational efforts.

IS IT WORTH IT?

Imagine the loneliness and despair of a wife who loses her husband in a traffic accident, or of a man who is hopelessly confined to bed as he continues to relive the horror of highway tragedy and brood on the emptiness he must face because his family was slaughtered in an accident of his making.

We know so little, really, about people and why they are involved in accidents. We list surface reasons—excessive speed, for example—but we don't know why the driver was speeding in the first place. We need to know with certainty what prompts that driver to fly in the teeth of disaster, and how we can reach him in time to prevent it.

I propose that the leaders in motivational research conduct extensive studies to depth probe the underlying reasons for some persons' irresponsible action on the streets and highways of this nation. What we learn from them would be extremely valuable in developing an effective educational campaign on matters of traffic safety needs and progress.

It is encouraging to note that Northwestern university at Evanston recently announced the inauguration of a three year research program in which the social scientists will assist in a study to determine the nature and causes of traffic accidents.

While this is being carried out, we on the official side of the traffic accident prevention picture will do whatever is in our power to carry out the recommendations for state and local government improvement.

MOVEMENT NEEDS LEADERS

We must, however, look to you—the leaders in industry and business—to provide our states and municipalities with the citizen support so necessary to conduct an effective and continuing program for life saving action. We will improve our engineering, our enforcement, and the education of drivers. You must back us, and I know you will.

We long ago passed the point where traffic safety was considered only an official duty, with no role for the citizen other than passive acceptance of laws and regulations. All of us now realize the importance, the vital importance, of public support through acceptance of the laws and regulations, and the value of the backing of public spirited organizations such as those which have made such marked inroads on traffic deaths here in the city of Chicago.

Business and industry can provide the sinews for that support. We seek from you that strength, and I do not believe I am presumptuous if I point out that it is to your best interests, to back this attack.

A recent study by the Citizens Traffic Safety Board of Metropolitan Chicago showed more employee time is lost to Chicago's industries through traffic accidents and traffic law violations than from any other single cause, with the possible exception of the common cold.

ACCIDENT FACTS

Lost time means lost money and reduced production. Industrial safety people are well aware of this. Their work was a direct outgrowth of management's desire to reduce on-the-job lost time accidents. How well that work has progressed and how successful industrial safety has been, is graphically presented in one of the National Safety Council's publications called *Accident Facts*.

The Council has compiled no-injury records in 36 different industrial classifications ranging from chemical to mining, from iron and steel products to meat packing . . . totalling millions of man hours without accident. It is a sad commentary on the ability of America's driving public to compare a record of one person seriously injured or killed about every 30 seconds on roads and streets, against this record of millions of injury-free industrial man-hours.

The study I referred to earlier also revealed that although traffic accidents and violations account for a big share of the absentee problem in industry, traffic safety education ran a poor second or third to other company-conducted off-the-job accident prevention education . . . and lags far behind industrial safety programs in emphasis and expenditure.

If all of you will go back to your companies armed with the knowledge that industry can reduce its absentee problem by taking a greater interest in community traffic accident prevention programs, then this nation will see the greatest strides in traffic safety improvement we have ever known.

ILLINOIS ENFORCEMENT

Traffic safety training in industry will pay dividends, not only to industry itself, but to all the public. Consider this when you return to your firms. I do not expect, incidentally, any company to become as strict in this matter as we have in the state of Illinois government. I have issued orders to my department heads that willful violation of traffic codes on the part of any employee is grounds for dismissal, and this order has been incorporated as part of our personnel regulations.

Needless to say I find fewer state-owned vehicles passing my car on the roads of Illinois than in the past.

I want to avoid technical discussion of the various facets of traffic safety solution. As I have emphasized, we have reached the stage where we must go into the theoretical aspects of traffic safety to brace up the accepted techniques of engineering, enforcement, and education.

I know, however, this group is interested in the work the governors' conference is doing in this matter. This month, our staff is forwarding to the president's committee for traffic safety a series of studies for its consideration. These studies include the concept of intergovernmental cooperation, the reporting and filing of accident records, the stress on coordinating meetings such as the one I mentioned earlier, a study of laws and ordinances, and the general problem of traffic information.

This fight is going forward on all fronts of government, from the president down to the local law enforcement agency. It must continue, because we are a growing nation. Our employment is growing; our wealth is increasing; our knowledge is expanding.

That expanding knowledge has given us an apparent answer to the dread disease of polio. It has apparently conquered tuberculosis. Pneumonia is no longer a certain killer. Smallpox is virtually a forgotten disease.

We know these advances have been made, because the rates of incidence, and of fatalities, are down. Mind you, the rates are down, in the face of expanding populations. *That is the criterion we must use in assessing our success or failure in the traffic safety fight.*

Let us look at the traffic situation in the light of that criterion. Here the numbers of deaths nationwide are increasing. That in itself might not be a bad trend in the face of booming mileages and increased numbers of vehicles. But the tragic fact is the rate is not decreasing. The death rate, after a few years of heartening decline, appears to have levelled off.

MUST PROTECT AMERICA'S SAFETY

In our race to launch satellites, to create new machines for war and for peace, we must not lose sight of the duty to protect the health and safety and welfare here at home. Only the Almighty knows what potential for scientific progress, cultural advancement, for the good of all, was snuffed out when five boys died at 100 miles an hour. We must find the way to stop this killing.

Personally, it is my determination to maintain Illinois in a position of leadership in this program. Everything on an official level will be employed—strict enforcement of sound law; education; better highways; total use of all our resources.

This we can do, but it is not enough. If we could spark in each motorist the intense interest and desire to save lives which pervades this room tonight—if we could transmit to all the zeal which marks the National Safety Council . . . there would be no traffic safety problem. I thank you, the workers and members of the council, for your help and for the programs you have devised, but I remind you that the success of your programs—and mine—rests with our ability to sell those programs to all the people. We have only partially succeeded.

Our sense of achievement must be tempered by realization of areas of failure. We fail when there is one needless injury, when one careless accident destroys our resources, either human or economic.

I know we have the overwhelming majority of the public backing us in this fight. It is up to us—in government, in civic groups, in business and industry—to justify that faith.▲

AWARD PRESENTATION

by PAUL G. HOFFMAN

chairman of the board, Hoffman Specialty Mfg. corp., Indianapolis, Ind.

(former president and director, Ford Foundation)

The annual Safety Congress has long been a Mecca for the safety leaders not only of the United States but of many other lands. This year is no exception. The presentation of this new highway safety award could not have a more appropriate setting, or a more sympathetic audience than the guests assembled here at this banquet. I am delighted that you can all join me in paying tribute not only to this year's winner, but through him to all the dedicated men and women who make their careers in highway safety.

In my many years of association with the safety movement, I felt that the amateurs in *this field have always received ample recog*nition, but the professionals far too little. It is the day-by-day work of these career people, with their know-how and steady application, that has been responsible for the substantial reduction in the accident rate.

Being of this mind, I was happy that there was a Beecroft Award in other years to honor such great professionals as Commissioner MacDonald of the Bureau of Public Roads, Chief Justice Vanderbilt, Sidney Williams, Frank Kreml, Ame Neyhart and others. It was men of this caliber *who shaped the course of the traffic safety* movement as we know it.

It was men like Williams and Kreml who said from the first that there could be no *simple remedy for traffic accidents—that* only a balanced program of education, enforcement and engineering could cope with a problem which is as complex and dynamic as traffic itself. As against a quest for magic panaceas, they urged the development of scientifically trained specialists. They counseled—and helped to chart—rational measures solidly based on facts.

REQUIRES BALANCED PROGRAM

Of course the concept calling for technical direction of the safety program by experts does not in any way exclude the amateur—the volunteer. On the contrary, the support of laymen individually and in the mass is imperative. Without the backing of an informed public, even the best-laid official plans are futile. Volunteers must assist the duly constituted authorities charged with the responsibility for doing the job.

Acceptance of this philosophy, for instance, led the automobile industry in 1937 to create the Automotive Safety Foundation, an organization which I had the privilege of heading for several years.

Later reinforced by other industries, the Foundation regularly has made grants of

funds available for the professional training of enforcement, engineering and other specialists, as well as for research. It also has provided funds or staff services, to a number of great national organizations active in this field, in the interests of a more coordinated effort.

HIGHWAY SAFETY GROUPS

The cooperative work of many official and volunteer groups resulted in the formulation of the Standard Highway safety program for states, embodying the general principles I have mentioned. Out of this subsequently evolved the Action Program of the President's Highway Safety Conference—now the recognized charter for traffic accident prevention in America.

The record shows unequivocally that we are on the right track. It proves that the rational, not the emotional, approach to highway safety pays off. In 1935—the year that J. C. Furnas tossed a bomb into the nation's complacency with his sensational article about traffic accidents, titled "And Sudden Death"—the national fatality rate stood at 15.9 deaths per 100 million vehicle miles. Last year the rate was only 6.4, a decrease of 60 per cent.

The organized safety effort the past 20 years has saved 500,000 lives, prevented 17 million injuries and curtailed economic losses by approximately $45 billion.

We should do even better in the future. For one thing, the Federal-aid Highway Act of 1956 offers an opportunity to bring into full play the Engineering E of the basic Three E's of safety. Heretofore, as we all know, ability to get the most out of this phase has been severely limited by lack of funds for roadbuilding. The experts predict that completion of the Interstate System alone will save 3,500 lives a year.

FUTURE'S ENCOURAGING

We may also assume added impetus the next few years from expanded research, from stepped-up professional training in our colleges and universities, from extension of high school driver education and adult safety education, from better licensing procedures, from refinement of selective enforcement and upgrading of traffic courts. We can expect, too, a constant broadening and deepening of organized public support.

Granting these plausible assumptions, there is no logical reason why the fatality rate cannot be pushed down to three within the next 15 years. This rate already has been reached or approached by more than one state. The public interest, the welfare of all of us, demands that all the states try to achieve this goal. I am convinced they can—given, on the one hand, the necessary determination; and on the other, the benefit of the knowledge and zeal of such professional leaders as the one we salute here tonight.

The recipient of the 1957 Award was chosen by an able board of judges: General Alfred M. Gruenther, president, American Red Cross; Dr. John A. Hannah, president, Michigan State University; Mrs. R. I. C. Prout, president, General Federation of Women's Clubs; and W. Earl Hall, editor, Mason City (Iowa) *Globe-Gazette*.

Theirs was no easy task. Almost without exception, the many candidates nominated for the Award are individuals of stature and high professional attainment in their respective fields. From among them the judges selected one of the foremost safety educators of our time, a great planner and organizer for the dissemination of safety knowledge, the man who headed New York University's famed Center for Safety Education from its inception in 1938 until his retirement from the post last month—Dr. Herbert J. Stack.

DR. STACK'S ACHIEVEMENTS

Citing Dr. Stack's great contributions to the cause of highway safety is doubtless superfluous, since most of them are already known to everyone. I limit myself, therefore, to just a few highlights.

More than 11,000 persons trained under his direction at the Center are now serving as leaders and teachers in colleges and universities, in elementary and secondary education, in commercial and industrial organizations devoted to safety, in commercial fleets, in governmental agencies, national, state and local safety groups and private safety organizations.

He has been instrumental in setting up teachers' institutes and special safety programs in numerous colleges throughout the country; and has helped to organize state safety education programs in many states.

He has written or edited more than 100 books and articles on safety education, some of them widely used as text material. He has guided significant research in such vital areas as driver behavior.

No less important have been his indefatigable efforts in behalf of teamwork in the attack on accidents and other traffic problems. For five years Dr. Stack has served on the Board of Directors of the National Safety Council. He has always stood for the closest possible coordination of safety education with the other basic disciplines and activities. In this role, he has been a pillar of strength in the organized safety movement of America for a quarter of a century.

Fortunately his period of service to safety is by no means at an end. He remains as chairman of the Department of Safety Education at the Center and as program associate will continue to supervise its research program. He will also continue as consultant and faithful co-worker with many major groups enlisted in highway safety.

It gives me great pleasure to present this plaque, symbol of the first annual Paul Gray Hoffman Award for outstanding professional services to highway safety, to Dr. Herbert J. Stack.

WOMEN'S ACTIVITIES

OUR ROLE IN SAFETY LEADERSHIP

Outline of Introductory Remarks

by MRS. RAYMOND SAYRE

vice chairman, Women's Activities Conference, N. S. C., Ackworth, Iowa

Our role is to promote effective safety programs. Traffic problems do not have genders.

1. What we can do through our organizations (not specific activities but general principles)
   a. Determine projects on the basis of greatest need after studying your local inventory or making a local survey.
   b. Be sure the safety activities of your group are tied into the overall balanced program for safety being carried on by official and other voluntary groups.
   c. Help build a strong local safety organization or work in one already established and give assistance to its program. (not money—but voluntary leaders and workers)
   d. Make all possible use of services available to you— highway safety department, National Safety Council, Extension Service, governor, mayor, and police department.
   e. Do everything possible to train yourself and your leaders to be qualified in the field of safety.
      (1) Understand all of the problems
      (2) Know your own laws relating to safety
      (3) Know services that are available
      (4) Know solutions that are effective so you can be for something (driver training)
      (5) Know how to measure what you have against accepted standards (Inventory—Uniform Code)
2. What you can do as individuals
   a. *Citizens*—Support law enforcement
      Support needed legislation
      Support community programs for safety (go to meetings)
   b. Accept positions of leadership
      (1) Be a leader who can be counted on
      (2) Be a trained leader
      (3) Be an enthusiastic leader—the job can be *done!*
      (4) Be a leader who is willing to work—even though you do not always get credit
   c. As creators of attitudes
      (1) In the community (citizens)
      (2) In the home (training of children)
   d. Safety problems, basically, have moral and *spiritual* values
      (1) Life is precious
      (2) We have a duty to others as well as ourselves—"We are our brother's keepers" "Watch out for the one behind you"

TIME FOR DECISION

by **WILLIAM G. JOHNSON**
assistant general manager for programs, National Safety Council, Chicago

The traffic situation today is a product of what was done and what was not done yesterday.

During the past 30 years agencies of the national accident prevention movement working with public officials and civic leaders, have developed a balanced comprehensive program which, when applied with reasonable vigor and intelligence, has produced marked reductions in traffic fatality and injury incidence.

The program agreed upon and reduced to writing, began with the Hoover Conference of the early '20s and has continued through White House Conferences and other meetings. It is represented by such books as the Action Program and Regional Conference workbook of the President's Committee for Traffic Safety, a Business Advisory Panel brochure on state organization, and the excellent report prepared last year by the Governors' Conference.

The immediate problem has gradually become one of applying known principles. We stress a balanced application of a comprehensive program because the general public seeks panaceas.

If three-fourths of the cities and states had applied these principles as well as the one-fourth with the best records, accidents in 1956 would have been one-third fewer, and not even those best cities and states fully applied the program.

REDUCED DEATH RATE

Results were achieved even though application has lagged behind the growth of the basic problems of increased population, car registrations, and travel.

From 1925 to 1940 the national death rate per one hundred million miles of travel was reduced 36 per cent and available data indicate that the non-fatal injury and property damage accident rate also declined. During that period motor vehicle travel was steadily increasing—it almost tripled. As mileage went up and the death rate remained constant traffic deaths rose steadily. The first major break in the traffic death toll occurred when the motor vehicle death rate took a sharp drop shortly after 1935. It was at that time, through the Automotive Safety Foundation and other agencies, that the first real impetus was given to the application of recognized programs.

From 1946 until 1954 the national death rate dropped another 36 per cent, but available data indicate personal injury and property damage incidence rates did not parallel the decrease in death rates. We see mileage rising sharply—mileage almost doubled from 1946 to 1954. The death rate had shown a sharp drop in the early part of the post-war period, and deaths remained about constant. Then as the death rate leveled off, deaths began to rise, almost keeping pace with travel. I re-emphasize that the non-fatal accidents which account for 97 per cent of accident-cost did not parellel this death rate decrease. Non-fatal accidents were rising.

NEED MORE PREVENTION WORK

Detailed program reports made as a part of the Annual Inventory of Traffic Safety Activities and other inventories reflected increased application of standard programs, but not at the same rate of growth as vehicle use and population. Thus, the additional prevention work needed has steadily increased. For example, 1953, data would be reported and analyzed in 1954; then perhaps in 1955 approximately one-third of these increased programs needed would be authorized by the state legislature or the city council.

The result, in 1955, we were no better off than we had been in 1953, and by 1956, with travel still rising, we were somewhat behind where we had been. However, reductions in accidents have continued to be reported from states and cities which have applied the balanced comprehensive program with sufficient strength to control a growing problem.

Today enough is known about traffic accident prevention so that reasonable attainable application of the program can cut accidents in half. And we emphasize that we are talking about reasonable and attainable application of the program, not about an utopia. Reasonable, attainable application can cut traffic accidents in half.

Yet traffic accidents hit an all-time high in 1956. Forty thousand dead, one million four hundred thousand injured, ten million accidents, and four and three-quarters billion dollars lost. Accident rates rose in 1955 and stayed up in 1956. That's the first such two-year set back since 1941. Travel has almost doubled in 10 years. Accident prevention programs are being swamped by the cumulative effects of more and more people, more vehicles and more travel.

THE PREVENTION PROGRAM

What is the action program? What are these standard programs? What are the objectives of the program? Let me read them.

Sound uniform laws—the responsible agencies are legislators and city councils.

Adequate accident reports used to guide programs— official record bureaus.

Good instruction for children and youth—in the schools.

Traffic supervision and firm enforcement—by the police.

Dispense justice and create respect for law—the courts.

I hardly need point out that objective has sweeping implications for many of our other social problems.

Strict requirements for obtaining and retaining driving privileges—license authorities.

Increased safety of existing roads and streets, through engineering, and construction of additional streets and highways to carry traffic safely—objectives of street and highway departments.

Vehicles progressively easier to operate safely and minimizing injury potential—the manufacturers.

Vehicles maintained in safe operating condition—inspection authorities.

Citizens, two objectives: informed and safety minded, and supporting accident prevention — the agencies: the media — press, radio, and TV; citizen groups such as service clubs, veterans organizations, PTA, Chambers of Commerce and safety organizations.

Last but far from least, coordination of state and local programs—the people responsible: governors, mayors, county officials, and citizen leaders.

NEEDS BED-ROCK SUPPORT

We emphasize a balanced program, with a structure which somebody said is several thousands of years old. Perhaps balance and soundness kept it standing. It's a structure to support our objective of good traffic—good traffic which is safe, smooth, and economical. We show the elements of that program—roads, traffic engineering, vehicle, public education, school, driver licensing, police, courts, accident records supporting the whole program, a foundation of sound laws, and all this tied together by teamwork and leadership. But you see that the structure would not stand up, it would not be substantial, unless it was on a bed-rock of citizen support.

How does our structure stand? The state accident prevention activities for 1955, and the results for 1956 are not much different: in the status of preventive activities, the average performance of 47 states was 66 per cent of the minimum program. I emphasize the minimum program. The average performance of 875 cities with more than 10,000 population was 50 per cent of the minimum program.

Now let's look at some of these elements in terms of our balanced structure.

HIGHWAYS, ROADS

From 1946 to 1956 we did not build enough additional roads to park the additional cars we were operating. Now, as a matter of national policy, we have created the Federal Highway program on an expanded basis to take care of the interstate road system. If we are alert to preserve against certain pressures the safety features, such as planned access, on that interstate road system, we will get substantial safety benefits. What about the cities which have lagged behind? Are they going to plan on that same basis to handle tomorrow's traffic?

What about the existing roads and streets? Traffic engineering on those is woefully inadequate. We do not have enough manpower to study the high accident locations. We do not have the budgets to

correct those locations after the studies are made. We do not have sufficient state staffs to give the proper assistance, the kind of assistance they need, to small communities.

The vehicle. Today we have a vehicle which is extremely easy to drive safely. Unfortunately, it is also extremely easy to drive dangerously. Until recently we felt that the automobile advertising programs would encourage the use of this potential in an unsafe way. The recent change in advertising policy of the motor vehicle manufacturers is a tremendous step forward. We do need to make additional progress in designing vehicles which minimize injury potential.

ADEQUATE ENFORCEMENT LACKING

Public education. We know that the quantity's enough—you hear enough, and read enough in all of the media—but what about the quality? Is this information effective in preventing accidents? Do we know enough about working with groups? I think not. We have a lot of enthusiasm in groups, such as the service clubs and veterans organizations, but how do we use that enthusiasm?

Elementary education is pretty good. Driver education in the secondary schools is woefully inadequate. Last year we trained approximately one-third of the eligible students in driver training. Safety in the colleges and universities? In many respects, this is just getting started.

Driver licensing. Examinations are good in some states, poor and inadequate in others. Driver improvement programs—calling in drivers for corrective treatment when their records so indicate—do not have enough manpower to study the records, to work correctively with drivers, and do not have a firm enough attitude on enforcement to take off the road the incompetent, unwilling driver, who will not drive safely.

The police. Inadequate manpower, inadequate training and administrative practices leave much to be desired.

Courts. Do we give dispense justice? I think not. Are the courts conducted with dignity, or do we still have the horse and buggy justice of the JP system prevelant throughout much of the country? Do we have integrated administration of state courts from the supreme court down? No, in most states.

Accident records. We do not have spot maps necessary to diagnose the trouble spots; we do not have the location files necessary to study them; and we do not have the manpower to use the records we do have.

Laws. We have non-standard hand signals; we have differences in rules of the road; and we have wide differences in attitudes on speed.

Teamwork and leadership tie this thing together. Often these are not even recognized as necessary ingredients of a program. And when they are recognized, often the tremendous trifles, the details of getting that teamwork and leadership are not recognized.

What about the foundation of citizen support? Unorganized. In many cases it has inadequate leadership, poor direction, and faulty technical information. Often we throw away our books and settle for supposedly cheap panaceas, special campaigns, shortcuts, and gimmicks. I wish I could tell you that there was a cheap panacea for this problem, but there isn't, and we must all recognize the need for a fully balanced, comprehensive and adequate program.

Now that we've marked up our current status, it's a pretty "ratty" looking structure. No wonder it won't support our objective of good traffic.

TOMORROW'S FORECAST

What about tomorrow? This nation will continue to grow: by 1966 one hundred ninety three million people, up 17 per cent; ninety million drivers, up 25 per cent; eighty two million cars, up 34 per cent; eight hundred twenty five billion vehicle miles of travel, up 47 per cent. It is anticipated that growth in travel will be the same in the next 10 years as in the last 10. If accident rates continue unchanged, 54,000 people will die in 1966, one million nine hundred thousand or more will be injured and 6.3 billion dollars will be lost.

In fact, the situation is becoming progressively worse. Rates will continue to rise, accidents will skyrocket if prevention programs lag behind travel. The results will be deaths, injuries, damage, congestion and a stunted economy—not only because of the accident and congestion waste, but because motor vehicle travel limitations impose a limit on economic growth itself.

What are we going to do? One element of the balanced safety program— building new roads and streets—will be doubled, comparing the past with the future. What about the other elements of the comprehensive program?—Laws which have been substandard—are we going to have sound, uniform laws? Uses of accident records.

INCREASE DRIVER TRAINING

Youth education—One-third of the students eligible for driver education in high schools were trained last year. We know that every youngster today for all practical purposes is going to drive a car. How long are we going to wait until we give those drivers the training that they need? At the present rate of progress it will be 1985 before we are training 100 per cent of the drivers in the schools. Can we wait that long?

Police supervision. I emphasize first that we are not just talking about more. We are also talking about better enforcement. We are talking about the non-fixed ticket. We are talking about selective enforcement at the times and places where violations cause accidents.

Court effectiveness. Will we have an integrated court system in each state comparable with the fine system in New Jersey?

Other areas of improvement are:

Driver licensing
Engineering on existing streets
Vehicle design
Vehicle maintenance

Public education. Will we have research work to give us the information we need to make better use of group enthusiasms? Will we have better aim in our public education program?

What are we going to do? What now? There is an alternative to these hard facts. It is federal control of traffic. The American people have exported to the national government many of their problems which were not solved at the local and state level. There have been rumblings in that direction already. The Roberts committee of the House of Representatives was told by many witnesses that the federal government ought to take federal driver licensing authority on the interstate highway system.

Fortunately, in our view, the Roberts committee does not see it the same way. But how long can that go on? How long can the states and the communities fail to live up to their responsibilities and still expect the federal government to stay out? The people will ask the federal government to come in I'm afraid.

The answers to these questions rest with citizen leaders who will help build public support for these official measures and will help imbue each driver and pedestrian with a sense of personal responsibility.

There are several questions that each of us has to answer. These questions are: first—Do you have influence in your community and your state? and second—Are you part of the problem or are you part of the solution?

I hope that you will definitely determine that you will be part of the solution. If you decide to be part of the solution, the people of America will owe you a debt of eternal gratitude. These days are truly the time for decision.▲

THE TRAFFIC PROBLEM

by JAMES D. HILL

district director, Field Service dept., National Safety Council, Dallas, Tex.

The traffic problem is our mutual interest. I think before we go too far into the matter of deciding how to use this tool of accident prevention, it might be well to dwell a little bit on what the traffic problem is . . . what it constitutes.

What kind of problem is the traffic problem? We get so busy sometimes I think in trying to solve the problem, we are on the run (it has us on the run) and we don't analyze the problem adequately before we try to do things to solve it. The question

arises whether we run into some lost motion in this procedure, so let's in some detail examine this thing that we call the traffic problem.

We can describe the traffic problem as a problem of knowledge. We have had automobiles 50 years, 50 years in history is a short time. People haven't learned how to drive . . . right. That is more or less obvious. I think we can all accept that description of the traffic problem.

WE JUST DON'T KNOW

Something that is not quite as obvious is that as civic workers trying to prevent accidents, and as officials working at the job of trying to prevent accidents, we too, are suffering from the impact of a new problem. We too, are delinquent in the knowledge of how we might do our job to prevent accidents. We are just as subject to it as the driver is to lack of knowledge. As we must be tolerant of the driver and understand him and the problem that he lacks basic knowledge of how to do his job of driving, so that driver must be tolerant of us too, and understand that we are still trying to find out how to do our job best.

When I say "we," I mean it very broadly; the National Safety Council doesn't know nearly so much about doing its job of accident prevention as it ought to know. If we knew all the answers to the problems, we wouldn't be having 35,000 to 40,000 people killed in the United States every year. One of the essential components of any kind of a successful and a defensive problem must be humility. We must admit we don't know.

IGNORANCE IS MISTRUST

We can call the traffic problem a problem of ignorance, an unprejudiced ignorance, perhaps, an ignorance that can't be helped, but an ignorance that should be recognized. People just don't know, just don't know. Now then, one of the characteristics of ignorance is mistrust. One of the almost constant corollaries of ignorance is mistrust. This is easy to recognize.

Some of you know what happens when you go into a small area, an area in a city where everybody is underprivileged about everything. People in such an area don't know who to follow; they don't know who to trust; they are loathe to accept what anybody says about anything. Leadership is irratic and frequently dishonest among such people. That we all recognize. It is easy to recognize because in most ways these people are ignorant or underprivileged.

It is not quite so easy to recognize when you find a bunch of people who are smart in most ways, well-informed in most ways; but, ignorant in one way, which is the situation we are in, in our so-called traffic problem. You can get a bunch of people together who are what we would call up-and-coming people of the community, well-informed, well-cultivated and well-motivated. You can ask them what to do about the smallpox epidemic and they operate at once with a minimum of lost motion.

You can get these people together and ask them what to do about polio, about cancer, about any problem of public health, and in general they waste a minimum of time deciding what to do about it and they get about doing what they have decided to do about it.

NO ORGANIZED THOUGHT

But you get these same people together at a meeting and let them decide what to do about motor vehicle traffic accidents, and they remind you of a man that jumps on his horse and tries to ride off in all directions. Everybody has a different idea, nobody likes to follow anybody, nobody wants to accept what anybody else says.

The chances are if I make a safety speech, there are people listening to me and wondering how fast I drive after I make my safety speech. They wonder how much of what I preach, I practice. Isn't that a characteristic of this thing we call the traffic problem? Don't we have the mistrust born of ignorance among otherwise well-informed people permeating our thinking about the traffic problem?

I recognize this sort of thing as an occupational hazard to me. There is abroad in the mind of the people a cult of unbelief. We in so many cases don't really think that much can be done. We don't like to follow what people suggest to us because we aren't really well sold that what we undertake will prevent accidents. I believe we can describe the problem in terms such as that.

I believe we can also describe the traffic problem as a psychological problem. You know the psychologist studies the behavior of individuals, and like most people who specialize in one thing or another, he comes up with some terms that are not familiar to laymen, but which laymen can perhaps use to benefit. So let's explore what this psychologist talks about and how it might apply to traffic.

DESIRE SELF-EXPRESSION

The psychologist describes a thing which, perhaps, we call the well spring of desire to be heard, to express one's self. The psychologist calls this two things; he calls it the id in one form, and the ego in another form. Suffice to say, but he tells us and we recognize, that within each individual there is a desire to consort with his fellows, a desire to speak and be listened to.

There is a desire to act and to influence others. As long as there is life in a human being this desire is present. However, it is subject to certain things that the psychologist calls repressions, or inhibitions. An individual when he is born, when he is an infant, has no repressions. Eventually, when he gets up to where he can walk around, he may run into a prohibition that eventually will turn into a repression.

Take, for example, a ceramic piece or something that must not be touched; he tries to touch it and he has to be physically restrained. As time goes on and he is restrained repeatedly, he gets to the point where there is within him a built-in inhibitor. He starts to reach for this piece of Dresden and he decides not to because he has been told not to so much, there is a repression against it.

But, as we go through life, the psychologists tell us, we gather and set up a regular system of repressions. As long as these repressions are in order, and as long as we are in order and reasonably well-adjusted, we get along all right because there is still ample outlet for our urge for self-expression in socially approved channels.

There are lots of ways man can express himself. Doing his job, playing a game of golf, playing a game of canasta, reading a book; there are just any number of ways we can do this all right, it is constructive. But, every once in a while all of us, during a great deal of the time some of us, get to where we rankle at all these repressions that society imposes on us. We may even do an overt act or revolt against them.

We may decide we are going to break the law just to see if we can get away with it. Now when I say "the law," I mean the code or rule, not necessarily the written law. When that happens, the psychologists tell us it is an escape mechanism, a way that we have of revolting against the system. It is kind of like when a boiler builds up a head of steam, and it breaks out at the weakest point when the steam is too much for the boiler to contain.

Now what is an example of an escape mechanism in traffic? One is the fellow that loses an argument with his wife at the breakfast table and tries to win it back driving downtown. Another example is the person who is a paragon of politeness in the living room, but who is a "heel behind the wheel." He sees here an opportunity to violate the code and get away with it. He can escape from this corral of inhibitions and repressions and at the same time escape social pressure, so he does it.

Another escape mechanism is the teenage boy, whose parents are very strict on him and he can't get away with a thing, but he gets behind the wheel of an automobile and lets off steam there. Somehow or another Pop has forgotten to lay down the law on that too, or maybe he laid down the law but the boy still thinks he can get away with it.

A young fellow has an argument with his girl and he sticks his foot in the carburetor all the way home . . . escape mechanism. I think, perhaps, here is a valid description of this thing we call the traffic problem. It attaches itself to individual behavior, individual psychology, and individual expression.

GROUP BEHAVIOR PROBLEM

We can also describe it as a phenomenon of group behavior. Now the sociologist is a fellow who studies group behavior; a psychologist studies the behavior of the individual; the sociologist studies the behavior of a whole group of people and he, too, has some terms that probably we can use.

The sociologist talks about culture. What he talks about is the sum total of the way people live and do things. He talks about the instruments of culture. Anything that man invents to make his life more gratify-

ing in one way or another may be described as an instrument of culture . . . a chair, a table, a tray, an ash tray, an automobile, all instruments of culture. The sociologist talks about folkways; the way folks do things. If I am a guest in somebody's home and a picture falls off the wall, I don't stand on his overstuffed furniture to hang the picture back up. There is no law against it, but folkways are against it.

The sociologist tells us that the strongest group motive we have is to get along with the group. The strongest hunger we have is to stand well among our fellows. We have individual hungers, but insofar as the group is concerned or two or more people are concerned, we want to be well thought of. So, if the fellow wouldn't think well of us for walking on his overstuffed furniture, we ask him if he has a ladder. That is what sociologists call folkways. Obviously, folkways build up around all instruments of culture.

LAWS REFLECT MORES

There is a thing to do or a group of accepted things to do with any instrument of culture. Now the sociologist says that as these folkways have more and more time to develop, people have more time to exchange thought and ideas about them; they solidify or they get more firm and definite and they become mores. Mores is a Latin or Greek word, I'm not sure which, meaning laws. Now the sociologist comes up with this term mores, and then he tells us something that gives the policeman, lawmakers, and all people in general, I think, some pretty good reasons for cause.

He says that a law passed by a legislature or an ordinance enacted by a city council is not original, it . a reflection. He says that these laws are valid, they are effective in controlling peoples' behavior only insofar as they reflect the mores. The only real law is what people think about it, says the sociologist.

Well, police officers know that there is a practical translation of this. There are some laws that are extremely popular and easy to enforce. There are some laws that are difficult to enforce. The sociologist says that the popular laws are the ones that coincide with the mores, and the mores preceded them. The laws then, only reflected the mores.

The sociologist says that the unpopular laws are the ones that vary or deviate from the mores. If you press him, he will cite you an example of a Constitutional Amendment of the United States Constitution that was destroyed because it was in contradiction to the mores, and that was prohibition. When I was a young fellow, I couldn't walk into a schoolroom without seeing some vividly colored charts on the wall showing my liver, my kidneys, my stomach, my lungs, my heart, and everything else would look like if I took a drink of alcoholic beverage. I was thoroughly convinced that anybody who would take a drink of alcoholic beverage was crazy.

EDUCATION BROUGHT LEGISLATION

The church was a part of a 20 years or longer campaign of education on the evils of alcohol. The educational campaign culminated in this condition of the folkways and the mores in this country to the extent that it was possible to pass the constitutional amendment prohibiting the sale or transportation of alcoholic beverages.

Now at that time, the mores were against the law. Then what happened? The people who had been carrying on this education for 20 years congratulated one another and went home. They said, "Now our job is done, we have legislated it and therefore made it so. It is now a police matter." The people were then left to their own voices and not subjected to education on the evils of drink or anything of the sort, and they went back to their old mores, which said that a man can transport it, or sell it, or do anything else with it as long as he doesn't unduly impose it on anybody else.

It then became smart, of course, to fool the cops about this prohibition. We didn't have force of the pressure of this educational campaign any more, and the mores and the law grew apart. Well, we all know the result of the thing. The mores won. The amendment was repealed. If we had had a continuing educational campaign after the amendment had been adopted, the chances are that today we would have a law of the land against selling or transporting alcoholic beverages. But the mores didn't say so. Well, that's pretty strong medicine.

While it was becoming the smart thing to do to fool the cops about this alcoholic beverage law, we had a new phenomenon developing called "traffic" that nobody had their minds well made up about anyway; so it more or less, by a process of osmosis, became the smart thing to do to fool the cop about traffic too. And we had a lot of comment about speed traps and the police mistreating the people, the disadvantage, the death-dealing disadvantage which is persisting, of course, to the present day.

TRAFFIC PROBLEM AROSE

These things I think we can use to describe the traffic problem. It's a problem of sociology, of folkways, of mores, and the like. The sociologist comes up with another term that I think is an interesting one, and it gives us a nice close application in traffic. He said that the traffic problem is a problem of culture lag . . . how far culture lags behind the lead . . . the difference between the way an instrument of culture is used, and the way it ought to be used.

He draws this comparison: If I was feeling pretty exuberant from one reason or another, natural or artificial, and decided I wanted to make a little noise to express myself, and I take my six-shooter and go out into the street and point it up in the air being very careful that nobody gets hurt and shoot it. A perfectly predictable series of events takes place. My next door neighbor calls the police, who come out and grab me and throw me into the jail. Before they have hung up the key, somebody is congratulating them for doing a wonderful job. The fellow might have killed somebody.

CULTURE LAG

But, let's say I'm more discreet. Let's say I feel the pressure of the folkways and the mores against using the gun in that way; let's say I get into my automobile and I go 50 mph down main street. Well, does anybody call the police? Chances are, not. Maybe they are a little upset, but nobody calls the police. If a policeman happens to come along, he pulls me over to the curb. He is not as unceremonious with me as if I were using a gun. he handles me rather gently.

He says, "You're violating the law, you were exceeding the speed limit and it is my duty to give you a summons." I am, of course, the soul of innocence. I say, "Officer, what did I do? I didn't hit nobody did I? Did I do something wrong? There wasn't anybody on the street." Maybe 10 people will walk by and nine of them will say, "Why doesn't that speed-crazy cop leave that poor fellow alone. He didn't hurt anybody. Why doesn't he go catch himself a burglar, or do something important. Why do they have to pick on good people for?"

Which is the most dangerous instrument of culture to misuse, the gun or the automobile? A gun kills six people without reloading, and an automobile kills 30 people at one shot. It's been done. The automobile is at least five times as dangerous misused. Yet, we condemn the misuse of the gun and condone the misuse of the motor vehicle. Why? The sociologist tells us it is culture lag. He explains it this way. We have had guns 400 years, and we have had cars 50. We haven't had automobiles long enough to make up our minds about the right way and the wrong way, and come to a unanimous agreement about how they should be used, and how they should not be used.

PROBLEM SOLVED IN 400 YEARS

Well, if we ask the sociologist then what we should do about it, he may in a detached and academic way say there is nothing really to worry about; by the time we have had cars for 400 years like we have had guns, that probably will have taken care of itself. We won't have a traffic problem any more than today we have a gun problem.

If I hand a gun to you, muzzle foremost, loaded, you say, "Don't point that thing at me!" And everybody standing around says, "Don't point that thing at him!" I loose face. But, if I go 70 mph between here and Fort Worth and you know darn well that 60 is just as fast as you can safely drive, what do you do? The chances are, you keep quiet. So we haven't got our folkways and our mores developed. We have a case of culture lag.

And in another 350 years it will have disappeared because people will have had time to think it over and talk it over, and come to an agreement. Of course, while all this is happening we will be killing 35,000 to 40,000 people a year. So why are we holding safety meetings, staging state safety conferences, publishing all this literature,

taking an annual inventory of traffic safety activities, and everything else?

What are we trying to do? We are trying to cover in 10, 15, or maybe 20 years the social development and group thinking that ordinarily would require 350 years to cover? But how do we do this? But how do we stimulate the rate at which concepts evolve concerning the use of the motor vehicle and concerning the control of its use? We stimulate it the only way, we accelerate it the only way it can be accelerated, by accelerating the rate at which people think and talk about it.

INVISIBLE ESSENCE

I think we can describe the traffic problem as a social problem. I think we can describe it in all of these ways. I think we can describe it as a problem of ignorance, a problem of sociology, and a problem of psychology. I think there is one other way to describe it . . . invisible essence. A couple of years ago I was reading the *Birmingham News*, and on the editorial page I read a parable written by Dr. Norman Vincent Peale. This was kind of an unexpected way to find some light on the traffic problem, but I would like to tell you this parable and my thinking following it.

Dr. Peale was telling about a game of golf he played one time. He was out in the woods looking for his ball and there was a young fellow out there raking leaves on the golf course. This young man knew Dr. Peale and approached him rather hesitantly and he said, "Dr. Peale, I need some help. I don't like my life and I've been aiming to come see you for more than six months."

Dr. Peale said, "Why did you wait so long?" He said, "Oh, I just haven't got around to it. I do need help. I want to get somewhere. Some time I would like to come see you and talk to you. Some time." Dr. Peale said, "Well, why don't *you* start talking to me now while I'm looking for my ball?"

So the boy poked his rake in his leaves and started. He said, "Dr. Peale, you see what kind of job I've got here, I'm raking leaves on this golf course. I want to amount to more than that and I want you to help me. You've helped other people. I want to get somewhere. I don't like my job, my situation, or anything about it. I want to get somewhere." Dr. Peale said, "Well, that's fine. Where do you want to go?"

The boy was taken back a bit, and said, "Well, I don't know." Dr. Peale said, "What would you like to do?" To which the young man replied a little bit defensively that he just had never thought about it definitely like that.

So then the good doctor was a little bit hard on him and he said, "It seems to me you have your mind made up a lot better about what you don't like than what you do like, about what you don't want than what you do want. You tell me you want to get somewhere, and I ask you where you want to get and you can't tell me. I ask you what I can do to get you there, if you had your mind made up, and you can't tell me. I ask you what you would like to do and you can't tell me. Now you must decide this thing for yourself, and until you do all the help in kingdom come will roll off you just like water off a duck's back. When you decide, then whether help comes your way or not, you're still on your way."

NEGATIVE THINKING

I reflected on that a while and it occurred to me that he was talking about the traffic problem. Dr. Peale went on to say the young man did make these decisions and eventually did get somewhere, was constantly and quietly failing himself. He was failing himself, and that is the traffic problem. Man's failure of himself.

Fundamentally, the problem is "no," isn't it? The problem is the negative mind-set: the propensity of people to say and act negatively, instead of positively. It came to me as a revelation; and, perhaps, I shouldn't be proud of it because at the time I had been in traffic safety for 17 years. It came to me as a revelation that traffic was not a new problem at all. It was a new kind, a new manifestation, a new form of a problem as old as man. The problem of man's failure of himself.

DESPAIR FACTOR

We've recognized it in lots of ways. This General Motors research director, Charles Kettering, expressed it this way: he said it is the despair factor. One of his favorite stories is about the time he invented the self-starter. Everybody agreed that something should be done to relieve people from having to crank automobiles; but, everybody agreed also that on the set-up that was available at that time on the motor vehicles, it was impossible to invent a self-starter so Kettering invented it.

Shortly afterward, an eminent electrical engineer accosted him and said, "Dr. Kettering, I resent your inventing that self-starter thing." Dr. Kettering said, "How so?" "Because you violated the laws of electricity." What he really meant was, you violated my hide-bound, negative mind-set that it couldn't be done. You violated the laws of electricity.

Shortly after that happened, Dr. Kettering called in all the research engineers. He had quite a number of brilliant, well-educated men who were extremely capable. Education doesn't seem to have anything to do with this negative mind-set. There doesn't seem to be much correlation. Ignorant people seem to be able to surmount it, and extremely well-educated people seem to be enslaved by it.

Well, anyway, Kettering called his research engineers together and told them to all bring their slide rules, so they did. He said, "Now gentlemen, we have just finished inventing the self-starter that everybody said couldn't be done. When I proposed the thing a few years back, a lot of you undertook to prove to me that it couldn't be done. Now I've asked you to bring these slide rules here today because I want to warn you something about them.

DON'T DISCOURAGE PROGRESS

"I want to give everyone of you fair warning that the next time I come to you with an idea that needs developing, and one of you pulls out one of these slide rules to prove to me it can't be done, we are going to burn them all up. If you want to prove to me it can be done, I'll listen; but don't start out on the premise that it can't be done and undertake to prove it to me, because I'm not interested . . . the despair factor."

Menninger, the famous psychiatrist in Topeka, Kan., has a way of saying it. He says that every man contains the seed of his own destruction. We recognize it in our everyday comings and goings. We talk about it colloquially; we say John, or Joe, or Jim, or Tom, or Dick, or Harry is his own worst enemy. He works against himself. And the payoff, of course, is that it is John, or Joe, or Jim, or Tom, or Dick, or Harry that does that. You never hear anybody say, "I'm my own worst enemy."

The traffic problem in its fundamental essence is a moral problem. It is the same kind of problem that the Master was sent here a little over 1900 years ago to do something about. It is the problem of negativism, of despair, of "no." The fact that it involves motor vehicles, the fact that it involves streets, traffic lights, pavements, and all that, is purely incidental. There is nothing new about the problem of man's failure of himself. Now then, do you need proof of that? I can sight you proof that is self-evident, like the things you read about in the Declaration of Independence. When an accident happens, somebody fails himself.

MECHANICAL PROBLEM?

I think the most striking proof of the fundamental nature of this traffic problem can be found in the fallacies that we professionals burden ourselves with as we go about our jobs trying to correct them. What are some of these fallacies? Let's nail some of them to the wall. Well, the first one is that traffic is a mechanical problem. You hear people on all sides talking about their grammis adjusters, grammis indicators, hayseed polishers, and incriminator filters, and so on. If we can just get enough gadgets, if we can just get enough policemen, and enough motorcycles, and enough traffic lights, and enough jail sentences; if we can just get enough mechanical things done, we can solve this problem.

Do we really believe that we can pile on these mechanical correctives deep enough that we can relieve ourselves of the necessity of facing out some of the seemy moral necessities in this business? Do we really think we can hire enough policemen to stop accidents if a judge turns loose people without justification that the policeman brings up? Do we really think that chemical tests will help us stop accidents if you can fix a DWI case?

Do we really believe that a fraud payment or an extremely complex signal system at an intersection will stop accidents when we will listen to this real estate promoter that says make it a night rate intersection so I can sell filling station locations on this corner, don't make it a clover-leaf intersec-

tion. Do we really believe we can solve the traffic problem mechanically? No, I don't think we do. Yet, we talk about it all the time, and we promise the world with a ring around it if you will just give me a $100,000 signal system, or just vote for this new bond issue to get all these streets paved. Aren't we deceiving ourselves, aren't we failing ourselves when we do that?

AGE OLD PROBLEM

Another fallacy is that there is anything new or different about the problem. There isn't. We, therefore, need experts to solve the problem. We don't. And fortunately we don't, because there aren't any. There has been one traffic expert in the history of the world, and that was the Man of Galilee. What the Man from Galilee told us 1900 and some odd years ago is all we need to know about traffic safety; nobody needs to add anything to it.

Whether we are operating as an individual driver, an official, a civic worker, or anything else, traffic is nothing more or less than applied Christianity. Traffic safety . . . applied Christianity. We need only to use our God-given intelligence to interpret and apply what is there, and what we know, and what we have been told until it is a part of our frame and bone and sinew. Yet we look for experts. Yet we look for some way around moral necessity.

Now then, here is a real tricky one, a real tricky fallacy that we professionals work under; that is the fallacy of public approbation. The public tells us we are doing a good job of accident prevention. How does the public know? They kill 40,000 of their own kind every year. How do they know? I make a speech at the Lions club, and they come up and shake hands with me. They are pretty conscientious folks, some of them have lots of money, some of them are successful businessmen; they come up and shake hands with me and say, "Mr. Hill, you are doing a very wonderful job."

LET SLEEPING DOGS LIE

Well, I want them to think so because that puts them in a receptive frame of mind, but I'm not kidding myself. I'm not doing a wonderful job just because they tell me I'm doing a wonderful job, they don't know. If I let myself be satisfied with public approbation of the kind of job I'm doing, I'm liable to get into any number of mantraps. One of them is the sleeping dog blind alley. If the public is happy, let them go ahead and kill 40,000 of their own kind as long as it isn't me. Let sleeping dogs lie. We are liable to get into a super-serious, cheap character building routine. If the public thinks I'm doing a good job, then I'll say the things the public enjoys hearing.

I go to the Kiwanis, Rotary, Civitan, or what have you; and I tell them what a wonderful safety program they have when I know darn well their safety program stinks. I please the public so the public will tell me how good I am, and the first thing you know I'm as phony as a three dollar bill, and they are too. That is the terrific mantrap we get into and we end up with an insecure feeling of walking on quicksand.

There are more fizzles, fallacies, phonies, and dreamers in the safety movement today than any other movement I know of. And one of the big reasons is because they depend on the public to tell them whether they are doing a good job or not. The public doesn't know. That is one of the things that makes it difficult. Where do I find out whether I'm doing a good job? I never know really, but I keep asking myself is this the best I can do, is this sound thinking, is this sound action?

TALK DOES ACCOMPLISH

A fallacy that we professionals succumb to from time to time, is the fallacy that a lot of talk accomplishes nothing. You hear it in any sort of meeting, take your choice, someone draws up very profoundly and they drop their voice an octave or two and get a hollow sound in it and they say, "Well, it is all very good, but it is a lot of talk that won't amount to anything. Everybody gets religion about it here today, and then we go home and forget about it. A lot of talk accomplishes nothing." I reject that as a fallacy.

I cite you again the first safety expert, the last, and the only one in the history of the world; the Man of Galilee, who lived about 34 years and did nothing but talk, and we are still listening. It took a lot of talk to make the Bill of Rights, the Magna Charta, the Declaration of Independence, the Constitution, all of the things that distinguish free men from slaves obviously had to be preceded by a lot of talk. So a lot of talk does accomplish something. This fellow who says a lot of talk accomplishes nothing means that a lot of talk with no more faith than I've put into it, accomplishes nothing.

Well, the problem is an old one, the problem is man's failure of himself. The corrective is an old one too, the corrective is faith. Unless we believe that something is reasonably intelligent and reasonably well-directed to prevent accidents, it won't prevent them. Unless we believe, we can't operate or act intelligently or in unity with anybody else. We will still be flocking around the tower of Babel, we will still be mistrusting our leadership, we will still be ignorant; and, as long as we persist in not believing, we will still kill one another and ourselves.

Traffic is a moral problem. Only its manifestations are mechanical. It is a new expression of an old problem and the same corrective will apply as it has applied to these old problems through the centuries. Well, I ask you then, to have faith in the efforts to solve this traffic problem. Can I give you justification for this faith? Yes, I can. I can give you a little bit of historical justification.

MORAL QUESTION

Back in 1925 we came out with our first records. They were admittedly incomplete, but they were our first records of a motor vehicle title in this country. Fatal accidents and those sets of records produced a rate of 19 people killed for every one hundred million vehicle miles traveled. Today it is six and two-tenths. I take that as fuel for faith and that what we do to prevent accidents, prevents accidents. Especially when we can relate directly and traceably what was done and how the rates came down through those years.

Here is that picture: from 1925 to 1932 we had our first national concerned cry about accidents. The legislatures passed laws, newspapers raised cane, and the police bought motorcycles and started arresting people, and we had a great deal of to-do about it. In 1932 the death rate had dropped from 19 to 16⅞ per one hundred million vehicle miles.

Then we had a wave of reaction and we had a lot of yammering about speed traps. We even had some laws passed that a policeman had to be dressed a certain way, and in a motion on a certain kind of a motorcycle on a public street or highway before he could arrest anybody for speeding. We also had the situation of a depression back in those days. Jobs were hard to get in 1932, and policemen had families in the habit of eating. Well, there was a let-up and the death rate increased from 16⅞ in 1932 to 18⅛ in 1934. Then the conscience of the American people began to catch up again, and in 1935 four significant things happened.

ESSAY HITS HOME

J. C. Furnas wrote an essay called *And Sudden Death* and finally got through the thick hide of the American automobile driver with that essay. He is the one that first so graphically described the brains on the fender, the blood on the streets, the scream of a child in the night, *the curious flopping* efforts of the injured, the moans and the screams of the oil-soaked body on the pavement, the apologetic expression of the face half gone away, and Brother Furnas got it through the heads of a great many people that unless they changed their driving habits, that was what they were headed for. That article reprinted five million copies out of the *Readers Digest*. It had an impact.

In 1935 something else was done to prevent accidents. The National Safety Council set up a five year accident prevention *publicity campaign* significant two ways: first, we can advertise safe conduct like we advertise cigarettes, and toothpaste, and automobiles, and all the other things we do. There is a potential here in publicity. We can advertise and sell safe conduct. We are also going to do it for five years, and we are not going to do it for a couple of years and quit. That was significant, too. Even today we have people who think that we can get this thing done in a couple of weeks and then forget it.

We have a lot more today who know that we must *live with it from now on.* The Council also started the National Traffic Safety Contest, which was a precedent or a granddaddy of our Annual Inventory of Traffic Safety Activities . . . a relating or pooling of experiences between cities. Also, the Northwestern University Traffic Institute was established in Evanston, Ill. . . . a step made toward scientific traffic policing.

All those things added up to something done to prevent accidents. The result, the death rate dropped from 18⅟₁₀ in 1934 to 12⅟₁₀ in 1939, five years later.

Now then, for the next seven years we had no more reduction. Why? We fought a World War, we didn't do anything about traffic safety. In 1946 the death rate was 11-5/10. In that year the war was over, everybody was getting concerned again and the President of the United States got into the act. He called the First Annual President's Highway Safety Conference. This conference has been held annually since.

PRESIDENT'S CONFERENCE

This President's Highway Safety Conference adopted an action program for voluntary implementation by cities and states. The death rate that year was 11-5/10, and three years later it was seven and five-tenths. Something had been done to prevent accidents. The rate is still going down and is now six and two-tenths. Those people who used to have the audacity to dream of a national death rate of six today are thinking of a national death rate of two or three in somewhere between five and ten years, if we don't get into a war or some other major national distraction.

Is there fuel for faith in that history? I think so. What we do to prevent accidents, prevents accidents. As further fuel for faith, on any Annual Inventory of Traffic Safety Activities we put a specific percentage evaluation score on what a state or city does to prevent accidents. Our national death rate currently is six and two-tenths. In some states, however, it is as high as 10-5/10.

In some states, as low as two and four-tenths. Invariably, the states with the low death rates are the states with the highest scores in the Annual Inventory of Traffic Safety Activities. The states that are doing the most to prevent accidents, are preventing the most accidents. The states with the high death rates are the ones with the low performance in the Annual Inventory.

We made a five year study of 32 cities in Wisconsin; we portrayed the results on a graph, in the beginning the total deaths in these 32 cities stood high on the graph, the inventory low, the lines crossing in the middle of the period. At the end of the period, the situation was reversed. The total inventory scores were high, the deaths were down about 40 per cent. They were the low point on the graph.

What we do to prevent accidents, prevents accidents. This I take as fuel for faith.▲

FUNDAMENTALS OF HOME SAFETY ACTIVITIES

by MISS EUNICE HEYWOOD

assistant director, div. of home economics programs, federal extension service, U. S. Dept. of Agriculture, Washington, D. C.

Over the years much has been said about home safety, but unlike the weather, much has also been done about it. However, not until 1955 had any attempt been made to find out "who was doing what"—or how much. That year a trial run of a Home Safety Inventory was made under the sponsorship of the National Safety Council. More than 600 reports were received, and for the first time we had some reliable information about home safety activities being conducted on local, state, and national levels.

Believing that home safety programs, to be effective, should be cooperative, we wanted to know what groups and organizations were interested and active in such programs. The results were most gratifying.

In 1956 the Home Safety Inventory was developed with two major objectives: first, to add to our knowledge of "who is doing what" in home safety; and second, to stimulate further home safety program activities. The Inventory sought answers to the following questions:

1. What organizations generally were most actively concerned with the problems of home accidents?
2. What types of activities were most frequently conducted by these organizations?
3. What community groups cooperated?
4. What determined the types of activities undertaken by an organization?
5. Who did these organizations attempt to reach through their efforts?

More than 4,100 program reports were received and analyzed. A summary has been published and sent to all state and local centers that assisted in making the Inventory.

The findings indicated that large numbers of people were being reached by a home safety message and that most of the organizations promoting home safety were attempting to make their efforts part of a continuous, long-range program. Some apparent gaps, however, were uncovered:

1. More attention than was reported could be directed at safety for young children and for the elderly;
2. More effective use than reported could be made of mass media, such as television and radio;
3. More inter-agency cooperation might be achieved than reported.

No national Home Safety Inventory will be made in 1957 but one is planned for 1958. The long-range objective of the Home Safety Inventory is to contribute to the reduction of accidental home injuries by helping those conducting state and local home safety programs to:

1. Stimulate the development, expansion, and coordination of home accident prevention programs in their respective areas.
2. Establish standards and norms which will encourage officials, voluntary agencies and business organizations to accept responsibility for home accident prevention.

Information gained through the Inventory serves as a valuable guide to those of us who are concerned with planning safety programs and activities or with the production of materials for use in safety programs. For example, a booklet on old-age safety is in process which we hope may stimulate more widespread attention to the special needs of our older citizens. Another publication planned for early 1958 will offer program ideas illustrated by examples of interesting projects gleaned from the 1955 and 1956 Home Inventories.

In 1958, more selective advice of organizations will be sought in developing a questionnaire tailored to fit organizations.▲

THE PHILOSOPHY OF THE BEADED SHOES

by CHARLES W. FERGUSON
senior editor, The Reader's Digest, Pleasantville, N. Y.

One good thing about conventions is the opportunity they afford to stand off and look back and decide whether the work done is worth while or might be better done.

To appraise accurately is one of the hardest jobs on earth; the very act of trying puts us in a critical mood toward our efforts and we usually end up with the mullygrubs. And because this is the case I have decided to tell three stories. These stories are so short that in each case I will have to reverse the usual process for a Digest editor and make a short story long. All the stories are designed to give you some consolation and some brightness of mind in the assessment of your work.

DRESS MORE PLEASING

The first concerns a woman, a writer who has done some wonderful articles for *The Reader's Digest*—Elise Miller Davis. Once on a trip to Mexico she took a fancy for a pair of beaded shoes. They looked exquisite as a piece of work and while she had no immediate or anticipated need for them, they caught her eye and held it—so she bought the shoes. When she got home she didn't know quite what to do with them; they didn't work in with any ensemble. But a friend saw her predicament and with skill made a beaded dress. That's not the way to describe the dress, but it had sequins on it and it was pretty fancy and she had something to go with the beaded shoes.

Came the evening when Elise Davis decided to wear the dress and the shoes. She got diked out and then started off to a dinner. The dress was a honey, but when she got outside in the early evening light she noticed that the beaded shoes were not as pretty as she had thought. In fact they just wouldn't do. So she went back into the house, much pleased with the dress, and changed her shoes.

Now the moral of this story is too plain to need elaborate emphasis: our final accomplishment may be far greater than our original objective. We may fail or discard, but what we have our hearts set on in the first place not uncommonly leads to something that is far better than we had planned.

I have found this repeatedly true in my business and could cite instance after instance to prove the point. Once in London Paul Gallico told me the story of the time he as a young sports writer just out of college got into the ring with Jack Dempsey. It was an amazing story: Gallico was mauled unmercifully by the Manassa Mauler. I tried to sell it to my associates by mail but nothing happened. Later Gallico came to Pleasantville and told the story again at a luncheon. It did not take an editor to see that this was a story worth telling but there was no excuse for bringing it up in the magazine.

On my way back from lunch I suggested that Paul do it as an art-of-living article, it being an art to live in the same ring with Dempsey. The emphasis and the argument would be placed on the fact that Gallico never took second-hand experience or hearsay evidence. He went in for the real thing. He wrote the story with this point and argument. It was accepted, but when I saw the proof I discovered to my dismay that the argument had been dropped. What led to the results had been discarded, but without this argument as a means, we would have no story at all.

FIND IMPROVEMENTS

So it goes in the experience of all of us. We cannot say with precision what will come of our efforts and often the thing that is dropped leads to something vastly better. Arthur Schopenhauer has a passage which states this principle beautifully:

"We often find something else, nay, something better than what we are looking for; and what we look for, we often find on a very different path from that on which we began a vain search. Instead of finding as we expected, pleasure, happiness, joy, we get experience, insight, knowledge—a real and permanent blessing instead of a fleeting and illusory one."

The next story I want to tell is the story of a word: *serendipity*. This is a word coined by Horace Walpole in a letter to Horace Mann written about 1754. Walpole felt the need of such a word and he based it on a 16th century fairy tale called *The Three Princes of Serendip*—Serendip being the ancient name for Ceylon. In this story the princes were "always making discoveries by accident and sagacity of things which they were not in quest of." Serendipity then has come to signify the detours and unexpected benefits of any journey, of any course of action.

The goal may not always be achieved but something better may bob up—as for example when Columbus, seeking a new passage to India, came across evidence of a land mass that proved later to be the Americas. Science is full of instances where the incidental discovery has outweighed in importance the real goals of the researchers —penicillin being a recent case in point.

We need to think of this story and remember this word in our evaluations. Norman Damon once defined safety as a by-product of doing things the right way. In the safety movement itself we may often get down in the mouth over the futility of our efforts to make people stay alive against what seems to me their own wishes. But we cannot appraise our efforts without seeing that there are values and experiences we encounter that may be good in themselves. The next time you wonder about your efforts, keep your eyes open for side results. Keep yourself on the line of discovery with a mind alert to the immeasurable value of incidental accomplishments.

LOST NIGHTINGALE

My last story is the story of the nightingale as told by Hans Christian Anderson. The Emperor of China had a beautiful nightingale which sweetened his life and his court with unsolicited melodies. The Emperor of Japan heard of this nightingale and, to please his brother ruler he sent the Emperor of China a marvelous mechanical nightingale. It sang with zest when it was properly wound and all at the court commented at the wonder of it. But the excitement over the mechanical nightingale was so great that in the midst of it hardly anyone noticed that the real nightingale had flown out the window.

In a push-button age that worships efficiency and progress, that forgets George Bernard Shaw's dictum that progress is merely the exchange of one inconvenience for another, we are likely to worship the mechanical, to think that if we but get properly organized and squared away, all will be lovely. But we must beware in a human thrust like the safety movement lest the real thing fly out the window. And in the appraisal of our efforts, let us examine this possibility and realize that there is no substitute for the heart and spirit. This can come only from dedicated personal interest. ▲

OFFICERS OF THE

WOMEN'S ACTIVITIES CONFERENCE

NATIONAL SAFETY COUNCIL 1957-58

Chairman and Vice-President—MARION E. MARTIN, Commissioner of Labor and Industry, State of Maine, Augusta, Maine.

Vice-Chairman—MRS. RAYMOND SAYRE, chairman, Women's Committee, The President's Committee for Traffic Safety, Ackworth, Iowa.

Board Representatives—MARION E. MARTIN; MRS. RAYMOND SAYRE; MRS. GERTRUDE FRESE, assistant to Vice-President, New York Telephone Co., Brooklyn, N. Y.; HON. IVY BAKER PRIEST, Treasurer of the United States, Washington, D. C.

Members-at-Large—MRS. ALMER ARMSTRONG, coordinator, Organization Relations, Indiana Farm Bureau Cooperative Assn., Indianapolis, Ind.; MRS. AGNES D. BEATON, director, Women's Division, Automotive Safety Foundation, Washington, D. C.; MRS. O. A. BEECH, president, Beech Aircraft Corp., Wichita, Kan.; MRS. RAE V. BIESTER, superintendent, United States Mint, Philadelphia, Pa.; HON. MARGUERITE S. CHURCH, Congress of the United States, House of Representatives, Washington, D. C.; HON. FRANCES COOK, Justice of the Peace, Beaverton, Ore.; MISS DOROTHY DOWNS, assistant to J. O. Herbster, chief engineer, Firemen's Mutual Insurance co., Providence, R. I.; MRS. GERTRUDE FRESE; MRS. JEAN WOOD FULLER, director, Women's Activities, Federal Civil Defense Administration, Battle Creek, Mich.; DR. LILLIAN M. GILBRETH, Montclair, N. J.; MRS. L. C. GILMOUR, chairman, Women's division, Seattle-King County Safety Council, Seattle, Wash.; MRS. ROBERT W. GUNDERSON, Rapid City, S. D.; BETTY GUNNING, Station WJAR, Providence, R. I.; MRS. J. RAMSAY HARRIS, Denver, Colo.; MRS. HELEN K. KNANDEL, educational consultant, Traffic Engineering and Safety Dept., American Automobile Assn., Washington, D. C.; MRS. JOHN E. KRUEGER, Milwaukee, Wis.; MRS. DOROTHY McCULLOUGH LEE, chairman, Subversive Activities Control Board, Washington, D. C.; MRS. ALICE K. LEOPOLD, assistant to the Secretary of Labor, U. S. Department of Labor, Washington, D. C.; HON. GERALDINE MACELWANE, judge, Lucas County Common Pleas Court, Toledo, Ohio; MRS. WALTER V. MAGEE, Ohio State Safety Council, Lakewood, Ohio; MARION E. MARTIN; MRS. CARRIE NOELLING, vice-president, Home Safety & Women's Activities, Kansas City Safety Council, Kansas City, Mo.; HON. IVY BAKER PRIEST; EDITH RAMSAY, Home Equipment Editor, The American Home, New York, N. Y.; MRS. MARY G. ROEBLING, president, Trenton Trust Co., Trenton, N. J.; MRS. RAYMOND SAYRE; MRS. ALMA K. SCHNEIDER, superintendent, United States Mint, Denver, Colo.; MRS. MAMIE KENNEDY TAYLOR, Executive Dept., Georgia Power Co., Atlanta, Ga.; MRS. BERNICE T. VAN DER VRIES, member, Chicago Transit Board, Chicago Transit Authority, Chicago, Ill.; MRS. MILDRED YOUNGER, Los Angeles, Calif.

Safety Exposition Exhibitors

Acme Protection Equipment Co., South Haven, Mich.
Industrial gas masks, chemicals and accessories.

Advance Glove Mfg. Co., Detroit, Mich.
Work gloves.

Aetna Casualty & Surety Co., Hartford, Conn.
Safety educational aids and services including Aetna Drivotrainer.

Akron Brass Mfg. Co., Inc., Wooster, Ohio
Fire hose nozzles and accessories.

Alan Wood Steel Co., Conshohocken, Pa.
Abrasive rolled steel floor plate.

American Abrasives Metals Co., Irvington, N. J.
Abrasive stair treads, threshold, door saddles and non-slip coatings.

American Allsafe Co., Inc., Buffalo, N. Y.
Drybrow the Nation's Sweat Band and Greenline Emergency Release.

American Biltrite Rubber Co., Chelsea, Mass.
Rubber, composition and neoprene safety soles.

American Chain & Cable Co., Inc., Bridgeport, Conn.
Sling chains and Kuplex sling chain assemblies, wire rope slings and assemble-your-own wire rope slings.

American Industrial Safety Equipment Co., Inc., Cleveland, Ohio
Face shields, goggles, gloves and mittens.

American La France Corp., Elmira, N. Y.
Fire apparatus and fire fighting equipment.

American Optical Co., Southbridge, Mass.
Head, eye and respiratory protective devices; safety clothing and safety specialty products.

Ampco Metal, Inc., Milwaukee, Wis.
Non-sparking, corrosion-resistant safety tools.

Ansul Chemical Co., Marinette, Wis.
Dry chemical fire protection equipment.

Arcadia Mfg. Co., Birmingham, Mich.
Plastic coated gloves and aprons for industry.

Award Incentives, Inc., New York, N. Y.
Safety incentive award programs, emblems, plaques and trophies.

Ballymore Co., West Chester, Pa.
Rolling safety step ladders, movable work platforms, mobile access lifts and hydraulic lift work platforms.

Bashlin, W. M., Co., Grove City, Pa.
Linemen's and industrial safety equipment.

Bausch & Lomb Optical Co., Rochester, N. Y.
Safety glasses, Ortho-Raters and "Titan" safety frame.

Beltone Hearing Aid Co., Chicago, Ill.
Audiometers, hearing aid tests.

The Beryllium Corp., Reading, Pa.
Safety tools.

Best, Alfred M. Co., Inc., New York, N. Y.
Safety publications.

Bethlehem Steel Co., Bethlehem, Pa.
Wire rope slings, standard and braided slings.

Bil-Jax, Inc., Archbold, Ohio
Tubular steel scaffolding and equipment. Portable steel bleachers.

Bomgardner Mfg. Co., Cleveland, Ohio
Emergency stretchers, cots, first aid equipment, resuscitators and respirators.

Bone Dry Mfg. Co., Neosho, Mo.
Outdoor footwear.

Boyer-Campbell Co., Detroit, Mich.
Safety equipment for industry—individual protective equipment.

Brady Co., W. H., Milwaukee, Wis.
Self-sticking safety products, Perma-Code pipe makers.

Breck, John H., Inc., Springfield, Mass.
Industrial hand cleaner; hair and scalp preparations.

Brett-Guard Co., Englewood, N. J.
New saw-guard combining safety with full work visibility.

Brossard, Lester L., Co., Chicago, Ill.
Klear-Vu traffic mirrors and Klear-Vu traffic lane markers.

Browne, Stewart R. Mfg. Co., Inc., New York, N. Y.
Electrical safety equipment, explosion-proof and vapor-proof portable inspection lites, explosion-proof flashlites, grounding devices.

Brulin & Co., Inc., Indianapolis, Ind.
Floor treatments, cleaners, disinfectants, insecticides.

Buffalo Fire Appliance Corp., Dayton, Ohio
Portable fire extinguishers and fire department accessories.

Buhrke, R. H., Co., Chicago, Ill.
Occupational safety equipment and products for construction and maintenance.

Bullard, E. D., Co., Sausalito, Calif.
Industrial safety equipment.

Cambridge Rubber Co., Taneytown, Md.
Non-slip safety soles, Vul-Cork and Vul-Cork Neoprene.

Chance, A. B., Co., Centralia, Mo.
Hot line maintenance tools and line construction tools.

Charleston Rubber Co., Charleston, S. C.
Lineman and industrial gloves, sleeves, aprons, safety devices.

Chemical Corp., Springfield, Mass.
Protective hand creams, cleaners and lotions.

Chicago Eye Shield Co., Chicago, Ill.
Head and eye protective equipment.

Chrysler Corp., Detroit, Mich.
"Chrysler Corporation—The Forward Look in Safety."

Clark, J. R., Co., Spring Park, Minn.
Industrial ladders.

Columbus Glove Mfg. Co., Columbus, Ohio
Coated gloves and aprons.

Columbus-McKinnon Chain Corp., Tonawanda, N. Y.
Alloy steel sling chains.

Cunningham, M. E., Co., Pittsburgh, Pa.
Safety marking tools.

Daisy Mfg. Co., Plymouth, Mich.
Air rifle.

Davids Gloves, Inc., Springfield, Ohio
Safety gloves.

Davis Emergency Equipment Co., Inc., Newark, N. J.
Respiratory protection, combustible gas indicators, safety and first aid equipment.

Detex Watch Clock Corp., Chicago, Ill.
Watchmen's clocks.

AMF DeWalt, Inc., Lancaster, Pa.
Radial arm woodworking equipment and safety features.

Dockson Corp., Detroit, Mich.
Welding helmets, face shields, cup and spectacle type goggles, respirators and eye savers.

Dow Chemical Co., Midland, Mich.
Safety solvents, germicides and insecticides.

Dow Corning Corp., Midland, Mich.
Sight saver cleaning stations, shoe saver, safety shoes.

Doyle Vacuum Cleaner Co., Grand Rapids, Mich.
Industrial vacuum cleaners, scrubbers and polishers.

Dunn Products, Chicago, Ill.
Protective clothing for industrial workers made from asbestos, leather, rubber, Neoprene and fire-proofed duck.

Du Pont I. E., de Nemours & Co., Inc., Wilmington, Del.
Flame retardant for fabrics and paper, anti-slip floor waxes, protective creams, *Neoprene products.*

Eagle Mfg. Co., Wellsburg, W. Va.
Safety cans, oilers, oil and gasoline containers.

Edmont Mfg. Co., Coshocton, Ohio
Coated fabric work gloves.

Elkhart Brass Mfg. Co., Inc., Elkhart, Ind.
Fire extinguishers, municipal and industrial brass goods.

Elliott Service Co., Inc., Mount Vernon, N. Y.
Accident prevention displays, safety conference programs, Supervisor's Weekly Bulletin, suggestion system service.

Emerson, J. H., Co., Cambridge, Mass.
Cotton, jersey, leather palm, all leather and plastic work gloves.

Fendall Co., Chicago, Ill.
Head and eye protection equipment.

Fibre-Metal Products Co., Chester, Pa.
Eye, head, and face protection and welding accessories.

Fine Organics, Inc., New York, N. Y.
High flash, low toxicity safety solvents.

Ford Motor Co., Dearborn, Mich.
Ford automobiles, featuring Lifeguard steering wheels, sun visors, seat belts instrument panel padding, and door latches.

Frommelt Industries, Dubuque, Iowa
Portable welding shield and protective heat cloth.

Fyr-Fyter Div., Fyr-Fyter Co., Dayton, Ohio
Fire extinguishers, resuscitators and respirators.

General Fire Extinguishers Corp., St. Clair Shores, Mich.
Quick-Aid fire extinguishers and allied products.

Glendale Optical Co., Inc., Valley Stream, N. Y.
Chippers and welders goggles, face shields, safety spectacles.

Globe Co., Grip-Strut Div., Chicago, Ill.
Grip-Strut grating, stair tread materials.

Grinnell Co., Inc., Providence, R. I.
Fixed pipe fire protection systems.

Gro-Cord Rubber Co., Lima, Ohio
Gro-Cord, Raw-Cord and Neo-Cord soles, heels and taps.

Haws Drinking Faucet Co., Berkeley, Calif.
Emergency eyewash fountains, emergency showers and goggle wash fountains.

Hild Floor Machine Co., Inc., Chicago, Ill.
Explosion-proof vacuum cleaners and floor machines.

Hy-Test Safety Shoes Div., International Shoe Co., St. Louis, Mo.
Safety footwear; also conductive and special types for atomic usage.

Hygiene Research, Inc., New York, N. Y.
Protective ointments and mistproofing cloth for goggles, welding masks, windshield.

Industrial Gloves Co., Danville, Ill.
Leather, asbestos, duck, wool, Woven-Gard, Permaproof, and aluminized duck and asbestos finger guards.

Institute of Industrial Launderers, Washington, D. C.
Industrial launderers and cleaners.

Insto-Gas Corp., Detroit, Mich.
Torches and furnaces.

Interstate Rubber Products Corp., Los Angeles, Calif.
Safety Trafficones for traffic control.

Iron Age Div., H. Childs & Co., Inc., Pittsburgh, Pa.
Linemen's and women's leather and rubber industrial safety footwear.

Jackson Products, Air Reduction Sales Co., Div. of Air Reduction Co., Inc., Warren, Mich.
Insulated electrode holders, cable connectors, face shields and goggles.

Jomac, Inc., Philadelphia, Pa.
Industrial work gloves, safety sleeves, hand guards, North P.V.C. gloves, North protective clothing.

Jones & Co., Rumford, R. I.
Full vision visor goggles.

Jones & Laughlin Steel Corp., Pittsburgh, Pa.
Wire rope slings, wire rope.

Jumkin Safety Appliance Co., Inc., Louisville, Ky.
Power press guards, grinding wheel shields, stretcher equipment.

Justrite Mfg. Co., Chicago, Ill.
Safety cans, oily waste cans, safety electric lantern, flashlights and fire extinguishers.

Karel First Aid Supply Co., Chicago, Ill.
Industrial hospital equipment and medical supplies.

Kelley Paint Co., Louisville, Ky.
Convoy skid-proof safety enamel, Halt-fire barrier paint.

Keystone View Co., Meadville, Pa.
Occupational and driver vision tests, lantern slide projectors.

Kidde, Walter & Co., Inc., Belleville, N. J.
Fire detecting and extinguishing equipment, ultrasonic burglar alarm.

Kimball Safety Products Co., Cleveland, Ohio
Personal protective devices for industrial workers.

Mathias Klein & Sons, Chicago, Ill.
Linemen's safety equipment and tools.

Knapp Bros. Shoe Mfg. Corp., Brockton, Mass.
Safety shoes.

Kunz, J., Glove Co., Chicago, Ill.
Linemen's, bridgemen's and welders' quality gloves.

Leader Mfg. Co., Inc., Briarcliff, N. Y.
Pressurized dry chemical extinguishers.

Legge, Walter G., Co., Inc., New York, N. Y.
Safety floor maintenance materials, conductive coatings, static eliminators.

Lehigh Safety Shoe Co., Emmaus, Pa.
Leather and rubber safety footwear.

Lighfoot Co., Inc., The, New York, N. Y.
Shin cleansers—powdered, liquid, bar and waterless.

Logan Emergency Showers, Glendale, Calif.
Industrial emergency showers, eye-wash fountains.

Lowery Brothers, Inc., Chicago, Ill.
Wire rope splicing service.

Maico Co., Inc., Minneapolis, Minn.
Maico audiometers for industrial hearing testing.

Marsh & McLennan, Inc., Chicago, Ill.
Insurance broker and agencies.

Martindale Electric Co., Cleveland, Ohio
Protective dust masks, eye protectors, face shields, safety electric test instruments.

Masury-Young Co., Boston, Mass.
Floor maintenance materials.

McAn, Thom, Safety Shoe Div., New York, N. Y.
Safety shoes.

McDermott, Julian A., Corp., Ridgewood, L. I., N. Y.
Warning and safety lighting for municipal, industrial, utility and aviation use.

McDonald, B. F., Co., Los Angeles, Calif.
Industrial safety equipment.

Medical Supply Co., Rockford, Ill.
Flexible unit aid, snake bite first aid, burn first aid.

Metropolitan Life Insurance Co., New York, N. Y.
Useful materials for use in community health and safety programs.

Micro Switch, Div. of Minneapolis-Honeywell Regulator Co., Freeport, Ill.
Safety interlock switches and electric controls for power machines.

Milburn Co., Detroit, Mich.
Ply skin protective creams, ply garb safety and protective clothing, plygloves plastic coated work gloves, ply waterless hand cleaner.

Miller Equipment Co., Inc., Franklin, Pa.
Linemen's safety belts, straps accessories and industrial safety belts.

Mine Safety Appliance Co., Pittsburgh, Pa.
Safety equipment for every industry.

National Medical Supply Co., Chicago, Ill.
Industrial first aid supplies equipment and instruments.

Neo-Plasber Mfg. Co., Burbank, Calif.
Industrial, traffic emergency flashing signals.

Newco Mfg. Co., Inc., Kansas City, Mo.
Wire rope fittings, safety hooks, load protectors.

New Castle Battery Mfg. Co., New Castle, Pa.
School crossing signals.

Nichols Engineering Co., Chicago, Ill.
Steel, unloading and tank car work platforms.

Notifier Mfg. Co., Lincoln, Neb.
Fire detection, sprinkler supervisory, watchman tour, municipal alarm systems.

Occupational Hazards, Cleveland, Ohio
Publishers.

Onox, Inc., San Francisco, Calif.
Onox Skin Toughener and Footmats for Athlete's Foot.

Osborn Mfg. Corp., Warsaw, Ind.
Safety Pliers and tongs for feeding punch presses.

Oxy-Catalyst, Inc., Wayne, Pa.
Catalytic purifiers for controlling CO and other automotive exhaust fumes.

Pac-Kit Co., Greenwich, Conn.
Unit type first aid equipment.

Packwood, G. H., Mfg. Co., St. Louis, Mo.
Safety industrial skin cleaners and dispensers.

Patent Scaffolding Co., Inc., Chicago, Ill.
Wood, aluminum and magnesium safety ladders, suspended sectional steel tubular steel and aluminum scaffolding sidewalk protection canopies, steel grandstands and fold-a-way scaffold.

Petersen Engineering Co., Santa Clara, Calif.
Pengo tension wire stringer, Pengo earth angers and other construction equipment for the utility industry.

Pioneer Rubber Co., Willard, Ohio
Gloves; all kinds, liquid proof.

Porto-Clinic Instruments, Inc., New York, N. Y.
Driver testing and training equipment and visual aids for driver and traffic safety.

Positive Safety Mfg. Co., Cleveland, Ohio
Power press guards.

Prairie State Products Co., Chicago, Ill.
Metal and electrical safety and directional signs.

Progress Industries, Inc., Norwood, R. I.
Safety goggles.

Protectoseal Co., Chicago, Ill.
Fire-prevention equipment for flammable solvents.

Prutsman, Ted Defrosto Mirrors, Inc., Lynwood, Calif.
De-Icer truck mirrors.

Pulmosan Safety Equipment Corp., Brooklyn, N. Y.
Respirators, eye protection, helmets, protective clothing, asbestos and leather gloves.

Putnam Rolling Ladder Co., Inc., New York, N. Y.
Reinforced plastic and extension and single ladders, and oak rolling ladders.

Pyrene—C-O-Two Div., The Fyr-Fyter Co., Newark, N. J.
Carbon dioxide and dry chemical extinguishers and systems. Smoke detectors.

Racine Glove Co., Inc., Rio, Wis.
Gloves, apparel, protective equipment—leather, asbestos, and steel reinforced.

Radiator Specialty Co., Charlotte, N. C.
Safe-T-Cone rubber traffic guides.

Randolph Laboratories, Inc., Chicago, Ill.
Carbon dioxide fire extinguishers, dry chemicals on automatic systems.

Reece Wooden Sole Shoe Co., Columbus, Neb.
Wooden sole safety boots, shoes and sandals.

Riegel Textile Corp., Industrial Gloves Div., New York, N. Y.
Industrial work gloves.

Rockwood Sprinkler Co., Worcester, Mass.
Automatic fire protection systems; sprinklers, waterfog, fogfoam and foam.

Rose Mfg. Co., Denver, Colo.
Industrial safety equipment.

Safeguard Mfg. Co., Woodbury, Conn.
Modern press guards.

Safety Box Toe Co., Boston, Mass.
Safety steel toes.

Safety Clothing & Equipment Co., Cleveland, Ohio
Safety clothing and equipment for every type of industrial worker.

Safety First Products Corp., Elmsford, N. Y.
Fire extinguishers.

Safety First Shoe Co., Inc., Holliston, Mass.
Safety steel toe shoes for men.

Safety First Supply Co., Pittsburgh, Pa.
Industrial safety equipment.

Safety Tower Ladder Co., Burbank, Calif.
Safety equipment for fixed ladders and scaffolds.

Salisbury, W. H., & Co., Chicago, Ill.
Linemen's rubber protective equipment.

Sarole, Inc., Linden, N. J.
Non-traumatic carrier.

Sawyer-Tower, Inc., Boston, Mass.
All types of protective and safety clothing.

Schrader's A., Son Div., Brooklyn, N. Y.
Pneumatic press controls, valves, cylinders and associated products.

Scientific Industrial Supply Co., Chicago, Ill.
Gloves, clothing and general safety equipment.

Scott Aviation Corp., Lancaster, N. Y.
Scott air-pak demand inhalator, demand respirator, hydro-pak.

Searjeant Metal Products, Inc., Mendon, N. Y.
Punch press safety guards, controls, and accessories.

Sellstrom Mfg. Co., Palatine, Ill.
Face and eye protection equipment.

Speakman Co., Wilmington, Del.
Industrial emergency showers, eye-wash fountains.

Standard Safety Equipment Co., Chicago, Ill.
Industrial safety equipment.

Stephenson Corp., Red Bank, N. J.
Automatic resuscitation equipment and chemical breath test for intoxication.

Stonehouse Signs, Inc., Denver, Colo.
Industrial accident prevention signs.

Stop-Fire, Inc., New Brunswick, N. J.
Fire extinguishers.

The Surety Rubber Co., Carrollton, Ohio
Personal protective equipment for industrial and electrical workers.

The Surty Mfg. Co., Inc., Chicago, Ill.
Linemen's safety equipment and industrial workers protective equipment.

Taylor, S. G. Chain Co., Inc., Hammond, Ind.
"Taylor-Made" alloy steel sling chains and allied products including Tayco patented alloy steel drop forged hooks.

Tect, Inc., Dumont, N. J.
Vythene and other Tecsolve safety solvents.

Titmus Optical Co., Inc., Petersburg, Va.
Safety eyewear, ophthalic instruments, lenses, frames and sun wear.

Tool & Mfg. Co., Inc., Coverdale, Pa.
Non-spalling hand tools and hand protectors for same.

Union Wire Rope Corp., Kansas City, Mo.
Wire rope "Tuffy" slings, "Tuffy" towlines.

United States Safety Service Co., Kansas City, Mo.
Industrial eyewear.

Universal Match Corp., St. Louis, Mo.
Safety programs for employees, match book safety programs, employee health, sanitation programs, fire prevention programs.

Wagner Sign Service, Inc., Chicago, Ill.
Wagner changeable copy displays.

Watchemoket Optical Co., Inc., Providence, R. I.
"Eye-Savers" plastic eye protection and Plasi-Glow safety signs.

Welsh Mfg. Co., Providence, R. I.
Safety goggles, lens, face shields and helmets.

Western Industrial Pharmaceuticals Co., San Francisco, Calif.
Poison ivy, oak and sumac ointment.

Westline Products Div. of Western Lithograph Co., Los Angeles, Calif.
Industrial signs, markers, safety signs, pipe markers, labels, letters-numbers-signs.

Wheeler Protective Apparel, Inc., Chicago, Ill.
Industrial safety clothing for heat and abrasive hazards.

Whitney, L. A., Associates, Inc., New York, N. Y.
Visual aids—flannel boards, programs—complete art and production service.

Williams Jewelry & Mfg. Co., Chicago, Ill.
Safety awards, badges and trophies.

Wilson Products Div., Ray-O-Vac Co., Reading, Pa.
Industrial goggles, gas masks, helmets and respirators, and allied safety devices.

The Wilson Rubber Co., A Div. of Becton, Dickinson & Co., Canton, Ohio
Rubber and synthetic industrial gloves for every use.

Wolverine Shoe & Tanning Corp., Rockford, Mich.
Industrial safety shoes.

EDUCATIONAL EXHIBITORS

American Optometric Assn., St. Louis, Mo.
"Vision For Safety"—On The Highway, In Industry.

Argonne National Laboratory, Lamont, Ill.
"Equipment and Guides Used in the Performance of Radiation Safety Work."

Boy Scouts of America, New Brunswick, N. J.
Exhibit of 1958 Good Turn Campaign.

Inter-American Safety Council, Inc., New York, N. Y.
The Safety Council serving all Latin America.

National Bureau of Standards, Washington, D. C.
"Loading Effects of Wind on Towers."

National Society for The Prevention of Blindness, New York, N .Y.
Educational material on conservation and utilization of eyesight in industry.

Other Volumes in this Series

Users of this volume will find much value in its companion volumes. Here is the list:

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

AERONAUTICAL INDUSTRIES SECTION
THE AIR TRANSPORT SECTION

This volume is a record of the sessions held at the 1957 National Safety Congress by the Aeronautical Industries Section and the Air Transport Section. The conduct of these Congress sessions each year is only one of the many cooperative activities which the Aeronautical Industries Section and the Air Transport Section carry on in behalf of their members, and for the benefit of accident prevention work in the aviation industry. These Sections give guidance in the preparation of a great variety of technical and educational material useful in the day-to-day safety programs of aviation.

The activities of these Sections are under the direction of their executive committees, the members of which are listed at the close of this volume.

COST OF OFF-THE-JOB ACCIDENTS TO INDUSTRY

by R. WILKINS
safety administrator, North American Aviation Inc., Los Angeles, Calif.

At a recent meeting of the 17th Annual Congress on Industrial Health, Dr. Dwight H. Murray, President of the American Medical Association, stated that "from 1940 to 1945, the accidental death rate in industry dropped 30 per cent, making most work places safer than the home and highways." From this statement it would appear that the industrial safety job has reached the stage of "a good job well done" but it certainly points to the necessity of added efforts in the off-the-job safety field.

Quoting from the 1957 edition of "Accident Facts," we find that off-the-job accidents cost the American public $4,850,000,000 as compared to costs of work accidents of $1,950,000,000, or a ratio of 2.5 to 1. This does not include indirect costs but reflects wage loss, medical costs, and insurance.

To get into the area of how much of this tremendous off-the-job accident cost is being borne by industry, one must reflect on the direct cost of group and disability insurance programs which are borne by industry, and under such programs, employees or their dependents draw benefits while disabled or hospitalized as a direct result of off-the-job accidents.

The cost of most disability insurance programs to industry is in direct relation to the amount of benefits paid under these plans, so it is fairly obvious that by reducing off-the-job accidents, there would be a direct result of lowering the cost of disability insurance to industry.

CONTRIBUTORY PLANS

While most group insurance plans are contributory in nature, that is, the employees and employers both contribute, the same premise as stated above would be true to a lesser degree. In a recent one-year period, a large aircraft company in the State of California showed the following cost experience in the three fields of so-called fringe benefit insurances.

Group Insurance .....$2,868,000.
Disability Insurance .....$1,352,000.
Workmen's Compensation ...$ 313,000.

These figures show that the ratio of group insurance to Workmen's Compensation is 9.2 to 1 and disability insurance is 2.3 to 1. The previous ratio as reflected from the figures quoted from "Accident Facts" is almost identical to the ratios of disability insurance to Workmen's Compensation noted here.

Throughout the safety engineering profession during the past years, the most often heard comments are the need for upgrading the profession and ways and means of effecting it. Certainly, in the present period of increasing austerity, the most fertile field for a safety engineer to develop as an important part of good management would be in decreasing the cost of doing business, and, without question, from the figures shown, much can be done in the field of reducing costs of fringe benefit insurance programs through the development and active participation in off-the-job safety programs.

INDIRECT RETURNS

Up to now, we have only been talking in direct dollars and cents costs with no thought being given to the indirect returns of off-the-job safety programs from the public and employee relations standpoint. A couple of years ago, during a most active phase of our off-the-job safety program, an attitude survey among a small, scientifically selected sample of employees was made, to determine which of our many fringe benefits our employees were most familiar with and which they most appreciated. They were not asked to comment on any specific benefit but were asked what they thought were the most important advantages to them in working at North American.

The results showed concretely that our safety program had made a bigger impression on our employees than any other single fringe benefit that North American offered. This is especially significant when you consider all of the fringe benefits furnished by industry these days. Certainly, this attitude reflects the good feeling brought about by doing something on off-the-job safety for the employee and his family.

There are many tangible returns from a sound safety program in the area of better employee relations, public relations, and more efficient production. We attempted to reach the people who make the man on the job "tick" through a joint on-the-job—off-the-job safety program. This program has been continuing for the past several years and it is called the "Good NAAbor Program." The most recent phase of this program was typified by direct mail into the homes of all employees at the Los Angeles, Downey, Canoga Park, and Fresno, California plants, representing some 23 geographic locations and fitting into 14 separate communities.

OFF-THE-JOB-PROGRAM

Special letters were mailed, accompanying a safety booklet or bumper sticker, playing up items of safety that had some specific appeal at the time of the mailing. The five most recent gimmicks we used in this program were:

1. the Good NAAbor Safety Show,
2. a Bumper Sticker Campaign,
3. "Dennis the Menace on Safety" Booklet,
4. Post Cards, and
5. Lifesavers.

The first project, the Good NAAbor Safety Show, incited employee interest and participation in *Doing* for Safety. A theater was reserved for North American's exclusive use for one day, with second shift employees being invited to the matinee performance. Attendance at the theater was limited to employees and their wives or husbands, who had been recognized by their supervision as having done something "extra" for their own or their fellow worker's safety.

At the time he was observed, he was given a pair of tickets to the show, plus tickets for free popcorn and Cokes. The program consisted of a presentation by North American's choral group, followed by a short subject comedy on safety, and a major studio feature preview.

Next, a traffic safety letter was mailed to the homes of all North American California employees, with the enclosure of a bumper sticker which was designed with the Good NAAbor Safety Insignia and bearing the wording, "When in Doubt—Play it Safe."

PROGRAM FOR CHILDREN

The next project, "Dennis the Menace on Safety," was especially well received by the children in the homes, and requests for additional copies of the booklet were received from schools and PTA groups. This booklet, a National Safety Council publication, was imprinted with our Good NAAbor insignia, and was mailed to the homes of our employees together with a home safety newsletter.

Next we mailed jumbo post cards with a full color picture of products built by North American Aviation, such as the atomic energy reactor and the Saber jet. The card carried an appropriate safety message or slogan on the reverse side.

The final phase of this campaign took place on the job. Miniature Lifesavers were obtained with a safety slogan imprinted on each package, "Good NAAbors are Lifesavers." These Lifesavers were given to our plant safety committeemen who passed them out to employees in their area on a given day. Interest in this project, as well as all other phases of the program, was incited by articles in the company newspaper.

Several weeks before the Lifesavers distribution, small brighteners, such as "Lifesavers are Coming." "Lifesavers—A Safety Treat," appeared in the newspaper, to arouse curiosity and interest in the program.

As in past phases of our Good NAAbor Program, we are allowing a lapse of several months before embarking on other phases. These are presently in the study stage.

It seems readily apparent to me that increasing activities in the off-the-job safety field are indicated, and, as a means of making the safety job a more important tool of management, it would behoove all of us to increase all of our activities in this field and thus continue to do a worthwhile service for employers, the community, and the nation.

EPOXY RESINS AND CATALYSTS HAZARDS

by PAUL LANGE

industrial hygiene engineer, Employers Mutuals of Wausau, Milwaukee, Wis.

During the last few years, a relatively new group of synthetic resins has been introduced into the aircraft industries. They are called the epoxy resins and are also referred to as epoxide and ethoxyline. These names are derived from the functional OXIRANE group and partially from the basic material epichlorohydrin. Chemically, these resins are condensation products formed from epichlorohydrin and bis-phenol or other polyhydric compounds.

The resins were first introduced in this country under such trade names as "Epon" and "Araldite." Needless to say, there is a large variety of epoxy resins on the market today under various trade names. It is estimated that about 90 million pounds of epoxy resins were used in 1956.

Because of their extensive range of desirable characteristics, epoxy resins have a wide application. Aside from good mechanical and electrical properties, they have excellent adhesion and insulation qualities, plus a remarkable resistance to corrosion. In short, their application appears to be unlimited. A speaker addressing a recent American Foundrymen's Society meeting, heralded epoxy resins as "perhaps the most important development in our life time."

APPLICATION OF RESINS

Typical industrial applications include aircraft fabrication; electrical components, such as transistors, capacitors, rotors and small motors; proofing of electrical splices; fabrication of foundry patterns; lining materials for detergent and paint cans; drill and checking fixtures; glass cloth laminates; bonding for milk tank fabrication; and even repair of metals such as automobile bodies and fenders.

Basically, epoxy resins are supplied in two reactive components, the resin and the hardener, which is also referred to as the catalyst, curing or setting agent. In some cases it is desirable to preheat the components, and in other cases tht components are mixed at room temperatures. Likewise, curing may occur at room temperatures or is hastened by additional heat in curing ovens. Shrinkage is small during curing, indicating that the amount of volatile material released is small. Depending upon the results desired, fillers plasticizers, diluents and flexibilizers may also be added.

HARDENER HAZARDS

The chief health hazard associated with epoxy resins lies in the handling of the hardener and the catalyzed uncured resin.

The hardeners are most often one of the aliphatic or aromatic amines. Occasionally, one of the organic acid anhydrides is used. As a group, the amines, substituted ammonia compounds, are caustic materials.

Human experience and animal studies have shown that the amines are not only primary skin irritants, but can also become generalized sensitizers with whole body reactions. From our knowledge of human experience it has been demonstrated that anyone with sufficient exposure to the amine catalysts or their vapors will develop a skin reaction. Frequent exposures to relatively low concentrations of amine catalysts will produce a sensitized-type dermatitis which becomes more extensive with repeated exposures.

The skin reaction generally appears on the exposed skin areas such as eyelids, hands, forearms, neck and face. The dermatitis generally appears as an inflammation progressing to edema, later vesiculation with weeping, crusting, and finally scaling. Continued exposure may propagate the dermatitis to other parts of the body.

SENSITIVITY VARIES

Developing a sensitivity to the amine catalysts is extremely variable. Some hypersensitive individuals develop a sensitivity after short exposures, while others may be exposed for years before becoming sensitized. In the case of a sensitized individual the mere inhalation of low concentrations of the amine catalyst may be sufficient to produce real symptoms.

The prognosis of most epoxy resin dermatitis cases is for the most part fairly

rapid recovery after medical treatment and complete removal from the exposure. Experience has shown that affected personnel must be completely cured of their skin irritation before returning to their previous exposure.

We were again reminded of this just recently with an epoxy resin dermatitis case in Milwaukee. An affected worker was removed from his original exposure and after proper medical treatment was permitted to return for work in another part of the plant where there was no epoxy resin exposure. Unfortunately, the newly assumed position was also on a lower pay scale. The employee's dermatitis had healed fairly well and was in the final stages of healing. The man clamored for immediate return to his old job.

RETURNED TOO EARLY

The Union representative thought he had the best interests of his fellow worker at heart and lent his support. The superintendent was pressured, against his better judgment, into returning the employee to his old job. The story is short. The man worked just one day. That night his dermatitis broke, covering not only his previous hand skin area but radiated up his forearms finally reaching his shoulders. The final report on the employee was that he was again on his old job but a very careful worker.

The hazards associated with the other catalysts such as the organic acid anhydrides vary from moderate irritation to the eyes, nose, and throat, to extreme irritation to the same organs.

UNCURED RESINS

The plastics industries were among the first to learn that the catalysts for epoxy resins were dermatitis producers. They extended research efforts to find less hazardous materials. It has been found, for example, that the hydroxyalkyl derivatives of diethylenetetramine do not produce sensitization and are equal to or better than the commonly used cross-linking agents. As a result, a low order toxicity amine catalyst is on the market.

While most of the uncured resins may in themselves produce skin and eye irritation, they are considerably less reactive than the catalysts. Some sources indicate that there is a relationship between the ability of the resin to produce dermatitis and the resin's molecular weight. It is believed that the irritant potential decreases with the increasing molecular weights of the resins. The theory is that with an increasing molecular weight resin there are fewer molecules per unit area for reaction with the skin.

The catalyzed uncured resin will have irritant properties dependent upon the reactiveness of the resin and catalyst used and the state of polymerization.

Once the resin becomes fused, there is little sensitizing danger except when performing grinding or other mechanical operations whereby small amounts of vapor may be regenerated. This may become significant if such work is carried out in confined unventilated spaces.

Likewise, there is also a possibility of generating considerable dust during the sanding of the hardened resin. There have been a few cases where sensitized individuals have experienced difficulty from the sanding dust when not protected with a respirator. Ordinarily, the dust is considered fairly inert. It is an organic material and under proper conditions may present a fire and explosion hazard.

PLASTICIZERS AND DILUENTS

The use of these materials may further increase the hazard of handling epoxy resins. For example, a diluent such as phenyl glycidal ether is an irritant affecting both the eyes and the skin. Plasticizers and diluents also increase the potential fire hazard.

Most of the fillers, with the notable exception of silica flour, present few health hazard problems. Likewise, the flexibilizers such as the organic polysulfides even with their foul mercaptan odor are considered less hazardous.

The handling of epoxy resin materials presents no unusual difficulty providing a comprehensive safe practices program is instituted and rigidly enforced. The principal objectives of the program are much the same as with the handling of any other hazardous material. Experience has shown that the following safe practices are effective.

EDUCATING FOREMAN, WORKERS

It is of prime importance to train the foremen and workers how to work safely with the epoxy resin components. They must know and be keenly aware of the potential hazards and how to cope with the reactive materials. The basic need for strict personal hygiene must be fully appreciated. It is not uncommon to hear plant safety directors remark that after men have been working with epoxy resins they develop better basic personal hygiene habits than they had before they started such work.

Even small items, such as keeping the finger nails short, not wearing rings or wrist watches while working, not wiping the perspiration from the face with a contaminated hand, using clean rags or paper toweling to remove excess resin, and wearing clothes not contaminated with resin or catalyst are of significance.

Frequent washing of the hands is necessary whenever the worker leaves the resin area before smoking, eating, or drinking. Care must be exercised not to contaminate door knobs and other common articles. Foot-activated water valves are desirable at the drinking fountain and in the wash room.

WATCH SKIN CONTACT

It is most desirable to keep the reactive epoxy resin components off the skin. Process mechanization is one effective method in minimizing skin contact, for example, mechanical mixers and mechanical pouring devices.

In many instances the operation is such that manual handling of the components is required. It is during these operations where gross skin contamination may result. Impervious gloves (preferably lined), aprons, sleeves, face shields, vapor-proof chemical safety glasses, respirators approved by the U.S. Bureau of Mines for protection against toxic vapors, and barrier creams are all valuable in minimizing skin contact.

There are some manipulations which require acute manual dexterity and gloves cannot be worn. In such cases it is desirable to use a barrier cream. There are many barrier creams available and generally any cream providing good protection against alkalies will provide some protection. Application of barrier creams to all exposed skin areas is advisable where there is a danger of the uncured epoxy resin or the catalyst vapors reaching the skin.

In cases of sensitized individuals this is extremely important. We frequently hear production people state that just walking through a curing area when small amounts of amine vapors are present will cause the face to break out with an urticaria condition if they had forgotten to apply their barrier cream.

SUPPLY REFATTING CREAM

Since workers must wash their hands many times during the day, it has been found worthwhile to supply the workers with a refatting cream such as the lanolin base type for use after the final clean-up at the end of the shift. This facilitates the replenishment of the natural skin oils and prevents the hands from becoming dried and cracked, conditioning them so they are less susceptible to infection.

Plastic gloves and tools contaminated with epoxy resin components should be washed in some suitable solvent such as acetone or alcohol, followed by soap and water. Since most of the solvents which may be used for this cleaning action are flammable, the solvent washing is best done by a worker protected with impervious gloves in a container equipped with a self-closing safety lid. Only tools contaminated with epoxy resin components should be cleaned in this container.

Face shields are helpful in keeping droplets off the face in many operations, for example, applying the catalyzed resin as an adhesive coating on a tank with paint rollers. Once the resin material falls on the skin, it should be removed as soon as possible with soap and water before the resin sets. Should the resin become set, care must be taken to use only clean solvent for removing the resin. There are also products now available for removing epoxy resins from the skin. These are said to be free of solvent.

RESPIRATORS SUGGESTED

Respirators approved for protection against toxic catalyst vapors have a place where ventilation is impractical. Likewise, chemical safety goggles are necessary under similar circumstances to prevent eye irritation.

Good housekeeping is essential in keeping the resin components off the skin. Sloppy handling of the reactive materials and allowing them to become spilled on the floors, benches and tools generally means that some of the material will eventually contaminate some worker's skin.

With some operations it is desirable to cover the work benches and other possible drip locations with a disposable material such as paper. This covering material may then be removed at the end of the shift or as the situation demands and disposed in suitable closed waste containers.

VENTILATION

One of the first controls an industrial hygienist considers when dealing with a toxic material is ventilation. We have placed ventilation as the third control since it in itself is not as importan. • education and keeping the skin contact to a minimum. Sensitized workers may argue this point but had they not allowed themselves to become sensitized, they perhaps would also concur.

It is desirable to apply local exhaust ventilation at weighing, mixing, and curing areas. Where oven-curing operations are utilized, it is also necessary to ventilate the ovens. The need for ventilation is somewhat dependent upon the type of epoxy resin and hardener and the temperatures used since some epoxy resin components have low vapor pressures.

MEDICAL CONTROLS

In some operations if the amount of epoxy resin used is small and the plant area large, good general ventilation is adequate. As mentioned previously, there are some operations where because of the mass of the material involved, local exhaust ventilation is impractical and general ventilation is inadequate; therefore, approved respirators must be worn to protect the workers.

One of the chief functions of the medical control is to assure prompt medical treatment of all skin irritations. This requires a close watch by foremen and supervisors so that a worker does not develop a full "bloom" dermatitis before reporting to the medical department. If the plant does not have a medical director, services of a dermatologist should be sought.

The treating physician should be supplied with complete information regarding the epoxy resin used. The worker should not be allowed to return to his job without a directive from the medical department and then his preventive measures become extremely important.

An attempt should be made in the preemployment physical examination to screen allergics and asthmatics so that these workers are not exposed.

Proper fire precautions should be observed with the resins, flexibilizers, catalysts and diluents. As mentioned before, dust control measures should be considered for sanding operations.

MANUFACTURERS' RECOMMENDATIONS

For interstate shipping regulation reasons and others, products are labeled with the manufacturer's recommendations for safe handling and use. This information should be studied and followed carefully as it contains a wealth of information.

Most manufacturers will gladly supply additional information at your request, and it is only reasonable that they know their products best.

The epoxy resins are finding wide application throughout industry. The main occupational health hazards associated with their use is contact dermatitis and sensitized dermatitis in some individuals.

Experience indicates that epoxy resins can be worked with safely provided basic safe practices are exercised. These include education, keeping the skin contact to a minimum, adequate ventilation, medical control, proper fire precautions, and following the manufacturer's recommendations.

AERO SAFETY EXCHANGE QUESTIONNAIRE RESULTS

The AERO Safety Exchange Questionnaire was submitted in advance of the program, summarized after returns were received, and in part, discussed at the program. Other matters were also discussed, but not recorded.

Members replying to the Questionnaire:
AiResearch—Division of Garrett Corporation—Los Angeles, Calif.
ARO, Incorporated—Tullahoma, Tenn.
Boeing Airplane Company—Seattle, Wash.
Boeing Airplane Company, Wichita, Kan.
CONVAIR—Division of General Dynamics Corporation, Fort Worth, Tex.
Douglas Aircraft Company, Inc.—Long Beach, Calif.
Douglas Aircraft Company, Inc.—Tulsa, Okla.
Hughes Research & Development Laboratories—Culver City, Calif.
Lycoming—Division, AVCO Manufacturing Corporation, Stratford, Conn.
McDonnell Aircraft Corporation,—St. Louis, Mo.
Orenda Engines Limited—Toronto, Ontario
Rohr Aircraft Corporation—Chula Vista, Calif.
Ryan Aeronautical Company—San Diego, Calif.
Solar Aircraft Company—Des Moines, Iowa
Wright—Patterson AF Base—Dayton, Ohio

A. *EMPLOYMENT OF PERSONNEL*

1. X-Rays taken of all Backs?
   No: 16* Yes: 0
   * 1—On ages over 30
   1—New hire past 40 (4 views)
   a. If not, are they taken on questionable cases?
   No: 2 Yes: 14
   * Questionable under 40
   b. Are records kept of individual X-Ray exposures?
   No: 2 Yes: 14
2. Is safety orientation given at time of employment?
   No: 2 Yes: 14
   a. If so, state length of orientation.
   1—40 Minutes
   5—60 Minutes
   1— 2 Hours
   2— None
   3—45 Minutes
   2— 5 Minutes
   1—20 Minutes
   1— 1 to 2 Hours
   b. Are safety rules given employees?
   No: 1 Yes: 15
   c. Are safety rules given employees at time of employment?
   General: 8
   Departmental: 1
   Both: 6
   None: 1
3. Are medically restricted cases checked by Safety Department for approval before actual employment?
   No: 6 Yes: 10
   a. Does Safety Department check include all restrictions, even to color blindness?
   No: 5 Yes: 11
   b. Are medically restricted personnel periodically checked by Safety Department?
   No: 4 Yes: 12
   * Every 6 Months (1)
4. Submit example of report on type medical restrictions which cause rejection of applicant.
   *1—Drill press operators
   1—Man with one eye
   1—Former back cases
   1—Not available for release
   1—Color blind person cannot work in stores, bar stock. Polio cripple cannot work in second floor departments because of stairs.
   1—Backs, respiratory, hearing, sight and some physically handicapped.
   1—See complete record on file.

B. *MEDICAL*

1. Are medical restrictions placed on employees who are given permanent disability awards?
   No: 1* Yes: 15*
   * Depends on case.

a. Does this include cases where company or company authorized physician does not find any disability, but employee given award?
No: 7 Yes: 8

2. Are cases considered industrial, where
a. Employee bends down, cannot straighten up, and disc results?
No: 3 Yes: 13
b. Stoops to plug in electrical plug-back strain-lost time only?
No: 3 Yes: 13
c. Dermatitus condition—No positive reason?
No: 9 Yes: 7

3. No reports.

C. *SAFETY DEPARTMENT*

1. Are tabulating cards prepared on all dispensory calls, broken down by type of injuries and reports made?
No: 11 Yes: 5
a. Are monthly reports also made by tabulating unit and printed off of master?
No: 11 Yes: 5
Note: One company reports that medical makes monthly report.

2. Do you keep accumulated record of manhours worked by each department?
No: 3 Yes: 13
a. Where do you get figures?
1—Accounting—15
2—Tabulating—1

3. On what basis are Safety Personnel Employed?
1—Direct labor hours—1
2—Two years or more of Safety Engineering experience.
3—No written procedure.
4—Salary for male safety engineer—hourly for clerical.
5—No comment—3
6—Qualifications, work background, personality, etc.
7—U. S. Government Standards
8—Education and Experience
9—Experience—2
10—Roughly one per each 750 employee
11—Basis of need.

a. (1)	7 Safety Engineers 1 Steno	$ 396.00—$ 665.00 1.71— 2.25		24,500 Personnel
(2)	1 Safety Engineer 5 Safety Inspectors 1 Steno	Salary Not Disclosed $ 98.00—$ 113.00 Week 82.80— 94.80 Week		30,000 Personnel
(3)	1 Safety Engineer 1 Steno	6400.00— 9800.00 Year 128.00— 260.00 Month		2,900 Personnel
(4)	1 Safety Engineer 5 Safety Analyst 1 Clerk 1 Safety Supervisor	Salary Not Disclosed Salary Not Disclosed Salary Not Disclosed Salary Not Disclosed		17,258 Employees
(5)	1 Safety Engineer 1 Safety Administrative 1 Safety Representative 1 Steno-Secretary	$ 800.00—$1100.00 Month 664.00— 932.00 Month 580.00— 806.00 Month 1.73— 2.33 Hour		5,500 Personnel
(6)	Safety Engineer Steno-Secretary	500.00— 600.00 Month 260.00— 290.00 Month		Personnel Not Mentioned
(7)	No Comment—2			
(8)	1 Safety Engineer 7 Safety Inspector 1 Safety Analyst 1 Steno-Secretary 1 Clerk	$5440.00—$8645.00 Year 4080.00— 6250.00 Year 3415.00— 4890.00 Year 2960.00— 3925.00 Year 2960.00— 3925.00 Year		80,000 Personnel
(9)	3 Safety Engineers 1 Steno-Secretary	123.00— 176.00 Week 1.76— 2.08 Hour		12,317 Personnel
(10)	2 Safety Engineers 1 Steno-Secretary 4 Clerks	94.00— 141.00 Week 1.85— 2.08 Hour 1.49— 1.89 Hour		28,000 Personnel
(11)	1 Safety Engineer 2 Safety Inspectors 1 Steno-Secretary	Salary Not Disclosed $ 410.00—$ 525.00 Month 240.00— 320.00 Month		5,000 Personnel
(12)	1 Safety Engineer 1 Safety Engineer 1 Safety Supervisor 1 Steno-Secretary	5400.00— 6300.00 Year 6700.00— 8400.00 Year Salary Not Disclosed $2700.00—$3800.00 Year		2,200 Personnel
(13)	1 Safety Engineer 2 Safety Analyst 1 Safety Inspector	Salary Not Disclosed $ 450.00—$ 636.00 Month Hourly		8,500 Personnel
(14)	8 Safety Engineers 1 Steno	$ 375.00—$ 665.00 Month 1.71— 2.15 Hour		28,000 Personnel

4. Does safety approve all tooling prints where safety involved?
No: 3 Yes: 13

5. Does safety approve plant engineering prints?
No: 2 Yes: 14

6. Does plant lay-out tie safety in on all moves, additions, etc.?
No: 2 Yes: 14

7. Does safety have monthly meetings with all unions?
No: 6 Yes: 10

8. Does safety check all additional safety requirements to all process standards?
No: 4 Yes: 12

9. Are all standard practices involving safety coordinated with safety?
No: 1 Yes: 15

10. Does safety check employee suggestions regarding safety?
No: 0 Yes: 16

11. Are safety standards added to engineering standards?
No: 1 Yes: 15

12. Are safety check sheets made out for departments?
No: 7 Yes 9

13. Do you have safety rules for each department?
No: 5 Yes: 11

14. Are awards other than Safety Plaque for department given each employee for a given number of no lost time hours?
No: 16 Yes: 0

15. What departments, or job classification, have a compulsory safety shoe requirement.
(1) No safety shoe program—9 companies
(2) Foundry, drop hammers, tooling & material handling
(3) Steel Foundry—3 companies
(4) Drop hammers, die yard, foundry
(5) Foundry, warehousing, machine shops & plant maintenance.

16. What departments have goggle areas?
(1) Fabrication & tooling
(2) All departments in shop—5
(3) Departments having grinding, welding, etc.
(4) Machine shop, fabrication & chemical processing.
(5) Machine shops, maintenance, burring, aluminum foundry, plating, sheet metal, spot welding, grinding, heat treat and Experimental Laboratory
(6) Welding, machine operations—maintenance
(7) All hazardous areas such as machine shop & sheet metal fabrication, etc.
(8) Plant wide, except final inspection & final assembly
(9) Grinding room
(10) Tool grinding
(11) Production machine shop, Tool & die, Tool grinding, etc.

17. Makes of goggles used
Spectacle type—14
Coverall type—13
a. Are they repaired?
No: 2 Yes: 14
b. Salvaged when repair needed?
No: 13 Yes: 1
c. Do you standardize on coverall type only?
No: 12 Yes: 4
d. Is goggle cart used?
No: 16 Yes: 0
e. What kind of goggle cleaning used:
Paper & fluid—11
Treated Paper—10

18. Do your safety personnel have a certain area for which they are responsible?
No: 8 Yes: 8

19. Have you tried to employ specialists or engineers for the various requirements, such as: chemical, structural, mechanical and electrical?
No: 14 Yes: 2

20. Is safety responsible for all proof-testing of handling fixtures, cranes, hoists, jacks, tri-pods, etc.?
No: 8 Yes: 8
a. Does safety maintain records & issue requests for proof-testing?
No: 7 Yes: 9
b. Does safety witness new or reworked proof-testing?
No: 7 Yes: 9
c. Are more important fixtures magnafluxed?
No: 4 Yes: 12

21. To what division head or executive dies safety report?
(1) Personnel or industrial relations—12
(2) Management—1
(3) Public relations—1
(4) Chief-general services division
(5) Plant engineer

22. Are compensation payments reported to top management?
No: 1 Yes: 15
a. Individually—23
b. Monthly—8
c. Yearly—12

23. Can employees purchase safety shoes through the company on time basis? (Payroll deduction)
No: 6 Yes: 10

24. Do you carry home-safety activities other than through your weekly news?
No: 7 Yes: 9

D. *TESTING EQUIPMENT*

1. Are all testing fixtures, including gauges, hoses, safety valves and operations periodically checked?
No: 2 Yes: 14

2. Are operating instructions posted on each fixture?
No: 4 Yes: 12

3. Are operators specially trained, certified, and authorized to operate most equipment?
No: 3 Yes: 13

4. Are assigned operators names posted on equipment?
No: 13 Yes: 3

5. Does safety approve design of each?
No: 5 Yes: 11

6. Do you have a special certification department for this equipment?
No: 8 Yes: 8

7. Do you have a special hose with safety pop-off valve for airing tires from nitrogen carts?
No: 6 Yes: 9

E. *MISCELLANEOUS*

1. Does all towed equipment, except that which has a mercury trailer hitch, have safety chains?
No: 3 Yes: 1

2. Do you use a substitute fluid for JP-4 fuel (such as Sol-Trol) for testing fuel system, including tanks, valves, fittings, tubing, boost pumps, etc, in aircraft under static test load or pressure?
No: 0 Yes: 8

3. What type protection is used to keep down skin scratches?
(1) Gloves—4
(2) Padded or sheared off corners—gloves—aprons, etc.
(3) Paper—2
(4) Spray-Lac
(5) Protective equipment—6
(6) Corregated paper coverings
Note: This question mis-understood. It was intended to concern keeping surface scratches from aircraft wings, etc.

4. Type ear plugs used:
(1) Rubber—3
(2) Plastic—1
(3) MSA—10
(4) Not used—2

5. Type ear muffs used:
MSA—6 AO—5 Other—4

6. Do you have protective guard in front of engine intake?
No: 2 Yes: 9

7. Do you have an emergency evacuation program?
No: 4 Yes: 12

8. Do you use electric eyes on:
Hydraulic presses? No: 13 Yes: 3
Shear machines? No: 14 Yes: 2
Vehicle doors? No: 12 Yes: 4

9. Are all punch press dies individually guarded?
No: 11 Yes: 5

10. What type cleaning solvent used to clean aircraft?
Turco 2851—2
Various—1
Alkaline type cleaner—1
Stoddord solvent-also trichloroethylene—2
Tect-safe solvent—1
Trichloroethelene-stanisol—2
Trichloroethane—1
Menthyl alcohol—1
Company compounded—1
a. Is trichloroethylene used in spray method?
No: 11 Yes: 3
b. Is trichloroethane used?
No: 5 Yes: 6
c. How are hydraulic line breaks cleaned up?
Oil sorb—3
Wash down by fire department—rags
Trichloroethlene
Wipe or spray

11. What type of substance that cannot be tracked on aircraft causing scratches or corrosion are used on icy and slick surfaces around doors and walkways?
(1) Pea gravel and employees wear shoe socks—1
(2) Floor sweep—1
(3) Abrasive strips—1
(4) Sand—11
(5) Mats

12. Do you have special device on tugs, fork lifts, eac, used in buildings to reduce carbon-monoxide concentrations?
No: 13 Yes: 3

13. Do parking lot stalls have:
Bumper stops—5
Post-wire stops—3
Wheel stops—6
Painted stall marked—3
a. If only painted stall marked, does it work out alright?
No: 0 Yes: 3
b. Would you rather have stops?
No: 3 Yes: 3
c. Are better parking spaces given those with riders?
No: 12 Yes: 4

14. Do you have test equipment for sampling all types of chemical and dust fumes which are toxic or irritant?
No: 6 Yes: 10

15. Do you have a standard practice where employees are sent home when humidity and temperature reach a critical level?
No: 14 Yes: 2

16. Are drop hammers periodically checked, "dogs" and bolts magnafluxed?
No: 2 Yes: 12

17. Do you have compulsory wearing of ear plugs around drop hammers?
No: 2 Yes: 10

18. How often are wing jacks proof-tested?
(1) Every 6 months—2
(2) When repaired —1
(3) Monthly —2
(4) Daily —1
(5) Every 3 months—1
(6) Yearly —1
(7) Every 2 months—1
a. Proof tested to:
(1) 1½—1 —6
(2) 2—1 —3

19. How often are overhead cranes proof-tested?
(1) Every 60 days —2
(2) Monthly or when reworked—5
(3) Inspected nightly only —1
(4) Every 6 months —2
(5) Yearly —1
(6) Every 3 months —1
a. Proof-tested to:
(1) 1½ —1
(2) Capacity, plus 10%
(3) Capacity, plus 11.1%
(4) 3 —1
(5) 2 to 1 —1
(6) 1¼ to 1 —1

20. Does safety check all vehicles?
No: 12 Yes: 3

21. Method of disposal of radio-active tubes:
Bury—4
Dumped in sea—7
a. Are standard TR and TRT tubes (slightly radio-active) treated as plain tubes?
No: 8 Yes: 1

22. What type of slings used in overhead crane work?
(1) 6 x 37 hemp center, preformed, improved plow steel—3
(2) Steel—braided type—2
(3) Tuffy—braided slings
(4) Cable
(5) 6 x 37 hemp center & aircraft steel core cable
(6) Hemp, wire center
a. Are chain slings used in general?
No: 11 Yes: 0

23. Maximum PSI (above sea level) employee allowed under for air pressure tests?
(1) 3½ PSI—1
(2) 6 PSI—2
(3) 2# PSI—1
(4)10 PSI—1
(5) Individually determined—1
(6) 2.8 PSI—1

24. Are electricians given a complete set of safety rules which include wiring of various plugs, splicing cables ,etc.?
No: 7 Yes: 10

25. Do you have an emergency disaster plan, including evacuation of employees?
No: 3 Yes: 10

Potential Hazards of Fuselage & Component

PRESSURIZATION TESTING

by FRANK W. STARR

safety and conservation administrator, Douglas Aircraft co., Inc., Long Beach, Calif.

In the development of pressure vessels, the prime concern of the design engineer is that the vessel be constructed to withstand the ultimate load pressures and stresses applied to the unit. In initial calculations, the design engineer will usually refer to the American Society of Mechanical Engineers Pressure Vessel's Manual as a guide to safety requirements of the vessel in considering the size of the unit, gauge and tensile strength of the material, type of construction and the installation of pressure relief valves. Adverse past experience resulting in numerous failures of fired and unfired pressure vessels has developed this caution and respect.

Approximately three years ago, the safety department at the Douglas Aircraft company, Long Beach division, was informed by the engineering department that the newly designed C-133 cargo airplane would require exhaustive fuselage, component, and static pressurization tests. At the time this did not cause any undue concern to the safety department.

When we were appraised, however, that the C-133 would be the largest cargo airplane ever developed in the United States, and that the fuselage tests would require ultimate loads of 13 psi, we were staggered by the magnitude of accident prevention problems which would confront us.

Following this initial notification, representatives from the engineering department attended a meeting with the executive safety committee at the Douglas Long Beach Division.

COMMITTEES SET UP

The safety committee decided at once to appoint a pressurization safety sub-committee to plan a pressurization program for the maximum safety of personnel and structures. This newly appointed committee was comprised of personnel from the engineering and test division, facilities department, materials and process group, tooling section, sealing, manufacturing and safety department.

One of the first questions considered by the committee was the advisability of conducting production tests in the manufacturing buildings. Considering the tremendous size of the C-133 fuselage—an overall length of 140 feet and a capacity of 25,000 cu. feet—it was obvious that to assure the safety of employee personnel and building structure in the event of failure, it would be necessary to isolate the fuselage during all pressurization tests. This was advisable because under ultimate pressure loads, the energy within the fuselage against the cargo door was approximately 60 tons. We now were confronted with a pressure vessel safety problem of first magnitude.

WATER TANK BUILT

Weekly meetings and concerted committee planning finally resolved in a program of controlled pressurization testing. At this point, after an evaluation of engineering data, Douglas Long Beach Management decided to construct a water tank large enough to isolate and test the C-133 fuselage while completely submerged. The construction of this tank, which is isolated by distance from any building structure, required considerable time.

The hydrostatic tank was 170 feet in length, 30 feet wide, and 27 feet deep. The lower section of the tank is steel reinforced concrete construction, 15 feet of which is below ground level. The upper 12 feet of the tank is ½ inch boiler plate. The tank has a capacity of approximately one million gallons.

In order to accomplish all testing on schedule, work proceeded on other fuselage and component pressure testing while the tank was constructed. The engineering and test personnel conducted five separate pressure tests:

1. C-133 nose cockpit pressure test.
2. 300 inch fuselage pressure test.
3. Hydrostatic test of entire fuselage.
4. Fuselage component panel tests.
5. Engineering static test of the airplane, with and without air pressure.

Various precautionary measures were used during these extensive tests. In testing the C-133 nose or cockpit section with air and no filler, the sub-assembly was placed in a large tank in an isolated section of our plant property. After anchoring the specimen, we attached a double mesh cyclone fence canopy at the top of the tank to trap or deflect any possible fragmentation in the event of a failure. Synchronized motion picture cameras and television equipment were installed at a port hole of the tank to observe and record the results of the test.

FAIL-SAFE TEST BEGUN

We were now prepared to proceed with our initial "Fail-Safe" pressure tests. Although maximum air pressure loads were applied on numerous occasions by our testing personnel, ironically it was finally necessary to cut the specimen with a remote control hydraulic saw in order to induce a failure. In this manner, engineers could ascertain the structural strength and integrity of the fuselage component and provide required reinforcements. There were also tests made of the nose section under water for ultimate pressure and for cycled "life spectrum" pressure.

In pressure testing the 300 inch fuselage section, on the recommendation of our engineering department, phenolic foam filler (balsa light) was used. This filler with paper barrels in the fuselage section provided a 95 per cent displacement of air and insured a maximum reduction of energy in the event of failure. As an additional safeguard, a canopy type cyclone fence enclosure was also installed over the entire 300 inch fuselage section as a precaution against possible fragmentation during the initial test. From results of these and subsequent tests, our Douglas design engineers provided a fuselage structure. If a crack developed in the pressure vessel a small leak type failure, non-catastrophic, would result, not an explosive type failure. The C-133 airplane does include this "Fail-Safe" design feature.

After completing the hydrostatic tank, the engineers tested the entire C-133 fuselage. This particular test stimulated considerable interest because of the tremendous size of the assembly and the problem of proper rigging, lifting, balancing and placing the unit safely into the tank. For this the engineers used several large automotive cranes directed by qualified riggers who supervised handling and placing the fuselage in the tank.

FUSELAGE SUBMERGED IN WATER

The tank was then filled with water which completely covered the entire fuselage assembly. At specified periods, a team of experienced skin divers studied the fuselage structure, seeking out leaks and inspecting for possible weaknesses or distortion in the assembly. This series of tests proved successful and was completed without incident. With the removal of the fuselage from the tank, the unit was ready for its final and most important test.

After joining the fuselage with the wing structure and empennage sections, the airplane was placed in the static test building for major testing. In essence, the static testing of an airplane subjects the entire plane and its components to the critical loads and stresses to guarantee strength and integrity, and to ascertain future performance of the product.

In preparing for this test, which must be performed in the building, the facilities engineers, in coordination with the safety department, provided extensive precautionary facilities to protect employee personnel and other aircraft stationed in the building. The task of cutting and fitting the plastic foam filler into every opening and crevice within the fuselage was a time consuming factor. In connection with use of the foam filler, the engineers also used large fiber drums in effecting a 95 per cent displacement of air prior to the static test.

A large shielded test room was installed in the building to house engineering test personnel and equipment. The dual type walls of the room were approximately 10 inches thick, the sections reinforced with an inner layer of sand. Dual bullet proof observation windows, 1 inch thick, were installed at strategic points in the observation and test equipment room.

In addition, cyclone wire type fencing completely enclosed the airplane. This cyclone guard was suspended from overhead building structure beams and rested loose on the floor during the static pressure test.

After draining the hydrostatic tank, the engineers used the unit for additional component pressurization tests. Separate and numerous fuselage panel sections were air pressure tested in the facility, the upper section was also shielded by cyclone fencing. The concussion from several of the induced "Fail-Safe" fuselage panel tests was comparable in intensity with the detonation of a dynamite charge. The tearing effects of this explosive decompression on the panels was quite severe.

NEAR-ACCIDENTS IN TESTING

Although all pressure tests were conducted without accidents, they were not free of incidents. Two rather humorous incidents occurred during the fuselage panel testing program conducted in the tank. During lunch period, one employee assigned to this program mounted the catwalk on top of the tank. After removing his shirt and stretching out on the walkway to enjoy a sun bath, he apparently dozed off. Unaware of this, two plumbers were attempting to repair an air leak in a pipe line connected to the panel specimen in the tank. The plumbers inadvertently turned on the air pressure and a full charge of air was forced into the panel section. This was followed by an immediate failure of the specimen and an intense explosive concussion. After this, none of the employees assigned to the testing function used the tank catwalk for sun bathing.

The second incident occurred when one mechanic saw a leak in a fuel line of a C-47 airplane parked near the tank. As he walked away from the ship to get a tool, one of the panel sections in the tank "Failed-Safe." The first reaction of the mechanic was to duck, run, and then drop to the ground with his hands over his head. He later said he heard the explosion and was positive the leaking fuel line had caused the airplane to explode. He was prepared for a shower of debris to engulf him, and he instinctively ducked and dropped to the ground.

In the pressurization of airplane fuselages and components, we are concerned with relatively low pressures when compared with the ultimate high loads and stresses which are applied to industrial type vessels. The aeronautical engineer is conscious of, and concerned with the responsibility of designing a structurally sound product, exhaustive tests which will insure the integrity of the airplane.

The success of the "Fail-Safe" C-133 cargo airplane pressure tests at the Douglas Aircraft company, Long Beach division, was a result of long range planning and coordination of activities.▲

ARDC GUIDED MISSILE SAFETY TECHNIQUES

by HARRY F. BOONE

Colonel, USAF, Deputy Assistant for Guided Missile Systems, Deputy Commander Weapons Systems, Hq. Air Research & Development Command, Baltimore, Md.

Since 1947, some 3,685 guided missiles and rockets have been launched at Patrick AFB, Florida, and Holloman AFB, New Mexico. During this time, we have had one fatality and three serious injuries from handling or operating the missiles and rockets. Although this record is not perfect, the Air Research & Development Command is proud of it. Moreover, as we gain experience, our record is improving. This is borne out by the fact that we have had no fatalities in this category since 1947 and no major injuries since 1951.

The purpose of this paper is to discuss safety techniques used in storing, handling, and flying guided missiles. In covering these subjects, we will touch briefly on safety responsibilities of a missile test range commander, and general planning for safety. We will then cover in more detail specific missile safety techniques used at Air Force Missile Test Center, Patrick AFB, Florida. Finally, we will discuss future missile safety problems.

Under the weapon system concept, ARDC contracts with industry to provide a guided missile and all necessary supporting equipment. Concurrently, we work with the contractor to develop training techniques and equipment to train Air Force personnel in employing the missile. At the end of the R&D, the Air Force conducts unit training. The training techniques and equipment developed during R&D assist in bringing units to an operational status. After this training, we have, a true weapon system: the missile, all necessary support equipment, and trained personnel.

PLANNING SAFE MISSILE TEST RANGES

To assist industry in developed missile systems, ARDC provides instrumented test ranges. The contractor operates on these ranges under safety regulations prescribed by the test range commander. These regulations cover every conceivable aspect of safety: personnel, vehicular, launch pad, aircraft flight and missile flight. The test range commander has special staff officers to insure compliance with safety regulations by all personnel—Air Force and civilian contractor.

A good safety program starts with good planning, particularly with missile test ranges. These ranges have expensive facilities and equipment for safe operations. All of the former and most of the latter are firmly hooked to the earth. Both the former and latter must be located to satisfy present and future requirements. A base master plan which separates hazardous and nonhazardous operations, places safety instrumentation where needed now and in the future, is the first step in missile range safety planning.

The next step in safety planning concerns personnel training. This involves basic safety indoctrination for all personnel and specialized training in first aid, fire fighting, fuel and booster handling, check out and operation of range safety instrumentation, and many other personnel skills required to operate a missile test range.

Ground and airborne range safety instrumentation must be developed. The complexity of this equipment increases as missile performance increases. In fact, the complexity of safety instrumentation approaches the complexity of guidance systems currently in use. Obviously a missile must be designed to provide space and power for the airborne safety instruments. Necessary data are provided to missile contractors, and design and configuration problems are left up to them.

Then the range commander publishes safety regulations and safety plans. The regulations prescribe general range safety policies, procedures, and responsibilities governing missile flight testing, and delineate responsibilities for the control of all personnel. The safety plans are more detailed. They are published for each missile program and specifically apply the broad policies in the regulations. It may be seen that the missile safety battle is pretty well won or lost before the missile arrives at the test range.

AIR FORCE MISSILE TEST CENTER

Up to this point we have talked about planning for range safety. It is now appropriate to examine a specific missile test range and observe the implementation of safety planning. The Air Force Missile Test Center (AFMTC) is located on the east coast of Florida. This is the only instrumented range for the Department of Defense to flight test long range missiles. The range extends southeast over the Atlantic Ocean about 4,400 nautical miles and is used by the army, navy, and air force. Some of the missile programs undergoing tests at this location are Atlas, Jupiter, Thor, Polaris, Vanguard, Snark, Navaho, and Bomarc. All except the last three are ballistic missiles.

The Air Force divides missile safety into two parts; ground safety and flight safety. The line of demarcation is not as definite as one would think. From launch until impact, we are in the realm of flight safety. However, prior to launch, we are in both ground and flight safety. This is because development, installation and check out of flight safety instrumentation, is a flight safety function even though this takes place before launch. Those activities definitely in the

realm of ground safety are installations, planning, and storage and handling of missiles, fuels, and boosters. Overall safety planning and personnel training cut across the board.

SAFE SIDE AND HAZARDOUS SIDE

Safety starts with a good facilities master plan so let's examine AFMTC from that point of view. The Center was two major parts: Patrick AFB proper and Cape Canaveral. The former houses administration, maintenance, supply, the airfield, aircraft, and personnel housing. The latter houses hazard items such as the launch complexes, fuels, and boosters, and also has the missile assembly buildings, missiles, and a considerable quantity of instrumentation. The 20 mile separation of the Base and Cape isolates the hazard area from the support area. The safety aspect of this separation is enhanced by a policy which restricts the number of personnel on the Cape to an absolute minimum.

As for the Cape itself, hazard isolation is again followed. Launch complexes are grouped *according to the type of missile* launched. Separation between elements of each group and between the groups is based on the danger radius generated by the fully fueled missile in question. The industrial area which consists of missile assembly buildings to house unfueled missiles is a safe area. It is placed on the Cape because it is not practical to haul R&D missiles for many miles before launching them. Finally, suitable areas store propellents and boosters, and site instrumentation.

Missile ground safety techniques for storage and handling are quite similar to industry's storing and handling hazardous substances and handling heavy equipment.

Storing the average missile poses no safety problem. An unfueled missile with no boosters or destruct packages attached is as harmless as an unfueled automobile. Storage and handling missile propellents, boosters, and explosives does pose a problem. Industry stores and handles vastly larger quantities of these items, and we follow principles used by industry. The test range commander receives guidance on this subject through Air Force publications. For example, *Air Force Manual 32-3* now includes the latest methods and techniques for handling and storing liquid propellents. Similar guidance on the storage and handling of boosters and explosives is provided through other manual and regulations.

The remaining ground safety area, missile handling, is complicated by the size of the modern missile. We have now reached lengths of 60 to 90 feet and dry weights up to 16 tons. These large masses must be handled tenderly. It is important not to mar the missile skin, and undue shock or jolt might damage installed electronic gear. The missiles are delivered directly to Cape Canaveral, either by air or ground transportation. In either event, they arrive on roadable trailers, and are taken to a missile assembly building.

PRE-LAUNCHING TEST SAFETY

The missile remains in a missile assembly building until ready to be launched. During this time, it is thoroughly examined and checked out. Several days prior to the launch date, the missile is moved to the launch complex or pad and a count down is initiated. This count down is a time phased series of events which leads to complete preparation of the missile for firing. All electronic, electro-mechanical, and mechanical sub-systems are checked out. The missile is fueled, boosters when required are fitted, and range safety destruct packages are attached. When all is ready, the missile is fired if the firing is cleared by the Range Safety Officer. (RSO).

What ground safety problems exist, and what precautions are taken during count down? The first problem involves movement around the ballistic missiles while servicing them. These missiles are in a vertical position and are surrounded by a missile servicing tower 100 feet high. People work from the tower at several levels. Safety techniques here are like those used on high steel work, and include wearing hard hats by all personnel. Aerodynamic missiles do not pose this particular problem.

As any missile is fueled, it becomes a fire and low order explosive hazard. From this time on, the number of personnel around the launching pad is strictly controlled. In addition, fire trucks and ambulances stand by at a safe distance. As the count down proceeds, adjacent launch complexes are evacuated. Finally, at launch time, remaining personnel involved in the missile launch retire to the block house, and ground safety gives way to flight safety.

As previously stated flight safety measures start prior to actual missile launch. We will now return to the count down and discuss those measures. Each missile flown on the AFMTC range must carry two separate and independent means of emergency flight termination. Both means must be capable of being energized by the RSO, who must have duplicate and independent energizing facilities on the ground. In the case of ballistic missiles, emergency flight termination results from cutting the engine and/or rupturing the fuel tanks.

Aerodynamic missiles have explosive packages installed for the RSO to sever a wing. A second fail-safe system will blow the wing off automatically if radar track is lost for a certain number of seconds. Most aerodynamic missiles have a third safety [illegible] for the RSO to control the missile [illegible] ground in the event the self contained [illegible] mous system fails to operate properly. [illegible] ing the count down, necessary explosive destruct packages are installed, and each safety circuit is carefully checked out. Each of these operations is double checked by personnel responsible to the Commander, AFMTC.

MISSILE CHECK-OUT FOR SAFETY

Another flight safety operation during the count down is the check out of the missile and all of its associated equipment. The best possible safety technique is to have the missile function perfectly. A perfect missile flight also contributes most to our R&D effort. In this case the pure R&D effort complements the flight safety effort. A missile is never lamched if the count down indicates that it will not perform properly.

During the count down, other actions contribute to flight safety. A five-mile area out to sea from Cape Canaveral is cleared of all surface vessels. Visual warning signals are displayed at the north and south Cape boundaries. Military and civilian air traffic is diverted from danger areas. Ground radars maintain continuous air surveillance to insure diversion orders are obeyed. Impact areas are visually checked. In some instances, airborne radar is also used for this purpose.

Airborne and ground receiving equipment record all electromagnetic radiation an its strength. This insures that stray radio frequencies are not present to endanger the flight by false signals in guidance systems. All communication systems, tracking radars and plotting boards are checked. The RSO receives reports on all of the foregoing and if all is o. k., and the missile is ready, he gives permission to fire.

The usual purpose of flight safety is to insure that a missile does not endanger life or property. The problem is complicated at AFMTC by diplomatic considerations. Most of the down range stations belong to foreign governments. Violation of their real estate or air space, even though no damage is done, could cause serious political repercussions. It is mandatory therefore that missiles be destroyed the instant they deviate from a planned flight path. This is the AFMTC policy.

ON BALLISTIC MISSILES

It is necessary to discuss ballistic missile and aerodynamic missile flight safety separately. Once a ballistic missile engine shuts down, nothing can change its point of impact. On the other hand, the impact point of an aerodynamic missile can be affected any time.

For ballistic missiles, the most dangerous portion of the flight is the first seconds after launch, because the missiles rise relatively vertically and accelerate slowly. It is difficult to determine initially if the missile will head down range at the proper azimuth, and a thrust failure brings the missile crashing back to the Cape even though guidance is functioning properly. An optical skyscreen is used to keep track of the missile trajectory during this difficult period. The optical screen is backed up by an electronic skyscreen which becomes the primary system when visual contact is lost. Operators of both skyscreens track the missile from launch and provide the RSO with instantaneous trajectory information on the missile's progress.

Once the ballistic missile gains altitude and speed, the RSO makes decisions about terminating flight with the aid of an impact predictor. This is an electronic computer device which receives missile position and velocity data as inputs (these data are measured by radar and radio) and computes the point the missile would impact if thrust

were lost. The RSO can cut the missile engine any instant. If a missile becomes dangerously erratic, and must be cut down, he chooses a time to cut thrust which the impact predictor shows will land the missile in a safe area. This system is of no value after engine burns out, and is not used with aerodynamic missiles.

From the safety point of view, problems posed by an aerodynamic missile launch are less than those generated by a ballistic missile. Generally speaking, an aerodynamic missile obtains flying speed with the aid of reliable boosters. This practically guarantees that the missile will clear the Cape and land in the water, if propulsion or guidance failures occur in the first few seconds.

Skyscreens are also used as a safety measure for these missiles. However, the basic safety system consists of a chain of tracking radars extending down range and a communications system which links the radar positions. For aerodynamic missiles, a RSO is at each radar site as well as at the Cape. Each RSO receives the X, Y, Z coordinates of the missile when it is within range of his radar, and these coordinates are transmitted by the communications system to all other RSO's.

AERODYNAMIC MISSILE LAUNCH

Responsibility for keeping the missile within range boundaries is passed from RSO to RSO as the missile progresses down range. Each RSO has ground equipment to transmit a missile destruct signal. The same radars used for range safety purposes are concurrently used to collect R&D trajectory data. This dual use is true of much of the instrumentation which is used for range safety.

Missile safety is a big and expensive business at a test center, and is an integral part of missile R&D and training taking precedence over all other factors. Safety, of course, would not take precedence during the operational use of missiles, but would remain an important consideration.

The personnel to implement safety are trained in various ways. Military and civilian schools provide some training. Civilian contractors sponsor training on material which they produce. Test range commanders provide on-the-job training within their capability. A fresh, modern outlook on safety is maintained at all times by a constant interchange of ideas with civilian organizations which face the same, or similar, safety problems.

The primary problem now and of the future is reliability. If we had 100 per cent reliability in each missile we flew, we would have very few safety problems. This is a difficult goal, but with the help of industry we can closely approach it. We must approach it in order to provide effective operational missiles for national defense.

MISSILE SAFETY PROBLEMS IN FUTURE

The next immediate problem concerns training with missiles. Operational units, equipped with aircraft or missiles, must train to reach and maintain combat proficiency. In aircraft, we have no problem. Aircraft flight over populated areas is accepted by the public. Therefore, manuever space is virtually limitless, and short range airborne armament can be exercised over relatively small restricted areas. Contrast this with firing a strategic missile for training. The popular concept now is that an unmanned vehicle must be flown on an established test range. Only one of two deviations from this concept have been granted to date.

When the missile age finally arrives, strategic missile sites will be scattered throughout the United States. The missiles will be reliable, and the most efficient way to conduct training would be to fire from the sites and impact in instrumented ocean areas. Except for those cases which involve booster fall off and impact, operational missiles over-flying the public would pose no greater hazard than manned aircraft.

Boosters would be impacted in restricted areas. Our problem is to educate the public and cause it to accept missile over-flights as a routine event. The alternative to this is expensive test ranges, unrealistic training, and weakening our defense when we pull troops from a missile site and move them to a test range.

Another future missile safety problem concerns propellents which possibly will be used. Nuclear fueled rockets are a possibility. Radiation hazards resulting from nuclear fission are well known. High energy fuels could pose similar problems. This is a new field, but quite possibly exhaust from some of the exotic fuels of the future will be toxic to animals and/or plants.

Finally we come to the acoustic problem. As engines become more powerful, acoustic energy produced will become more harmful to man than that produced by our present engines. Structures, particularly windows, might damage at great distances under proper atmospheric conditions. Another acoustic problem would result from shock waves formed by a low altitude missile flying at hypersonic velocities. These shock waves would definitely damage light structures. There are other safety problems, but these are typical of matters which must be considered and solved.

To conclude, the Air Research and Development Command plans and implements an aggressive missile safety program. We take every reasonable precaution to preclude personnel injuries and property damage. Reliable equipment is the keystone to missile safety as well as to an effective operational missile arsenal. We rely heavily on industry to help in attaining our reliability goals.

Missile safety is costly. It delays R&D firings, and necessitates procurement of expensive equipment. Fortunately, much of the equipment can be used for dual purposes. Finally, the missile safety problem is dynamic. Safety techniques are constantly reviewed and modified to meet changing requirements and to insure maximum safety at minimum cost.▲

OFF-THE-JOB ACCIDENTS

Statistics are such boresome things
And figures rather dull.
It's hundreds, millions, billions, trillions,
Over which we mull.

But facts are facts where ere we go
Regardless of amounts,
So here's some facts on accidents,
And that's what really counts.

It isn't always big machines
With blades of sharpened steel
That rob a man of arm or leg
And make his senses reel.

Nor is it always "on the job"
Most accidents take place,
But just the opposite is true
And figures prove our case.

It's carelessness in little things
At home and on the street
Neglect in moving objects small
Away from running feet.

A makeshift ladder, sliding rugs,
Electric cords that spark
A disregard for cellar stairs
And stumbling in the dark.

Crossing where no crossings are
While looking at the sky,
Driving on a slippery road
With milestones whizzing by.

These are the things that take a toll
We all should frown upon
So watch for them when off the job,
As well as when you're on.

—Humble Pipe Line Company, Houston, Texas

Air Transport Industry Section

JET GROUND HANDLING HAZARDS

by J. T. DYMENT

chief engineer, Trans-Canada Air Lines, Montreal, Que., Canada

The purpose of this paper is to outline a few of the new hazards that will be encountered with our future transport aircraft. The new hazards are due chiefly to two things: the use of the turbo jet engine, and the larger size of the airplane. The most dangerous characteristics are invisible ones, namely, those associated with the jet intake and weather radar.

Strictly speaking, radar is not peculiar to jet transports as it is now being installed in a number of our current airplanes. However, as it is still relatively new and will be a part of all future jet operations it will be included in our review.

As we know, accidents do not occur without cause. Less than two per cent can be attributed to "Acts of God," that is, accidents over which we have no control. Since there is an avoidable reason for almost every accident, one of the many jobs confronting the airlines is to study every phase of its future operations and identify probable sources of accidents, and then control the situation so that an accident will not occur. The latter is no mean task because people will be people. Regardless of the care taken in the design of equipment, the human element will remain the weak link against which we must always guard.

JET ENGINE INTAKE

The greatest hazard associated with the new aircraft will probably be the danger to personnel who come too close to a jet intake. It is possible to approach a running jet engine from an angle at which its noise is practically inaudible.

Since a person can be drawn into an intake with fatal results, and since loose objects can be sucked into and severely damage a $¼ million engine, two things must be done. Personnel must be imbued with the utmost respect for a jet engine regardless of whether or not they believe the engine is running; and everyone must consider it as part of his job to keep the ramp and intake cowling clean at all times.

As long as there is one engine running at a terminal ramp, it is difficult to tell whether or not others are also running, or even which engines are the ones that are running.

No one should ever pass within 10 feet of the intake of a running jet engine and caution should be exercised if within 25 feet. The Air Force insists on the use of some means to warn personnel of the danger of approaching within a radius of 25 feet throughout an arc of 220° of the intake opening during ground running.

USE TWO MEN

At least two persons should be used for running jets on a ramp. One person should be stationed on the ground where he definitely has a clear view of anyone approaching the front of the airplane's engines and, at the same time, be in clear view of the person in the cockpit operating the engine. The person controlling the engines must maintain an alert watch of the ground man—particularly before increasing power.

The engine operator should be responsible, at least to a certain degree, for the safety of personnel regardless of the use of warning flags and/or a ground assistant. This we believe will ensure a more continuous alertness during his operation of the engine.

Loose fitting clothing or head gear should not be worn by service personnel who have to perform duties near the intake of jet engines when running. Similarly such personnel should not carry loose items in large pockets of their clothing.

Considering that one of the larger turbine engines costs close to a quarter million dollars, anyone who leaves tools lying around in an inlet duct should be asked to earn his livelihood elsewhere.

Hazards associated with the exhaust end of the engine are not generally as serious as the intake end. One simple statement might sum up the situation by saying that "the exhaust will blow you out of the way before it will burn you." The question is "what happens during the process of being blown out of the way?"

JET ENGINE EXHAUST

The temperature at a point about 25 feet from the rear of a jet engine producing power sufficient to start the airplane rolling may be around 250°F and the exhaust velocity around 300 mph. Both dissipate rapidly however so that at a point 100 feet from the rear of the engine (that is just back of the tail of a transport) the temperature will be down to around 80°F and the velocity down to 50 mph, which latter differs little from the slip-stream of a propeller driven airplane.

Normally, the start-to-roll power, which need only be applied for a few seconds, will be the maximum encountered on the ramp at an air terminal as lower power is required for starting, idling and manœuvering.

Engine checks requiring higher powers should only be done at special locations away from the terminal ramp. Itinerant personnel not aware of what is going on would not likely be around such a location to get into trouble. At a point 100 feet behind an engine developing take-off power, the temperature could be 100°F and the velocity 100 mph, sufficient to do considerable damage if not diverted upwards by a blast fence or into an exhaust silencing duct.

NEVER SHORT CUT

Personnel should be warned never to take a short cut between the rear of a jet and a blast fence in case someone is in the cockpit and about to apply high power.

Although a blast fence is not required for normal engine starting, rolling away, and taxiing, insofar as ramp personnel are concerned, it might still be desirable at the terminal to prevent debris being blown toward nearby aircraft which might be either loading passengers or have their engines running and thus suck the flying debris into the intakes.

It is evident that while the blast will generally be felt by a person in time for him to keep out of trouble, personnel can be injured by equipment being blown around unless great care is always exercised to have nothing within 200 feet of the rear of a jet engine that can be moved by jet blast.

No person, vehicle, or aircraft should be permitted to pass behind ground operating jet engines closer than 200 feet. The danger area behind the engine covers an arc of about 60 degrees.

A periodic visual examination is required of the compressor and turbine blades as part of routine maintenance. Therefore, the utmost care is required to ensure that the engine cannot be started when someone is inside a turbine intake or the tail pipe.

It might be advisable to tie a rope around the person making the inspection, with an assistant to help pull him out quickly should he get stuck in the duct or the engine be started through someone's negligence.

The Air Force requires personnel who enter the tail pipe of a jet engine to wear special clothing over their regular clothing. Frequent inspections of the protective clothing is made to check for harmful lead particles and it is washed frequently with soap and water.

TWO TYPES NOISE

There are two distinct types of noise associated with the jet engines; the high pitched piercing scream of the compressor and the powerful low-frequency rumble of the exhaust. Insofar as ground personnel are concerned, the former creates the real trouble. From the standpoint of the airport neighborhood, the latter is the problem.

The noise level that may cause temporary or permanent deafness has not been established but it could be as low as 100 db for prolonged exposure.

The threshold of discomfort is about 120 db and at 130 db discomfort is supplemented by an unpleasant tickling in the ear. At 140 db the discomfort may be further complicated by sharp pains in the ear and above 140 db the noise is usually so intense that it cannot be accepted voluntarily. At these latter intensities, eardrums have been punctured.

Since taxiing turns may be accompanied by a sound level of close to 100 db at 100 feet from the engine (37.9, 9600 cps overall) the noise associated with the start-to-roll power will be even higher, reaching possibly 110 db.

Earplugs or more efficient ear muffs are therefore essential for all ramp personnel to protect them from the high frequency compressor noise. Readily accessible soundproofed enclosures are also desirable for ramp personnel who do not have to remain outside on the ramp all the time.

The service personnel of the Boeing Company are equipped with earplugs and a helmet, and receive periodical medical checks. So far with these precautions they have experienced no loss of hearing from the jet engine noise. The Boeing personnel are also rotated to reduce the time of exposure to any one person. They have also developed equipment so that the trimming of the engine is now done remotely from the cockpit by electrical means and hence no one need be close to the engine under full power conditions.

Noise suppressors have also been designed to reduce the exhaust noise of the civil jet to a level less objectionable to the neighborhood or an air terminal than many of today's propeller driven airplanes.

The compressor noise, for which no suppressor has yet been developed, dissipates rapidly with distance so it should not create any nuisance insofar as the neighborhood is concerned. The remaining problem is for the airline to provide adequate ground equipment to suppress engine noise during full power maintenance checks.

Adequate equipment is being used today by the Air Force so once again need not be a nuisance to the neighborhood or a hazard to maintenance personnel. The precautions to protect personnel from the harmful effects of such noise must be much more elaborate than those required for terminal ramp personnel.

KEROSENE FUEL USED

Although the Air Force and a few of the airlines will be using PJ4 wide cut gasoline for their turbine engines, the vast majority of civil operators have selected kerosene as the fuel they will use.

While kerosene improves safety under certain conditions, it will create new hazards under other conditions. For instance, because it does not evaporate as quickly, spilled kerosene can create a hazard for a longer period than spilled gasoline.

Because freshly spilled kerosene is not nearly as likely to ignite from a spark or an open flame in the vicinity as gasoline, personnel might become careless and overconfident in handling it.

This would be bad because kerosene is equally as dangerous as high test gasoline when the ambient temperature exceeds 80°F. It will also ignite should it come in contact with a hot object at a bit lower temperature than required to ignite gasoline. It will also produce an ignitible mixture in the air space inside a tank over a wider temperature range.

MORE STATIC ELECTRICITY

The larger quantities and high rates of flow during fuelling that will prevail with the new big airplanes should generate more static electricity than heretofore. Kerosene will be a greater hazard than gasoline in this respect although this characteristic is still being debated. To be on the safe side, the need for adequate bonding and grounding techniques are even more essential regardless of the type of fuel used.

Accumulation of fuel in the combustion chamber or in pockets in some tail pipe designs, can result in a long flame being ejected from the tail pipe when the engine starts. This is more likely to occur with kerosene as it will not evaporate as quickly when lying in a pocket. Personnel and inflammable materials should therefore be kept well away from behind the tail pipe during engine starts.

Since certain parts of the engine, such as the turbine wheel, will reach temperatures as high as 1700°F, they can retain this heat for a considerable time. Care is therefore required both to avoid touching them and spilling fuel on them.

For instance, turbine wheels have remained hot enough to ignite JP4, 30 minutes after engine shut-down. The period would be a bit longer for kerosene. As the tail pipe is exposed and at a convenient height to grasp, care is required not to touch it until it has cooled down.

Because of the high rates of flow and large quantities involved in fuelling the large transports, the sudden stopping of the flow must be guarded against or hydraulic surge pressure might result in the bursting of the refueling hose with serious consequences. Automatic shut-off devices should be provided in the re-fuelling system so that dependence is not placed upon human action to shut down the system in the event of a bursting of a fuel hose or line.

To avoid stopping a bit short and having to gun the engines to bring the airplane into its final position on a ramp, the pilot will probably taxi in a bit faster than today and depend more upon the use of his brakes to stop him on his mark. The increased speed of maneuvering will require greater care in the location of equipment or personnel to avoid being run over should the pilot misjudge his distance.

This increased hazard over today might be counteracted by the fact that the visibility from the cockpit of the new airplane will be generally better than today. On the other hand we must not forget that around a third of the fatal ground accidents is due to collisions with objects or other aircraft.

If we had a machine capable of earning $50 to $75 per minute as compared with the earning capacity of your present machine of $13 per minute, and if you could not help but remember that your new machine had cost you over five million dollars as compared with a bit over two million for its predecessor, what would you do?

I believe you would do the same as the airlines will have to do with their new turbo jet aircraft; that is, they will have to work them harder and longer than ever before. Ground personnel will therefore be under greater pressure to shorten station stops and servicing times.

SPEED COULD CAUSE ACCIDENTS

Since the majority of ground accidents today are not due to the design of the airplane but to the inadequacies in the design of the airplane ground servicing equipment and to poor operational procedures, the speeding up of the work might lead to carelessness and more ground accidents unless a concentrated effort is made to avoid it.

Most airlines today are continually plagued by damage incurred through mishandling ground servicing equipment. Damage to fuselage skin will be much more important than heretofore because of the much greater pressure differential being encountered when flying at 30-40,000 feet altitude in routine service.

Much greater care will therefore be required in the use of fork-lifts to raise galley equipment, and service the airplane. Because minor damage incurred in ground handling can cause a subsequent accident in flight, it must always be reported, no matter how trivial, to permit some qualified person to pass judgment as to whether or not the damage is sufficient to require immediate repair.

Since the new transports will be considerably heavier than today's, weighing up to 300,000 pounds when loaded as compared with less than half that amount today, it is essential that equipment used in towing, jacking, slinging and mooring, be adequate. Similarly, new and special servicing equipment will be required for lifting heavy objects such as wheels.

EDUCATE SERVICING MEN

Personnel will be required not only to examine the servicing equipment carefully before using each time, but must be taught to employ the proper physical attitudes when they are lifting anything manually.

Servicing personnel will be required to be even more conscious of good housekeeping than they are today because misplaced tools or loose equipment can damage an engine and if undetected it could subsequently cause a serious situation should the final failure occur in flight.

The connection and disconnection of 115 volt 60 KVA ground power units must be considered hazardous, particularly under wet weather conditions. This can be overcome by provision of an interlock circuit in the ground power unit which will only permit excitation of the unit when the ground and aircraft receptacles are fully mated.

Ground servicing personnel should be taught to stand clear of the plane of the turbine wheels when a turbine engine is running at high power, just as it is advisable today to stand clear of the plane of a propeller. Neither should fail but it is safer not to be in the way if one does.

The installation of weather radar in airplanes requires no special precautions as far as the airplane itself is concerned. However, if the weather radar is operating, definite precautions are required to avoid fire and other hazards with nearby objects within the beam of the antenna.

For example, radar can ignite dry steel wood at 100 feet. It can explode gas vapor from the sparking of aluminum chips at 250 feet. It can set off photo flash-bulbs at

850 feet and has set off photo flash bulbs when tossed in the air, up to 2500 feet. It can kill animals in front of, and close to the antenna.

Although some of the above are merely tricks for demonstration purposes to illustrate the hidden power of a radar beam, such a beam must be treated with greatest respect.

I understand that United Airlines has adopted a policy of not turning on their radar within 100 feet of a ramp because of the possibility that a photo flash bulb being carried by someone could be ignited by the beam. During tests, it was found if one bulb in a photographer's utility bag went off, all the bulbs in the bag went off.

There is a difference of opinion as to the degree of hazards involved on the basis that 75 KW output is actually by pulses of only two micro second duration, thus making the average power output about 60 watts which is not likely to ignite fuel or flash bulbs.

DON'T FUEL NEAR RADAR BEAM

To be on the safe side, however, fuelling and defuelling should not be conducted within 300 feet of the radar antenna along its beam. This may be reduced to 130 feet provided the set is operated at a power not to exceed 1.8 megawatts.

Warning signs and flashing lights should be placed in conspicuous spots as a warning that the radar is being checked or operating. All fuel trucks and other unauthorized vehicles should be kept at least 130 feet away.

Since the radar beam will not penetrate metal, the hazard is not the ignition of the fuel within the truck's tank but from a fire starting from oily rags around the truck.

It has been found that N.E. 51 Neon bulbs provide a very effective warning light to show that the radar is operating when located in the beam close to the airplane. It has also been found that a fine mesh metal screen set at a 45° angle to the ground could be used to deflect the radar beam upwards and away from equipment and personnel.

It is evident from what has been said that the radar should be turned off before the final approach of the airplane to the airport. We understand the USAF do not operate radar below 3,000 feet during a landing.

Insofar as personnel are concerned, they should not look directly into a radar antenna with the equipment operating but not rotating. Prolonged exposure such as five minutes could be dangerous.

The pathological conditions induced by the thermal effects of absorbed microwave energy should be noticed first in those parts of the body having poor heat-regulatory mechanics such as the eye-cornea, the gastro-intestinal and genitourinary tracts and in the effect on the various blood cells.

HAZARDS WILL BE REDUCED

We have mentioned a number of hazards associated with the forthcoming jet transports. We should not, however, forget the fact that many hazards with existing transports will be reduced. For example, there will be better visibility from cockpits so there should be less likelihood of taxiing into an obstacle. There will be no need for walking about on top of a wing during routine station servicing because the airplane will be fuelled from below.

The cockpit controls and displays, and engine and auxiliary installations, will all be simplified and thus reduce the human element which might create a subsequent hazard to the airplane personnel in flight. Too often today, ground personnel can preset a situation so that an accident becomes inevitable in spite of everything the flight crew might subsequently do.

This fact must never be forgotten and everything possible should be done to simplify every situation so as to reduce the human element to a minimum. The new jets make this possible. Let us not complicate it because we are accustomed to complexity today.

We believe that safety records will continue to be broken year by year. A possible exception could be in 1959 and 1960. History indicates that accidents will increase for a few months with the introduction of anything differing in many respects from what personnel are used to handling.

Our objective should be to confound history and see that adequate training, warning, and facilities are provided to get through this introductory period with the new transports while still maintaining our annual reduction to the industry's accident rate.▲

JET NOISE ON THE AIRPORT— WHAT TO DO ABOUT IT

by HOWARD C. HARDY and JAMES E. ANCELL
Howard C. Hardy and Associates, Chicago

It would be presumptuous folly to think that all the problems of the aircraft industry could be completely predicted, especially in such a complex phenomenon as noise. However, we can attempt to extrapolate from the experience we have in military operations and present airport activity.

When we do so, we conclude that there is reason for concern. Not only will we be worried about the exhaust noise of the jet, severe as it is during takeoff, but a larger number of the operating personnel will be exposed to the whine from the front end of the engines. This whine will be similar to that of the turboprop engines now in operation.

CAUSE OF NOISE

This noise is due to the rotation of the turbine blades and is similar to a propeller or fan noise except that the rotation is at high speed and there is a large number of blades. This same condition exists in either jet or turboprop planes with the exception that future turboprop planes will be considerably larger than those we have now.

We can make some reasonable estimates of what this noise will be like, but first, let us examine some figures on what might be considered acceptable human environment. *(Editor's note: The figures to which Dr. Hardy refers are glass slides which he used in his presentation. Although the mechanics of publishing these volumes prohibit reproduction of graphs, interested readers may request tear sheets of the December, 1957* National Safety News, *which contain the figures mentioned here.)*

Figure 1 presents some such data. The acoustical engineer measures the sound in decibels, referred to a standard reference level. These figures are presented in the vertical axis of this graph. On the other axis is a method of presenting the different frequencies of the sounds. This is necessary because the human hearing mechanism responds quite differently to various frequency bands.

Our frequency scale is divided into sections each an octave wide, running from the first band of 37.5=75 cps. up to the last band which has frequencies of 4800=9600 cps. The low frequencies sound like hums and thuds, the middle frequencies like rattles and clangs, and the high frequencies like hisses and clicks.

ACOUSTIC FATIGUE

The middle curve specifies how much noise the average person can be inflicted with for six to eight hours a day exposure, day after day, for many years before suffering a hearing loss. Constant exposure, of course, does not exist on an airfield where the noise is intermittent and the worker has a chance to get an occasional rest from the acoustic fatigue. Under such conditions, the intensity of the noise environment can be increased many times without damage.

We recommend, however, that the exposure never exceed the figure given in the upper curve because such exposure would be painful and might cause hearing damage, if there were many exposures over a period of years.

If hearing loss prevention is the main criterion, the amount of allowed exposure for a worker will depend almost entirely on how often and for how long he is in the noise.

HINDERS COMMUNICATION

However, there are other reasons why noise should not be intense. Speech communication or conversation will be practically impossible and the normal use of the ear as a means of receiving warnings or danger signals may also be seriously inhibited. At conversation levels there is little chance of hearing loss even after years of exposure. The noise should not exceed that given in the lower curve if one wishes to communicate by voice at a distance of about three feet.

These curves then provide a frame of reference to describe the potential environ-

ment which will exist in commercial aviation.

There are three environments which should be of concern to operating personnel:

1. The idling and taxiing activities around the airport terminal or near hangars.

2. Ground run-up and take-off of jet engine aircraft which would be expected to be at some distance from the terminals and hangars.

3. Testing of jet engines alone at overhaul bases.

IDLING AND TAXIING

The idling and taxiing environments will influence the most personnel. These environments will be somewhat similar for both turboprop and turbojet airplanes. The severity of the problem can be imagined if we consider the conditions which would exist at Chicago's Midway Airport, for instance, if two-thirds of all planes had a whine which was 10 db. higher than that of the Viscount, a plane which is now operated by only two air lines at this airport. This is the operating condition predicted by the air lines by 1963.

The noise during idling and taxiing, the compressor whine, is emitted from the intake and is beamed to the front. The octave band spectrum of this noise is given in Figure 2 for a Viscount plane at a distance of 50 feet. The idling noise of the future jet engine is estimated to be that given in the upper curve. These data are only approximate and depend considerably on the rpm. of the engine.

It can be seen that these curves extend considerably into the undesirable regions of auditory perception and therefore become quite annoying to operating personnel. As a result they may, as has already been the case, become of concern to management and to labor unions.

CONSIDER PUBLIC REACTION

This noise will also be quite unacceptable to the public. Unfavorable public reaction to ground operations is not expected to be great from the neighboring residences because these high frequency sounds are rapidly attenuated with distance. We are thinking instead of the public boarding adjoining planes, in waiting docks, waiting platforms, or other parts of the airport facilities.

The magnitude of the noise at the major airports due to a multitude of taxiing and idling activities will undoubtedly bring about an adverse reaction of the public. Most anything which is done to give a more satisfactory airport acoustic environment for the public will undoubtedly help get a better environment for the working personnel.

For personnel not protected by building structures only four solutions are possible:

1. Hearing protection, which, of course, is unlikely to be used by the passenger or visitor.
2. Operating at low rpm.
3. Towing the airplane into the ramp.
4. Hasty installation of small portable mufflers on each engine on the field just after landing and before taxiing to the loading area.

None of these suggestions is convenient and we can see operating personnel shuddering at the difficulties. What will be evolved no one can predict. The importance here is for us to realize that there is a problem and that it demands study. The fact that there is going to be noise around the loading docks should be in the forefront of the mind of those planning future operations.

GROUND RUN-UP

In the case of ground run-up the noise of the intake is drowned out in the intense noise created in the atmosphere by the ejection of the high speed exhaust gases. This is the well-known roar we hear from the jet engines on take-offs. This noise environment during run-up is more important than take-off because it will last longer with usually more personnel at a closer distance.

The intense noise created will be important not only to operating personnel, but in most commercial airports it will cause complaints from residents in the nearby area. It will therefore be necessary in most cases to use ground run-up mufflers to which the airplane is attached during these tests. When such run-up mufflers are used to reduce the community noise, they will also reduce the noise for operating personnel.

Figure 3 shows the noise pattern around a jet engine in the very important band for hearing, 2400=4800 cps. The intake noise is most prominent during idling. The noise of the exhaust of a jet engine appears at higher rpm. and is at maximum at an angle of approximately 45° from the axis of the tail pipe. It is unlikely that operating personnel will have to operate in this cone. The conditions immediately adjoining the fuselage will be less severe.

USING MUFFLERS

When mufflers are used, the noise will be ejected somewhat upwards. The effect of the reduction will not be as great for the airport personnel as it will be for the surrounding community, since almost the same amount of energy will be ejected in all directions around the aircraft. Even with mufflers and protection afforded by the directional pattern, all personnel working around the aircraft must use hearing protection.

Ear muffs give about 30 db. protection in the important high frequencies. Ear plugs can also be used. They are only a little more uncomfortable, but they provide as much as 40 db. protection at the higher frequencies. The combination of helmet, ear muffs, and ear plugs can give as much as 50 db. attenuation in the higher frequencies.

The problem of the commercial air lines will be considerably less than that for the military aircraft. None of the commercial aircraft will be using afterburners. The afterburner engine makes about 10 db. more noise than the engine at full rpm. without afterburner.

Personnel also are more likely to be near the intake side of the engine than the exhaust during ground run-up. The severe intense whine in front of the aircraft is another reason for wearing hearing protection. We know of no problem involving the acoustic environment of commercial aircraft during run-up for which the available hearing protection devices are not adequate.

ENGINE TESTING

The last acoustical environment involves the testing of engines themselves. For commercial aircraft this will probably be done only at overhaul bases. However, there are large numbers of personnel at such bases. The testing of the engine will require running it at high rpm. for long periods of time. This will in many cases cause a neighborhood noise problem. In most such cases, if the noise is reduced adequately to prevent neighborhood complaints, it will be sufficiently low in intensity for the operations at the overhaul bases.

In a few cases, however, the design of the test cells will have to be such as to prevent excessive noise in the immediate vicinity of the cells. This can be determined only by a survey of the site. The problem at the overhaul base is rather similar but not as severe as that in most jet engine production facilities.

All such companies find it necessary to build test cells with sound attenuations which run from 25 to 60 db. Our firm has had an opportunity to study the noise problems of the overhaul bases of American Air Lines at Tulsa, United Air Lines at San Francisco, and Continental Air Lines at Denver, and has found that at these sites about 40 db. reduction or less was adequate.

TEST CELLS USED

Jet engine test cells in use at Ford Aircraft Company in Chicago have reductions of about 60 db. and are designed for considerably larger engines than are now being produced. The noise of the jet exhaust is quieted by passing through a labyrinth of 180° turns, the walls of which are lined with acoustical absorbing treatments especially designed to stand up under the high temperatures, velocity, and intense vibrations which exist in this region. Similar labyrinths quiet the air intake and the air introduced for cooling. The sounds from these cells cannot be heard one-quarter mile from the cells.

This structure is the most economical and rugged which has been designed for the large sound attenuations specified. It proves that it is possible to get almost any amount of sound attenuation required with good design. The size requirement for overhaul bases will be much less than that at Ford because there will be no afterburners used and the amount of noise permitted will usually be considerably higher. There will also be at the overhaul bases ground run-up tests which will require similar mufflers as discussed above.

The jet age will bring new problems in regard to the safety and well being of personnel. Not the least of these worries will be concerned with noise. Solutions for these problems are not readily evident because they depend on the whole over-all operation. ▲

OFFICERS OF THE

AERONAUTICAL INDUSTRIES SECTION

NATIONAL SAFETY COUNCIL 1957-58

General Chairman—JOHN S. T. SWANSON, safety engineer, Orenda Engines Limited, Toronto, Ontario, Canada.

Senior Vice Chairman (West)—FRANK W. STARR, safety & conservation administrator, Douglas Aircraft Co., Inc., Long Beach, Calif.

Vice Chairman (Central)—LYLE A. GATES, safety engineer, Douglas Aircraft Co., Inc., Tulsa, Okla.

Vice Chairman (East)—KENNETH L. STEBBINS, director of safety, Lycoming Div., AVCO Manufacturing Corp., Stratford, Conn.

Secretary and Newsletter Editor—HUGH J. McRAE, safety director, AVRO Aircraft Limited. Toronto, Ontario, Canada.

Newsletter Editor (East)—GEORGE LOUDON, ground safety director, Hq. 58th Air Division (Defense), United States Air Force, Wright-Patterson Air Force Base, Ohio.

Newsletter Editor (Central)—RICHARD P. DENTNER, safety engineer, Rocketdyne—A Division of North American Aviation, Inc., Neosho, Mo.

Newsletter Editor (West)—C. W. LOWREY supervisor, Health and Safety Office, R&D Personnel, Hughes Research and Development Laboratories, Hughes Aircraft Co., Culver City, Calif.

Senior Program Chairman (West)—JOHN D. DONOHUE, safety supervisor, Rohr Aircraft Corp., Chula Vista, Calif.

Program Chairman (Central)—W. H. STAPLES, safety and medical supervisor, TEMCO Aircraft Corp., Dallas, Texas.

Program Chairman (East)—E. E. COLE, deputy chief, Ground Safety Office, Headquarters AMC (MCAS), Wright-Patterson Air Force Base, Ohio.

Senior Education and Training Chairman (West)—M. M. CLANCY, general supervisor, Safety, Insurance and Medical Services, The Ryan Aeronautical Co., Lindbergh Field, San Diego, Calif.

Education and Training Chairman (Central)—FRED E. KEIENBURG, ground safety director, Hq. San Antonio Air Materiel Area, Kelly Air Force Base, Texas.

Education and Training Chairman (East)—B. J. WILKE, JR., chief safety engineer, Grumman Aircraft Engineering Corp., Bethpage, Long Island, N. Y.

Senior Engineering Chairman (Central)—FRED L. DENTON, general supervisor, Safety Section, Boeing Airplane Co., Wichita, Kan.

Engineering Chairman (East)—FRANKLIN KNIGHT JR., chief safety engineer, Georgia Division, Lockheed Aircraft Corp., Marietta, Ga.

Engineering Chairman (West)—M. C. VAL DEZ, chief safety engineer, CONVAIR—A Division of General Dynamics Corp., San Diego, Calif.

Senior Industrial Hygiene Chairman (Central)—J. K. LEVERETT, M.D.; chief plant physician, CONVAIR—A Division of General Dynamics Corp., Fort Worth, Texas.

Industrial Hygiene Chairman (West)—MRS. HELEN W. GIERE, R. N. first aid nurse, Missile Systems Div., Lockheed Aircraft Corp., Holloman Air Development Center, Alamogordo, N. M.

Industrial Hygiene Chairman (East)—J. C. SEWELL, safety and workmen's compensation division manager, Wright Aeronautical Div., Curtiss-Wright Corp., Wood-Ridge, N. J.

Senior Membership Chairman (East)—E. L. NEWMAN, Chief of Ground Safety (EWABG) Headquarters, Wright-Patterson Air Force Base, Ohio.

Membership Chairman (Central)—EDWARD V. SISUL, supervisor, Safety & Medical Dept., McDonnall Aircraft Corp., St. Louis, Mo.

Membership Chairman (West)—HOWARD R. KIENLE safety supervisor, Transport Div., Boeing Airplane Co., Renton, Wash.

Off-the-Job Safety Chairman (Central)—F. E. VAN HORN, safety and security supervisor, Industrial Relations Div., Solar Aircarft Co., Des Moines, Iowa

Off-the-Job Safety Chairman (East)—HAROLD L. RUSH chief, Ground Safety Div., Hq. Tactical Air Command, United States Air Force, Langley Air Force Base, Va.

Senior Statistics and Contest Chairman (West)—LEE B. JOHNSON, chief safety engineer, Northrup Aircraft, Inc., Hawthorne, Calif.

Statistics and Contest Chairman (Central)—GEORGE H. BEECK, safety director, Denver Div., The Martin Co., Denver, Colo.

Statistics and Contest Chairman (East)—JOHN W. KENT, chief safety engineer, AVCO—Research and Advanced Development Division, Lawrence, Mass.

THE VALUE OF GOOD RECORDS AND HOW TO USE THEM

by CLYDE C. RUDDICK

assistant manager, Safety and Plant protection,
Pittsburgh Plate Glass Co., Pittsburgh, Pa.

When accidents are many, anyone can reduce them. When they are few and the record is approaching the irreducible minimum, it is much more difficult. In the dim distant past, when safety was in its infancy, accident frequencies were literally astronomical compared to our accident experience today.

The safety engineer of that era was certainly not less intelligent than those of later years. He did have his hands full with the multitude of unsafe machines and conditions typical of that industrial period. He made great strides in reducing the accident frequency by a gigantic guarding program.

As the time went on and the accident rates dropped in the companies which pioneered in safety, a leveling off took place in their accident curves. That posed a problem and the safety engineer was in a real dilemma. There had been little need for anything but a guarding and a poster program up to that time.

ANALYTICAL ACCIDENT PREVENTION

As a measure of the keen and resourceful men in safety work at that time, many of them ventured into unexplored fields of analytical accident prevention. This relatively new approach did not blossom forth overnight. It began slowly in many places, particularly where safety enthusiasts faced temporary frustration because their accident rates were more or less static.

Please do not misunderstand. The rates were good for that era and much better than in the majority of industrial plants. Necessity thus created the need for using native intelligence and those few daring thinkers spread the good word.

Records were kept from the beginning of the safety movement. But they were mostly kept to justify safety activities, particularly the high cost of guarding and to compare those records with other plants. The ranks of those who ventured into analytical accident prevention grew. One safety leader assembled the combined thinking of those daring souls, with a considerable amount of his own individual and original thought. H. W. Heinrich of the Travelers Insurance Company will be remembered for his book entitled, *Industrial Accident Prevention.*

ADVENT OF THE CODES

The idea of analyzing accidents, for more than just unguarded machines, grew by leaps and bounds. Many more safety engineers joined the "analytical" surge with almost as many ideas and variations as there were safety engineers. The National Safety Council asserted great leadership in trying to guide American industry in standard methods of recording accident rates and causes. But the task really became one of gigantic proportions. Thus came the call for comprehensive standards.

So the best safety minds known were assembled under the guidance of the American Standards Association and the sponsorship of the National Safety Council. As a result, we can now refer to ASA Code Z16.1, "Method of Compiling Industrial Injury Rates"; ASA Code Z16.2 Part I, "Compiling Industrial Accident Causes—Selection of Accident Factors"; and ASA Code Z16.2 Part II, "Compiling Industrial Accident Causes—Detailed Classification of Accident Factors."

Thus we came into the realm of cause codes and today they are bywords of the safety engineer. Unfortunately, the codes are still not used as they were intended. This has been mainly because many industrial firms were content to remain as they had been before the entire code package was formulated.

Many of them had really advanced considerably from the unsafe conditions period but because of inertia or lack of desire, did not care to overhaul their pseudo forms of record keeping for the "ultra modern"

as recommended by the codes. Many companies, new in accident record keeping, begin with mistaken or misunderstood ideas and are then reluctant to change.

THE CODES

First let me dwell briefly upon ASA Code Z16.1-1954. The computation of accident severity was changed from a "thousand hours basis" to "one million."

$$\text{Frequency} = \frac{\text{Disabling Injuries} \times 1{,}000{,}000}{\text{Hours Worked}}$$

$$\text{Severity} = \frac{\text{Days Lost Due Disabling Injuries} \times 1{,}000{,}000}{\text{Hours Worked}}$$

However, the new Z16.1 should be a veritable dog-eared reference. Never before have we had such a concise, clear cut outline of injury recording rules. We now know precisely when a disabling injury is not counted and vice versa. New values have been given the time charges for permanent partial disabilities. Perplexing questions can be answered such as:

Is an injury in the parking lot chargeable?

When is an employee considered at work?

How about an injury during an athletic event?

What about disabilities arising out of a physical disability?

These and many other questions can be readily answered by the code. Keep in mind that the code deals only with recording injuries and has nothing to do with liability or moral obligation. The states have various measures of liability and the one is not to be confused with the other.

The entire Z16.1 code should be familiar to everyone in safety activities. If you do not have a copy, send 50 cents to:

American Standards Association
70 East Forty-Fifth Street
New York 17, New York.

The selection of accident factors—Code Z16.2 Part I, deals with the accident and its casual factors. These are: Agency—agency part—unsafe mechanical or physical condition—the accident type—the unsafe act and the unsafe personal factor. Here are brief definitions of the accident factors:

2.1 The Agency

The agency is the object or substance most closely associated with the injury, and which could have been properly guarded or corrected.

2.2 The Agency Part

The agency part is the particular part of the selected agency most closely associated with the injury, and which could have been properly guarded or corrected.

2.3 The Unsafe Mechanical or Physical Condition

The unsafe mechanical or physical condition is the condition of the selected agency which could have been guarded or corrected.

2.4 The Accident Type

The accident type is the manner of contact of the injured person with an object or substance; or the exposure, or the movement of the injured person which resulted in the injury.

2.5 The Unsafe Act

The unsafe act is that violation of a commonly accepted safe procedure which resulted in the selected accident type.

2.6 The Unsafe Personal Factor

The unsafe personal factor is the mental or bodily characteristic which permitted or occasioned the selected unsafe act.

The scope of the classification of the accident factors as related in Z16.2 Part I, by groupings, are important. Thus, I urge you to study them by hauling out that filed copy or obtaining one at once. The same applies to Z-16.2—Part II.

ACCIDENT FORMS

General Office Form of Pittsburgh Plate Glass Company

Some 50 odd industrial locations with quite diversified activities require a little different approach in an accident report. Thus we find:

A. Detailed statistical information, very necessary to the general office far removed from the plant location. This form, used since 1937 and having a few obsolete items, is still valid.

B. The injury and what happened, very necessary to classify properly. Many plants attach more details by stapling a slip to this part of the form or writing a covering letter.

C. Machine, appliance or thing causing injury. This section is essential to establish causes.

General Office Form of Pittsburgh Plate Glass Company

If properly filled out by the foreman, this section can tell a story of supervisory attitudes and knowledge of responsibility. The safety committee report reveals the effectiveness of the committee and its function in the plant.

An Electrical Manufacturer's Method of Tabulation

A mass of information in one record. This type of information must be coded.

Supervisor's Accident Report and Code Card

The small form is used by supervision for all injuries except disabling ones. The code card is used by the medical department of that plant, for coding every accident. The same code is also the basis for coding the McBee card. All foremen are given this code card for reference since the medical department reports indicate injuries by code number and letter.

Another McBee Tabulation Card

This and the previous method of tabulation and coding offers a ready reference for accident statistics. IBM—Remington Rand and others will install an efficient system of information which is promptly available, by classification, whenever desired. This card is used at our Lake Charles plant of the Columbia-Southern Chemical Corporation.

An Electrical Manufacturer's Supervisory Report Form

Every one of the six causal factors are covered. This form is used only for disabling injuries.

Lake Charles Plant—Columbia-Southern Chemical Corporation—Supervisory Accident Report Form

This form also covers the six causal factors. The supervisor is charged with finding the unsafe acts and unsafe conditions. He must also name them and state his idea of the remedy.

Lake Charles Plant—Columbia-Southern Chemical Corporation—Supervisory Accident Report Form

A continuation of the cause factors. Here we have attitude, skill and lack of information covered.

APPLYING THE ANALYSIS

The Lake Charles plant studied its records and drew up some charts. Keep in mind this plant had already reduced its disabling injuries to approximately one in 14 months. I would say that the situation has almost reached the irreducible minimum—but the plant safety director does not agree. Consequently, their charts showed statistics of all minor accidents and doctor cases in addition to possibly any disabling injuries. Incidentally, all accidents required a supervisory investigation report. Their previous analyses indicated a closer review of the service department activities. So to prove the suspicion, these following charts were assembled.

The Service Dept. Accidents by Time and Location—This chart indicated the number of accidents in each department and showed the time within the half hour that each occurred.

The Service Dept. Accidents by Location—This chart totaled the number of accidents occurring in each department during 1955 and 1956.

Five graphs were drawn up indicating: the total accidents occurring in each shop each half hour of the day; the total accidents in each cell each hour of the day; the total accidents and times in the caustic dept.; in the power house and in the liquefaction.

These charts did not show the causal factors—Agency, Agency part, etc. But could you imagine anyone as detailed in his approach to perfection forgetting the cause code. Of course not, and you can bet that such analyses are either already made or are in the offing.

Because of the foregoing study, the safety director assigned one engineer to concentrate on an intensive visitation and observation in one location for an extended period. Each location will be studied in the order of accident frequency, until all have been covered. The study will not only be a statistical one but appropriate action will follow each incident found. I have no doubt that this plant will reduce its low disabling rate and its present, rather high all-accident rate still further. My prediction is that the present favorable accident experience will continue for a long time to come. What else could result from such a painstaking approach.

Here is another analysis by another company. Of course, it may be assumed that "hook-on crane disabling accidents" pre-

sented a problem for study and solution. Here a 10 year study, carried on in the most detailed form, presented ample ammunition to ask management for the most drastic reforms. Fortified by this kind of information, the safety engineer can expect management to come through with any reasonable and practical request.

HOOK-ON CRANE DISABLING ACCIDENTS
1946-1955 INCLUSIVE

Nature of Injury	
Fractures or crushes	45 per cent
Lacerations and contusions	26
Amputations	14
Strains	9
Bruises	6
Location of Injury	
Foot and Toes	38 per cent
Leg and ankle	22
Fingers	15
Body	15
Head	6
Arm and wrist	4
Type of Injury	
Struck by an object	55 per cent
Caught between objects	25
Falls	11
Slips	6
Strike against	3
Unsafe Personal Factor	
Unaware of safe practice or unskilled	41 per cent
Inattention or absentmindedness	41
Disregard instructions or wrong attitude	8
Physical weakness or nervous	6
No unsafe personal factor	4
Unsafe Acts	
Exposed under suspended loads or to shifting loads	34 per cent
Taking unsafe position or placing hands in unsafe place	27
Unsafe piling or arrangement, failure to block material	14
Using equipment unsafely or overloading	11
Working at unsafe speeds or giving wrong signal	7
Using unsafe equipment	4
Jumping from vehicle	3
Unsafe Conditions	
No unsafe conditions	36 per cent
Misalignment or improper hook-up	22
Unsafely piled materials—congestion—uneven and slippery floors	19
Unsafe method	11
Defective equipment	8
Not wearing safety shoes	4
Years of Experience	
0 to 5 years	72 per cent
6 to 10 years	17
11 to 15 years	4
16 to 20 years	3
25 to 30 years	4
Under Five Years Experience	
0 to 6 months	33 per cent
7 months to 1 year	15
1 to 2 years	14
2 to 3 years	14
3 to 4 years	12
4 to 5 years	9
5 to 6 years	3

FOR THOSE WITH FIVE YEARS OR LESS EXPERIENCE

Unsafe Personal Factors	
Unskilled	47 per cent
Inattention	33
Improper attitude	9
No unsafe physical factor	5
Nervous	3
Bodily defects	3
Unsafe Acts	
Taking unsafe position	50 per cent
Unsafe arrangement of material	21
Unsafe use of equipment	10
Positioning hands unsafely	5
Wrong signal	5
Unsafe speed	3
Improper lift	3
Jumping	3
Location of Injury	
Feet	40 per cent
Legs	24
Fingers	10
Head and face	9
Body	7
Arms	5
General	5
Nature of Foot and Leg Injuries	
Fractures	52 per cent
Bruises (Hematomas and contusions)	22
Strains	8
Cuts	5
Amputations	3

Is it any wonder that this large plant recorded a frequency for 1956 which surpassed any previous record of that plant? Can you be surprised that this same plant turns in a frequency, each year, far below the national average?

In a similar manner, our own plate glass plants enjoy frequencies occasionally under 1.0, and more frequently between 1.0 and 2.0. Our chemical plants come through, year after year under the national rate and even below the low average rate of the Manufacturing Chemists' Association, and all because of searching for the factors of causes as outlined by the codes.

We can all do more in the field of analytical accident prevention. Surely the rewards are great. If national leaders in safety, such as Dupont—Dow Chemical—Westinghouse and General Motors, to mention a few of the large companies, can have frequencies as they do each year—then we can certainly afford to do the same. All of those corporations use and follow the codes, but they do more. They follow up their analyses with intelligent action. And that is exactly what the codes will do for you.

Keeping records for the sake of gathering statistics is not productive. Designing a course of action based on those statistics will ring the bell for any safety engineer who does and has the patience to stick to such a course of action.▲

HOW DO YOU INVESTIGATE AN ACCIDENT?

by EARL H. STOCKDALE

assistant director, Accident Prevention division, Gulf Oil Corp., Pittsburgh, Pa.

The investigation of accidents is good practical business and is an essential part of any accident prevention program. Any business can improve its records by determining the causes of past mistakes and applying the needed correction. Accidents resulting in injury, damage, loss, or any combination represent circumstances that have actually occurred and are not probabilities. Similar accidents will occur if causes are permitted to exist.

The investigation of accidents is not for the purpose of placing blame, but a fact finding operation to gather information needed to determine reasonable and practical action for the solution to the problem. In this connection, it is not only the individual or individuals involved in the particular accident that we are concerned about but all other employees that may be exposed to situations.

When investigating an accident, frequently the tendency is to skim the surface and think in terms of injury prevention. But this approach does not penetrate deep enough to get to the root of the problem. Possibly I can explain the difference between injury investigation and accident investigation by using this typical example.

Let us assume that my job is to drive a fork lift truck and pick up a pallet loaded with cases of product and deliver the load to a waiting trailer truck. On the way to the trailer truck, some cases fall off. Now if I think in terms of injury prevention, any damage and extra work of reloading the fork lift truck may go unnoticed. If one of the cases just missed hitting an employee, we may say we had a near accident and forget it.

If one of the cases happened to hit an employee and only bruised him, we may say it was only a minor injury and again forget it. If the case happened to hit an employee and broke his leg, we become concerned because the results were spectacular, a serious injury, necessitating injury investigation and when thinking in terms of injury prevention, the question becomes "what was the cause of the case hitting and breaking the leg."

CAUSES OF MISHAP

But if we use the accident prevention approach, the question becomes "what did anyone do or fail to do that led to the case's falling off in the first place," and/or, "What defective condition by its very existence contributed to the case's falling off."

Certainly cases fall off many times for each time someone is struck; but each time one falls, some economic loss results. Whether or not it strikes anyone is a matter of chance; and if it does strike someone, the extent of injury is again largely a matter of chance. So why wait until the serious injury occurs to investigate an accident, or why limit our investigations to those few accidents that result in serious injury?

Once we have determined the causes of the cases falling off, we take the specific action needed with the specific people who have the problem, so that cases can be moved on a continual basis without any falling off. If we do, we move more cases and at the same time move them without injury or damage.

As everyone knows, the supervisor is the one who should make the investigation, as he is the one responsible for getting his men to put the cases on the truck in the way he wants them loaded and when he wants them loaded. Investigating unplanned, unwanted occurrences and taking the action needed to control the causes is an integral part of a supervisor's job.

TRAIN HOW TO INVESTIGATE

In this connection, the staff accident preventionist can strengthen the company's accident prevention program by providing any needed supervisory explanation or training in how to make an investigation to identify causes that are reasonable and practical to control.

One nice feature of being in a staff position is the privilege the staff accident

preventionist has of investigating anytime, anywhere that the immediate supervisor or any level of supervision needs help, or when help is indicated from a review of the report of accident investigation. But the staff accident preventionist should be concerned when a supervisor continually solicits help as some supervisors may feel that preventing accidents is solely the job of the staff accident preventionist. This is a little like saying that it is the fault of the accounting department when a company loses money.

One of the fundamentals of successful accident investigation is a knowledge of the chain of events which produce all accidents. Undoubtedly, we are all familiar with Mr. Heinrich's accident sequence. Briefly stated it is this:

> "In every accidental occurrence, there is always a chain of events which occurs in a logical and fixed order. Each link in the chain is dependent upon the preceding link."

This chain of events or sequence of factors always exists whenever an accident occurs whether or not an injury results. We may not be clever enough to identify each factor in the sequence but each exists nevertheless. Termination of the accident sequence may be in the form of injury, damage, loss, or any combination of undesired results which we usually hear of first.

Final factor in the sequence is the undesired result: injury, damage, loss.

There are many types of injuries such as burns, cuts, fractures, fatalities and many different types of injuries may result from the same accident. But knowing the type of injury, damage, or loss is of little value as it does not tell us what to do to prevent a recurrence. When an accident occurs, the degree of severity is largely a matter of ...ance.

For example, when two cars collide, we may recall cases where one or more occupants were injured severely while other occupants had no apparent injury and the extent of damage to the vehicles also varied. We would, of course, allow the severity to guide us to a degree in how we concentrate our efforts, but we do this by moving on to the preceding factor which is the accident itself.

Second factor in the sequence is the accident

An accident is not an injury nor a cause: it is the unplanned, unwanted occurrence. It is what happened that was not planned or wanted in our method of performing the job. A few examples would be:

1. Left front tire blew out, car struck pole, and overturned
2. Fell from scaffold to ground
3. A one inch line broke and sprayed acid
4. Hammer slipped out of employees hand and struck co-worker
5. Valve leaked chlorine gas

These typical accident examples are movements of people, objects, or substances that are unnecessary, or irrelevant toward completion of the job.

The accident, when the man fell from the scaffold to the ground, is evidence of failure to use the needed work method or the existence of a defective condition or both. The undesired result, whether this man fractured his arm, or leg, or only bruised himself, and the accident type "fall to a different level" give no indication as to what anyone did or did not do that was wrong or what condition was defective.

The third factor in the sequence is the cause —the unsafe act and/or unsafe condition.

UNCOVER UNSAFE ACT?

In trying to determine if an unsafe act was performed, we might consider: what did anyone do or fail to do that caused the unplanned, unwanted occurrence? What did anyone do differently, this time? In other words, what specific movements, or acts, are needed to eliminate or add to this work procedure in order to prevent the same accident from recurring? The direct answer to this question indicates the unsafe act.

A few examples of unsafe acts would be:

—Failed to check oil in crankcase
—Used a pipe wrench for a hammer
—Used a broken ladder
—Did not use the guard on the saw
—Did not stop at an intersection stop sign

In trying to determine if an unsafe condition existed, we might consider: the mechanical or physical condition of the piece of apparatus, tool, equipment, work platform, floor or handrail, to see if a mechanical or physical defect existed which contributed to the accident. There does not have to be an unsafe condition involved in every accident. Experience has proved that the majority of accidents are caused by unsafe acts.

A few examples of unsafe conditions would be:

—Rotted out walkway
—Overloaded electrical line
—Lack of a relief value on a pr... ...e vessel
—An unguarded fan
—Unanchored decking on scaffold

FIND UNSAFE CONDITION

Each example of unsafe acts and unsafe conditions says specifically what was wrong. We all know this is most important because it tells exactly what we must fix. We should avoid the use of ambiguous terms such as carelessness, improper, awkward because these terms mean something different to different people and correction is frequently in generalities. Yet, experience has proved over and over that too frequently the unsafe act or the unsafe condition was not specifically identified, even though it is the heart of accident prevention work.

In fact, when generalities are used, it could indicate that the accident was not investigated to the point where the specific cause was known. And with the use of generality terms, our job becomes more difficult to show tangible results.

If it is stated that no unsafe act was performed or no unsafe condition existed then the accident could not have occurred. There is always a cause and there may be both an unsafe act and an unsafe condition. If we identify exactly what is wrong, correction is closely related.

In any particular accident investigation, emphasis should not be placed on separating an unsafe act from an unsafe condition, but a determination of the cause that is most reasonable and practical to control. Actually if we want to be technical about it, a good number of our unsafe conditions were created originally because someone failed to modify, repair, or maintain.

ACCIDENT CASE

Let us check the first three factors in the accident sequence by considering this accident example:

An employee is sent to work on a high scaffold. He falls to the ground and breaks his back. The first two steps in the accident sequence are apparent:

1. Undesired result—broken back
2. Accident (the unplanned, unwanted occurrence that broke the back)—fell from scaffold to ground

The broken back was a result of falling to the ground. But the cause is unidentified. Unless we determine the work method he should have used or the defective condition which caused him to fall, we have no assurance that the next man to ascend the scaffold will not fall.

But a supervisor is interested in avoiding another fall and a few of the things he might do in determining the cause would be:

- Discuss the accident with the injured employee, when the injured is in condition
- Question any witnesses
- Determine what the employee was doing just before and at the time of the accident
- Visit the scene of the accident and determine whether or not: the handrail was in place, handrail was standard height, man was standing on handrail, man was standing outside handrail, boards in decking were weak or rotten, decking unanchored or scaffold legs not firmly supported.

The supervisor must find out what anyone did or did not do that caused the employee to fall from the scaffold to the ground, so that he will know what to do to prevent another fall. Unless he has determined accurately the specific cause, it will be a matter of chance whether or not he will apply the needed corrective action.

If he fails to examine a defective scaffold, and incorrectly assumes that the man fell because he stood on the handrailing, then the real cause of the accident would remain to endanger other employees. If the supervisor fails to determine the cause, it is probable that another accident will eventually occur.

On the other hand, failure to find out exactly what the employee was doing may keep the supervisor from finding the cause of the accident. If he assumes the "handrailing too low" when actually the man fell because he was standing on top of the railing, the true facts are not brought to light. Installing a new handrail will not stop this

cause. Furthermore, other employees will not learn from this experience.

DETERMINE REASONS

Once we have determined the cause, we know what we must fix but we don't know how to do it unless we know why the employee performed as he did or why the defective condition was permitted, which brings us to:

The fourth factor in the sequence—Reason

Why did the employee perform as he did, or why was the defective or unsafe condition allowed to exist? Answers to these questions provide information needed not only to take corrective measures to prevent another possible injury, but also to improve operating methods. These reasons sometimes called contributory causes represent the underlying inefficiencies that actually laid the ground work for the unsafe act and/or unsafe condition.

For example, a lack of adequate instructions or a failure to comply with instructions is usually an indication for the need of improved supervision. If the worker complains of fatigue, there is every reason to believe that a slow down in production has occurred. Fatigue can result from noise, poor lighting, or unnecessary movements due to location of equipment or controls. A wrong attitude on the part of the worker may be due to discomfort or a lack of supervisory interest.

TALK WITH WITNESSES

What better way can a supervisor strengthen his supervisory qualifications than to talk to those involved in the accident or any witnesses to determine the specific reason which indicates where and how the supervisor can improve his work records. Until we get to the point as to where the immediate supervisor determines the reason, we have no assurance that we will progress toward accident records.

By using these basic accident sequence factors as guides when investigating any accident, we can channel our investigation to causes and reasons that are most reasonable and practical to control. This technique prevents misuse of terminology such as quoting the accident, or reason as the cause.

For example, I recall a recent accident where the cause was quoted as "left front tire blew out and car struck a bridge abutment." That is the accident itself, the unplanned, unwanted occurrence, but what caused the tire to blow out and strike the bridge abutment? In other words, when investigating an accident, we start off with the final factor "undesired result" and trace the chain of events, each factor in the sequence, back to the point that suggests a reasonable and practical solution. Let us demonstrate witht this accident example:

A new inexperienced employee was given a gasket and sent to flange a six bolt flange in a pipe line. He put in the gasket but in tightening the bolts, he did not pull the flanges together evenly. As soon as oil was pumped through the line, the flanges leaked spilling several barrels of oil over the ground before it was discovered.

1. What was the undesired result? Loss of oil, rework
2. What unplanned, unwanted occurrence put the oil on the ground? What happened? (Accident) Oil running out of flanges
3. Cause: What did anyone do or fail to do that caused the oil to run out of the flanges? (Unsafe act) Tightened bolts unevenly
4. What condition by its very existence contributed to the oil running out of the flanges? (Unsafe condition) None
5. Reason: Why did the employee tighten the bolts unevenly? Had not been told "What was the right way to tighten the bolts." (Lack of knowledge)

In many cases after the reason has been determined, there may be unanswered questions in need of further investigation: possibly a point of entry by the staff accident preventionist. For example, in the accident just discussed:

1. Why hadn't the employee been told how to tighten flanges?
2. What other employees are tightening flanges unevenly?
3. What is the procedure for tightening flanges?
4. What is the supervisor's indoctrination procedure for new employees?

It is impractical to disassociate the work of investigation from the task of corrective action, so after necessary correction has been taken, check observations should be made until we are convinced that the action taken was sufficient to prevent a recurrence of the cause.▲

WHY SET UP INSPECTION PROGRAMS?

by **FRANK W. KELSEY**

coordinator of safety, Jones & Laughlin Steel Corp., Pittsburgh, Pa.

Safety inspections can alert those preventing accidents to be on guard and to do something about potential hazards. Safety inspections are a necessary and vital part of any well-rounded accident prevention program. Inspections concern the identification of unsafe conditions and unsafe acts before they can contribute to an accident. They are the principle means for locating accident causes.

The finding and correction of unsafe conditions and practices are one of the best means by which management can show employees its interest and sincerity in accident prevention. Safety inspections help sell the accident prevention program to employees. They also encourage employees to inspect and correct conditions in their own areas. They afford the safety department an opportunity to contact the individual workman and provide the workman with an opportunity to point out unsafe conditions and practices which might otherwise go unnoticed.

WHY NECESSARY TO INSPECT?

Some years ago, our steel works divisions initiated an unsafe condition and practice report. After a vigorous effort to sell it to supervisors and workmen, many of these reports were received—so many in fact that the works manager asked whether or not we wouldn't have all unsafe conditions in the works soon corrected. He failed to realize that inspections are constantly needed because unsafe conditions and practices are continually being created. Most unsafe conditions and practices do not remain corrected.

Many unsafe conditions are the result of objects wearing out through prolonged use—and sometimes abuse. The side rails of ladders and their rungs develop cracks and become weakened. Ropes become frayed and worn. Power transmission belts deteriorate. Stair treads get worn or broken.

This means that unsafe conditions are continually being created by people and machines. It also means that unless steps are taken to detect and eliminate such conditions, accidents will inevitably result.

Unsafe conditions have been likened to water leaking into a boat. If the water isn't continually bailed out, the boat will be swamped. Left uncorrected, unsafe conditions will grow in number. The result—a high injury frequency rate.

EMPLOYEES CREATE HAZARDS

Many unsafe conditions are the result of employee actions. No matter how well-trained workmen may be, they can cause unsafe conditions. Material may be piled where someone could stumble or trip over it or it may be stored in a hazardous manner.

Guards may be removed but not replaced. Hand tools may be left in a defective condition. Here again, is a continuing source of unsafe conditions—pointing out why safety inspections are an absolute necessity.

Not only must the plant be inspected for unsafe conditions, but workmen must be observed to see if they are working safely. We know that unsafe practices occur even among well-trained men—men who know better. Unsafe acts may be the result of:

Lack of knowledge or skill.

Improper motivation—that is, for various reasons men prefer the unsafe way.

Defective capacity—that is, unsafe acts may be due to physical conditions such as poor eyesight, overweight, lack of coordination, worry, etc.

Safety is everybody's business; consequently, in the accident prevention program, responsibility for safety inspections is broadly shared.

Members of the safety department must be continually on the alert for unsafe conditions and practices. All employees should be encouraged to report unsafe practices and conditions.

Works labor-management safety committees, working within contract requirements, may make inspections to improve safety and

to recommend to management new safe practices for adoption.

In the larger plants, joint departmental labor-management alternating inspection committees, assigned by the department head for a limited period only, could inspect for unsafe conditions and practices and report their findings to the department head. The principle advantage of such an inspection procedure is that it affords every employee in the department an opportunity to become familiar with and to participate in the accident prevention program.

Special safety inspections may involve the services of trained personnel.

Certainly, all supervisors and foremen should have a well-defined responsibility for the inspection and safe maintenance of equipment within their area.

WHAT IS INSPECTED AND FOR WHAT?

First there should be a clear understanding as to who has the responsibility for safety inspections. Then, the problem of what to "look at" and "look for" should be settled.

Experience has determined that the following 24 categories, which may or may not be of equal importance in any specific area, will provide a general answer as to what to "look at" when inspecting for unsafe practices and conditions.

1. *Atmospheric Conditions:* hazardous conditions of dust, gases, fumes and sprays.
2. *Chemical Substances:* all liquids and solids that are toxic in nature.
3. *Containers:* all objects for storage of materials, such as barrels, boxes, bottles and cans.
4. *Conveyor Systems:* any system that transports materials to or from operations or processes.
5. *Electrical Conductors and Apparatus:* wires, cables, switches, controls, transformers, lamps, batteries and fuses.
6. *Engines and Prime Movers:* sources of mechanical power, excluding electric motors, steam engines and gas engines.
7. *Elevators, Escalators and Manlifts:* Requires no further explanation.
8. *Firefighting Equipment:* all firefighting equipment plus related structures as sprinklers and fire plugs.
9. *Guards and Safety Devices:* all removable and fixed guards, and safety devices or attachments, excluding personal protective clothing and equipment.
10. *Handtools, All Kinds:* equipment that is held or carried when in use.
11. *Hoisting Equipment:* cranes, derricks, power shovels, dredges, air hoists, hydraulic jacks.
12. *Inflammables and Explosives:* Requires no further explanation.
13. *Machinery and Parts Thereof:* power equipment that processes or modifies materials, e.g., agitators, grinders, forging machines, pulverizing machines, drilling machines.
14. *Materials, Raw or Processed:* materials and supplies essential to production of finished product, excluding materials elsewhere classified.
15. *Mechanical Power Transmission Systems:* shafts, bearings, gears, pulleys, drums, cables, belts, sprockets, ropes and chains when used to transmit power.
16. *Overhead Structures and Equipment:* any structural parts or equipment that may fall from above.
17. *Personal Protective Clothing and Equipment:* goggles, gloves, aprons, leggings.
18. *Pressure Vessels, Boilers, and Pipes:* objects subject to internal pressure from compression of liquids or gases.
19. *Pumps, Compressors, Blowers and Fans:* objects that move or compress liquids, air or gases.
20. *Shaftways, Pits, Sumps, and Floor Openings:* all types of openings into which persons may fall or trip.
21. *Walking and Standing Surfaces:* floors, aisles, stairs, platforms, ramps, roads, scaffolds, ladders.
22. *Warning and Signal Devices:* direct communication systems as radio, telephone, buzzers, bells, lights.
23. *Vehicles and Carrying Equipment:* trucks, cars, trains, motorized carts as well as non-motorized equipment for transportation of materials.
24. *Miscellaneous:* other potentially hazardous objects or conditions that do not fall into the above categories.

In our own corporation we adopted the use of a safety inspection inventory form to determine the items which need inspection in any particular area of supervision. This particular form reviews all potential sources of accidents from an inspection point of view.

The procedure involved in the use of this form consists of two basic steps: 1. Determine what to "look at" and 2. Determine what to "look for."

This safety inspection inventory calls for a list of items that fall into the inspection category, and describes where these items may be found. It identifies the critical parts of the item which should be inspected for unsafe conditions, and the unsafe conditions which should be "looked for."

A thorough job calls for a safety inventory of each of the 24 categories should they apply. It would also provide a complete inventory of all the potential accident agents in a specific supervisory area.

"LOOK-FOR" GUIDE

Items to be considered under the "Look For" guide can be grouped under the following five major headings:

Safety Devices, Signal Devices and Guards
- Missing or inadequate guards.
- Lack of or faulty bracing support.
- Missing or faulty warning devices.
- Missing or faulty safety devices.

Structural Defects and Material Characteristics
- Sharp-edged, jagged, splintery conditions.
- Worn, frayed, cracked, broken conditions.
- Uneven, rough.
- Slippery conditions.

Functional Defects and Characteristics
- Unsafe susceptability to breakage, collapse.
- Unsafe susceptability to tipping over, falling.
- Leakage of gases, fumes, or fluids.

Ventilation, Illumination, Noise
- Noxious fumes, gases.
- Inflammable or explosive fumes, gases.
- Insufficient illumination.
- Excessive noise.

Hazards of Storage, Positioning and Arrangement
- Congestion of traffic or walking space.
- Protruding objects.
- Poor housekeeping.

This inventory would hardly include every possible hazard. But it will provide a permanent record, listing most of the items to be "looked at" and what to "look for" in each department when making safety inspections.

This inventory will also determine who is to do the inspecting. Some of the responsibility will fall to the foreman, some to safety inspectors, some to maintenance men and other responsibilities to skilled specialists.

WHEN SHOULD INSPECTIONS BE MADE?

When inspections are made will depend on the items to be inspected. Some items or conditions require continual inspection to make employees always alert for their occurrence. Gas and fume hazards are an example.

Some inspections are called for *immediately prior* to certain work operations. For example, entry into a manhole may call for a preceding check for gases. We use a field clearance report which requires the signature of department maintenance and operating supervisors before outside departmental personnel are permitted to work within a department.

Some items require periodic inspection—daily, weekly or monthly. Other inspections may be semi-annual or annual. Special inspections may be in order because of particular occurrences, for example, the investigation of an accident may reveal a special type of hazard.

This safety inspection inventory when completed, will indicate: what must be inspected, what to inspect for, who must do the inspecting, and when the inspection should be made.

IMPORTANCE OF CORRECTIVE ACTION

Inspections themselves are important; but follow through for correction is of utmost importance. Only by correction can unsafe conditions be made safe and workmen made to realize that management is earnest to promote the accident prevention program.

While the correction of unsafe conditions is an important phase of the accident prevention program, we believe that the observance and correction of unsafe practices is more important, because unsafe practices occur with greater frequency than unsafe conditions. Hence, improvement in the number of unsafe practices corrected should have a more significant effect on the frequency injury rate.

This statement is not made to discourage the correction of unsafe conditions, but to emphasize the need for locating and correcting unsafe acts or practices. Some of the common unsafe practices may be grouped under the following headings:

1. *Operating without authority. Failure to Signal or Warn.*
   (Ex. Start, stop or move equipment without authority.)
2. *Failure to Make Secure.*
   (Ex. Failure to lock, block, tie or otherwise secure materials or equipment against unexpected movement.)
3. *Operating or working at unsafe rate.*
   Running.
   Jumping.
   Operating vehicles too rapidly.
4. *Improper use or failure to use.*
   Guards, safety devices and personal protective equipment.
5. *Using unsafe equipment. Using equipment unsafely.*
   Use of unsafe hand tools.
6. *Taking unsafe position or posture.*
   Exposure under suspended loads.
   Improper method of lifting.
7. *Unsafe loading, placing, storing, mixing.*
   Overloading.
   Crowding.
8. *Working on moving or hazardous equipment.*
   Getting on and off moving equipment.
   Working on equipment in operation.
9. *Miscellaneous unsafe acts.*
   Distracting, teasing, horseplay.
   Wearing unsafe personal attire.

With these common unsafe practices in mind, you can plan observations for unsafe acts.

As with unsafe conditions, after an unsafe act or practice has been observed it is essential that something be done about it.

The correction of unsafe acts or practices involves a problem in human relations. The employee must be approached in such a way that there will be no resentment on his part. Certainly he should not be subjected to humiliation. He should be talked to in private and informed of the safe way to do the job and an effort made to get his agreement.

HOUSEKEEPING

Good housekeeping looms large as a very definite factor in the prevention of accidents. A well-planned periodic housekeeping program, set up on a rating basis with awards to the unit with the best score will do much to help the cause of safety.

A continuing systematic method for finding and correcting unsafe conditions and practices is great value in the prevention of accidents, since unsafe conditions and practices are continuously being created.

Safety is everybody's business and responsibility for inspections should be specifically delegated both as to "when" and "by whom."

After indicating what items or practices should be inspected and presenting a safety inspection inventory form we again emphasize the importance of corrective action after unsafe conditions and practices have been determined.

"Why Set Up Inspection Programs?" To emphasize: *ORGANIZE — DEPUTIZE — SCRUTINIZE.*

MACHINE TOOLS AND PRINCIPLES OF GUARDING

by HAROLD MOORE

safety engineer, Remington Rand Inc., Elmira div., Elmira, N. Y.

The measure of a good safety program is the determination of top management to back the movement and actively support all those to whom the duty has been given to supervise, develop and engineer the safety program in their organization.

Most assuredly, the success that has been gained and maintained by those companies whose no-accident records are outstanding, has been attained by the whole-hearted backing of the safety engineer, or director, in his program of injury prevention. For, after all, injury prevention is the goal at which we all aim.

This present situation has been a matter of growth, in just the same way as there has been a definite growing in production methods. Management realizes that good production depends on accident-free operation. So in the beginning let me say that if your management, I mean the chief of your company who has delegated the safety job to you will co-operate, you start with few handicaps, nothing like the handicaps which those of us who have pioneered the accident prevention movement.

It doesn't matter whether you are a newly appointed or even a more matured individual in the no-accident movement. This job you have been given bristles with opportunities to progress in this field of injury prevention. If it should be thought necessary to choose a motto or a watchword we would declare—"They shall not get hurt."

So, let us first break down some of the essentials that govern the province of machine guarding and, second, the scope of the responsibilities and duties connected with the job.

MACHINE GUARDING

Fortunately today we do not have to start from scratch. The progress made in the field of machine guarding has been phenomenal, and it has been stimulated by the acceptance of the principle that it is the inescapable duty of the industrialist to accept that responsibility. Answers to this program of machine guarding are available to those who will make it their business to study and apply the principles.

First—Where do we find them?

We can and should make use of the text books—The Safety Manual, Safe Procedure pamphlets and job Instruction Cards, in addition to all other stimulating literature of the National Safety Council.

It is probable that the companies you represent are subscribers, members or supporters of the National Safety Council and thereby can, at little extra cost, provide you with a knowledge of the tested methods which have proven effective insofar as the material—or physical aspect is concerned.

BE A SAFETY DEVOTEE

However, these manuals, text books and such to which we have referred are of little use if they remain on your bookshelf. This means, of course, that you shall not be a mere safety job-holder, but a devotee, one who is imbued with the spirit of his work and whose studies are not a task but an opportunity and an investment.

One or two points about machine guarding do stand out in our experience. The first is that the primal parts of most machine tools today are already taken care of by the machine tool designer and manufacturer. We mean such things as gears, universal joints, accessibility of stop-start motions and the combination of those operating features which are designed to prevent the casual or inconsidered act of the operator.

There are still some old-time machine tools which may need your attention. However, the more important, "point-of-operation" protection will always provide the greatest scope, and challenge, for investigation, study and ingenuity of the safety man, —the devoted safety man. Let us analyze this a bit. We have learned that injuries don't just happen. They are caused. The accidental injury is merely the effect of the cause. So in considering these points of operation we shall, we must accept the axiom that no one wants to get hurt. If that were not true, then injuries would not be accidents: they would be routine.

MAN CAUSES MOST ACCIDENTS

What then is one of the main causes of accidents and the one which needs the intensive consideration of all of us in the accident prevention field? In our opinion it is the unpremeditated, the instinctive, the automatic act of the human individual as opposed to the Robot.

A machine is designed to do certain operations. The machine does not think; it takes no regard of any conditions, just merely operates as it is designed to do, and if the operator doesn't realize and accept this he is an accident liability. Let us illustrate.

Take a punch press which has been, and properly, looked upon as a number one maimer.

Thousands of dollars have been invested in the design of punch-press guards—de-

signs accepting the frailty of the human operator, and to make the guard what euphemistically we call "*fool proof.*"

Actually what is being done is meeting the situation so as to combat the effect of the instinctive action we spoke about.

As an illustration of an instinctive or unpremediated action think of yourself driving up a knoll, say at 40 m.p.h. and at the top 50 yards ahead you see a farm wagon crossing, or some cattle, or some children playing. Do you go through a long process of thinking what you will do?

No. Instinctively your foot leaves the accelerator, you step on the brake—and you slow down. By the same token, if you are sitting beside an open window and a moth, or a bug, flies in and alights on your face, you brush it off in an instant. Well, a press operator seeing something on the die, a chip or a misplaced part, has the instinct to reach in and sweep it off.

DRILL JOB SAFETY

An impatient drill operator doing a drill job in sequence, will when closing one drill operation retard the drill by using his hand. What does a point-of-operation guard do? It prevents, or must be designed to prevent, such incidents before they become accidents. And the success of the design of the guard and the insistence on its use is the accident preventor.

We cite this type of machine because, in safety parlance these machines are considered bad offenders. We shall not go into detail regarding the many varieties of machine guarding, that is the physical guarding of machines. As we said, a large percentage of machines in this day are in incentive production—and this brings to light the would-be "corner cutter"; the guard dodger and the "take-a-chance" boys.

Where does our safety man stand here? Oh no, it is not simple; it is a challenge. Let us emphasize. The safety man, if he is ever going to make a success in accident prevention, must work with the tool designer; the ranks of supervision from foreman down to set-up man with methods engineering, time study man and union stewards. He does not give orders. He is not a dictator, but he is a salesman for injury prevention and a friend to the employee and others.

In his sphere he has much need for publicity of his objectives and support to back them up. For aids, he arranges for and makes up safety committees. If need be he uses plant publications—if there is one, posters illustrating the danger of certain procedures and he also disseminates news regarding safety activities, outstanding safety performances and gives credit to safety suggestions submitted from the floor.

USE FIRST AID FACILITIES

He can and should make use of the first aid and medical departments and their facilities; keep in touch with the plant nurse *and be immediately advised if* and when a condition arises which requires prompt attention and maybe drastic action.

We need hardly tell you that to-day in the safety field, there is opportunity for the safety man to keep abreast of new developments in automation with its prospect of monotony-promoting drowsiness. Also the new aspects of compensible liability available. Radio activity is one that should be the subject of investigation, consultation with specialists in this field who can—and will—gladly help.

Another field which is becoming a cause of worrysome consideration is noise—with the possibilities of producing hearing defects or losses. This divides itself into two divisions: The factual study of noise producing machines or other conditions by the use of detector devices; and *the evaluation* of noise-reduction, baffles, insulation and personal protective equipment.

The safety man should be included, and, if permitted by the scope of his authority, a consultation with the specialist, the engineering division, the medical department and industrial training group, in fostering a successful safety program.▲

PLANT CONSTRUCTION AND MAINTENANCE

by THOMAS B. COLEMAN

safety supervisor, Kearny Works, Western Electric Co., Inc., Kearny, N. J.

The key to injury free performance in any endeavor is, has been and always will be the safe worker. This is particularly true in construction and maintenance work because of the nature and environmental conditions of this work. There are federal, state and local laws which specify definite requirements for safe working conditions. Books, brochures and printed articles give all the information needed to determine what is safe or unsafe in equipment facilities, conditions and tools.

An outstandingly good job of building safety into most tools and equipment has been done by the engineers. However there will always be opportunities to develop engineering improvements for the tools and equipment used by the construction and maintenance men.

The work assignments of the construction and maintenance men are not repetitious. Each job the men do presents a different set of circumstances, conditions and problems. Therefore the tradesmen, journeymen and master mechanics must be well grounded in the techniques of safe work methods. A broader knowledge of the work, use of the equipment and protective devices is essential.

Even with the knowledge of how to protect against the unexpected and of things that make the work area safe, we must depend on the man working safely because the supervisor cannot give the same time to *the individual* or group as can be devoted to the fixed location workers.

Because the construction and maintenance men are widely scattered the supervisor does not have as frequent contact with them as the supervisor of a group of production workers confined to a particular space.

Therefore the men on this type work must be thoroughly familiar with the problems and potential hazards. We must of necessity place more dependence on these men.

TRAIN SAFE EMPLOYEES

To obtain safe workers we must select men with care, and then train them for safe work. When instructions are given to a man we dare not assume he knows what to do, or how to use all the necessary safeguards.

We must take time to review all points of danger, all the pitfalls and inform him of the exact requirements and expectations for safe work. We must also equip the man with sufficient and suitable equipment to meet the safety requirements.

If we hire an electrician and tell him to wear a hard hat to withstand high voltage contact, and we give him a hard hat that has no value except impact resistance, we have not given the man adequate or suitable safety equipment. The safety equipment must give the protection we want the man to have.

After adequate instructions have been given, suitable safety equipment provided, the environmental conditions are good, every hazard considered and the employees follow our demands—then some member of the supervisory staff is called to aid a man in an area where eye protection is required.

This supervisor goes to the tradesman but does not bother to wear his safety glasses. He is setting a bad example for the employee. Within a day or two that employee will probably be working without the specified eye protection.

You must insist that all members of management help in setting a good example. The staff must always use the safety devices specified for use in any work area they visit. There must be rigid compliance to all safety rules and regulations. You dare not disregard or fail to use the proper equipment in the approved manner.

Circumstances that lead to a fatal accident only can be eliminated by exacting rigid compliance to all rules and regulations. We must outline and review them when indoctrinating a new and inexperienced worker. Never leave any part of the rules unexplained. To be sure no information is missed, make up a guide list or induction procedure and follow it.

The newly hired experienced tradesman should be given just as thorough an indoctrination as the inexperienced man because

he may have formed bad habits in his last place of employment.

Here's what happened to one man with a bad habit. In his indoctrination the supervisor covered the local rule against hitching rides on industrial trucks. However, the new man disregarded the rule and jumped onto the forks of a passing truck. His left foot slipped and was caught under the frame of the truck. When the injured man was interviewed he said, "I always hitched rides on the trucks in the last place I worked and got away with it. I did not expect to go wrong this time either."

This indicates a need to go a step further in our training procedure. We must review some of the rules for safe work each time there is a change in work assignment. The training given by the supervisor must be continuous.

The master mechanic, journeyman or lead-off man are important in the day-to-day training of the apprentice and helper. They must set a good example and be thoroughly familiar with the rules and procedures. Any lead-off man who decides upon a change in method or procedure that reduces or eliminates safety from the task is unworthy of continuing in that role.

Management has the responsibility to provide safe equipment for the men to work with and the workers have a responsibility to themselves and management to use all that is provided. We might consider each employee as having been hired conditionally. Every occupation has certain conditions to be met, such as the welder and his eye protection, the millwright and his boatswains chair with a safety line and the man who builds and works from a scaffold that requires a toe board and guard rail.

TRANSFER UNSAFE WORKERS

Each man who fails to use the specific safety equipment for the exposure or job has failed to meet the conditions of employment. The man who is unwilling to comply with the conditions for safe work should be transferred to less hazardous work or his service should be terminated. To continue him in an occupation where he does not meet the conditions will surely result in disaster.

The supervisor must set a good example at all times by using all the safety devices he expects his men to use when exposed to the hazard of the job. If an employee is having difficulty on a particular task and calls the supervisor for help, the supervisor must use whatever equipment the man must use. If the job is dusty and calls for a dust mask he should use a dust mask. If he goes on a scaffold where a life line is required then he must use a life line.

The older employee will have a great influence on the new men and helpers. If the older men do not set a good example we will never achieve complete acceptance and use of the safety equipment. There are a few ways to secure acceptance and use of the safety equipment, job methods and operating techniques that guarantee the greatest safety.

First, rules must be stipulated and followed. They must be clear cut and as simple as possible. When outlining the rules to the employee the supervisor must make certain there is complete understanding. Leave nothing to guess work. It may be necessary to repeat and repeat until you are understood.

The supervisor must make no exceptions to the rules. They must apply uniformly. The moment he lets one man work contrary to the rule he is in for trouble. Other men in the gang will be found working without the item that was excepted for the one man.

REVIEW SAFETY RULES

When job assignments are given out, the supervisor should review the safety requirements of that job. He must not assume the men will remember or that the man knows all the danger points of the new assignment. One supervisor covered the area fully. After giving the millwright all the information for the job, he then reviewed the safety requirements. He pointed out the need to lash the ladder on the building truss and the need to wear safety glasses.

Finally the supervisor said "and button up your shirt collar because those metal chips from the drilling will be hot. If you get one of those hot chips down inside your shirt it may cause you to fall off the ladder and we don't want that to happen, ever."

This supervisor did an excellent job of instructing his employee; nothing was left to chance. The employee followed through on the instructions because they were complete and explicit. He knows that this supervisor will not tolerate short cut methods or failure to follow orders.

There may be times when non-compliance with the rules and safety requirements cannot be enforced except by some disciplinary action. This step should be taken whenever it is warranted. It is important that the action be uniform. It must be fair yet adequate.

Good judgment must be used in leveling the penalty or else it may be turned into a joke as in one instance. The man was to be given two days off for an infraction. The days were to be a Thursday and Friday but the supervisor decided he wanted the man on Saturday because they needed his particular skill.

When the employee was informed of the penalty and then was told they expected him on Saturday he laughed at the supervisor and said "You must be crazy to think you can give me two days off at the end of the week and then say you expect me in on Saturday. This is just what I have wanted. This gives me a four-day weekend. I'll be able to put my new boat in the water and try it out. You won't see me until Monday Mr. Supervisor."

LEARN THROUGH PENALTIES

This action was not a penalty because it gave the man something he wanted and in turn the entire gang looked upon this action as a huge joke. At another time three men would not continuously wear the eye protection that was required. After a reasonable interval in which every effort was made to have these men comply they were placed in other occupations where eye protection was not required.

Arrangements were made for the change and the men were told what was to happen. Three men after their initial protest about the loss in earnings said, "You never convinced me that you meant what you said about wearing those safety glasses. Give me another chance on this job and I promise I'll wear the safety glasses all the time." They were were given another chance and they have fulfilled their promises.

We have given a lot of thought to the supervisor and what he must do to run a safe job. But let's look at the duties you and I must fulfill to help make the job as safe as possible.

First, every hour spent on writing reports of injuries is an hour that could have been used in personal visits to search for unsafe conditions, human failings, and damaged or defective tools and equipment that often result in injuries.

VISIT JOB LOCATIONS

You should be seen in the field each day by as many employees as possible for you to visit. You must never pass by an unsafe condition, act, or piece of equipment. You should make arrangements for some corrective action before you go on to the next area. Show righteous indignation when such a show is justified. Do not accept anything but the best efforts in every aspect in the fulfillment of your safety program.

The only way to come down near the zero mark in injury frequency is by the elimination of every conceivable hazard and by wholehearted and complete acceptance and use of the safety equipment, rules and regulations that may be established for the protection of the employees. There is no easy way to accomplish the desired results. It takes hard work on your part, your supervisor's part and on the part of your management.

The key to injury free performance is the safe worker. In construction and maintenance work there is hardly any repetition to the work because each job and location presents different hazards. The men's knowledge must be much broader to meet the constantly changing conditions. The men must be well instructed and dependable because the supervisor cannot be with them constantly. Their training must be thorough and they must be adequately equipped to work safely.

There is a constant need for you and the supervisor to set a good example. Compliance with all the safety regulations is imperative. Training the men is and must be exacted from all employees. There can be no exceptions.

When disciplinary action is required it must be uniform, fair, and adequate. Remember that every occupation has certain conditions that must be met. Therefore every employee is hired conditionally and when he does not meet the conditions of employment he is no longer employable on that job.

You, Mr. Safety Man, must spend every available minute searching for the unsafe practice, the unsafe condition, and the unsafe equipment so they can be corrected before anyone is injured.

PRINCIPLES OF INDUSTRIAL HOUSEKEEPING

by PETER CONTARDO

safety director, John A. Roebling's Sons Corp., Trenton, N. J.

Housekeeping must be ranked at the top of the list of things we should do to prevent occupational accidents. It is the one activity which more than any other is used as the spearhead of the safety effort.

Housekeeping is usually described by the following well-known statements. Some people say it means "keeping the plant clean and orderly"; others describe it as "a place where everything is kept in place."

In plants which have had good housekeeping for many years most of the employees use the well known expression "a place for everything and everything in its place."

In a recent survey taken in a manufacturing plant 30 employees were asked to define housekeeping. It included the superintendent, industrial engineers, safety personnel, industrial nurse, maintenance men, janitors, equipment operators, an accountant, machine operators (laborers, and others. All of them included either the word clean or the word orderly in their replies. Twenty-four of them used both words. This seems to indicate (at least on the basis of this survey) that housekeeping consists of "order and cleanliness."

STOP SQUALOR

I once heard it referred to as the elimination of industrial squalor. We may find it advantageous at times to use this definition in our work because despite the great progress made in industrial accident prevention, and particularly in plant housekeeping, squalor in industry exists as surely and probably to as great a degree as it does in blighted tenement districts and so-called backward rural communities.

In addition to controlling or eliminating work hazards, order and cleanliness in our plants provides an unusually strong sales appeal for our way of doing things as opposed to a state-owned and controlled economy. It is difficult to persuade a visitor, whether a local citizen or from a foreign land, that in our system we have genuine concern for our working people if we keep our plants in a sloppy condition.

Industrial squalor does not enhance the prestige of the free enterprise system at home or abroad. The habit of squalor becomes contagious and (if it exists in our plants) spreads beyond the confines of the plant gates. Witness the alarming harm done to the countryside by the so-called "letterbugs."

SAFETY IS SERVICE

Safety-men should be in the forefront of any efforts to clean up (and keep clean) America. It is an opportunity to render a real service not only to our employees and industry, but also to our communities.

Our obligation for industrial housekeeping does not begin and end at the plant. Through our Chambers of Commerce, our local safety societies, our local governmental officials, we must do our share to help make the entire community, and especially the industrial community, "housekeeping minded."

Let us analyze the real meaning of industrial housekeeping. What is it? What does it include? It may be defined as "all those activities which are necessary to keep the interior and exterior of the plant in a reasonably clean and orderly condition."

The plant includes all buildings and structures, equipment, machinery, yards, roads and parking areas. The interior includes the inside of all buildings from cellar to attic, and the contents. The exterior includes not only the outside of all buildings, but also, tanks, trestles, stacks, roofs, fire-escapes, window ledges, plant yards, roads, parking areas, and storage areas.

A "CLEAN" PLANT

To be "clean" a plant must be reasonably free of controllable dirt, grime, rubbish, garbage, and other material—and in its broadest sense includes the protection of employee health through adequate sanitary facilities, the prevention of occupational diseases, and the protection of the community from air and stream pollution. The latter are special problems which will not be discussed here by the speaker.

"Orderly" means to install, store, use or move material, equipment and machinery in as straight a line as possible, making economical use of available floor space, so that operations are conducted with maximum efficiency and safety and minimum effort and confusion.

Safety men may be functioning under any one of the following conditions with or without sincere, active management direction and support.

a. A new plant in either the planning stage (i.e. before construction begins) or immediately after completion of the plant structures.
b. A reasonably new plant with or without an established, successful safety program.
c. A so-called old plant (over 30 years old) with or without an established successful program.
d. A comparatively new or old plant which had a program but for a variety of reasons it fell into disrepute.
e. A plant which really never had an effective program.

What ever the circumstances, the principles and methods which we must follow to develop and administer the industrial housekeeping phase of the accident prevention activity remain unchanged. How should we proceed?

INSTILL DESIRE FOR CLEAN PLANT

● Create and instill in top management the desire for a clean plant. The most effective means at your disposal is to make one or more members of top management "housekeeping champions." Every company, small, medium, or large, fortunately has a number of top officials who are instinctively sympathetic to reasonable efforts to clean up their plants and will support your plans.

These are the men who will not only react favorably, but will "go to bat" to influence other members of management on the wisdom and advantages of good housekeeping. You must reach the group by thoroughly selling and enlisting the help of the few in the group who can aid you most.

● The next step is to persuade management to adopt and publicize a housekeeping policy. In short this policy should simply state that the executives of your company want a reasonably clean, orderly plant.

● The policy should be translated into specific orders from executives to operating heads, to foremen, to employees.

● It is our experience that initially the operating people consider housekeeping just another chore or job to do because the owners and/or managers want it. In the beginning there may be little enthusiasm for this additional job and it is the wise safety man who will literally get on his soap box and slowly but diligently sell all, particularly supervisory personnel on the value of a clean shop.

● The next phase in the evolution of the housekeeping effort is the development of a program, the spelling out of *who* and *how* the job must be done.

● The last phase is the enviable position reached (after many years of patient work on the part of many individuals) where housekeeping becomes a tradition. You have heard from time to time, the expression—that in a certain company or corporation "housekeeping is a tradition which started a good many years ago and is being maintained as strong as ever today."

MANAGEMENT'S RESPONSIBILITY

The steps which management must take to organize and maintain a good housekeeping program, can be summarized as follows. Management must—

1. Tell everybody in the organization—keep telling them.
2. Tell them why they want housekeeping—enumerate advantages.
3. Tell them who is responsible for accomplishing it.
4. Tell them how it should be done.
5. Provide necessary equipment and personnel to do the job.
6. Get everyone in the act.
7. Reward them when they are doing a good job: penalize them when they do a poor job.

Before telling you how we followed the seven steps in our own corporation it might be well to repeat a fact with which many of us are familiar, namely that about 75 per cent of all manufacturing plants in this country are 25 or more years old. This

complicates the housekeeping problem and makes it more of a challenge. Many of the older plants enjoy better housekeeping than some of the newer ones which have more space and better facilities. We must remember to do the best we can with the facilities available, rather than using lack of modern buildings as an excuse not to do anything.

1. How did we at Roebling tell everybody, and how did we keep telling them? First our formal safety policy was prepared, published, and distributed. (It contained strong emphasis on housekeeping.) The vice president in charge of production made certain that all supervisory personnel received copies. It stated, in effect, "that management wanted a clean plant."

He frequently at manufacturing manager's meetings, and in his inspections, reminded them of the company's desire. All service and staff department heads were notified of the new "party line"—namely, "we're going to have a clean plant."

HOUSEKEEPING ADVANTAGES

2. At staff meetings of various departments, and in our safety training programs for supervision we emphasized advantages as follows:

a. Reduction in work injuries.
b. Increase in efficiency—brought about by easier flow of materials, and higher productivity.
c. Improvement in morale of employees—they like to work in an orderly atmosphere.
d. Sales—favorable effect on customers. In one particular instance, an important customer visited our plant (after our program was in progress) and then increased his purchases from 15 per cent to 30 per cent of his needs because he was so favorably impressed by the orderliness he saw.
e. Community relations—one of the best avenues to winning and holding the esteem of the community is by having the plant pleasing to the eye.
f. Labor relations—reduction in employee complaints and grievances.
g. Fire losses minimized.

3. Who is responsible? We placed responsibility on—

a. Operating personnel—supervisors, foremen, janitors, laborers—each have a responsibility. Staff personnel also have an obligation to do what they can to promote housekeeping.
b. Maintenance personnel—barricades, cleanup during, and after each job.
c. Safety department—training, safety meetings, posters, inspections, contests, and publications.

4. How the job should be done. We made haste slowly. In my experience, even the most enthusiastic management can be overwhelmed if you try to get too much done too quickly. Keep in mind that good housekeeping habits are not acquired over night. It takes years.

We ordered all of obsolete material, surplus, scrap from exterior, and interior of buildings, removed. Inspections were made, and inventory taken in each department, and to give you an idea of what can be hoarded, 13 cars of scrap were removed from the plant in the first week of the campaign. A vacuum cleaning of the walls of our carpenter shop produced two barrels of wood flour.

Each foreman was given orders to clean up his own office and keep it clean, and made responsible for housekeeping in his own department. Each foreman was given orders to instruct and train individual employees in good housekeeping habits, emphasizing the importance of each man keeping his own work area clean.

HOUSEKEEPING EQUIPMENT

5. Over a period of years we equipped various departments with:

a. Vacuum cleaners, power floor scrapers, power floor sweepers; however, in the hard to get places we still use considerable hand sweeping.
b. Aisle markers. One plant uses compressed air aisle paint markers. One plant uses gravity fed paint aisle markers, and another plant uses plastic discs, which are nailed and cemented to the floor.
c. Use of mineral absorbent on floors, and elimination of the use of sawdust, where oil and grease is spilled or splashed.

d. Outdoor storage bins for scrap, chips from machines, etc., were installed.
e. Central bundling area for scrap was set up.
f. Distinctively painted rubbish and scrap cans were furnished.
g. Incinerators were constructed where needed.
h. We reviewed our toilet, washrooms, showers and facilities, and developed a long range program of modernization of same.
i. Oily waste receptacles were provided.
j. Lighting facilities were reviewed, and still being reviewed, with improvements being made where necessary.
k. Exhaust ventilation was provided at processes requiring same.
l. Bulletin boards were installed and traffic warning signs were repainted on the exterior and interior of the plant.

STRESSED COOPERATION

6. All of our promotion, all of our publicity, and all of our training stresses the notion that housekeeping is something that is accomplished by having everyone do his share.

7. Reward system. We do not have formal housekeeping contests, and do not favor awarding "booby prizes" to departments with poor housekeeping. We find a word of praise from a top executive, a customer, or a visitor is sweet music to our operating people. However, we are now considering initiating a contest in our present program.

A schedule of sweeping and scrubbing floors, of collecting and removing scrap and rubbish, of cleaning walls and machinery, of washing windows, and cleaning lights, of washing, sanitizing, and deodorizing toilet-rooms, washrooms, and locker rooms must be worked out on a trial and error basis. The cleaning job must be tailored to fit the needs and requirements of variable conditions in different departments, and in dissimilar plants and industries.

We must set a housekeeping standard for ourselves—how? We must select the best plants in our industry and make it our objective to establish as good a reputation for housekeeping as they enjoy. Eventually we should excel to the point that other companies will use our plants as models for their housekeeping program.

Here are some of the attitudes which retard progress in housekeeping.

1. We must guard against objections of operating people that lack of space makes housekeeping impossible.
2. We must not permit ourselves to blame poor housekeeping conditions entirely on employees or employee's bad habits.
3. We must refute the quaint, but out moded, notion that a dirty plant is a barometer of good business because only busy plants are dirty. Surprisingly, there are still a number of people who believe this.
4. Last, but not least, we must constantly debunk the notion the housekeeping costs too much money.

After developing a housekeeping program we must not relax our efforts. Just as other elements in the safety effort require constant, repetitive attention, so also does housekeeping. In short we must not only get the plant clean and orderly, keep it clean and orderly, but most important of all we must not let the housekeeping program take a backward step. That would be fatal—because while the climb to success in housekeeping is a long hard one, the road back to industrial squalor is a quick easy one.▲

INITIATING AND MAINTAINING INTEREST IN SAFETY

by E. CLARK WOODWARD
director of safety, A. O. Smith Corp., Milwaukee, Wis.

Initiating and maintaining interest in safety is a broad subject and can be discussed for hours. Therefore, let's consider this problem in its simplest terms. Initiating and maintaining interest in safety is essentially a selling job.

Selling safety is no different from selling any tangible product so far as selling principles are concerned. Too often we think that selling "intangibles" is more difficult than selling washing machines or refrigerators or stoves or lawn mowers. Actually, the principles are the same. All we have to do is change the name of the product from "lawn mowers" to "safety."

If you really want to sell safety and keep it sold, I advise you to get ahold of the sales manual of any large appliance manufacturer or read any good book on how to sell merchandise. Just change the words around a little bit in your mind and see for yourself how well the principles apply to selling safety or, in our case, to initiating and maintaining interest in safety.

KNOW YOUR PRODUCT

Before you can sell any article you must know that article thoroughly. Suppose you were selling washing machines. You would be expected to know your brand of washing machines thoroughly. You would be coached in all the workings of the machine. You would have to learn all of its many advantages to the user. To be a good salesman, you would have to be proficient in your knowledge of what benefits your device would bring to the prospect.

On the other hand, you would have to learn all the objections which might be raised by a prospect in the course of making a sale. In other words, you cannot wait until you get in the customer's home before you think of the answers to the prospect's doubts in regard to your product. You must know the answers beforehand and be ready to answer them.

All this is true about selling safety. You must know and be completely sold on the advantages safety brings to the employee. You must know in advance and be ready to answer the usual objections which are raised by most people before they accept safety as a part of their way of living. If you are selling the idea of wearing safety glasses, you must be ready in advance to answer the argument that the prospect thinks safety glasses are too heavy, etc.

WHY PEOPLE BUY

People buy safety for the same basic reasons that people buy washing machines. In order to complete a sale, certain requirements must be met.

All of us have common desires. The psychologist can outline them to you and they will include such motivations as a desire to live, desire for profit, desire for prestige, desire to compete, and quite a few other natural inclinations. The sales manuals will tell you that we all have these basic desires.

However, we have them to varying degrees. One man has a greater desire for profit than another. Another man is greatly in need of feeling superior to his fellow men; and so it goes. A sale is made when the salesman is able to play upon human desires and convince the prospect that the thing he desires is actually a "need." Once that is accomplished, the prospect feels his desire is justified and he will buy what you have to sell.

My wife wanted an electric dishwasher for many years. We raised three children and managed to get along all those years without an electric dishwasher. However, after all of our children were married and had left our home I suddenly learned that my wife "needed" an electric dishwasher. She absolutely had to have it!

I attempted to argue the point. I said, "All the kids have left home and you only have dishes for the two of us. Why should you have a dishwasher?"

"Because," my loving wife replied, "I lost my dishwashers when the girls got married."

I didn't have a chance to overcome that argument. Some salesman had persuaded her that her desire for an electric dishwasher was now a real need. You know what happened. We have a very beautiful dishwasher in our home.

KNOW YOUR PROSPECT

Not all people buy products or buy safety for the same reasons. As I said before, we may all have the same basic desires to varying degrees. But, certain desires will be stronger and therefore, the most logical for the salesman to work on, depending upon our position in life. Thus, the appeals that are effective with top management will not mean much to a lathe hand or a sweeper in the factory. By the same token, we cannot use the same appeals to top management or middle management, or the foreman as we use for the people in the lower echelons.

In our company we make definite efforts to appeal to the desires and needs of every level and we use definite devices for the purpose.

In order to sell top management, we devote considerable effort to getting the facts and presenting them properly to show that accident prevention is good economy, that it increases efficiency, and that it is a measure of good management generally. To do so, we have even published special booklets in which we have charted, somewhat dramatically, the savings made in our company through accident prevention and have pointed out the need to continue our efforts in bringing down our frequency rate year after year. As a result of that kind of selling and the resulting "buying" by our management, they have taken certain steps which help us to sell safety to the levels of the organization below them. This, of course, is a necessity in selling safety. The top management must be sold and must make it evident to one and all that they are sold.

As a positive indication of such attitude, our president issued the following statement of policy:

> "When a man enters the employ of A. O. Smith, he has a right to expect that he will be provided with a proper place in which to work, proper machines and tools with which to do his job, and that he will be able to devote his energies to his work without danger to his life and health.
>
> "Only under such circumstances can the association between employee and employer be mutually profitable and harmonious. It is our desire and intention to provide a safe work place, safe equipment, proper materials, and to establish and insist upon safe methods and practices at all times.
>
> It is a basic responsibility of all those carrying executive authority to make the safety of human beings a part of their daily, hourly concern. This responsibility must be accepted by each one who conducts the affairs of the A. O. Smith corporation, no matter in what capacity he may function."

AWARDS SAFETY TROPHY

In addition, our President awards a beautiful bronze trophy each year to that division which makes the greatest contribution toward accident prevention in our corporation. That device inspires competition and has proved effective.

By the same token, we devise special appeals to the staff organization such as engineering, time study and purchasing. In our training programs for executives we attempt to point out, in keeping with our President's philosophy, how each specialist is concerned with accident prevention and how the prevention of accidents will benefit his function.

Our superintendents, general foremen and foremen are also approached with a knowledge of their desires and needs. We carry on certain campaigns and programs which bring the line supervisors into the act in various ways. Sometimes we have the supervisor show movies. In some campaigns they all wear lapel buttons and ribbons, or they may utilize yellow flags to mark hazards, and we often supply them outlines for brief safety talks. We try to keep them all active by providing selling material for them to use.

MAKE IT POSITIVE

Safety is inherently a negative subject. It is a silly business in some respects. The harder you work to prevent accidents, the less happens. We safety people must always be striving to work ourselves out of a job. Perhaps the day will come when some-

one in my company decides they do not need me anymore because "we don't have any accidents around here."

Seriously however, good selling should be positive rather than negative. Human beings do not respond as well to negative appeals such as fear of punishment or threats to their well-being as they do to more positive approaches. If you show a man a gruesome picture resulting from an accident, he is instinctively inclined to think "it won't happen to me." On the other hand, if you show him happy and favorable results of working safely, he is more inclined to think "that will happen to me."

We have tried out this theory in many ways including a series of monthly safety posters which are carried throughout a calendar year. The whole thought of the campaign lay in the idea that there are many enjoyable activities in life. We want our people to enjoy those things. However, the employee cannot enjoy them if he gets hurt. Following this theme, we have issued colorful cartoon posters of many seasonal activities such as swimming, fishing, skating, picnics, traveling, card playing, bowling and golfing with the repeated advice that "You can't do these things if you get hurt." We found the campaign very effective and we think the answer lies in the fact that it was positive.

My argument is not complicated. Put in its simplest terms, I am convinced that every salesman of safety should study the basic requirements for selling any product. Let's forget the idea that safety is intangible and devote our efforts in making the "product" we have to sell a tangible, real and positive thing in the mind of our prospects. Let's be sure we know our product, its advantages and the arguments against it.

Let's try to understand the desires and needs of human beings in a realistic sense and to understand how those desires vary between groups in different levels of our organization. With that knowledge in mind, let's go to work to accentuate the positive and to build an all-around selling campaign that will bring results because it's built on a knowledge of what it takes to make a man buy safety as his way of life.▲

JOB SAFETY ANALYSIS AND PRE-PLACEMENT PHYSICAL EXAMINATIONS

by WILLIAM E. GRUBER

manager, engineering dept., Standard Accident Insurance Co., Detroit, Mich.

Of all of the fundamentals of accident prevention that have been taught and applied this subject, and in particular job safety analysis, has perhaps received the least usage in industry—even in the large corporations. Pre-placement physical examination programs are fairly common in industry but there are still many small manufacturing organizations that have not realized their value.

Job safety analysis is often confused with plain job analysis or job specifications—actually it has different purposes and different aspects. The similarity exists in that both are aimed at achieving efficient production.

Job safety analysis has four major objectives:

1. To establish a written break-down of a job that can be used for training workers to do their job safely.
2. To analyze a job for the purpose of determining the hazards with the view of possible elimination of these hazards.
3. To determine the tools and equipment that are necessary for safe operation.
4. To establish a basis that can be used in connection with proper selection and placement of employees. It is this objective that we are primarily concerned with here.

JOB SAFETY ANALYSIS

The following is a suggested method to be used in making the job safety analysis:

1. First, select the jobs for study with priority given to those which present the greatest hazard either from the standpoint of catastrophe possibilities, severeness or those which have the most exposure in terms of number of persons, length of the job, etc.
2. Divide the job into its components so that the analysis can become simplified. If the component is too large the analysis may become too complicated and thereby confused.
3. Analyze each component by first obtaining details of the operation either by observation or from a regular systems analysis and by discussion with the person who plans or supervises the job. You should then record all of the details of the operation and it may be advisable to use line drawings in some cases. Finally it is necessary to analyze each of the problems of movement as they relate (1) to the person who works on the job and the various materials and and equipment (2) the adequacy of clearance between moving and fixed objects (3) any mechanical means that can be considered for use in place of manual operations when it is possible and practical to do so.

KNOW JOB REQUIREMENTS

If the analysis is being made primarily to place personnel then it is necessary to obtain additional information about the physical requirements of the job such as the amount and kind of lifting, whether prolonged sitting or standing is required, the use of general and specific functions, the vision requirements, etc.

As a result of the conclusions reached in your analysis you may wish to make certain recommendations for the correction or control of the various hazards noted such as the alteration of the existing operation, the substitution of less toxic chemicals or less hazardous equipment or the provision of personal protective equipment.

Pre-placement physical examinations are used for the purpose of determining the physical abilities of prospective employees so that they can be related to the demands of the job in such a manner that the employee will be able to do the job safely—so that he will not endanger himself or others.

There are numerous benefits to be derived from the use of a good placement program. A few of the more important benefits are:

1. A reduction in the number of accidents.
2. Improved labor relations.
3. Improved job placement.
4. Economic benefits for both the employer and the employee.

There is a popular misconception as to the purpose of a physical examination program. Some people believe that it is used for determining the physical defects of an employee so that he can be rejected from employment. Actually this is not the case. Modern management has adopted a positive approach and is actually seeking a means for employing people who, years ago, were considered unemployable.

PROPER PLACEMENT POSSIBLE

To do this it is necessary to have excellent coordination between the personnel man and the industrial physician so that together they will come up with a concept of the man's psychological and physiological abilities to compare with the skills and requirements of the job. In this way the man will be in a good position to do his job well.

The physical examination program may be very simple or very complex depending on the needs and the facilities that are available. Every concern should find it possible to conduct a program regardless of whether or not they have a personnel department or a medical department. The average industrial physician, with a little training and a working knowledge of the operations being conducted in the specific plant can perform a valuable service.

Of course, to do even a better job a proper analysis of each job should be made to determine the physical requirements that are applicable such as the amount of lifting, use of fingers and other body functions as outlined earlier in this presentation.▲

PRACTICAL SAFETY EDUCATION AND TRAINING

by ROBERT G. REEVE

administrative supervisor, safety services dept.,
Allis-Chalmers Manufacturing Co., Milwaukee, Wis.

Before we discuss these factors, it would be well to explain what we mean by the terms "education" and "training." For convenience, we *shall define education as the* broad process of effecting behavior by appealing to individuals and groups through general approaches with the intent of selling them on our safety philosophy.

Training, however, appears to be the process of giving our people definite experiences that will cause them to develop, to stamp in, habits of working safely. For example, our children are "educated" to a liking for a certain breakfast cereal by watching their cowboy hero favor it; but their final attitude is developed when they actually try it themselves.

Now it's obvious that either negative or positive attitudes may develop toward any proposal or program. Hence, it is necessary that we tailor our program to produce positive attitudes, just as the salesman presents his wares in the manner best calculated to get the customer's name on the order blank.

HUMAN FAILINGS=ACCIDENTS

This, one would think, ought to be easy to do. The benefits of working safely are obvious to us; but apparently much less so to the average employee. In fact, with a little observation it can be seen that, while we have improved machines, processes, and guarding, installed conveyors, and eliminated belts and nip points, we are still having too many accidents. In a big majority of the cases, these accidents are found to be caused by the unsafe acts of individuals.

Accordingly, our problem boils down in the main to the motivation of individual safe behavior. Hers is a real challenge! It doesn't appear within the realm of human nature to want to be safe; in fact, if you observe many automobile drivers, you will be impressed with their apparent desire to commit suicide. The worker on the job displays some of the same tendencies.

But the picture isn't quite that dark. It is possible to re-educate people, to convince them factually, to enlist them in a cause that impresses them as being worth their time and effort. Our job is to determine how. This, then, becomes a campaign plan.

There are many tools available. Let's look them over.

MANAGEMENT ATTITUDE

First, it's basic to any good safety program to have management "sold" on it. That's a big area, and we must here assume that this has been accomplished. The fact that you're on the payroll is some indication.

It helps greatly to have a safety policy—written, and openly supported by top management.

Management can and should be brought into the educational program: via personal appearances at meetings, safety talks, letters to homes and articles in company publications. By the way, that's good education in two ways, of management as well as employees.

Then don't forget that management must be kept informed of company progress via reports such as this Executive Report; of developments in the field by publications and invitations to conferences. You can't expect supervisors and employees to be vitally interested in safety if management is not.

SUPERVISORY PROGRAM

Now let's look at the supervisor. He is the key man in safety, production, quality control, and employee morale. He is not necessarily a specialist in all these fields, but he can be made sufficiently well-versed to do a good job.

First, he too must be "sold" on safety, just as top management must. To measure his interest—observe him in action. His employees will. Does he cut corners on safe procedures, pass up hazards for convenience, wear safety equipment, talk safety with zeal? People sense these things, and it's up to us to get the supervisor to the positive stage.

To do so we use foreman's safety sessions. Here we will cover topics from philosophy to specific programs. These sessions should give him a chance to participate, discuss, question, relate experiences. Frequently, the supervisors severest critic is another supervisor or himself.

Second, publications such as our *Safety Highlights* may be a valuable mode of communication.

Case reports issued as *Accident Digests* or *APB's* which describe cases that have happened. This gives the foreman a chance to appraise his own area for similar hazards.

Accident investigations with analysis of causes and steps to prevent recurrence give a good ground for his actions.

Job safety breakdowns to locate job hazards and to set up safe operating procedures.

Safety inspections, in the foreman's presence, not only evaluate hazards of his department, but also give him the basis for his own inspections.

Analysis of suggestions and grievances may help him find clues for unsafe spots or hazards.

Statistical analyses, such as accident summaries, trend indicators, and cost breakdowns give the foreman ammunition for an attack on hazard areas and can improve production and lower costs.

The safety department can supply the supervisor with:

1. Materials for employee safety talks (cases or National Safety Council material).
2. Accident breakdowns for trends and clues.
3. Services such as protective equipment and liaison with medical and compensation departments.
4. Standard and safe operating procedures.

And finally, the safety man can be an open "ear" for the foreman to cry into, to consult on problems or new ideas. If you give him enough chance, he'll make himself a part-owner in your safety program.

EMPLOYEE TRAINING

Now the suggestions made to this point have been building up toward one main objective—to make the employee what we choose to call "safety-conscious," that is, to effect his attitudes and behavior on the job.

Let me point out that the degree to which you have been successful in selling management and supervision on safety will have a marked effect on the employee. It's sort of contagious—in either the positive or negative direction.

But we have many points of attack in this area of employee motivation or education.

First, the general approach—sort of a broadside attack. Here we use posters, publications such as the company house organ, handouts, movies, contests, radio and TV programs. Unfortunately, there are no accurate ways to evaluate the effects of these programs on employee attitudes. We only hope they correlate with lower rates and costs.

The second approach may more accurately be termed actual "safety training," and time spent in these areas pays off in changes in employee attitudes that can be observed and measured with some degree of accuracy.

1. *New employee orientation.*

   General—held at the employment office, this period is spent outlining policies and general safe practices.

   Supervisory—actual instruction in the safe operation of a specific job, pointing out hazards and methods of work. This includes showing, observing, and follow-up.

   Note: In plants fortunate enough to have a setup utilizing "Vestibule" training, safe practices are made an integral part of job instruction and training.

2. *Supervisory contacts.*

   Again the key man in production is the key safety instructor. Inspection of work areas, and instruction and insistence on proper housekeeping produce positive employee attitudes. Observation of work habits with instruction in safe practices insures employee compliance.

   Five minute safety talks (at least three daily in our plant) keep the employee informed and motivated to better efforts.

Crew "tailgate sessions" should be led by the foreman (or lead crewman if trained and properly prepared).

The foreman may find job safety analysis a good technique in locating hazards and bringing them to the attention of employe. Safety manuals, standards, and other published procedures from a good basis for foreman—employee discussions.

Let me emphasize that if I had the choice of only one means of employee contact—this would be it! By virtue of his position, the supervisor is the most effective means of motivating safe work attitudes.

COMMITTEEMAN TECHNIQUE

This technique follows the idea of enlisting employees directly in the program. Just a title has little value; a function should be included. Our committeemen are rotated at four-month intervals, and appointees are given four hours of preliminary training in basic accident prevention before their term begins. Monthly meetings during their term as committeemen give further opportunity for discussion of cases, inspections, etc.

Apprentice Training

Apprentices follow a prescribed course, and safety should be made an important element. Our apprentices hold monthly safety meetings over their four year course, and they have compiled a fine record of accident-free work over the years. Also, they become good supervisory material with an excellent grounding in safety.

Home Approach

The approach through home influence is a separate category. We may not think of it as education, but it is a fact that an informed family may well contribute toward making the breadwinner safety-conscious. While much of this educative material will concern off-the-job safety, it will relate to the development of attitude, which is our basic concern.

One final word of caution. With few exceptions, training procedures must be tailored to fit the individual organization. Don't try to superimpose another program on your people. Substitute your plant experiences, cases, organizational peculiarities, make it your own.

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

CEMENT AND QUARRY INDUSTRIES

This volume is a record of the sessions held at the 1957 National Safety Congress by the Cement and Quarry Section. The conduct of these Congress sessions each year is only one of the many co-operative activities which the Cement and Quarry Section carries on in behalf of its members, and for the benefit of accident prevention work in cement and quarry industries generally. The section gives guidance in the preparation of a great variety of technical and education material useful in the day-to-day safety programs of cement and quarry companies.

The activities of the section are under the direction of its executive committee, the members of which are listed at the close of this volume.

FATALITIES IN THE CEMENT, QUARRY AND MINERAL AGGREGATES INDUSTRIES

by ARVID TIENSON
safety director, Material Service Corp., Lyons, Ill.

Since reviewing these cases I certainly have a greater awareness of "lessons to be learned from fatalities." Let us now look together at a number of typical case histories to bring more sharply into focus, the "lessons" most of us know and on occasion forget.

YOU CAN "DROWN" IN SOLIDS

A relief man and a roll tender were found suffocated in a gypsum bin. On a routine check the foreman noted the employees' absence from their jobs. The hopper bottom of the bin was finally cut away disclosing the suffocated men. A safety lifeline provided for the employees' use while in the bin was not used. A long blow rod for barring the gypsum also lay untouched.

We have, in this case, an interesting sidelight. One of the two employees had been to the doctor two days before complaining of recurrent headaches and dizzy spells during the past year. The plant safety rules called for wearing a life belt when entering a storage bin or silo.

Another point—the need for entering the bin at the time was questionable since a car of gypsum was being unloaded into the tank directly feeding the mill flow.

A new sheave, life line and belt, portable working platform and additional safety walkways were installed to prevent a similar occurrence. Also under consideration is a new steel bin which would eliminate the necessity of barring material. Management is insisting that supervisors properly instruct their employees of the hazards in their jobs. Also that they maintain strict compliance on the part of employees in the use of the safety belts.

A truck driver employed three months with a company was changing a screen cloth. The bulb in the lead light caused a short involving the screen and electrocuting the employee. 110 volts can kill particularly with moisture or water present. Under the proper conditions as little as 30 or 35 volts can cause death.

I understand that a transformer outlet is on the market that reduces the 110 volts to six or 12 volts for use in lead lights to prevent such an accident.

In another case there was a transformer bank that steps down 4,160 volts to 480 volts with an inadequate wooden fence guard about four feet high. There were two water valves within the enclosure. It had been standard procedure to cover the valves with straw and manure each fall to prevent them from freezing.

The employee who was killed was told several times not to enter the enclosure under any circumstances. However, he did. This individual had personal problems. Despite warnings he did not understand the extent of or heed the electrical hazard present.

A much safer enclosure for the same transformer bank is a cyclone fence with barbed wire and a locked gate. The key is in the possession of the electrical department. No one is allowed to enter the enclosure unless it has been de-energized. The water valves have been removed.

CHECK YOUR ELECTRICAL GROUNDS

A laborer employed eight years, but at his present job for five months was electrocuted. The victim grasped the handrail and stepped on motor base hold down bolt charged with 2,400 volts by "floating ground." Five minutes after reporting for work, the victim was found lying on the floor beside wooden platform next to tube mill motor. His pulse was weak and because it was assumed he had fallen and might be injured internally, he was not moved.

Within 10 minutes his pulse had stopped. Then it was determined from burns on his left foot and right wrist that the victim had been electrocuted. Meanwhile, an attempt to start raw mill caused oil switch to explode. Chief electrician's investigation disclosed a "floating ground" in starter which cause the motor to ground to frame.

Tube mill motor base was grounded the following morning with 2/0 wire and all other installations were checked for grounds. All electrically operated equipment should be so checked regularly by qualified personnel and methods.

COVER FLOOR OPENINGS

A machinist employed 33 years was killed when he fell 20 feet through a floor opening. The victim and fellow employees were installing equipment in a new raw storage building being erected by an outside contractor. The opening in the floor for the motor base to be installed next to the top of the new elevator had been covered with planks.

Six feet away a section of the floor grating had been removed to make hoist opening. It too, had been covered with planks but two of the three planks had been removed by contractors and placed beside a 30 inch by six foot opening. As the victim and a helper started to carry the first plank from the motor base opening, the victim either tumbled or tripped and pitched head first through the floor opening.

All floor openings should be either covered or barricaded whether in a permanent plant or during construction. When it is necessary to have plant men work in the same area with outside construction men it is always necessary to take extra precautions. Outside contractors should be required to comply with plant safety rules.

MOVING MACHINERY ACCIDENT

We have here what I consider a typical type of moving machinery accident. See what you believe was the principal cause of this fatality.

The deceased, age 22, had been employed as a floor and car sweeper nine months prior to the accident and one month later transferred to a helper in the super hydrate department.

During the course of employment this man worked three different shifts under three different foremen. The deceased at the time of the accident was taking an hourly lime sample. Using a gloved hand he dipped the can below a revolving cooler shaft to collect a sample. The glove caught on one of the bolt heads of the shaft. The employee was unable to free himself and was pulled head first through a small lid opening and into cooler chamber.

Because his neck was broken, it was assumed that his head hit the cooler casing. The limp body was then pulled feet first down into surge tank bucket elevator boat a distance of six feet. One of the buckets caught his foot and dragged him to the top of the 50 foot elevator. The drag caused the machinery to overload and it stopped.

After searching for the victim and the source of trouble his body was finally located. Welders were summoned to cut into shaft and remove the body. Two hours before the accident this employee had a "quarrel" with his wife who had been living with another man.

HAZARDS ELIMINATED

Why did this particular accident occur? Was it because of his personal problems, the protruding bolt, wearing gloves, new on the job, not properly trained, because the opening was too large, the work procedure unsafe or sampling was at an improper location or while machinery is moving?

These hazards were eliminated as follows:

1. Future samples will be taken through a four inch by six inch opening at the base of the chamber away from all moving parts.

2. The cooler shaft has been covered to prevent clothing from catching on protruding bolts, even though a regulation exists prohibiting any one to put an arm into chamber.

3. Job instruction including integrated safety measures have been drawn up more definitely. This is a continuous program to be developed for all jobs.

A shovel operator, aged 30, employed seven months and at present job nine weeks, was struck by falling material. He sustained crushing injuries resulting in death.

FALL OF MATERIALS

The victim was loading stone into trucks with electric shovel near a quarry face where blast had been shot two days previously. Middle 20 feet of 60 feet face was approximately perpendicular. Loose rock from this section tumbled in a 40 foot arc striking and crushing the corner of the operator's cab.

The victim was pinned in the cab and could be released only after twisted metal was cut away. He died three hours later. Report states that the quarry supervisor was distrustful of dangerous face and had instructed the victim to move his shovel away just 15 minutes before rocks fell. He should have worked in another part of quarry until unsafe conditions were corrected. The deceased was well instructed in safety. Although this man was safety conscious, his desire to be an efficient operator resulted in safety becoming secondary.

Was it lack of job experience or not following instructions? Did the supervisor fail in his responsibility by not insisting that the shovel move immediately? Was the face inspected after blasting?

FOUR HORSEMEN CAUSE ACCIDENTS

Now I would like to make a few observations on not only the half a dozen fatalities mentioned above but also on my impressions after reviewing a number of deaths in our industries.

More than 80 per cent of all fatalities in industries represented by our section are caused by the Four Horsemen as publicized by the P.C.A. They are High Places, Electricity, Moving Machinery and Haulage. In other words we know where to expend our efforts to do the most good.

Apparently the greatest single "killer" in [illegible] industry is asphyxiation by solids that are in a fairly divided form, due to falls or slides of materials. Sand, cement, gypsum, sand, slag; any one may be the "culprit."

The construction and maintenance of our buildings, equipment and quarries is such that high place hazards are the rule rather than the exception.

Heavy mobile equipment are all over the place. We have probably the highest ratio of varied heavy mobile equipment per employee of any industrial section in the council.

HIGH VOLTAGES HAZARDOUS

It is also obvious that the accident involving electricity is common. Why? We use high voltages through out our operations under the most adverse conditions both in use and abuse by our men and the weather conditions. Our maintenance standards and abuse of electrical equipment as an industry would horrify some other sections.

Many of the fatalities that occurred involved inexperienced men on the particular job. In the majority of the cases reviewed, some company safety rule was being violated by the victim. The review of these cases indicated that first line supervision in many instances were not doing their job.

SAFETY SUGGESTIONS

We know in what areas of our operations most of our fatalities occur. We know that inexperience is a large factor. We know that safety rules are not complied with and/or not enforced. We know that first line supervision on occasion are not doing what they are paid for. We know that we have a personnel problem. We know that our training program is inadequate. So what do we have to do?

Here are a few suggestions that should be a basic part of any safety program in our industry if we are to save additional lives.

1. The establishment and enforcement of basic safety rules is necessary and must receive full support from top management. This should be a condition of employment.

2. New employees should be instructed as to the hazards of his job and follow the safe procedures outlined by his foreman. Every foreman must instruct new employees on the hazards of the jobs before they are permitted to start work. Wherever possible specific safe job procedures should be worked out.

3. The use of personal protective equipment is essential. For example the use of the safety belt alone would prevent almost all suffocation deaths and many falls. They protect the car dropper and the electrician. Another example—the hard hat to protect against falling material and equipment. There have been a number of drowning cases where employees must work over water.

However, the use of personal protective equipment must be enforced. Only a 100 per cent program is effective.

First, only electricians or trained personnel are to do electrical work.

Secondly, have an adequate grounding program for all electrical equipment including portable electric tools.

Third, have periodic inspection and testing of all electrical equipment parts of adequate ground and other defects.

Finally, use lockout procedures and work on de-energized equipment whenever possible.

Adequate guarding of all "nip points" is obviously essential. On maintenance the use of lockout also must be an integral part of the job procedure. Guards must be replaced before machinery is started up again.

HAULAGE

Here the use of proper work procedures well understood by engineers, drivers, switchmen, and everyone else involved is most important. Unauthorized riders or riding on the outside of vehicles should be prohibited.

Suitable warnings by horn, bells or other signals should be given whenever movement occurs particularly while backing.

Almost invariably there is more than one factor in the chain of events involved in a given accident. In most instances the particular accident would not have occurred if one link, one protective measure had broken the chain of unsafe practices.

We notice that in a number of cases there was a factor of emotional distress due to personal problems at home or to illness. We also note that there is not too much correlation between accidents and degree of injury. Why? I believe it is because the sample (the number of fatalities) is not, fortunately, large enough.

How often do we say or ask ourselves this question after an accident that did not result in death; "but for the grace of God that employee would have been killed." Not until we ask ourselves that question after every accident no matter how minor, will we give fatalities their true statistical meaning.

Not until we take the same corrective action on each accident that could have killed as we do with an actual fatality, will we benefit in any large measure from "Lessons to be Learned From Fatalities."▲

SAFETY DISCIPLINE

by CARL HEINICKE

safety engineer, Electromotive Corp., La Grange, Ill.

Is a [illegible]-day penalty lay-off for not wearing a hard hat good safety discipline? Is a three day suspension for wearing unsafe shoes helpful in obtaining safety discipline? Is it better to close your eyes to what is happening than to face the fact that discipline cannot be made to "stick?" These questions are asked every day, not only by safety personnel, but also by other members of management and by labor itself.

Most of the confusion results from the use of the word *discipline*. To some people discipline is punishment, to others it is training. If a standard definition for discipline can be used, most of the problems we face can be solved without too much difficulty.

Webster defines discipline in this manner: "Teaching or instruction; that which is taught to pupils; training which corrects, molds, strengthens, or perfects; punishment or chastisement; control gained by enforcing obedience or order as in a school or army, hence, conduct as troops noted for their discipline; rule or system of rules affecting conduct or action—to develop by instruction and exercise, to train for self control or obedience to given standards; to chastise or punish; to train or drill."

Two of these definitions are especially appropriate, mainly, "training which corrects, molds, strengthens, or perfects," and "rule or system of rules affecting conduct or action."

Using these definitions then, we can say safety discipline is a system of rules affecting conduct or action which involves training to correct, mold, strengthen, and perfect. In the production concept of this definition, safety discipline is the organized safety

program in any plant. Good safety discipline therefore, depends on a good, well-organized safety program.

General Motors recognizes this problem and as a corporation set up seven basic principles for safe plant operation. These seven principles are:

—Provide active top management support
—Maintain adequate safety personnel
—Develop safety instructions for every job
—Instruct each new employee
—Operate through supervision
—Make every employee safety-minded
—Extend efforts beyond the plant.

Let us examine each of these principles in the light of our definition for safety discipline and see how they apply.

NEED ORGANIZED PROGRAM

A good safety record is clear evidence of good management. Accordingly, General Managers and other top division and plant executives will make safety their responsibility by maintaining a comprehensive safety program at all times, meeting with key supervisory personnel at least once a month to review safety, taking any action necessary to improve safety conditions. In thus giving its concrete support, management will imbue the entire organization with a continuing zeal for safety.

Safety discipline necessarily must start with the top echelon of the organization. These are the men who must decide whether the rules of conduct from a safety standpoint are the rules which they will support and enforce.

For instance, if the rule states that hard hats are to be worn in certain areas, then unless the men at this level of the organization wear hard hats in those areas, the rule will be frequently broken, and there will be poor safety discipline. The same is true of the wearing of safety shoes, wearing of eye protection, rules and regulations covering the operation of machinery. Good safety discipline must start at the top.

Each plant should have sufficient, well-trained personnel to insure continuous careful attention to safety. A qualified man should be assigned to direct the safety program, handle safety education, and assist the supervisory force in maintaining safe working conditions. The staff of safety engineers and inspectors should be sufficiently large to cover all operations.

Good safety discipline does not originate in the safety department. However sound, reasonable, logical rules of conduct from a safety view-point must be suggested and recommended by this group. If the rules are illogical, hard to administer, and difficult to maintain, good safety discipline will be difficult to maintain. On the other hand, the safety department is not the police force but the watch dog of safety discipline.

It should not be the responsibility of the safety department to see to it that proper eye protection is worn or that proper clothing is worn, but on the other hand, when those conditions are noticed by safety personnel, the supervisor in the area should be notified. If the conditions are repeatedly noticed in the same area, then the safety personnel must refer the problem to higher supervision.

Calling the attention of the supervisory organization in an instructive manner to the discrepencies in the manner in which safety discipline is carried out is one of the principle responsibilities of the safety department.

Safety rules and instructions as to safe practices should be set down in written form covering each job in the plant. This material should be used as a basis for safety instruction of new employees and of employees transferred to new jobs.

INSTRUCT NEW EMPLOYEE

The purpose of writing rules and instructions for each job is so that all of the employees will receive the same instructions; at least the supervisor will have some written material rather than depending on his memory. Supervisors have a lot of things to remember and an important safety instruction might be over-looked if the rules were not written.

Since it would be impossible to write a complete set of instructions covering every phase of every job, these written instructions serve the supervisor as a guide and a rule of thumb for those operations which are not specifically spelled out.

Each new employee should be thoroughly instructed in general safety policies, rules, and procedures before being referred to his supervisor for job training. In turn, the supervisor should review with him thoroughly the safety measures of the particular job before he starts to work. Subsequently, the employee should be followed-up closely to make sure that he understands and is carrying out the safety instructions applicable to his job.

This follow-up should not be entrusted to anyone, but should be carried out by the supervisor who at the same time watches the new employee for a period up to 15 minutes before talking to him. This enables the supervisor to determine bad or poor habits which the employee may have developed and also gives the supervisor an opportunity to become better acquainted with not only the process, but also the tooling used on the job.

OPERATE THROUGH SUPERVISION

At our plant no new hire or re-hire is started on the job until someone from the safety department talks with the new employee about the general safety policies of the plant, and advises him of the safety equipment and other protection available to him. We have found that it is helpful to invite members of the supervisory organization into our induction meetings so that they have some idea of what we tell the new employees.

The put-on card which the supervisor uses in introducing new employees to their new job has a check list for the supervisor on which he checks off the safety information for the specific job that this employee is going to do. Good safety discipline starts with the new employee at the time he is indoctrinated. Unless he is thoroughly indoctrinated, he may get started on the wrong foot and consequently make the supervisor's job more difficult.

We have found it advisable to treat employees who are being transferred to new jobs as though they were new employees. Our safety record during the past year clearly showed that we have a problem with employees who have had 10 or more years seniority. The problem consists of keeping these people safety-minded. This is particularly true any time there is an up-grading or when there is a lay-off, and people get bumped from job to job.

The supervisor is the key man in the safety program because he is in constant contact with employees. Each superintendent should hold meetings with his foremen at least once a month to review safety conditions, general policies and specific situations. Foremen should take the initiative in making a success of the safety program in their own departments.

As a part of this effort they should talk about safety to two employees daily for at least five minutes each. Good plant safety discipline does not originate with the supervisor, but depends upon the supervisor's success in his day to day contacts with employees. The five minute daily talks are the key to this success. If the talks are used to reprimand an employee, they will fall short of what they are intended.

The safety talk should be constructive and informative with the employee not only listening but participating in the conversation. If the supervisory organization uses the safety rules as a matter of convenience, then safety discipline will be weak. Supervisors must realize that when safety instructions are given, they must be carried out for the safety of the employees, not only when it is convenient, but also when it is inconvenient and when production is behind schedule.

MAKE EMPLOYEES SAFETY-MINDED

The cooperation of the individual employee is vital to the success of a safety program. Continued attention is required to make certain that all concerned, management and employees alike, do their part in protecting the safety of the individual at all times. Every available medium: safety booklets signs, posters, and plant papers may be used to good advantage in furthering the objective of such a program.

Safety discipline starts at the top of the organization and depends upon the supervisory organization for its success. And we find that the employee is the foundation of safety discipline.

We do not have good safety discipline if our employees do not work and act safely of their own accord. Safety talks, safety booklets, poster, signs, and safety puzzles and safety contests, are all aimed at getting the employee to think of safety for his own good at all times.

Special attention should be given to off-the-job safety as employees have more accidents away from work than they do on

job. Our objectives should include efforts to promote the safety of employees and their families by: maintaining a comprehensive safety program for employees driving company owned vehicles; providing material on highway safety to aid employees driving their own cars; encourage employees to develop safe practices in their homes, on the farm, or in recreational activities; participating in community safety activities.

EXTEND EFFORTS OFF-JOB

The fruits of plant safety discipline should be shown in the off-the-job activities of the employee. If we have really sold him on the rules of conduct not only for machinery operation, but all phases of personal safety, then the employee will practice these rules not only in his own home, but also in driving his car or while using recreational facilities.

This does not answer the question of how many days' suspension an employee should receive for an infraction of safety rules. I have purposely refrained from attempting to answer that question because in my opinion that is not a safety problem. The punishment for the infraction of rules is actually the responsibility of the supervisor in conjunction with the Labor Relations Department.

Where there are many infractions of rules, it is probably due to the fact that the top echelon of the organization are not whole-heartedly in agreement with them or that the supervisor in immediate charge has used the rules as a matter of convenience rather than as a matter of protection for the employee.

Good safety discipline cannot be measured by the number of people suspended for violation of safety rules but rather can be measured by the spirit, the push, and the sincerity with which top management operates the safety program. Safety discipline is the direct result of sound, reasonable, logical rules of conduct as recommended by the safety department, and enforced by all levels of management.

Safety discipline depends on the attitude and the manner in which the supervisor carries out his day to day assignments and contacts with the employee. Safety discipline is the day to day activities of the employee carrying on his routine duties not only on the job, but also off the job.

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

THE CHEMICAL SECTION

This volume is a record of the sessions held at the 1957 National Safety Congress by the Chemical Section. The conduct of these Congress sessions each year is only one of the many cooperative activities which the Chemical Section carries on in behalf of its members, and for the benefit of accident prevention work in the chemical industry generally. The section gives guidance in the preparation of a great variety of technical and educational material useful in the day-to-day safety programs of chemical companies.

The activities of the section are under the direction of its executive committee, the members of which are listed at the close of this volume.

SAFETY IN HIGH PRESSURE CHEMICAL REACTIONS

by M. R. KINTER

assistant director, high pressure laboratory, The Dow Chemical co., Midland, Mich.

Before we can intelligently discuss the subject of high pressure, we must first define it. Any definition we propose will be arbitrary since it depends on your frame of reference. To a pipefitter, a 400 p.s.i. steam line may well be "high pressure." To the mechanic in an ammonia plant, the term may mean 5,000-10,000 p.s.i. The gunsmith will think of "high pressure" in terms of the breech pressures in a 30-06 rifle with a heavy powder load, which go to 50,000-55,000 p.s.i. For many purposes we might say that anything above 500 p.s.i. should be considered as high pressure.

However, when discussing this topic from the viewpoint of safety, we must remember that any amount of pressure may be hazardous. A few years ago an auto mechanic in our city suffered serious permanent injury when a new auto tire, which apparently was defective, ruptured while he was inflating it. A pressure of less than 30 p.s.i. was involved. The hazard attendant on working with liquids or gases under pressure is not strictly a function of the pressure alone, but is more properly considered in terms of the amount of stored energy involved.

A consequence of my last statement leads to another point we must always keep in mind. There may be hundreds, or even thousands of times more energy in a gas at a given pressure than in a liquid under the same conditions. We do not commonly think of hydraulic pressures of a few thousand p.s.i. as being particularly dangerous. However, a gas under the same conditions presents an entirely different situation.

I shall try to discuss the philosophy, principles, and pitfalls of working safely with high pressures. In doing this, I hope that we may come up with some ideas which may be of value to anyone working with high pressure, be it in a large elaborate, industrial high pressure laboratory, or in the limited facilities found in many schools or small companies.

Let us first briefly mention the principal hazards we find in high pressure work:

Projectiles—In event of an uncontrolled reaction or explosion, parts of ruptured vessels, gauges, or fittings may be propelled at high velocity from the equipment. Such missiles can easily kill a man.

"Secondary" Explosion—The sudden release of flammable gases into the cubicle or work area followed by ignition may result in a violent explosion. The shock wave from such detonation can result in serious damage to the cubicle and injury to personnel.

Toxic Materials—Failure of high pressure equipment may release substantial quantities of toxic gases—e.g., when working with carbon monoxide.

Fire—The failure of high pressure equipment or a burst frangible safety when working with flammable materials frequently results in fire. Although usually of short duration, these "blow-torch" type fires are often very intense.

The safety measures taken in high pressure work do not basically differ from good laboratory safety practices. However, the potential severity of the consequences of a given incident—e.g., rupture of a vessel at 30,000 p.s.i. compared to a crack in a glass flask—demand considerable extension and amplification of safety measures.

BASIC PRINCIPLES

Our first basic premise must be that all reactions under pressure are hazardous. Not that the types of experiments we may carry out are fundamentally any more unpredictable than most laboratory reactions, but we must consider the amount of energy stored. This emphasizes the importance of conducting unknown or exploratory experiments on a small scale.

In addition, a basic characteristic of high pressure vessels must be kept in mind. It is very easy to have a large safety factor in strength built into a small—say 500 ml. or less—pressure vessel. This however, becomes more and more difficult as size in-

creases, due to size and weight considerations.

Conduct all pressure experiments behind barricades, and base practices and procedures on the assumption that the experiments will get out of control. The barricade or cubicle may vary depending on the scale of operation. It is essential that the men never, except under extremely unusual circumstances, enter the cubicle while the system is under pressure.

Strict adherence to safety rules is essential and presents the usual problem of "familiarity breeds contempt." We have found no magical solution to this problem. I know of no other approach than repeated and repeated instruction and education of all people who have any contact with this type of work. Also, one must never assume that, because an experiment has been carried out many times without incident, it may then be regarded as harmless.

This calls to mind an accident resulting from just such a situation. The experiment, conducted at 500-1,000 p.s.i., had been run countless times in an open laboratory without barricades. One morning a technician unthinkingly changed the order of the application of heat and the addition of catalyst. The resulting explosion did extensive damage to the laboratory and, but for extremely good fortune, could have resulted in very serious injuries.

CUBICLE LAYOUT, BARRICADES

The purpose of a high pressure cubicle or cell is to protect operating personnel from injury as a result of a mishap with the experiment. This is best accomplished by directing flying fragments and the force of an explosion away from the workers rather than trying to confine them. There are many possible arrangements which may be used to accomplish this, but they all have one thing in common—at least one wall acts as a "blow-out wall."

Care should be taken in the installation of doors to be certain that they cannot blow out. When considering the labyrinth type entrance, the possibility of shock wave rebound should be kept in mind. Many instances of serious injury by a reflected shock wave are known.

The materials used for the construction of cubicles may vary, but steel plate or concrete are most common. A number of "sandwich" types may be used, e.g., a double steel plate wall filled with sand. This latter type presents some annoying problems if any new openings through the wall are to be made. We use steel walls for small-scale work and heavily reinforced concrete for large-scale experiments. Welded construction is much preferred with steel plate, because of the possibility of bolts being sheared by an explosion.

I know of a case in recent years in which extensive damage was done by flying half-inch bolts which were sheared by an explosion of a vessel in a bolted steel cubicle. They were propelled with sufficient force to penetrate a concrete block wall and would have easily killed a man. Metal cubicles may be lined with wood which will absorb much of the force of a high-velocity fragment and reduce the possibility of penetration of the metal plate.

ONE UNIT CUBICLE

One type of cubicle we use for small scale work is arranged so that the platform on which the equipment is mounted and the front wall of the cell are one integral unit. When the equipment is in place the cubicle cannot be entered, since the area behind it is restricted. This system is useful where frequent equipment changes are necessary. Transparent plastic sheet is used as a "blow-out wall" in these cubicles. It has the advantage of low cost and it admits additional light, thus making the area safer.

A concrete cubicle is used for larger-scale work. The walls and roof are 15-inch, heavily reinforced concrete. The observation windows are of two-inch laminated glass which is capable of withstanding a .38 caliber magnum shell at point-blank range. All lines and valve handles enter the cubicle through steel strips or sleeves mounted in the concrete.

The area behind our high pressure cubicles consists of a river and a large waste pond. We have no wall behind the area. Placing a large wall behind a high pressure area presents the problem of reflection of a shock wave, particularly from a secondary explosion of flammable material in the cubicle. Of course, it is not always possible to locate near a large, vacant area. The next best thing is a hill or slope of some sort. This will absorb any fragments and tend to dissipate the force of an explosion.

Good ventilation is important in a high pressure area. We recommend 10 to 20 complete air changes an hour. This is sufficient to remove any flammable or toxic materials which may be released through leaks, which are an everlasting problem in high pressure work. Rapid air flow through the cubicle may also prevent the detonation of a quantity of flammable material released by rupture of the equipment.

Such ventilation should be arranged to prevent the accumulation of heavier-than-air vapors on the floor of the cubicle. An added safety feature may be the use of automatic detecting and alarm devices for such materials as hydrogen cyanide, carbon monoxide, or hydrocarbons.

The use of systems to flood the cubicles with carbon dioxide are useful. Such installations vary from a simple manual arrangement to empty the contents of a large carbon dioxide cylinder into the cubicle quickly to an automatic system triggered by temperature sensitive elements. An installation of the latter type recently prevented extensive damage to pilot-scale equipment in our laboratory when several pounds of a pyrophoric material were suddenly released into the cubicle. The ensuing fire was so quickly and effectively snuffed out that the paint inside the cubicle was not even scorched. The hazards involved in working with purely hydraulic systems are much less than with gaseous systems. It is not uncommon to work at extremely high hydraulic pressures without any protection. I know of an instance in which this practice resulted in an unusual type of injury. The failure of a fitting in a high pressure system resulted in the release of an extremely high velocity jet of hydraulic fluid. The spray hit a worker in the face, penetrating the unbroken skin. The resulting injury was quite painful and was several months in healing. Therefore, some sort of shielding, even if quite light, should be used even with strictly liquid systems.

A high pressure system should never be operated without some sort of pressure relief mechanism. This usually is in the form of one or more frangible safety discs, depending on the number and location of pressure vessels. However, it is not sufficient to place frangibles in the system—there have been innumerable cases of vessel rupture in systems in which there were frangibles. Except for cases of an extremely violent detonation in a vessel, such failures can usually be laid to one of two causes.

In the case of a sudden pressure rise, the frangible safety cannot do its job if the vessel fails before the pressure surge reaches it. It is therefore essential to place the frangible as close as possible to the vessel, and to use as large a diameter frangible and connection to it as possible. We frequently conduct experiments with solids or liquids which can freeze, either of which can solidly plug a line.

EQUIPMENT

Thus, it is essential under such circumstances to arrange the equipment to minimize the possibility of such materials entering the safety assembly. Careful inspection of the safety assembly after each experiment is also necessary to be certain that it is clear.

A frangible safety assembly should be pointed in the direction of the "blow-out" panel and must be securely anchored. If it is deemed necessary to vent a frangible to the outside, this must be done through a large line with no bends. One should not attempt to use a frangible disc at an operating pressure which is close to its rated burst pressure because of deviations of actual rupture pressure from rated pressure. Corrosion and fatigue of frangibles must also be kept in mind to prevent unexpected failure.

CONSTRUCTION MATERIALS

A few general comments concerning materials of construction may be in order at this point. First, I should like to consider the question of hardness or ductility of the metals used in the construction of such equipment. This is important when we call to mind the relatively smooth, tangential "tear" type ductile failure as opposed to the unpredictable, random shattering effect of the brittle failure. Ductile failures rarely yield any fragments, whereas a brittle failure may result in almost anything.

For this reason, hardening is a poor way to achieve strength in high pressure equipment. The most frequent occurrence of a

highly hardened component in high pressure equipment is the cap of the common, flat-gasket type high pressure reactor or "bomb." This is required for practical, structural reasons, but we attempt to avoid it by using other types of closures in all but small, medium-pressure vessels.

With this one exception, a minimum of 10 per cent elongation should be specified for materials used in the construction of high pressure equipment. When purchasing metal stock for this use it is wise to specify metal that is free of flaws or inclusions, and is warranted by x-ray or other suitable tests.

Before a vessel is placed in service it must be pressure tested, preferably to one and one-half times its maximum working pressure. A log sheet should thereafter be kept for each vessel so that a history of its service is available. Frequent inspection of each vessel and regular periodic pressure tests are required to avoid failure resulting from corrosion, small stress cracks, embrittlement, etc.

CONED CONNECTION

The common coned high pressure connection has frequently been a source of difficulty, most of which is easily avoidable with a little care and attention. The sealing surface is on the tapered end of the tubing, and the force is applied from the threaded gland via the collar on the tubing. First, the seating surfaces and threads should always be smooth, clean, and in good order. If not, they should be remachined or replaced as may be the case.

A common error in assembly of one of these connections is in not placing the collar the proper distance back on the tubing. If it is too far back a good seal can be made but all of the force is taken by only a portion of the threads of the gland, resulting in failure under pressure.

High pressure gauges present some problems, but a little thought when locating them will easily remedy this. Always use the solid front or "blow-out" back type of high pressure gauge and remove the glass face cover. A piece of plastic film may be placed over the front of the gauge to keep out dirt. Gauges should never be placed in such a position as to be directly in line with operating personnel, but are best located behind a barricade and observed with mirrors. They should not be used to more than 70 per cent of rating, and will last a lot longer and maintain accuracy better if used at only 50 per cent of rated pressure.

Gas storage or supply cylinders are rather "thin-skinned" and should not be located in an operating cubicle. In event of trouble, their presence can only add to the problem. The use of check valves in lines between vessels, reactors, supply cylinders, etc. adds greatly to the safety of the operation. These one-way valves prevent the possible backing up of a reactant or catalyst, which can have disastrous consequences.

However, a word of caution concerning the use of check valves! They are usually a spring-loaded ball valve and are easily fouled and rendered inoperative by small amounts of foreign material or dirt. Frequent inspection and testing of these devices is imperative, otherwise one may be led into a false sense of security.

In essence, the human side of safety reduces itself to one point—education. The problem becomes one of teaching men to understand their equipment and to think carefully before they act. For instance, one must somehow get across the idea that high pressure equipment, just because it looks rugged, does not require a strong arm and a long-handled wrench for assembly. Care, cleanliness, and a sawed-off open-end wrench will usually do a much more effective job on research scale equipment.

OPERATING PRACTICES

Points such as this must be emphasized, demonstrated, and then continually reemphasized. We had a technician with whom we had to go so far as absolutely to forbid him to operate a high pressure valve with any more force than he could exert by holding the valve handle between his little finger and thumb. This may have been an extreme measure, but the man finally understood.

We use job description sheets, our accident prevention Key Point Cards and other means of discussion to review important points and hazards with the men. One must cultivate the idea that the safety practices are ground rules which are just not to be broken. In a large plant such as ours the men who come into the area from the shops and services department present a difficult problem. These people may be in the area only occasionally and for short periods of time.

They may have little knowledge of the equipment or work, and must be carefully instructed regarding safety practices which may be peculiar to high pressure work. This type of situation will vary with the particular installation and circumstances, but we should always keep in mind the uninformed "stranger" who has occasion to be in the area.

Clear thinking and attention to detail are essential in this type of work. Always be on guard for signs of trouble. For instance, when releasing the pressure from a system it is possible to detect an obstruction in the entry to a pressure vessel by observing such things as the rate of fall of pressure in the lines. Abnormal behavior in this respect is a sign of danger.

Observation of such signs may avert the disastrous consequences of opening a supposedly vented vessel while it is still under full pressure. Men must learn to detect plugged lines, leaks, etc. by these subtle signs and to deal with them safely.

The same philosophy applies to disassembly and maintenance work on such equipment. Each line and vessel must be treated as though it is a loaded gun until you are absolutely certain about it.

High pressure work may be done safely if we use clear, critical thinking and careful planning. We cannot afford to be hasty, to disregard safety practices "just this one time" or to let our guard down in any other way. This applies to all types of high pressure work, be it large or small, simple or elaborate.

Even if the installation is small and funds are limited, it is still possible to keep this basic philosophy and conduct the work in a safe manner. In that respect, safety is like happiness—it is the man that counts and money just cannot buy it.

CONTROLLING HEALTH HAZARDS IN A CHEMICAL PLANT

by ROBERT A. KEHOE, M.D.
head, Dept. Preventive Medicine & Industrial Health, College of Medicine, University of Cincinnati, Cincinnati, Ohio

Hazards that are likely to be present in a chemical plant are:

1. Ordinary mechanical hazards
—accidental injuries (falls, dislocations, sprains, fractures, contusions, lacerations, thermal and chemical burns, foreign bodies in eye or skin)
—in association with mechanical equipment, noise, vibration, fires, explosion, flying particles or missiles, slippery floors, rigging, stairs, ladders, elevators, vehicles

2. Modern physical hazards
—ultraviolet and infra red radiation; ultrasonus, high frequency waves; X-ray, radium, other alpha, beta or gamma radiation

3. Chemical hazards
—old and well known (but not fully controlled) chemicals
—new products of research and development (often unexplored)
—exposure in course of research on new products
—pilot plant development of new products or processes
—new manufacturing processes involving new ways of handling well-known chemicals or new chemicals.
(1) locus of hazards—aspect of portal of entry—local effects, such as contact with skin, dermatitis—sensitization, gross injury to skin, skin cancer, or inhalation of gases, vapors,

mists, fumes, dusts. Also asphyxiation, irritation of lungs—acute (edema, pneumonitis), irritation of lungs—chronic, pneumoconiosis, fibrosis, emphysema, and granuloma (Be). In addition cancer of lung, deposition—radition within lung and hilar lymph nodes; specific carcinogenic agents are hazards. Ingestion of chemicals, following upper-respiratory trapping of dusts, following contamination of hands and handling things that go into mouth and following contamination of food stored in work rooms—eaten in dirty lunch rooms are potential dangers.

(2) nature of hazard—aspect of absorption—systemic effects such as: acute intoxication, percutaneous, respiratory, alimentary absorption (often two or all three combined); chronic intoxication—remote enzymatic or metabolic effects and organic damage; or remote radiation effects following absorption and distribution of radioactive materials in body—example—bone and marrow, following absorption, distribution and metabolism of specific carcinogins—example—bladder tumor.

RECOGNITION AND IDENTIFICATION OF HAZARDS

1. Toxicologic investigation (in laboratory) (stepwise with progress of research and development in industry)
   (a) screening—preliminary choice or elimination of materials under consideration—
   —immediate toxicity—indicative of type of control measures based on portal of entry (type and point of application of preventive procedure) (degree of precision required in protection, i. e. extent of apparent danger) (medical criteria—type of anticipated injury or disease)
   (b) Comprehensive—(adapted to the problems to be met)
   —manufacturing hazards
   —hazards of transportation and use as raw materials by others
   —hazards of consumer of final product
   —cumulative effects if any
   —metabolic fate in body—remote effects—long-term—chronic—injurious effects
   —diagnostic and prognostic procedures based on results of investigation
2. Toxicologic investigation—(in plant) clinical investigation of personnel
   —basis of all specifications for safe environment
   —sometimes the only basis for recognition of hazard, e. g. beryllium, occupational cancer

CONTROL OF HAZARDS

1. Medical measures of control—environmental—(operations, plant conditions and (how men work)
   —clinical examination—all types.
   —policing the plant—(clinical findings and tests on personnel)
   —identification and quantitation of responses to observed exposure—within physiological (tolerable) limits—beyond physiological limits
   —warning of need for further protection
   —disposition of personnel with respect to exposure restriction of time (duration) of exposure—removal from exposure —temporary or permanent
   —personal protective equipment (choice and supervision, physiological criteria) adequacy of equipment employed—adequacy of its maintenance—adequacy of its use
   —education, group meetings, written instructions, hygienic manual, combined with operating manual
   —reports to engineering personnel (in both operations and industrial hygiene) and to management
2. Engineering measures of control
   —designing and applying measures of control—physical devices for protection against chemicals—plant design—operations design—ventilating design
   —policing the plant (environmental monitoring) inspection—critique of maintenance operations—analysis of materials —air analyses.
   —personal protective equipment (choice and supervision—engineering criteria)
   —reports to medical personnel, and management (directly or through physician)

3. Administrative measures of control
   —appropriate organization of hygienic facility in relation to operations
   —appropriate budgetary provision for hygienic effort

Adequate control depends upon the complete understanding of the hazard through physiologic and toxicologic research.

In addition, satisfactory team work includes:

1. Physician (including nurse and technicians) measures applied to personnel measures to be applied to environment (hygienic specifications)
2. Engineer (including chemist, physicist and technicians) measures to be applied to environment (hygienic technologic applications)
3. Management
   proper organization
   proper financial implementation▲

LIVING IN THE AIR WE BREATHE

by H. H. FAWCETT

safety director, research laboratory, General Electric co., Schenectady, N. Y.

Living in the air we breathe has been a problem since God created man from dust and then breathed into him the breath of life! But even today, the vital role of breathing in our daily life has not been completely appreciated. This paper reviews briefly (1) air contaminants, and (2) commercially available respiratory protective devices, with emphasis on their limitations, and on the training and maintenance necessary for safe and effective use.

Each of us is a creature of habits, but none of our habits is more vital to life than is breathing. So automatic and effortless is this habit that we give almost no thought to our respiration, although most of us cannot live without air for more than five minutes. From the second of our birth when we descend from in utero (where the oxygen partial pressure corresponds to 33,000 feet altitude) into a world with a mixture of gases called air, we must breathe several quarts of air each minute so our body cells can exist, grow, and perform their functions.

For an average lifetime of 70 years, we may breathe in excess of a half billion times. By contrast, we consume "three square meals" and "six glasses of water" daily. Our air requirements which we obtain virtually without effort are of greater significance by any standards than water, food, clothing, and shelter, which demand much "day-by-day" thought and deliberate action to obtain.

We live at the bottom of an ocean of air called the atmosphere, a name given to a mixture of several gases which consist mainly of four-fifths nitrogen and one-fifth oxygen. Virtually limitless in volume and mass as we view it from the ground, it thins out into space. Half of its density is under 18,000 feet. In a multitude of ways the air assists all living things to exist.

FUNCTIONS OF AIR

Besides providing oxygen for breathing-oxygen which lungs transfer to the blood—air conveys both sound and light, absorbs heat, enables fires to burn, propels boats, turns windmills, makes possible air brakes, vacuum cleaners, and other useful machines. Air in motion forms winds which modify climate, equalize heat and cold, and distribute rainfall. Rivers high in the air, such as the jet stream, greatly influence weather and are an increasingly important factor as airplanes travel at higher altitudes. The ancient Greeks ranked air with earth, fire and water as one of the four fundamental elements.

Since each of us has been breathing several times each minute from our birth, respiratory protection and devices to aid or supplement breathing might seem unnecessary. If pure air were truly ubiquitous, and no harmful gases, vapors or dusts existed,

breathing problems would be confined to underwater or to travel in high altitudes. Unfortunately, pure air is a relatively rare commodity, and is much harder to obtain pure than many chemical elements and compounds.

Some variations of the air are caused by natural forces (such as moisture from rain or dust from winds on dry earth), while some are due to man (such as combustion products, unburned or incompletely burned fuels, solvents, vapors, dusts, fumes, inert and toxic gases). When these variations are small, we say that the air is "pure," but when the variations, either alone or in combination, exceed our ability to adapt to them, or our ability to tolerate them, we say the air is "bad."

AIR POLLUTION

No simple yardstick has yet been devised to tell us when air ceases to be "pure," although numerous air pollution studies are underway, and threshold limit values (maximum allowable concentrations for industrial exposures) are available as a guide. We have just begun to realize that air pollution control may be even more important than stream pollution control. When extreme conditions exist, as in London, Meuse, Donora or Los Angeles, we know that human life is more difficult than other times when smog is not present.

On a minor scale, every year a serious problem exists from dust or pollen (such as rose fever, hay fever, or ragweed fever) for allergic persons, and we have found that respirators are frequently considered a a welcome supplement to medication for the relief of such conditions.

Most breathing air supply problems can be controlled with adequate ventilation. If air could be properly treated to remove particulate matter, noxious vapors, and toxic gases, heated or cooled, and then distributed as required, breathing can be reduced to a minor problem insofar as purity of air is concerned. Unfortunately, adequate ventilation and air treatment is sometimes impossible or impractical where emergency action must be taken to preserve life and property.

Therefore, we must provide man with respiratory protection if we expect him to survive. A glance at the case histories of incidents collected at random from many sources and appended to this paper shows that respiratory problems have occurred in many diverse activities. Specialized knowledge and action in advance is essential if such injuries are to be prevented.

It is sometimes glamorous or unusual incidents which produce serious results; failure of a pressure system in an airplane at high altitudes will cause blackouts in seconds; above 43,000 feet, even breathing pure oxygen is not adequate— a pressure suit or a pressurized cabin is essential. On the other hand, no less serious are the problems when commonplace materials, such as a few sausages overheating and burning on a frying pan on a kitchen range produced sufficient smoke and toxic gases to overcome the occupants; firemen required respiratory protective apparatus to effect a rescue of the unconscious victims.

Gases and smokes resulting from fires have been studied for years, and excellent reports are available, but it is impossible to predict what gases may be encountered or in what concentrations in a given fire. A large number of different flammable chemical compositions or chemical combinations that change with heat, such as plastics, fabrics, insulation, refrigerants, solvents, paints, insecticides and building materials, play important roles in our daily lives.

VARIETY OF GASES IN FIRES

In addition to carbon monoxide, carbon dioxide, and water (present in nearly all fires), one may expect ammonia from burning wool, cyanogen from burning silk, acrolein from burning fats, sulfur-containing gases from burning rubber and leather, and chlorine-containing gases from burning or smouldering chlorinated plastics. From piled newspapers smouldering in limited oxygen, 41 per cent of the total gases given off was found to be carbon monoxide, and 43 per cent was carbon dioxide.

A pile of newspapers in a large open hallway would give an entirely different concentration of carbon monoxide and carbon dioxide within the breathing zone than the same pile burning in a small enclosed basement. Determinations ranging from two per cent to four per cent carbon monoxide have been made using recognized CO detectors in the smoke of building fires in the same room in which firemen were engaged in extinguishment, by a medical doctor wearing self-contained breathing apparatus. A vigorous movement is now underway to encourage fire and other rescue services to use adequate respiratory protection more effectively.

AIR CONTAMINANTS

The conventional classification of air contaminants follows:

A. Aerosols (dispersoids) (particulate contaminants)—dusts, fumes and mists.

A better classification of aerosols is based on physiological effects:

A. Nuisance and Inert: produce no known injuries: calcium carbonate, magnesium carbonate, gypsum

B. Inert pulmonary reactions: produce non-specific pulmonary reactions: silicates, carbon, aluminum

C. Minimal pulmonary fibrosis-producing barium compounds, tin, iron oxides

D. Extensive pulmonary fibrous-producing silica, asbestos

E. Chemical Irritants: produce inflammation or ulceration alkaline reactions: acids, fluorides, chromates

F. Toxic systemic poisons: produce pathological reactions: lead, manganese, antimony, arsenic (not more toxic than Pb), arsenates, organic-phosphates, cadmium, radioactive, beryllium (more toxic than lead)

G. Allergic manifestations: produce allergic reactions: pollens.

H. Fever-producing reaction: action unknown or allergen: metal fumes, certain textile dust, (hemp, cotton, jute, bagasse)

A. *AEROSOLS*

Formerly called dispersoids or particulate contaminants, these are substances present in the air as minute particles (such as dusts), as fumes (such as metal fumes), or as mists (such as chromic-acid mists). In grouping these together, it is recognized that they may be physically filtered, screened, or adsorbed from the air with properly designed filters. Aerosols may range in size from 150 microns to a thousandth of a micron in size (1 micron equals 39.37 millionths of an inch or 1 x 10-4 centimeter). Many dusts are also fire and explosion hazards.

Pneumonokonioses (Greek for lung dust) or pneumoconioses are a group of lung conditions which result from the inhalation of dust. Silicosis is one of the most common types of pneumoconiosis, and is caused by the inhalation of "free" or "uncombined" silica, such as quartz, opal flint and crystobalite. Many other dusts may produce lung involvement such as absestos, talc, the silicates, carbon, iron and barium.

Other dusts cause chemical irritation, such as the acids, alkali substances, fluorides and chromates. Allergic reactions may be caused by common dusts such as pollens, synthetic resins, plastics, felt, fur, gums, spices, tobacco, paper, rubber, wood, starch, flour, and wool. The Bureau of Mines groups all the above dusts as "Pneumoconiosis-Producing and Nuisance Dusts."

TOXIC DUSTS

Another classification of dusts refers to "Toxic Dusts." Some have a lower threshold limit or maximum allowable concentration than does lead, although the Bureau of Mines classification uses lead as a reference. Among aerosols more toxic than lead are: cadmium oxide fume, chromic acid and chromates, mercury, mercury (organic), yellow phosphorus, picric acid, selenium, tellurium, calcium arsenate.

Respirators approved for all the above dusts (both toxic and pneumoconiosis-producing and nuisance dusts) are called "dust" respirators. A few substances, such as beryllium and radioactive substances, are not currently covered by Bureau of Mines schedules.

"Fumes" include aerosols formed by the condensation of vapors from heated metals. Melting, cutting, and welding of zinc, lead, cadmium and other metals produce such fumes.

"Mists" and "Sprays" include liquid droplets formed when liquids are carried into the air or are formed by a reaction with the moisture in the air. An interesting example is 0.3 parts per million sulfur dioxide, with sunlight, forms 20,000 particles per c.c. of sulfuric acid mist.

The availability of filters with pore sizes from 10 millimicrons (approximately the size of the polio virus) to five microns (the size of common contaminants in liquids) has greatly improved and speeded up analyses

of aerosols such as acid mists, metal fumes, smokes, and radioactivity.

In recent years, study and measurements of even smaller particles in air than previously observed, known as condensation nuclei, have contributed greatly to our understanding of the nature and number of particles in air. The particles in the air on which water will condense are called condensation nuclei; under natural conditions only the larger particles are so effective. When the air is sufficiently super-saturated apparently any particle will serve as a condensation center.

Particles from such diverse substances as platinum, silver, stearic acid, glycerin and lubricating oil will all form droplets at a sufficiently high supersaturation of water vapor. Practical methods are now available to measure the number of particles in an aerosol in free air. A wider use of the technique already available for size and numbers of an aerosol would not only throw light on some of the problems of air pollution but would certainly lead to further improvements in our knowledge of aerosols.

Respirators for insecticides are tested and listed by the U. S. Department of Agriculture.

B. *GASES AND VAPORS*

In this major group may be included most of the air contaminants which are not classified as aerosols.

1. *Irritant gases* are those which produce inflammation of tissue, such as the skin, the eyes, and the respiratory tract membranes. They are divided into two general groups:

a. action is limited to irration (such as hydrogen chorıde)
b. action extends to systemic effect (such as oxides of nitrogen)

Some of these gases and vapors have pronounced odors, but the nose cannot be depended upon as a reliable method of estimating concentrations.

2. *Asphyxiants* are substances which deprive the body tissues of oxygen, causing hypoxia (oxygen starvation). Two general methods of action are known: *simple* asphyxiants (such as nitrogen, hydrogen, helium, and methane), which dilute or replace the oxygen partial pressure in air; and chemical asphyxiants (such as carbon monoxide, hydrogen cyanide, hydrogen sulfide, acetonitrile, aromatic nitro and amino compounds like aniline, nitrobenzene and derivatives), which combine with the hemoglobin of the blood to prevent oxygen-carbon dioxide exchange.

The insidious nature of the action of the simple asphyxiants, and the speed with which they can act, is still not widely appreciated; whereas most people have a healthy respect for the chemical asphyxiants. Under proper medical supervision, pure nitrogen may be breathed for several seconds and this technique has been used clinically by Himwich and others. However, nitrogen and the other simple asphyxiants give almost no warning between the time breathing air is replaced with the asphyxiant and unconsciousness overtakes the subject.

PHYSICAL REACTIONS

A loss of mental facilities begins within a few seconds, and unconsciousness may occur shortly after with no warning. The brain is the first organ of the body to be affected seriously by oxygen want, and the subject "blacks out" quickly. Mention is made of this little-appreciated phenomenon not only because asphyxiants can be released in a room or tank with inadequate warning from the action of a fixed carbon dioxide fire extinguishing system, from a large spill of liquid nitrogen, from a leaking gas system, from an inert-gas producer, or from a leaking cylinder, but also because airline-supplied respirators, hoods and suits are frequently attached to a plant air supply with little appreciation of the hazard.

For example, at the Acids and Heavy Chemicals sub-section meeting, Chemical section, National Safety Council, October 25, 1956, no company present reported use of a special air system for respiratory equipment. If a cross-connection should occur anywhere in the air system which would permit an asphyxiant, toxic, or flammable gas to enter the air used for breathing, the results can easily and rapidly be fatal.

Oxygen, used indiscriminately, may also be a hazard, since serious fires have been reported where oxygen, either from a cylinder or an airline, or a leaking hose or pipe, was used for breathing purposes in an airline respirator or hood where welding or other flames were involved. Only a completely separate air supply, supplied by a compressor which cannot evolve carbon monoxide, carbon dioxide, oil mist or other unwanted impurities or from cylinders of tested known purity should be used for airline respirators, hoods or suits. In any event, regardless of supply, the system should include pressure relief valves, filters and absorbents as recommended.

2. *Anaesthetics* are gases and vapors whose action is primarily by inducing the symptoms of anaesthesia when inhaled in sufficient quantities. These include the substances which come to mind when the word "anaesthetics" is mentioned, such as the ethers, chloroform, methyl chloroform (1,1,1-trichloroethane), trichloroethylene, ethylene oxide and nitrous oxide (laughing gas), as well as hydrocarbons, aldehydes, ketones, other halogenated hydrocarbons, the aromatic hydrocarbons, alcohols, esters, and carbon disulfide.

DECOMPOSITION OCCURS

In addition to the physiological action of these materials alone and in combination, decomposition products are produced in a fire or when they are otherwise subjected to heat. Even relatively harmless substances such as the Freons and the Genetrons, (widely used as non-flammable refrigerants of low toxicity, as replacements for ammonia, sulfur and ethane), will evolve toxic decomposition products if they are heated above their decomposition temperatures. This has occurred where Freons and Genetrons were used as cleaning solvents.

Metal parts, after cleaning, were heated above the safe limits in order to dry and flash off the remaining solvent. Several persons were hospitalized with pulmonary congestion. Trichloroethylene degreasers, properly installed, maintained and operated, are safe, yet the failure or misuse of these vapor degreasers has created serious hazards including both fires and toxicity.

Mass hysteria and unconsciousness due to the little-appreciated anaesthetic action of the trichloroethylene has occurred in seconds; in one incident 72 persons were overcome, and in another, 26. Fortunately, all recovered after removal to fresh air and oxygen inhalation. The hazards of carbon tetrachloride mixtures in fire fighting and in other applicatuons are well documented.

4. *Substances producing other effects*—This classification includes several substances whose action differ from previously-mentioned substances. Included in this group are mercury, white phosphorus, tetraethyl-lead, nickel carbonyl, arsine, the boron hydrides, phosphine, hydrogen sulfide, and the widely-publicized military "nerve gases." The initial action of these gases and vapors is primarily on the nervous system, with respiratory arrest following.

CONTAMINANTS COMBINE

If the above classifications appear complicated, it must be remembered that these air contaminants seldom occur alone, and that even less is known about the combined action of two or more substances, especially if they are in different groups, than of the individual substances. Even if particles in the air are non-toxic in themselves, they are known to act as carriers of condensable toxic vapors—formaldehyde can have its toxicity increased five times by the presence of an aerosol.

It is little wonder, then, that respiratory protection can become a highly complicated subject, and that the practical application of respirators, gas masks, and self-contained breathing apparatus (all with their limitations), even by persons thoroughly trained in their use, is not cut-and-dried or foolproof.

Relatively untrained persons in an emergency situation, are in especially vulnerable positions. Many of the case histories attached to this paper clearly point to the need for more widespread appreciation of the nature of the hazard, as well as of the limits of the various respiratory protective equipment used.

RESPIRATORY PROTECTIVE DEVICES

A. *AIR-PURIFYING RESPIRATORS*

The fundamental limitations of any air purifying device are that the air must be within the limits for which the respirator was designed (for example, the oxygen content must be more than 16 per cent); the particular unit will only protect against the specific substance or combinations for which it was designed, (for example, aerosol [dispersoid] [filter type] respirators will give no protection against gases and vapors); and the canister or filter must be

maintained in proper working condition (on a properly maintained facepiece that fits snugly enough to exclude leakage).

Aerosol (filter type) respirators require frequent changes in filters when breathing resistance becomes uncomfortable when used where excessive dust or fumes are involved. Chemical cartridge respirators will safely protect only against the specific vapors and gases in non-emergency situations where no more than 0.1 per cent is encountered.

Extremely toxic materials, such as acrolein, acrylonitrile, aniline, dimethylaniline, arsine, bromine, carbon disulfide, carbon monoxide, dimethylsulfate, hydrogen cyanide, hydrogen fluoride, hydrogen selenide, hydrogen sulfide, iodine, methyl bromide, methyl chloride, nickel and iron carbonyl, nitrobenzene, nitroglycerine, nitromethane, oxides of nitrogen, ozone, phosgene, phosphine, phosphorus, trichloride, stibine, sulfur chloride, the boron hydrides and others are too toxic even in low concentrations for reliance to be placed on simple cartridge type respirators.

NOT FOR ODORLESS GASES

Chemical cartridge respirators should not be used against gases which are odorless or whose odor threshold is high, since the only warning of failure of the respirator or of concentrations which are above the ability of the respirator is odor. Methyl chloride is an example of such a gas whose warning properties are too slight for practical purposes. Substances which are highly irritating to the eyes, such as sulfur dioxide, require eye protection (such as a gastight goggle, an air-supplied hood, or a full-facepiece).

Several lacrimatory (tear-producing) substances, such as benzyl chloride, are in the same classification, and a respirator alone is clearly inadequate. Some substances, such as carbon monoxide, cannot be stopped by a chemical cartridge (except by the Hopcalite in the Type N universal gas mask and in the miner's pocket self-rescuer). Ammonia cartridge respirators will protect against ammonia up to 1,000 p.p.m., while eye irritation from ammonia begins at about 700 p.p.m.

Mercury cartridge respirators are effective against concentrations of mercury vapor normally encountered at ambient temperatures, but service life is proportionately reduced where higher concentrations of mercury from elevated temperatures and pressures are present. (There is no Bureau of Mines approval schedule for mercury respirators). Combination cartridges have the limitation of a shorter service life when used with one particular type of hazard than the equivalent specific single-purpose canister would have for the same hazard.

FACEPIECE TYPES

Normally, respirators use a "half-mask" facepiece, covering the nose and mouth, while gas masks use both full-masks and full facepieces. (Only full facepieces on gas masks are approved by the Bureau of Mines). Recently, the "self-rescue" or "pocket" respirator, normally used with a cartridge containing Hopcalite with a dryer and designed for escape from mines, has been extended into other cartridges.

The mouthpiece of this style respirator is held tightly by the front teeth of the wearer, and the breathing is accomplished through the mouth. A nose clamp blocks off the openings of the nostrils, and prevents irritation of the membranes of the nose. A neckband permits the respirator to be worn ready for instant use. Twelve different filter cartridges will fit the basic holder and mouthpiece.

Industrial canister-type gas masks, with canisters designed for specific substances or combinations, have the same limitations in general as chemical cartridge respirators, except they are effective in concentrations of any specific gas or members of the same group of gases for which they are designed of not more than two per cent in air or a two per cent total for a mixture of gases for which the canister is designed.

The ammonia canister is approved for three per cent ammonia. For shorter periods of time, industrial canister-type gas masks can be used in higher concentrations, but the time of service life will be reduced. Depending on the size of the canister, and the service for which it was designed, the service time varies.

Protection for a combination of various gases, such as acid gases, organic vapors, and ammonia can all be obtained in one canister, but the service life of such a combination is shorter in the combined canister when used with one specific substance, than is the life of an equivalent canister designed for specific substance alone. The only warning that a canister or cartridge is "exhausted" is the detection of odor of vapor or gas passing through the canister or cartridge.

Persons who need corrective lenses in order to work properly when wearing the respiratory protection, especially full facepieces, may find of interest two methods of incorporating lenses inside a facepiece. One method consists of wire frames which fit around the circumference of the sight lenses, and hold a 50-mm round prescription lens.

PRESCRIPTIONS IN FACEPIECES

A second method consists of a center post built inside the mask, onto which can be attached 40mm rimless glasses. Such arrangements seldom allow perfect alignment of the prescription lenses to the viewer's eyes, but, with adjustment, a sufficiently accurate fitting can be achieved for most purposes for reasonably long periods of time.

The type N universal gas mask canister is constructed of several layers including activated carbon (to remove organic vapors), soda lime (to remove acid gases and carbon dioxide), copper sulfate (to protect against ammonia gas), silica gel and other dryers (to remove moisture both before and after the Hopcalite), and Hopcalite itself (a mixture of metallic oxides which catalyzes the conversion of carbon monoxide to carbon dioxide), plus a filter for smokes.

This canister can be used as protection against smoke and gases which do not exceed two per cent by volume total, where adequate amounts of oxygen are present. Sixteen per cent oxygen is cited as the practical minimum, but life is not actually in danger until about 14 per cent or less oxygen is present. A timer is used to count the number of inhalations, and indicates about two hours total use.

DISPOSE OF CANISTERS

A canister should be discarded at least as soon as the timer indicates the pointer has completed one revolution, if not sooner. One authority recommends that universal canisters be weighed immediately on receipt from the manufacturer, and that they be discarded as soon as they have gained 45 grams. This 45 grams limit was imposed since it represents the limit of the dryers to keep the Hopcalite dry, and also to prevent excessive breathing resistance from developing as the dryer becomes moist.

The shelf-life of the universal canister, once the canister has been attached to the facepiece is one year, if stored with the bottom seal in place, even though the mask has not been used. If stored with both top and bottom seals unopened, as received from the manufacturer, the shelf-life is considered by some to be four, and by others, five years.

With an respirator or gas mask, the problem of proper fitting of the facepiece is critical. In addition to the time honored technique of holding the hand over the opening in the bottom of the canister while inhaling gently to see that the facepiece will collapse on the face, another technique recently suggested by the A.E.C. is to use isoamyl acetate.

Since isoamyl acetate (which smells similar to bananas) can be detected in a concentration of as low as one part per million, a small leak will be detected if the acetate is placed on cotton and the cotton passed slowly around the edges of the mask without touching either the wearer's face or the mask. If the wearer can detect the odor, a leak is indicated and the mask should be further adjusted until the odor can no longer be detected.

CIVIL DEFENSE MASKS

As part of its chemical warfare defense program, the Federal Civil Defense Administration is stockpiling a mask designated as CD V-800 organizational mask for use by civil defense personnel. The canister on this chin-style mask is the same as used in the U. S. Army Assault Mask. This mask is reported to give "excellent protection against CW (Chemical Warfare) and BW (Biological Warfare) agents, as well as against the inhalation of radiological particles, or CBR (chemical, biological and radiological)".

Designed to be used in conjunction with a detection kit, CD V-810, which will detect and distinguish between the nerve gases and the mustard gases, the V-800 mask is a specific mask for war gases (including nerve gases) and will not protect against carbon monoxide, ammonia and other gases. The Army Chemical Corps recently an-

nounced a new E-13 mask for troops. It is designed to give the soldier complete protection against the inhalation of war gases, germ warfare agents and airborne radioactive fallout particles, but does not protect against direct radiation.

The new mask does not have the protruding canister used in current masks. This was made possible through development by the Chemical Corps of a new light-weight, pliable gas-aerosol filter material. Pads of this material are enclosed within cavities molded into the rubber facepiece of the mask. Lower breathing resistance, superior vision, better speech transmission, and greater comfort are claimed.

It should be noted that the CD V-800, the existing and the new Army gas masks should be used for purposes for which they were designed only. After both World War I and II, several instances were reported where "surplus" Army masks were used for protection against gases for which they were not designed, with serious consequences. It is important that gas masks are not misused.

B. *AIR-SUPPLIED RESPIRATORS*

Since the simplest solution to all respiratory problems is to supply pure air to the breather, the use of an air supply from some remote source where the air is not contaminated is both simple and logical. For many applications, air-supplied equipment has real advantages, but this equipment is subject to definite limitations. The simplest type is the Bureau of Mines Type B hose mask, which is a facepiece to which is attached a hose without a blower which must extend to a respirable source of air. This mask depends on the breathing action of the wearer to move the air. For this reason, a maximum hose length of 75 feet has been established for the hose mask without blower.

Low pressure blowers, operated either by hand or by power (power blowers do not carry Bureau of Mines approval) are used to supply Bureau of Mines Type A hose masks up to 150 feet. All hoses should originate at the blower.

A respirable source of air must be assured, and a safety man must be present at the blower at all times. Fouling of the hose may cut off the air supply, and the exit route must be the same as the entrance route. These hose masks can be used safely only if the above precautions are observed.

Airline-supplied Bureau of Mines Type C respirators are divided into two classes: (a) the continuous flow type and (b) the demand or intermittant demand flow type; (a) is usually used with a powered compressor or blower, while (b) is usually used with breathing air supplied from cylinders. The use of such equipment in atmospheres immediately hazardous to life is not recommended since failure of the air supply or fouling of the hose would be serious, and further, it is absolutely necessary to have respirable air of unquestioned quality.

We have previously noted the hazard of using a plant air supply for air-supplied breathing equipment. It is recommended that a separate air system be used exclusively for breathing air. Depending on the pressure available and the diameter of the hose, there is a limit to the length of hose which is practical.

Wherever possible, such systems should be piped as close to the outlet as possible, so possibility of fouling of the hose and cutting off the air supply will be minimized. Exit from areas where air-line respirators are used must, of course, be the same as the route in. If a compressor or tank supply is used, sufficient pressure relief control must be available to protect the wearer against pressure in excess of that prescribed for the equipment.

AIR-INFLATED SUITS

Air helmets, air hooks, and air-supplied suits have the same general limitations as for air-line respirators. An interesting development in this field is the use of air-inflated suits for protection of the whole body against hazardous materials.

In one form, the large impervious plastic tunnel or pipe allows a man to work in one room while using air from another—the slight air pressure supplied giving both breathing air and inflation (or body) to the suit. The front of the suit is tailored into a facepiece, and arms with gloves are attached. Mobility is reported good within the obvious limits imposed by the length of the tunnel attached.

In another form, a complete suit with built-in arms and legs is supplied with air for inflation and a hood, also air supplied, is used for head, face and respiratory protection. Depending on the particular fabric, plastic, or composition used in its construction, this suit allows work inside tanks, reaction vessels and other confined space which still contain a hazardous atmosphere.

Properly used, together with safeguards to insure that the wearer's air supply and lifeline are always in proper position and working order, this suit has increased safety and decreased operating costs in maintenance work inside tanks containing materials which are corrosive or are easily absorbed through the skin such as aromatic amino and nitro compounds. The same limitations noted above for air-line respirators should be noted.

Regardless of the type "respirator" used, a definite program of control is necessary to insure the device is used properly, is properly maintained, and that it is doing what is expected of it. After the Canadian Chalk River atomic reactor incident, respirators were used to prevent inhalation of radioactive contaminants. This program was successful only after a respirator official was appointed to control the use and maintenance of respirators, regular urine-samples were analyzed to show definitely the degree of absorption, and an improved respirator was made available.

C. *SELF-CONTAINED BREATHING APPARATUS*

Self-contained breathing apparatus supply complete respiratory protection in any concentration of toxic gases and under any oxygen deficient atmosphere. However, certain gases and vapor will cause systemic poisoning by skin absorption. Although a small group, these exceptions are highly important, including hydrogen cyanide, nitro and amino aromatic compounds, ethylene imine, phenols and a few others. These gases and vapors require complete skin protection of an impervious type in addition to respiratory protection.

EARLY REBREATHING APPARATUS

The early self-contained rebreathing apparatus, which was imported from Europe, had serious deficiencies. Loss of life was reported by users in this country; 19 accidents are reported involving 26 facilities between 1911 and 1940, due partly to equipment failure and partly to improper use. Where life-lines and standby rescue squads were employed, the apparatus was generally satisfactory in the hands of well-trained users.

The first self-contained breathing apparatus to be approved by the U. S. Bureau of Mines was of the two-hour rebreathing type.

The oxygen rebreathing type apparatus is relatively heavy (39# for the two-hour type) and is bulky. Most self-contained (closed circuit) oxygen breathing apparatus in use today require mouth breathing with a nose clip, but a full facepiece has recently been approved. Careful training is required in use and in maintenance of this apparatus. A minimum of 20 hours initial training is recommended by the Bureau of Mines.

RESTRICTS MOVEMENT

Demand-type air and demand-type oxygen breathing apparatus is available in half-hour, quarter-hour and 7½ minute ratings. Only the half-hour demand apparatus is Bureau of Mines approved; the Bureau has no approval schedule at present for any self-contained apparatus of less than a half-hour. Although the schedule of work on which the Bureau's half-hour rating is exhausting, large men under extreme stress have exhausted a half-hour (40 cu. ft.) cylinder in significantly less than a half-hour.

Differing only in whether it is supplied with compressed oxygen or compressed air, the apparatus weighs nearly 30 pounds for the half-hour type, with the large cylinder (40 cubic feet) on the back. It is relatively awkward to put on and it restricts action in confined spaces. With practice, it may be put on and into operation from a mounted backboard in less than 20 seconds.

The back position of the cylinder makes it difficult to crawl under equipment. Climbing in and out of small openings, such as manholes, requires care when wearing this type apparatus. Operation of a motor vehicle is awkward when wearing a cylinder on the back. (15-minute and 7½-minute demand apparatus use smaller cylinders slung on the side of the wearer, which overcomes this objection to some extent.)

The purity of the air or oxygen with which the cylinder has been charged should always be questioned since other gases such

as nitrogen, acetylene and carbon dioxide and gas mixtures other than air have actually been found in "breathing air" cylinders. Errors in compressed air used for breathing may be rapidly fatal, and every newly-filled cylinder should be checked to insure it actually contains "breathing air," regardless of the source of supply.

Unless the user has his own compressor producing air of an unquestioned purity, no cylinder should be put on a demand breathing apparatus or air-supplied respirator, hood or suit until the contents have been checked for purity. The Orsat gas analyzer or the Beckman paramagnetic oxygen analyzer are often used in analyzing oxygen percentage while carbon monoxide may be checked with the National Bureau of Standards colormetric tester available from two manufacturers.

High pressure cylinders may leak, and frequent inspection is necessary to insure that the air or oxygen is actually available for use in an emergency. High pressure valve, gauge, and demand regulator must be maintained in top operating condition by inspection and a regular preventative maintenance schedule as recommended by the manufacturer.

ATMOSPHERE CUTS SERVICE

If demand-type apparatus is worn in environments where pressure above one atmosphere is present (as in caissons or tunnels under higher than atmospheric pressure), the service time is reduced as the pressure increases. This is also true of underwater use of the regular demand-type apparatus; a special adaption is available for underwater swimming. Other peculiar effects have been reported when demand and closed circuit oxygen breathing apparatus was worn under pressure.

The use of oxygen in atmospheres above two atmospheres absolute pressure should be avoided since oxygen produces a toxic effect under such conditions. For periods up to 12 hours at normal atmosphere pressures, however, oxygen may be used without apparent ill effects by healthy persons—persons in questionable physical condition should *not* wear *any* emergency breathing equipment, but should remain away from contaminated air and underwater.

When the supply of air or oxygen has been depleted, the supply in the demand type apparatus cuts off abruptly, and the facepiece must be removed immediately or asphyxia can occur. One British half-hour breathing apparatus has available as optional equipment an automatic warning whistle (Pat. No. 644105) which will start to blow when the cylinder pressure falls to 300 pound/square inch, to aid in warning the wearer to return to fresh air at once.

The seal around the facepiece must be absolutely gas-tight in a toxic atmosphere since in the demand-type apparatus the facepiece is under slight negative pressure momentarily during the beginning of the inspiration phase of the cycle. A recent revision by one manufacturer eliminates this negative pressure part of the cycle. Another novel feature of another demand mask (54 cubic feet of air or oxygen divided between two 26 cubic foot cylinders for balance) is a plug-in attachment carried with the mask for administering resuscitation to an overcome person on-the-spot while still in a toxic atmosphere.

In the above discussions, no mention has been made of the fire and explosion hazard of air which is richer than 21 per cent in oxygen, or of pure oxygen itself. Certainly air should not be replaced with oxygen, either in a breathing apparatus, in a ventilation technique, or for any other purpose, without full consideration of the increased potential hazards from fire, as the oxygen concentration increases above the 21 per cent oxygen content of air. A flammable vapor-oxygen mixture requires only about one thousandth the energy to ignite it as does a corresponding flammable vapor-air mixture.

The resulting fire or explosion is many times more violent. Failure to appreciate these facts (which have been published and well documented for years) has cost many lives. For this reason, it is as important to analyze a suspected atmosphere for oxygen concentration as for flammable vapors and gases, and for toxic gases. By using either the time-honored mine safety lamp as an oxygen indicator, or the more recently available Beckman paramagnetic oxygen analyzer, it is possible to obtain fast and sufficiently accurate oxygen analyses for practical purposes.

Combine such oxygen analysis (which will reflect inert gases or oxygen deficient atmospheres as well as excessively high oxy-

gen concentrations) with a check for flammable vapors and gases (using one of the many instruments commercially available), and a check for whatever toxic gas is suspected (for CO, for example, the National Bureau of Standards glass tubes containing palladium chloride which changes color with CO). To ignore any one of these fundamentals is to run risk of trouble.

SAFE 45 MINUTES

The self-contained oxygen-generating breathing apparatus is approved by the Bureau of Mines, and is rated for 45 minutes. Some of the models produced for the military are not Bureau of Mines approved, however. The weight of 14#, carried on the chest and stomach, gives it a decided advantage both in weight and convenience over the demand-type apparatus, although the chest position creates limitations in use under some conditions.

The highly exothermic reaction which generates oxygen from the potassium superoxide (K_2O_4) evolves significant heat, which might serve as an auto-ignition source to carbon-disulfide or nickel carbonyl vapors under extreme conditions. This temperature of the canister surface may reach 250°F, and is equivalent to the hazard presented by unshielded incandescent lamps, hot plates and steam pipes in such an atmosphere.

When worn in hot areas, or while working hard in the heat, the oxygen generated may occupy a volume which requires "dumping" of surplus oxygen to maintain comfort. The apparatus requires care in starting, especially in sub-freezing temperatures—for this reason it is considered good practice that both the apparatus and the canisters be stored inside or in a heated truck cab or automobile, and that the apparatus be thoroughly started above freezing temperatures, if possible.

Unless the sub-freezing starting is thorough, the wearer may be aware of insufficient oxygen during the first few minutes, by a feeling of "light headedness" and difficulty in coordination. If such a condition is noted, he should return to fresh air, deflate the bags and re-start the apparatus, until the breathing rate and the generating rate balance before re-entry.

In inserting the canister in the canister holder (canister is stored separately), care must be exercised to avoid cuts from the torn top seal when removing it, and the canister brought securely into place after it has been punctured by the sharp point designed into the apparatus for that purpose. The facepiece should not be donned until the canister is completely seated. A fresh canister should always be used in any emergency.

Once opened, a canister will continue to evolve oxygen even when removed from the apparatus and re-capped. To enter a hazardous atmosphere with a used canister is a highly dangerous practice—a fresh canister must be employed to insure safety. In view of the relatively high cost of these canisters, the temptation to re-use canisters is great, but should be avoided, and canisters promptly disposed of to insure the safety of the next user.

DON'T RE-USE CANISTERS

The disposal of the self-contained oxygen-generating canisters must be performed according to the instructions. Oil, grease, gasoline, or other flammable or combustible liquids must be kept from the canister mouth, or an explosion will occur. Only clean water in large quantities should be used to destroy a canister. The canisters should be promptly disposed of, and not be left sitting around where they could contact combustibles.

For reasons noted under discussion of demand-type breathing apparatus, the self-contained oxygen-generating apparatus should not be worn under pressures greater than two atmospheres absolute.

Smaller Self-Contained Breathing and Oxygen Inhalation Devices

U. S. Bureau of Mines approval for self-contained breathing apparatus currently makes no provision for apparatus rated for less than 30 minutes. In emergencies where a smaller, less cumbersome device with a shorter life would give adequate protection, the only available devices until recently were regular demand masks with smaller cylinders for 20, 15, and 7½ minutes service, using the same facepiece, reducers and regulators as on the larger approved devices.

Recognizing that many (perhaps most) breathing emergencies can be brought under control in 10 minutes, and that the first 130cc of expired air contains relatively lit-

tle CO_2, there is now available a lightweight device in which oxygen from small cylinders, supplemented by the first 100cc of the previous exhaled breath, is used for breathing at a rate of seven liters per minute. The device is still too new for extensive field experience, but represents a novel and new approach to the weight, bulk and cost of presently approved equipment.

Another recent development is a small portable anaesthesia and oxygen breathing device which is designed for use by medical personnel primarily, but which has obvious application as a "self-rescuer" for escaping toxic atmospheres. The device consists of a face piece with pressure limiting valve, an aluminum central body, a soda lime canister in volumes of 100cc to 500cc, two aluminum cylinders, each containing three liters of oxygen, and a six liter rubber rebreathing bag.

Using the device for escape, it is claimed a young male adult walking three mph can travel safely for 1100 yards using a 200cc soda lime canister, and 1800 yards using a 500cc canister. Since the complete unit weighs less than two pounds, and the oxygen cylinders are pocket-size, the device may rightly be called pocket-size, and, in the hands of trained personnel, should be useful for self-rescue oxygen inhalation or resuscitation.

Maintenance, Training and Medical Precautions

In discussing respiratory protection, we have shown the importance of breathing "good" air, briefly reviewed the major air contaminants, and discussed briefly apparatus available. We have stressed the limitations of each type, rather than the advantages, since we believe that limitations were not as widely appreciated as advantages. The ideal breathing apparatus has yet to be developed. We have tried to create the impression that a thorough knowledge of the particular apparatus used is essential for its safe use under various conditions.

Maintenance of the apparatus in first-class condition so it is immediately ready for use at any time is likewise important. Metal parts of apparatus will wear, tarnish or corrode; rubber parts will slowly "age." Facepieces will take a "set" and must be discarded. Cylinders, regulators and valves on demand-type apparatus must be checked frequently for leaks; canisters on industrial or universal service masks or chemical cartridge respirators must be replaced.

Washing the facepiece with an antiseptic solution or soap, rinsing in clear water, and drying will assure that sanitation and cleanliness is not neglected. This also prolongs the useful life of the facepieces. Proper storage conditions and frequent checking for deterioration are as important with respiratory protective equipment as with fire extinguishers, parachutes and life-lines.

TRAINING DEFICIENT

Training is the third, and perhaps most important leg of the triangle of respiratory safety. There is serious deficiency in this phase of the respiratory program. Putting on a device for a few minutes once a year is not adequate training. The U. S. Bureau of Mines Health and Safety Activities, through its district and sub-district offices, conducts training courses in first-aid, and also in the use of various emergency breathing apparatus.

The course can be modified to meet special needs on request. Addresses of offices which offer these courses may be obtained by contacting the Health and Safety Division of the Bureau of Mines, 4800 Forbes St., Pittsburgh 13, Pa. This service of the Bureau is available to the mineral and allied industries, as well as to governmental agencies. The Bureau has at each of its Health and Safety field offices throughout the country mine-rescue equipment, and will make it available to trained personnel in any emergency.

During training, breathing apparatus should be worn for relatively long periods, in dark and confined spaces, climbing hills or stairs, duplicating all manual labor expected, and in smoke-filled atmospheres by hand-carried lights while performing work. Smoke generators are available, which will quickly fill a room, a basement, a tunnel or a small building with a smoke that is realistic, but which is relatively harmless and can be ventilated out without any damage.

The "buddy" system and team drill should be practiced, as in a real emergency. The use of life lines should be a part of this training, and should be a standard part of any underground, tank or smoky operation.

Signals as used by mine rescue teams based on OATH (O=OK=1 pull; A=advance=2 pulls; T-take-up=3 pulls; H=help=4 pulls) should be employed and stand-by men, ready to enter the area for rescue, should always be on hand.

Hand-carried short-wave two-way radios may also prove useful for communication between base and field party. When used in atmospheres which may contain flammable vapors or gases, any electrical devices should have a "permissible" rating by the Bureau of Mines for the gases or vapors involved.

PHYSICAL EXAMS LACKING

The need for proper physical examinations for persons wearing emergency equipment has not always been appreciated in the past. A regular program of physical checkups with particular attention to the respiratory and circulatory system as well as general physical condition probably would have prevented some cases where inhalation of a smoke combined with physical exertion with or without respiratory protection, has produced serious illness.

Pulse rates before, during and after exercise, general physical condition, moderate weight, good eyesight and proper teeth alinement (where mouthpiece breathing is involved) are considered vital to pre-training by the Bureau of Mines instructors. A practice of not permitting persons to return unprotected to smoke or fumes after they have been overcome and revived, would help prevent more serious inhalation effects.

Such restraining action may require physical force to implement it in practice, since a patient who is partially recovered from fume or smoke inhalation may display highly irregular behavior. One recommendation is that persons sufficiently exposed to smoke and carbon monoxide to require treatment should not return to active duty in less than four to six hours, while those who have been rendered semiconscious or unconscious should rest 24 to 48 hours.

Properly maintained breathing apparatus, used with full appreciation of its limitations, by healthy persons, properly and adequately trained, will eliminate most "fume" disabilities in the future. However, the ideal breathing apparatus for all applications has not been developed, and may not be developed until there is sufficient demand for it.

CASE HISTORIES

AMMONIA

The incident in question took place in Singapore, Malaya, during the early days of the war 1942, just prior to the fall of the city to the Japanese.

Our ship was tied alongside the docks, having just completed a mission. The city was under air attack continually, so that we maintained a full scale Battle Watch, ready for any emergency. It was after one of these raids that a strong odor of ammonia was observed on our ship; our blower ventilating system was picking it up. Investigation by our shore patrol informed us that a large cold storage plant had been hit and that the local fire department was attempting to rescue several members who were trapped inside the buildings.

Our fire and rescue section was dispatched to the scene at once; we were equipped for such work with demand-type breathing apparatus, with proper protective equipment and safety lines. Upon arrival we were briefed as to the plant layout and the possible location of 10 men inside the building with a British type canister mask for protection. We entered the area working in pairs, and during the next 20 minutes removed 10 firemen, who had been well trained by the best of British methods, but unfortunately ill equipped for such violent conditions.

When found, all men were unconscious and upon removal from the building were rushed to the hospital, oxygen being administered enroute by a fine Australian medical team. Of the 10 men rescued, six died from the effects of ammonia inhalation, four men recovered completely.

During the entire operation none of our team experienced any breathing difficulty; the teaching of damage control, fire and rescue work by Naval standards are very good. Their careful selection of reliable equipment has been the result of careful research and experience.

NITROGEN IN AIR-LINE RESPIRATOR

Employees in an area were required to use air-line respirators as a precaution against inhalation of radioactive particles. The air line was also used to provide instrument air.

A regular compressor and a standby compressor were provided on the air line. Over a week-end, both compressors were out of service, so bottled nitrogen was manifolded into the line by a temporary jumper connection to maintain instrument air pressure. An employee, aware of the circumstances, was told to wear a filter-type mask. By habit, however, he entered the area and was found dead several minutes later due to nitrogen inhalation in the air-line respirator he had worn instead of the filter-type mask.

Breathing air systems, using an approved compressor or tank system, should be closely supervised and used only for breathing. Employees whose work takes them out of contact (visual or audiable) with others should be closely supervised. Human error caused this fatality.

CARBON TETRACHLORIDE AGAIN

Bunker C oil leaks had sprayed oil over the walls and ceiling of a small boiler room. Fearing the fire hazard which might result from using kerosene on the electrical equipment, the plant engineer had four men use a bucket of carbon tetrachloride with a long-handled brush.

Respirators of the proper type were provided and worn, but due to a missing part and poor fitting on one mask, one of the men became ill and was hospitalized three weeks with typical carbon tetrachloride poisoning symptoms.

A properly adjusted respirator, a less toxic solvent (such as 1,1,1-trichloroethane), and ventilation—any combination of these measures would have prevented this injury. It was also noted that the injured man occasionally consumed alcoholic beverages—a contra-indicated action in solvent areas.

PHOSGENE

A chemist suffered a major injury when phosgene gas containing dissolved HCl escaped from a cylinder too fast for the capacity of the hood. The chemist was wearing a Type N universal canister mask, but he noticed that his eyes were irritated when he took the mask off moments later in the fresh air.

Two men who worked alongside him were wearing air-line respirators and did not smell phosgene nor notice any eye or throat irritation. The chemist was hospitalized for 10 days from a toxic exposure to phosgene fumes, and was absent from work for about one month. The two other men suffered no ill effects whatsoever.

NO RESPIRATORY PROTECTION

A chemist was decomposing a reaction mixture containing phosphorous oxychloride in a hood by pouring it over ice onto a four-liter beaker. While his back was turned, the reaction became violent and the mixture overflowed onto the hood floor. A small amount also spilled onto the laboratory floor, since he did not have a catchpan under the beaker.

He directed his laboratory assistant to leave the room promptly, but stayed behind to throw some ice on the spill on the floor and open windows. He re-entered the laboratory after 10 minutes, when the fumes had subsided considerably, and cleaned the spilled material off the floor. This required 10 minutes, during which period he inhaled some of the fumes, chiefly HCl. He did not use any respiratory protection, although it was available.

He did not notice any ill effects that day, other than eye and throat irritation, but he was hospitalized on the following day for bronchial and pulmonary congestion. He was in the hospital for four days.

* * *

A vertical catalyst bed was being rodded out to remove solids. Dust and fumes from the solids being discharged at the bottom of the reactor were sufficient to cause coughing and discomfort to the operator, although spot ventilation was being used at the top of the column.

The operator continued to work out his shift, but that night he had an attack of nausea and vomitting, accompanied by persistent coughing. Following a recurrence of the original attack, he was admitted to a hospital for four days.

An air line respirator was readily available, although the magnitude of the dust hazard was not fully appreciated at the time.

* * *

During the operation of a small scale reactor housed in a barricade, it was necessary to enter the barricaded area and withdraw condensate every half-hour. This removal consisted of opening a valve at the

bottom of a condenser to check for and remove any unconverted by-products. In performing this operation it was necessary to discharge some vapors to insure complete withdrawal of the condensate.

The injured had been doing this during his shift without using the air-line respirator which was prescribed protection equipment for this operation. In addition to this exposure, he had entered the barricade during the early part of the shift to make minor repairs to a leaky blower.

The injured worked for several days with no apparent ill effects. While at home he developed a fever and shortness of breath which was subsequently diagnosed as acute bronchial asthma. He was home for three days.

In this case, the injured failed to obey written and verbal instructions to wear an air-line respirator, and the injured's shift leader failed to enforce this rule. Since then, all operators in this group have been reinstructed in the necessity for observing regulations regarding barricade entry, and have been informed that repeated violation of safety regulations may constitute grounds for dismissal.

WRONG TYPE MASK

An employee washing out a chlorine tank car passed out due to insufficient oxygen. A fellow employee put on a Type N universal canister gas mask and entered the car for rescue purposes. He, too, passed out and it was necessary to use self-contained breathing apparatus to rescue both. Fortunately, both men recovered.

* * *

Fire was located in a drying-storage room of steel construction, measuring 8 feet x 50 feet x 30 feet closed by an absestos curtain at one end. There was no possibility of ventilating. The room was located on the sixth floor of a factory and contained a large quantity of "wood flour" (pulverized saw dust), used in casting ornaments, contained in 100# bags. Fire was started by an electric motor in the rear-most portion of the room.

The fire had smoldered for some time and this room was heavily loaded with smoke, and obviously a high CO and CO_2 content. Alarm was sounded when the heat finally built up enough to activate a sprinkler head, which transmitted an A. D. T. alarm. Since very little smoke was visible external to the drying room (which was held at approx. 150°F) the first firemen went in without any protection. They were quickly overcome.

Members of the rescue company followed closely behind using Type N universal canister masks. These functioned well on the sixth floor outside the drying room, but inside, one of these five men was overcome. The other four heeded the warning sign of "overbreathing" and retreated to fresh air before being overcome. These same men returned to the room after donning self-contained breathing apparatus. In all, 30 men were overcome in this multiple alarm fire—multiple only because all men from the first companies were overcome. All the firemen recovered.

NO RESPIRATORY PROTECTION

A chemist was preparing to use hydrogen sulfide for a determination and when the valve was opened, a leak developed because a washer did not seat properly.

Before the employee could close the valve, the hydrogen sulfide was ignited by the flame from a bunsen burner located in the same hood. In an attempt to close valve, the employee re-entered the room, without wearing protective equipment, was overcome, and struck his head on the edge of a bench as he fell to the floor. He was rescued by another employee who was wearing a demand self-contained breathing apparatus. He was hospitalized for three months and as a result of this incident lost his sense of smell.

ANOTHER SOLVENT INCIDENT

Two electricians, journeyman and apprentice, were working in a concrete pit—four by six foot top opening and standing on the bottom, the ground level was in the proximity of their eyes, nose and mouth. Repair of the small motor involved using a solvent an inhibited grade of 1,1,1-trichloroethane. Approximately 10 minutes after entering the pit, the one electrician appeared to be swaying, somewhat in a stupor and somewhat incoherent. A combination of lifting and pushing forced the man out of the pit. The other electrician used the ladder in leaving the pit.

A few minutes exposure to fresh air and the "overcome" electrician stood up and walked to the dispensary. Examination revealed him to be coherent and no signs of narcosis. He rested for about half an hour and returned to his job—by this time the job in the pit was completed.

A few pertinent facts are in order: solvent was not spilled on the floor of the pit, the "overcome" electrician had returned to work that morning after being off for several days due to a bronchial inflammation, and the other electrician never demonstrated or mentioned any ill effects.

INERT GAS IN TANK CAR

A tank cleaner entered a tank car (which had previously contained caustic soda) and started to wash it down with a hose with the bottom outlet open. After failing to reappear in a normal time, investigation revealed the man lying in the bottom of the car. Upon removal and attempts at resuscitation, it was determined that he had died as a result of weak alkali solution having been taken into the respiratory tract.

This is strong evidence that the inert gas used to unload the car was a byproduct of chemical operations, low in oxygen and could have contained carbon dioxide, carbon monoxide, nitrogen and other constituents. Upon checking the air oxygen and 2000 ppm of reducing gases which would commonly be reported as carbon monoxide.

Inasmuch as the official coroner's report stated that the man fell to the bottom of the car apparently due to heat exhaustion, there was no significant publicity concerning this incident. Corrective measures have been taken to avoid any recurrence.

TANK JOB CLAIMS LIFE

A maintenance mechanic lost his life, and his assistant narrowly escaped in tank incident.

Repair work had been scheduled inside the tank to begin after lunch, and two men assigned to the job. The mechanic decided to look over the job about 11:30 a.m. and went into the tank after sending his helper for certain supplies. The inert gas (which contained essentially nitrogen with small percentages of CO and CO_2) supply to the tank had not been shut off, since the mechanic had not informed anyone of his entry. The mechanic was quickly overcome.

His helper returned a few minutes later, shouted for help, then went into the tank to aid the first man who was unconscious. Before help arrived, the helper was also overcome, but both men were promptly removed to fresh air. The helper was successfully revived, but the mechanic could not be brought back to life.

Failure to follow established tank-entry procedures was the reason given for this fatality.

INERT GAS

Two men entered a kettle to repair an agitator, which is normally a two day job. On the first day nothing unusual happened. On the second day the men went into the kettle, worked for an hour, and came up for a coffee break. When they re-entered kettle, they began to feel weak. They were actually too weak to climb out of the manhole after 15 minutes, but finally crawled out. They came to as they stepped out into the air.

After investigation, it was discovered that one of the men had opened an inert gas line instead of an air line. Close to the top of the kettle was a section for a hose line to be piped to outside the building. The hose was only half-way down into the kettle. The inert gas was heavier than air, when they bent over to pick up tools, they would get inert gas until they eventually were made ill.

* * *

An engineer went down to inspect a kettle. He began to feel sick and came out. Upon investigation later they found the kettle had been "blown-out" with inert gas and did not follow through by removing the gas with proper air ventilation. (The engineer recovered immediately upon leaving the kettle)

* * *

A man went into a non-enameled kettle. The complete kettle was blanked off with exception of entrance. The kettle had been "blown-out" with inert gas. He was overcome. It was necessary to resuscitate the man quite a while before he recovered.

ILLUMINATING GAS IN TRENCH

Two men were working in a series of three by seven by seven foot trenches dug along a 75-foot length of a street. While tapping a high pressure illuminating gas main to install a jumper line into a low

pressure main, a drill slipped and opened a valve in the tapping machine. Gas was released into the trench.

One man immediately left the trench, but the other was overcome. A laborer standing on the bank observed this, and immediately descended into the trench. He tied a rope around the waist of the unconscious man before he, too, was overcome. Meanwhile the foreman of the job put on an air-line respirator and went into the trench to close the valve. By the time the two unconscious men were brought to the surface by the foreman, one was sufficiently ill that inhalators could not revive the laborer even after a half-hour of resuscitation. The other unconscious man was revived.

The final score: three men treated at hospital for gas inhalation while one man was dead on arrival.

MASK IMPROPERLY ADJUSTED

A near fatality occurred when an operator went to tighten a chlorine line in the Waste Treatment Plant and the line disintegrated, thus exposing him to a full blast of chlorine. He had his face mask on, but due to maladjustment, he was hospitalized for twenty-four hours.

NARROW ESCAPE

A plant protection officer entered manhole to inspect water valves, collapsed after about three minutes, was unconscious for three and one-half hours, revived by artificial respiration. If there had not been another officer watching and a truck with a rope on it nearby, this would likely have been a fatality. A six inch artificial gas main 30 feet away had broken and the gas had seeped into the hold. No respirator was worn.

METHYL CHLORIDE

A leak developed in the methyl chloride compressor which was being used to transfer methyl chloride from the drier through a tank to storage. The leak was first discovered by a foreman who had heard the compressor pounding and who entered the area to investigate.

Two men inhaled excessive quantities of methyl chloride. An operator entered the area with a filter type respirator, but left when he detected methyl chloride through his respirator. Shortly afterward he was observed staggering and shouting outside. He was wearing a dust respirator. Both men were given oxygen and sent to the dispensary. Each of the men had a pale white complexion with a bright red overtone.

An examination of the compressor after the incident showed a crack along the base of the compressor housing. This was caused by liquid methyl chloride in the compressor.

The tank had been full for three days and had been frosted over, indicating the presence of liquid.

The incident was caused by attempting to transfer through the full tank.

OXYGEN WASN'T THERE!

During degreasing operations involving the use of Freon-113 (Trifluorotrichloroethane), it appears that one operator fell into the tank while attempting to disengage the basket. The other operator, without calling for help, immediately entered the tank to go to his assistance. Both men lost their lives due to suffocation in the oxygen-deficient atmosphere.

In fire safety, we have long hammered at the point of calling assistance before tackling any fire alone. The same point should be reiterated again and again in training personnel where the hazards of suffocation or entrapment exist. In many large chemical plants, personnel are often widely spaced and telephones are not always readily available at all locations. In practically all plants, however, a fire alarm box is located quite conveniently to all operating stations. Pulling the fire alarm box summons trained assistance and supervision in a matter of seconds. Where feasible, employees should be trained to use the fire alarm box instinctively to summon assistance before attempting on their own.

In any case where hazard evaluation discloses the possibility of suffocation or entrapment, personnel should be thoroughly trained to overcome the instinctive reaction to go immediately to the victim's assistance and to summon help first by the fastest available means.

HYDROGEN SULFIDE!

One man suffocated and two escaped death when exposed to H_2S.

This accident was caused when a precipitation tank overflowed and spilled acid-bearing liquor on the floor. The liquor drained into a sump near the leach station and was then pumped into a reserve holding tank. Later, pipes from a reserve sulfide holding tank were disconnected, allowing the contents to drain on the floor.

The sulfide, during clean-up was washed into the sump and then pumped into the same reserved holding tank. An immediate reaction generated large quantities of H_2S, filling the area surrounding the tank. Unaware of this, three employees entered the area.

The first employee collapsed just as he passed the tank. The remaining two men walked a few feet further; one collapsed and the other reached a window and called for help. Other members arrived and gave artificial respiration while the ambulance was summoned. On arrival at the hospital, the first employee was pronounced dead.

Processing plants and laboratories in the program contain the elements to produce not only gases like H_2S but disastrous fires and explosions as well. These can occur from an uncontrolled chemical process reaction or, as in this case, from improper mixture of two chemicals. Infrequently, storage of incompatible chemicals can be separated physically for safety, which was done here afterward. More reliably, however, the employees should be instructed fully in the adverse effects of chemical combinations possible in the operation.

ALIPHATIC HYDROCARBONS

A pipe-fitter, aged 26, was gassed by aliphatic hydrocarbon fumes in a pit 20 feet by 10 feet by 6 feet deep in an oil refinery while he and another man were inserting a blank in a pipeline which had been shut off. Both men were wearing breathing apparatus supplies with air from a hand-pump, a Y piece being used to supply the two sets of apparatus from a single pump.

While working in the pit, the pipe fitter, who was apprehensive and difficult to reassure, was seen to remove his mask. The safety attendant, who, with the foreman, was watching from ground level, replaced the mask and assured him that it was working properly. When the joint was opened, some liquid escaped owing to residual pressure, and the pipefitter endeavored to come away, but was persuaded to return.

Later, when he again attempted to leave the pit, his airline caught on the bottom of the handrail and impeded his exit. This caused him to panic and he took off his mask. The foreman and the safety attendant running to his assistance, pulled him to safety as he collapsed. His workmate continued to work in the pit without any trouble.

After being given artificial respiration and an injection of coramine, the pipe-fitter was removed to hospital where he recovered. The apparatus which he had been wearing was subsequently found to be in good order, but it was unwise to compel him to work under circumstances of which he was obviously afraid.

AMMONIA

One afternoon, while the engine-room foreman of an ice-cream factory was standing near an oil separating unit, there was a report and ammonia liquid and gas issued from the sump. It was later found that the rubber seal between the sighting glass housing and the sump had "blown." The engine room was immediately evacuated, the foreman taking with him a canister respirator from a rack.

The fire brigade was called and warning given to all employees in the factory. As the concentration of gas was too high for the canister respirator, the foreman was unable to re-enter the engine room to reach the ammonia isolating valve. The gas spread rapidly through the factory area and many of the 100 employees, most of them women, were affected.

There was some degree of panic and some women were rescued from the canteen by firemen. Sixteen women employees and two firemen were admitted to hospital but only three persons were detained overnight. Seven of the women were sufficiently affected to require notification. Occupants of houses within a radius of 50 yards of the factory were also affected. The firm had already been advised to provide self-contained breathing apparatus and they were again advised to keep apparatus of this kind outside the engine room as well as the canister respirators.

TWO FATAL ACCIDENTS WITH BENZENE VAPOR

In one accident a laborer, aged 23, was fatally gassed and an ambulance room attendant and a fireman were also gassed while

attempting to rescue him. The foreman had given instructions for four of a series of 16 benzol tanks to be cleaned after they had been steamed out, tested and declared free from gas. While the laborer with his workmate was preparing to start work on a tank which had been steamed out, he enquired about another tank which had not been steamed and was told they were not instructed to clean that tank.

When the workmate returned after fetching a respirator and a lifeline he saw that a ladder and hose pipe had been lowered into the unsteamed tank and that the laborer had unaccountably entered without a lifeline or respirator. After shouting for help he attempted to enter the tank, at the bottom of which there was about 12 inches of liquid, but was forced to come out because of the fumes.

During the rescue operations a fireman, who in his hurry entered the tank without a mask, was gassed, as was the ambulance room attendant who had donned a fresh-air mask and a lifeline but dislodged his face mask while in the tanks and lost consciousness. The laborer was given artificial respiration and oxygen but failed to recover.

The other fatal case was a benzol house attendant aged 47, who was found lying prone and unconscious on the floor, which was saturated with benzol. He was immediately dragged into the open air and artificial respiration was started at once, this being continued with the aid of a rocking stretcher, oxygen also being given. Despite this treatment, he was found to be dead on arrival in hospital.

When the distillation temperature had been reached it was the attendant's duty to reduce the steam sufficiently to allow distillation to proceed in the normal manner. If this was not done, the crude motor spirit would boil rapidly and would eventually overflow on to the floor. After the accident, the plant was found to be in order, and it was assumed that the accident was due to the use of too much steam.

CARBON DISULPHIDE

Following the discovery of a leak at a rotary valve on an electric arc furnace used for the preparation of carbon bisulphide, the manager decided that breathing apparatus was necessary while repairs were being effected and he issued a permit-to-work certificate accordingly. Without being instructed to do so, a laborer climbed up a ladder to the top of the furnace.

He was not wearing breathing apparatus and, being overcome by escaping gas, he fell to the ground about 10 feet below. After recovering consciousness he was able to walk to the ambulance room.

FOUR CASES OF CHLORINE POISONING

In four cases in which only slight exposure to chorine gas occurred, the effects were stated to have been aggravated by the existence of a previous chest condition. One of these cases was a plant operator who inhaled a whiff of chlorine when adding hydrochloric acid to a reaction vessel under negative pressure, after having put in a slurry of sodium chlorite. The doctor who treated him in hospital considered that the inhalation of a small amount of chlorine had "triggered off" an acute attack in a man subject to asthma.

A process operator, aged 32, whose exposure to chlorine from a leak in a plant for the chlorination of dimethylacetal was slight, suffered from cough, breathlessness and pain in the chest. The chest physician, who found a lesion in the left upper zone and kept him under observation at rest at home to assess the activity of the tuberculosis lesion, thought the infection was a factor greater than chlorine exposure in this case. A night watchman, aged 58, said to have had a previous chest condition, suffered from a sensation of choking, cough and respiratory tightness following a slight leak of chlorine from a control valve.

The fourth case in this group was a fitter, aged 57, who, with other men was cleaning an air-cooler plant from which some water containing four p.p.m. of chlorine was leaking. The other men were unaffected by the small amount of chlorine, but the fitter, who was stated to be a heavy smoker, which caused him to cough continuously, became unconscious and suffered from lachrymation and cough.

IMPROPER VENTILATION

A laboratory technician was cleaning a vessel with a mixture of hydrochloric and nitric acids. The work was being done at a sink in front of an open window. However, there was not sufficient ventilation to prevent the worker from inhaling fumes to make him sick to his stomach. The proper type Canister Respirator was available on the lower floor but the person was not familiar with its use.

NO RESPIRATORY PROTECTION

Several specific instances are known where personnel should have worn protective equipment and did not although it was available and the specific personnel were familiar with use. For the most part these instances involved professional grade personnel of the "difficult personality" category engaged in Research and Development. Injuries were in all of these cases from volatile vesicants, and though injuries were serious enough to have resulted in lost time, there was, in fact, no lost time.

In one instance the employee was convinced to use recommended safety procedures by a combination of greatly increased supervisory pressure and alarmist industrial hygiene propaganda. In another instance such stresses produced no apparent effect.

RESPIRATORY PROBLEMS

We have had people injured while they were wearing respiratory equipment and also we have them injured by not wearing them even though they were available. Some of the latter are the "Smoke Eater" type who think they can get along without the stand-by equipment.

A basic problem with any respiratory protective equipment is knowing the limitations of a particular device. Actually, the popularity of the self-contained breathing apparatus can be attributed to the fact that its limitations are far less than any of those that depend on chemicals for air purification. In addition, the operator does not have to be concerned in knowing whether there is sufficient oxygen in the air.

In one particular process we were confronted with a number of stages in which reactants were more or less open to the atmosphere. In spite of a number of spot ventilators there was a prevalence of noxious odors, most free chlorine.

Chlorine is considered here for its nuisance and noxious characteristics rather than for its toxicity. Even small amounts have a definite odor and they usually cause an operator to get out of the contaminated area. This latter incidently provided cause for an additional problem and usually ended in a lost time injury. Many times the individual would go outside for fresh air where it was too cold for his condition. He would catch cold and would come near to developing into pneumonia.

During the time this particular process was being developed, operators got used to the chlorine type odor. At this same time the self-contained breathing apparatus was not the popular item it is today. A chemical cartridge respirator was what they generally carried draped about their neck. Probably many times the trouble was located and the mask removed after the contaminated area was under control without the operators' having an exposure.

A number of times though, the capacity of the cartridge was unknowingly depleted by prior uses. Then again, the general contamination would instill in the operator the idea that his mask was O.K. when it really wasn't. The operator would then prolong his trip beyond limits and have an exposure. To sum up then an operator:

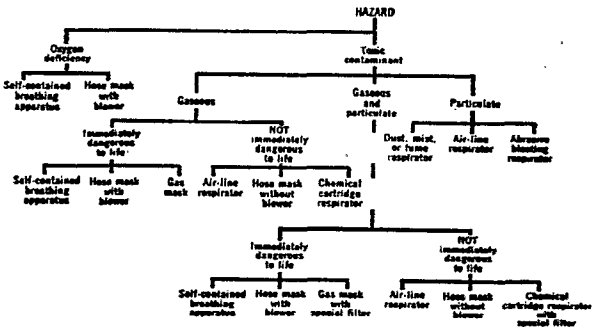
a. would not know the conditions of his mask because he was generally conditioned to the contaminant.

b. would not know the remaining capacity of the mask.

c. would realize that the mask was not working but would remain in the area thinking he could get by or hold his breath a moment longer in order to complete the job.

The second part of the problem refers to the people that do not use the equipment that is available. These are the "Smoke Eaters" or the ones that think they can chance it. Even today with the self-contained breathing apparatus available, this practice continues. I witnessed an entry to a contaminated area (FH fog).

This particular entry was made for no good reason at all. Two men were putting their self-contained breathing apparatus on and this fellow decided to go in with a handkerchief over his nose. It turned out that the men wearing self-contained breathing apparatus made the necessary emergency shutdown, ventilators soon decontaminated the area, and normal entry could be made.



1957 National Safety Congress

SOAP DUST

Our operation is essentially a soap manufacturing plant and the air in our factory is frequently contaminated with soap dust from detergents and dust arising from fine woodflour and cornmeal. We issue our employees a dust mask (not Bureau of Mines approved). The filter element consists of a honeycomb construction of whipped foam latex.

This device does a modest job of filtering, however, we have never been completely satisfied. Despite the fact that we have issued masks to all personnel about half of our personnel prefer to use an ordinary handkerchief wrapped about their face which appears to do a satisfactory job without the unpleasantness of the dust mask.

LABORATORY AND PILOT PLANT SAFETY

(A Symposium)

LABORATORY BARRICADING OF HIGH PRESSURE AND EXTRA HAZARDOUS REACTIONS

by GODFREY J. MOLL

chemical engineer, CIBA Pharmaceutical Products, Inc., Summit, N. J.

Safety engineers are often called on to formulate or approve plans for laboratories in which high pressure or extra hazardous reactions will be safely operated. In these designs the protective shield or barricade is the only fixed piece of safety equipment which will remain operable 100 per cent of the time. Equipment, instrumentation, and safety devices are all apt to fail at any time regardless of maintenance and inspection. The judgement of the best-trained operating personnel need only be wrong once. The barricade may be considered as the primary safety device.

High pressure and extra hazardous research projects are being carried out in unbarricaded laboratories in many universities and at some industrial research centers in the United States. Workers at these installations will point with pride at their perfect safety record, but tomorrow might yield their first and last accident. The management of CIBA Pharmaceutical Products Inc. of Summit, N. J., has recognized the risk involved in not barricading high pressure reactions.

Our high pressure laboratory was constructed in a built-up area presenting the problem of not only protecting the operating personnel but also the personnel of adjacent buildings from the effects of missiles and shock waves. A suitable barricade was constructed of 16-inch reinforced concrete with a reflector wall of similar construction eight feet from the frangible wall. Further protection was provided by hanging one-half inch wire rope blast mats between the building and the reflector wall, which would operate on the ballistic pendulum theory in stopping missiles and dissipating shock waves. This is but one approach to the problem of barricading.

The question often arises as to what should be considered hazardous enough to warrant the expense of barricading. Some authors feel that when equipment is installed to handle inflammable materials at pressures greater than 500 psi the use of some form of barricade should be considered. When research at high gas pressures or work on known explosives is conducted the protection of personnel and other facilities with an adequate barricade must be considered.

In small-scale flow experiments where the amount of material in process is small, it is common to use pressures as high as several thousand pounds without special barricades. Once it has been decided to build a barricade there are still many questions to be answered. The two most important as far as the barricade is concerned are the materials of construction and their thickness.

MUST KNOW MISSILE

If we knew the velocity, weight and shape of the missile and the maximum force expected from an explosion, we could design a barricade using a minimum wall thickness. Barricades must be designed to prevent penetration by large missiles at low velocity, such as reactor heads, and also small missiles at high velocity, such as tubing, nuts or other small fittings. Penetration is dependent upon the velocity of the missile at impact, the physical properties of the missile, and the characteristic of the material used to construct the barrier.

The speed of sound has been suggested as a velocity, as most objects when propelled through air decrease in velocity to the speed of sound. If missiles of higher velocity are expected, the modified Petry equation for penetration can still be used to calculate a

satisfactory wall thickness. Ballistic tests have shown that if the velocity of missile is twice that of sound, the depth of penetration is almost quadrupled. High pressure autoclave heads have sheared eight-inch "I" beams without being stopped and have penetrated as much as 40 feet into dirt embankments before being stopped.

A barricade which will prevent penetration if designed properly can withstand the blast effects of explosive gases and the shock waves of a detonation within the equipment. The thrust of an explosion should be absorbed by the main framing of the building behind the barrier and the floor of the cubicle should be of sufficient thickness and weight to resist the turning moment created by the pressure on the barricade. It is assumed that some form of frangible wall or relief area will be included in the design with a recommended minimum of five square feet of relief area for every 100 cubic feet of volume.

Many formulas have been proposed to find the resistance to penetration of various materials. Although most of them have a theoretical basis, practically all involve constants for different types of materials. The formulas which seem to be the most logical are the sectional pressure formulas. The formula proposed by Petry in 1910 with additional constants arrived at by Bazant in 1937 for more recent building materials were the standard used in British bomb shelter construction. Knowing the weight and area of contact of the largest probable missile it is possible to calculate the minimum thickness of any desirable building material to be used as a barricade.

CONSTRUCTION METHODS

There are seven basic methods of constructing effective barricades in use today:

1. Earth embankment or underground cell
2. Sand bag barrier
3. Rope or steel matting
4. Steel boiler or armour plate
5. Various sandwich-type constructions
6. Reinforced concrete
7. Protection based on the ballistic pendulum theory

Of these reinforced concrete and steel in various forms are the most widely used.

For extremely hazardous reactions the use of earthen or underground barricades provides a maximum in protection at a minimum in cost. For every eight feet of sandy soil placed between an operator and a reactor the equivalent of one foot of reinforced concrete is realized. The added cost of complete remote control operation in some instances might offset the savings afforded by the use of the natural barrier earth. The advantage of soil over the other types of materials can be realized in the construction of embankments as safety or reflector barriers to protect the surrounding area. Army and Navy Ordnance have long made use of this type of barricade.

As a temporary protective shield a three-foot thick wall of sand bags filled with dry sand cannot be beat in cost and availability. When a hazard is recognized and a shut down would cause delay of a research project, a sand bag wall would solve the problem until a more permanent installation could be constructed.

ROPE, STEEL MATS USED

The use of rope mats as protection against missiles has been practiced many years. Steel blast mats have found their maximum use as missile-proof ceilings in installations where the roof is part of the relief area. Mats are also hung a few feet away from frangible walls to deflect missiles. As an additional or auxiliary protective barrier the steel mats cannot be excelled.

Modern tanks require a minimum of five inches of steel armour plate to stop high-velocity armour piercing shells. Fortunately the missiles encountered in a normal laboratory explosion do not have a propellant to maintain their velocity and will decrease in velocity to the speed of sound in air. Steel plates may therefore vary in thickness from a quarter inch to one inch according to the severity of the hazard. Accidents involving barricades of the riveted or bolted type construction have shown that the weakness of the rivet or bolt can produce additional missiles on the operating side of the barricade.

It has been found that a continuous weld on both the inside and outside of the steel plate will provide five times the resistance to shock wave damage as a single weld on the outside. Steel panels should be fastened to angle irons or structural members that are an integral part of the building and not bolted to the concrete floor with expansion bolts which would not prevent the entire barrier from being overturned by a major explosion. Care must be exercised to prevent corrosion of the steel which would rapidly lower its effectiveness as a barricade.

Field tests performed by the Ordnance Department of the U.S. Army have shown that two steel plates with an air space in between are 20 to 30 per cent more resistant to penetration than a single plate whose thickness is equal to the two plates. This essentially is a sandwich-type construction and eliminates the necessity of bracing to increase the steel plates' resistance to shock waves. The steel plates are often welded to two-inch pipes imbedded in the concrete of the structure or to four-inch "I" beams which are part of the structural steel.

REDUCE SHOCK WAVES

By introducing dry sand into this steel sandwich it is possible to reduce the shock wave transmitted to the outer member. Other fillers which will not pour through holes drilled for control purposes have been successfully used, such as cotton batting, rope, wood, and more recently fiber glass insulation which will also contribute to the warmth of the building.

Another method of reducing the shock from flying missiles is to place a wooden barrier on the inside with the steel on the outside. This may also be filled with a desirable filler. Where space is extremely limited the entire sandwich wall can be mounted on floor casters and overhead trolleys so that it can be rolled out of the way when not required. Steel has one distinct advantage over concrete as a material of construction in that it is able to absorb about 1,600 times as much energy per unit volume; hence, enormous masses of concrete are required to provide energy capacities equivalent to steel.

During the war it was shown that massive walls of concrete do not afford unlimited protection. A test missile with a velocity of 2,000 feet per second was able to penetrate 23 feet of reinforced concrete and emerge with a residual velocity estimated at 300 feet per second. Missiles of this velocity are not likely in laboratory work, and walls of this thickness are out of the question. Many factors determine the effectiveness of reinforced concrete as protection against penetration by missiles. Concrete with a crushing strength of less than 4,000 psi should not be considered for barricade construction. To obtain resistance to penetration, one-half to three-quarter inch reinforcing rods should be placed in both faces of the wall with a maximum spacing of six inches in both a horizontal and vertical direction.

Lateral reinforcement with three-eighths to one-half inch rods on a maximum of 12 inch centers would decrease scabbing on the outside of the wall. One laboratory uses an "anti-scabbing" plate of steel on the operating side to guard against spalling. Welding at all intersections would provide additional protection against penetration. Data from the Bureau of Yards and Docks on the use of reinforced concrete is included in the Appendix.

There is a wide spread of opinion as to what is an adequate barricade, which is evidenced in the manner in which the various laboratories have constructed their barricades. The type of research conducted determines the best type of barricade to use. One research laboratory has an extremely flexible system using one-half inch steel plate as the barrier. The high pressure equipment is mounted on a one-half inch steel plate welded to two pieces of six inch channel iron to which a front one-half inch steel plate is welded and braced. This assembly is placed into a cubicle which has a frangible wall and relief type ceiling.

The necessary facilities are connected from the outside through steel overhead hatches. The front panel is fastened rigidly only at the top which in case of an explosion will allow the unit to take advantage of the ballistic pendulum theory developed by Robins in 1740. This flexibility allows the shock wave time to burst the frangible wall without creating undue stresses in the barricade wall.

Having established a satisfactory method of barricading a reactor, care must be taken not to reduce the effectiveness when introducing the remote control systems necessary for operation. Openings for tubing, control rods, visual inspection, and other

necessary breaches of the barrier must be engineered so as not to weaken the wall. If the method of entry to the hazardous area is to be through the barricade wall, the closure used, whether it be a sliding or swinging door, should be designed to withstand the same conditions as the barricade itself. Baffled entries leading into an operating area have not proven satisfactory for stopping or dissipating blast waves which are not affected by turning corners. It takes only about one pound per square inch to hurl a person about and at seven pounds per square inch the ear drums are fractured.

LOOSE ITEMS DANGEROUS

The hanging of control instruments and other accessory equipment on the outside of a barricade wall has proven to be a dangerous condition. Shock waves passing through the wall are transmitted to these relatively loose items casting them about the operating area. If at all possible the barrier wall should serve only one function and that is to protect the operating personnel. It should not be weakened by drilling and tapping to support items which could be easily supported in other ways.

The physical location of the high pressure or extra hazardous laboratory will determine the type of construction and the need for a safety or reflector wall. Regardless of the amount of open space behind the frangible wall the hanging of a steel blast mat curtain or the forming of an embankment should be considered to protect personnel who might accidentally wander into this area. When a laboratory is located in a built-up area the reflector wall should be at least as heavy as the barricade itself.

Barricades are too often based on the make-it-big and make-it-thick principle. If the operators of high pressure and extra hazardous laboratories would pool their accident histories, it would be possible to evaluate the various barricade designs and check the validity of the application of ballistic information on missile penetration.

APPENDIX

Sand Bag Walls—Filled sand bags are 20 inches by 10 inches by five inches and contain one-half cubic foot of sand. These walls require about 40 to 50 bags per foot of length.

Proportions, Strength Requirements for Portland Cement Concrete

Nominal Mix	Minimum resistance to crushing (cube strength) in lb/in² within 28 days after mixing	
	Preliminary	*Works*
1:1:2	5250	4500

Concrete (1)	0.00799
Limestone	0.00538
Reinforced concrete (2)	0.00476
Specially-reinforced concrete (3)	0.00282

1. Mass concrete with a crushing strength of 2,200 psi
2. Normal reinforced concrete with a crushing strength of 3,200 psi and a 1.4 per cent of reinforcement
3. Specially-reinforced concrete with a crushing strength of 5,700 psi and 1.4 per cent of reinforcement.

When calculating the depth of penetration, D, the effect of relative thickness must be considered. If the barricade thickness is only 2D, the wall will be penetrated. The thickness must be not less than 3D to prevent penetration.

Various Barricades Used by Industrial Research Laboratories

Steel

1. 3/8-inch all welded steel plate with 2 x 2 x 1/4-inch angle iron stiffeners welded with 3-inch welds every 6 inches.
2. 1/2-inch steel plate fastened at the top and weighted-down by the weight of the reactor attached to a steel platform welded to the front plate and braced by angle irons.

Steel and Wood

3. 1/2-inch steel plate with 3/4-inch plywood fastened to inside wall.

Double Steel

4. 1/4-inch steel plates welded to 4-inch "I" beams, no filler.

Double Steel, Sand-filled

5. 3/8-inch steel plate inside and 1/4-inch steel outside welded to 4-inch "I" beams with space in between filled with dry sand.

Steel, Wood, and Sand

6. 1/2-inch steel plate with 2-inches of wood on the inside and 4 inches of sand in between.

Reinforced Concrete

7. 8-inch reinforced concrete.
8. 12-inch reinforced concrete, two companies.
9. 12-inch concrete with 3/4-inch steel reinforcing rods on 6-inch centers, both horizontally and vertically in both faces of wall.
10. Same, except with 1/2-inch steel rods.
11. 16-inch concrete with 1/2-inch steel reinforcing rods on 6-inch centers, both horizontally and vertically in both faces of wall. 3 companies.
12. Same, except with 3/4-inch rods on 4-inch centers, and lateral reinforcement with 3/8-inch rods on 12-inch centers.
13. 18-inch reinforced concrete.

Reinforced Concrete and Steel

14. 18-inch reinforced steel with a steel plate on the operating side to prevent injury from scabbing.

FLAMMABLE MATERIALS—SYSTEM FOR RATING

by **WILLIAM S. WOOD**

safety engineer, research and development dept., Sun Oil co., Marcus Hook, Pa.

The purposes of this committee as set up last spring were as follows:

1. To review published information on flammable materials.
2. To collect ideas from the members of the laboratory subsection by means of a questionnaire.
3. To present information on flammable materials as applied to laboratory and pilot plants.
4. To study the definition of flammable hazard in the hope of improving standards of use in laboratories.

This last objective could permit the most realistic recognition of flammable hazards in laboratories and lead to better control of amounts, improved procedures for safe use and the optimum in protective measures.

Perhaps the most promising approach is that taken by the National Fire Protection Assoc. Committee on Classification of Materials under the chairmanship of J. Sharp Queener. The three part proposed classification system is briefly outlined at the bottom of the page.

A questionnaire was made up by the committee to find out how laboratory safety men evaluate the flammable hazard of materials frequently found in their areas of work. About 150 questionnaires were mailed out and 30 were returned answered. A few declined to answer because of insufficient experience. Others were unwilling to answer the questions as presented and expressed their reasons.

A number of notes and comments on the questions and their answers are listed following the question. These remarks were perhaps the most important gain from this effort.

NEW NFPA COMM. ON CLASSIFICATION OF MATERIALS

Flash Point & Vapor Pressure	*Stability*	*Health Hazard*
1. Flash above 140°F	1. Normally stable	1. Low hazard. No injury if no treatment is given.
2. Flash 100-140°F	2. Reactive with strong contaminant or catalyst.	2. Light hazard. Minor injury if no treatment is given.
3. Flash 73-100°F	3. Reactive with contaminants including water. Self reactive at elevated temperature or pressure.	3. Major injury if no treatment is given.
4. Flash below 73°F a. BP over 100°F or RVP below 14.7. b. BP under 100°F or RVP above 14.7.	4. Detonate with shock.	4. Major injury in spite of prompt treatment.

QUESTIONNAIRE ON FLAMMABLE MATERIALS

1. Please indicate below in order of importance the factors you consider in evaluating the flammability hazard of a material.

	Gas			*Liquid*			*Solid*		
	1st	*2nd*	*3rd*	*1st*	*2nd*	*3rd*	*1st*	*2nd*	*3rd*
Flash Point	3	2	2	16	4	1		4	
Fire Point		1			4	2	4		1
Vapor Pressure	1			2	9	2	1		2
Lower Flammable (Explosive) Limit	13	5	2	2	4	6	1	1	1
Upper Flammable (Explosive) Limit		6	2			2			
Spread of Flammable Limit	3	3	2		4				
Autoignition Temperature	3	3	5	3	1	3	5	2	2
Vapor Density		2	3		1	1			
Boiling Point					1				
Melting Point								1	1
Water Solubility						1			
Particle Size								5	3
Special Properties									
Impact Sensitivity	1			2			4	2	2
Spontaneous Heating					2		2	2	2
Friction Ignition		1	3					2	
Ignition by Moisture Absorption						1	1	1	2
Spontaneous Ignition in Air	1		3				4	2	3
Ignition by Moderate Heating		2				3		1	5
Other (Specify)									
Compatability with other chemicals									
Decomposition during storage									
Means of fire fighting									
Rate of flame spread									
Toxicity									

Comments: The order of importance varies with material and also with environmental circumstances. The relative importance of a characteristic depends on its test value. NFPA Committee on Classification of Materials had 35 hazard characteristics.

2. In your laboratory, do you limit quantities of flammable materials on the basis of items marked in (1)? Yes 25 No 2

	Single factor	*Combination*
a. In laboratory areas	10	15
b. In process in glass	5	9
c. In process in pilot plants	1	7

If combination, give an example showing relationship.

Comments:

—Limit solvents in glass to 1 quart.

—Generally keep less than 1 liter of volatile materials.

—Limit solvents in safety cans to five gallons.

—Five gallon limit—avoid five gallons in glass where possible.

—Limitation based on amount of damage possible if all of the material were to catch fire.

—Should be limited, usually on a combination of factors but occasionally on one outstanding.

—NFPA classification (which?)

—Would allow methanol in dry ice traps in areas not explosion proof since the methanol temperature would be below the flash point.

—Due to nature of work we must disregard lower explosive limit and provide more than adequate ventilation.

—Sodium, metal hydrides, aluminum alkyls, sodium amide and extremely toxic materials are segregated.

—Raney nickel in glycol is not hazardous, in acetone it is a great hazard.

3. Do you specify safety cans or other containers for use in laboratories based on the properties indicated in (1)?

Yes 23 No 3
Single factor 13
Combination 10

Comments:

—No Class I or II liquid in glass larger than one quart.

—Original suppliers metal containers not larger than five gallon.

—All solvents must be stored in safety cans.

—Safety cans specified for more volatile flammable liquids, acetone, ethyl acetate, etc.

—Should require safety cans for larger quantities. Small amounts in glass or plastic may be justified to avoid contamination.

—Specified in some cases for large quantities.

—Containers specified primarily for insurance and toxicity reasons—based on volume of use.

4. Do you provide special or additional fire equipment based on the properties indicated in (1)? Yes 20 NO 5

Single factor 5
Combination 15

Comments:

—Provide automatic dry chemical units in hoods where 5-12 liters of flammables are used.

—Combination of extinguishers for various materials.

—Provided on basis of flammability and reactivity of the chemical with the extinguishing agent.

CO_2 extinguishers used throughout. May be supplemented by dry chemical or powdered sand for metals.

5. On what basis do you specify Class I Group D electrical equipment in areas where flammable materials are used?

Do not specify 3
Do specify 22

Comments:

—National Electrical Code, Article 500.

—Local state laws.

—Plant standards.

—For all test cells from floor level to about four feet.

—Where Class I flammables are used or stored.

—Where Class I or II flammables are used or stored.

—Where extremely flammable materials are to be used.

Where high vapor pressure, low explosive limit gases or solvents are used.

—where highly flammable liquids or gases are customarily used.

—Where flammable vapors may be present in the atmosphere.

—Where large quantities of volatile flammables are used.

—Where oxidizing or flammable metal powders are used.

—Quantity of gases and liquids and degree of hazard in (1).

—Where spills will occur.

Each area analyzed separately and classification made on basis of all factors considered in (1).

—All centrifuges and vacuum pumps are equipped with explosion proof motors so they can be used anywhere.

6. How would you rate the following with regard to flammable hazard? Check in proper column.

Gases	*Extreme Hazard*	*High Hazard*	*Moderate Hazard*
Acetylene	21	7	2
Ammonia	—	3	27
Butadiene	11	11	7
Carbon Monoxide	5	14	10
Coal Gas	4	17	4
Ethylene	7	18	3
Hydrogen	24	6	1
Hydrogen Sulfide	9	5	15
Methane	2	17	6
Oxygen	5	8	9
Propane	5	15	5

General Comments: (apply to gases, liquids and solids)

—NFPA Committee on Classification of Materials has four categories.

—Hazard depends on circumstances of use.

—An explosives laboratory considered that none represents more than moderate hazard assuming (1) Control of quantity. (2) Skilled and trained personnel and (3) Proper laboratory equipment.

7. How would you rate the following with regard to flammable hazard?

Liquids	*Extreme Hazard*	*High Hazard*	*Moderate Hazard*
Acetic Acid (Glacial)	—	4	25
Acetone	8	15	8
Benzene	7	18	6
Carbon Disulfide	22	7	1
Cellosolve	—	8	21
Cyclohexane	7	14	7
Diethyl Ether	21	6	3
Ethyl Alcohol	1	13	17
Gasolune	10	14	7
Isopropyl Alcohol	1	11	17
Kerosine	—	2	29
Methyl Alcohol	3	14	14
Methyl-ethyl-ketone	3	19	8
n-Hexane	6	18	6
Oleic Acid	—	—	25
Stoddard Solvent	—	6	22
Turpentine	—	4	22

Comments:

—Low hazard category designated by one respondent for 10 liquids including MEK.

—Very moderate hazard designated by another for cellosolve, cyclohexane, kerosine, oleic acid.

—Alcohols, methyl, ethyl and isopropyl were considered extremely hazardous because of flammable limits.

8. How would you rate the following with regard to flammable hazard?

Solids	*Extreme Hazard*	*High Hazard*	*Moderate Hazard*
Benzoyl Peroxide	18	6	4
Cellulose Nitrate	15	9	3
Excelsior	1	7	18
Li Al Hydride	12	9	3
Lithium	8	12	4
Magnesium Chips	4	16	7
Paraffin Wax	—	2	23
Phosphorus Yellow	14	4	5
Potassium	16	10	2
Raney Nickel	8	13	2
Sodium	14	11	2
Sulfur	—	6	21

Comments:

Cellulose Nitrate Dry—extreme hazard
Wet—moderate hazard

General comments on the entire questionnaire.

Cannot be rated without knowing conditions of use. The questionnaire showed how little we knew about properties of hazardous materials. Most standards are based on NFPA recommendations. One NFPA subcommittee is covering "dangerous reactions."

Demonstration of flammable hazard of alcohols suggested. (Put alcohol on rag, place in can, shake, ignite.)

Conclusions from results of the questionnaire.

Although flash point and flammable (explosive) limits are the most widely accepted criteria of flammability, most people take other properties into consideration as well.

Sometimes one particular property other than flash point will carry great weight as for example, shock sensitivity, reaction with water, spontaneous ignition or low ignition temperature.

Notations as the questionnaires returned showed that knowledge of the environmental conditions and of the properties of the individual material are essential to the proper evaluation of flammable hazard.

Some answers indicated a lack of information about the properties of materials and also an insufficient grasp of the significance of the properties listed in literature. Laboratory safety men need the best in educational background, adequate information sources and then constant study to prepare them to do an adequate job.

Recommendations:

I suggest that this committee be continued and that it work closely with others such as the NFPA Committee on Classification of Materials contributing such ideas as may stem from laboratory experience.

To this end a complete bibliography and library of information on classification systems should be maintained as a service to the subsection. Information on new compounds and materials should be sent to the committee for general reference or distribution.

Another suggested activity is the collection from many people in the laboratory subsection of accounts of fires they have had involving flammable materials. Large or small they would help instruct all of us in proper measures for fire prevention and extinguishment.▲

TOXIC CHEMICALS

by R. V. MONTELLO

Research division, National Cash Register co., Dayton, Ohio

We do not have to let them die!

Many millions of man-hours with no lost time due to serious injuries to employees are being worked in one of the most hazardous occupations of all times, the field of atomic energy. This is possible only because the hazards are recognized and the proper precautions to preserve human life are faithfully observed.

Great strides have been made in overcoming many occupational diseases which a few years ago due to a lack of safety knowledge meant a serious loss of health and even death.

This improvement has come about not without much personal effort on the part of many individuals either singly or through committee action.

The laboratory sub-section of the Chemical Section of the National Safety Council has appointed a new committee to study the problem of Toxic Chemicals. The members of this committee are John E. Fox, Monsanto Chemical company, Texas City, Texas; Robert A. Quisno, Hill Top Research Institute, Inc., Miamiville, Ohio; and Ralph V. Montello, National Cash Register company, Dayton, Ohio.

INFORMATION DECENTRALIZED

Today there is much good and useful information on the toxicology of dangerous chemical materials. The unfortunate part is that this information is not available in any one place. Talk to any two people on the subject of toxicology and you soon realize that each will have some different source of information about dangerous chemicals. A study of the availability of information regarding the hazards of chemicals used in the chemical laboratory or pilot areas shows a rather varied list of sources for this type of information.

Virtually every technical magazine features articles from time to time on some hazardous chemical or process which yields hazardous chemical by-products. A check on the number of scientific magazines estimated by one librarian revealed 50,000 current world-wide publications. When we consider the field of insecticides, pesticides and herbicides, we find important safety articles in magazines that are distributed in the suburban and farm home.

If we move over to the field of paints and organic coatings and finishes, we find in addition to the technical magazines, interesting articles in such magazines as the *Ladies Home Journal*. Countless articles covering a wide number of hazardous chemicals are published by various governmental agencies. It is indeed fortunate that manufacturers of new chemical products both raw and finished materials go to great lengths to thoroughly analyze their products to obtain toxicological data.

COLLEAGUES EXCHANGE NOTES

This information is available through the manufacturer and may not appear in published form anywhere else. The practice of writing to a colleague with particular experience in the field of the new chemical is believed to be widespread. Supplementing all this information on dangerous chemicals with books on specific fields like the solvents, with the many excellent safety articles in safety magazines, and with the wealth of unpublished information in private, university, and industrial laboratories, we are impressed with the formidable task required to be well informed on toxic chemicals.

The tremendous growth of chemical research in recent years has created an expanding field of industrial toxicology. One author estimated that more money was spent on chemical research in the past eight years than was spent in all of the rest of this century.

This committee aims to cooperate with all persons promoting safety in the use of toxic chemicals so that the hazards of these materials to human health can be recognized and proper protection used to meet these hazards in the most efficient manner.

Deciding which chemicals are toxic and those that are not depends upon the definition one chooses. *Webster's* dictionary, for instance, defines the word, toxic, as "1. of, pertaining to, or caused by poison or a toxin 2. Affected by a toxin 3. Poisonous."

Handbook of Dangerous Materials by Sax lists "toxicity as the sum total of all harmful effects upon a warm-blooded animal." It goes on further to explain that "toxicology is the study of the manner in which these toxic materials produce their poisonous effects on the body."

VARIED DEFINITIONS

In the new, completely revised and enlarged edition of the *Handbook of Dangerous Materials* by Sax which is entitled "Dangerous Properties of Industrial Materials" toxicity is defined as "The ability of a chemical molecule or compound to produce injury once it reaches a susceptible site in or on the body."

It goes on to state that "Toxicity hazard is the probability that injury may be caused by the manner in which the substance is used." The new definition of toxicology is: "In simple terms, toxicology may be defined as the study of the action of poisons on the living organism. Industrial toxicology is concerned with the human organism and consequently lies within the broad field of medicine. Since medicine cannot be considered an exact science in the same sense as chemistry, physics or mathematics, toxicologic phenomena cannot always be predicted with accuracy or explained on the basis of physical or chemical laws. It is this unpredictability which frequently reduces conclusions and decisions to opinion rather than fact."

The Manufacturing Chemists' Association states in their Manual L-1, under Warning Labels, "POISON—A chemical or mixture of chemicals which falls within any of the following categories:

a. Produces death within 48 hours in half of a group of 10 or more laboratory white rats weighing 200-300 grams at a single dose of 50 milligrams or less per kilogram of body weight, when administered orally; or

b. Produces death within 48 hours in half or more than half of a group of 10 or more laboratory white rats weighing 200-300 grams, when inhaled continuously for a period of one hour or less at an atmospheric concentration of two milligrams or less per liter of gas, vapor, mist, or dust, provided such concentration is likely to be encountered by man when the chemical product is used in any reasonably foreseeable manner; or

c. Produces death within 48 hours in half or more than half of a group of 10 or more rabbits tested in a dosage of 200 milligrams or less per kilogram body weight, when administered by continuous contact with the bare skin for 24 hours or less."

The writer has associated toxic chemicals as those materials which enter the body by the nose, mouth, or skin and produce an adverse effect on the blood composition. This change in blood composition is such that the vital organs (liver, heart, kidneys, etc.) are restricted in performing their life-giving functions and death can result.

TOXIC CHEMICALS ABSORBED

If the above can occur to the operator through absorption into the body by any chemical handled in a routine fashion which is normal for that class of chemical materials generally considered non-toxic, then the material is a toxic chemical.

The committee has received many valuable suggestions on areas of interest to our subject.

One letter suggested that a large compilation of references on toxic chemicals available to all interested persons would serve immeasurably to further the cause of safety in the chemical field. There is so much new information being printed that the books that we have become accustomed to using are soon out of date. Work has already started on this idea. A list of references has been compiled and is available. While the list is extensive, it is not believed to be complete.

Another letter suggested an index of toxic chemicals. Such an index may be a refinement of just a straight-forward compilation as suggested in the first letter above. The references could be catalogued according to the chemical name, the common name, or perhaps by the type of industry in which the laboratory or pilot plant is associated.

PUBLISH CASE HISTORIES

Still another letter recommended publishing actual case histories of the misuse of toxic chemicals and their results. Since the same toxic chemicals are used in many laboratories or pilot plants, it would no doubt be worthwhile to make available information of this kind.

Setting up a toxicology chart was another idea received. This chart could contain columns giving the name of the toxic material, maximum allowable concentration, appearance, the type of operation where this material would be used, how it is absorbed by the body, the symptoms, first aid and the safe way to use the chemical.

These are all good ideas but your committee on Toxic Chemicals needs more information both on an expansion of the preceding ideas listed as well as new ones.

It is the responsibility and moral obligation of each of us to do what we can to further the cause of safe practices which will prevent suffering and the loss of human life. Please send your ideas on the use of toxic chemicals to R. V. Montello, Research Division, National Cash Register Company, Dayton 9, Ohio.▲

A BIBLIOGRAPHY OF TOXIC CHEMICALS

Prepared by: Toxic Chemicals Committee, Laboratory and Pilot Plant Group, Chemical Section of the National Safety Council

This compilation of references on toxic chemicals is made possible through the cooperation of the following committee members: John E. Fox, safety director of the Monsanto Chemical co., Texas City, Tex.; Robert A. Quisno, president, Hill Top Research Institute, Inc., Miamiville, Ohio and Ralph V. Montello, head, materials dept., Research Div., National Cash Register Co., Dayton, Ohio. Assistance was also given by J. B. Black, department of health, education, and welfare; A. H. Christian, American Viscose Corp.; H. H. Fawcett, General Electric Co.; and J. N. Romine, Phillips Petroleum Co.

The scope of this work is aimed at presenting a list of references on the toxic chemicals useful to members of the chemical industry. It covers books and periodicals.

WASTE DISPOSAL

by **EARL R. WALLACE**
senior safety engineer, Eastman Kodak co., Rochester, N. Y.

Editor's Note: The information presented in the following "summary of waste disposal questionnaire" should not be construed as recommended procedures. Many of the methods reported are not in keeping with safe standards. The summary was presented primarily as a beginning of committee activity to develop a good, recommended safe disposal data sheet or recommended procedures which could be used by all industries.

In order to report to you on the subject of waste disposal, a questionnaire was sent out asking for information dealing with waste disposal methods throughout the mailing list of the Laboratory Subsection. Approximately 50 corporations are represented in our mailing list and of this group 36 companies answered the inquiry.

Many of the companies who answered the questionnaire indicated the definite need for assistance, and it is my hope that this group can, through the ensuing discussion, come up with information which can be presented to industry at large as a published report through the National Safety Council's Chemical Section.

Dealing with, first, flammable liquid disposal, we find that more companies are using the incinerator method of disposal than ever before. This method may vary in its actual application, but, in general, the system operates by using an oil burner nozzle in the combustion chamber through which the flammable liquids are vaporized and burned.

Many flammable liquids can be redistilled for recovery at a fairly nominal cost thereby providing a continuing source of material for reuse or sale.

Open field burning of flammable liquids is used by many, although it is felt by some that this system presents hazards which might best be removed. The hazards of premature ignition, of odd winds and of smoke, are among those to be considered.

Today, with the high rate of community growth, indications are that available space for open field burning will be lessened considerably in the near future.

Certain groups bury flammable liquids and here, I think, we might make a note for general discussion later in the program to determine if possible the hazards of burial of flammable liquids.

Plant sewer disposal of flammable liquids is used by many, but most of those have indicated that only water miscible materials are so disposed and always with copious quantities of water.

Radioactive wastes are presenting problems to many today who, a short time ago, had no idea such a problem would exist. In this case, the best source of adequate information on disposal, we believe, is the Atomic Energy Commission.

Rivers are not used for frequent disposal of any industrial waste by nearly all plants reporting. Most plant waste water systems are operated today on the basis of well engineered and controlled systems where harmful materials (to fish, wild life, and humans) are removed. Treatment plants for industry are proving themselves valuable additions to the company's holdings.

Many hundreds of organic and other materials were forwarded with the questionnaire together with other valuable information which we hope will prove to be of some later value to our groups and others.

ACIDS AND HEAVY CHEMICALS

Discussion Report

R. L. ALLINSON—Discussion Leader

director of safety, Texas div., The Dow Chemical co., Freeport, Tex.

The first subject was presented by a gentleman who had asked in last year's meeting if the group felt it was reasonably safe to transfer strong acids from carboys by using air pressure. The reaction of the group at that time was negative and the gentleman on this occasion described a new system he had since set up that still utilized compressed air.

This system has a gauge in the line, then a valve, next a pressure regulator set at 2.5 pounds, then a 3/8 in. T in the line with one opening venting air to the atmosphere. The line then goes through the stopper into the canvas covered carboy but also has a leg going into a mercury seal that is an additional safety and will blow at 5 lbs. This rig is operated by the simple method of "thumbing" the small open T while visually watching the flow of acid from a dip pipe.

Another man attending suggested the use of Thompson hand pumps for this service.

The next question was on fire fighting techniques on fires around or involving storage of chlorosulphonic acid. There was no one present familiar with this problem and it was suggested that the DuPont company might be able to help.

USE OF LARGE HOSES

A discussion on the use of large hoses brought out the following points:

1. This is a specialized field because of the variety of services but in general, we have learned to use the best available for the specific purpose.
2. In attaching hoses to flanged nozzles it is wise to secure clamps to flange by steel straps.
3. The use of hose made with the rubber flanges vulcanized in place was recommended.
4. High pressure testing of hoses is practiced. There was no sure answer to the question, does this weaken the hose?

The next question dealt with the affect of ammonium nitrate on steel cables. This man has guy lines on large towers that are being deteriorated by ammonium nitrate fumes. No one present knew of anything easy to apply that would protect the steel. Coverings of rubber or plastic were suggested.

The next discussion subject was snap-on or quick couplings for small hoses. This apparently is not a problem in most plants represented. Those who did use a good many quick couplings said it is best to confine specific makes and types of couplings to specific uses to eliminate the danger of using hazardous materials in equipment and tools operated by water or air.

In answer to a question on new loading racks, one man stated that they had installed a Nichols rack and were well-pleased with it.

The next series of questioning dealt with *phenol*:

Question—any experience of fires where substantial quantities of phenol are involved?

Answer—no experience.

Question—are two people desirable in unloading phenol?

Answer—yes.

Question—is ethyl alcohol being used for first aid?

Answer—no—water is best first aid for this.

The next question resulted from the above and was, "Do any medical people recommend the neutralization method in field first aid on chemical burns?" No one present knew of any medical doctor that recommended anything other than water.

The subject of heating water for eyebaths and safety showers was discussed briefly. Tracing with steam and resistance heaters was suggested as well as holding tanks with regulated heat.

The techniques of fighting fires in bulk ammonium nitrate was discussed. There was little experience evidenced on this but *simple water extinguishment* was suggested.

Radiation was introduced but the group as a whole had little experience as yet in the use of radiation sources. One man explained the use of an elementary educational plan for employees that is available from A.E.C. The point was also made that the technical people who actually use the sources are the ones most apt to become injured due to familiarity.

One simple little test of use to people not too familiar with solvents was mentioned. This was the old trick of putting some solvent in water to determine if it is *chlorinated. If it does not float, it is chlorinated.*

The next question was on the use of electronic guards for machinery. There were several affirmative answers and the feeling was that most applications had worked out very well at a reasonable cost.

The next question was on the use of capacitance probe. These are used a good deal and no hazards were reported in their use.

Returning momentarily to radiation, one man stated that they had discovered that *through a periodic (four times a year)* dental X-ray of some employees, these people were receiving more than the recommended amount of radiation.

Floor grating was the next subject. Very few thought that common checker plate was much good. The new plate with embedded abrasives seems *to work well; others* recommend plates with beads welded on them for stair treads. Some of the adhering abrasives are good but need replacing periodically.

A new method is to punch plates with small holes and then invert the plate. It was also mentioned that twisted rod was superior to round stock for ladder rungs. Someone stated that they used reinforcing steel for rungs. Welding characteristics might be a problem here.

Life jackets for use around water were discussed next. Evidently not much exposure represented except some barge loading. In most cases jackets were available here and sometimes their wearing was compulsory.

The next question was on the availability of "break-away aprons." By this was meant *a chemical resistant apron that could be* ripped off easily. No one knew of any commercially available▲

INDUSTRIAL GASES DISCUSSION GROUP

H. F. REINHARD, Discussion Leader
manager, Safety Codes dept., Union Carbide & Carbon corp., New York city

The meeting opened with a brief resume of the notes from last year's meeting. Some of the important safe practices mentioned in these notes were re-emphasized.

The compressed gas industry has been interested from the beginning in the safety of people who handle and use its products. The Compressed Gas Assn. and several other associations such as the National Safety Council, Manufacturing Chemists Assn., National Fire Protection Assn., National Board of Fire Underwriters, International Acetylene Assn. and The Chlorine Institute publish pamphlets on the safe handling of compressed gases. A list of 35 commonly used pamphlets published by these associations was circulated among the group. During the past year, the National Safety Council revised and reissued its Safe Practice Pamphlet 95 entitled "Compressed Gases."

Compressed gas cylinders are safe containers provided they are handled with reasonable care. Valve protection caps, if provided, should be on the cylinders hand-tight except when the cylinder is in use. Also, cylinders should not be dropped with great force on hard surfaces. Several pictures of special pallets, troughs and other devices used for the safe handling of cylinders in plants were circulated. Some of these pictures appeared in the article "Safe Practices for Handling Compressed Gases" by Messrs. H. F. Reinhard and F. R. Fetherston, published in the October issue of Industrial and Engineering Chemistry.

SULPHUR DIOXIDE FACTS

A participant asked if there is any new data on the toxicity or physiological effects of sulphur dioxide. The MAC for SO_2 which is the maximum concentration that can be safely endured for eight-hour periods is about 10 parts per million. Although he was unable to obtain a reading of one part per million in his plant, the employees complained of headaches, nausea, sore throat, etc. Since the SO_2 concentration in his plant was far below the MAC, the group felt that other factors must be responsible for the discomfort of the employees in his plant.

There is no special cylinder valve outlet thread for breathing air. The outlet connections described in American Standard B 57.1 are arranged so that each connection is used for a group of gases rather than for an individual gas. The exception to this rule is Connection 540 (.903"—14-R.H.—ext.) which is used only for oxygen, industrial and medical. Connection 580 which is recommended for water pumped (breathing) air, is also used for argon, helium, crypton, neon, nitrogen and Xenon when water-pumped.

Fetherston suggested that people interested in using small breathing air cylinders for deep sea diving etc., consider the adoption of the pin index system as used on small medical gas cylinders equipped with standard flush outlet cylinder valves. Two holes are drilled in the valve at specified locations for the particular gas that is in the cylinder. Matching pins are installed in the yoke connection so that only a matching yoke may be connected to a particular valve. The present system provides pin locations for eight different medical gases.

The familiar question of rocketing cylinders was raised. It was revealed that industry experience over the past 15 years includes only two or three instances where high pressure non-liquefied gas cylinders had apparently rocketed. The last instance occurred in Norway, a year or two ago. A cylinder valve is installed in such a way that it will shear off when struck with a sharp blow, leaving the valve inlet in the cylinder. The hole in the valve inlet is small, usually 3/16 to 1/4" which restricts the flow of gas so that the cylinder may move but will not rocket. However, the escaping gas or moving cylinder may injure nearby personnel and therefore, it is strongly recommended that valve protection caps be kept in place on the cylinders except when in use.

The question was asked if the functioning of a safety device would cause a cylinder to move. On high pressure industrial cylinders, the safety device discharge ports are designed so the flow of gas produces opposing forces. Thus a cylinder may fall over or move when a safety device functions but it will not cause dangerous propulsion. Acetylene and other low pressure cylinders will not move. However, the group agreed that cylinders should be secured at all times.

In handling a flammable gas cylinder which is involved in a fire, it is recommended that general fire fighting principles be followed. First, evacuate all personnel except those actively engaged in controlling the fire. Second, use water to cool exposed materials and the cylinder. If the flame is impinging upon structural steel or another cylinder, use a hose stream or other method to move the cylinder so that the flame does not impinge upon the steel or other cylinder. Do not extinguish the flame unless the flow of gas can be shut off because the escaping flammable gas might cause an explosive mixture which is to be feared far more than the burning of gas from a functioned safety device.

If a cylinder is involved in a fire, the user should bring this fact to the attention of the owner by attaching a tag to the cylinder valve. Fire might weaken the cylinder wall and therefore, the ICC requires that all fire damaged cylinders be retested before being charged with gas. Above all, do not try to hide the fact that a cylinder has been fire damaged by painting it.

Most compressed gas cylinders with the exception of acetylene must be periodically tested or inspected to requalify them for service. Oxygen and other high pressure cylinders are subjected to a non destructive hydrostatic test in such a manner that the permanent expansion resulting from the hydro test is measured. If the permanent expansion is below a certain limit the cylinder is suitable for continued use. Cylinders are not discarded or removed from service after a specified number of years. As long as a cylinder can pass the retest requirements it remains in service.

HELIUM IN "AIR" CYLINDER

"Is there a chance of getting nitrogen or other gas in a certified breathing air cylinder purchased with self contained breathing apparatus?" was asked. One member of the group reported that in 20 years experience of using several cylinders a year, only one such mistake had occurred. In this case the "air" cylinder was filled with helium.

Howard H. Fawcett, who presented a paper, "Living in the Air We Breathe," at the Chemical section of the Congress, mentioned that a similar mistake was made a short time ago. He recommended that "no cylinder should be put on a demand breathing apparatus or air supplied respirator, hood or suit, until the contents have been checked for purity." An orsat gas analyzer, or a Beckman paramagnetic oxygen analyzer are often used for this purpose.

A discussion on color coding of cylinders resulted from a request for information on color coding of cylinders in international service. The group indicated that color coding of cylinders was not desirable for many reasons including the fact there are more than 100 different compressed gases used in industry making it necessary to use up to four different colors on each cylinder. The only positive way to identify the contents of a cylinder is by the name of the gas printed on the label.

LIQUID OXYGEN CODE

Receiving departments should check cylinders as they are unloaded to be sure that the label is legible and intact on the cylinder. Unlabeled cylinders should be returned to the supplier without using the contents. Cylinders in international service should be labeled with both the name of the gas in the language of the country of origin and the chemical symbol of the gas. Details for labeling of cylinders are described in American Standard Z48.1 "Method of Marking Portable Compressed Gas Containers to Identify the Material Contained." This standard is available from the Compressed Gas Assn., 11 West 42 Street, New York, N. Y.

At last year's meeting of this group, a member of the missile industry pointed

out that liquid oxygen is commonly referred to as LOX in the Missile and Rocket Industry. The oxygen manufacturers were not aware of this practice but felt that it should be discouraged because for many years the term LOX has stood for liquid oxygen explosives in which liquid oxygen is only a part. Also, tanks, sold under such trade names as LOX and LOXETTE, may be used for the storage and handling of many liquefied gases such as oxygen, nitrogen, argon, hydrogen, etc.

At that meeting the group suggested that the secretary of the International Acetylene Assn. take steps to discourage this usage. The secretary of the IAA wrote several letters to principals of the Rocket and Missile Industry. A safety engineer in the Air Force read the minutes of last year's meeting in the Chemical Section Safety Newsletter and contacted the IAA. Through his efforts, the Air Force has taken steps to discontinue the use of the term LOX. This was reported in the October 1957 issue of Missiles and Rockets in an article entitled "Liquid Oxygen Replaces LOX Abbreviation in USAF."

The Air Force is undertaking this action to prevent dangerous and possibly disastrous results of the use of the term LOX for liquid oxygen. The term LOX will be deleted from all USAF technical orders and contracts including re-identification to the Department of Defense that it also take steps to abolish the use of the term LOX.

A member of the group reported they had received a full tank car of helium, compressed in long tubes manifolded together. In attempting to open the single outlet valve, they twisted the stem off. He wanted to know how to release the pressure. It was the group's recommendation that the gas supplier be contacted in any case where the valve is found to be inoperative, whether it be on a tank car or individual cylinder.

OFFICERS OF THE

CHEMICAL SECTION

NATIONAL SAFETY COUNCIL 1957-58

General Chairman—CARROLL A. HEBERT, Ethyl corp., Baton Rouge, La.

Vice-Chairman in Charge of Program—R. L. ALLINSON, The Dow Chemical co., Texas Div., Freeport, Tex.

Secretary—A. B. RITTER, Hercules Powder co., Wilmington, Del.

Newsletter Committee: E. G. MEITER, Chairman, Employers' Mutuals of Wausau, Milwaukee, Wis.; A. H. CHRISTIAN, American Viscose corp., Philadelphia, Pa.; J. T. TROLINGER, Nitrogen Div., Allied Chemical & Dye corp., Hopewell, Va.; FRED LORENTZ, Hoffman-Laroche, Inc., Nutley, N. J.

Engineering Committee: H. F. REINHARD, Chairman, Union Carbide and Carbon corp., New York, N. Y.; F. C. GAUGUSH, Sherwin-Williams co., Chicago, Ill.; D. F. HAYES, U. S. Atomic Energy Commission, Washington, D. C.; PAUL C. LAMB, Lever Brothers Company, New York, N. Y.

Public Relations Committee: R. G. WHEELDON, Chairman, The Drackett co., Cincinnati, Ohio; ALDO P. OSTI, Chas. Pfizer & co., Inc., Brooklyn, N. Y.

Data Sheet and Instruction Card Committee: H. H. FAWCETT, Chairman, General Electric co., Schenectady, N. Y.; D. W. GIBSON, Columbia-Southern Chemical Corporation, Barberton, Ohio; J. N. ROMINE, Phillips Research Center, Phillips Petroleum co., Bartlesville, Okla.

Health Committee: J. B. BLACK, Chairman, National Institutes of Health, Washington, D. C.; T. W. NALE, M.D., Union Carbide & Carbon corp., New York, N. Y.; H. W. RAPP, JR., The Travelers Insurance co., Hartford, Conn.; J. A. HOUGHTON, Liberty Mutual Insurance co., Boston, Mass.

Membership Committee: J. J. PRABULOS, Chairman, National Distillers Products corp., New York, N. Y.

Poster and Visual Aids Committee: G. R. CUMMINGS, Chairman, Eli Lilly & co., Indianapolis, Ind.; A. L. KLING, American Cyanamid co., New York, N. Y.; E. BONER, The Chemstrand Corp., Pensacola, Fla.

Statistics and Contest Committee: M. A. SNELL, Chairman, Hartford Accident and Indemnity co., Hartford, Conn.; T. J. LANIGAN, General Electric co., Syracuse, N. Y.

Off-the-Job Committee: E. R. WALLACE, Chairman, Eastman Kodak co., Rochester, N. Y.; G. G. FLEMING, Celanese Corporation of America, Charlotte, N. C.

Nominating Committee for 1958-1959: J. J. WHALEN, Chairman, Solvay Process div., Allied Chemical & Dye corp., Solvay, N. Y.; S. F. SPENCE, American Cyanamid co., New York, N. Y.; G. L. GORBELL, Monsanto Chemical co., St. Louis, Mo.

Advisory Committee: R. H. ALBISSER, Merck & co., Inc., Rahway, N. J.; ALLEN L. COBB, Eastman Kodak co., Rochester, N. Y.; J. J. DUGGAN, Carbide & Carbon Chemicals co., South Charleston, W. Va.; G. L. GORBELL, Monsanto Chemical co., St. Louis, Mo.; S. M. MacCUTCHEON, The Dow Chemical co., Midland, Mich.; E. J. MEYERS, E. I. DuPont de Nemours & co., Inc., Wilmington, Del.; S. F. SPENCE, American Cyanamid co., New York, N. Y.; R. C. STRATTON, The Travelers Insurance co., Hartford, Conn.; JOHN J. WHALEN, Solvay Process div., Allied Chemical & Dye Corp., Solvay, N. Y.

Staff Representative—EDWIN L. ALPAUGH, National Safety Council, Chicago, Ill.

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

THE COAL MINING INDUSTRY

This volume is a record of the sessions held at the 1957 National Safety Congress by the Coal Mining Section. The conduct of these Congress sessions each year is only one of the many cooperative activities which the Coal Mining Section carries on in behalf of its members, and for the benefit of accident prevention work in the coal mining industry generally. The Section gives guidance in the preparation of a great variety of technical and educational material useful in the day-to-day safety programs of coal mining companies.

The activities of the Section are under the direction of its executive committee, the members of which are listed at the close of this volume.

PROCESS IN CEMENTATION OF COAL-MINE ROOF

by E. R. MAIZE

mining methods research engineer, Bureau of Mines, Pittsburgh, Pa.

Inasmuch as more than 70 per cent of the roof-fall fatalities have occurred within 25 feet of the working face and 60 to 70 per cent of these occurred beyond the line of permanent support, attention has been focused upon the necessity for better roof support in this relatively small area. In the search for better means of supporting and controlling coal-mine roof many methods and devices were, and still are, being considered and evaluated.

One of the first ideas presented as a means of controlling or preventing falls in this area was a movable shield. The idea of a shield is sound; however, to design a practical workable model for use in each working place has been almost impossible. There is still the possibility that a shield attached to mobile face equipment can, and will, be developed. However, a movable shield used for temporary support or protection does not solve the problem of when and where permanent supports should be placed.

After a great deal of investigation and review of the reports of fatalities, the conclusion was reached that an attempt should be made to strengthen coal-mine roofs further since roof bolting has given such favorable results. It was conceived that it might be possible to strengthen the roof over passageways, and possibly the roof in advance of a face, if a high-strength adhesive material could be injected into the bedding planes of the roof strata to bond the stratum, thus preventing lateral shifting and increasing the strength of the structure as a whole. In fact, if this system should prove successful, a type of permanent shield would result.

ROOF SUPPORT METHOD

The proposed method of strengthening the roof with a bonding material may be compared to the process of making plywood, wherein thin, structurally weak, layers of wood are bonded together to form a member that is stronger than a like thickness of a solid wood.

When the proposal to study this means of roof support was approved, it was decided first to determine if fluids under pressure could be injected into a coal-mine roof. The preliminary work of injecting fluids was, after a few setbacks, successful. This work has been reported in Bureau of Mines Report of Investigations 5304, Cementation of Bituminous Coal-Mine Roof Strata, Part I, Determining Penetrability of Mine Roof by Injecting Oil and Water.

The tests received sympathetic reception from all phases of the industry. Manufacturers, particularly the Joy Manufacturing co., the Rockwell Manufacturing co., and the Bakelite co., loaned equipment and manpower and gave advice without which it would have been impossible to advance to the present stage of development. Coal companies, National Mines corp., Bethlehem Steel co., and Pittsburgh Consolidation Coal co., willingly provided test areas and manpower. The mine workers' officials, particularly in the safety division, voiced sympathetic understanding of the tests, but the interest of the individual miners and their ready personal help in the underground tests were most astonishing.

INJECTING OIL, WATER INTO ROOF

Here are the highlights of the Report of Investigations 5304:

The first injection tests were made at the Experimental Coal Mine of the Bureau of Mines at Bruceton, Pa., where water from a tank was forced into the mine roof through a sealer or packer by admitting compressed air into the water tank at 80 to 90 p.s.i. In these tests water flowed readily through the bedding planes of the strata. In two instances the flow measured 54.7 and 45.9 gallons in two nine-minute periods.

In most tests the water, other than a small quantity that emerged from test holes, was contained in the strata. Attempts to duplicate the tests in freshly exposed roof of a commercial coal mine were unsuccessful because of the low pressure of the test equipment. At this stage the high-pressure equipment was developed and used in all subsequent tests.

The high-pressure equipment consisted of a permissible four horsepower motor directly connected to a hydraulic pump with the necessary electric and hydraulic controls. With this equipment it was possible to reach injection pressures of 1,150 p.s.i.

Using the high-pressure pump, tests of the penetrability of the roof strata were made in several commercial coal mines operating in the Pittsburgh and Upper Freeport coal beds. In these tests hydraulic oil was injected into the strata, and pumping was continued until oil emerged from the roof. The procedure follows:

1. A roof bolt was removed from a hole near the face.

2. The injector, which consisted of two rubber sleeves mounted on an expanding bolt which forced the rubber against the sides of the hole, was inserted and tightened in the hole.

3. The lead from the pump was connected to the injector, and the oil was pumped into the strata.

Four tests were made in a mine in the Upper Freeport coal bed, which were typical of many of the tests in other mines.

Test 1

The injector was inserted to a point 12 inches from the collar of the hole. After the pressure was increased 100 p.s.i. every 30 seconds up to 1,000 p.s.i., oil began to flow into the roof. After 35 seconds, during which 0.6 gallon was utilized, oil emerged from the three nearest boltholes. Pressure in the hole was released; after a 10 minute pause the hole was repressured at 1,000 p.s.i. for an additional 30 seconds, and flow was obtained to three additional boltholes, utilizing 1.3 gallons of oil.

Test 2

Test 2 was at the face of another entry. The injector was installed 12 inches from the collar of a 60-inch-deep hole. After the pressure was increased 100 p.s.i. every 30 seconds up to 500 p.s.i., oil began to flow into the roof. After two minutes and 30 seconds, during which 0.8 gallon of oil was pumped, oil came out bolthole one. The hole was repressured an additional three minutes at 500 p.s.i. and had utilized 0.9 gallon of oil when flow developed from holes two and three. In hole four water drippers developed and increased in amount.

Test 3

Test 3 was at the face of a crosscut. A roof bolt was taken out, and the injector was inserted 18 inches in the hole. The pressure was increased 100 p.s.i. every 30 seconds. At 900 p.s.i. oil began to flow and after the pressure was maintained for 30 seconds, using 1.2 gallons of oil, flow was observed from hole one. Shortly thereafter oil appeared in holes two, three, and four, and after eight minutes water drippers were noticed in hole five.

Test 4 was at the same location as test 3. Holes A and B were drilled 1¾ inches in diameter and 35 and 75 inches in depth respectively. After the injector was installed eight inches from the collar of hole A, the pressure was increased 100 p.s.i. every 30 seconds. At 500 p.s.i. oil began to flow into the roof. When oil flowed from the adjacent boltholes, 0.9 gallon had been pumped. Flow could not be obtained in hole B at a maximum pressure of 1,200 p.s.i. maintained for five minutes.

SELECTION, INJECTION OF EPOXY RESIN

Following the successful oil penetration of roof strata in commercial coal mines in two coal beds, our next problem was to find a material that, having been pumped into the stratum, would bond the members together and form a competent plate, or beam, as the case may be.

Through correspondence with numerous chemical manufacturers and from visits to their research departments, the conclusion was reached that an epoxy resin appeared to have the desired characteristics of low viscosity, rapid setting time in thin layers, and high adhesive as well as cohesive qualities, and should be tried. Other bonding agents were suggested, but to date we have not had the manpower or equipment to test them.

Epoxy resins are complex organic compounds in liquid form, requiring a second solution, called an "activator," to be mixed with it just before use to start the process of solidification. The speed of the solidification can be regulated through the selection of the activator or catalyst, several of which are available.

The activator used in our tests was hydroxyethel diethalene triamine. The resin and activator were manufactured by the Bakelite co. and are designated as resin ERL 2795 and hardener ZZLD 0814.

Test 1

The first injection test of the epoxy resin was made on January 7, 1957, in an area of Renton mine of the National Mines corp. that was being developed into blocks with entries on 80-foot centers and rooms on 100-foot centers, all of which were driven 14 feet wide. The immediate roof was coal overlain with laminated carbonaceous and sandy shale.

Under normal operating conditions the roof is supported by six foot-long roof bolts, four bolts to the row and rows on four foot centers. In many instances, because of roof fissuring, it was necessary to supplement the bolts by posts and crossbars. In this test area the roof was exceptionally good, and additional supports were not being used.

CROSSBARS SUPPORT ROOF

To prepare the test area roof bolts were not used. The roof was supported by crossbars set on stub-hitched rails on five foot centers. Twenty-eight 72 inch holes were drilled in pairs in a regular pattern spaced approximately two feet from each rib and the pairs on 14 foot centers parallel with the direction of the opening. The injectors were installed in each of the holes before pumping operations began.

A 4-to-1 mixture of resin and hardener was hand-mixed in batches of 1.75 gallons as needed and was injected into the roof at a pressure of 1,150 p.s.i. in the order of the numbered holes. Each hole, except Nos. 14 and 20, was pumped to refusal; hole 20 refused fluid; and water dripped from hole 14 during the pumping of hole 13; therefore, it was decided to miss this hole. The elapsed time of pumping the area was four hours and 10 minutes.

The total amount of resin and hardener used was 29.75 gallons. One and one-half gallons of fluid was injected for each 14 feet of entry, or ¾ gallon per hole and 0.107 gallon per linear foot of exposed roof. It must be realized that the amount used per hole was not uniform. The roof at intersections had sagged, leaving greater voids than in areas of better natural support. In hole 13, 8.75 gallons of resin were used, and 3.50 gallons in hole 23. Resin was extruded from boltholes 10 feet from hole 13 during the pumping operation. On the day following the tests, it was noted that resin had migrated to hole 14.

The crossbars supporting the roof of the test site were removed on the first shift of operations, and the area was dangered off following the pumping. The area was standing intact without roof falls up to the last report on about September 6, 1957.

The equipment used to pump the resin was rather crude and consisted of a hydraulic cylinder driving an identically sized cylinder which forced the resin into the roof. The hydraulically driven cylinder was actuated from the pumping equipment used during the oil-injection tests.

Test 2

The second test of the injection was made in an area two blocks away from test area 1. The test was made to determine the effectiveness of the resin in stopping a fissure that had developed in the entry. The roof was supported in a normal manner with roof bolts; the center posts had to be added when the fissure developed. The equipment for injecting the resin was the same as that used in the previous test.

During this test approximately 26 gallons of material were injected into the roof through 10 roof-bolt holes spread over a distance of 55 feet along the fissure. Bolts were removed from their holes along alternate sides of the fissure. On the day following the injection the area was dangered off and the center posts removed. As of this date the area has remained stable, with no further fissuring.

During the injection the flow of resin was across the fissure, and in several instances resin emerged from boltholes on the opposite side of the fissure. None of the resin emerged through the fissure.

FLORESCENT DYE INJECTED

It was not possible to determine accurately the flow pattern of the resin in the previous tests. For this reason an attempt was made to inject resin containing a quantity of florescent dye, sodium florescence, into another test area so that the flow pattern and the number of horizons could be determined. In this work, four 72-inch injection holes were drilled in the roof during normal development of the entry. These holes were spaced similarly to those of test 1.

Five gallons of resin were pumped into the four holes. The pumping time was seven and one-half minutes. Following injection of the resin into the roof, the roof was cored with a lightweight Joy core driller using a bevel wall N.X. diamond core bit. The vertical cores contained resin in the bedding planes in the contact between the carbonaceous shale and white shale approximately 28 inches above the normal roof line.

We were fortunate in obtaining one core which showed that resin had filled the vertical cleats. An attempt was made to drill angle holes in the roof to search for more filled vertical cleats, but it was not possible to obtain good cores while angling across the bedding planes.

Test 3

This test was made in an area of the mine where the normal roof conditions were extremely bad. The general area consisted of eight entries being driven on the face course, with openings 14 feet wide. The entries were driven on 60-foot centers and the crosscuts on 80-foot centers. Normal roof support necessitated bolting with four bolts per row with rows on four-foot centers, and in most instances the bolt-supported roof had to be reinforced by the use of steel crossbars set on about five-foot centers.

Crossbars were erected in this area immediately after the next cut of coal was removed. The normal pattern of bolting was discontinued and crossbars were spaced on three-foot centers. Two vertical holes, one and one-half inch in diameter and four feet in depth spaced two and one-half feet from the coal face and three feet from either rib, were drilled in the roof and injected with the resin mixture after each cut had been loaded out.

Inasmuch as the average depth of each cut was 10 feet, the pairs of holes were on approximately 10-foot centers. The work was begun June 26 and completed July 23. A total of 179 gallons of resin was injected in the two entries and the crosscut for a total distance of approximately 140 feet. The amount of resin per hole ranged from 0.3 to 24 gallons.

While hole seven was being pumped, resin was forced out of holes in the shale strata in the left rib; this is an area in which the roof fell above the normal roofline. Where resin emerged from fissures or breaks in the roof, the pumping was discontinued. Under normal conditions the holes were pumped to refusal; this occurred in 19 of the 32 holes. The other holes were not pumped to refusal for varying reasons.

The test work proved that resins could be injected easily into the roof strata over entries of the Upper Freeport coal bed. The flow pattern of the resin has not been accurately determined, nor has the depth of penetration over solid coal found, but the work indicates that favorable results can be obtained.

The effectiveness of the resin in bonding roof structure has not been completely determined, but test results lead us to feel optimistic on this point.

Additional tests must be made with equipment able to provide higher pressures and tests must also be made in other coal beds before definite conclusions can be drawn.

THE EFFECTS OF CORROSIVE ELECTROLYSIS ON METALLIC ROOF BOLTS

by JOHN M. MUCHNOK

electrical inspector, Pennsylvania Department of Mines & Minerals Industries, Hopwood, Pa.

The support of roof strata of underground excavations is a major factor in mining. As long as wood props were used the miner depended upon his experience and judgment in adapting the supports for the varying conditions. Wooden supports carried weight up to a certain point; when loaded further the prop split, dropped the load and the support pattern was lost.

Props with higher strength and elasticity made of iron, steel or light metals were tried and showed advantages over wooden timber. Some of the advantages of this type of support were:

1. Safer because of higher mechanical strength.
2. Installed more easily.
3. Re-used repeatedly.
4. Paid for themselves in a very short time in spite of the higher initial cost.

As mechanization began to increase, efforts were made to find a roof support that would increase production efficiency so that mining machines could advance more rapidly under safer conditions. This method led to the exploitation of the steel bolt inserted in a split rod or an expansion unit.

The basic principle is the reinforcement of mine roof with steel rods imbedded and anchored in the strata at points least likely to be affected by stresses. This holds the strata together preventing ordinary sag and forming a strong consolidated beam by the mine roof. In the overall picture, bolting is effective when properly applied. As with any innovation it has not been a panacea. Although it eliminated some undesirable features it created others that need attention.

Bolts to be fully effective in supporting a mine roof must be uniformly stressed when anchored. Any variation in stress or anchorage weakens the roof support and renders it ineffective. Where conventional props were usually placed under the mine roof, metal bolts were inserted into the roof strata. Metal bolts imbedded in the earth can then be literally described as ground rods driven into the earth. Since all metals have an electrical potential, and more so in contact with the earth, there arises the problem of corrosion by electrolysis. To maintain a safe and sound roof control program we must consider corrosion.

CORROSION REVERTS METALS TO THEIR ORIGINS

A definition of corrosion is, "the destruction of a metal by chemical or electrochemical reaction with its environment." It is a precipitation of ferruginous metals back to their natural state. Corrosion is, therefore, nature's efforts to revert refined metals back to the forms they were originally found in the earth. The corrosion of metallic bolts by electrolysis is a chemical decay under environment influences in which nature reverses the process by which man obtains his construction materials.

The rapid formations of iron rust when a clean metal is brought in contact with air and water can be classified as ordinary oxidation and is retarded when ferrous oxide forms a protective film. The rusting of iron has been looked upon as the same reaction under all conditions. We now find it complicated by many variables, the majority of which have not always been taken into consideration.

The electrochemistry of corrosion is relatively simple. First there is the metal; it is hard, dense, opaque, firm, insoluble in water and is a conductor of electricity. But metals can exist as ions, soluble in water, charged positively and help carry an electrical current through a solution. When metals change to ions we have the fundamentals of transporting metals in an electrolyte.

When two metals are immersed in water a voltage is set up. Adding salt, acids and placing dissimilar metals in the solution, increases the voltage. Combining two metals or electrodes in an electrolyte constitutes an electrolytic cell. A cell that generates its own voltage is called either a voltaic or galvanic cell. Placing metals in earth we create such cells when one or more rods are used. Earth does not have equal properties as an electrolyte. The more active the earth as an electrolyte the more current will flow and the rate of corrosion will be faster.

When current from an outside source is forced through a cell we have what is called an electrolysis cell. A good example of this would be stray DC currents from the mine distribution system.

A concentration cell forms when a metal passes through areas of unequal electrolyte. This can be caused by natural soil changes, by the additions of chemicals from the surrounding environment or by the intermixed strata of the mine roof. Variation in the concentration of a solution in contact with metal tends to localize corrosion. When different concentrations are in contact with a metallic structure, the area of metal in contact with the more dilute solution will become anodic and corrode.

When a current flows through a cell a chemical change takes place. To simplify corrosion work current flow is designated as flowing from anode to cathode. The current flow from anode to cathode in an electrolyte is the same under all conditions. The flow of current from a metal causes loss of metal but at differing rates depending upon the type of metal involved. For example, one ampere of current flowing from iron for one year carries 25 pounds of iron, whereas 75 pounds of lead are carried by one ampere in the same period.

Therefore, unless certain precautions are taken, corrosion can be a continuous process that can ultimately cause serious damage to roof bolts and produce dangerous conditions in a number of ways. The seriousness of this may not always be realized. Usually the hazards are not readily apparent because the action, whether slow or rapid, cannot always easily be detected. This situation can ultimately cause serious hazardous conditions for the personnel.

The preceding paragraphs are the basic fundamentals why corrosion occurs. It must be remembered that all metals possess an electrical potential. Since all mines use metal to a greater or lesser degree, they are all susceptible to corrosion in one or more forms. . . . . none can deny this. This paper deals mainly with roof bolts but the fundamentals can be applied to any metallic structure such as track, pipe, trolley hangers, beams, armored cables and any other metals offering a path for electric current.

WAYS CORROSIONS OCCUR

There are a number of situations favorable to corrosion. The following could be elaborated upon a great deal more but has been made brief and condensed so that it can be covered in the space allocated:

ENVIRONMENTAL CORROSION: When metals are exposed to locations containing chemical elements such as salts, alkalis, carbonates and acids, corrosion occurs.

GALVANIC CORROSION: The contact of dissimilar metals or dissimilar parts of the same metal structure in an electrolytic medium will create corrosion. It is also created by contact of metals in dissimilar electrolytes, dissimilar concentrations of the same electrolyte and any number of atmospheric dissimilarities. Dissimilarities form galvanic cells which permit the flow of electrical current in an internal generating unit permitting the transfer of metal in an electrolyte.

STRAY CURRENT CORROSION: When current from an external source flows or is impressed upon a metal structure, a polarity difference is set up within the structure. The metal then becomes a conductor. No difficulty is encountered where the current enters the metallic structure. Where current leaves corrosion occurs; corrosion can be very rapid and extensive if any great amount of current is present.

STRESS CORROSION: Tensile stresses build up at metal surfaces under static loading. Stresses, either by applied loads or of a residual nature, can influence the rate, nature and distribution of corrosion in some of the following ways:

1. By shifting the electro-chemical potential wherever the greatest point of strain occurs
2. By accelerating the rate of corrosion

3. By damaging protective films
4. By changing the characteristics of the metal and precipitating solutions
5. Increasing corrosion by mechanical effects, i.e., elongation of the roof member

Stress corrosion through research has been analyzed as the most destructive and difficult to control.

Corrosion of iron and steel depend on different factors that control environment. Three common types can be considered as atmospheric, water and soil corrosion. Associated with coal bearing measures are large quantities of sulphur bearing materials. Shales and geologic formations above the coal measures contain precipitation of solutions of sulphate of aluminum, ferrous iron, ferric iron, calcium, magnesium, sodium, potassium and chlorides. These are some of the most highly corrosive elements known to man. The mining environment is, therefore, nature's ground bed for an exceptional corrosive atmosphere.

The two conditions that cause the most difficulties in underground corrosion of bolts are stress and concentration cells. Metals subjected to constant stress fall considerably below their static ultimate tensile strength. For carbon steels this endurance limit is about one-half tensile strength. Even a small amount of corrosion with cyclic stress will considerably reduce the endurance of the metal. Concentrated cells and stress tend to accelerate the rate of corrosion. The combined action of stress and corrosion is called, "corrosion fatigue". Corrosion fatigue is independent of tensile strength. The combination of stress and galvanic corrosion can be construed as probably the most destructive form of corrosion found anywhere.

WAYS TO PREVENT CORROSION

Thus far, there has been demonstrated only the destructive effects of corrosion, but as with everything else there can be some protective measures applied. Deterioration of metals can be prevented or reduced in three ways:

1. By using a more resistant metal
2. By the application of a suitable protective coating
3. By making the environment less corrosive

There can be effective protective means employed and designed to meet the particular conditions prevalent in each mine. A recognition of the corrosion problem affects the design, choice of materials and application and general maintenance and economy. We cannot do too much about mining environment, but we can institute protective coating that has:

1. High insulation resistance
2. High dielectric strength
3. Unaffected by acids, alkalis, salts, organic solvents and soil and metal stresses
4. Manufacturing bolts with alloys that resist or reduce corrosion

We encounter similar difficulties with wooden props. The original props were green timber with preference given to wood cut in the fall or winter season because the moisture was in the root system. This gave a higher tensile strength and some resistance to deterioration. Little attention was paid to timber in short-lived face areas, but where timber on haulageways and air courses had to stand indefinitely the resultant deterioration became a matter of concern.

To alleviate this situation it was treated with a preservative which increased immeasurably the life of the timber. Some of the same treatment can now be applied to bolts, especially where entries will stand for long periods of time. The rate of corrosion will vary with the change of seasons, change of atmosphere, the kind and extent of environment, and the concentration of cells reacting with stress and elongation of each bolt.

To conclude, here's a brief summation of how some of the findings of this paper came about. When Honorable Joseph T. Kennedy became Secretary of Mines and Mineral Industries of Pennsylvania, he recognized the merit of roof control programs. He felt that if improvements were to be made, it would be necessary to analyze roof problems more thoroughly.

Secretary Kennedy felt to reduce the number of fatalities we must understand the causes that lead to the fatalities. He alerted the Deputy Secretaries and Inspectors to investigate to find *WHERE* and *WHEN* men were injured and killed and at least to theorize *WHY*.

Concentrated efforts have already shown results. We recognize that future improvements will have to have the best efforts of all of us. Safety with the Pennsylvania Department of Mines and Mineral Industries is not an effete and vicarious slogan. Working together with labor, management and other safety-minded organizations we are trying to alleviate unecessary suffering and distress by all lawful means.

Corrosion is one problem that deserves considerable attention and research to be reduced to safe proportions. The mining industry cannot afford to ignore it. Applied research and technology can begin to visualize the broad field that corrosion covers. These are not the potential hazards created by electrolysis. But if enough emphasis is placed upon the subject, mankind can answer some of its problems in electrolysis and other related fields. Regardless of what is accomplished now it should lay a foundation for a clearer understanding of our present problem and a better tomorrow.

MINING WITH THE COAL PLANER INCLUDING SAFETY ASPECTS

by ROBERT J. MARRS
general inspector, Eastern Gas & Fuel Associates, Mount Hope, W. Va.

At our Stotesbury operation of Eastern Gas and Fuel Associates, we use what is called retreating semi-longwall in the 39 inches Pocahontas No. 4 seam. We develop parallel sets of three butt entries 2200 feet deep by conventional mining method leaving a solid block of coal 130 feet wide between these entries. The back ends or inby ends of these butts are connected by two entries, one used as a bleeder and the other as the longwall.

From this point the planer retreats to within 260 feet of the main entries leaving the butt entry chain pillars unmined. The right hand entry of each butt has slated bottom and is used for belt haulage and track supply haulage; it also carries the necessary compressed air, power, and communication lines. The head end of the planer moves down this entry, while the left hand entry of the other butt carries the tail end.

STRUCTURE OF PLANER

The machine itself consists of a headpiece, tailpiece, armored double-chain conveyor, and plow. The conveyor is built up of pans 39 inches long, and is flexible at each joint to the extent of five degrees in each direction; the continuous chains carry flights every 42 inches and move at a speed of 150 feet per minute.

Attached to the conveyor is a heavy guide tube which carries the plow. The plow chain is continuous also, the return strand carried inside the guide tube. Chain sprockets at both ends of the conveyor pull the plow at 75 feet per minute while it planes in either direction to a depth of 2 inches to 6 inches. Drive units are located at each end of the conveyor and are called the headpiece and tailpiece. The number of drive units depend on the length of face, each end using either one or two 50 H. P. motors.

Power is transmitted through a fluid coupling to a gear reducer which runs the chain sprockets for plow and conveyor. An air-operated clutch allows the conveyor to move while the plow is idle. Air cylinders spaced at 20 feet along the conveyor keep the conveyor advanced to the face. The headpiece and tailpiece can be advanced by an automatic ratchet shifting device or by separate electric hoists.

Control of the machine is achieved at two stations. The main control panel is mounted on skids about 300 feet back from the face. These controls are set at the beginning of the shift and actual operation of

the planer is effected at the headpiece by a small four switch panel.

Coal from the conveyor spills into a speeded-up standard mother line chain-conveyor where it goes to the panel belt and is loaded into mine cars in the main entry.

We in the coal mining industry are interested in production. But our primary objective is or should be the safety of our men. Some of the safety advantages planer mining offers over other types of mining can be seen in our Stotesbury operation in southern West Virginia, the only planer set-up we operate.

SAFETY IN PLANER

Some safety features in planer mining that are advantageous over other types of mining at Stotesbury are:

1. Timbering and roof control
2. Ventilation and mine gases
3. Coal dust and rock dusting
4. Explosives and blasting
5. Electricity
6. Communication
7. Planning

TIMBERING AND ROOF CONTROL

Roof support along the Longwall face is designed to provide three things:

1. Protect men and machinery.
2. Allow subsidence of the roof under the dead weight of the overburden.
3. Lower the roof to the floor in a systematic manner.

At Stotesbury we support an 11 foot width of roof along the face. Five feet of this area are taken up by the planer conveyor and must be prop free. This is effected by the use of steel collapsible props with steel roof bars projecting over the pan line. The remaining six feet of the face area are roof supports where the miner works.

In starting our panels, the first roof falls usually occur after planing about 50 feet of coal. The falls are usually preceded by the unsupported roof sagging, working with considerable noise, and then sections of the unsupported roof falling.

After the immediate roof falls and the face has retreated further, falls involving the higher strata occur, accompanied by the strong cracking noise of normal pillar falls that practically all miners are familiar with. When 300 feet of coal has been mined out, a good break line has been established and subsidence can occur as it should for the remainder of the panel.

MINOR FALLS

Subsidence or minor falls of the immediate roof usually occur in four feet to six feet wide blocks. They are seldom more than four feet thick and vary from 10 feet to 40 feet in length. These minor falls, usually accompanied by smaller debris from the crevices, come in soon after supports have been removed but sometimes they drop during the process of removing the last jack and the debris covers it.

However, all steel supports are recovered. The condition that governs the line of break is usually a crack that forms over the face. Since there is about three inches of convergence from the face to the gob line, the rock must break. At times this break will shear a few inches making an off-set in the roof. If the breaks are close together, about 12 to 18 inches apart and there is no support between them, slabs of rock are liable to fall onto the conveyor necessitating fore-poling.

The *props* must incorporate four important features:

1. They must be of adjustable height to allow for variation in the thickness of seam.
2. They must be set under a load, usually five to 10 tons, to secure an even resistance to further load.
3. They must yield mechanically as the load increases. Our jacks have a total yielding pressure of approximately 60 tons.
4. They must collapse instantly to facilitate removal.

Because each mine has its own characteristic roof conditions, the preceding requirements have been met in a variety of ways. Six different makes of props have been used at Stotesbury, all of which are manufactured in Europe. They are either of the hydraulic type or the mechanical type.

Mechanical props are the most popular type today because of their higher load-carrying capacities. Friction is the principle behind the yielding feature.

These jacks are set in staggered rows of two jacks to the row, about 42 inches apart and are set on a maximum of 30 inch centers along the face. Approximately 330 jacks are used across a 330 foot face, set on a staggered pattern. In other words this equals one jack for each lineal foot of face.

We support only 11 feet of roof behind the face and by using 330 jacks to 330 feet of face the place is timbered about as closely as possible to leave working space for the men to move about.

Further support is offered by the props through the use of steel headers called cantilever bars. At Stotesbury we use a 13 inch "H" section bar weighing 55 pounds. Lugs on the bars mesh with the lugs on the head plates of the jacks to keep them from kicking out under weight. Two-thirds of the length of the cantilever bar extends toward the face offering support over the conveyor line.

Further forward support can be effected by hinging another cantilever bar to the end of the first bar and then loading it against the roof with a special drive shoe. This process is called fore-poling. When the conveyor has moved forward enough, a jack is set under the fore-poled bar and the shoe is removed. At our mine we do not normally connect the bars or use fore-poling.

OTHER WOOD REINFORCEMENT

Secondary reinforcement is offered by wood cribs set 10 to 20 feet apart as conditions warrant. They have a four-fold purpose:

1. Prevent props from penetrating soft bottom.
2. Lessen the danger of any side thrust of the roof.
3. Provide additional reinforcement when used with props.
4. Allay the fears of the miners psychologically.

Thus, at Stotesbury we use cribs for psychological reasons as well as reinforcement. A man works only as safely as he thinks he is; therefore, it has proven advantageous to use cribs at all times. They are built from 6x8x24 inch wood blocks, with one tier comprised of steel chock releases to facilitate their removal. Tripping is accomplished with a hammer, at which time the crib collapses and is then rebuilt against the conveyor.

I will venture to say for the amount of roof exposure, a planer face when timbered to our standards is better protected than most other types of face mining. Not only from the standpoint of the quantity of jacks and cribs used in the timbered area, but also from the total weight carrying capacity. For the last inventory of jacks on our 330 foot face, the total weight carrying capacity was around 20,000 tons.

VENTILATION

The ventilation for a planer face is simplified by a positive ventilation at all times without the use of line curtains. Only 6,000 to 8,000 c.f.m. are required to ventilate the face adequately and keep the methane percentage below ½ of one per cent.

Positive pressure is maintained against the gob line toward a bleeder and a return entry. Two flame safety lamps are in use at all times, one on the return side of the face and one carried by the foreman.

Intake emergency escapes are established in entries on either side of the face. The men farthest from an escapeway would be the men working near the middle of the face or approximately 165 feet away.

COAL AND ROCK DUSTING

Practically all coal dust accumulations are eliminated by close pillar falls. Suspension dusts are at a minimum due to the plowing effect of the planer along the face allowing the coal to turn over gently on the pan line, and, of course, the short distance the coal falls is another factor. Water sprays are maintained at the dumping point.

The many hazards connected with handling of explosives and blasting are totally eliminated since none are required in this type of mining.

All electric cables crossing the face are installed in double chanel irons in sections to the conveyor line. No cables are on the floor to get cut, bruised or otherwise damaged by falling objects or by moving equipment. This greatly eliminates the possibility of short circuits, electric shock and cable fires.

Communication across the face and from head to tail piece consists of yellow non-

glare signal lights installed 20 to 25 feet apart along the line. All workmen can see these signal lights and can give signals from any point, all the way across the face.

Telephones are installed at both the head and tail pieces.

Six trolley phones serve as a public address system across the face. These phones operate on a different frequency than the dispatching and haulage phones and the units are spaced about 50 feet apart. All men can clearly hear instructions given at any point across the face. If trouble arises at any point along the face everyone is informed.

PLANNING OPERATION

While one face is on retreat, another set of butt entries is being driven with bleeder entries established at the back end of the new section. We also have another complete plow unit which we use as a standby. While one unit is retreating, the other unit is completely repaired and set up on the next section.

This gives management time to make a complete move, try out the equipment and correct any faults before the new section is put into operation. Thus, the change over from a worked out to a new one is orderly and the rush usually accompanying major moves is eliminated.

To get clean even roof falls behind the face of the planer it is necessary to keep the face even and on a 90 degree angle to the butt entries. To keep the face straight, paint marks are made on the ribs of the head and tail entries. These marks are 25 feet apart and serve to keep the headpiece on one entry even with the tailpiece on the opposite entry.

The planer went into operation September 1953 and has mined 1,000,000 tons of clean coal, an average of 250,000 tons per year. During this time 17 injuries have occurred, the large majority being finger accidents while handling jacks and most of these during the first year of operation.▲

SAFETY AND OPERATING PROBLEMS OF A MODERN HAULAGE SYSTEM

by WILLIAM KEBBLISH
production engineer, Mathies Coal co., Pittsburgh, Pa.

The importance of a safe and efficient haulage system is invaluable to any coal mine. Coal must be produced at a fast rate at the face and transported to the cleaning plant safely and without unnecessary delay.

Analyzing the 82 haulage fatalities that occurred in the bituminous coal mines in the United States in 1956, it is found that 71 occurred underground and 11 on the surface. Motormen accounted for 20 of these fatalities and brakemen 24 or nearly 54 per cent of the total haulage fatalities.

These accidents occurred by collisions, contact with low roof or crossbars, derailments and workers being caught by moving haulage equipment or being squeezed between the equipment and the rib.

Of these fatalities 72 per cent occurred on the haulage roads, 28 per cent to men with nine years or more of job experience, and 30 per cent of the victims had less than one year job experience.

The average age of the victims was 44 years and the average mining experience was 21 years. This shows that well-experienced men as well as others are susceptible to fatal injuries in haulage accidents.

A study of the principal causes of fatal accidents indicates that 29 per cent of the victims were caught by moving haulage equipment, 23 per cent came in contact with low roof or crossbars, 16 per cent were squeezed between haulage equipment and the rib, 13 per cent occurred by collision, 10 per cent by derailment, and nine per cent from other minor causes. Nearly one-third of these accidents occurred between 9 a.m. and noon.

VIOLATED SAFETY CODE

Of the 82 haulage accidents, 44 per cent were violating the Federal Mine Safety Code. Nine accidents were in violation of section 6-g of Article VII, which states that no person should get on or off moving locomotives or cars moved by locomotives provided, however, that the brakeman may get on or off the rear end of a slowly moving trip.

Nine accidents were in violation of section 6-f and 4 violations in section 4-1. Fifteen other accidents violated various sections of Article VII, which deals with transportation.

Since 54 per cent of the haulage accidents affected motormen and brakemen, the management at Mathies Mine planned to develop a safe and efficient haulage system to reduce haulage accidents.

Mathies Mine was opened in 1944 and 18 million tons of coal have been produced. No fatalities have occurred involving rail transportation although a few minor accidents each year involved motormen or brakemen.

One haulage safety feature at Mathies is the two main parallel tracks, one for traffic in and the other for traffic out. This permits fast, safe and efficient handling of coal trains with minimum interference between the loaded and empty trips. Double track requires fewer mine cars, no passing siding and no dispatcher.

BLOCK LIGHT SIGNALS

Trolley phones are installed on all main line locomotives as well as gathering locomotives. The motormen keep in touch with one another and when passing certain known points along the haulage road their location is given to other motormen in that vicinity. Each working unit in the mine has a telephone. When a shortage of cars exists the lampman is called and he relays the message to the swing motorman or main line motorman.

At all main intersections, face entries, and crossovers Cheatham electric switches align the switches for fast transportation. Block signal lights are also installed at these intersections to stop traffic in all other directions. These block signals are also installed on down grades and around turns.

At Mathies Mine only one locomotive is allowed in one set of block signals at one time. Each motorman must get his own green light before moving the trip. As a result, a constant flow of empties and loads without interruption are taken into and out of the mine.

In 1956, five per cent of the haulage accidents in the United States occurred because the motorman failed to get a clear track from the dispatcher; as a result three men were killed.

Many mines with a small daily output and a limited coal reserve could not install two main haulage roads due to the high initial cost. At Mathies Mine, a large reserve and a large tonnage are produced and two haulage tracks are necessary. In case of a derailment or wreck traffic can be rerouted over the other track until the first is cleared.

DRAINING WATER FROM TRACKS

A high standard of track installation is followed. A. C. E. 85 pound rail is used exclusively on the loaded road and on all radius curves. On the empty track 60 pound rail is used. With the introduction of the 50-ton locomotive both main line tracks will use 85 pound rail. All main line track joints are welded.

The thermit-welded joint gives a stronger and more durable joint than the electric arc welded joint. Practically all the frogs on the main line connections are number five with number three and four on the face entry tracks.

Creosote treated six inch by eight inch by six foot ties are laid on 24 inch centers in slag ballast. The slag is forced down under the ties to a minimum depth of six inches by using air tamping hammers. Rail is carefully aligned, and the track spikes driven by air hammers.

In 1956, five fatalities occurred in the United States due to derailments, two because of the poor condition of the track. At Mathies Mine, well laid track is stressed.

Additional measures are taken to keep the track properly drained. Wherever water appears on the road a sump five to six feet

is dug in the nearest breakthrough, preferably between the two main haulage roads. The sump is covered with three inch plank or a concrete slab and a small automatically operated centrifugal pump is installed.

In a parallel entry an eight inch cast iron universal pipe follows the main line and also the face entry track. This eight inch line has fire connections at frequent intervals to provide fire fighting protection along the entire length of track. This eight inch line acts as a discharge line and water can be pumped back through the line in case of fire along the main line tracks.

For adequate roof support, roof bolts four or five feet long are placed three and one-half feet apart and the rows are on four foot centers. Whenever doubtful roof is encountered six inch by six inch steel "H" beams are set on a minimum of 10 foot centers, supported by pin rails or cement block piers. Salt treated planks three inches thick are placed either in the webbing or on top of the beam.

In the last 10 years these beams are never placed lower than 70 inches above the top of the rail. Adequate clearance above the track is necessary for a safe haulage road. Last year 16 fatalities occurred in the United States coal mines because men came in contact with low roofs or crossbars.

Levels are taken on all the track entries to determine whether to grade bottom or top before laying the track. Minor bumps are leveled by shooting off the bumps or leveling the track. The empty track is not graded to the same extent as the loaded track. It has been possible to maintain a grade of two and one-half per cent or under against loads. At one place it was necessary to remove 13 feet of bottom and 10 feet of top within a 1500 foot distance.

To overcome this two and one-half per cent grade which acts against the loads, 50-ton locomotives are used. At present three locomotives are used and each hauls 45 to 50 loaded mine cars up this grade. These cars are of eight-wheel swivel truck design, 320 cubic foot capacity with a tare weight of 4.25 tons and a gross weight of 14.25 tons. They are 17 feet long inside and seven feet wide, 46 inches above the top of the rail and measure 18 feet 10 inches center to center of the Willison Automatic couplers.

Whenever cars are pulled up grades, spring latches are placed at intervals of 500 feet to derail the cars in case they are separated. These derails are possible with single direction track and eliminate the need of a trailing locomotive.

SAFETY IN LOCOMOTIVES

Since Mathies Mine has grown in size a locomotive was needed that would have little trouble on adverse grades and could handle 45 or 50 loaded mine cars at one time. Three 50-ton locomotives were purchased and good results have followed.

These 50-ton locomotives are at present the largest single unit locomotives being used in the coal mines today. They are 37 feet long, have eight wheels—four on each swivel truck, a draw bar pull of 25,000 pounds, a 31-inch wheel diameter can negotiate a 55 foot radius of curvature, a nominal weight of 100,000 pounds, operate on a 44 inch track gauge and 500 volts D.C. current.

The more important safety features on this locomotive are:

Dynamic braking.

It has ten steps of parallel motoring and seven steps of dynamic braking. Movement of the handle clockwise from OFF, arranges control circuits for motoring, cutting out increments of resistance until the tenth step which has no resistance and is a free running position. Movement of the handle, counter clockwise from OFF, arranges control circuits for braking.

Dynamic braking is used mainly for holding trains at uniform speed on grades, and decelerating trains. Operation for dynamic braking can be continuous at 175 amperes or below. Operation must be intermittent above 175 amperes. If speed of train is under four mph dynamic braking is greatly reduced and air brakes stop the train. With a loss of power dynamic braking is interrupted.

Trolley Retractor.

When the trolley retractor valve is depressed, air enters the retractor housing causing the plunger and plunger shaft to rise and relieve spring pressure on the trolley pole. This allows the trolley pole to drop down and clear the overhead wire. Removing hand pressure from the trolley retractor valve cuts off the supply of air to the retractor housing, and spring pressure again raises the trolley pole.

End Sections.

Both end sections of the 50-ton locomotive are rounded and the sides are tangent to both ends. The end section on the operator's side is two and three-eighths inches thick of a heavy duty steel. The end plates conform to the height of the side frames. A small opening in the side of the end section allows the motorman to enter the locomotive safely.

Head Lights.

Both head lights in front and rear of the locomotive are recessed into the end sections and a five-eighth inch steel plate surrounds the light inside the cab.

Fire Extinguishers.

On each main line locomotive as well as each gathering locomotive a 20 pound dry chemical fire extinguisher is carried for fire protection.

Rerailers.

Rerailers together with tacks and chains are standard equipment on all haulage locomotives.

HAULAGE PLAN

At present coal is hauled two miles to the cleaning plant from the furthest face entry; the shortest haul is five miles. The number two locomotive, a 50-ton tandem, hauls coal 38,000 feet to the cleaning plant and averages five round trips of 50 cars each. A one and one-half per cent grade for a distance of 4,000 feet is in favor of the loads. This main line locomotive serves six working units in this face entry.

Each main line locomotive is manned by one operator and the side tracks are arranged so the empties are pulled into one side track and the loads are immediately picked up from another one. If it is necessary to make up a coal train from two side tracks the gathering haulage crews give any necessary help.

The number three locomotive serves five working units in two face entries and travels 30,000 feet to the cleaning plant. This 50-ton locomotive averages 45 to 50 cars per trip and makes four round trips per shift. Another 50-ton locomotive which hauls from a farther point in the mine takes any excessive amount of loads that accumulate in either of the three face entries. Empties are dropped off on the return trip in proportion to the amount of loads taken out.

Two 50-ton locomotives number four and five, haul coal 38,000 feet to the cleaning plant and serve eight working units in two face entries and one main development entry.

The number one locomotive, a 30-ton tandem, is a spare locomotive in event of a breakdown on any of the main line locomotives.

Within a year and a half three of the nearest face entries from the cleaning plant will be worked out and these 10 units will move into two of the new face entries now being developed. It will then be possible to confine all of the working units into two or three face entries and one main development entry. As the main haulage entries are developed, the third main face entry to the south will be turned to the left of the present haulage road.

This last face entry will naturally create a haulage problem since the coal will be hauled 18 miles underground to the cleaning plant. Although this problem will not be faced until 10 years from now, plans must be made now to avert any future bottleneck.

DERAILMENT PROBLEMS

Derailments of coal trains also cause serious haulage problems. Traffic can be rerouted over the empty or loaded road. But this practice is not followed unless the derailment can be corrected within two hours. The majority of the more serious derailments involve the loaded mine cars.

The last one derailed 56 loaded cars and more than 1,000 feet of track. Since it would be inconvenient to reroute traffic over the empty track the next two operating shifts were idle. This derailment was caused by taking a trip over a broken rail. Failure of the main coupler pin on a mine car has also caused derailment of a loaded coal train.

The coal train was being pulled up a two and one-half per cent grade when the pin in the coupler broke. The loaded coal train drifted down the hill and was derailed by the first spring latch. This wreck prevented the mine from operating efficiently that day and mining operations were cancelled.

Whenever a broken rail is found the general foreman is notified immediately. He will send one or two trackmen with acetylene torches and splicing bar to repair the broken rail. This rail will be electric-welded on the first idle day.

A careful check on mine cars is made each shift at the cleaning plant. Whenever a car needs repairs, it is sidetracked, repaired and put into service as soon as possible. If mine cars need repairs in the working sections, they are clearly marked with chalk with the word SHOP and are taken outside for repairs.

A record is kept of mine cars that require new trucks and their performance is noted from year to year. Each mine car travels over 5,000 miles each year and 800 cars are now in service and the labor cost for mine car maintenance is .015 cents per ton.

The per ton mile cost for transporting coal at Mathies Mine is one of the lowest in the industry because of the large tonnage handled over a main line system. The cost includes installation and maintenance cost for track, annual locomotive costs and labor, power for locomotives, and mine car annual cost and labor maintenance costs. This installation track cost is high but is necessary to insure a steady flow of cars into and out of the mine at a high speed.

OTHER SAFETY FEATURES

Much planning and heavy expenditures are put into this haulage system. Entries are not driven more than 14 feet wide. Roof support is obtained with five foot roof bolts and where necessary beams, piers and three inch planks are used. All road beds are graded especially on the loaded track to maintain a two per cent grade or less. Haulage roads are drained by sumps and automatic pumps.

For much of the distance the two parallel main haulage roads consist of 85 pound and 60 pound rail. On all new roads now under construction 85 pound rail will be used exclusively. All rail joints are electric arc welded and/or thermit-welded. Creosote treated ties are laid on 24-inch centers with a slag ballast.

The sidetracks are located in each face entry to transport empties and loads safely and efficiently with a minimum amount of interference. Block signal lights and automatic electric switches control all main intersections.

Each haulage locomotive is equipped with trolley phones and the motormen communicate with each other constantly. Telephones are located at each loading point in the working sections. Messages from the working units are telephoned to the lamphouse and are relayed by trolley phone to the motorman.

It was necessary from the start of Mathies Mine to design a safe, fast and efficient haulage system that could handle up to 20,000 tons of material per day. The same principle has also been applied to the tipple and preparation plant. This high standard haulage system has practically eliminated haulage accidents at Mathies.

REDUCE HAULAGE ACCIDENTS

Management at every mine has the primary responsibility for haulage system. The 82 haulage fatalities that occurred in the bituminous coal mines in the United States in 1956 must be reduced. This can be accomplished by strict compliance with the Federal Safety Code, the State Mining Laws, and the various safety rules of the mine. Accidents can also be reduced by:

1. A high standard of track installation and maintenance.
2. Properly designed and protecting equipment for the safety of the workers.
3. A positive communication system with safety auxiliaries such as automatic switches and block signals.
4. Necessary accessories for safe operation such as skids, reraling device, lifting jacks, fire extinguishers, and other safety equipment.
5. A well engineered haulage system that will meet today's problems, as well as those in the future.
6. A preventive maintenance program whereby defective haulage equipment is taken out of service before it breaks down.
7. Selection of employees who are capable of performing their jobs safely and efficiently.
8. Establish good safety practices to govern all haulage operations.

By following such a program, coal mining men can greatly reduce haulage accidents.

HOW TO AUGER MINE SAFELY

by HARRY J. DUSZ
chief, Division of Mines, State of Ohio, Columbus, Ohio

Records of coal produced by auger mining in Ohio date back to 1954 when 940,915 tons of auger mined coal were produced. This was three per cent of the total production that year. Auger mined coal in Ohio in 1956 amounted to 1,364,303 tons or 3.44 per cent of the total. Strip mining accounted for 61.90 per cent and deep mined coal, 34.66 per cent.

Our mining laws do not specifically deal with auger mining. However, under the law, the Chief of the Division of Mines has broad discretionary powers. Section 4151.06, Revised Code, defining the powers and duties of the Chief, states, "He shall issue such written orders and permissions as will permit the owner, lessee, or agent of a mine to take advantage of the developments of new types of machinery and mining methods as they are developed, when demonstrated to his satisfaction by the owner, lessee or agent that they are in the interest of safety and efficiency." Under these provisions we formulated regulations for auger mining.

Much difficulty at the beginning of auger operation was because no regulations had been promulgated and each deputy mine inspector had his own rules. Augers were mining in 11 different inspection districts and operating under 11 sets of rules. In the early part of 1954, the 11 inspectors visited all auger mines in the state and each submitted a separate report.

A meeting was held to organize these reports and recommendations into tentative rules and regulations. A committee of six members and myself met with representatives of three auger manufacturers who agreed to place the requested guards and improvements on all augers delivered in Ohio.

RULES FOR AUGER MINES

The following regulations were established.

1. A safety light shall be kept at the workings while augering.

2. No person shall enter auger holes except to save a life or recover equipment.

Only experienced miners can enter these holes and a lighted safety lamp must be carried.

When augering first started workmen went into auger holes for various unnecessary reasons, one being "we just wanted to see what it looked like in there." Many of our auger mines are working the crop coal left after deep mining is completed. These worked out mines contain black damp, which diffuses into the auger holes when the auger cuts through. Often the roof is bad and is a hazard to persons entering the holes.

Even with the definite rules, on October 12, 1956 two fatalities occurred from disregarding rule 2. The first auger hole in a new series was cut through to an abandoned mine 38 feet deep. One workman entered the hole and collapsed, another workman then entered and also collapsed. They died in the hole and three others were overcome trying to rescue them. This accident was due to a complete disregard of safety rules.

3. All augers shall have a shield or protective device for material falling from the highwall. This shield shall be constructed of heavy screen or expanded metal so the

operator can see the condition of the highwall at all times. It shall be constructed to deflect falling material toward the highwall to protect workmen while changing bits or working on the auger near the highwall.

We have the highwall cleaned and prepared properly before augering is started, but small stones still fall from the highwall. The screen can protect against these but not against large falls or slides. Once approximately 20,000 cubic yards slid off a highwall that looked perfectly solid. This highwall consisted of a conglomerate of fire clay and shale intermingled with limestone boulders of various sizes. The auger and a large truck were completely demolished but luckily no one was injured.

4. Before beginning operations the highwall shall be cleared of loose material to be safe. Unsafe highwall areas shall not be augered.

RAILINGS, EXHAUST PIPES, WALKWAYS

5. Where men walk on equipment, such as along the auger pit, on top of the motor cab, on top of the chain conveyor, across the back end of the machine or in front of the motor cab, there shall be a hand railing erected.

When augers first came into Ohio no hand railing was provided. The manufacturing companies provided these safety requirements.

6. The exhaust pipe from the motor operating the hydraulic system shall be extended to keep exhaust fumes away from the operator. The exhaust pipe shall be guarded to protect persons from being burned by contact. Several workmen were burned by a hot exhaust pipe. These pipes are now covered with a shield of expanded metal or a heavy screen.

7. The fan of the motor shall be guarded. Previously many fans were not guarded and created a hazard.

8. A walkway shall be installed over the bit coupling directly in front of the motor cab. The larger machines were a definite hazard when workmen stepped across the moving bit.

9. Steps shall be provided on the large machines opposite the hydraulic motors.

10. The openings between the steps and walkway near the large upright post on left side of auger should be covered to make a larger landing for men to stand or walk. On some of the larger machines large holes in the walkway created a hazard.

11. If the auger is worked at night, lights shall be installed to illuminate the work. The electric wires shall be in conduit.

12. Rope drums, chain drives, shaft couplings and motor fans shall be inclosed to prevent persons from being injured by moving parts. The manufacturers are installing this protective equipment.

13. No person shall cross over the bits while they are in motion.

14. Mapping requirements: Engineers or surveyors should not enter the holes to make survey measurements. Therefore, mine foremen should record the depth of all auger holes, so the engineer or surveyor can show the excavation by cross-hatching on the map.

Besides the two men killed in 1956 no fatalities and very few serious injuries have occurred in Ohio auger mines. The fatality rate per million tons of coal produced in such mines in 1956 was 1.47 compared to 0.43 for all Ohio mines. As stated before, this accident would not have happened if the rules were followed.

OTHER AUGER MINING PROBLEMS

Another problem of the auger method of mining occurs when a solid tract is mined along the crop and no provisions are made to recover the solid coal beyond the auger holes. When the crop is augered completely along the crop line, it is impossible to reach remaining solid coal by conventional deep mining methods.

Our inspectors know that when this condition occurs, the operator should leave at least 200 feet of solid coal at intervals along the crop line. This is a minimum, since Ohio law requires one hundred feet of solid strata between all openings to underground mines. Our policy prohibits opening underground mines in augered areas where the necessary protective pillars cannot be provided.

Another bad practice is bootlegging coal after the augering is completed. Occasionally people living near these abandoned mines get coal for their own use from the pillars between auger holes. We discourage this and require that holes and face be covered after the augering is completed.

One occurrence demonstrates that the auger can be a life saver as well as a potential danger. Last June 26th a sudden cave-in trapped five men at an "island mine" being worked by a continuous miner. A 42 inch auger on the same property was taken to the location where the men were trapped and three angling holes were drilled from the highwall. The first two holes intersected the entry in the caved area. However, the third hole intersected the entry ahead of the fall and the five men walked out behind the drill. These men were trapped about 14 hours. However, had the auger not been available, it would have required at least three or four days to clean up and properly timber the caved entry.

We are not proud of our safety record for auger mining, but do believe that a strict compliance with the following recommendations will provide the maximum of safety.

——Proper preparation of the highwall. Removing all loose material including trees on the edge of highwall. Daily inspection of highwall including an examination on top of same for cracks or other signs of possible slides.

——Not entering auger holes unnecessarily and if holes are entered a lighted safety lamp should be carried.

——Proper guarding of all exposed moving parts.

——A shield to protect workmen from falling stone from highwall.

——Being alert at all times.

——Wearing protective shoes and hats.

——Careful, strict supervision by the foreman.

——Strict, efficient inspection by the mine inspector.

A COOPERATIVE PROGRAM IN ACCIDENT PREVENTION

REMARKS OF ARTHUR BRADBURY

assistant to manager, Coal Properties, Inland Steel co., Wheelwright, Ky.

The further advancement of safety and the prevention of accidents in coal mines will result in inestimable benefits to labor, management and the general public. The responsibility for safety should be shared by both parties chiefly concerned, labor and management. However, the responsibility for planning and initiating a successful program is up to management.

The coal industry has been plagued with high frequency and severity rates of accidents throughout its history, but great improvements have been made during the past 10 or 15 years. Much more remains to be done before we can point with pride and be completely satisfied with our accident experience.

Programs for the prevention of accidents have acquired increasing importance in all segments of the industry. In recent years great improvements have been effected in attitudes towards safety among management people and workers, which have resulted in excellent examples of cooperative and successful effort.

The operators of coal mines can obtain great benefits from a successful program effective in substantially reducing accidents. Safety and efficiency are inseparable. Fewer accidents result in increased production and lowered costs, direct savings through lower compensation charges and improved labor and public relations.

Present-day conditions are much more favorable for conducting a successful safety program than ever before. Some features, which in my opinion have contributed to this desirable situation, are:

- Operators' associations have organized safety departments rendering safety service to member companies.

- The United Mine Workers of America also have their own safety department with headquarters in Washington and officials in charge of Union safety activities in the various districts.
- Local Union mine safety committees have developed stature and display a more genuine interest in safety problems.
- Operators of responsible coal companies have conclusively shown that they want safe mines.
- The United States Bureau of Mines has expanded its safety education and research facilities.
- The greater helpfulness of the Coal Mine section of the National Safety Council.
- Improved state and federal mining laws.
- More frequent and thorough safety inspections by the United States Bureau of Mines and State Mining departments.

MANAGEMENT'S SUPPORT

When organizing for safety, the greatest possible use should be made of all available services. It is management's function to provide a safety department manned by an adequate and qualified staff, and it is vitally important that top management's unequivocal support of this department is recognized throughout the organization.

As long as we are dealing with human beings, hazards will continue to exist. The natural hazards involved in producing coal from beneath the earth's surface have not lessened since mining began on a commercial basis. Gas and coal dust are just as explosive now, but knowledge has been gained and techniques developed until explosions from these sources have been almost eliminated.

Roof falls have been for many years the principal source of fatal mine accidents, but we are constantly improving methods of supporting roof.

ABIDE BY RULES

Mechanization has created new problems. The handling of heavy face machinery and haulage equipment in confined spaces with poor illumination is conducive to a high accident frequency. The same thing can also be said for the tremendous growth in the use of electricity in coal mines.

New methods of combating these hazards must be sought constantly. Emphasis should be placed on providing the safest possible working conditions and insisting on their being maintained. Rules and standards embodying good safety practices should be established and an inspection service provided to insure that these are not relaxed.

When planning new mining operations, safety considerations should certainly play a prominent part in reaching decisions regarding mining systems and the type of equipment. These same considerations should enter into the plans for modernizing old mines.

The Wheelwright Mines operated by the Inland Steel company were started 42 years ago and for many years all coal produced was loaded by hand. The company has kept pace with the constant improvement in methods and equipment to remain competitive, and safety has shared largely in this improvement.

Evidence of this can be found in the progress in safety made by the company from 1942 until the end of 1956. Using the frequency rate as the yardstick for measuring this progress, we find that in 1942 the rate was 61.44 per million man-hours, which was steadily reduced during the 15-year period to 7.18 in 1956. This latter figure was the best in the history of the company.

SAFETY SUGGESTIONS

Among the noteworthy changes which have contributed to the safety and health of the workers are: increased ventilation, elimination of coal dust accumulations, more thorough rock-dusting, control of airborne dust, provision of special covered man-trip cars and increased use of roof bolts.

A major advancement in safety on the haulage system was recently accomplished at great expense by introducing large, modern mine cars equipped with automatic couplings and safety uncoupling device. Preparations for this change consisted of improving the track over miles of underground haulage roads and replacing timbers with roof bolts to support the roof over large sections of main line haulageways.

The employer and his representatives must do everything possible to neutralize the hazards and plan a safety program to arouse the interest of all supervisors and workers.

Many coal companies have successfully achieved this result with varied programs.

In my opinion, the individual components of the program are not too important. They have to meet the needs of the various types of operations. It is most important that they be presented in an attractive and appealing manner with evidence of sincere and genuine endeavor to prevent accidents. New means of maintaining interest must be constantly sought and variations adopted to meet changing conditions.

MAKE IT APPEALING

Some of the principal recognized aids to a program for reducing accidents include safety inspections, first-aid and mine rescue training and contest participation, safety meetings of various kinds, safety competitions incentive plans and special campaigns.

However, one of the most universally accepted aids to a successful program is the United States Bureau of Mines 100 per cent Accident Prevention Training course for workers and supervisors. This type of safety education has met with unprecedented success, has the approval of management and mine worker officials, and the cooperation of workers has been outstanding.

The employer should organize a program of safety which will utilize to the fullest practical extent all available services. This should include the active participation of the mine safety committees and all supervisors.

The key to accident prevention is the degree of interest that can be aroused and maintained among the entire working force, and this should be the objective of the program.▲

REMARKS OF CHARLES A. PURCELL

director, Indiana Bureau of Mines & Mining, Terre Haute, Ind.

The word "co-operation" means two or more people working harmoniously together for the attainment of a common goal. In this case, the goal would be to reduce and possibly eliminate, accidents in the coal industry.

Who are the co-operating parties? The two principals are management and labor, and I might add, management must take the lead. There are the various inspection agencies, who can do much with the right approach and attitude of being helpful rather than playing the role of a policeman. Then the mine suppliers and manufacturers of mine machinery should follow a "Safe it as you make it," policy.

Soon after I became director of the Indiana Bureau of Mines, in January of 1953, I was invited by the Lynch Reciprocal Coal Operator's Association, the insurance carriers for the majority of our operators, to participate in conducting a miner's First Aid contest. The contest was a success and everyone was pleasantly surprised to see all the segments of the industry working together. It was then suggested that we meet once a month and discuss ways and means to eliminate accidents. In a short time these meetings led to the organization of "The Indiana Joint Committee for Coal Mine Safety."

Those co-operating to form this committee are, the United Mine Workers of America, through their district officials and Charles Ferguson, safety director of the United Mine Workers of America; the Indiana Coal Operator's Association, through some of their officers and mine superintendents; Harry Gandy, safety director of the National Coal Association; the Lynch Reciprocal Coal Operator's Association, the Federal Bureau of Mines and the state Bureau of Mines.

Since its organization, we have met every month discussing accidents with ways and means of preventing a re-occurrence and planning First Aid contests, slogan contests, incentive programs, first aid and mine rescue training.

Recently, in addition to our monthly meetings, we have planned to meet three times a year and to invite mine supervisors, local union officials and safety committeemen to participate in a Saturday morning meeting. We feel these meetings have done much to bring about a better understanding with the men working in the mine of the things we are trying to do.

FATALITIES DECREASED

We feel there has been a definite improvement, not only in our accident record, but in relations between the various agencies charged with safety in the industry and everyone connected with the mining and marketing of coal.

When I became director of the Indiana Bureau of Mines, there was more or less the general feeling that at least 12 men were predestined to die each year in our underground mines. However, the last annual report, which covered a period from July 1, 1951 to June 30, 1952, reported only seven deaths, for which my predecessor was feeling very happy and justly proud, because that was the lowest record our state had in fatalities.

At the same time, I recorded six fatalities in my first annual report, ending June 30, 1953. We finished that year with 11 fatalities; 1954 showed 10. In 1955 our new law went into effect, and it called for an annual report based on a calendar year. To keep the records straight, we reported both a fiscal year and a calendar year. The fiscal year showed two, the calendar year showed three. Our 1956 report showed no fatalities. In fact, we went from November, 1955 to May, 1957, without a fatality.

A word of explanation, these figures come from under-ground mines only, and may vary from other reports which include all mining. The reason for this is that the Indiana Bureau of Mines, under our State Coal Mining Law, has jurisdiction, receives reports and keeps records of under-ground coal mines only. When it comes to non-fatal accidents, we do not fare so well, though we do show some improvement since we have been working co-operatively.

The following report was taken from the files of the Lynch Reciprocal Coal Operator's Association and represents about 80 to 90 per cent of our total production.

We do not feel that we have the answer to all of our safety problems, and good records have no value unless they inspire us to greater effort and achievements. My purpose has been to be helpful by showing the tremendous and unlimited benefit that comes from honest co-operative efforts.

	1953	1954	1955	1956

REMARKS OF LOUIS W. SCHULER

assistant director, Safety Div., United Mine Workers of America, Washington, D. C.

The Safety division of the International Union since its inception in June, 1947, has had one primary goal—increased safety in the industry and a resultant decrease in the accident rate. However, to increase safety in coal mines, cooperation is an essential requirement.

There are few things which can be accomplished as individuals, whether it be in our own personal lives or the business world. In the field of safety, it is an absolute necessity that we act as a group with one thought in mind—"the saving of lives."

A safety program to be successful must enlist the help of everyone and the safety division recognizing its share of the responsibility for such an undertaking works in conjunction with the membership of its local unions and district offices, representatives of the U. S. Bureau of Mines, coal producing companies, safety directors headquartered in Washington, D. C. and other correlated agencies or organizations that promote coal-mine safety.

The most compelling reason for a safety program is the welfare of the men who produce the nation's coal, and the job of promoting safety is one at which everyone must work all the time. Safety should be one of the most important considerations in the efficient operation of any business and certainly this precept is especially applicable to the hazardous coal-mining industry.

UNION SAFETY WORK

In an effort to gain cooperation, the safety division of the International Union has done everything within its power to bring about a closer understanding among the agencies. We have engaged in a multiplicity of activities, none of which by themselves is an answer to the entire problem, but taken as a whole, have made major contributions to the safety movement. The following are some of these activities:

More than 163,000 members of our organization have taken the Accident Prevention course sponsored by the U. S. Bureau of Mines. This number includes many safety committeemen and the total membership of approximately 255 local unions. The entire membership of one district was awarded a certificate for 100 per cent completion of the course. This was District Four in Pennsylvania.

Another cooperative keystone to safety which benefits the membership of the United Mine Workers of America is the Bureau of Mines' First-Aid Training course. Several local unions have completed this course as their contribution to the safety program.

We have joined with and participated actively in the formation and perpetration of Holmes Safety councils and chapters throughout the nation. We have affiliated with the National Safety Council and have participated actively in furthering the programs of this organization.

FIGHT ROOF-FALLS

We have joined the Council and the industry in a campaign to reduce roof-fall accidents—the number one killer. It is gratifying to note that more than 1,000 mines enrolled in this campaign to reduce roof fall-injuries by 50 per cent. This campaign commenced on July 1, 1957 and will terminate on June 30, 1958. The Federal and State agencies, coal operators association, together with the United Mine Workers of America have joined hands in an attempt to make this campaign successful.

There exists in Washington, D. C. a group comprised of safety directors from the National Coal Association, the Southern Coal Producers Association, the Bituminous Coal Association, the United Mine Workers of America and the Assistant Director of Health and Safety of the U. S. Bureau of Mines. These gentlemen meet monthly to discuss problems of safety and the accident and fatality rates of the coal-mining industry. The group informally discusses all problems pertinent to safety, mindful at all times that cooperation and understanding is the key to many a knotty problem.

The safety division of the International Union to clarify its position on safety grievance procedures inaugurated a program outlining specifically the steps to be followed by local unions and districts involved. The primary thought was to extend cooperation in adjudicating safety matters as they arose at the respective levels. This program has been accepted widely throughout the industry and has done much to avoid confusion which existed on previous occasions.

DISTRICTS WORK ALONE

In addition to the above, our various district organizations which are authorized to function within their jurisdictional areas have initiated and carried out programs designed to meet their particular needs. One of these programs is currently in effect in our West Virginia District Twenty-Nine. Many coal-producing companies in that area and the district safety department launched a new program which required the creation of joint safety committees on the local mine level.

The committee consisting of eight members—four representing the personnel of the local management and four representing the local union—works on a cooperative basis to advocate full and strict compliance of the company's safety regulations, the Federal Mine Safety Code and Act and the State Mine Law, together with whatever safety regulations the committee adopts to combat any existing hazard at the mine.

The committee's first obligation is to have all physical violations of the mine corrected,

and secondly—encourage the performance of work in a safe manner. If there should be a tendency on the part of any workman to be careless, this committee attempts to rehabilitate the individual to become a safer worker. Further, the committee is authorized to draft its own program in addition to other safety requirements to be observed by persons employed at the mine.

INDIANA'S EFFORTS

In District Eleven, located in Indiana, a program of cooperation has proven to be highly successful. This program stems from a permanent committee which meets monthly to discuss means and ways of furthering it. The committee is composed of top management from the underground mines, top district officials, the insurance carrier and representatives of the State and Federal Bureau of Mines. The idea has recently spread to the strip mines of that state and has been equally successful.

It is an impossibility to give a more detailed outline of our safety program. For instance, I have not mentioned the thousands of miles traveled each year to extend our cooperation at safety meetings, the numerous conferences involving our membership held with state and federal authorities and representatives of management, seeking to achieve a better relationship and a more cooperative approach in the settlement of safety problems.

The cooperation we have extended and the cooperation extended us has had much to do with the advancement of our safety program. We shall continue our cooperation along this line to further promote and expedite safety in the coal mines of America.

However gratifying results may seem, statistics for the year 1957 show beyond a doubt the necessity for an unceasing search for an even better safety program than that now in existence.

REMARKS OF JAMES WESTFIELD

assistant director, Health & Safety, Bureau of Mines, Washington, D. C.

Webster defines cooperation as "collective action for mutual profit or common benefit." This definition fits the objectives of the health and safety activities of the Federal Bureau of Mines.

Throughout its 47 years of existence, the Bureau has been essentially an educational institution. Yet, none of its efforts to promote health and safety in the mineral industries coal mining being the most hazardous ——— could have produced results if the companies and employees had not cooperated with the Bureau and with each other.

In the Bureau's early days the cooperation was obtained from necessity and desperation. Personnel of the original Safety Division literally went from one coal-mine disaster to another, rescuing the dead and injured and restoring mines to normal operation. The industry soon realized it must have trained rescue and recovery crews and people trained in first aid, since mining towns in those days were largely "off the beaten path" and difficult to reach. Many coal-mining people soon realized the advantage of having their own trained personnel on the scene if or when disaster or injury struck and not depending solely on outside help.

BUREAU "SELLS" SAFETY TRAINING

In the early days, however, the Bureau had quite a "selling job" to convince others to have trained first-aid and mine rescue men on the job. On the whole, the mining industry has cooperated admirably, and recently this sales work has been materially reduced.

Nearly two million people have taken Bureau of Mines first-aid training and more than 100,000 the basic mine rescue course. Although a substantial percentage was trained by Bureau personnel, most training was conducted by persons qualified according to Bureau standards. The large totals could not have been achieved without the cooperation of the teachers, the companies, and, most important, those who took the training.

First-aid and mine rescue training is fundamental in arousing safety consciousness. But more was needed for a substantial reduction in accidents and injuries.

In the 1930's the Bureau instituted its first coal-mine accident-prevention course, mainly for supervisors. This was accepted with reasonable enthusiasm; but during World War II, it was necessary to recess this work. In 1947 the course for supervisors was reactivated, and in 1950 a course for mine-safety committeemen began. The demand for this course was so great that it was expanded to include all mine workmen.

Since safety promotion depends on united effort, it was realized that for better results the workmen and their supervisors should train together. Also the best results could be obtained if every employee took the course. Since 1947 approximately 195 thousand workmen and supervisors completed the Bureau's Coal-Mine Accident-Prevention Course; more than 95,000 of these represent 100 per cent participation. Without the cooperation of the coal-mining companies and the United Mine Workers of America, this record would have been impossible. The Bureau provided the instructors, text material, and visual aids.

Recently we had numerous requests for relatively brief "follow-up" courses. For most follow-up work, the Bureau provided instructors and instruction materials. In a few instances the Bureau was asked to furnish textual material or assist the company in preparing it.

COMPANIES MUST PROVIDE INSTRUCTION

The Bureau has a limited number of qualified instructors. Therefore, once the Bureau's basic accident-prevention course is completed—preferably with 100 per cent participation, the companies themselves should keep interest alive by continuing this work through their supervisory and engineering staffs. The Bureau, of course, will always give advice and help prepare texts for instruction.

Other aspects of the Bureau's work are: development, testing, and application of permissible explosives and blasting devices, permissible electric equipment, permissible respiratory-protective equipment, and permissible dust collectors.

The Bureau also does research, experiments, and investigations of the causes and prevention of mine explosions and fires, particularly at the Bureau's Experimental Coal Mine, and research, investigation, and service on roof-control problems, including roof bolting. The director plans to extend the mine-safety-research program and increase the Bureau's services to the coal-mining industry.

Although these activities are mentioned only briefly, the Bureau has done marvelous pioneer work in these areas. In some instances it conducted educational campaigns to gain acceptance by the coal-mining industry. Nevertheless, significant accomplishments would have been impossible without the wholehearted cooperation of the industry, including workmen and supervisors, in testing new ideas and equipment.

Again the definition of cooperation—"collective action for mutual profit or common benefit." In the broad sense, accident prevention increases profits since accidents are wasteful and costly. The common benefit accrues to all in a very material way by avoiding the loss of skilled manpower and the suffering that accompanies all injuries.

The Bureau benefits because, in soliciting the cooperation of industry and helping to improve the accident and injury record, the Bureau fulfills its obligation both to Congress, which votes the funds to conduct its work, and to taxpayers, who pay the bill.

SAFETY FEATURES IN THE DESIGN AND DEVELOPMENT OF IRELAND MINE

by G. W. McCAA

general manager, Hanna Coal co., Div. of Pittsburgh Consolidation Coal co., Moundsville, W. Va.

The Ireland Mine is a new operation of the Hanna Coal company, division of Pittsburgh Consolidation Coal Company, and is located in Marshall County, W. Va., seven miles South of Moundsville, and adjacent to the Ohio River. This mine was developed to meet the demand for coal in the industrial expansion of the Upper Ohio Valley.

The coal from Ireland Mine will supply the Kammer Power Plant of the American Gas & Electric System, a large power plant built primarily to supply power for the new Olin-Revere Aluminum Plant. Plans for the design and development of this mine were started in November 1955. Construction of the surface facilities, shafts and slopes was started in January 1956; first coal was produced October 15, 1956. It is expected to have the preparation plant completed and in operation in December 1957.

In designing and developing this mine our aim has been to make it the safest and most efficient mine possible. Safety in the design of all equipment and mining plans has been given primary consideration to protect the lives of the employees. It is also self-evident that you cannot have an efficient mine without having a safe operation. The fact that Ireland Mine is a completely new mine with all new equipment, has made it possible to incorporate the safest possible methods and devices in its development.

There are many different operations and facilities to be planned and constructed in the operation of a new mine and safety has been considered in every individual case.

FALLS OF ROOF

The most serious safety consideration is the protection of the underground employees from falls of roof and rib in the working face area. The Ireland Mine is being developed in the Pittsburgh, or No. 8 coal seam, and in this area the seam is approximately five feet thick and immediately above the seam is a strata of draw slate that ranges from 0 inch to 48 inches. The draw slate strata is weak and must be supported if mining is to be conducted under it.

Above the draw slate is a seam of coal from one to two feet thick. The next strata is a mixture of shales from eight to 10 feet thick, which is a poor structure. Above this strata is a thick bed of limestone which is strong and fairly uniform.

In our original mining plans we decided that we would employ continuous mining machines to the fullest extent possible. We would try to operate them under the draw slate safely by the use of roof bolts, or the combination of roof bolts and timber. At the time the coal was reached in the development of the mine, the only type continuous miner applicable to the height of seam and could be adapted to supporting the roof was the ripper type of continuous miner.

The manufacturer had not designed roof bolting equipment to be used on this machine. When the original mining was started, we supported the draw slate with crossbars and posts. We found that the draw slate could be supported with crossbars and posts, but the draw slate soon became loose and sagged down on the timbers presenting a dangerous condition in case a post or bar was knocked out by any of the mining equipment.

The continuous miner was followed up with a conventional rubber-tired roof bolting machine, which installed five-eighth inch —1040 steel bolts six feet long, and which successfully held the draw slate. The places were approximately 16 feet wide and bolts were placed on four foot centers four feet apart. When this was done we found that the draw slate did not become loose and the support appeared adequate. The roof bolting, however, was a separate operation and did not protect the operator of the continuous mining machine while he was working at the face.

HYDRAULIC ROOF BOLTING

By utilizing the power from one of the cutter motors to drive a hydraulic pump with V belts, it was possible to design hydraulic roof bolting equipment that would fit within the space available on the machine. Two roof bolting units, one on each side of the machine, were installed in place of the hydraulic timber jacks. This permitted roof bolts to be installed ahead of the operator and within 13 feet of the working face.

The hydraulic timber jacks were moved to a position approximately two feet ahead of the roof bolters, and two No. 60 rails were installed on the jacks as crossbars to protect the roof bolters. This unit was put in operation with two bolts installed eight feet apart through a two inch by eight inch by 12 feet hardwood plank. These planks were installed on approximately 36 inch centers. This was purely an experimental method of supporting draw slate, and at the start crossbars and posts were installed between the planks. Several crosscut lengths were driven in this manner.

It was soon evident that the planks and bolts were supporting the draw slate and the posts and crossbars were not necessary. When the bars and posts were removed, it was found that there was no movement of the draw slate and the bolt and planks were doing an adequate job. Since that time approximately 50,000 lineal feet of entries and crosscuts have been driven using this method, and although we have experienced slate falls at the face ahead of the roof bolting, there have been only five small falls of roof where the area has been bolted.

THICK SLATES CAUSE FALLS

These falls have generally occurred where there was a slip or abnormally thick draw slate. One item of interest is that in all cases there has been warning of the impending fall, and the bolt and planks worked for a considerable time before the fall occurred. Some of these falls can be attributed to improper installation of roof bolts or spacing planks too far apart under heavy draw slate.

We are, at the present time, experimenting with a continuous miner of the boring type, using the same type of roof support, except in this case it is not possible to attach the bolters to the machine as the machine is continuously moving forward. The bolters are satellite units which operate independently but are attached to the machine with a hydraulic jack and rope. The roof bolters install the bolts and planks as the miner continues to advance. When the bolting operation is completed, the bolting units are pulled ahead with the rope and hydraulic jack to the next position.

The roof of main haulage roads and air courses cannot be supported for the life of the mine in the above manner. Additional height is also required on haulage roads. Since Ireland Mine will possibly have a life of from 50 to 100 years, it is necessary to plan the best possible method of maintaining the main entries. Our original plan was that we would shoot down all the strata above the coal to the limestone and use the limestone as a permanent roof.

The ribs and roof would be protected from weathering with wire mesh and gunite. At the bottom of the supply slope the construction of our main entries was started in this manner. Removing the strata above the coal proved to be a slow and dangerous job. The scaling of the ribs after the shooting and a subsequent loading of this material was hazardous. We experienced one fatality due to the operator not taking down a rib which had become loose in this operation.

CONTINUOUS MINER PREVENTS WEATHERING

Shortly after this method of developing the main line began, we observed that the ribs and even the limestone, started to weather and there was a continuous loosening of ribs and roof. In adjacent places which had been mined with a continuous miner and the draw slate bolted. Little weathering of the draw slate was observed and no falls were encountered. We soon decided that the shooting of the roof had opened up cracks which was conducive to the weathering of the ribs and roof.

The only strata between the coal and the limestone that does not readily weather is the one to two feet of roof coal directly above the draw slate. If this coal strata could be held by roof bolting, safe haulage roads and air courses could be maintained. A continuous miner was taken off of production and placed on the job of ripping down the draw slate which had been left up in primary mining.

The roof coal was then bolted, wire meshed, and gunited. To obtain haulage height, the bottom was graded with as little shooting as possible. We now have about 1,500 feet of this construction work completed and an additional 3,000 feet where the draw slate has been ripped out with a continuous miner and rebolted.

STOP DOUBLE OPERATION

In comparison with the haulage entries that were taken to the limestone, it appears that this method of supporting the main entries will be more successful. It is our belief, that the fact that we are not doing any shooting which would tend to crack the roof or ribs, will greatly reduce the number of falls in air courses and along the haulage road.

When the preparation plant is in operation we plan, on main haulage roads and air courses, to rip the slate down when the coal is mined. This will eliminate the double operation of mining the coal and brushing the top separately.

The use of continuous miners and the heavy cover over the coal seam at Ireland Mine made it necessary to consider changes in the mining practices as compared with the conventional plans normally used in the Eastern Ohio Section of the Pittsburgh, or No. 8 seam. Pillaring has never been successful in this area, and although pillaring will be tried in this mine, the general plan of mining is projected for partial recovery.

Observations of the mining conditions and the methods used in the relatively shallower cover in Eastern Ohio and the West Virginia Panhandle, convinced us that the wide room with the narrow pillar would not work successfully under the 1,000 foot cover encountered at Ireland Mine.

FOR FAST EXTRACTION

The following plan for mining has been projected and will be started in 1958. It is planned to drive working panels of six or seven headings on 80 foot centers approximately 2,000 feet long. Each panel will be driven with three continuous miners with the coal hauled from the miner by shuttle cars to a 36 inch conveyor belt. The reason for using three continuous miners on a panel is to get the most rapid extraction possible. When the panel is developed, each of the 64-foot-square blocks will be split both ways, leaving four square stumps.

These square stumps will give the maximum roof support with a maximum amount of recovery. Three miners will be used also on the retreat work, and it will be possible to develop and work out a 2,000-foot panel in approximately 60 working days. The rapid extraction and the method of leaving square stumps on the retreat, we think is necessary if our method of supporting the draw slate with bolts and planks is to be successful.

Future experience will dictate the centers on which these blocks will be driven and the width of the places splitting the blocks. The variation of block centers and width of the places under different mining conditions will permit maximum recovery with maximum safety.

USE A.C. POWER

All the mining equipment at Ireland Mine except for the haulage, is operated with A.C. instead of the conventional D.C. power. The underground power will be distributed at 6900 volts through "Mine Power Cable" insulated for 8000 volts. One of the three underground wires is insulated to form a circuit to insure continuity of ground wires throughout the entire system.

In case of a ground circuit failure or a fault, the automatic breaker on the surface will disconnect all A.C. power in the mine. Air-cooled transformer units reduce the primary voltage to 440 volts for use in the working areas; 440 volt power is distributed through Type G Cable with ground conductors connected through relays and current limiting resistors to the transformer neutral.

This limits the voltage to ground and cuts off power to any circuit in which there is a fault. Distribution panels have ground trip devices so that all electrical failures are confined to a single piece of equipment or cable. With this system when there is a trailing cable fault, there is no arc or burning that usually occurs on conventional D.C. cables. This distribution system is practically the same as the 4160 volt system that has been used successfully in stripping operations for the past 15 years.

The main haulage system has been designed to be as safe as possible. The roof and ribs will be wire meshed and united; the main haulage track will be 85# welded rail on treated ties ballasted and drained; adequate clearance will be maintained on both sides of the haulage road; the trolley and feed wires will be installed six and one-half feet above the rail; automatic electric switches, electric block signal system, and trolleyphones will be used for control. Ventilation throughout the mine will be provided from dual fans with automatic controls. Newly designed wet rock dusting units are used in the working face and are followed up with the conventional high-pressure dry type dusting machines.

The three shafts at this operation were sunk using the method developed at Hanna Coal Company's Eastern Ohio mines. A ring of holes is drilled with a heavy-duty stripping drill around the perimeter of the shaft from the surface to below the coal. These holes are approximately 16 inches apart and eight inches in diameter, and their primary purpose is to act as breakers. Seven holes are drilled to form a shooting pattern inside the rings of breaker holes, and these shot holes are then filled with sand.

Approximately 10 feet of sand is blown out of each shot hole with an air line and each hole loaded with 25# of 60 per cent gelatin. A round is fired and the rock loaded out of the shaft with a power shovel on the surface using a clamshell bucket. In this method of sinking the only time that men are in the shaft is to scale the ribs and to blow out and load the shot holes. This greatly reduces the man hours of exposure of men working in the shaft.

Two slopes were driven at this operation, 600 and 1300 feet long. They were driven with mechanical equipment. Roof bolts were used to support both the roof and ribs in the slope driving. An exhaust fan was used and a curtain wall erected of corrugated sheet iron so that all the equipment was operating on intake air in the slopes.

In developing Ireland Mine the most serious safety feature that has been encountered is the training of employees. The United States Bureau of Mines conducted their Accident Prevention Course with a 100 per cent participation which was very successful. We are at the present time starting classes in safety and mining at the mine conducted by various members of the organization. First Aid and Mine Rescue classes are planned to train properly employees and supervisors.

At Ireland Mine we have received excellent cooperation from both the Local and District organizations of the United Mine Workers of America, U. S. Bureau of Mines, and the West Virginia Department of Mines; and with this assistance, we hope to make Ireland Mine the safest mine in the country.▲

DUST COLLECTION AT THE COAL MINE FACE WITH CONTINUOUS MINING OPERATIONS

by RAYMOND J. WACHT

product engineer, Joy Manufacturing co., New Philadelphia, Ohio

This paper summarizes the results of a two-year investigation on dust collection at a coal mine face as applied to continuous mining operations. Tests were confined to a portable high efficiency wet inertial type dust collector in conjunction with a continuous mining machine.

Comparison of dust counts using the collector alone and with additional face ventilation are made. Results show that the collector tested can supply total ventilation to the face area and remove most of the airborne dust from the airstream before discharging the air in subsequent mine areas.

When continuous mining equipment and methods are used, high production is confined to a small working face. Relatively high tonnage is extracted at a rapid rate and the resulting dust concentration, which is a function of the rate of coal breakage,

obviously increases with increased extraction. This is apparent regardless of the type of continuous mining equipment employed.

When this dust is permitted to accumulate, three hazards present themselves.

a. The danger of dust explosion.
b. The danger of accidents due to poor visibility.
c. Physiological effects.

PROPER VENTILATION

Adequate and proper ventilation can keep these hazards to a minimum. However, when a muning machine nine feet wide by four feet high, and five men are confined to a working face, 16 feet wide by six feet high, it is often difficult to get a good air sweep of the face to keep the dust count within acceptable figures.

Line brattice and adequate air supply combined with water sprays are used with success in keeping dust particle counts below one billion particles per cubic foot. This is well below the amount necessary to propagate an explosion; however, poor visibility and the physiological effects due to prolonged exposure are still present.

In customary ventilation practice, the dust from the face is normally diluted with incoming air and directed towards other working faces in series and ultimately arrives at the exhaust fan and discharges into the atmosphere. When there are several working faces ventilated with the same air in series, the faces downstream receive ventilation containing the dust generated from preceding mining areas.

Tests have been conducted where as little as 3,500 cfm of air in a face 14 feet wide by 6½ feet high, with a 4JCM continuous miner working, maintained dust counts as low as 17 million particles per cubic foot at the machine operator's location.

USE SUCTION TUBE

This was accomplished by extending a suction tube along the rib close to the face with a properly designed inlet bell at the end of the tubing. A vaneaxial fan located outby the tubing provided the negative pressure necessary to maintain the flow.

Forced ventilation is an effective means of eliminating the dust problem at a working face but does not remedy the situation at subsequent areas, unless of course, the tube or duct can be brought directly past these other working places. Generally this is uneconomical and impractical. A solution is to combine forced ventilation with a dust collector, not only to eliminate the dust problem at the face, but to dispose of the dust before the ventilating air enters the subsequent workings.

The obvious question which presents itself is: "What kind of a dust collector should be used?" The answer to this question is dictated by the characteristics of the dust handled, safety requirements, space limitations, portability, secondary dust handling and maintenance.

Here is the size range of typical airborne dust present with continuous mining operations. The geometric mean size is 1.7 microns which suggests the need for a collector with high collection efficiency in the minus ten micron range. A bag type of collector would meet the collection efficiency requirements.

However the tremendous physical size required because of low face velocities makes this type of unit somewhat impractical underground. A dry inertial type of separator such as multicyclones could possibly be made compact enough to be acceptable for the space limitations; however, its collecting efficiency in the minus 10 microns range would not be acceptable.

It is for the reasons mentioned above that the Joy Manufacturing company decided to investigate the possibility of applying a new type of high efficiency wet type collector for underground usage.

PRELIMINARY FIELD TESTING

A dust collector designed specifically for underground use was field tested in 1955. This unit was 10 feet long, three feet wide and three feet, four inches high with a maximum rating of 6,000 cfm at 11 inches water gage total pressure. The unit was powered with a vaneaxial type fan, using a 15 horsepower, 250 volt, DC motor.

The fan was mounted on the discharge or clean air side of the collector. Provision was made at the intake end of the collector to accommodate an 18 inch diameter flexible tube with a maximum tube length of 300 feet. The entire assembly was skid mounted so that it could be moved to various working faces as desired.

The dust collector was placed in a section of the mine operating on a modified room and pillar system. Three Joy Continuous Miners each equipped with an extensible belt, extracted the coal. Coal from the extensible belts was subsequently transferred to main haulage belts.

During mining operations the dust collector was placed in an open crosscut with a check curtain surrounding the collector. Flexible tubing in 25 foot sections was suspended from the roof timbers as the room was advanced. These rooms were driven to 1,000 foot lengths which means that the collector was moved at least three times to a different crosscut during the 1,000 foot advance. When brattice cloth was used, it was positioned on the return air side of the room. With this arrangement the tubing was kept within the return air course behind the brattice.

The ventilation normally supplied was 24,000 cfm into the first room. Of this amount 5,000 cfm was picked up by the flexible tubing and passed through the collector. The remaining 19,000 cfm passed behind the brattice and over the collector through the check curtain in the crosscut. This air then passed into the next room and supplied the ventilation for the subsequent working area where retreat work was in progress.

The results of these tests are condensed in Tables I and II. The tests conducted in Table I, reference 1, were made within the room neck before any crosscut was made. No line brattice was used; consequently no ventilation other than the 5,000 cfm supplied by the dust collector was available. The dust collector intake tubing varied in position from directly opposite the operator to six feet outby the operator.

TABLE I

Dust Concentration at Machine Operator

Ref.	Dust Concentration (MPPCF)	Ventilation (CFM) Total	Collector
1.	39		5,000
2.	71	24,000	
3.	10	19,000	5,000

The dust concentration at the machine operator ranged from 12 to 55 million particles per cubic foot. The higher dust figure corresponded to the time when the intake tubing was six feet outby the operator. This shows the need for keeping the tubing up close to the dust source.

Reference 2 shows the effect of using line brattice for return air without the dust collector operating and 24,000 cfm ventilation available. The end of the line brattice varied from directly opposite the machine operator to four feet outby during this test. The dust concentration varied from 51 to 91 million particles per cubic foot. The higher dust figure corresponded to the time when the line brattice was four feet outby the operator.

In Reference 3, the line brattice and dust collector were both operating with 5,000 cfm passing through the collector and 19,000 cfm passing behind the line brattice and over the collector. The intake tubing was three feet inby the operator, and the line brattice three feet outby the operator. The dust concentration varied from five to 15 million particles per cubic foot during this test.

TABLE II

Return Dust Concentration in Crosscut

Ref.	Dust Concentration (MPPCF)	Ventilation (CFM) Total	Collector
1.	156	24,000	
2.	14	19,000	5,000

Dust samples were also taken in the crosscut where the collector was situated. Table II shows the dust concentration in the total return air approximately 25 feet behind the collector discharge. Reference 1 is with line brattice and no dust collector operating.

A midget impinger sample indicated 156 million particles per cubic foot with line brattice and no dust collector. In the same location with the dust collector operating, the dust concentration varied from five to 22 million particles per cubic foot. The return air through the crosscut is the ventilation received at the second working face doing retreat work.

It is interesting to note from Table II that when only ⅛ of the total 24,000 cfm of air was diverted through the dust collector, the total dust concentration in the return air was reduced from 156 to 14 million particles per cubic foot. The reason for this

is in the proper placement of the intake tubing with respect to the mining machine.

The maximum amount of dust in this instance was generated near the roof. Consequently the position of the tubing up close to the face and to the roof was an ideal location for picking up the dust before it could spread.

The results of these early tests indicated that much less air than the 24,000 cfm could be used to keep the dust concentration below, say 25 million particles per cubic foot, at the working face. Likewise, practically all of the dust in the return air could be eliminated by passing all of the return air through an efficient dust collector.

CURRENT FIELD TESTING

A dust collector, embodying the precepts learned from past work unique to underground usage, is currently undergoing field tests. The portable Joy Microdyne Dust collector is 12½ feet long, three feet, eight inches wide and four feet high with a mean rating of 12,000 cfm at 11 inches water gage total pressure. Water consumption is approximately eight gpm at 60 psi. The unit is powered with a vaneaxial type fan using a 30 horsepower, 250 volt, DC motor.

The fan is mounted on the discharge side of the collector. Provision is made at both the intake and exhaust end of the collector to accommodate a 24 inch diameter flexible tube with a maximum length of at least 300 feet. The entire collector is mounted on pneumatic tires and is steerable by means of a draw yoke.

During operations the collector was placed in an entry which served as a return air course. No brattice cloth was used for room ventilation and no water sprays on the miner were used to allay the dust. Flexible tubing in 25 foot sections was suspended from the roof timbers as the room was advanced. With this arrangement the only room ventilation was the air handled by the dust collector which was held to 12,000 cfm.

When the dust collector was situated in the center of the return air entry, the tubing on the discharge side of the collector was used for sampling purposes only and was not necessary for operation of the collector. The eight gpm of water used by the collector was picked up by a gear pump from a sump in the mine and was delivered to the collector at 60 psi pressure.

The slurry was discharged from the collector into a shallow ditch at the rib and eventually found its way to the sump. Seepage from old workings also drained into this sump; consequently the water from the collector was essentially re-circulated. The working parts of the collector are constructed of Type 316 stainless steel; therefore, corrosion from acid mine water is held to a minimum.

TABLE III

Dust Concentration at Machine Operator

Ref.	Dust Concentration (MPPCF)	Ventilation (CFM) Total	Collector
1.	256		
2.	16	12,000	12,000

Tables III, IV and V are condensed results of current field tests at the Joy Experimental Station. In Table III, Reference 1, the dust collector was not operating; consequently no appreciable face ventilation was obtained. The dust concentration at the machine operator's position for this condition rose to 256 million particles per cubic foot.

Reference 2 indicates the improvement with the collector operating and pulling 12,000 cfm across the face and through the collector. The dust concentration varied from 11 to 21 million particles per cubic foot with an average of 16 million particles per cubic foot at the operator.

TABLE IV

Return Dust Concentration in Entry

Ref.	Dust Concentration (MPPCF)	Ventilation (CFM) Total	Collector
1.	6	12,000	12,000

The dust concentration in the return air entry behind the dust collector discharge was also sampled. From Table IV it may be seen that only 6 million particles per cubic foot were being discharged into the entry from the dust collector. The entire 12,000 cfm of room air was passed through the collector.

Samples were likewise taken at the inlet and outlet of the collector to determine the collection efficiency. The standard thimble method was used to determine efficiencies by weight and the Greenburg-Smith impingement flasks were used to determine efficiencies by count.

TABLE V

Dust Collector Efficiency

Efficiency %	Remarks
99	By thimble weight method
90	By impinger count method

Table V indicates the type of efficiency of the collector on typical airborne coal dust resulting from mechanized operation. By particle weight method, 99 per cent collection was the average efficiency obtained. An efficiency of 90 per cent by particle count was obtained. A microprojector with 1,000X magnification and resolution to .2 microns was used to obtain the count efficiencies.

This study indicates that a collector of a type used in this study can be used in conjunction with normal ventilation practice. Dust concentration at the face as well as dust in the return air can be materially reduced by dividing the air between the dust collector and the return air brattice cloth.

Tests indicated that with proper placement of the inlet tube with reference to the coal face and machine operator, the dust count at the operator was reduced from an average of 71 million particles per cubic foot to 10 million particles per cubic foot. The count in the return air, which was mixed with untreated air at the face, was reduced from 156 to 14 million particles per cubic foot with only ⅛ of the total ventilation being diverted through the collector.

This study also showed that by dispensing with line brattice and using the collector to provide total face ventilation, dust at the operator's position can be held well below 25 million particles per cubic foot while the dust in the return air can be as low as 6 million particles per cubic foot.

Collection efficiencies for the collector tested showed 90 per cent by count and 99 per cent by weight on dust normally found in continuous mining operations.▲

RESUME OF GAS IGNITIONS AND FIRES IN COAL MINES

Since Enactment of the Federal Coal Mine Safety Act;

RECOMMENDATIONS TO PREVENT RECURRENCES

by H. F. WEAVER

chief, Division of Coal Mine Inspection, Bureau of Mines, Washington, D.C.

Is the law of averages again catching up with the coal-mining industry?

This is a rather cryptic introduction to the subject but, referring to major coal-mine disasters, it should give the industry deep concern.

During the 4½ year period from the Federal Coal Mine Safety Act through 1956, only two major disasters occurred in coal mines. The first causing the death of five men in 1953, was a coal-dust explosion initiated by a blown-out black-powder charge in an Iowa mine. A temporary restraining order, issued by a State Court, had prohibited Federal inspectors from enforcing the ban on the use of black powder under the Federal Act.

The second, in a West Virginia mine, November 1954, killed 16 men. A violent explosion and fire occurred while explosives charges were detonated in pillar stumps near an explosive atmosphere, using power from a trailing cable.

Following a 26-month disaster-free period, two major disasters occurred in the first two months of 1957. In January, five men were killed in an Alaska mine when an explosives charge was improperly detonated in an explosive atmosphere. In February, 37 men died in a West Virginia mine explosion when electrical equipment was operated in an explosive atmosphere.

The aforementioned 4½ year period, with only two major disasters and 21 deaths and the subsequent 26-month disaster-free period are commendable and encouraging. But it is hoped they have not engendered a state of complacency or smugness in the industry.

Immediately after a similar disaster-free period beginning November 1948, the year 1951 numbered five major disasters, and 157 deaths. Thus my earlier reference to the law of averages is apparent.

Administration of the Federal Coal Mine Safety Act has reduced the probability of major disasters in coal mines. Nevertheless, the frequency of minor mine fires and gas and dust ignitions indicates that much must be done before the possibility of serious catastrophes can be controlled, and the law of averages—based on past experience—will not catch up with it.

334 FIRES REPORTED

Since the Federal Act (July 1952) through June 1957, 198 mine fires have been reported to the Bureau with eight fatal and 39 nonfatal injuries. Moreover, 136 gas or dust ignitions were reported with 91 fatal and 162 nonfatal injuries. Undoubtedly, others occurred, but the Bureau was not notified.

Fortunately, none of the 198 mine fires was of major-disaster proportions. But those combatting mine fires know that each has disaster potentialities, especially in gassy mines. Investigations indicate that, in many instances, injuries and extensive property damage were held to a minimum because alternate escapeways and fire-fighting equipment were available, as well as men trained in using equipment and reasonably good rock dusting in the areas where ignitions occurred. However, many others were not catastrophic only because of unbelievable good fortune.

Coal mines in general are in better condition today in ventilation, rock dusting, fire prevention, alternate escapeways, and other preventive measures. These reduce the probability of major catastrophes; nevertheless, the continuing frequency of minor fires and gas and dust ignitions presages eventual trouble, unless additional efforts are made for full-time compliance with accepted preventive measures.

A breakdown of the igniting agents reveals that electrical circuits and equipment should be of primary concern in reducing these occurrences. Of the 198 fires, 121 (61 per cent) were of electrical origin, and 53 (39 per cent) of the 136 ignitions resulted from electric arcs. Next in importance in initiating gas or dust ignitions is improper use of explosives. Friction on belt conveyors ranked second as a cause of mine fires.

Inadequate ventilation is the primary cause of gas ignitions. Next, but almost as important, is elimination of sources of ignition, by proper installation and maintenance of electrical circuits and equipment. Poorly made temporary splices in trailing cables, inadequate overload protection, run-over cables are all too common. Failure to make proper, suitable tests for gas where electric equipment is operated is another important contributor to these ignitions.

NO SHORT CIRCUIT PROTECTION

Technical electrical surveys by Bureau electrical engineers revealed that too few coal mines have adequate overload protection against short circuits in remote areas of the mine. Some mines have virtually no protection at all, although they have installed circuit breakers and fuses that are supposed to provide it.

These conditions exist because of inadequate current-carrying capacity of the conductors, caused by cables of insufficient cross-sectional area, poor or too many splices, and lack of proper rail bonding, as well as length of circuits. These build up the resistance to a point where a dead short circuit could occur any place and insufficient current would flow to trip the protective device.

The proper procedure to overcome these hazardous conditions is a periodic technical survey of all electrical circuits. When high resistance is indicated, this condition should be corrected. However, other signs forewarn dangerous conditions. For example, low-voltage conditions in working areas may be inadequately protected power circuits. Overheating of cables, sluggish operation of equipment, and excessive dimming of lights during periods of high power demand indicate low voltage.

Where power is supplied from more than one substation, observations should be made to determine whether there are periods when power is interrupted from a nearby station but not from a distant station or stations. This condition may be indicated by inadequate power for operating equipment and by lights connected to the power circuit becoming very dim. When such conditions are observed, the cause should be determined and remedied.

BUREAU FIRE PREVENTION PROGRAM

In addition to administrating the Federal Coal Mine Safety Act and conducting accident-prevention training for coal-mine personnel, the Bureau develops ways and means to eliminate the major causes of mine fires and explosions. Some features of this program follow:

1. With representatives of the industry, fire-control standards that define and explain the minimum requirements for providing "suitable fire-fighting equipment, adequate for the size of the mine," as said in Sec. 209(g)(1) of the Act, were published in the Federal Register of March 9, 1957.

2. Experiments on foam plugs to fight mine fires was started to supplement the extensive basic research in Great Britain. By spraying a dilute solution of a wetting agent on a tilted cloth net stretched across a mine opening as close as possible to a mine fire, a mass of foam bubbles is developed and carried along the entry by the air current.

The foam fills the workings and readily travels over obstructions, such as roof falls, and around turns, until friction halts its progress. Distances up to 200 yards have been achieved; within this distance, fires are quenched or quickly cooled to the extent that a direct attack can be made. A separate progress report describes the Bureau's experiments with foam plugs.

3. A study of causes of fires in underground conveying belts, and extensive research, resulted in Bureau of Mines Schedule 28 covering testing of conveyor belts for fire-resistive qualities; this schedule has been effective since November 1955.

4. Schedule 2E, Regulations Governing Permissibility Tests for Electric Face

Equipment, was revised and approved in August 1955 as Schedule 2F, to conform more nearly to the provisions of the Federal Coal Mine Safety Act.

NONFLAMMABLE HYDRAULIC FLUIDS

5. Late in 1955, a study began to determine the procedure to test for research and development of economical nonflammable hydraulic fluids for mine equipment. A cooperative program with mine operators and manufacturers of mining equipment and hydraulic fluids was started. The present flammable fluids in hydraulic-controlled equipment present serious hazards when fires occur. Bursting hydraulic systems have caused many mine fires to spread out of control. Development of an economical, efficient, nonflammable fluid would decrease fire spreading materially.

6. After research suggested by the Bureau, a cable manufacturer developed an incombustible, thermoplastic trailing cable that passed the flame and damage tests for fire-resistant cables under Schedule 2F. Favorable reports from field tests of these cables indicate that the cable durability exceeds some fire-resistant cables previously available to the industry. These cables should greatly reduce the frequency of cable failures—the most serious mine-fire hazard confronting it.

7. Mining-electrical engineers and electrical inspectors conduct special investigations and surveys of electrical facilities in coal mines and notify operators of hazardous or sub-standard conditions. These engineers also cooperate with the industry in research on electrical apparatus to design safer equipment. In addition, an electrical-safety course is available to train electricians and maintenance personnel in the fundamentals of electricity and proper installation and maintenance of electric equipment and circuits.

8. The reduction of effective insulation and the increased rigidity of trailing cables necessitated by incorporating an additional conductor for frame grounding have caused many trailing-cable failures, some with disastrous results. Through research by the Bureau and the cooperation of manufacturers improved equivalent protective devices to replace frame-grounding conductors have been developed and certified by the Bureau as acceptable. Personnel of the Bureau is making field surveys to determine the effectiveness of these devices in actual service.

9. Bureau studies have revealed that, when properly done, rock dust can be adequately applied to the roof and ribs of working places as a premixed slurry or by mixing with water at the nozzle of a hose. This permits application of rock dust close to the faces during mining without the hazards and inconvenience of clouds of airborne dust.

10. A substitute for rock dusting—a viscous spray material that will entrap mine dusts—is being studied by a company that manufactures such materials.

11. To improve illumination, the Bureau has established Schedule 29 for approval of fluorescent lamps installed safely in face areas.

SPOT CHECKS CONDUCTED

In addition, certain mines are spot-checked between regular inspections to improve between-inspection compliance with the provisions of the Federal Mine Safety Codes and the Federal Coal Mine Safety Act. Also, the Bureau investigates all mine fires and gas or dust ignitions, large or small, and distributes reports for the industry to prevent recurrences.

Experience reveals that most gas explosions in coal mines could have been prevented with adequately controlled, continuous, positive ventilation. With continuous mining, face ventilation poses a difficult problem that may have to be solved by auxiliary means. However, if we wait until explosive gas is detected before ventilation is improved (which, unfortunately, is still too often the general practice) disasters will be inevitable.

It should be an established operating rule that, when the ventilating system undergoes any major revision (involving volume, pressure, or direction of air flow), all persons affected should be given explicit information. Moreover, major changes in ventilation should be made during an idle rather than a working period, so that only those making the changeover will be in the mine at the time.

Means of preventing coal-dust ignitions are well known to all in the industry, but adequate cleanup of loose coal and coal dust and proper application of rock dust in areas that are not wet must be prompt and continuous. Spotty, intermittent enforcement of these regulations will not suffice.

Coal mines cannot be entirely freed from fire hazards. The mineral mined is combustible, wooden timbering support the roof, doors and brattices control ventilation, rubber in belts, tires and other accessories, flammable oils and hydraulic fluids are used, and many sources of ignition are present (of which electric power is of primary importance).

These hazards can, however, be so minimized that there will be little danger of fires disastrous to life and property by proper installation and maintenance of equipment, particularly electrical installations and belt conveyors, provision of safe, travelable, well-marked alternate escapeways, and maintenance of adequate, readily available fire-fighting facilities, with employees trained and familiar with their limitations.

Means of preventing mine fires and explosions are adequately covered in Federal and State laws. However, as with most safety laws, 100 per cent enforcement is virtually impossible, unless those affected do their own policing conscientiously. Safety-education training has proved of inestimable value in improving safety consciousness—an absolute essential if progress is to be made.

Spasmodic compliance with accepted safety practices is not enough, because each act of carelessness, thoughtlessness, or neglect could lead to a serious accident or disaster. Only unrelenting, constant vigilance by each person in the coal-mining industry can avert gruesome penalties involved when you gamble against the law of averages in safety. ▲

OFFICERS OF THE

COAL MINING SECTION

NATIONAL SAFETY COUNCIL 1957-58

General Chairman Emeritus—CHARLES FERGUSON, United Mine Workers of America, Washington, D. C.

General Chairman—GEORGE SAMBROOK, U. S. Steel Corporation, Coal Div., Pittsburgh, Pa.

First Vice-Chairman—L. H. JOHNSON, U. S. Bureau of Mines, Pittsburgh, Pa.

Second Vice-Chairman—JOSHUA SMITH, Eastern Gas and Fuel Associate, Mt. Hope, W. Va.

Secretary—H. F. WEAVER, U. S. Bureau of Mines, Washington, D. C.

Labor Representative—CHARLES FERGUSON, United Mine Workers of America, Washington, D. C.; M. F. BRENNAN, United Mine Workers of America, District No. 7, Hazleton, Pa.; JAMES LEEBER, JR., United Mine Workers of America, District No. 29, Beckley, W. Va.

Bituminous Coal Representatives—J. W. PERO, Pocahontas Fuel Company, Pocahontas, Va.; C. E. LINKOUS, Island Creek Coal Co., Holden, W. Va.; M. E. PRUNTY, Bethlehem Mines corp., Jenkins, Ky.; WAYNE SNELL, U. S. Steel corporation, Coal Div., Pittsburgh, Pa.; R. L. HAIR, Colorado Fuel and Iron, Pueblo, Colo.; FRANK KOLISEK, Freeman Coal corp., Benton, Ill.; GEORGE STACHURA, Old Ben Coal Corp., West Frankfort, Ill.; E. E. QUENN, Peabody Coal co., St. Louis, Missouri.

Anthracite Representatives—GEORGE CLARK, Reading Anthracite co., Pottsville, Pa.; CHARLES KACZINSKI, United Mine Workers of America, District No. 1, Wilkes-Barre, Pa.; W. W. EVERETT, Glen Alden corp., Wilkes-Barre, Pa.

Coal Associations' Representatives—J. B. BENSON, Southern Coal Producers' Association, Washington, D. C.; HARRY GANDY, JR., National Coal Association, Washington, D. C.; FORD SAMPSON, Ohio Coal Association, St. Clairsville, Ohio; GEORGE TREVORROW, Bituminous Coal Operators' Association, Washington, D. C.; GEORGE COLVILLE, JR., Jewel Mining Company, Paris, Ark.

U. S. Bureau of Mines Representatives—M. J. ANKENY, U. S. Bureau of Mines, Washington, D. C.; JAMES WESTFIELD, U. S. Bureau of Mines, Washington, D. C.

Mine Inspectors' Institute of America Representative—R. D. BRADFORD, U. S. Bureau of Mines, McAlester, Okla.

State Mine Inspectors' Representatives—H. J. DUSZ, Ohio Division of Mines, Columbus, Ohio.; CRAWFORD WILSON, West Virginia Department of Mines, Charleston,

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

THE CONSTRUCTION SECTION
THE PUBLIC EMPLOYEE SECTION

This volume is a record of the sessions held at the 1957 National Safety Congress by the Construction Section and the Public Employee Section. The conduct of these Congress sessions each year is only one of the many cooperative activities which the Construction Section and the Public Employee Section carry on in behalf of their members, and for the benefit of accident prevention work in the construction industry and public employment generally. These Sections give guidance in the preparation of a great variety of technical and educational material useful in the day-to-day safety programs of construction companies and public agencies.

The activities of these Sections are under the direction of their Executive Committees, the members of which are listed at the close of this volume.

CONSTRUCTION INDUSTRY

THE ETHICS OF SAFE CONSTRUCTION

by REV. ROBERT C. HARTNETT S. J.
Dean, College of Arts & Sciences, Loyola University, Chicago

Safety is like democracy, a sort of permanent revolution. We cannot allow ourselves to drop our guard for a single moment. Indeed, we have continually to improvise greater safeguards against new hazards to life and limb.

In glancing through the 1956 edition of *Accident Facts*, I noticed that of the 90,000 persons killed by accident in 1954, a rather alarming number died from accidents connected with construction. For example, more than 19,000 died in falls. Nearly a thousand died from contact with electric current. The boy killed in our community by contact with a TV set dramatized how difficult it is to make new inventions absolutely safe.

More than 6,000 were killed in 1954 by fire and the explosion of combustible materials, and 1,600 died of mechanical suffocation. Of the 5,000 who died of drowning, quite a few died in floods. Some might have been saved had their houses been constructed better to withstand floods or had flood-prevention or flood-containment been established by appropriate construction.

I suppose similar statistics could be found regarding the causes of personal injuries—serious, though nonfatal, injuries causing permanent or temporary disabilities. In 1955 there were nine million such injuries, of which four million occurred at home and nearly two million at work.

SAFETY IS INTELLIGENCE

Now safe construction is in the first instance, a question of intelligence, imagination and technical proficiency. Architects and engineers try to design and build safe buildings and highways. Like the rest of us, they must learn from experience the kind of buildings and highways which will involve some people, accident-prone people, in accidents.

The approaches to and exits from Edens Highway leading north out of Chicago are wide arcs. A car driven at the 20-mile-an-hour speed posted as "safe" could make the turns in less distance. But the architects and engineers have learned from experience to maximize the safety factor by extremely gradual turns. I certainly would not suspect them of elongating the turns just to make a bigger job of it.

SAFETY—MORAL OBLIGATION

In other words, I don't want to give the impression that safe construction is primarily an ethical problem. It is primarily an engineering problem. As far as zeal for safe construction is concerned, the desire and determination of architects and engineers is to build buildings and highways to minimize dangers to life and limb. The construction industry, both out of self-interest and out of public interest, give the highest priority to human safety.

On the Ohio Expressway the designers not only provided a parkway between the Westward and Eastward highways but hollowed it out so that no one would even be tempted to make a U-turn where it would be dangerous and is forbidden.

My topic, however, is the ethics of safe construction. So let me enumerate a few moral considerations which may help to fortify us in our determination to design and construct buildings and highways in as safe a way as possible.

The first moral consideration is that human safety is an integral part of everybody's job. Nobody can ever become so specialized a technician as to divest himself of responsibility for the safety-aspect of what he does. There is a very important principle in moral philosophy dealing with what is called cooperation.

According to this principle of cooperation, moral cooperation, an agent is guilty of wrongdoing if he is in any way involved in it, if he participates in it, without doing whatever he reasonably can do to prevent it.

Moral cooperation includes many actions besides those of the principal agent. For example, a person who gives bad advice cooperates in evil. A person who supplies bad material, or even good material which he knows will be badly used, cooperates in moral evil. Even a person who remains silent when he ought to speak up against an evil transaction is tarred with the guilt of moral evil.

Now this business of moral cooperation becomes extremely complicated. The fundamental moral principle is simply this: every human person is morally obliged to do what he reasonably can to prevent moral evil. If he is reasonably certain that nothing he can do or say will have any effect on the transaction whatsoever, he may be justified in letting things ride.

But we have to be very careful not to kid ourselves, not to lull our consciences by jumping to the conclusion that there is nothing we can do to prevent what we know is wrong. Self-interest such as the desire to make a handsome profit, is no justification for cooperating in moral evil. A person who goes along with unsafe construction without doing what he can to prevent it, just because he is too greedy to take a chance on losing business, is guilty of moral cooperation in an immoral action.

TAKES MORAL COURAGE

The second moral consideration is this: it takes a lot of moral courage sometimes to take a firm stand against politicians and business colleagues—especially your boss—when you know full well that you are cooperating in unsafe construction. Sometimes I think that the greatest need of this country today (maybe it's the greatest need of every country in any age) is moral courage.

People are afraid of getting hurt, especially in their pocketbook. Sometimes it seems as if they have adopted a purely utilitarian moral code according to which money excuses everything. In their own way, such people worship a golden calf.

They would never for a moment enunciate their philosophy of life as consisting of a worship of money. But when the chips are down, they always seem to put money first.

Now if the National Safety Council and this Congress mean a thing, they mean that *safety comes first.* They mean that human lives and bodily integrity are more important than money. Not somebody else's money, mind you, but your money and my money.

I wonder how a construction engineer feels when he reads that the floor of a building he is building collapsed, killing five men, all fathers of families—if he knows in his heart that he is partly to blame. *What doth it profit a man to gain the whole world and suffer the loss of his own soul?*

TECHNICAL ETHICS

Let me emphasize I am not talking about purely technical errors. An engineer could be guilty of many mistakes which would be honest errors of judgment—not too many mistakes, but quite a few in a life-time. I am talking only about deviations from what he knows to be the principles of safe construction, in cases where he failed to do what he could have done to prevent such deviations.

Moral courage, especially the kind needed to beat back the serpent of fear of loss of money, is an ethical must for safe construction. There are other kinds of fears, of course, that contribute to unsafe construction: fear of getting into a public hassle, fear of newspaper attacks, maybe even fear of one's wife when honesty would jeopardize one's income. We need moral courage to overcome all these fears. And I am not suggesting for a moment these are idle fears.

Now here is an ethical consideration which touches on technical ability. We are too much inclined today to divorce technical know-how from moral principle. This is unnatural. If a man is an engineer or an architect or even a bricklayer, *he has a moral obligation to acquire and apply whatever technical skill is necessary for him to do his work with full justice to the safety factor.*

For example, if an architect bids for a job when he knows that he lacks the skill to discharge it safety, he is being unethical. Anyone who neglects to apply all his skill to maximize the safety factor, to give it the No. 1 priority, is being unethical.

In other words, the moral principle that we must build safely, governs the use of technical skills. Technical skills are means, instruments, which must be directed by moral agents. A man's moral purposes are much more important than his technical skills. He must subordinate his use of skills to the paramount moral purposes of human life.

PHILOSOPHY QUESTION

Some people think that we Americans have become so proficient in technology that we have endowed technology with the halo of ultimate value. We no longer know how to think about means and ends in terms of man's ultimate purpose on earth, but only in terms of the here-and-now job to be done. If so, this lopsided fascination with technical achievement may completely undermine our allegiance to moral achievement. What are we made for, in the ultimate analysis, technical achievement or moral achievement?

The ethics of safe construction, like every other question of ethics, boils down to that unavoidable philosophical question: in what does the ultimate good of man consist? If it consists in making money, in our so-called high standard of material comfort or in any other purely temporal form of self-satisfaction, I do not see how we can expect architects and builders to make personal sacrifices, even very great sacrifices, in the interest of safe construction.

Any egocentric ethics would allow loopholes for unsafe construction if the price-tag were high enough. After all, people who worship the golden calf have never lost much sleep over a few dumb-cluck miners who lost their lives in explosions in unsafe mine shafts.

No, the ultimate reason for going all out for safe construction has to be respect for the moral worth and dignity of every child of God, respect for his bodily integrity and his right to "life, liberty and the pursuit of happiness"—in other words, to pursue his moral perfection as his highest temporal goal, as a means to the ultimate destiny the Creator of all mankind has put us on this planet to seek.

Doing all we can to prevent injuries to our fellow-pilgrims, whether fatal or non-fatal, is an important part of God's holy law for all of us.▲

SAFETY AND HEAVY CONSTRUCTION ST. LAWRENCE PROJECT AND THE HIGHWAY PROGRAM

by ELLIS L. ARMSTRONG

Utah director of highways, former ass't project manager, St. Lawrence power project, Salt Lake City, Utah

In this "Miracle of America" the progress in production of goods and services to make life better has reached a stage far above any other in the history of man. This evolved because we have begun to reap the benefits of harnessing the unlimited potentials of the human being, cooperatively pooled for the common good.

Man controls nature for his good more than ever before. If he can expand his concept that he is his brother's keeper to be all inclusive with his expanding ability [illegible] mar-ness the forces of the universe, perhaps we are entering the "Golden Age" of man.

There are many problems still unsolved —and solutions are not easy. Yet the history of civilization is marked by milestones where man recognized the need for cooperative effort to survive. Each construction feat in history advanced man along the path of civilization and cooperative effort was pitted against the forces of nature to control man's environment. Progress has been made by realizing that each man has a moral responsibility to respect and protect his neighbor.

Accomplishment of heavy construction requires the working together cooperatively of many men. The billion dollar St. Lawrence project is an outstanding example of what can be done when nations and states and groups of men, with some differences in objectives and interests, pool their efforts for the common good. The harnessing of power from the St. Lawrence in the International Rapids section will produce 2,200,000 horsepower of electrical energy and will open the Great Lakes to ocean-going ships, creating the "Eighth Sea."

NATIONS COOPERATE FOR PROGRESS

It is certainly a top achievement in man's struggle to improve his environment and harness the forces of nature. More important, perhaps, to the future of mankind, is the demonstration that international, national, local, and individual interests, can cooperate and can be co-ordinated for positive accomplishment. It is a successful practical demonstration of what is needed to solve many problems of our troubled world.

One of the major problems of our "Miracle of America" is the needless yearly loss of 95,000 lives and the crippling and maiming of nearly 10 million people by accidents. The National Safety Council has been a potent force towards reducing the appalling loss. Progress has been made. In the last 50 years the accidental death rate of all accidents has decreased from 100 per 100,000 population to about 53 per 100,000. However, the progress made is not enough —much remains to be done.

NOT "ACCIDENTS"—"MISTAKES"

In construction operations last year, 2,600 workers died in accidents on the job and 225,000 were injured, making construction one of the most hazardous occupations. Some 25 years ago, the rule of thumb quoted was that one man would be killed for each one million dollars worth of work accomplished. This was inevitable to get skyscrapers, dams, bridges, tunnels and highways constructed; a sacrifice of the life of man to the "God of Accomplishment." There was only a passive interest in safety, the same as the Sunday sermon on "Love Thy Neighbor." But safety was regarded as foreign to the rough, tough environment of heavy construction. A hard hat was regarded as "sissy" and taking unnecessary chances was a mark of distinction.

Fortunately, through the efforts of devoted, dedicated men in government, labor, and industry, safety today is recognized as an essential part of heavy construction. Accidents are no longer considered "Acts of God" but rather mistakes that can be corrected.

It has been demonstrated and accepted by the construction industry that "safety pays" in better worker performance, more production per man hour, less expense and certainly more happiness and well being for all concerned. Exposures of a million manhours without a lost-time accident still merit praise but are often accomplished; a record of 6,735,000 continuous accident-free manhours on a construction project has been established.

Improvement has not just happened. It has taken effort, work, perseverance, patience, sweat, vision and understanding of men and the cooperation of all concerned. It has taken the realization that there is an obligation to our fellow workmen that makes aggressive, positive effort toward accident prevention the only tenable course.

LOCKS AND CANAL WORK

The St. Lawrence project is unique in construction history. A large number of entities of international and national level are involved in one of the biggest, concentrated construction projects of all time. The work of constructing the dams and reservoirs to drown out the rapids and harness the power in the International Rapids Section will cost about $700,000,000.

This is being done by the Power Authority of New York and the Hydroelectric Power commission of Ontario. Engineering and supervision of construction on the American side was contracted to Uhl, Hall and Rich Engineers and on the Canadian side to the engineers of Ontario Hydro. To insure adherence to international treaty provisions of the river, several control agencies of an international character exercise review powers over all operations.

The two lock structures and the canal on the American side to bring deep water shipping into the reservoir are being constructed by the St. Lawrence Development corporation, a federal agency, at a cost of about $140,000,000. This agency utilizes the United States Army Corp of Engineers for engineering and construction supervision.

The St. Lawrence Development Authority of Canada is constructing the $25,000,000 lock at Iroquois on the Canadian side and the $280,000,000 canals and locks from the International Rapids to Montreal, utilizing largely its own engineering forces.

Most of the construction is being done by private construction contractors obtaining projects through open competitive bidding. In the 40-miles of the International Rapids more than 70 contractors, with about twice as many sub-contractors, have been in operation at one time. Approximately $80,000,000 worth of construction equipment and 17,000 workmen have been working around the clock to complete the project.

From a safety standpoint the following are factors of importance on the St. Lawrence:

1. Fast construction schedule.
2. Large number of workmen required in short time.
3. Relatively inexperienced heavy construction workmen.
4. Hazard of work in controlling the 250,000 cubic-feet-per-second flow of the St. Lawrence river.
5. Safety "written in" to construction contracts.

WORK AROUND THE CLOCK

The project was scheduled for the earliest practical completion date. The power portion was financed through the sale of bonds to private investors and there was a need and a market for power as soon as it could be produced. The schedule made necessary the pushing of all work around the clock and through hazardous winter seasons. Organizations were "under pressure" to get the job done.

With the fast start and the large number of contracts underway, it was difficult to man the jobs with experienced labor. Although the unions and the contractors did a Herculean job in getting workmen from all over the country, the carpenter reporting for work with new pair of overalls, a new hammer, and a meat saw was not fictional. This problem required additional efforts to teach workmen how to perform their tasks and to observe safety practices. Discipline presented a problem since a workman dismissed for safety infractions on one job, could immediately get employment on another.

The work of moving the large flow of the St. Lawrence river around to accomplish the construction presented hazards not usually encountered. The fast currents and the large constant flow of the river made necessary constant vigilance against the hazard of drowning. Wearing life jackets was mandatory on all operations over water. Winter work at the river produced the additional hazard of floating, grinding ice.

The specifications for the Power Authority of New York provided that:

> "The contractor shall at all times exercise reasonable precautions for the safety of persons engaged in the performance of the work.
>
> The contractor shall provide adequate equipment and facilities as are necessary or required, in the case of an accident, for first aid service to any person who may be injured in the prosecution of the work under this or other contracts for the St. Lawrence Power Project, and he shall have standing arrangement for adequate medical care, and for removal and hospital treatment of any person who may be injured or who may become ill. Such equipment or facilities and arrangements shall be satisfactory to the engineer.
>
> The contractor must report immediately to the engineer every accident to persons or damage to property, and shall furnish in writing full information including testimony of witnesses, regarding all accidents. The contractor shall comply fully with the provision of the booklet entitled, "Safety Requirements" as published by the U. S. Army Corps of Engineers and with N. Y. state laws. The contractor shall employ a full-time, qualified safety engineer, who shall report to and cooperate with the safety representative of the engineer."

Other agencies had similar provisions, thus recognizing that the owner, as well as the builder, has a moral obligation for the

welfare of the workmen. Further the specifications reflect the conviction that a safe job is the most economical job. The Corps of Engineers "Safety Requirements" is recognized as an excellent guide for job safety on heavy construction.

PLAN OWN SAFETY WORK

The engineers for the Power Authority instigated an aggressive positive safety program for their portion of the work, as did the other entities. A project safety engineer was appointed to head the program reporting directly to top management. He had assistants and acted as a staff advisor to top management with the prime function of providing advice and guidance for the program and directly assisting the various resident engineers. He was responsible for compiling the overall job safety records, statistics and reports, and to point up weak points in the program.

Enforcement of the safety requirements of the specifications was through the regular line organization, with each resident engineer held accountable for the safety features of his project through his field engineers and inspectors. Safety requirements were as important as requirements for quality of construction.

Each contractor had a safety engineer on its project to actuate the safety requirements of the specifications, working through the job superintendents, foremen and workmen. Contractors' safety programs were carried out as line functions.

At a monthly meeting with top management, the engineer and each contractor formulated policies, discussed weaknesses, reviewed accident records and devised improvements. Each contractor's project manager, the general superintendent, safety engineer and shift superintendents were required at these meetings.

NEW EMPLOYEES SCREENED

These meetings were followed by similar meetings at each job level with the resident engineers, their staffs, the job supervisors and foremen. Each project carried out a program of safety education through meetings of foremen, leadmen, and workmen. Probably the most effective means of furthering the safety program were the short "tool box" meetings between the foremen and his crew held daily or as required to cover the particular hazards of the crew.

On each job a new workman was given a list of safety rules for the project and an interview with a member of the contractor's safety organization who discussed the particular hazards of the project. The program provided for a similar discussion by his immediate foreman, who screened employees to prevent assigning unfit men to particularly hazardous work.

Large National Safety Council billboards were erected at each project and accident posters displayed. Smaller posters were displayed at the check stands where the accident record of the job was illustrated. Pertinent, timely safety reminders were issued with pay checks. The indoctrination lectures and the literature appealed to the workers' responsibility to his family and his fellow workers and to his pocketbook.

Area-wide competition was promoted for the best safety record of different crafts and for the different projects. The job with the best monthly record was awarded a large safety flag to fly for the following month. The awarding of the flag was done with ceremony and publicity.

Contractors maintained safety records of the foremen and presented them with awards when they reached admirable accident-free exposure totals.

The cooperation of the unions was obtained in promoting safety education in their meetings and in having them assist with safety indoctrination of new employees. The union stewards worked with the engineers and the contractors in policing safety regulations and devising safer methods and procedures.

The program was a coordinated all-out effort to further safety on the project. The result has been a record accident frequency of about half the national average for heavy construction in the approximately 60 million man-hours of exposure so far encountered.

Good accident records don't just happen —they are caused. And they are caused by formal, aggressive, positive safety efforts by all—by the owners, the engineers, the contractors, the insurance carriers, the governmental agencies, the unions, and the workers themselves. No halfway measure can be fully effective.

We, in America, are now embarked on a highway construction program that is the largest public works endeavor of all time. One of the program's main objectives is to reduce the appalling accidents, death and destruction on our present crowded inadequate highways. These accidents have aroused public indignation so an all-out effort for reduction is now underway.

HIGHWAY CONSTRUCTION PROJECT

However, embarking as we are on this unprecedented construction program, we should not overlook our obligation to reduce accidents during construction. Actually the progress in reducing the accident rate of highway travelers has been better than the reduction of our accident rate on construction.

The size of the construction program will attract new contractors into the field and expand existing organizations. Many of these will not have the experience or the personnel to carry out a good safety program and they will need help. Some undoubtedly feel that adequate safety precautions will mean added expense; particularly so from the standpoint of safety of the traveling public through the construction areas. While this may be true from a short-range, individual contractor approach, from the overall standpoint adequate precautions and safety measures must be taken. This will require that reasonable safety requirements are an integral part of the contract to place all competitive bidders on an equal basis.

In my state, as in many others, there has not been a formal safety program on highway construction work. This has been left to the contractors' insurance carriers and the states' industrial commissions or labor departments. The results have not been good. The accident rates are high, the insurance rates are high.

We are proposing to "write in" safety requirements in our specifications—not just general references to state statutes—but specific reasonable safety requirements included in a safety manual to be specifically patterned to highway construction with its additional hazard of the traveling public through the construction area. We are proposing a better record of our construction accidents so that we can better define our problems.

We are in the process of defining in writing our safety policy and in working out the details of a program to accomplish that policy. This will include an educational program through all the chain of command. It will make a safe job as important to our inspectors and engineers as a quality job.

With the big construction program ahead of us, we cannot do less—and still fulfill our obligation for the welfare of our fellow workman, and to the taxpaying motoring public to see they get the most highway possible from their tax dollar.

The St. Lawrence project illustrates what can be done in a formal, positive safety program made an essential part of construction. The same type of approach should provide an equally favorable record on our highway construction—a program bringing the governmental agencies, the engineers, contractors, the unions, the insurance carriers, and the workman into a coordinated, cooperative all-out effort to reduce needless accidents.

MEN, MACHINES AND METHODS

by DONALD B. WILCOX

professor of industrial engineering, University of Florida, Gainesville, Fla.

Accident prevention is one of the best, and certainly one of the most humane and socially desirable ways to increase profits. Industrial engineers, by virtue of their unique training, are well qualified to decrease costs. They are prepared to lead in accident prevention efforts in addition to performing their primary function of coordinating, facilitating and expediting production.

Accidents are extremely costly. Even the basic minimum expenditures demanded under compensation laws are an appreciable item in most cost estimates. Insurance covers these expenses, but what about damage to vital equipment and materials, delays to the job, liability to third parties and other "indirect" costs resulting from every accident?

The insurance companies cover these costs through the premiums paid by the contractor. These premiums are usually set through experience ratings and thus successful efforts to eliminate personal injury accidents bring a prompt and direct reduction in the cost of doing business, which results in increased profits.

The construction industry presents a complex picture. Representatives of large and small concerns, representatives of government, insurance and various other types of agencies concerned with the problems met in building a wide range of structures covering industrial, residential and public works all have certain interests in common: getting the job done—quickly, safely and economically.

NEW TYPE ENGINEERING

Most everyone is familiar with the basic divisions of engineering—mechanical, civil and electrical. Industrial engineering is relatively new, established less than 50 years ago, and only coming into prominence as a result of World War II. Many learned authorities have propounded elaborate and detailed definitions of the field, but I would choose to describe it more simply.

The collegiate industrial engineering curriculum is an outgrowth of mechanical, is based on a solid grounding in the fundamental sciences, and includes survey courses which acquaint the student with the principles of surveying, structures, electrical and mechanical equipment.

However, and here is where we offer something different, and something which employers seek and appreciate, the industrial engineering training places emphasis (1) on human nature and considerations of the physical capabilities and adaptabilities of workers and (2) on cost considerations and the vital importance of producting goods and services efficiently and economically to sell at a profit.

Some of the earliest investigations in the field of industrial engineering were made in the construction industry. Mr. Frederick W. Taylor, one of our pioneers, was struck by the waste effort and fatigue in the methods then used by the bricklayers. He devised a scaffold to deliver bricks to the worker at the working level thus eliminating back-bending fatigue and also increasing production.

TRAIN, EXAMINE MEN

To get down to cases, let me take up my topics in order. First of all: *Men*. The selection, training and ultimate job assignment of the workers has been a fertile and rewarding area of investigation and study. Native intelligence, education, and physical limitations or capabilities should be evaluated and the findings intelligently used.

Countless accidents have been traced to the fact that the injured man was poorly adapted to the type of work in which he was engaged, either through failure to comprehend and deal with certain hazards, or because he lacked necessary coordination, dexterity of physical strength and stamina.

Pre-employment physical examinations, properly made and recorded will reveal many potentially expensive hernias, back injuries and other types of claims. Many concerns are enlarging their preventive medical program to include periodic physical examinations to detect incipient allergies and progressive forms of physical ailments which might otherwise culminate in accidents or industrial health claims.

The supervision of men is the keystone of successful production. A job is as good as the supervision wants it to be. If management is truly interested in turning out good work and makes clear to its supervision that it demands accident free conditions, a supervisor, be he superintendent or foreman can transmit through education, enforcement and example an enthusiasm which will make the job proceed smoothly.

GOOD SUPERVISOR QUALITIES

There is much help available to those who would be good supervisors. An understanding of human nature, its motivations, the inter-relationships of fatigue, worry and the personal needs for an occasional word of commendation, discipline and instruction are all involved. Taylor once conducted an interesting experiment on the psychological requirement of the average workman to understand his part of the job in the scheme of things.

He hired a group of common laborers to carry a large number of "pigs" of iron from one end of a long yard to the other. When they had finished he asked them to carry them all back. Then again to carry them back to the other end, and again to return them, whereupon they tried to quit. He offered them more money, but with little success. They just didn't want to do a job where they could see no accomplishment from their efforts. Pay alone is not enough.

Workers' cooperation in an accident prevention program cannot be purchased outright. They must feel it is a team effort. There must be recognition of accomplishment and incentive to improve the record.

The industrial engineer can select and enforce the use of suitable protective equipment for your men. This is a field where technical knowledge is important. Hazards are elusive and the "hunt for the hazard" is only the beginning. It remains to select proper protective devices to reduce exposure without interfering with production. Finally, there are problems of making equipment available where and when needed, seeing it is used as intended, and maintained and accounted for.

UTILIZE MACHINES EFFICIENTLY

Now consider the topic of *Machines*. The contracting industry has been slow to take advantage of modern mechanization. Many material handling methods are still primitive. On other jobs equipment is used which was not at all suited to the work being done. Other sites have equipment needed and, although owned by the contractor, was not available either because of preventable breakdown or because it was standing idle on some other job site.

We have a big contractor in Florida who reportedly had similar items of equipment pass each other en route on long hauls simply through failure to plan and know where his equipment was, and where and when it was needed.

There was an item in the paper about a laborer who took off in a company truck, painted out the sign and engaged in his own independent hauling operations for several weeks. Finally he parked it on a side street where the police eventually found it. When it was turned back to the owner they found it had never even been missed. This is inexcusable and extremely costly. Some solid industrial engineering planning and control can prevent such occurrences.

I make no claim that we industrial engineers know all about the great variety of types of equipment encountered in construction work. But industrial engineering training prepares the graduate, after a little experience with your organization, to keep abreast of the technical press, make economic studies and recommendations on selecting proper equipment, adequate depreciation charges and replacement policies. Scheduled, preventive maintenance will yield more efficient production, with the very important by-product of preventing the possibilities of many expensive accidents.

Machinery is expensive, accidents involving power equipment are usually serious ones, and the exigencies of building operations demand ingenuity, resourcefulness and accurate, positive and informed decisions.

Have you ever had anyone in your organization analyze the feasibility of using flight conveyors or straddle trucks in handling your materials? Have you attempted to standardize procedures and methods? What about maintenance?

A foreman worth his salt will devote most of his time to supervising the progress of the work. This embraces assigning work, arranging for needed materials and equipment, instructing the workers, coordinating with various crafts and other working groups, and making a multitude of on-the-spot decisions. If he is to accomplish all this effectively and efficiently, little time is left for other matters.

SAFETY BY MECHANICS

An industrial engineer can use his mechanical background to devise needed guards, evaluate and counteract hazards and promote safety through training, inspection and protective measures. Working with the foreman he can see that barricades guard floor openings, that operators are properly trained to use power equipment, and that neither circuits, machines nor men are overloaded —with consequent expensive breakdown.

The inherent perils of construction machinery can be practically eliminated by enforcing a few simple measures.

1. Only trained operators should be permitted to operate power equipment—be it a swing-saw in the yard, or a crane swinging a head-ache ball. A man unfamiliar with the controls can forget to set a ratchet, tip over the equipment or snap a cable.

Also the operator should be able to see clearly the entire area of his maneuver or he should be assisted by reliable signal-men. I have seen many near-accidents due to faulty or sloppy signals.

2. Crane operators must realize that high tension usually means instant death and that they must stay clear of all power lines.

3. Personnel must not ride the equipment. In Florida seven men were killed and 12 seriously injured in one material hoist accident. Steelworkers often elect to ride the ball down. In Miami, when two men did this and the operator momentarily lost his view of them and applied his brake suddenly, both were jarred off and serious injured.

4. When equipment is closed down all pans, blades, buckets and booms should be lowered and the machine be made inoperative should children or other trespassers tinker with the controls.

The communication of these and a host of other important management policies can best be effected through an organized, continuing, supervisory training program. Such a program does not have to be formal but must be practical, up-to-the-minute and authoritative. The development of your supervisors will yield more and better production at less cost.

Equipment will be better cared for and fewer accidents will occur. Insurance companies and governmental agencies are prepared to help in such efforts, but an industrial engineer on your own staff can keep abreast of current conditions and put real vitality and value in your employee training.

Now as to *Methods*. Industrial engineers have had to live down the epithet of "Efficiency Experts." Unfortunately, in the early stages of our field there were certain unqualified and unscrupulous individuals who wanted to get on the band-wagon and make a fast buck. These men went about the country claiming to work miracles in reducing costs and increasing production.

METHODS DETERMINE PRODUCTION

Many of their recommendations were ill-conceived and poorly worked out, with catastrophic results for some of their unfortunate clients. Labor resented the so-called stretch out of work and the practioners were dubbed in derision as "Efficiency Experts." This has been, extremely unfair because the respected industrial engineer of today is truly an expert in efficiency and his abilities in methods improvement have much to offer construction companies.

First consider the matter of layout. You have all seen job sites where material is piled helter-skelter, all over the place. After the first few consignments of brick, pipe, lumber and reinforcing steel are delivered, it becomes every man for himself as each new truck drives up and looks for a place to dump its load of material.

Materials have to be moved from place to place before they are finally used. Those on top are shoved aside; material gets broken, lost, stolen, mis-used,—and people get hurt in the confusion. Extra efforts are needed to get what is needed, when it is needed, where it is needed. Sub-contractors get sore when their material is made inaccessible, or when they are required to trot way around the job every time they need an elbow or require a piece of conduit.

How much better it would be if the superintendent on the job would make it his first order of business to plan the site and consider proper storage provisions and space requirements for materials handling. A little attention given to the segregation of various sizes of brick, block, steel, pipe and conduit can save time and crushed fingers or toes when material is needed in the course of erection.

Proper methods of piling will pay similar dividends. Bricks, blocks and lumber can all be palletized or otherwise prepared for mechanical handling. Reducing hazards is enough to justify such treatment, but if you are interested in more immediate profits you will find they come from reduced labor costs incidental to unloading and handling materials by modern power equipment.

GOOD SCHEDULING EASES JOB

Another approach to this same general problem, employed by industrial engineers, is that of scheduling. Material delays can certainly hold up a job and incur payroll expense for idle workers and so we try to stockpile in advance, but this is an elementary approach. Good purchasing involves dealing with responsible suppliers through binding contracts.

Deliveries can then be scheduled to reach the job when and as needed—not six weeks before. Should weather or other conditions require changes, or should the job proceed more rapidly than anticipated, good scheduling demands that progress be related to plans in a realistic manner and prompt and complete coordination be effected. This the industrial engineer is trained to do.

The industrial engineer is indoctrinated in his undergraduate curriculum in the intricacies of legal relationships. Contracts and contracting procedures, real estate law including easements, riparian rights, rights to vertical and lateral support, and liens, workmen's compensation and public liabilities, purchasing, common carriers, labor law and insurance are all encountered daily on the job.

The maintenance of complete and accurate records and the ability to estimate quantities and costs are invaluable when making progress reports, submitting certificates of completion, or analyzing costs. An industrial engineer on the job will far more than repay his cost through recommendations developed by analysis of accident reports, material utilization and payroll audits. His familiarity with budget procedures, cost control and accounting is invaluable.

GOOD PUBLIC RELATIONS

In public relations, again the industrial engineer is especially effective. Although contractors do not deal with the man-on-the-street as a day-to-day customer in the sense of the corner druggist or delicatessen, they should be keenly concerned about their relationships with the general public.

Their reputation as conscientious, considerate, competent builders will do much to foster trouble-free labor relations, attract better grade help, facilitate favorable legislation and financing, and counter-act the probability of criticism for the public nuisance complaints which accompany most jobs.

The paving contractor who displays a large sign calling attention to his name and then puts a sloppy looking, disagreeable, uncouth individual at the job of flagging traffic can turn every driver that passes into a surly critic. If a little care is taken in selecting that flagman and he is properly instructed to explain necessary waits to delayed motorists and caution them to drive safely, lawsuits and litigations which might otherwise arise may be avoided.

Construction work is notoriously of interest to pedestrians. You have no doubt shared my frustration at passing jobs which were secreted behind closed board fences, and my satisfaction at pausing a moment at peep-holes thoughtfully provided by a contractor who was conscious of the importance of good public relations. I have known cases of such vantage points creating the initial interest of some excellent job applicants.

The attractive nuisance problem with its attendant liabilities is still another facet of public relations. Warning signs, explanations, press releases and attention to barricades and watchmen can do much to educate parents in the neighborhood to assist in keeping children away from dangerous areas.

Every contractor who knows his business will agree that housekeeping is one of the

most important aspects of the well-run job. Yet almost invariably I have found more alibis than efforts in this direction. Accident statistics readily reveal that a great many accidents which cost money and interfere with production, are directly traceable to poor housekeeping. Debris should not be allowed to accumulate.

HOUSEKEEPING SAVES DOLLARS

It is penny wise and pound foolish to kid yourself that you are cutting costs by reducing the labor force assigned to clean-up. Three dollars an hour, or $2, or $1.85 is too much to pay for a craftsman's time in pawing through a pile of scrap to clear a place to fasten a brace, or to place a ladder. The up-turned rusty nail, the littered stairs, and the stumbling block await their victims on too many jobs.

The fire hazard is vastly increased by the presence of trash piles of empty sacks and scrap lumber. Temporary wiring should be kept up off the floor and out of the way. I would like to see the pop bottle banned for it has led to falls and broken bones.

Good materials are wasted, possible salvage is ignored and accidents breed when trash is left lying around. Why not turn to an industrial engineer to devise a system of segregation, removal and disposal?

May I conclude with a little rhyme penned by Mr. Rudyard Kipling:

"I keep six honest serving men
(They taught me all I knew)
Their names are What and Why and When,
And How and Where and Who."

These six are combined in the person of the capable industrial engineer, and he has much to offer your industry.▲

LOOK UP AND LIVE

by RAYMOND W. WHITE

manager of claims and safety dept., Pacific Gas and Electric co., San Francisco, Calif.

This slogan has been adopted as a theme to help in the elimination of deaths and serious injuries resulting from contact with overhead electric power lines by equipment, tools, and other mobile objects. If all persons engaged in work which involves the raising of objects into the air will first "look up" and then take the proper steps to avoid contacts with any overhead electric power lines in the immediate vicinity, they and their fellow workers will live to work again.

WHAT IS BEING DONE

I shall present this problem to indicate its vital interest to your group, to state what is being done by the electric utility companies, and to seek your active programming of a campaign in the construction industry to eliminate such accidents.

Many of the electric utility companies throughout the nation, in cooperation with state and local governmental agencies, are conducting such accident prevention programs as a public service. These campaigns have included the following:

1. Newspaper advertising.
2. Radio and television programs.
3. Sound films.
4. Pamphlets.
5. Direct mailing to contractors, union members, farmers.
6. Personal appearances before contractor groups, union meetings, farmer groups, public service groups, etc.

The construction industry, by joining in this campaign, can bring about substantial accomplishments.

Both contractors and workers have the overriding motivation of the saving of human life in the prevention of these accidents. In addition, contractors and owners have vital financial reasons for eliminating such accidents. Insurance companies, damage

claims, work stoppage, contract losses, cost of training new skilled employees, etc., are but a few of such reasons. The workers are vitally interested because they are the ones who will be killed or injured, and because their families and their job opportunities also suffer.

Electricity in our modern civilization is a wonderful and indispensable servant. However, like many other modern conveniences, such as the automobile or airplane, it must be used or treated with proper respect. Carelessness can transform a wonderful servant into a horrible master!

Overhead power lines have long been used as the only feasible way of bringing electricity to the majority of our citizens. Almost all construction jobs find the use of electricity essential today. Your electric utility companies construct overhead electric lines to high standards of safety. This method of distributing electricity has been used since its discovery and will continue to be used for a long time in our present civilization with reliability and safety. It is the failure to "look up" and keep a safe distance from such overhead lines that brings about accidents.

WHAT CAN BE DONE

If the "Look Up and Live" message is carried far enough, loud enough, and often enough to those persons having potential exposure in their work, we can eliminate or reduce to an irreducible minimum this type of accident.

There is a need for concentrated action, properly coordinated, between contractor associations, labor unions, state and local authorities, electric utility companies, and the National Safety Council. This action should provide the thorough and repeated dissemination of information to all members of the construction industry, emphasizing the theme of "Look Up and Live." It stresses how proper care in the movement of objects when in the vicinity of overhead electric power lines will save the life of a fellow worker and prevent horrible suffering for those who might be maimed, but not killed outright.

Many of your local power companies will be glad to assist in preparing written information, developing programs, and preparing special material which you can deliver to your members and associates.

WAYS TO AVOID ACCIDENTS

Many suggestions for avoiding such accidents have been advanced, such as blocking crane wheels or tracks, blocking turning or lifting mechanisms, so that booms may not be moved beyond a safe point, building physical barriers, proximity alarm systems to warn when a boom is brought too close to power lines, contacting local power company in advance so that line can be de-energized, raised, re-routed, or other precautions taken. The exact solution will differ, depending upon circumstances.

In California the law requires maintaining a minimum distance of at least six feet from overhead electric power lines at all times. State safety inspectors require mechanical blocking or locking of equipment to preclude the possibility of contact.

The first rule to be followed is to look up frequently to discover whether overhead electric power lines are in the vicinity. Once this is determined, the other steps should be taken. However, it must be noted that visual observation of an overhead wire from the ground can be misleading. The angle of sight, light conditions, atmospheric conditions, background conditions and other factors may make determination of exact distances difficult.

Perhaps one of the most graphic illustrations of the need for continual observation and awareness can be quickly given by a brief summary of the tragic facts of a case which happened in our territory a few years ago. A salesman was demonstrating a boom equipped truck designed for trimming trees. He intentionally brought it to an area in the immediate vicinity of a 12,000 volt overhead electric power line to demonstrate its mobility.

FAILED TO OBSERVE

After several conversations concerning the proximity of the wires and how the equipment would avoid them, the salesman proceeded to demonstrate the equipment and in doing so, misjudged the distance and moved the bucket in which he was standing directly into the 12,000 volt line. Both he and the bucket were engulfed in a tremendous flame and eventually the bucket disintegrated, dropping what was left of the salesman to the ground.

Needless to say, he was horribly burned and was dead upon his arrival at the hos-

pital. This indicates that mere awareness is not enough. Further precautions must be taken. The equipment should have been located and blocked so that the farthest extension of the boom could not have brought it closer than six feet from the power line.

A discussion of the problem in advance with the local power company is recommended if careful appraisal of the job indicates no method of performing the work without coming in close proximity to the power lines (any distance closer than six feet).

DISTANCE ELECTRICITY JUMPS

Statements about electricity arcing and jumping through the air while booms are several feet away from power lines have been made. Such statements are incorrect and misleading. They do a disservice to proper understanding of this subject. The distance which electricity will arc or jump in the air gap or space under given conditions is a scientific fact. Air acts as an insulator or non-conductor of electricity.

The American Institute of Electrical Engineers, in cooperation with the American Standards Association, has published Standard No. 4 (American Standard for Measurement of Voltage in Dielectric Tests, September 11, 1953), which sets forth arcing distances. Table IA on Page 19 of this Standard shows that the arcing distances of electricity is normally considerably less than one inch at voltages as high as 40,000 volts. For example, the table shows that at 12,000 volts the arcing or jumping distance is only 0.5 CM or 0.197 inches (approximately ⅛ of an inch).

Most distribution voltages range from 2,300 to 12,000 volts. Higher voltages are used for transmission, but such lines are fewer in number. Even the very highest transmission voltages now in use in the United States will not arc or jump several feet through air, as has been claimed.

Perhaps some of the confusion has arisen from the fact that once a contact is made, an arc will be caused to stretch out when the contacting object is drawn away from the power line, and there may be a spectacular display of "fireworks" before the arc thus induced is actually broken. This cannot happen until direct contact is made or the boom has been brought so close to the line that it is within the arcing distances shown in Standard No. 4, which as I have indicated, for the normal power line distribution voltages is less than one inch.

A short television safety cartoon was prepared by the Pacific Gas and Electric Company of California as a public service. This cartoon warns of the need to "LOOK UP" and keep away from power lines.

FILMS AND PAMPHLETS

Two pamphlets have been prepared for distribution. The first is entitled, *Look Up—Power Lines Are Overhead*, which was published by our company. The second is entitled, *Keep Away from Power Lines* (Bulletin 140, April 1955) published by the Division of Industrial Safety, State of California.

The construction industry and its workers have an obligation to reduce these accidents. Knowledge and information to bring this about are available. We solicit your action to bring this message to the attention of every person engaged in construction activities. Our message is simply this: Whoever you are—wherever you work—if you have any equipment that reaches into the air—REMEMBER: Power lines are overhead—look up.▲

REMARKS OF GENERAL CHAIRMAN

by WILLIAM G. HAWKINS
director of insurance and safety, Winston Bros. co., Minneapolis, Minn.

It is with sincere humility and considerable pride that I accept the privilege and honor to serve as your general chairman this coming year.

In accepting this gavel from our outgoing general chairman, Robert L. Jenkins, I want to say that Bob has established, during his two years administration, a pattern of accomplishment that is going to be difficult to equal. We may be, indeed, thankful that he has agreed to continue to serve as an active member of our executive committee.

We may be justly proud of our executive committee, of its heritage and accomplishments since its founding in 1919, where today it has earned a reputation of being one of the most outstanding in the National Safety Council. But neither reminescence nor laurels-resting have ever been a part of our makeup. We must be concerned only with the tasks that lay ahead.

When we consider that we are the national safety committee for the biggest industry in this country today, the importance of our responsibilities become apparent. To be truly representative of the vast construction industry, we must furnish the leadership, coordination, and services that will provide the safety movement with a united front for all divisions and segments of the industry. Today, through direct and association memberships we are offering accident prevention services to more than 25,000 construction firms, employing several millions of construction workers throughout the United States, Canada and every corner of the globe.

The success of our leadership is largely dependent upon the effectiveness of our services and our ability to obtain participation from the contractors as active cooperators—all doing their share as individuals.

In planning and developing our committee activities, careful thought will be given to two goals, namely:

1. Developing effective materials and programs that will assist in setting up and carrying out a safety program, particularly at the job level, for our present participants and cooperators.
2. Developing activities that will "sell" our service, thereby, not only assuring broader and more effective use of our materials by our present participants, but also to reach out to the thousands of contractor associations and individuals who neither have a safety program today, nor are participating in our united national effort.

It is fully realized that it is going to take a heap of teamwork on the part of each member of our executive committee, but I have every confidence in each committee chairman and every individual member —truly representative of the construction industry and the best in the business of accident prevention.

Our Construction Section executive committee is now comprised of five divisions to cover Heavy, Highway, Building, Home Building and Specialty Construction safety problems. We have doubled the size of our committee, and are accepting the challenge of leadership with the ambitous determination to win.

Every member of our committee has complete faith and confidence in our fellow Constructors of America, for once a contractor is convinced of the importance of any task needed to be done, no matter how impossible it may seem, he will find a way. So it is with accident prevention.▲

PUBLIC EMPLOYEE SECTION

DRIVER TRAINING AND/OR REFRESHER COURSES

(A Panel Discussion)

DRIVER TRAINING

by FORREST S. ADAMS
safety coordinator, county of San Diego, San Diego, Calif.

In the spring of 1949 Arthur B. Groos, county training officer and secretary of the Central Safety Control committee, "viewed with alarm" the increasing number of vehicle accidents involving county vehicles driven by county employees.

Plans were made and in September, 1950, the County Board of Supervisors approved driver training for employees driving county vehicles, to be put into operation October 1, 1950. Sergeant J. T. Biddle of the San Diego Police Department was appointed as instructor and the San Diego Police Traffic Education Department cooperated by supplying materials, films, charts and testing equipment. The San Diego City Schools System assumed the cost of the instructor's salary.

The program was to consist of six hours of instruction in rules of the road, the vehicle code, defensive driving techniques, courtesy, vehicle maintenance and psychophysical tests.

The six hours of the program were divided into sections to suit the needs of the various departments participating; i.e., three, two-hour periods, two, three-hour periods and/or one six hour period.

The content of the course was based upon the ideas of Professor Amos Neyhart of Pennsylvania State College, a program developed by the County of Los Angeles, and other material appropriate to the local situation. Sergeant Biddle had gained national recognition for his work in driver education and is currently head of driver training for the United States Post Office Department.

During the year following the inception of the program 1,121 out of 2,800 employees completed the course and were awarded Safe Driver Certificates.

An almost immediate decrease was noted in county vehicle accidents. A six months survey indicated a 32 per cent reduction in accidents and a 65 per cent reduction in costs of accidents. These reductions occurred in spite of an increase of nine percent in the number of cars in operation and a six per cent increase in mileage driven.

The course was continued on a periodical basis up to the time of the appointment of a County Safety Coordinator in 1954. Since that time the course has been conducted on a monthly basis with new employees participating.

A continued decrease in vehicle accidents and their attendant costs has been noted each year since the course was started.

Obviously both mileage and the number of cars in operation have almost doubled since 1950, and of course the exposure to an ever increasing number of cars on the road points up the fact that the trained county driver is better equipped to do, and is doing, an excellent job of safe driving.

As compared to the numerous complaints by the community regarding the irresponsible attitude of county drivers prior to 1950, and the few complaints now voiced, it is quite obvious that the Safe Driver Program has paid off very handsomely.

The planned purpose of the county driver training program develops good drivers from the average run of the mill driver. Attitude is stressed, together with an awareness that good public relations with the tax paying public is enhanced by the golden rule of driving; i.e., courtesy, common sense and caution. Driver training does pay dividends.

SELLING THE DRIVER ON THE NEED FOR DRIVER TRAINING

by ALFRED M. NOYES
manager, safety div., Chief Administrative Office, county of Los Angeles, Calif.

Before the individual driver can be influenced to accept a driver training program, top management must be sold on the idea and give the program its full endorsement. This will be achieved if top management is fully informed of the extent of the problem and the method by which it is proposed to improve driver performance.

THE PROBLEM

A brief résumé of the history of driver training programs in the county of Los Angeles will show you the problems we faced, how we faced them, and what we are doing currently to develop and maintain safe driving procedures among all employees of the county.

The county of Los Angeles has more than 3,000 vehicles ranging from passenger cars to sheriff's interceptors, station wagons, buses, ambulances, bookmobiles, pickup trucks, fire fighting equipment, road building and maintenance equipment, and heavy trucks including trailer units and one special 300 horse power unit. In addition to this county-owned equipment, some 4,000 employees are authorized to drive their own vehicles on county business as "permittees." This poses a special problem because we do not exercise control over the physical maintenance of permittee vehicles.

This paper will be limited to land based motor vehicles, and will not include our small air force in the sheriff's Aero Detail of two light planes and three helicopters; nor the small navy of motor launches in the Flood Control District and the Parks and Recreation Department.

The terrain covered in our motor vehicle operation exceeds 4,000 square miles and includes travel in the heavy metropolitan areas interlaced with an extensive freeway system, level areas, foothills, mountains, valleys and deserts.

In recent years the total mileage covered annually by county-owned equipment has been approximately 25 million miles, and permittee vehicles have covered an additional 19 million miles annually, for an average annual total of approximately 44 million miles. Twelve of the 59 county departments and districts total more than one million miles of driving per year and three of these departments—county engineer, road department and sheriff, each covers more than three million miles per year.

With all of these drivers, all these vehicles, all this terrain, and all of these miles piled up each year, we have also been piling up too many vehicles and injuring too many drivers. Both frequency and severity of vehicle accidents were too high to be ignored and too many vehicles were out of service due to shop repairs. A number of these were major repairs and too many involved total losses.

THE ATTACK

On October 5, 1934, the county of Los Angeles' Board of Supervisors recognized the problem by officially establishing the County Safety committee, which, among other responsibilities, was instructed to investigate automotive accidents involving county equipment and personnel "to promote safety and develop a program of accident prevention and assign penalties as prescribed by the Board of Supervisors," as a means of reducing serious personal injuries and costly property damage.

For a number of years attempts were made to augment driver selection with some kind of a driver training program administered by the Civil Service Commission. However these efforts failed to arouse any real enthusiasm among the drivers and department heads did not provide the necessary support for the driver training efforts.

Several years ago the entire program was reviewed and advice was sought from such groups as the automobile clubs, insurance companies in the commercial vehicle field,

and the Greater Los Angeles Safety Council, regarding an effective driver training program for county personnel. The Safety Council proved to be the most productive resource due to its many contacts.

From this survey and the advice received, we developed a driver training program to be directed to all county drivers. Before it was launched, the chief administration officer was approached for his blessing, without which we knew the program could not make an effective start. The idea was adopted and the new driver training program was inaugurated as one of the first projects when the Safety division was established in the chief administrative office.

SAFETY AMENDMENTS

Since the start of this new program approximately 4,000 county drivers have taken the special one-day training course. Official support for this revised Safe Driving Program has been gained through several significant amendments to the County Administrative Code, notably:

Section 125.2 Supervision of Safety. . . . He(the chief administrative officer) shall take all measures which he deems necessary or effective to reduce or eliminate all industrial and vehicular accidents and the costs thereof.

Section 125.3 Investigation. The chief administrative officer shall investigate and ascertain the cost of all industrial and vehicular accidents . . .

Section 125.4 Safety Instruction. The chief administrative officer . . . shall conduct or provide for the conducting of courses and other instruction in . . . motor vehicle operator education and motor vehicle operator training.

Section 125.5 Motor Vehicle Operator Education. The aims and purposes . . . shall include . . . knowledge of the Vehicle Code . . . and a true appreciation of the causes, seriousness, and consequences of traffic accidents.

Section 125.6 Motor Vehicle Operator Training. The aims and purposes . . . include the development of the knowledge, attitudes, habits and skills necessary for the safe operation of motor vehicles.

As with any new effort, the effects of this training were not felt immediately, nor were they evident throughout all county departments. However, one department in which the majority of the authorized drivers have taken the new driver training course showed a 25 per cent decrease in vehicular accidents during the year following the completion of the driver training. An analysis of their vehicle accident reports shows a progressive decrease in preventable accidents during the last three quarters of the 1956-1957 fiscal year.

In addition, several other departments have informed the Safety division that in recent months their departmental automotive subcommittees have not been convened because there were no automotive accidents for them to review. For the first time in years, these subcommittees can now focus their attention on vehicle accident prevention programs rather than a review of accidents.

In this revised program, we started with the following objectives: reduction of automotive accidents; reduction of operating costs; reduction in maintenance costs; promotion of good public relations; developing safe, courteous, skillful driving habits; improving habits, skills, and attitudes; promoting defensive driving practices.

DRIVING TRAINING PROGRAM

The driver training course now operated by the County of Los Angeles is really neither a beginner's course nor entirely a refresher course. We attribute our success in gaining driver acceptance for this training to the fact that they are immediately informed that they are not being treated as beginners, but that we are starting with the premise that they are good drivers and that we are bringing them together in order to give them an opportunity to review their knowledge and skills and their attitudes, and compare their problems with those of drivers in other departments.

Realistically we let them know that we hope to strengthen their defensive driving habits by reviewing accidents in which other county drivers have been involved. We use psychology liberally in our driver training program, and we find that by emphasizing good driving habits and good driver performance we invariably have a more responsive class.

We purposely do not point the finger of guilt at any of the drivers attending the class for we feel that there is nothing to be gained in letting the entire group know that some of those attending the class have been directed by their supervisor to participate because of recent accidents in which they were involved.

In advance of the day's session, drivers who will attend are issued a brief résumé of the principal items we plan to cover, a timetable of the program, and a definite invitation to present their problems to the class and be prepared to join in the discussion for the general good of all drivers who will attend.

CLASSROOM CONFERENCE

In this one-day, 8-hour, driver training course, the morning session is taken up entirely in the classroom by the session which is conducted entirely as a conference. Each driver is made a part of the conference and brought into the discussion by posing the obvious question: What do you think is responsible for most accidents on the road?

Through skillful previous planning we manage to bring out in these conferences through discussion of the answers to the basic question, important parts of the Vehicle Code, local ordinances, driver skills, public relations, physical laws affecting vehicle operation and county policy regarding vehicles. In addition, we develop the importance of maintenance and care of motor vehicles and the correct procedure in reporting accidents. We wind up with a demonstration of driving skills with emphasis on reaction time and stopping distance.

CLASSES ARE MIXED

About two-thirds of the day's session is conducted in the classroom and the last item discussed is the basis for the demonstrations which will be conducted in the field. The class then adjourns to the paved Flood Control channel (which is dry most of the year) where each driver is given a forceful demonstration of his own limitations in maneuvering and stopping a vehicle. We conduct several reaction and stopping distance tests at normal speeds of 20-30 m.p.h.

At the wind-up we provide one dramatic demonstration of panic stops which might occur on the freeway at 50-60 m.p.h. These demonstrations invariably have impressed even the most unimpressionable drivers. Most of them remember that prior to the demonstration they were convinced that they were better drivers than the test revealed.

We are in the process of extending the demonstration to include driving skills such as parking, backing and maneuvering through offset roadways.

In general, each day's class is a mixed class, not limited to operators of county-owned vehicles, so that we may have truck drivers, social workers who drive as permittees and life guards, and among this group there may be drivers with a 10 or 20 year no-accident record and others who have been involved in accidents within recent weeks. We make liberal use of visual aids, but we try not to go overboard.

In addition, we start the session in the morning with a multiple choice quiz which covers most of the driving skills and significant sections of the Vehicle Code which we feel are important to most county drivers. These quizzes are for informational use only; each driver corrects his own paper and the real purpose is to let him know where his weaknesses lie so that he can correct them.

These classes have been conducted in a special classroom in the headquarters of the Safety division. However, in certain cases, we take the class to the facility, notably the Road Department, Fire and Sheriff. In the latter two cases, we conduct a special one-day course for recruits. In the recruit training we emphasize the legal limitations of operating emergency vehicles on emergency runs and we put all recruits through a skill course. A special quiz on emergency driving operations is used in recruit training.

In all of our classes we distribute resource material such as: California Vehicle Code Summary, Chauffeur's Supplement, and Summary of the Financial Responsibility Law.

CAN BE REFRESHER

While the course generally is not operated as a refresher course, we do make it available for re-training purposes when the Main Automotive Safety committee, or one of the departmental subcommittees, recommends further training for drivers who have had a number of accidents within a relatively short period. This training is often supplemented with a test drive in traffic by a qualified driver coach, usually an automotive safety engineer of the safety division.

From the critiques and evaluations following these classes, in which the driver is not required to identify himself, we have picked up a number of good suggestions for improving the course. We have been encouraged by such comments as the one expressed by a county engineer who stated he had been exposed to all kinds of driver education and training courses in the past 25 years, both in civilian and military life, but he had never received as much tangible benefit as in the driver training program we are now conducting in the county of Los Angeles.

We plan to link the driver training program with control of driving practices through a County driver licensing program. All newly hired employees, whose work would involve any driving, would be required to attend the driver training class and to demonstrate the necessary skills on the type of equipment to be handled by them, before receiving this county driver's license.

USE OF VISUAL TESTS IN DRIVER TRAINING

by BAYNARD A. SWITZER
chief safety engineer, Calif. div. of highways, Sacramento, Calif.

In the Division of Highways we do not have an organized driver training program.

In our state an examination is required for anyone to obtain a driver's license and no one is permitted to drive a motor vehicle unless he has such a license. The only requirement that the Division of Highways has regarding qualifications for driving is that the employee possess a valid driver's license.

We have little trouble with our employees not having adequate knowledge regarding the mechanical operations of driving a motor vehicle. Our problems have been largely in the field of attitudes and our program is geared toward the development of defensive driving techniques.

REACTION TIME TESTED

In an effort toward an indirect approach in driver training and attitudes, and also other accident prevention, the division in 1951 purchased two Keystone vision screening machines. One of these machines is used by a traveling assistant safety engineer in checking the vision of employees in Northern California and another one does the same in Southern California. Employees have their eyes checked on a volunteer basis and are advised to consult their own doctors when tests indicate poor visual performance.

When an employee has his eyes checked, he also receives a test for reaction time. In order to emphasize the importance of reaction time in driving, the examiner measures out the distance that a car travels at 20, 25 and 30 mph and indicates to each employee the distance the car would travel in his reaction time at those particular speeds.

The employee is given a card on which his reaction time is marked. This card also gives the stopping distances at various speeds divided into reaction plus braking distances.

DEFECTIVE VISION CASES

The eye test has several objectives. We know, for example, that our drivers with only one eye usually have better accident records than those with supposedly better vision. The employee with the one eye knows of his limitations and compensates for his disability. Therefore, we believe that employees who are familiar with visual limitations will compensate for them and have a better accident record.

We have found in our testing of employees' vision that approximately 17 per cent could have their vision impaired and do not know that they need glasses.

When we started our program, we found that approximately 48 per cent of our employees with or without glasses had defective vision. We found 7 per cent did not have satisfactory depth perception and 1 per cent was partly or wholly color blind.

The employees are anxious to have the vision test and retain the cards which are given them.

We have found few employees who are really conscious of the distance that a car travels in reaction time and we emphasize this part of the test. In some cases, we use the flash gun method of measuring distance traveled and in other cases we use an electrical device which is attached to the examiner's car.

We make no limitations on the employees who take the vision test. They may be operating or staff personnel. We have found that district staff members are just as anxious for the test as highway equipment operators and we have run into some rather odd situations.

Recently, tests were being conducted at the district headquarters in one northern district and a young lady took the vision test. It was found that her vision was quite defective. Upon the advise of the examiner, she visited her doctor, and some months later when the examiner was again in that area, she searched him out to thank him for his previous test. She explained that up until that time she had always thought moving pictures were foggy and indistinct and that it was natural to be unable to read sign boards or messages at a distance. Her entire life has been changed by proper glasses and she has an entirely different outlook on life than she had before.

In connection with the eye program, we have arranged with the Optometric Association and with the Registered Dispensing Opticians of our state for employees, who are properly identified, to obtain commercial discounts and standardized costs for prescription ground safety glasses. This program in which the eye specialists have cooperated has worked satisfactorily. It does not, however, in any way approach the programs which are put on by larger companies in private industry such as the Telephone company which not only give vision tests but also pay for the cost of the first pair of safety glasses.

This particular program is well accepted by employees who are appreciative of the fact that they are obtaining a special service for their personal benefits. We have found it necessary for our examiners to be careful in their discussions with the employees on their approach of the eye test. Our examiners are not in any way eye specialists and it is carefully explained to the employees that we are giving them information determined by a mechanical analysis of the eye and if the machine indicates defective vision they should consult an eye specialist.

REMARKS OF WARREN D. WILT

safety engineer, city of Detroit, Detroit, Mich.

Detroit requires pre-employment physical examination. The city plans to hold training to teach men their equipment—both inside and out—and how to operate same. It is the responsibility of the supervisor to screen his employees insofar as possible—with a probationary period before full employment—to ascertain whether many are safe and capable.

HOW TO TREAT THE PROBLEM

We plan to conduct an eight hour training course for all city drivers and construction men. It is important not to depend on rules and regulations — we train a man so he knows only the right way—use positive approach.

Men should be taught maintenance of equipment and vehicles, with the safety engineer to help out in case of trouble—in filling out reports—or in determining the cause of accident.

We use films—don't want to scare employees but show them damage and results of accidents. The program includes a written test to see that each class learned what the instructor was teaching. This tests the instructor's ability as well as student's knowledge. We also have tests—like a sort of obstacle course—putting into action what the student has learned. A new driver should drive with an old driver as passenger—checking errors and correcting same—taking up errors with new man—roadeo style test. The results: maintenance costs have been reduced which proves need for schools for employees to improve Safety. Statistics don't show results we want—talk about preventable accidents is not enough—what will we do?

Seeing habits are important. Drivers should train their eyes for expert driving—mechanical failure is not a factor—control is not a factor—people are not seeing what they look at. Fixed focus is not good. We insist on eye examinations. We do not want drivers to be experts—they should be professionals.▲

JOB TRAINING AND PLACEMENT

(A Panel Discussion)

REMARKS OF GEORGE F. KUHNS,

Discussion Leader

safety supervisor, Illinois div. of highways, Springfield, Ill.

I have revised the topic slightly and call it "Employee Selection, Placement, and Training." Any training and placement program should include a sound method of employee selection, since the hiring of workers without regard to mental, physical and health limitations would put too great a restriction on the job of placement and training.

The Illinois division of highways, like many agencies, is faced with the selection, placement and training of appointees, members of various units, civil service personnel, and exempt persons, such as engineers and other professional people.

Because of its diverse activities, the division has representatives of numerous trades and professions in its employment; therefore, it would be virtually impossible to discuss the selection, placement and training of employees in all job classifications. Since the highway section man represents one of the job classifications with a large number of employees, and his exposure to hazards appears to be great, I feel that he and his equivalent in your organization should be considered the front line man of "offense" in the war against accidents. I will try to limit my comments to his classification.

HIGHWAY MAN'S DUTIES

The highway section man, under supervision, directs a regularly assigned helper and one or more laborers, as the work volume may demand, in the ordinary maintenance and upkeep of an assigned section of the State highway system. This work may include a variety of highway surface types and drainage structures.

The following are examples of the work performed by a highway section man:

1. Inspects highways for hazardous conditions, such as ice, snow, dirt, fallen trees, water, or other obstructions on pavement, and removes the same.
2. Repairs and replaces broken pavement; repairs shoulders; mows weeds; keeps ditches open; maintains drainage structures; and polices right-of-way.
3. Operates truck, grader, mowing machine, snow plow, concrete mixer, and keeps the equipment in good repair and working condition.
4. Paints and repairs guard fences; repairs and replaces route marking and traffic signs; erects and removes snow fences.
5. Performs semi-skilled work as principal worker in maintaining highway in good condition.
6. Makes reports on work accomplished and distribution of time.
7. Performs other duties as required or assigned.

The department of personnel has set up certain desirable requirements of applicants, for the position of highway section man, even though he is subject to appointment.

Education—Requires knowledge, skill and mental development equivalent to completion of eight years elementary school.

Experience—Requires two years experience in highway maintenance or construction work, such as might be acquired as a highway section helper, including some equipment operation; working knowledge of highway construction and maintenance materials and operations.

Significant Responsibilities — Requires ability to make simple specified reports; skill in the operation and repair of highway maintenance equipment; mechanical aptitude.

Significant Mental Requirements — Requires ability to understand and to carry

out effectively written or oral instructions; ability to observe hazardous or improper road conditions and to take appropriate action.

In addition to the above requirements the applicant must have a physical examination by a licensed physician. The applicant is responsible for the examination fee and may have a physician of his choice make the examination.

PHYSICAL CONDITION CONSIDERED

When a district maintenance engineer has an opening for a highway section man the personnel office will send an applicant for interview. The district maintenance engineer is furnished a copy of the completed physical examination form and a completed employment application form. The district maintenance engineer may accept the applicant and assign him to a maintenance section, or he may recommend against employment because of past performance, lack of experience, or because of a mental, physical or health limitation. If there should be some question as to the physical fitness of an applicant or an employee, the division may request that he submit to an examination by a physician selected and paid by the division.

When an applicant is accepted for employment, he is given a detailed course of indoctrination by the district maintenance engineer. In addition to an explanation of the policies and procedures of the division, the district maintenance engineer informs the new employee of his responsibilities and duties as a highway section man in regard to his work and employee safety. The new employee is given a copy of the division's "Safety Code" at the time of his indoctrination.

SUPERVISION RESPONSIBILITY

The work of the highway section man is supervised by a maintenance supervisor, who is accountable to a maintenance field engineer. The supervisor, or field engineer will visit each maintenance section at least once each week and hold group meetings with their men once a month at the supervisor's or the field engineer's headquarters. The district maintenance engineer will hold occasional meetings at field headquarters with all employees in that area.

The maintenance meetings are held shortly before the highway section man will be involved in some seasonal work, such as snow removal and ice control operations, vegetation control, crack pouring, or other major maintenance operations. Although the district maintenance engineer and his field engineers make job safety an integral part of their work instructions, separate safety talks have been included in the field meetings.

When a new piece of equipment is purchased by the division and assigned to a district, the district maintenance engineer will have a representative of the equipment supplier meet with the field engineers and supervisors to instruct them in the operation of the new equipment. The supervisors and field engineers will then instruct their highway section men.

I do not wish to appear as one offering excuses or apologies for our relatively poor rates; on the contrary, I would like to make a few observations which I feel would aid in reducing the number and severity of work injuries and accidents generally.

MERIT SYSTEM PROMOTES TRAINING

I am confident that our respective maintenance organizations would have more suitable and younger applicants from which to choose for the various maintenance jobs, if the employees could be assured of continuous service based on merit. Also, if we could expect to have maintenance men in service for 15 to 20 years or more instead of only four to eight years, a greater expenditure of time and money in the training of those men could be justified.

At the present time several highway departments have maintenance men in their 70's and can expect to have many more within the next three years. The duties of maintenance men within highway departments require that they do arduous physical labor and, at times, operate snow removal equipment for long periods of time.

There are few men in this age bracket who are in such good physical condition that they can long survive this type of work. If a maximum age of 55 were set for applicants, this would give assurance that seldom would men over 63 be called upon to operate snow removal equipment or engage in other strenuous activities.

If the number of men supervised by each field engineer were reduced, the field engineer could exercise closer supervision over his men and thereby learn more about their work habits as well as the work they do.

There are many more suggested changes that could be made which would no doubt assist in improving our accident record if put into effect; however, no ideas we now have or that we may pick up here at the Congress will be of value if they are not properly evaluated, adjusted to our own organization and then put into operation.

It is hoped that some of the ideas projected by this panel today will find their way into your safety programs and thus become a vital force in reducing the number of injuries suffered by public employees across the nation.

REMARKS OF LORIN J. ELDER

supervisor safety div., Pennsylvania State University, University Park, Pa.

You should have no drivers past 50 years of age. When that age is reached—give them lighter duties—don't release them but make use of their years of experience and know-how.

Causes of accidents frequently can be traced back to home life. Therefore, check accident records back for five years—show them to employees—this makes them think. Keep check on records from that time on. If employee seems to work carefully but continues to have accidents, remove him from that job and give him another job he can do.

Try to investigate every accident in some form of report so they realize there is a particular hazard. Even in an accident that is "slight"—when you go out to investigate it—the things you find!

Accidents are caused by manufacturing faults—unminded conditions—carelessness. If manufacturers don't install safety devices on their products—don't use them.

The safety division of Pennsylvania State University tests various machines. When the manufacturer refuses to put safety devices on their machines, saying it would run the cost up beyond competitive prices, the safety division either refuses to accept them for testing—or requires their immediate removal—if they have been installed.

REMARKS OF JOHN J. HOBAN*

safety coordinator, City of Seattle, Wash.

Seattle is no different than your city as far as the new employee is concerned for he comes to you after he has demonstrated his ability and competence by passing a civil service examination. The next step is to teach him the job you expect him to do. For this training you place him under the supervision of your foreman or supervisory person. The key to the successful training and placement of the new employee, is therefore the capable supervisor or foreman.

A supervisor may be a capable person in knowing his work, yet not be able to teach what he knows. You have seen supervisors who are unable to get their message over to the new man. And the new employee is, to say the least, bewildered and confused. The supervisor sometimes assumes the new employee knows all the answers. In the discussion of job training and placement it is fatal to assume anything about the new employee.

With the new employee you must spoon feed him until he knows the job and we know that he knows the job and what is expected of him as a safe competent workman. He is thus thoroughly indoctrinated in all operating procedures but more basically in the integration of accident prevention and all aspects of our city safety program. This is what we are trying to do in Seattle with our new employees.

PROPER PLACEMENT

We know that the proper placement of the new employee is equally as important as recruiting that employee. Assigning the new man to a position where he can work at his highest level of efficiency in city service, is a basic consideration of Seattle's placement program. The other factors considered in Seattle's program of Placement and Training are:

a. Minimal physical standards for the many hundred job classifications.
b. Job surveys. A technique applicable to the placement of all employees, male or female, young or old, able bodied or handicapped.
c. Job analysis for physical fitness requirements so you will know:
   1. The job is completely and accurately identified.
   2. The tasks of the job are completely and accurately described.
   3. All physical and environmental demands the job makes on the employee for successful performance, must be shown.

An excellent publication on this subject *Analysis for Physical Fitness Requirements*, U. S. Civil Service Handbook. No. M-605 U. S. Printing Office 20c.

In Seattle we do not have a formal training program for the new employee. He is indoctrinated by the supervisor and foreman, after his initial interview with the personnel officer, who outlines the overall operations and functions of the department. He is given a handbook of Civil Service rules and department rule book, entitled *Your Job with Seattle City Light.*

His instruction is sometimes given by a fellow employee who "breaks in" the new employee to his job. At the monthly safety meetings, through the bulletins issued by the department, tail gate meetings or departmental conferences, his training is continued and advanced.

Award presentations, either for safety effort or service attained, all tend to stimulate the employee's interest in his job. The employee publication carries the story of how and why the employee can do a better job for the department. These media stimulate and arouse his continued interest. He may serve as a safety committeeman, and thus become acquainted with the hazards of the job in the department. Many a mediocre attitude toward on-the-job safety has become an aroused and inspired attitude, dedicated to accident prevention, when exposed to a safety committee membership.

To summarize, therefore, what the Seattle city departments are doing in job training and placement, I might conclude:

1. The employee is introduced to the job by the personnel officer and safety official.
2. The individual instruction of the employee by the foreman or supervisor or his assistant.
3. Supplementary aids are given by conferences, bulletins, posters, movies, employee meetings and publications, incentives and all types of morale building activities.

There is a great deal more we can and must do in Seattle and every city to meet the challenge of industry in recruiting and making more attractive municipal employment in the years ahead.▲

*John Hoban was unable to present this manuscript at the Congress because an illness prevented his coming to Chicago.

REMARKS OF J. F. DE VIVIER

personnel dir., Colorado dept. of highways, Denver, Colo.

Does training come before placement—or vice versa? It comes both places. In job recruitment and placement, keep politics out. Select the best qualified personnel—a lot of training can be done for you by selecting trained employees for the position open.

Rules are for when brains run out—unless an individual has brains to apply rules—rules will not solve accident problems.

There will still be a lack of necessary trained personnel after screening. Then you must provide a training program under supervision—to watch and coach.

One-the-job training: train employees beyond their present duties to higher level jobs. Supervision must come from management to train beyond routine to higher level.

When an employee reaches an older age—don't start him down the hill—take advantage of his knowledge and pass it to younger men. Supervision should be responsible for training in an organized manner—supervisors should be trained in training.

Safety should be put on an over-all training program. Use a variety of equipment for training.▲

PARKS MAINTENANCE SAFETY — TREE TRIMMING — BRUSH HANDLING AND RELATED SUBJECTS

(A Panel Discussion)

IMMUNIZATION EXPERIMENT—1956 RESULTS

by J. F. HUZVAR

Pennsylvania State highway dept., Harrisburg, Pa.

During the spring and summer of 1956 an effort was made by the Bureau of safety to determine the efficacy of homeopathic medicine in desensitizing Highway department workers to poison ivy.

Preference in treatment was given to those employees who had reported ivy poisoning in 1955. Eighty-two of these volunteered to take a product named Imun-Ivy. Two one cc doses were taken orally by each person at a 24-hour interval. Of the 82, 72 reported that they did not get ivy poison during the 1956 season.

At the same time, with the surplus Imun-Ivy, an additional 158 men (who were known to be susceptible to ivy poisoning) were given similar doses. Of these, 138 were apparently rendered immune. The ratio remained the same and showed an effectiveness of 88 per cent in each case.

The work habits of these men remained essentially the same during the years 1955 and 1956.

In District #5 where Oral-Ivy was used instead of Imun-Ivy, even more startling results were obtained, but unfortunately the sample was not large. In this case, the medicine was given to 29 men, of whom only one reported ivy poison, showing an effectiveness of 96 per cent.

As a result of this campaign we cut down our lost time from poison ivy from 31 cases to 12 and the actual lost time from 178 days to 88.

RESULTS—1955 EXPERIMENT

District	*Took Imun-Ivy*	*No Poison Ivy*	*Poison Ivy*
1	5	3	2
3	9	9	0
4	12	12	0
9	13	7	6
10	11	10	1
11	16	15	1
12	16	16	0
TOTALS	82	72	10

88 PER CENT EFFECTIVE

DISTRICTS 2—6 & 8—no immunization—just treatment

Dist. 2	46 worked	13 had poison rash of some sort	4 lost time
Dist. 6	51 worked	17 had poison rash of some sort	4 lost time
Dist. 8	67 worked	21 had poison rash of some sort	9 lost time
TOTALS	164	51	17

51 cases in 3 districts

The cost per man was approximately $1.00. The immunization period was approximately nine months. It was recommended that in those sections of country where poison vines grow year around—immunization product be administered about every six months. This taken on strictly voluntary basis—but when others saw effectiveness— all requested same.

Showers are provided in each shed and men are required to take a shower at end of each day. Some disregard the requirement with consequent cases of poison ivy. Bland soap is used.

Firm rule that no poisonvines be burned if it can be avoided. If you must burn the vine, stay out of the smoke because poison oils from vines are carried by the smoke and will affect persons susceptible to it.

THOSE EMPLOYEES WITH KNOWN ALLERGIES

NO IMMUNIZATION

District 2—46 worked—15 had poison rash —5 lost time.▲

REMARKS OF JOSEPH F. WICKLESS

supervisor of safety, city of Baltimore, Baltimore, Md.

This phase of parks maintenance is performed by the forestry division of the Baltimore bureau of parks. The personnel consists of chauffeurs, climbers, foremen and laborers.

High tree trimming is done by experienced climbers only. These men are selected on their experience and then given additional training by foremen. They must be physically fit.

The climbers handle their own individual one-half inch manilla rope safety line which must be inspected each time it is coiled and before re-use. Climbers use belts with an extra seat strap with a rope safety tie line. They also use rope lines and sliding knots, and are always tied to the tree with a safety line. Limbs are lowered with one inch lines except in isolated cases. Removal of logs, stumps, etc. is done with a winch and cable.

Climbers are started up the tree with a ladder since steel climbers are only used on exceptionally large trees and those to be felled. Ground men are always available and are trained for working beneath overhead work.

Brush in most cases is fed into the chipper. All brush is pruned before being fed into the chipper to avoid binding and possible kick back. The operator must wear goggles when feeding chipper. The chipper is equipped with a power cut off within easy reach of the operator.

When brush is hauled on trucks it is passed from one man to another who wear gloves and then to the top man on the truck who loads systematically. Brush is hauled to a dump area and burned. Goggles are worn when pulling brush.

All overhang of brush on sides of trucks is pruned before hauling. Flags are attached to overhang in rear. Hauling to dump requires two men: the chauffeur and a back-up man.

Logs are always cut up into lengths convenient to handle and logs large in diameter are loaded mechanically.

All tools and equipment are subject to frequent inspection. Adzes are not used. All cutting tools are kept sharp and can be exchanged anytime if any defect is noticed. Ladders are inspected frequently and before each use. Time is allowed for tool

sharpening. All cutting tools are carried in sheathes or guards by climbers.

Work locations are set up with proper arrangement of warning signs (men working in trees), flags, cones and barricades where needed as related to traffic.

A hi-ranger has been purchased and is in constant service. All exposed metal equipment and tools are insulated against 20,000 volts of electricity. Three men usually operate the ranger, a foreman, tree climber and ground man.

The ranger can be controlled from the basket by the climber or from the ground and is equipped with a reserve hydraulic equipment for emergency use. It is never operated with less than two men.

A chipper is attached to the rear of the ranger into which brush is fed and chips loaded into a provided bin on the ranger chassis. The chipper blades are inset to a distance impossible to reach under ordinary conditions.

For night emergency work, fusee flares are used along with barricades and warning signs with flashers. Flood lights and spotlights of 1,000 watt are used for illumination. The rear of trucks is well lighted and painted yellow with black stripes.

Spraying operations are performed after posting of area and respirators are used.

Reporting all accidents is demanded and victims interviewed to determine causes. Unusual cases are interviewed by the superintendent to determine safety infractions and action.

The forestry division, bureau of parks, city of Baltimore is administered by the city forester, the superintendent, Charles A. Young. This division is responsible for the care of more than 250,000 street side trees and those on more than 5,000 acres of parks.

BRUSH—HANDLING

Lifting
Secure footing
Wear eye protection
Look out for overhead work
Removing trees—grubbing operation
  Care in position while using axe
  Not too close to fellow worker
  Don't lay tools around carelessly

PARK MAINTENANCE

Inspect Mowers—motor—when to shut off
  Keep feet away
  Look out for foreign objects
  Be alert to fellow mower
  Be careful when filling gas tank
  Be careful of traffic when in center plot

Steep Slopes
  Operator wears cleats
  Mower held in place by rope
  Attached to another person—on slope
  Prevents sliding

Care of Hand Tools
  Place rake in safe position when not in use

Care in tool house
  Use care in parking vehicle near center plot.
  Use cones for barricade

SAFETY IN TREE TRIMMING

a. Safety belts—Rope or life line
b. Make and care of equipment
c. Ladders
   Safety factors
   1. Construction
   2. Shoes
   3. Extension type
   4. Use of ladders
   5 Examine tree—determine ladder needed
   6. Where to place ladder
   7. Clothing

Tools for tree trimming

Saws—Pruners—Knives
  a. tools sharp and in good condition
  b. care of tools—location for keeping
  c. Clean—strong
  d. Wood handles

POWER LINES—KEEP AWAY
CHAIN SAW
CHIPPER

Tree Trimming

1. Safety Belts and lines
2. Ladders—shoes on them
3. Clothing—high shoes—gloves (leather)
4. Tools—saw, pruner, knife, pole saw

5. Power line—Hi voltage
6. Power saw—chipper, hand saw, all saws

Don't lean against or grab dead limb or tree

Park Care

1. Power motor
2. Keep toes and feet away
3. Alert to traffic if on parkway
4. Never park vehicle without barricading or warning
5. Use cleat shoes on incline
6. If scythe is used—keep far away—beware of hard objects.

▲

REMARKS OF JOHN H. WILLIAMS

director of safety, Chicago Park District, Chicago

CONSTRUCTION SUB-SECTION SAFETY

TREES

Digging:

Dig trees so that balls are only slightly tapered on sides and flat on bottom, so they will not tip over easily when setting around work area. Be sure ball is deep enough, according to size of top, so that tree will lay on its side and not automatically fly up. Block ball if deemed necessary.

Avoid injury from thorns. Be alert at all times when working with thorny trees.

Machine operator and others in near vicinity should be constantly on the alert when tree digger is in use to avoid being hit by branches as tree tips.

Wear goggles when breaking frozen ground.

Hold frost wedges with holder not hands. Grind off mushroomed heads on wedges or send to blacksmith shop for repair to avoid breaking off pieces that might fly through air.

Be sure sledge head is not loose on handle.

Moving and hauling:

Check chains and ropes for safe condition and attach so they won't slip.

Watch hands when hooking onto chain with winch cable. One man only in charge give signals to winch operator, except in emergency anyone call yell, STOP.

Always keep clear when handling heavy material, chain or rope may break or slip. One man handle, others stand clear.

Tie branches in whenever handling, loading, unloading and hauling.

On trucks, block tree balls well and also tie in place.

Use red flags on extended ends.

Unloading heavy trees, roll down skid while snubbing, even medium weight. Use mechanical devices, hydraulic tail gates, etc. whenever possible.

Control top also at all times.

Don't haul men and trees together, except when absolutely necessary. Watch going under viaducts.

Tree holes:

Determine whether or not there are any underground utilities in area before starting to dig. Use special care around underground electric cables. Notify electrical department of your activities.

Be certain of ability of soil to not cave if digging hole near standing balled tree. Can dig closer, in heavy clay or frozen soil, than in sandy or loose soil. Prop ball with strong timbers to protect men working in holes under or near standing tree.

Planting:

Use mechanical equipment if possible.

Grip ropes properly. Never "take a wrap" around hands. Keep ropes clear of feet. Keep clear of whipping branches.

Trimming:

Wear soft soled shoes to avoid slipping. Shoes should have firm arches to avoid discomfort or injury from prolonged standing on ladder rungs or branches.

Wear goggles when any possible eye hazard exists. Wear safety belts or use safety ropes always when in trees. Tie self in when working high in "flat-headed" trees.

Be sure of safe condition of climbing rope and that it is looped over a strong crotch

and around trunk to catch on next limb down if limb breaks. Examine rope carefully and frequently. Should be treated rope. Can tell bad rope because it swells oversize and softens up.

Use taut-line (skinner's knot) and double bowline for swing line in tree.

Use barricades or flagman to keep people out from under trees while they are being trimmed.

All tools used in tree should always be safely secured. Ground man should service trimmer with tools but stand clear for safety.

When using power saw in tree, both man and saw should be roped in, separately, and in such a way that if either should fall, they would swing apart not together.

Ladders, either of wood or of aluminum with non-slip rounds:

Base 1/4 of length out from bottom of tree.

Should have safety shoes on legs of ladder.

Be sure top is anchored in well to not move when climbed.

Remove ladder after trimmer has gone above it to avoid damage to ladder from falling branches.

Never trim heavy limbs or top a tree while on a ladder, falling limbs can break ladder, or knock trimmer off.

Watch for bare wires in trees. Insulate wires or call utility for co-operation in clearing branches from wire. Keep out of trees with wires through them in damp weather.

Don't trim at all in any weather that endangers the men except in extreme emergency: too cold to have good grip on trees or tools, extreme heat can cause fainting, dangerously high winds, enough precipitation to interfere with work.

Removal:

Properly diagnose exact condition of tree before climbing. Do all necessary guying to protect men and property. With forked tree, divided near base, treat as separate trees for fear of each part falling separately.

Lower heavy branches or sections of trunk with ropes in proper size sections. Cut into sections small enough to be loaded easily by no more than two men. Men should always be wearing gloves. Use mechanical loader when available.

Shrubs:

Wear gloves, goggles and safety shoes when indicated. Wear suitable clothing including head covering.

For frost bite in winter, for allergies and poisoning in summer and traumatic injuries anytime.

Keep fingers out of shear blades when trimming. In fine work don't hold with fingers of one hand while operating shears with other. Let trimmings fall free.

Use proper manpower in handling heavy material or use mechanical equipment if available or necessary.

Soil:

Always use right tool for job in handling soil.

Wear goggles if soil is dry and there is wind. Loading trucks, work on windward side.

Put on gloves before hands blister instead of after.

Don't leave soil working tools lie around, teeth or blade up. Lay face down with teeth or blade pushed into soil, or stand tools up against building with back out.

Tools and Equipment:

Keeping all tools clean and sharp is good housekeeping.

Watch for slivers on handles of all tools. Store properly on racks completely off floor if feasible.

Axes: Don't use as sledge. Dull axes are dangerous, they slip off work instead of entering. Handles should be strong and whole, not slivered partly away. Be sure head is tight on handle. Use right weight for work being done. Sharpen correctly. Don't let axe blade cheeks get too fat. Don't use beyond temper on clean cut work. Can save and use for chopping roots in soil.

Stand clear of axeman and of flying chips. Axeman and others in immediate vicinity

should wear goggles. Carry with blade turned away from head.

Chisels: Carry in scabbard or kit, not in pocket. Don't stand or work under man using chisel. He may drop it. Wear goggles.

Mallets: Have wrist strap on end of handle to avoid dropping.

Paint: Wear goggles to protect eyes.

Power Equipment: Shut off motors to:

Adjust

Repair

Gas and service

Clear stoppages

Rotary Tillers: Run in lowest gear that will do work properly for more safety. Keep tiller in soil whenever it is rotating. Disengage rotor when out of soil to turn or cross walks, etc. Keep apron on back and floating on soil for protection of operators.

Tractors: Check parts that might cause injury if defective. Hose on hydraulic system. Don't over-tax machine or use on unsafe inclines risking tipping. Prop bucket up securely when working under it. Turn off motor and put in neutral gear when not in use.

Trucks: Don't jam small trucks full of mixtures of men and tools. Don't mount or dismount while in motion. Never ride in truck except while sitting down. Keep all parts of body completely inside at all times. Never hang legs out over tail gate.

Saws: Keep sharp and clean for safest use. Keep handles tight and never use with cracked handle. Hook on belt to leave hands free for climbing in tree. Never drop to ground, lower with rope. Don't use back of saw for axe. Load and unload carefully to avoid injury to personnel if riding in same body of truck. Better to have separate trucks for men and for tools.

Power Saws: Recognize the possibility of extreme dangers involved. Never get careless. Don't store where wood floor will get soaked with fuel mixture.

Pole Saws: If hung in tree when not in use be certain it will stay where hung. Never drop from tree, lower with rope.

Shears: Don't overtax shears or [illegible]erator.

Use lopping shears for stock not easily cut with hand shears.

Make diagonal cut, cuts easier. Use saw for stock not easily cut with loppers. Carry locked and in sheath when not in use.

Pole Pruners: Should be insulated to work around wires in trees. Watch knuckles when using handle operated type. Rope on handle type preferable, with knots in rope for easy grip. No stoop on low branches either, can reach up rope instead of down to handle.

Winch: Check cable frequently for defects, weak spots, worn, etc. Stand clear when there is strain on cable. Wrap straight on drum by guiding with bar but not with hands.

Never handle without leather gloves and never let moving cable pass through hands. Use "solder-in hooks" on cable, not clamps that leave a frayed end.

Fertilisers:

Use respirators and goggles under dusty conditions. Use two men in handling any quantity of 100# bags especially for loading or stacking. Lift with leg muscles not back muscles.

Spraying:

Use goggles or masks or respirators with materials calling for same, or when face is exposed to danger due to wind, overhead spraying, etc.

Wear proper clothing to protect from absorption of, or contact with spray materials: Slickers, rain hats, boots, rubber gloves.

Be careful of slippery platform on tower trucks, or gangways alongside tanks. Use soft soles for safe footing.

Wash or bathe as necessary, before eating and to prevent absorption.

Don't use personnel known to be allergic to spray materials or specific plants.

Avoid horseplay around equipment or conditions that could cause injury.

Forbid strongman exhibitionism with heavy equipment or materials.

Insist on proper clothing that protects from sunburn, frostbite or exposure to scratches, abrasions or punctures from plant parts, ropes and equipment.

MAINTENANCE SUB-SECTION, SAFETY

ICE MAKING

Must wear creepers.

Wear on ice only, not to and from on concrete or climbing on and off trucks. Dulls points, and unsafe to wear other than on ice.

Shoe type best, hinged with calks. Should have adjustable leather straps with pin and hole buckles. Instep type hard on arches, no help to heel or sole.

Handling hose:

Always shut off fire hose to move it, using a minimum of three men. Should use shoulder straps like firemen do.

Carry over shoulder, walk forward, no less than two men (especially at night). Can pull hose around on ice with hook. Assistant should stay close to nozzle man and facing him to give ready and complete co-operation.

Wheeling hose, wear creepers. Have wheel barrows in good operating condition. Axel greased and tire inflated. Use hose reel when possible, safer than wheel barrows.

Frost Bite:

Proper housing and warming facilities. Arrange for access to inside of buildings at hours necessary.

Insist on proper clothing, especially with young fellows who don't realize danger from exposure.

Lighting at Ponds:

Should be lighted area to aid workmen and for safety of public.

Arrange with buildings for lights, if controls are inside.

Suggest parks be less indulgent of demands by public to avoid having men work without proper facilities.

SANDING, SALTING, SNOW REMOVAL:

Trucks:

Boxing rings on trucks to protect men from falling off. Mechanical section should see to it that all trucks to be used for this work are so equipped. If Standards to be used have clamps on bottom they would fit all trucks.

Equip all trucks with blinkers that might ever work on boulevards, both one-half and one and one-half ton trucks. Red lanterns on back of truck, better yet, "plug in" lights on extreme ends of spreader.

Always have a supply of red lanterns or portable battery type flashers on hand. Could mount them permanently on ends spreader.

Use reflector buttons also.

Don't board or dismount from moving trucks.

Mounting and dismounting spreader. Keep fingers clear of between spreader and truck. Weld handle on tail gate for opening to insert blocks. Don't try to remove tools, etc., by hand, while motor is running on spreader, always shut it off first. Should have wind protection on tractors for plowing. Tractors are not suitable equipment for work, trucks are much more desirable.

Snow shovels and pushers hitting cracks in sidewalk can cause hernias. Keep handle out of line with belly. Hold to side.

Sand Boxes:

Set back two feet from curb to protect boxes, cars and person using material from box. Spread some in front of box first if slippery. Should have "no parking" painted right on boxes, so they are always available.

LEAF DISPOSAL:

Wear respirator and goggles when operating any leaf mulcher.

Rotary type mulcher.

Be sure guards are in place, keep hands and feet out from under.

When burning leaves, always extinguish fires before leaving them unattended.

Fire might spread and do damage.

Children might play with fire.

Athletic Fields:

Keep lime out of eyes, wear goggles or mask, when marking fields.

Keep toes out from under rollers. Danger in loading rollers and other equipment on trailer to move, may tip off edge of ramp.

Service yards should have hydraulic lifts to load with or trailers with hydraulically raised and lowered deck.

Full plate to hook on rather than narrow hooks on end of skid planks to prevent tipping of plank. Diving mat on skids for traction for machine and operator. Snub equipment to front of trailer.

Watch slime on bottom and sides of wading pools, clean daily. Warn new men of slipperiness under foot. If bad scatter sand first. Don't pick up broken glass by hand without gloves. Use extension rods on water valves that can be operated through hand hole in cover making it unnecessary to handle basin covers.

Don't combine working on athletic facilities with playing by patrons, if any danger exists. Stop play if emergency calls for it, otherwise try to schedule work to not conflict with use of facility.

GOLF COURSES:

Golf balls: Wear helmets (boiled hats).

Wear helmets (boiled hats).

Distinctive colored shirt or safety belts, color of shirts could match hats. Could see shirt at greater distance. A number of men together with one kind of shirt would be recognized as workmen not golfers.

Two men watering, for weight of hose and protection, especially at night.

Screen for emergency repair work on course, for plumbers, etc., can also spot trucks for protection.

Personnel from other departments working on golf course should always contact golf course maintenance man for his co-operation before working.

Motorized equipment should be painted yellow or other bright color.

Mow golf greens early and get out of way or move flag to temporary green while working on regular green.

Respirators for spraying insecticides and fungicides, or gas masks.

Wash hands after using insecticides and especially before smoking or eating.

Grass, Mowing:

Men or tractors should always wear helmets, when mowing on golf course or ball fields and have a screen or cab on tractor.

Use safety club in reel of mowers to remove obstruction, don't use fingers. Shut of motors. When clearing reels, disengage reel.

Don't ever leave mower while its running, there is danger to others, especially children.

Operators should be required to sign safety rules card before operating power mower and other motorized equipment. Duplicate cards should be signed, one to go to safety section and one kept in local office. This impresses the employee with seriousness of rules.

Police lawn area in advance of first mowing in spring to prevent objects on grass being propelled by mower injuring operator or by-standers, or damaging mower. Keep eyes open all the time for obstructions.

Shut off motor while gassing up and servicing. Don't smoke while handling gas. Keep gas in safety containers only. Use care in carrying shears, hooks, whips. Make scabbards out of one and one-half inch hose to cover sharp edges.

Suggest back rest or wear belt for back strain from riding Toros Triplex or other Sulkies.

Catch Basins:

Stand close to curb to clean if possible. Barricades, warning flags, use flashers while working at night and flag man during day, safety belts and shoes, and wear gloves.

Keep handle out of street when cleaning. If trees are in the way barricade off wide enough to tip handles into street.

Use special tool for opening covers.

Bridle Paths:

Should be sprayed with light oil to lay dust.

Goggles and respirators while cleaning if dusty, or sprinkle down area.

Barricades to control equestrians while working on path, far enough away to stop safely.

Stand still, don't excite horses when they are passing.

Lagoon Cleaning:

At least two men at a time in boats, with life preservers.

Scows preferable for sea weed instead of row boats.

Watch for allergies of men, give protection.

Litter and Garbage Cleanup:

Use goggles when working around shrub beds.

Use two men below to a basket when heavy when handing up to trucks.

Wear gloves.

Use lighter gauge garbage cans in field houses and boiler rooms.

Don't fill ash cans with water.

Avoid use of those too heavy to carry out. Use demountable winches on back corner of trucks where there is no stationary one, to hoist out of deep basements.

Examine condition of stationary hoist and report any defect.

Hand rails on cabs and expanded metal on running boards for safety getting on and off trucks used for close pickups.

Beach Maintenance:

Use gloves on broken glass.

Goggles and respirators for men on sand-sifter.

Short handle rakes for screen cleaners to keep out of drum.

Take care when carrying heavy baskets on sand to not slip.

Use bale hooks, one man on each side of basket.

Buildings:

Ramps going into basement tool rooms, etc., get slippery, watch and correct.

Remove snow and ice.

Roughen concrete with acid or use chicken ladders, if steep.

Snow Fence:

Wear gloves, avoid slivers.

Bend ends of fastening wires in.

Pickup cut wires in container when dismantling to avoid foot injuries and damage to lawn mowers.

Two men to boost rolls up, one on truck to receive.

Use post puller to prevent back strain, don't try to pull by hand.

Boulevard Maintenance:

Work against oncoming traffic. Work on slack side when possible.

Wear safety belts.

Red flags on wheel barrows.

Wear goggles when dust or other eye hazards are present.

Keep off of boulevards during rush hours. Use knockdown barricades for safe transporting and to collapse if hit.

Blocks and flags 50 feet to 75 feet from piles of debris, to protect men loading material off boulevard, unless motorists' vision is obstructed by curves, underpasses, etc.

Then set as far back as necessary, 200 feet or more, and also use flag man if situation warrants. If piles stay for night put lantern or pot on each pile.

All trucks with crews should be equipped with mercurochrome and 1" adhesive compresses in first aid kits.

Avoid horseplay and strong man exhibitionism.

Insist on employees' wearing clothing that protects from the elements and from hazards of the particular operation. Protect head and body from exposure to sun and to cold. Don't permit working stripped to waist, in shorts, or barefoot. Wear safety shoes on work hazards to feet.

All new employees should be made aware of our safety and medical program before starting to work.

FLORAL SUB-SECTION, SAFETY

GOOD HOUSEKEEPING:

Keep all premises orderly at all times. All materials, tools and equipment should be properly stored in racks, on shelves, in bins, or in cabinets. Keep all tools hanging off the floor if possible.

Mechanical equipment stored in such a way that it does not have to be climbed over to get to other facilities. Power operated equipment should not be stored on wooden floors unless wood is protected from drippings of oil and gasoline because of fire hazard.

Make every effort to procure sufficient proper storage area for equipment.

Greenhouse and Conservatory walks:

Special care should be taken to never leave objects in walks or projecting out over walks at anytime but especially at night, when the already poor visibility is even worse. Stretch hose out straight and keep to side of walk or under bench.

Never permit anything to interfere with proper access to heat control valves and ventilator control machinery. Chain valve on mains are safer than hook and wheel.

Algae should not be allowed to accumulate on walks as it becomes very slippery. Temporarily sand can be thrown on walks but algae should be destroyed with algaecides and completely removed. "Captan" gives good control. New walks should have brushed finish and old walks worn smooth should be roughened with 20 per cent muriatic acid.

Small trucks used for summer servicing of outside work should be cleaned up daily and not allowed to become cluttered with tools, flats, plant parts, flower pots, and so forth.

Broken glass being one of our most hazardous problems, special care should be taken to clean it up and dispose of it promptly and properly. Special effort should be made to keep broken glass out of potting soils or any materials that are likely to be mixed into potting soils.

Auxiliary supports, etc.:

Wires, pipes, brackets, shelves, etc., used seasonally, should, if possible, be at least six feet above walks, while in use. Flag wires if hazardous. They should be removed entirely when out of use, if feasible or stored in such a way as to not be a hazard. May have to give additional support to shelf brackets.

Administrative:

Insisit on prompt first aid for minor injuries and on first aid reports being made out. First aid courses should be given to office workers especially. Their hands are generally cleaner and office is centrally located.

Representatives of department should attend safety conferences and demonstrations, in and out of park district.

Gardens and servicing trucks should be equipped with first aid kits.

Lifting:

Instruct new employees and remind old employees of proper methods of lifting by hand. Lift with strong leg muscles not weak and vulnerable back muscles. Watch for proper footing to avoid slipping, causing hernias or bad falls. Use adequate number of men for lifting heavier things according to weight.

For heavier things use machinery whenever obtainable even if work has to be delayed, in case of very hazardous operations. Obtain cooperation of other departments, if necessary, to use motorized equipment. Fork lifts, electrical tower trucks, cranes, front-end loaders, low trailers, tail gate lift trucks.

Use other aids or methods such as: skids, rollers, pry bars, tub-lifters, or other devices with which to get a safer hand hold.

Store materials in such a way as to minimize lifting. Stack heavier material lower.

Trucks:

Never get in or out of trucks while they are in motion.

While riding in trucks keep all parts of body inside at all times.

Never ride standing up, always sitting down.

Climb in and out of truck bodies with extreme care. With trucks used constantly for hauling personnel, have steps installed to facilitate climbing in and out safely.

Use red flags or lanterns on parts of load extending beyond body of truck.

Snub all machinery or other materials that might shift around dangerously, especially if body of truck is occupied by men also.

Report any defects concerning trucks to Mechanical Section immediately.

Bamboo stakes:

Cut square across with shears, preferably blade and anvil type, not with knife. Square cut is not dangerously sharp like sloping one.

When re-using used stakes cut off end that has been in the soil, to avoid danger of it snapping off.

Inspect stakes for infestations of borers and discard if infested for fear of braking and slivering in users hand.

For inserting heavy stakes, make hole with steel bar first and then drive in with hammer if workable.

Give immediate first aid treatment for injuries caused by bamboo stakes as the experience in the incident of infection from such injuries has been high. Take employee to doctor if wound is puncture wound or any complications seem possible.

Exercise caution in the handling of staked plants to not injure handler or others near with stakes, especially watch for eye injuries.

Allergies: Watch for sensitivity among employees to specific plants and materials and protect them from same or avoid trouble by not assigning susceptible personnel.

Operations:

When edging lawns or trimming hedge mechanically wear face masks that cover all of face.

Using insecticides and fungicides.

Read carefully the instructions on the the container of all insecticides. There are often special instructions concerning safety to the grower.

Cover as much of your body as possible while handling toxic materials. This may mean a slicker, rain hat, shirt or jacket buttoned up tight, sleeves rolled down, boots and rubber gloves.

Use goggles and respirator or gas mask with materials calling for same or when face is exposed due to wind, overhead spraying, etc.

Do not eat or smoke while handling these materials.

Bathe thoroughly when through, launder all clothing worn, do not wear it over and over for spraying. Warn laundry of what clothing was used for.

Be especially careful in weighing out and handling the concentrated dusts and powder. If 15 per cent Parathion is poured carelessly onto a scale, a cloud of dust will soon surround the user. This dust is many more times concentrated than the spray and is correspondingly more dangerous. It is much better to figure out volume measures for the materials you use and wear a respirator when handling them any way.

Burn old containers but be careful of inhaling the smoke.

Types of masks and respirators for greenhouse use.

Full face gas masks with canister. The canister is of course, the little can of chemicals which take the "sting" out of the poisons. Various types of canisters containing different chemicals are used depending on the insecticides being applied.

Vapor or gas respirators. A sort of abbreviated gas mask. It contains a cartridge of decontaminating chemicals plus filters much like the regular mask, but on a smaller scale.

Dust respirator. Unlike the gas respirator described above, this dust respirator is essentially a dust filter mainly for "nuisance dusts." In greenhouse spray or dust work, this refers mostly to such fungicides as Zineb, Ferbam, etc. This dust respirator does not contain a chemical cartridge to decontaminate gasses, and must be used with poisonous sprays or aerosols.

Use warning signs on greenhouse doors when gassing and use any other precautions necessary to prevent anyone entering while gas is present.

Potting:

Watch for glass, wire and other foreign objects in potting soil that might cause hand injuries.

Don't use cracked pots, might finish breaking while in use and injure user.

Use safe potting stakes on large plants, watch for slivers.

Give proper protection from plants with thorns or plants of a toxic nature.

Use gloves if necessary.

Keep debris from potting operation out from under foot to prevent slipping on, or tripping over same.

Handling wooden containers and equipment:

Use gloves, preferably leather or leather palmed to avoid splinters.

Flats, wooden tubs, planks, and tool handles.

Be careful not to drop on feet.

Prop lids of tool boxes open securely, while reaching in to avoid injury if lid should close.

Wheeling:

Don't overload, either by weight or bulk. Watch for strain on wheeler and possibility of dangerous tipping. Never load so that wheeler can't see where he is going.

Keep tires well inflated to relieve strain and for safer handling.

Don't allow wheels or body to become wobbly.

Guard against injuries to hands when wheeling down walks between benches. Equip handles with guards and/or wear gloves.

Hand trucking:

Don't overload, either by weight or bulk, or by total work expected by a crew in a given period of time. Men are not machines and become fatigued. Use sufficient manpower for any given load. Don't risk a heavy load getting away from crew. Keep trucks in good maintenance and repair at all times.

Watch for handle of trucks dropping on feet. Handles should be modified so they can't drop on feet.

Planting heavy materials:

Use mechanical equipment whenever possible.

Grip ropes properly, never take a wrap around hands.

Keep ropes clear of feet.

Control tops of plants at all times, keep clear of whipping branches.

Use precautions to prevent caving in of holes, and stand clear to avoid being injured.

Supporting top-heavy plant material to keep it from toppling:

Wear gloves and goggles where indicated. Exercise care when climbing high in conservatories to secure supports. Use proper safety equipment or call on experienced personnel from other departments if necessary for safety.

Applying and removing shade on greenhouses and cleaning glass with chemicals:

Use only personnel who are willing and able to stand height and precariousness of job.

Clean gutters first if needed, of broken glass, leaves, mud, water.

Use chicken ladders of proper length to make work as safe as possible.

Wear goggles and protective clothing.

Wear rubber boots, aprons, and gloves when handling glass cleaning chemicals. If any should happen to get in eyes or on skin, flush immediately and very thoroughly with water. Keep running hose at hand in gutter at all times while working.

Mix chemicals with cold water only as hot water will cause dangerous vapors to arise.

Fertilizers:

Use respirators and goggles under dusty conditions.

Give protection to hands when handling manures, especially horse manure.

Have personnel immunized against tetanus by periodic protective shots.

Power equipment:

Whenever possible use recoil or kick starters on gas powered equipment rather than dangerous rope starter.

Train special men to handle and don't permit untrained personnel to operate.

Never "gun" any machines except when actually performing operation.

Never gas up while machine is running. Don't smoke while handling gas.

Shut off motor to adjust, repair, clear stoppages, or any other operation that might be hazardous while motor is running.

Always wear goggles when operating soil shredders.

Don't operate equipment not in good working order.

Use proper ramps and with care when loading and unloading on to or off of

trucks or trailers. Ramps or bottoms of tilt trailers should have expanded metal or diving board matting on them for traction for machine and operator.

Tools and equipment:

Turn tines and blades down and even push into soil when necessary to lay tools down on ground.

If leaning against other object turn back of tool out.

Knives: Should be clean and sharp

Keep closed when not in use, especially while carrying.

Use thumb guards whenever feasible.

Shears: Keep closed or in scabbard when not in use.

Keep non-operating hand out of way.

Let trimming fall clear instead of holding, to prevent cutting hand.

Never overtax shears or man operating same. Use kind of shears with proper capacity for work being done or saw or axe if work is too heavy for shears.

Grass hooks: Carry in scabbard when not in use.

Hang up properly or store in such a way that they cannot fall causing injury

Never use makeshift tools. Use proper tools for work indicated.

Carry tools properly with sharp ends down or in view of carrier.

Ladders: Inspect ladders frequently for safety.

Be sure spreaders are locked when using step-ladders.

Straight ladders should be equipped with safety feet and base should be set out approximately one-quarter of length of ladders from support.

Keep aluminum ladders away from electric wires.

Prescribe protective clothing for outside work to avoid frost-bite or sunburn as the case may be.

Hazards to public in conservatories:

Watch for hanging pieces of glass and remove same and have repaired. In case of high winds, violent storms and always with hail storms, barricade off dangerous sections or evacuate as rapidly as possible and deny admission.

Give proper instructions on the spot for each operation not previously performed by individual personnel with special emphasis on possible hazards and avoidance of injury.

All new employees should be made aware of our safety and medical programs before starting to work.

There are so many new and different kinds of chemicals coming into use as insecticides and fungicides, that it is wise to have on hand some pertinent advice to overcome the dangers to personnel who have been exposed to them. The following advice from The Illinois State Florists Association Bulletin Number 160, is valuable to have around for the use of those applying the materials, their bosses, and even any members of the medical profession that might be called on to come to the aid of a victim of exposure.

ADMINISTER FIRST AID

See to it that your employees report to you at once if they feel ill, if poison has been swallowed, or if poisoning by any other means has occurred.

Either call for a doctor immediately, or get the patient to a doctor or hospital without delay. Take this advice yourself. Some first aid should be given while waiting for the doctor, or if the poisoned person cannot be gotten to a doctor immediately.

GENERAL FIRST-AID RECOMMENDATIONS

1. When poison is spilled on skin, flush off right now with lots of soap and water.
2. When poison has gotten into eyes, rinse eyes repeatedly with lukewarm water.
3. When poison has been inhaled, move patient to fresh air, and administer artificial respiration if necessary.
4. When poison has been swallowed, empty stomach as soon as possible:
   a. Should patient be vomiting, make him drink large amounts of water.
   b. If not, put finger or tongue depressor into patient's throat to induce vomiting, or
   c. Give an emetic to induce vomiting, such as one of the following:
      (1) 1 to 2 T. (tablespoons) salt in glass of warm water, or
      (2) Ground household mustard (1 t. (teaspoon) in glass of warm water).
   d. If doctor has not arrived, give salt water emetic until vomit fluid is clear. Then administer Universal Antidote: 2 parts pulverized charcoal (burned toast will do), 1 part milk of magnesia, 1 part strong tea. Give ½ oz. in half glass of warm water.
5. If poison is corrosive acid or caustic alkali, do NOT use an emetic! Solutions to use in these cases are:
   a. For neutralizing acids—
      (1) Milk of magnesia, diluted until it flows easily, or
      (2) Two per cent bicarbonate of soda, or
      (3) Soap solution.
   b. For neutralizing alkalis—
      (1) Vinegar in water (1 to 10) or
      (2) Orange or lemon juice (½ to 1 cup, straight or diluted).
6. Keep patient lying down, warm and quiet.
7. Never give an unconscious person anything by mouth.

HELP THE DOCTOR

In case of accidental poisoning, try to find out exactly what material was being used. Your doctor may be unfamiliar with this poison, or the proper antidotes for it. Therefore, give him all the information you can—and it might be a good idea to show him this article. Also take along the label from the can, which usually gives suggested antidotes and treatment. See that the name and address of the manufacturer are included, since he may be contacted by phone for further information on antidotes, if necessary.

Administer first aid before the doctor arrives. But, in some cases this requires a specific antidote (see below). Be prepared by having some of the more important antidotes on hand at all times—you may not be able to get them in time if you wait for an accident to happen. For example, you should have atropine sulfate tablets in case of poisoning with one of the organic phosphates, such as Parathion or TEPP.

Some Specific Antidotes and Treatments

Aramite—Also known as 88R (alkylaryl sulfite), Niagaramite, and Ortho-Mite.

First Aid: Remove from skin with soap and water. If accidentally swallowed, empty stomach using salt water emetic.

Physician: Aramite is relatively nontoxic (its LD-50 is 3,900 mi. per kilogram), although the manufacturer recommends: (1) Avoid excessive inhalation of dust or spray mist, (2) Do not get into eyes, (3) Use with adequate ventilation. If ingested, probably a good idea to empty and lavage stomach.

Arsenic Compounds—(Such as arsenious oxide; calcium, lead and magnesium arsenate; Paris Green, etc.)

First Aid: Empty stomach, using 1 T. salt in glass of warm water; repeat until vomit fluid is clear. Give milk, raw eggs, lime water, or flour and water. Have patient lie down and keep quiet.

Physician: Empty stomach after giving Universal Antidote:

1. Universal Antidote (for use by physician): Pulverized charcoal (2 parts), magnesium oxide (1 part), tannic acid (1 part): ½ oz. in half glass of warm water.

Lavage solution may be Universal Antidote, one per cent sodium thiosulfate. Five per cent sodium bicarbonate, or warm water. Use BAL as listed for mercury.

Benzene Hexachloride—Known as Bentox, Benzahex, BHC, Chemhex, Cpd. 666, Gamiso, Gammacide, Gammaloid, Gamoxo, Gamtox, GBH, G-tos, HCCH, HCH, Hexachlorocyclohexane, Hexadow, Isotox, Lexone, etc. (Lindane is a gamma isomer of benzene hexachloride of not less than 99 per cent purity.)

First Aid: For external exposure, remove clothing and wash skin thoroughly. If swallowed empty stomach thoroughly. Give hot tea or coffee, and 2 T. Epson Salts in water.

Physician: Treatment essentially same as for DDT—no specific antidote and treatment is symptomatic. Wash contaminated skin thoroughly with soap and water. Clear alimentary tract if taken internally, but never use acid substance for washing stomach. Barbiturates for convulsions, and stimulants for depression. Choice of drugs is pentobarbital, with penobarbital a good second choice. Should be given in large doses and pushed to limit of therapeutic effectiveness. Not desirable to depress patient to point of hypnosis. However, persons poi-

soned by stimulants may tolerate large doses of barbiturates without undue depression and with great benefit. Intravenous calcium gluconate reported to have some effectiveness as antidote and may be used in conjunction with the barbiturates.

Chlordane—Known as Chlordan, Cpd. 1068, Octoachlor, Octa-Klor, Velsicol 1068, etc.

First Aid: If on skin, wash off thoroughly with soap and water. If taken internally, empty stomach and lavage with warm water, or salt water (1 T. in glass of warm water).

Physician: Treatment essentially same as for benzene hexachloride. Remove poison from skin or alimentary tract. Avoid oil laxatives. Use barbiturates for convulsions and stimulants for depression. Nervous symptoms best combatted with pentobarbital or phenobarbital.

Cyanides—(Including acrylonitril, calcium cyanide, hydrocyamic acid, potassium cyanide, prussic acid, and sodium cyanide).

First Aid: Get patient to fresh air, remove contaminated clothing, and keep warm and quiet. Administer artificial respiration if breathing has stopped. If cyanide swallowed, give 1 T. salt in glass of warm water, and repeat until vomit fluid is clear. (Give only *if patient is conscious.*)

Physician: Break pearls of amyl nitrite, one at a time, in handkerchief over victim's nose. Repeat five times at about 15-second intervals, leaving over the nose about 15 seconds for each pearl. Give (through same needle and vein) 10 cc. of 30 per cent (0.3 gm.) sodium nitrate followed by 25 per cent sodium thiosulfate (12.5 gm.). If swallowed, give five per cent sodium thiosulfate or 0.2 per cent potassium permanganate lavage, and simultaneously use the injection treatment. Give five per cent carbon dioxide in oxygen, or oxygen and artificial respiration if necessary.

DDT—Known as chlorophenothane, Detex, Dicophane, Gesarol, Neocid, and many other names.

First Aid: Same as for Chlordane.

Physician: Treatment similar to that for Chlordane and Benzene Hexachloride. Depending on condition of patient, attention should first be given to sedation, or to removal of poison which may have been taken internally. Gastric lavage and saline laxatives may be used. Avoid oil laxatives; they tend to promote absorption of DDT and of many organic solvents. Five drugs of choice, arranged roughly in order of their effectiveness are: phenobarbital, penetobarbital, paraldehyde, urethane, and calcium gluconate. Phenobarbital, which has been used in doses up to 0.7 grams per day in epilepsy, and pentobarbital (0.25 to 0.5 grams) are the barbiturates known to control convulsions of central origin. Epinephrine is contraindicated.

Dieldrin—Known as Cpd. 497, and Octalox.

First Aid: (Same as for Chlordane).

Physician: Treatment similar to that for Aldrin and Chlordane. Every effort should be made to remove from skin by thorough washing with soap and water, or from alimentary tract by use of lavage and/or saline laxatives. Oil laxatives should be avoided. Administer phenobarbital as an antidote, adjusting dosage to symptoms.

Dithiono—Known as Dithione, Sulfo-TEP, and tetraethyle dithio-pyrophosphate.

Treatment: (See Organic Phosphates).

HETP—Known as Hexaethyl Tetraphosphate, Hexotine, Pladon, etc.

Treatment: (See Organic Phosphates).

Malathion—Known as Cpd. 4049, malathon, etc.

Treatment: (See Organic Phosphates).

Nicotine—Known as Black Leaf 40, etc.

First Aid: If gotten on skin, remove clothing and wash skin thoroughly. If swallowed, empty stomach using mustard emetic. Give strong tea or coffee, or spirits of ammonia aromatic (1 t. in water). Also have patient drink water freely. Keep patient warm, and lying down. If necessary, use artificial respiration.

Physician: If taken internally, give Universal Antidote and lavage stomach with 240 cc. 1/1000 potassium permanganate, leaving 60 cc. in stomach. Give stimulation with adrenaline, or 0.5 grams of caffeine sodium benzoate I.M. and oxygen inhalations and artificial respiration if indicated. Increased fluids should assist in elimination of the poison. Manufacturer recommends 1/30 gr. strychnine by hypo every hour until four doses are taken.

OMPA—(Octamethyl pyrophosphoramide).

Treatment: (See Organic Phosphates).

Organic Phosphates—(Including Demeton, Dithiono, EPN, HETP, Malathion, OMPA, Parathion, Sulfo-TEP, Systox, TEPP, Vapotone, and others).

First Aid: Remove contaminated clothing, and wash skin with soap and warm water or soda bicarbonate solution. If swallowed, empty stomach with emetic. Use 1 T. salt in glass of warm water to induce vomiting; repeat to cleanse stomach thoroughly. Give two 1/100 grain atropine sulfate tablets. Artificial respiration if necessary. Call for a doctor immediately—these are deadly poisons!

Physician: If a patient has not yet shown symptoms or they have been allayed by first dose of atropine, he must be completely and quickly decontaminated. Wearing rubber gloves, remove clothing and, with due regard for his condition at the moment, bathe him thoroughly with soap and water. Using washing soda, or any relatively mild alkali; organic phosphates hydrolized by alkalis.

If any suspicion that material has been ingested, induce vomiting; give some neutral material such as milk or water and induce vomiting again. Nausea often occurs from this poisoning but if vomiting is not profuse, gastric lavage may be used.

Keep patient fully atrophinized if symptoms appear. Give one to two mg. (1/60 to 1/30 grain) of atropine sulfate every hour up to 10 to 20mg. in a day, particularly for the control of respiratory symptoms. The I.V. route is most rapid. Atropine relieves many of the distressing symptoms, reduces heart block, and dries secretions of the respiratory tract.

Never give morphine, theophylline, or theophylline-ethlyenediamine (Aminiphylline).

If pulmonary secretions have accumulated before atropine has become effective, patient must be turned upside down or in some other positions of postural drainage in order to drain out mucus. Use suction and a catheter if necessary. If stomach is distended, empty with a Levine tube.

Atrophine does not protect against muscular weakness. Mechanism of death appears to be respiratory failure. Use of an oxygen tent or even use of oxygen under slight positive pressure is advisable and should be started early. Watch the patient constantly, for the need for artificial respiration may appear suddenly. Equipment for artificial respiration should be placed by the patient's bed in readiness as soon as he is hospitalized. Cyanosis should be prevented by the most suitable means, since it aggravates the other signs of poisoning. Complete recovery may occur even after many hours of artificial respiration have been necessary.

Acute emergency lasts 24-48 hours, and the patient must be watched continuously during that time. Favorable response to one or more doses of atropine does not guarantee against sudden and fatal relapse. Medication must be continued during the entire emergency.

Following exposure heavy enough to produce symptoms, further organic phosphorus insecticide exposure of any sort should be avoided. The patient remains susceptible to relatively small exposures of these materials until regeneration of cholinesterase is nearly complete.▲

DIGGING OUT AFTER MOTHER NATURE GOES ON A RAMPAGE

(A Symposium)

HURRICANES—THOSE WILD WOMEN OF THE ATLANTIC

by JOHN L. GUILMARTIN
safety engineer, Connecticut State highway dept., Hartford, Conn.

The first hurricane that we ever had in connecticut, occurred 19 years ago, in September, 1938. That was before we knew hurricanes by their names or that they were supposed to be ladies.

From the standpoint of damage caused by high winds, the '38 hurricane was the worst one we ever had. It came after two or three days of steady rain, which softened up the ground, and with the foliage still full and heavy on the trees, they were literally a "pushover" for the winds that blew more than 100 mph. The wind started to blow in the late afternoon and without the slightest bit of advance warning. Our maintenance crews were scattered out on various jobs on what was just another rainy day.

When the storm struck, many of them found themselves without the proper tools or equipment, stranded along with thousands of motorists in a maze of fallen trees, utility poles and wires. Communications were knocked out all over the state and it was impossible to organize a uniform clean-up procedure. Consequently, maintenance crews were more or less on their own and tackled the job the best way they knew how.

MAKE-SHIFT CLEAN-UP

In the particular section where I worked at the time, those in charge proceeded to hire every man and growing boy they could find, and put them to work with axes and saws to cut a path through the jungle which used to be our state highways. From the standpoint of safety, the result of such a procedure was just what you might expect it to be. We didn't have any safety program in those days, nor did we have the type of accident reporting and record keeping that we have today.

Therefore, it is impossible to say just what our accident experience was, following that storm, but, if what I personally saw and heard was any criterion of what occurred throughout the department, I am sure that our accident rate was certainly not one to be proud of.

We have had a few more hurricanes since 1938, and we have learned a bit more about the job of cleaning them up. We have a good warning system now, thanks to the U. S. Weather Bureau, the Army, Navy, and a few others, and we know several days in advance when a storm is expected. This gives us plenty of time to prepare for it, and from the standpoint of preventing accidents, we can issue timely bulletins and instructions on how to avoid being injured on this type of work.

When it is reasonably certain that a storm is going to hit us, the first thing we do is to get our maintenance crews into their respective garages. Whether they are out working at the time, or if they are off duty, they are contacted, and instructed to report to their garages, well in advance of the expected arrival of the storm.

In one storm we had a few years ago, some economy-minded official of the department decided to wait and see what was going to happen before calling in the men. When the storm did hit us, many of them were unable to get to work. Therefore, it is now the policy to call them in if any possibility we are going to get enough of the storm to cause damage.

After the crews have reported to work, they are required to "stay put" in the garages until after the storm has passed. We do not allow our men to go out on the roads where they will be exposed to the high hazard of falling trees, poles, and other objects that fly about during the height of a hurricane.

DANGEROUS FIRST HOURS

Following the storm, the clean-up work is begun, and the first few hours are probably the most dangerous. With the pressure on to get the roads open as soon as possible, there is a tendency for the men to hurry, and in doing so, to get careless. Also at this time, there is the danger of coming into contact with live wires. Usually, when utility poles and wires are knocked down, the power companies will shut off the main switches in the affected areas to avoid fires and prevent injuries.

Our men are instructed to stay clear of any wires and to regard all of them as being "live" until they are definitely assured that the power has been cut. In the event that someone does come in contact with a live wire, we have trained first aiders in every crew, who know how to remove a wire from the victim, or the victim from a wire, as the case may be.

At the beginning of the clean-up operation, the main objective is to open the roads as quickly as possible, at least to one way traffic. To accomplish this, we use our dump trucks, hooking onto trees and limbs, with chains and cables, and dragging them off the highway, leaving a minimum of hand work. This method, rather than using saws and axes, gets the roads open a lot faster, and by the same token, reduces the possibility of personal injuries. Caution must be exercised by drivers in this back and forth operation, and proper guidance must be obtained while moving about in the work area, particularly while backing.

NIGHT WORK INVOLVED

This initial clean-up usually involves at least one night of operations, and for this we have a number of portable generators and lights. We make the best possible use of truck headlights to light up the work area, and although the traffic hazard is not high under these conditions, our trucks are equipped with flashing lights to warn motorists of their presence on the highway.

After the roads are opened enough so that traffic can get through, sometimes with detours, the job of widening out can be done a little more leisurely, without the pressure of an emergency situation, and usually in daylight, when more efficient and safer work can be done. The usual procedure is to cut the trees back beyond the shoulder line and pile the wood and brush on the roadside, where it can be later picked up. Wherever available, power saws are used to cut the wood into convenient lengths.

This equipment is operated by members of the tree crews who are familiar with its use. We don't allow the chain saws up in the trees, and never over waist high unless the operator has a firm footing on a platform or ladder, and the saw is properly slung. Only skilled tree workers are used to do any climbing to remove hangers or to do any other necessary trimming. All of the men are cautioned to exercise extreme care with sharp tools.

Axes, hammers and similar tools must have secure heads and be in good condition, and when swinging them, employees should obtain a firm footing and be sure of sufficient clearance of obstructions and other workers. Because of the high incidence of eye injuries on brush handling, the men are furnished goggles, and for handling limbs, debris, ropes, chains and cables, they are required to wear gloves.

OTHER EQUIPMENT USED

For removing the wood from the roadsides, we use winch trucks, with tripod attachments to load the heavy logs; the lighter ones are loaded by hand. Brush chippers are used to dispose of brush and smaller limbs. When necessary, trained flagmen control traffic to protect our men, equipment, and the public.

Many times, hurricanes are accompanied by floods. In fact, the most devastating storm in the history of our state in August, 1955, started out as a hurricane. But when it reached Connecticut, it wasn't even a good breeze. It dropped the heaviest rain in 36 hours that we had ever had before, resulting in floods that caused tremendous property damage and took the lives of 90 persons, including two state highway employees.

All in all, our accident experience on disaster clean-up work is not bad. As a

matter of fact, the records show that our accident rate following storms is as good and sometimes better than it has been in similar periods when we had no storms. I don't know exactly what that proves, but we can at least hope, if nothing else, that our year-round efforts to reduce accidents on the hundreds of other activities in which our men can be injured, may be the reason we have not had too much trouble with our hurricane clean-up operations. ▲

HURRICANES AND GOVERNMENT

by JACKSON G. FLOWERS
director of safety education, Dade County, Miami, Fla.

October 17, 1957 saw the seventh anniversary of the last hurricane passage through the South Florida area. One might feel, and it is the general consensus of opinion, that Florida has been fortunate to escape the destruction of hurricanes for seven years in a row. However, our weathermen state that after a review of the hurricane statistics which go back to 1875, a normal period between storms is between six and seven years.

While we are most happy to be relieved of the destruction and possible injury and death, year after year, there is, however, created a feeling of false security on the part of our populace. The recent hurricane which visited Louisiana, stands as living and dying proof of the effects of overconfidence and lack of vigilance as related to the power hurricanes pack.

PARK DEPT. PREPARATIONS

From the standpoint of our public employees, some 5,000 county employees, it is necessary for us to have detailed hurricane preparation plans available for immediate use. In view of the wide variety of services performed by the County, it is also necessary for us to review continually our hurricane plans, making changes to compensate for added public service responsibilities. The county family is responsible for the maintenance of some 2,800 miles of roads, the collection of garbage at 50,000 homes and 5,000 business establishments, the operation and maintenance of the second busiest airport in the United States, the control and maintenance of two major causeways, the operation and supervision of seven major parks, as well as the operation of two police departments and fire department.

In the "Land of Sunshine," South Florida is renowned for its many outdoor activities —so let's tee off with the Parks Department and its plans for handling its vast county's facilities as related to hurricanes. Their plan consist of two parts: a Blue Alert and Red Alert. When it is determined through close liaison with the weather bureau that in all probability South Florida will feel the sting of a hurricane, the Blue Alert goes into force, which calls key employees into action to accomplish preparation which can be quickly undone.

1. Secure garbage cans.
2. Turn over park tables.
3. Secure loose material and equipment.
4. Shutters are taken out of storage and placed near the buildings.
5. Remove and store all types of signs.

With the announcement that a storm is eminent, the Red Alert goes into effect, and all Parks employees are pressed into service, at which time, final preparations are made:

1. Put up shutters.
2. Remove all equipment from job areas.
3. Communication posts are established at the various park offices where all activities are co-ordinated with the parks director.
4. The plan calls for pre-arranged crews to report to various parks to lend assistance to the accomplishment of the various preparations.
5. One big factor in the preparations is the possibility of high tides and blowing sand. Therefore, electrical equipment such as compressors are disconnected and stored in a high place. Selected supplies are also stored in a high place.
6. Through pre-arrangement, the use of motor vehicles is kept at a minimum and are controlled from one central motor pool.
7. An interesting point is the establishment of a hurricane chest at each park. These chests consist of various types of tools for putting up shutters, two by four's, wire, rope and hammers. These chests are inspected prior to the beginning of the hurricane season, and their contents are utilized only for hurricane purposes.
8. Dade county operates a zoo at Crandon Park which has the usual kind of animals, including a giraffe, and the buildings which house them have been constructed to hurricane-proof specifications. The cages are built four feet above ground, based on tide and flood criteria. The giraffe with its periscoping neck, also lives on a platform two feet above ground level. Many of the animals are transferred to a specially built barn prior to the onset of the storm.

All of our hurricane plans by departments are predicated on two factors:

- Sufficient time to accomplish the work and allow the employees to be dismissed in sufficient time to secure their own personal homes and property.
- To allow the maximum safety factor to the employee through prior planning and sufficient time to accomplish the work which reduces the possibility of personal injury.

After the storm, all personnel report for work to start the job of clean-up and restoration of the facilities as quickly as possible. As an example of this type of work, in 1950 there were over 1,000 palms blown down in Crandon Park, which is our largest park. The painters have a busy time of it after the storm as the blowing sand often times has the effect of sandpapering a building down to the stucco.

Taking another department, the Dade County engineers' plan includes the completion of any roadwork underway, and the securing of all materials and equipment.

The Water Control division plays a vital part in clearing canals to insure proper drainage of heavy rains dropped by the hurricane. Included in their function is an interesting factor that they remove specially constructed dams prior to the hurricane, which are normally left in place to keep the salt water out of our canals.

CLEAR CANALS TO DRAIN LAND

The Water Control department which was established in 1953, has made a thorough study of the entire county and set flood criteria stage levels.

Standby crews are strategically located throughout the County for the purpose of placing lights and barricades where road obstructions have occurred as a result of the storm.

After the passage of the hurricane, the Engineering department is faced with the principal problem of repair of road damage which primarily comes about as a result of standing water. This repair is necessary on those roads which were constructed prior to two years ago. All roads which have been constructed since 1955 must meet certain specifications which will cause them to withstand water damage and patching is not a problem.

From the employee standpoint, road patching crews are faced with many hazards which are found in our heavily travelled roadnets. From a safety standpoint, we have made every effort to give these crews a maximum of protection by painting the trucks yellow with black stripes on them, numerous flashing red and amber lights, as well as red flags mounted on the trucks. Our experience has shown that the rainy months, August, September and October require extra patching crews which naturally increases the employee exposure.

AIRPORT IS READY, TOO

Turning to the Miami International Airport which is controlled by the county, we find that their plan includes securing all loose material and placing shutters on all buildings. In addition, fire extinguishers are checked and tested; owners of all planes are advised through the Operations department of the forthcoming storm, and they are encouraged to evacuate all flyable aircraft.

The Maintenance Department of the airport has a truck standing by loaded with road barricades and emergency supplies, as well as lanterns.

Auxiliary power and hand pumps are placed into position for possible use if power failure occurs. All fire and crash equipment is distributed to various locations on the airport. All radio controlled units of the Port Authority are assigned to various locations to assure immediate communication in the event of an emergency. Immediately following the storm, crews are dispatched to clear away any debris that might be on the runways.

Turning to the Waste Department, their preparations include disbursal of 256 trucks with all gas tanks filled, and immediately following the storm, they are pressed into service to collect all garbage which could become a health menace if not collected immediately.

The County Road Patrol and County Police secure their headquarters and place auxiliary units into position to insure adequate communications to the radio-patrol cars in the event of power failure. Road Patrol units which are responsible for the protection of the unincorporated areas, are placed in pre-designated garages within their zones to ride out the storm, and at the same time, are available for emergency calls. The County Fire Units secure their stations and recall all off-duty firemen.

Experience in South Florida has proved over the years that with adequate advance planning and preparations on the part of the various units of government, as well as the general populace, death and injury can be virtually eliminated. In spite of our tremendous growth in the past seven years, property damage can also be held to a minimum as the result of strict compliance with rigid building codes.

Only indifference and lack of preparation can set the stage for disaster.

SAND STORMS

by CHARLES P. DUNWIDDIE

safety program director, New Mexico State Highway Commission, Santa Fe, N. M.

Having lived in New Mexico for 43 years I have seen thousands of sand storms. The Highway department gets the blame for everything that happens, including sand storms. Let me give you a few typical daily headlines and comments, from the Newspaper angle. "Winds, flood borne sand clogs important highways." "Sand whipped by winds and borne by flood waters slowed or halted New Mexico's holiday traffic in two parts of the state Thursday night. Motorists were halted by blinding sheets of sand (I like the descriptive words, 'blinding sheets') in the nine mile stretch of US-70-54 between Alamogordo and Tularosa.

"One flood left two feet of sand on a US-83 bridge across an arroyo six miles south of Belen. State police were discouraging south-bound traffic from Albuquerque. State police put up four roadblocks to halt the traffic between Alamogordo and Tularosa. Winds were estimated up to 60 mph. NO VISIBILITY. Visibility at the intersection of NM-83 and US-70-54 north of Alamogordo was non-existent. The same situation existed at the US-70-54 junction in the town of Tularosa."

Here is another. "Bus and car crash during dust storm south of Tularosa. Twenty-three passengers aboard a Santa Fe bound Greyhound bus escaped injury last night when it collided with a car two miles south of here on US-70-54 in a dust storm. The mishap occurred just as the bus was pulling back into its lane after passing another car. The vehicles collided head-on, but were moving slowly, police said."

SAND STORM FACTS

These are exemplary and only point out a few facts worthy of early comment. First, that sand storms can be either dry or wet. Sand can be and is deposited on the roadways by either wind or water.

Second, that preliminary to the clean-up or digging out program, which is a continuous maintenance problem, is the terrific job of trying to control traffic in the danger areas during the storm and immediately after. Motorists are most obstinate and will not take care of themselves.

Third, that a huge portion of the state has a top-soil that is easily picked up and moved with the wind. This top-soil can be unbelievably deep.

Fourth, that the sand storms present a tremendous problem in engineering.

Let's consider the first point. Sand storms occur in all varieties in New Mexico. We don't call them tornadoes, nor hurricanes.

The Air Force and its weather people at Kirtland Air Force Base at Albuquerque gave me some wonderful information. I am now on speaking terms with air-currents, low pressure areas, high-pressure areas and storm-belts. I have seen winds plotted on maps. I know that when cold air meets warm air in collision, something is going to happen.

New Mexico has a lot of more or less flat country. The flat areas, after centuries of erosion, are mostly sand areas. They are typical desert areas. Little rain leaves the areas dry. Sparse vegetation can't hold the sand. So it is easily moved by hard winds. Winds pick up the surface and carry it miles high. Or, just as easily rolls it along the ground.

An example of the movement of sand and dust is seen frequently in the capitol, Santa Fe. The city is bounded on three sides by mountains. The elevation is 7,000 feet. Mountains to the east and north range to 14,000 feet, to the west 11,000 feet, to the south the land levels off and slowly loses elevation. Prevailing winds come from the southwest.

With the mountains as a back stop the air above Santa Fe can be so completely saturated with sand and dust, thousands of feet high, that the sun is completely obliterated. Or, it can be as easily rolled along the surface, coming uphill and leaving ground visibility at zero. The sand and dust deposited in the area during these storms have been traced to various points as far away as several hundred miles.

Mountains throughout the state more or less determine the prevailing winds in the flatter areas. So the movement of sand and those points where wind carries it onto or across our highways is, of course well known and the movement can be anticipated to some extent. Actually in some areas the winds are seasonal.

These winds and other atmospheric conditions are also responsible for rain and hail storms. New Mexico is a land of unexpected rains, in the form of cloud-bursts. These never occur in the same place twice. They drop tremendous amounts of water over a small area in a matter of minutes and the resultant run-off of water that cannot be controlled is often disastrous to our roads.

The heavy run-off and the loose top soil that can easily be carried leaves heavy deposits of sand on the roads. It makes for a very dangerous situation when it involves heavy moving traffic. Water courses can be traced, of course. Structures can be designed to carry anticipated water fall. But cloud-bursts can not be anticipated. It can be readily seen that it sets up a hazardous situation for motorists.

I have been leading up to the second point. This is the practically impossible job of controlling the flow of traffic during the danger periods. Consider the factors. Interstate bus lines have to maintain schedules, if possible. Drivers of these lines are inclined to take chances, in spite of their safety training. The movement of heavy freight along the highways must be maintained at as fast a rate as possible. Tourists and common citizens are all inclined to be in a big hurry, whether they are going two miles or 2,000. So, the problem, during these storms is to slow down or stop them.

Signs don't mean a thing. Why try to tell the drivers that there is a sand storm ahead when the sand is probably blowing so hard that he couldn't read it, even if he was inclined to read signs and take cognizance of the warning. Drivers hate to be slowed down, and lose time. I've seen them creep along at two mph, straining their eyes to see the radiator ornament, much less the road ahead. And when a guy going in the opposite direction is doing the same thing, somebody's gonna get hurt. On the other hand to pull off and stop on the shoulder may also be extremely hazardous. In certain areas police controlled road blocks are the only answer.

The third point that I mentioned is important in this discussion. The soil, or various soils, and sand and gravel, go to make a top soil product, that, when dried out and subjected to heavy surface winds will be quite easily picked up and moved. Much of our good farming land is just such soil. A crop planted on one side of the road today may be blown to the other side tomorrow.

LOSS OF TOP SOIL

In the sandy desert parts of the state vegetation, natural vegetation, does little to hold the soil, and keep it from shifting. We have several famous examples of shifting sand.

The principal one is known as the white sands. It is a national monument, located in Dona Ana and Otero Counties in south central New Mexico. It is quite extensive, covering an area of 176,000 acres. That's about 275 square miles. Here is found an albino desert of gleaming, dazzling pure gypsum. Vast reaches of ever shifting and changing opalescent dunes form a paradise for photographers.

A National Play Day occurs here every April. Many persons enjoy skiing on the dunes.

The dunes can be quite dangerous to the tenderfoot. The sand is so white that there is danger of sun-blindness. Persons with a poor sense of direction can easily be come confused and lost. As the years go by the sands turn up an occasional skeleton, as the surfaces of the dunes shift. These are not always human. The Sands are supervised by the Park Service and daily tours are made during the year. A black-top, two lane road has been built into a portion of the dunes and it requires continual maintenence to keep it clear of blow sand drifts.

Another example of moving sand, and this is a yellow sand, is found in Socorro County.. It is found on US-85 and is a headache for our department. It is difficult to explain the movement of this sand and the problems involved.

Most engineers can realize the problems involved in the building of our highways over such terrain. My fourth point covers all of the difficulties from preliminary location surveys, through all the stages of planning and design, the actual construction, the opening to moving traffic and finally the tremendous job of proper and fast maintenance. Actually, future maintenance must play an important part in the design stage itself.

New Mexico has never been a wealthy state. Funds for road construction have always been limited. Many miles of our roads are in flat country where watercourses are shallow and wide, yet serve huge drainage areas. Bridges, and long ones at that, were not feasable, nor from the factor of cost, were they possible. Paved dips were used for many years. Many of them still exist and will for years to come.

Many of these are the points where upcountry cloud-bursts send water across the highways. At such times they become the danger points that require road blocking. Maintenance crews must be available at all times, in all areas to take over. Their work of course is to try to maintain a movement of traffic, halt it when necessary and clean up the mess afterwards. In the parts of the state where these dips are prevelant, equipment is available for any type of required operation.

The cleanup job often involves gathering up the sand and silt deposited by water and hauling it away. This wouldn't, of course, have to be far. In this type of country it is an expensive bit of maintenance to keep the ditches clean and serviceable. Shoulders are hard to maintain. When rain soaked they are dangerous. To make it more difficult, drivers will not believe a sign that reads "soft shoulders." They always try it anyway.

LESSONS LEARNED BY GIVING SERVICE DURING AND AFTER THE RECENT FLOOD

by MELVIN G. LYELL

safety engineer, Virginia dept. of highways, Richmond, Va.

Flash floods are not uncommon to the area along the Cumberland Mountain Range separating the States of Virginia and Kentucky. Such floods occur with a certain frequency in this region. Their intensity has been confined to some particular small area, so damages were not widespread, and the repairs were made quickly with the regular personnel, equipment and materials.

On January 29, 1957, after several weeks of rainfall, a heavy concentrated downpour fell over a large area of southwest Virginia, eastern Kentucky, and southern West Virginia. Small streams and large rivers overflowed. The flood reached five to seven feet higher than any previous flood.

The cost to Virginia highway department for repairing and replacing its facilities was $2,141,000. This includes funds from emergency federal aid and Civil Defense. These aid funds are very restrictive and very difficult to fit into an emergency program.

To show the extent of the damage, here are a few statistics:

—396 miles of roads damaged, from complete washouts to shoulder washouts

—74 vehicle bridges—16 feet to 142 feet long—damaged to the extent that practically new structures were required

—28 bridges required repairs.

—24 swinging footbridges completely destroyed and required replacements

Recovery, partial or complete, from such a disaster depends on personnel, equipment and materials. Command should be centralized but not to the point that leadership is not properly delegated to the local superintendents and foremen.

The period of greatest confusion is during and immediately following the disaster, and during this period proper leadership begins to show its effectiveness. During a state of emergency the public looks for guidance and leadership in its highway organization.

The public depends on the local engineers to bring food, clothing, medical, and other aid into the stricken area. And rightfully so, because the engineer is the field commander for his area, and he must provide the leadership to clear the highways for travel.

Calm and confident leadership which processes the work efficiently, has an exalting affect on the morale of the civilian population and the recovery organization.

When a disaster like Virginia's January flood occurs, the local organization is neither large enough nor equipped well enough to handle the situation alone. Damage must be determined quickly and requirements for recovery evaluated in proportion to the need. This calls for good planning on the part of leadership. Reinforcements must come from an area outside the disaster.

Personnel reinforcements bring the added problem of housing and feeding. To alleviate this problem our equipment division set up a temporary camp in an area which presented our biggest problem. This camp had kitchen trailers and sleeping trailers.

Personnel were sent into the disaster area without knowing weather conditions and they are not properly clothed. Although the deluge had passed and the streams had subsided to some degree when reinforcements began arriving, rain continued without interruption for another 18 days and many found themselves without the proper clothing. Boots and raincoats were needed —the employee's welfare is an important part in the effectiveness of his work.

As in the case of personnel, the equipment requested was based on actual need and was placed at the proper point upon arrival. This saved time and operations started with maximum efficiency. Bulldozers, motor graders, and power shovels were the prime movers. This equipment was used on major

washouts, slides, and erection of Army H-10 steel bridges. Trucks, fronted loaders, and backhoes were used for removing small slides, hauling materials, repairing or replacing small bridges and installing pipe lines.

All available hired equipment was used to supplement state owned equipment. Some of this equipment was available from the vicinity of major roadblocks on main arteries, which were given first priority.

Metal pipe culverts were used extensively to replace small bridges. It was simply a matter of placing a pipe or pipes, dozing in a fill composed of gravel from the creek and moving to the next trouble spot.

Army H-10 bridges were sent from other districts through the state and were erected where major bridges were destroyed. In all instances temporary structures were installed so as not to interfere with the installation of the permanent structure.

An entire organization can be used to maximum efficiency in a disaster of this kind. For instance, personnel secured permission, easements or purchasing rights for repairs, detours and local materials. Sign crews relieve local forces of putting up detour signs, barricades and warning signs. Survey parties secure measurements and staking abutments and piers for large bridges.

Recovery is accomplished in two steps. First, re-establishing traffic quickly by every known temporary measure and second, replacement in kind.

The first step, or initial recovery, is most important and generally accomplished without formality or for permanency. Beginning immediately after the flood waters began to recede, this stage is both costly and temporary, therefore efforts must be made not to waste personnel, equipment, materials, or funds.

This first stage, with one-way traffic in many places was completed in about a week except for major bridges. After this we gradually restored the roadways to normal widths. Step two soon got under way, requiring time, funds and patience.

Now all replacements have been completed except the construction of a few major bridges, reconstruction of certain road sections, and the construction of a few protective devices such as walls and riprap.

An outstanding accomplishment was that none of our employees was seriously injured and no time was lost as a result of accidents. The foreman and superintendent said they worked under hazardous conditions but prevented a serious injury by:

1. The daily, five-minute safety meeting kept employees safety conscious.
2. While working under hazardous conditions, everyone was accident conscious and remained alert.

In contrast, serious accidents sometimes occur on bright, sunny days when employees tend to be lax and apparently do not fully realize just how quickly an accident could be serious and sometimes fatal.▲

REMARKS OF J. C. McDONALD, JR.

safety supervisor, Mississippi State highway dept., Jackson, Miss.

Organization is the thing needed most during any disaster. Get a good man—don't let too many outsiders into disaster area. They know nothing of the operations and are likely to panic causing additional trouble and problems.

Work with portable radios—keep in constant contact. Get trained personnel on the scene immediately. There is the problem of care for your men. Organizations such as Red Cross and the like will take care of the victims but you must plan for housing and feeding your men while they are operating in the disaster area.

Good signing is essential for the protection of your men and any outsiders who might come into the area. For safety put signs at least a mile out from work area. Depend on your district men as much as possible.

Get safety into operation—and get your area men to do the job. In case of need a safety engineer is good but your men on the scene from that district know best the problems which will arise.

SELL YOURSELF

Don't try to catch your men in errors—set the proper example and build their confidence and respect for you. You must sell yourself to your men—then they will count on you. You can't get anywhere with "police action."

You must stay on the job always—with safety. You can sell more safety with laughs. Safety is a serious matter but gets across easier with your men when you can make your points with a laugh because you can hold their interest with jokes.▲

SNOW AND ICE CONTROL

by GEORGE C. MURPHY

safety supervisor, Maine Highway Commission, Augusta, Maine

There are many hazards to both the public and public employees in most snow and ice removal problems.

We have many hazards that could be lessened by mechanical means and money. But strangely, few of these hazards produce injuries. Probably our most hazardous operation is sanding. Conditions calling for this operation are usually at their worst. The highways are slippery; it is probably storming, and it seems that it is nearly always dark.

We have men perched on a truck body elevated to the angle of a ski slope. During any state wide storm we have 500 to 600 men working under these conditions. This would appear to be a perfect climate for injury-producing accidents. But injuries are rare and more than half of these are caused by the dangerous driving habits of the public.

But after the sanding is done, when the dangerous part of the operation is completed, this is the time that injury producing accidents are likely to occur.

Dangerous conditions produce few accidents. Unsafe acts of people produce many. Adequate supervision will take care of some of the unsafe acts. But the greatest number of the unsafe act injuries are produced by the people who do not have their minds on the jobs at hand. They are far away with their multitude of problems and worries.

How are we going to deal with these people? To me they represent the real problem in accident prevention.▲

Health and Safety Programs for Governmental Employees

(A Symposium)

THE PROFESSIONAL VIEWPOINT ON A CITY PROGRAM

by DR. FRANK H. HERRINGTON

chief physician, Employee Health Services, City of Columbus, Columbus, Ohio

A health and safety program planned for a municipality must of necessity differ greatly from one for a contained industrial set-up. "Contained" means that the physical plant of an industry is limited to a certain area, and fixed in location and size. A program may be designed to serve this unit to the maximum of efficiency.

Problems of health and safety can be dealt with satisfactorily due to the stability of the working units in this contained industry. On the other hand, we face divergent and constantly changing elements. Our health and safety measures must be geared to small mobile units which perform many different tasks; for example, street cleaning, road repair, and electricity, not to mention the various units of the police and fire divisions. Out of approximately 3,500 employees serving the city of Columbus, at least 50 per cent are constantly mobile and most difficult to reach. These mobile units are made up of small groups, therefore we must depend on supervisors to carry out our rules and suggestions regarding safety measures.

MUNICIPALITY SAFETY PROGRAM

The main purpose of our program is to institute measures necessary to protect the employee, insure his maximum efficiency on the job, and prevent him from injuries by reducing the various hazards to which he is exposed. We encodrage prompt reporting of all injuries and see that they receive the necessary care.

We in our division provide emergency care only. Any continuing care is the responsibility of the employee's family physician or competent specialist. If an employee has no family physician, we refer him to a specialist on our consulting staff. We do not wish to be accused of practicing socialized medicine and above all, we wish to and have maintained a friendly and cooperative liaison with the local medical society.

The main duties of our program consist of routine pre-employment physical examinations including a complete history, physical, urinalysis, serology, chest x-ray, visual acuity as measured by the orthorater, audiometric test, EKG and BMR when indicated. After this examination the applicant is rated as employable or unemployable. The result and rating are sent to personnel and to civil service. There has been only one case in which an applicant certified by us as unemployable has been hired and this case was later satisfactorily taken care of when the employee had a hernia repaired.

RETURN TO WORK EXAMINATIONS

To reduce the number of days lost due to illness, and to satisfy us that an employee absent from his job because of illness or injury has fully recovered and may return to work, we have a civil service rule. This says than an employee absent from his job for more than two consecutive days must be certified by the medical department before he may return to his regular duties.

Depending on our evaluation of him at the time of this examination, he may be certified to regular duty or we may allow him to return to so-called light duty with certain restrictions.

Routine annual physicals are offered to all city employees who wish an evaluation of their physical condition. The results of our findings, with the consent of the employee, are available to the family physician. These examinations are not mandatory for all city employees but are set up primarily for the police and fire departments.

During the past 18 months we have completed more than 1,000 annual examinations and are presently starting over again. This will be an annual affair, since we believe this is necessary to maintain these essential employees in the best of health.

These routine pre-employment and annual physicals have already turned up cases of malignancy, diabetes and hypertension, which had produced no symptoms and were therefore unknown to the employee.

As stated earlier, we provide emergency treatment of illness and injury *only* and for this purpose we have a well equipped emergency room.

The salary differential between private industry and public service does not provide us with the best material—lack of adequate personnel staff prevents proper screening of applicants.

One of our biggest problems is motivating the employee toward his job. Outside stress and strain plus improper motivation toward his job make for an inefficient and accident prone worker.

PROBLEMS OF HEALTH PROGRAM

All of us who are closely associated with industrial and environmental medicine feel that we are compelled to deal with more than the physical aspect of an employee's health. The mental and emotional components are a very important factor to maintain workers at top efficiency.

Each type of job has its particular hazards with which we must cope and for which we must find a solution if we are to reduce injury and the subsequent cost of industrial claims.

THE SAFETY ENGINEER'S VIEWPOINT ON ACCOMPLISHMENTS

by JOHN E. PAGNARD

safety coordinator, City of Columbus, Columbus, Ohio

The safety engineer must be equipped with certain tools if he is going to do a job. These tools are often much different than those used by machanics, welders and electricians. The safety engineer must rely on his own imagination and personal qualities that enable him to work with people and sell ideas.

In many cases the safety engineer is asked to perform tasks only the most skilled magician would attempt. But through patience and his belief in serving humanity, the most unbargained for task is successfully completed.

From 1951 to 1956 I have seen and felt the need for an occupational health program for all city employees in Columbus. Before our present medical policy, the only available medical services were for employees in the department of public safety, chiefly to the fire and police departments.

After a number of conferences with various city officials, a request was submitted in August of 1955 to the Department of Preventive Medicine of Ohio State University, for assistance in surveying the need and advisability of an occupational health program for the 3,500 employees of the City.

From a study of the municipal organization, physical requirements, and specific job hazards, a detailed proposal for establishing an employee occupational health program was prepared by Dr. James P. Hughes, Associate Professor, College of Medicine, Ohio State University, and submitted to the Mayor and city council.

FIRST LOCAL LAW FOR EMPLOYEE HEALTH

From this proposal, emergency legislation was prepared and presented to city council. An emergency ordinance was passed unanimously by the City Council and approved by the Mayor on December 17, 1955, thus creating by local law, the first occupational health program for employees on a local

level. Before passing this ordinance, the city law department was unable to find a similar existing ordinance in any other major city.

On January 1, 1956, the Columbus Employee Health Services opened its doors. As facilities increased, a nursing staff was recruited and trained and services were quickly made available. Six months later the medical program was supported enthusiastically by the city administration and employees alike.

Dr. Frank H. Herrington was appointed *full time Chief Physician and Director of* the Columbus Employee Occupational Health Program. By now the medical staff had increased to three part time physicians, three nurses and a secretarial staff.

Why so much emphasis made on this one item: "Occupational Health" or "Industrial Medicine?" From the humanitarian viewpoint, no service is as important to any group as that which safeguards the health and well-being of every employee. Secondly the economic aspect is tremendous when savings are important and a must with management. Successful management today, be it industry or government, will insist on economy. The waste of man power due to *injury or illness, is a tremendous drain on* the American prosperity of today.

The State Industrial or Workmen's Compensation premium rate for Columbus has increased steadily from 1950 through 1955. Employment has been at a high peak and payrolls also have increased considerably. The City of Columbus paid in Workmen's Compensation premiums during this five year period, more than one-half million dollars. No city in this country can pay such an industrial premium and prosper, because this is a waste of tax payer's dollars and a reduction in good, efficient, public service.

COMPENSATION PREMIUMS CUT

After one year of operation, the Employee Health Services program cut the Workmen's Compensation premium more than $75,000.00. The basic rate for Columbus dropped from $2.39 per $100.00 of payroll to $2.23. Our modification or penalty rate, dropped from a plus 73 per cent to 63 per cent. The risk rate dropped from $4.13 per $1,000.00 of payroll to $3.63.

Along with this record of direct cost of Workmen's Compensation the partial cost of sick leave for city employees in one year was more than one and one-half per cent of the total payroll. This figure is much less than previous years.

Another factor is the effect of the medical policy in regard to the number of Workmen's Compensation claims filed with the State Industrial Commission. During the first six months of the Employee Health Service program, the total number of Workmen's Compensation claims filed was reduced by 12 per cent.

Also, the total number of injury claims for payment of Workmen's Compensation was reduced 29 per cent. The number of industrial claims filed, payment of medical fees only, was reduced by five per cent. This was for the first six months only and is good evidence of expected benefits as far as top management is concerned.

It is not easy to persuade a budget director or finance committee of City Council to appropriate $40,000.00 or $50,000.00 for a proposed program. This is especially true for an accident prevention program because of the lack of tangible evidence to prove your argument. Prior to revamping our entire safety program so as to include the proposed medical program, the yearly budget alloted the Department of Industrial Relations was $14,000.00

SAVE TAXPAYERS' MONEY

The approved budget for the first year of our complete medical and safety program was $63,000.00. The budget for the year 1958 will be approximately $68,000.00. Final approval of our budget request is yet to come, and as in every governmental agency, we expect reduction of the initial request. I will say the city officials have been most cooperative and understanding when additional monies are needed.

The aim of our program is to prevent injury, have physically capable people performing public service and relieve the tax payers of excessive cost in payment of Workmen's Compensation and medical fees. From a monetary point of view we anticipate a savings to the city of over $200,000.00 a year in industrial premiums.

Another advantage and service is the certification to duty. Except for uniform personnel of the fire and police departments, it was my responsibility in the past to approve persons returning to duty, when a statement from the family physician was presented. This practice was unfair to not only the employer, but to the employee as well.

A layman should not have this responsibility—he is neither qualified nor licensed to judge the physical fitness of a person. Many times I felt that the employee should not return to regular duties because of the strenuous activities involved. But with a statement from the family physician, there was no alternative. The employee will—in some cases—tell his physician that his job is "not strenuous" or whatever excuse is needed to get back to work.

Financial hardship in the home and medical fees will effect the physician's decision to permit the employee to return to duty. This situation does not exist within the framework of our organization since the inception of our Employee Health Services program. No employee returns to duty now, unless certified by our medical staff.

Periodic inspection of work areas are a part of our safety program. Before our new policies, these inspections were carried out by myself and a foreman or supervisor. The chief physician and myself now make these inspections accompanied by supervisory personnel within the department or area inspected, and the success of correcting hazards found is most surprising.

There is no argument or question from any supervisor or superintendent or division head when the medical expert makes a recommendation for correction. A safetyman is fortunate indeed who has a medical section, especially a physician to advise and assist in the problems pertaining to the well-being of all employees.

The success of accomplishing that which is good for all peoples depends on the initiative, perseverance and determination you yourself inject in this or any other program.

There have been no political pressures or interference whatsoever in carrying out our health and safety policies and procedures. This is definitely not a problem with our Employee Health and Safety program.

There is no room for politics in safety but there is a lot of room for safety in politics.

WHAT RED CROSS FIRST AID TRAINING HAS DONE FOR OUR ACCIDENT CONTROL PROGRAM

by TARVIA JONES

engineer-director of safety, North Carolina State Highway & Public Works Commission, Graham, N. C.

We started our state-wide American Red Cross and First Aid courses on October 5, 1956 and we believe this is the best forward step we have ever taken in the SAFETY field.

Is there any thing more noble than teaching people to save life? Everyone should have the know-how of safety and all of the numerous things about life and living safely.

Did you know there is a bandage for every part of the human body? Who should know what, where and when to use such bandages more than the public employee?

We have been informed that we are the only state in the Union that has ever attempted such an all inclusive prevention and first aid program on a state-wide basis for every employee. We haven't had time as yet to evaluate our frequencies or severities as a result of our all-out red cross training but we have seen and heard enough to know it will pay dividends in more ways than one—like when we had a tree fall on a man and break his leg.

A first aider cared for him until they could reach a doctor who took an x-ray of the fracture to learn the nature and type

and ordered the injured person to a hospital 144 miles away. Our first aider said, "Aren't you going to re-splint and bandage?" The doctor replied, "That's as good a job as I could do, take him on."

Another man in our instructors' class stated, "Had I known two weeks ago what I know now I could have saved the life of one of my neighboe's children and the reason that's so important to me is because I have three children of my own."

All of our men have been elated over the privilege of having this course made available to them. It helps them—as well as their wives and children.

Everyone knows the American Red Cross is on the job in times of stress and disaster. Many of you know what it means to have some one with the know-how when a hurricane strikes or a tidal wave sweeps over the country side, perhaps some of you remember my article—"Wild Girls of the Atlantic"—which showed it pays to train all of our men in this most vital art. Life may be saved and shock prevented.

I am happy to report that in North Carolina we have approximately 400 qualified red cross instructors in our highway department and more than 4,000 qualified first aiders among our employees. We hope to continue our instruction until every highway employee is the proud holder of at least an American Red Cross Standard First Aid card. This will be the day when the real pay-off comes.

We unreservedly and whole heartedly recommend to every public employee group—the American Red Cross Prevention and First Aid course.

WHAT WE EXPECT FROM OPERATORS OF HIGHWAY VEHICLES

by MELVIN G. LYELL

safety engineer, Virginia dept. of highways, Richmond, Va.

This is part of a booklet written to acquaint drivers and operators of our vehicles and equipment with what the Highway Department expects of them in the way of driver performance to maintain a good safety record, and promote courtesy and good will toward the traveling public.

It also outlines our system of driver safety awards, and the system of penalties in the event of an accident which our operator could have prevented.

DEFENSIVE DRIVING

A key factor in this safe driving program is to require a high standard of performance. We know that if we are satisfied with mediocre standards we will get nothing better.

High standards create an additional incentive and become a challenge to each driver. The skilled drivers have a chance to prove their ability. They spur the other drivers to improve their performance.

A defensive driver is a driver who not only avoids causing accidents but also prevents pedestrians and other drivers from causing accidents involving him. He uses his skill and experience to insure that others are not able, through their own faulty actions, to involve him in an accident. He is a superior driver who obeys all traffic regulations. He realizes that many other drivers do not have the same degree of skill or knowledge that he has. He recognizes the need for extra safety measures to protect himself from the unpredictable actions of others—drivers and pedestrians. The defensive driver:

—readily concedes the right-of-way to others when encountering them at narrow bridges, intersections, converging traffic lanes, rotary intersections, and traffic circles.

—makes all allowances for: poor weather conditions, reduced visibility and slippery roads, narrow untreated, gravel roads.

—learns to anticipate accidents and takes precautions that will prevent them.

Drivers are generally classified into three groups, namely:

Amateur Drivers—who are so poor that they actually cause collisions by the way they drive.

Semi-pro Drivers—who drive well enough not to cause collisions by the way they drive, but not well enough to avoid being hit by amateur drivers.

Professional Drivers—who are so good that they not only do not cause collisions by their driving methods but who, in addition, are smart enough to outguess the amateur driver and not be hit by him. In other words, he is the defensive driver.

A safe driving award for one or more years without an accident should be awarded to the defensive driver. Then every other driver would try to achieve those standards. If the award were given to the amateur or semi-professional driver, then he would not recognize our skilled operator, the defensive driver.

STANDARD OF PERFORMANCE

How then can our standard of performance be described?

A perfect safety performance is operating a motor vehicle without having an accident at all. That is too much to expect. Our operators may become involved in accidents over which they have no control. Obviously it would be unfair to charge an operator or penalize him for this type of accident.

In most cases it takes two to make an accident. One driver usually violates some traffic law, the other some principle of defensive driving relating to safe speed, right-of-way, or alertness.

Either could have prevented the collision and therefore both contributed.

Here then is the clue to what we expect of a reasonably safe driving performance from our operators. We do not want to charge them and penalize them for all accidents in which they are involved, but we do expect them to prevent accidents.

Therefore, our standard is this—for an operator to have the ability to drive without having a preventable accident. Every possible precaution should be exercised to prevent the accident.

Of course the word "possible" is subject to various interpretations. If it is applied strictly, operators will think us unreasonable. However, if it is applied too loosely, driving errors will be overlooked and the same types of accidents will re-occur.

PUBLIC RELATIONS

So the problem of classifying accidents as "preventable" or "nonpreventable" and "avoidable" or unavoidable" is most important. We want our operators to feel that they have been treated fairly and impartially. We want to penalize the careless, non-attentive operator and reward the alert, skillful operator. The assessing of a penalty is not for the sole purpose of making the operator pay a fine, but to also point out what he could and should have done to have prevented an accident.

The majority of our accidents are usually preventable. In the assessing of a penalty or determining responsibility, we are not concerned with whether our operator was legally right or wrong. We are concerned with whether or not the accident could have been avoided by defensive driving.

Every possible precaution must be taken to avoid and prevent accidents. Both the traveling public and employees of the department engaged in the performance of work must be safeguarded effectively.

All employees of the department shall act with courtesy at all times, and shall so conduct themselves as befits a representative of the Department of highways. There must be no display of temper. Arguments with the public must be avoided, regardless of provocation. The value and effect of courtesy is inestimable.

Inquires shall be answered as completely as possible in a business-like manner; however controversial subjects and certain policies should not be discussed with parties outside the department.

In case of highway accidents being witnessed, regardless of whether or not state equipment is involved, employees of the department shall offer assistance.

It must be remembered that defense in case of any accident involving state employees or equipment, requires that the em-

ployee or employees do and have acted entirely within the law, and that occupational and personal conduct should be above reproach.

In offering services, the employee must be certain that his actions will not place him, or the state, under liability for damages.

No employee will make any statement as to responsibility for any accident at the scene of the accident in which he is involved. Such statements will be made only on the accident report submitted to the Highway Department, and or as outlined in the paragraph of "What Not to Do" on the last page.

GUIDE TO ACCIDENT PREVENTABILITY

Responsibility—Responsibility to prevent accidents is not based on who was primarily responsible or at fault. Responsibility to prevent accidents goes beyond careful observance of traffic rules and regulations. Drivers must drive in a manner to prevent accidents, regardless of the other fellow's faulty driving or non-observance of traffic laws.

Important: Unless thorough investigation shows extenuating circumstances quite beyond the control of the driver, the following types of accidents will be regarded as preventable. This list has been prepared as a guide to help you determine whether or not an accident should be charged as "preventable" on a driver's record and the driver assessed with a penalty.

Accidents at Intersections

a. Driving Straight Through Intersection—Collisions with vehicles coming from either the left or the right, regardless of the presence or absence of stop signs or traffic lights, or whether the light was green or changing.

b. Driving Straight Through Intersection—Collision with approaching vehicle making left turn in front of our driver.

c. Starting Through Intersection When Light Changes—Collision with cross traffic which has not cleared the intersections.

d. Making Right or Left Turns—Collision with approaching or cross traffic. Turning left-when other driver is approaching from the rear and attempting to pass on the left at intersection. Collision with adjacent traffic even when the other vehicle is illegally passing at the intersection. Also collision with a vehicle leaving curb as our driver makes a right turn.

Grade Crossing Collisions—Collisions with trains at grade crossings, regardless of where the accident occurred. Trains always have the right-of-way.

Backing Accidents—The care with which a vehicle is backed depends entirely on the driver's ability to make certain the way is clear. The driver is not relieved of his responsibility to act safely when someone guides him. The flagman does not have control of the vehicle and can neither start it nor stop it.

Collisions with Vehicle Ahead—Having the vehicle ahead stop suddenly is a common highway hazard. Collisions with such vehicles are considered preventable because professional drivers should always follow at a safe distance and have their vehicle under control.

Our Vehicle Struck in Rear—Will be considered preventable when:

a. Our driver was passing traffic when close to an intersection, then stopped suddenly at the intersection for a red light, stop sign, pedestrian or other vehicle.

b. Our vehicle was improperly parked.

c. Our vehicle rolled back in preparation for starting ahead.

d. Our driver made sudden stop to park, to load, or unload merchandise or passengers, for a grade crossing, or for similar reasons.

Accidents resulting from other drivers entering the main road from driveway, alley or side street—It is our driver's responsibility to enter traffic safely from such locations. These accidents may be prevented by proceeding with caution and being alert when approaching these intersections.

Weaving right or left—Failure to keep in line in multiple lane traffic. Some accidents may seem unavoidable if it appears that the other vehicle tried to pass through a space too narrow, when actually the space was made too narrow by the weaving of our driver.

Forcing off of road—Usually due to the leading driver forcing the other driver to the left of the center line—into viaduct

columns, parked vehicles, adjacent traffic, or off the roadway. Drivers should not get into a position where they may be forced into trouble, nor should they swerve so as to force others into trouble.

Accidents in pulling away from the curb—It is the responsibility of our driver to enter the flow of traffic safely.

Collisions with vehicles from opposite directions—Includes both head-on and sideswipe collisions when our driver was not on proper side of roadway.

Pedestrian accidents—All types of pedestrian accidents, including collisions with children and with persons coming from between parked cars. This can be avoided by always expecting or anticipating that some one will step from an obscure place.

Non-collision and collision with fixed objects—Includes overturning in roadway, running off roadway, and collision with culvert, traffic signal, parked vehicle, or other object.

Accidents due to poor visibility—Darkness, fog, rain, snow, sleet and glare. The burden of responsibility is placed on the driver to operate his vehicle within the limits of his ability to see ahead, stop and maneuver safely.

Accidents due to faulty brakes—It is the driver's responsibility to report faulty brakes. It is also the driver's responsibility to drive within the limits of the mechanical condition of the vehicle. This classification includes accidents caused by trucks rolling away from parked position, due to failure to block the vehicle, to set hand brake, air lead, etc., properly. (Includes failure to scotch vehicle parked on steep grade.)

Mechanical failure—When the investigation of a "mechanical failure" accident shows that the mechanical failure which caused the accident was due to rough and abusive handling on the part of the driver, the resulting accident should be charged against the driver. We should not permit nor require our driver to operate mechanically defective equipment.

Skidding Accidents—In which our vehicle skids.

WHAT TO DO IN CASE OF ACCIDENT

1. Set out flares or flags if vehicle cannot be removed from pavement.

2. Render first-aid to the injured if you are qualified.

   a. Telephone for a doctor. (Have someone else do this while you stay with the injured.)

   b. Telephone for an ambulance if needed. Notify the state police, asking them for assistance.

   c. Describe the location and tell briefly what they may expect to find.

3. Direct someone or yourself to act as flagman to handle traffic.

4. See that all precautions are taken against fire or further destruction and injury, by prohibiting unsafe practices.

5. Fill out Driver's Report of Equipment Accident, form S-9.

6. Report the accident to your immediate supervisor as soon as possible.

What Not to Do

1. Do not accept responsibility or blame for the accident either at the scene or later. Remember that such admissions may be used against you in court.

2. Do not discuss the accident with anyone except the police, your superiors or our insurance company representative.

3. Do not give a signed statement or a court reporter's statement to any person other than representatives of the Highway Department or our insurance company.

LEGISLATION AS IT AFFECTS PUBLIC EMPLOYEE SAFETY PROGRAMS

by H. P. "PAT" GOODIN
safety director, city of Minneapolis, Minn.

According to the United States Department of Labor, Maryland is the only state that has adopted legislation specifically aimed at the public employee safety problems.

Francis Otto said that this was the main reason that we do not have a report from his committee. It only proves that all public employee programs that have been successful have only been so because we have had outstanding men that have adapted the regular laws of the states to accomplishing the wonderful job that has been done in this field. This is I believe one of the reasons that we do not have more Public Employee programs than we have. There seems to be a reluctance on the part of some public administrators to assume their liability regarding protecting their employees. It appears that most laws covering workers and working conditions leave public employees as second class citizens.

We have a law on our books in Minnesota, 182.05 Minnesota Statutes, which reads "Manufacture and sale of unguarded machinery prohibited. When practicable the points of danger in any machine shall be securely guarded by the maker, and the manufacture or sale of any machine or mechanism not so guarded is hereby prohibited."

We had a request from the Industrial Commission, which has the responsibility of administrating this law that the law be changed to cover machines or mechanisms leased to producers in the state. There are many machines that are leased and kept maintained by manufacturers outside the state and the wording of the law seemed to exempt them from so guarding.

This amendment to the law almost was lost, the argument being that a farmer loaning his tractor or other farm equipment would be liable if he loaned unprotected machines to his neighbors, this in spite of the fact that the law only applied to industry. We finally got the bill through but we found out that this type of legislation is difficult to explain to those who don't want to be convinced.

In our state we have taken this up with the League of Minnesota Municipalities and we did get a small booklet out covering Public Employee safety and the responsibility of government in realizing that its employees are as necessary as any group of employees in any industry. It is beginning to pay off but there must be considerable more push behind this movement if we are to take care of our public employees.

GOVERNMENT'S RESPONSIBILITY

We must write into our laws language that will bring our public employee under the law by reference rather than by the present method of implication. What success we will have will depend to a great extent on what we as a public employee group do toward taking care of our people.

In 1951 we started a safety program in our city. We used the state laws as if they were written to cover our people and succeeded in getting some recognition from the city council with whom we deal in our city. Of course being a member of the state legislature helped in getting them to listen to what we had to offer. They helped us get authorization to try and cut the costs of lost time as a result of accidents which for the year 1950, was $200,000.00, disregarding other costs which go along with losses of this kind.

We started a safety glass program along the lines set up by industry starting in our equipment department. This was similar to a large maintenance shop in which we had been having an average of, loss of vision in one eye, every year for quite a while back. We had the council authorize the payment of half the cost of corrective glasses or the full cost of planos in safety glasses.

Shortly after we had a few fitted there was an accident in which a piece of steel struck one of the employees in the center of one glass. Had it not been for the fact he wore safety glasses, he would have lost an eye.

I kept this pair of glasses as a horrible example and succeeded in getting most of our employees either plano or fitted safety glasses and they wore them. We went into a period of economy and in 1954 we had a little difficulty getting enough on our budget to cover replacement or issuance of new glasses until it was pointed out that the horrible example I had been using had saved about $3,000.00 to the city. We have been getting our budget since that time and we have enlarged our program by having the council pass our budget allowing additional departments, where hazards exist, come under the program.

USED AS EXAMPLE

This had the effect of being accepted as legislation recognizing the responsibility of the Public subdivision complying with the state law covering employee safety. This has broadened out to include hard hats, and other protective equipment required by industry under the law.

Where do we go from here? This is a question we as Public employee safety men have to answer. I believe that we must reactivate the legislative committee. We must have one of our people who is active in safety activities chair the committee. We should have Otto or someone from the department serve as an advisor to this committee. We must assemble all data possible from Public laws covering Industrial and labor safety with the idea in mind of assembling a set of laws that will serve as a model for Public Employees.

This will take some time. Someone from the Department of Labor in Washington on the committee will have to help get the information from states with safety laws and regulations. Let's get away from the idea that state and other public officials have regarding these laws—that they apply to everyone else except our employees.

Let's get back of a movement to draft legislation for Public Employee Safety that will accomplish what we want, take our people out of the category of second class citizens and give them legislative protection equal to that provided for labor and industry. Let's make this the year that the Public Employee assumes his place as a valuable employee and gets the benefits and privileges granted other employees and the protection of a set of proposed laws we can all be proud of.

Report of Traffic Accidents with City Vehicles for Six Months of 1957

	1951	1952	1953	1954	1955	1956	6 Mo. 1957
Total Accidents	195	153	127	106	133	101	45
Frequency	34.2	273.8	226.5	196.5	182.2	174.0	164
Chargeable Accidents ..	83	69	51	40	50	33	12
Frequency	150.6	125.5	91.2	74.2	68.2	56.8	35.3

Frequency rate is per million man hours which on motor vehicles is about ten million miles.

Total accidents means all accidents involving city vehicles.

Chargeable accidents means those in which our operators were at fault. There may be some contributing negligence on the part of our operators in some of the others which hasn't been determined.

Of the 12 chargeable accidents the first six months of this year:

5 were caused by our operators not having control of their vehicles and running into the rear of either parked or moving vehicles.

4 were caused by our operators backing into other vehicles or stationary objects.

1 was caused by our operator misjudging the operation of his snow plow and striking another vehicle.

1 was caused by our operator turning from the wrong lane and squeezing other vehicle.

1 was caused by defective equipment.

All except one accident were caused by *the operator not having proper control of* his equipment. Here is where defensive driving comes in. You are the representative of the city when you meet the public with your equipment. Maybe some of the non-chargeable accidents could have been avoided if we just gave a little. These are the people who pay the taxes that your wages come out of, so it's up to you to bend over backward a little to see that they get a break. Even though they may have the right of way, you can't give the right of way, you only take it; so be a bit generous and let the other fellow take it. DON'T try to take it on your own.

Backing up is again causing some accidents and you who have helpers use them. *If you haven't be extra sure your rear is* clear before you back. Look back—keep looking—then back.

Only one wrong lane accident, but there were several near misses. Get in the lane you should be in and stay there. Get in the right lane to turn from at least a block before you turn, then signal and turn properly. Keep on the right side of the street and stay on the right side of the motoring public.

The next six months will determine what we can do. Practice safe driving on the job and you will play safe at home. Safe driving is happy driving.

Fre. means frequency, accidents per million man hours.
Sev. means severity, days lost per million man hours.
L.T.A. means lost time accidents.

The committee activities in the Water Department seem to be *paying off. The average* frequency from 1951 through 1956 was *27.41*; the first six months of 1957 it was 21.46, and after a bad Spring, not much snow and with slippery conditions. This shows about $10,000 less for lost time as a result of injury as well as the relief of *pain and hardship that goes along with dis*ability to an employee.

The Equipment Department had quite a few L.T.A., but they were of a minor nature. However, they could have been serious. Most of these were in the first quarter. Maybe a Safe Practice Committee here would bring some results, Eh?

As usual paving has been having several L.T.A., and mostly from careless handling. A little instruction and help from you older fellows could do a lot to help. Maybe a safety meeting among foremen might help.

Sanitation has had too many accidents, mostly in collection. Here again a little help from you older fellows would help.

Sewer Department has been doing real well, but there is always room for improvement, so let's keep trying and cut the L.T.A. out altogether.

Bridge Department had a couple of bad ones and a couple of minor ones. In that work any minor accident could have been bad. It looks like there is some improvement. Let's hope the final report will show it.

You fellows using jack hammers and breakers on concrete—better wear your goggles or safety glasses. Many of you have been neglecting to protect your eyes in this kind of work. Cover one eye and try to work and you will see how necessary it is to have both. You foremen must enforce the rule that all men exposed to chipping and breaking shall wear protective equipment. This means safety glasses, hard hats, or whatever is needed.

Let's put more safe thinking in our work. Report all unsafe conditions right now. Call me if I can help at any time. Let's make all our people safety minded at home and on the job. The City needs you—so does your family.▲

STATISTICAL COMMITTEE REPORT

by WARREN D. WILT
safety engineer, city of Detroit, Mich.

The year 1956-57 has seen much progress in Public Employee Accident control work. This opinion is based on the number of governmental agencies sending statistics to my office.

Not many years ago we crusaded to have governmental agencies make records of all employee on-the-job accidents. Many, in fact a large per cent of the agencies contacted had no records or concealed records of employee on-the-job accidents.

It was common practice to include time-lost due to accidental injury in "sick leave" making it difficult to distinguish if the time lost was due to natural sickness or accidental injury. At the time we encouraged keeping accident records, we made suggestions of methods of recording and analysis of these records according to the American Standards *216.1.*

At first many agencies thought this impractical as it would mean major changes in existing procedures and involve considerable cost. Today, many of these same agencies are doing a fine job of accident reporting along the A.S.A. methods. Smaller agencies, as well as the so-called larger ones have seen the value of full time safety personnel.

FREQUENCIES DROPPED

It was common to receive reports of accident frequency of 60, 70 or 80. Today it runs 16, 18 or 20. Several report frequency below 10. This shows real progress.

No attempt has been made by the statistical committee to tabulate and publish a summary of Public Employee Accident figures. The National Safety Council is doing this in its "Accident Rates." Our industry is large enough to be included in the N.S.C. "Accident Facts." The main reason for not being in this publication is that not enough agencies are reporting to be representative of the Public Employment which is necessary for a publication such as "Accident Facts."

The statistical committee has several recommendations to make:

1. All accident statistics submitted to the

committee be properly identified. The only identification on several of the reports received this last year was the return address in the upper left hand corner of the envelope.

2. That annual summaries of the calendar year accident experience be forwarded to the National Safety Council's Statistical division as soon as possible after the close of the year. This report must be made on the N.S.C. report form, on your own summary form. These forms can be secured, free of charge, from the N.S.C. headquarters.
3. All agencies to report their Vehicle Accidents according to the N.S.C. standards. No comparisons can be made if each agency has a standard of their own for reporting.
4. That the National Safety Council be requested to record and report Municipal Government Vehicle accident statistics on a total city basis. The large variety of work, and the difficulty in securing a fine break-down of mileage for each class of operation now being used by the Council, make it impractical to compare like statistics of different municipalities.

ENGINEERING COMMITTEE REPORT

by DWIGHT C. CROFFORD
state safety director, Idaho dept. of highways, Boise, Idaho

The year 1957 has been a year of foundation laying for the Engineering committee. We learn by trying, and sometimes we learn not to try the same thing again.

During 1957, part of the Engineering committee worked up a brochure which it was felt would adequately represent the section in the hands of interested friends. This brochure was forwarded to the chairman of the section and from there to the National Safety Council where it was worked over for five months, and as yet no proofs have come to the committee for recommendations or approval.

Also during the year an effort was made to gather information about the emergency signing used by state, county, municipal and school levels throughout the nation. The response was spotty, there being those who would divert this attempt to gain a semblance of uniformity. However we were able to come up with a few conclusions in the response received. Time did not permit the development of specific recommendations.

After due [illegible] correspondence with representatives of the N.S.C. it was discovered that NSC furnishes little in the way of helps or materials for the section. The section is responsible for the composition and compilation of all approvals given

devices and placement of signs can and should be worked out. In actual interviews with violators in our state, there was confusion due to lack of uniform action between us and our next door neighbors. Recall that we have referred to minimums, leaving the door wide open to those who want additional warnings.

The apparel, equipment and procedures of the flagman are other sources for study and uniformity.

In this realm, we can accomplish some real good for the safety and protection of our charges, the unsung heroes of the highways. If there are any accomplishments made, our section will have to do the work from start to end.

There is much work to be done, and we are the only ones who will do it. We urge you to cooperate with the new Engineering committee in doing something constructive for our people and their welfare.

OFF-THE-JOB ACCIDENTS

Statistics are such boresome things
And figures rather dull.
It's hundreds, millions, billions, trillions,
Over which we mull.

But facts are facts where'er we go
Regardless of amounts,
So here's some facts on accidents,
And that's what really counts.

It isn't always big machines
With blades of sharpened steel
That rob a man of arm or leg
And make his senses reel.

Nor is it always "on the job"
Most accidents take place,
But just the opposite is true
And figures prove our case.

It's carelessness in little things
At home and on the street
Neglect in moving objects small
Away from running feet.

A makeshift ladder, sliding rugs,
Electric cords that spark
A disregard for cellar stairs
And stumbling in the dark.

Crossing where no crossings are
While looking at the sky,
Driving on a slippery road
With milestones whizzing by.

These are the things that take a toll
We all should frown upon
So watch for them when off the job,
As well as when you're on.

—*Humble Pipe Line Company, Houston, Texas*

OFFICERS OF THE

CONSTRUCTION SECTION

NATIONAL SAFETY COUNCIL 1957-58

General Chairman—WILLIAM G. HAWKINS, director of insurance & safety, Winston Bros. co., Minneapolis, Minn.

Vice-General Chairman—HENRY J. MASSMAN, III, vice-president, Massman Construction co., Kansas City, Mo.

Vice-Chairmen—(Heavy Division)—W. M. GOLDSTON, president, The Goldston co., Corpus Christi, Tex.; *(Highway Division)*—SHELDON CARLSON, vice-president, Park Construction co., Minneapolis, Minn.; *(Building Division)* FRANK R. RUNDELL, president, Frank R. Rundell co., Austin, Tex.; *(Home Building Division)*—Earl W. HORTTOR, Kansas City, Mo.; *(Special Division)*—W. K. COX, sales promotion manager, Caterpillar Tractor co., Peoria, Ill.

Secretary—ROBERT L. MOORE, director of technical & engineering div., Lumbermens Mutual Casualty co., Chicago, Ill.

Assistant Secretary—E. N. ZINER, president, Ziner Construction co., Malden, Mass.

Nominating Committee Chairman—GEORGE P. O'ROURKE, SR., president, O'Rourke Construction co., Dallas, Tex.

Newsletter Committee Chairman—SAM S. ELKINS, chief, safety branch, Southwest div., Corp of Engineers, U. S. Army, Dallas, Tex.

Program & Publicity Committee: Chairman—HENRY T. PEREZ, editor, Construction Methods & Equipment Magazine, New York, N. Y.; *Vice-Chairman*—W. K. COX, sales promotion manager, Caterpillar Tractor co., Peoria, Ill.

Membership Committee Chairman—HENRY J. MASSMAN, III, vice-president, Massman Construction co., Kansas City, Mo.

Service (Research & Screening) Committee: Chairman—R. J. HENDERSHOTT, manager, A. G. C. of Minnesota, Mineapolis, Minn.; *Vice-Chairman*—FRANK M. BOODRO, safety director, B. Perini & Sons, Inc., Framingham, Mass.

Engineering Committee: Chairman—JOHN L. JUNKERT, safety consultant, Marsh & McLennan, Inc., Minneapolis, Minn.; *Vice-Chairman*—RUDOLPH J. BEHLEY, supervisor, construction engineer, Travelers Insurance co., Hartford, Conn.

Visual Aids Committee: Chairman—DONALD F. MANGUSON, assistant manager, A. G. C. of Minnesota, Minneapolis, Minn.; *Vice-Chairman*—LLOYD E. MOSS, district engineer, Texas Employers Insurance Assn., Dallas, Tex.

Health Committee Chairman—N. GILLMORE LONG, M.D., chief surgeon, Lumbermens Mutual Casualty co., Chicago, Ill.

Public Relations Committee: Chairman—ROBERT L. JENKINS, chief, safety div., Office of the Chief of Engineers, Dept. of the Army, Washington, D. C.; *Vice-Chairman* H. W. HEINTZ, safety director, John A. Volpe Construction co., Inc., Malden, Mass.

Division Secretaries: Heavy—WILLIAM BERRY; Highway—E. N. PETERSON; Building—MISS FANNIE DAVIS, executive secretary, Austin Chapter, A. G. C., Austin, Tex.; Home Building—CLARENCE F. STURGEON, insurance manager, The Home Builders Assn. of Chicago, Chicago, Ill.; Specialty—WILLIAM H. WHITMAN, Goodyear Tire & Rubber co., Chicago, Ill.

Staff Representative—CLEMENT J. LUEPKE, National Safety Council, Chicago, Ill.

OFFICERS OF THE

PUBLIC EMPLOYEE SECTION

NATIONAL SAFETY COUNCIL 1957-58

General Chairman—CLARK J. FISCHER, safety engineer, City of Milwaukee safety commission, Milwaukee, Wis.

First Vice-Chairman—DANIEL F. MILCHMAN, coordinator, New York city safety program, dept. of personnel, New York, N. Y.

Second Vice-Chairman—M. VAN MECHELEN, safety engineer, Washington State dept. of highways, Olympia, Wash.

Third Vice-Chairman—ALEX G. THOMPSON, safety engineer, City of Los Angeles, Los Angeles, Calif.

Fourth Vice-Chairman—JACKSON G. FLOWERS, Dade County safety director, Miami, Fla.

Secretary—MRS. LOUISE RATNER, safety & claims examiner, Ohio dept. of highways, Bureau of Accident Control & Claims, Columbus, Ohio.

Program Committee: Chairman—RALPH L. ALTHOUSE, personal injuries supervisor, State of Illinois div. of highways, Springfield, Ill.; *Vice-Chairman*—JOSEPH F. WICKLESS, supervisor of safety, City of Baltimore, Baltimore, Md.

Legislative Committee Chairman—H. P. GOODIN, safety director, City of Minneapolis, Minneapolis, Minn.

Engineering Committee Chairman—BAYNARD A. SWITZER, chief safety engineer, California div. of highways, Sacramento, Calif.

Advisory Committee Chairman—DR. B. L. CORBETT, M.D., managing director, City of Milwaukee safety commission, Milwaukee, Wis.

Statistics Committee Chairman—WARREN D. WILT, safety engineer, City of Detroit, Detroit, Mich.

Newsletter Committee Chairman & Editor—GEORGE F. KUHNS, safety supervisor, Illinois div. of highways, Springfield, Ill.

Membership Committee Chairman—DANIEL F. MILCHMAN.

Nominating Committee Chairman—TARVIA H. D. JONES, engineer-director of safety, North Carolina State highway commission, Graham, N. C.

Staff Representative—CLEMENT J. LUEPKE, National Safety Council, Chicago, Ill.

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

THE PUBLIC UTILITIES SECTION
THE ELECTRICAL EQUIPMENT SECTION

This volume is a record of the sessions held at the 1957 National Safety Congress by the Electrical Equipment Section and the Public Utilities Section. The conduct of these Congress sessions each year is only one of the many cooperative activities, which the Electrical Equipment Section and the Public Utilities Section carry on in behalf of their members, and for the benefit of accident prevention work in the electrical equipment and public utilities industries generally. These sections give guidance in the preparation of a great variety of technical and educational material useful in the day-to-day safety programs of electrical equipment and public utilities companies.

The activities of these sections are under the direction of their executive committees, the members of which are listed at the close of this volume.

ELECTRICAL EQUIPMENT SECTION

IS "HOT" ELECTRICAL WORK NECESSARY?

by W. F. LIPPINCOTT

electrical maintenance engineer, Chambers Works,
E. I. DuPont De Nemours and Co., Inc., Penns Grove, N. J.

At the Chambers Works "hot work" is, "work in which energized parts of wires, bus installations, switches, starters or panels, must or could be contacted by hand, body, tools, or equipment while a potential of 50 volts or more is present."

The definition itself is simple, but the successful, practical application is difficult. Too often, people who work on "hot" circuits over the years fail to recognize when they might get into a hazardous position, for example, in a crowded pull box. To work in a pull box, it is frequently necessary to rearrange a jungle of wires to get to the circuit involved. The definition of "hot work" applies here when *all* circuits in the box must be shut down. Field experience is required by both supervision and employees to determine when the definition should apply.

Electricians often feel that some energized work is unavoidable in their jobs. Eliminating "hot work" takes the "bravado" out of humdrum day-to-day work. The man doing "hot work" feels it sets him apart from the ordinary mechanic. Too often he resists a change in his accepted way of doing maintenance. However, facts prove that "hot work" is dangerous even for the most experienced craftsman.

ELECTRICAL SAFETY RECORD LAGS BEHIND

It is a generally accepted impression that the electric utilities have a good safety performance. However, their accident frequency rate for 1954 through 1956 was 7.69 injuries per million exposure hours, contrasted with the chemical industries' record of 3.57, and Du Pont's safety performance of 0.39.

Naturally, not all electric utility accidents were due to "hot work" but a greater proportion of their work is done without de-energizing circuits, and this undoubtedly contributes to their greater accident frequency. In fact the Edison Electric Institute had 122 fatal accidents in 1955 from the utility group. Electrical shock and burn caused 95 of these deaths.

The Du Pont Co's. safety and fire protection division indicate that in the past 26 years, out of 21 electrical fatalities, 15 were the direct result of "hot work". Thirteen of the 15 fatalities occurred among qualified electricians.

Can we be complacent if 62 per cent of the fatalities from electricity were among men supposedly trained and experienced? How is it possible to justify the continuation of "hot work" knowing that even the most earnest efforts will probably only delay the next injury?

A review of the past 14 years indicates that during the first seven years (1943 through 1949), the Chambers Works had 14.7 per cent of the electrical injuries in the Du Pont Company.

"NO HOT WORK"

An accident on the Chambers Works in 1948 resulted from using full potential to test an exposed, oil-immersed starter. A short circuit caused burns that hospitalized an employee for several months. To eliminate such accidents, management established the policy of "*No Hot Work*" and told the line organization to develop a program for adhering to it. All electrical work and methods were reviewed.

Finally, it was concluded that proper planning could permit all necessary work with circuits de-energized, so that no production loss would result. The "No Hot Work" rule was adopted and the practicability of the program has been confirmed. The corrective action, both by its direct and psycho-

logical implications, has been unprecedented in reducing electrical injuries on the Chambers Works.

Since the "No Hot Work" program began in 1950, no serious injury has been caused by electricity. However, this year a fatality did occur when a mechanic disregarded regulations and violated his foreman's specific instructions by working on an open starter without pulling the switch.

Chambers Works is the largest Du Pont Company plant and employs more than 125 electricians including nine linemen and nine elevator mechanics. The facilities include miles of 11,000, 2,300, 550, and 110-volt outside electric lines, eight primary transformer banks, 35 secondary banks, and 100 lighting transformers. These facilities service 552 buildings, having a total demand of 25,000 kilowatts.

AN OVER-ALL PLAN

Normally, production areas demand continuity of electric service and are reluctant to accept shutdowns. Electrical maintenance groups also avoid outages. To eliminate "hot work" both groups must be convinced that planned shutdowns can be arranged without production schedules. The change from working on energized electric circuits can not be made quickly. There must be an "acceptance" of the new way by all levels of supervision in both operating and maintenance groups and the path must be carefully prepared.

On the Chambers Works, the approach to the goal of "no hot work" can be divided into four categories:

1. Management
2. Program
3. Equipment
4. Education

MANAGEMENT

Plant management must desire safe performance above all else and actively sponsor the basic policy of "No Hot Work". Operating supervision must understand that anything can be shut down; that production can be scheduled to make up for these interruptions. Maintenance departments must be convinced by management not to risk "hot work" and to arrange their plans accordingly.

Further, all activities and services must be co-ordinated to adhere to this basic policy. The engineering department must design facilities to work circuits de-energized without frequent and extensive shutdowns. Plant power divisions must carry out planned shutdowns smoothly.

Management must provide needed electrical equipment and replace hazardous installations. They should prepare a defense against the criticisms of short-range production losses.

PROGRAM

Management must delegate responsibility for the program to direct supervision, and supervision should understand that a "No Hot Work" policy does not mean simply shutting down each time electrical repairs are made. The program involves dovetailing electrical repairs to coincide with planned production outages, and maintenance work should embrace all parts of the circuit involved. Such planning can avoid shut-downs for electrical work alone. Only those who know day to day electrical problems can develop a workable "No Hot Work" program.

Line organization reviewed each part of the electrical activities with the following results:

1. Certain shortcomings in the accepted voltage tester were found. Improvements were made for a positive, safe means of determining the presence of potential. Rules governing when and how this device should be used were outlined. These improvements would have prevented several accidents in the past.

RUBBER GLOVES, FUSES, LOCK-OUTS

2. Methods for the use, care and testing of rubber gloves were developed, which included a monthly glove test in accordance with A.S.T.M. methods. The program is still in effect since rubber gloves must be used for potential testing and fuse pulling. The regular test serves as a psychological aspect of our overall safety program and as a regular reminder to use gloves the few times they are required.

3. Ways to remove and replace fuses were included so the electrician would understand how each type of fuse was to be handled.

4. The nature of an electrician's work on

electrical equipment prohibits normally accepted locking-out procedures. Regulations for "blocking-out" electrical circuits were worked out with the safety department. This system assigns two personal "blocking-out" tags to each electrician. These are used in addition to his lock when he is actively working on the circuit. An "Out-Of-Service" tag is used to designate the condition of the circuit to other electricians.

5. Frequent errors have occurred when 2300-volt disconnects were operated. The most prevalent error was opening them under load. The proper technique for opening 2300-volt disconnects was established and each man doing this work was given training. The procedures were clearly written to avoid misunderstanding.

6. In the past we had experience with fuses exploding. Investigation and field tests found that the ability of the fuse to interrupt a short circuit was being exceeded. The field tests included new devices not used on the Chambers works and they opened the test circuit successfully. These improved types are now used and have proved their value in service.

7. An interim procedure "Electrical Work on Circuits" was formulated. This procedure defined the authority of each supervisor for regulating work on circuits according to the type of work and voltage involved.

8. The final step was to write a simple rule for work on electrical circuits—"No "Hot Work."

These eight items were put into effect as they were developed. Each measure became part of the day-to-day working habits of the electrician and each in his turn conditioned him so that there was minimum resistance to the final logical step of establishing the "No Hot Work" policy.

EQUIPMENT

Expenditures were required to rearrange outside electric lines to reduce the area of shutdowns when circuits were de-energized. These facilities enabled maintaining primary transformer banks without extensive outages. A gradual replacement of hazardous obsolete equipment inside buildings was made and is still in progress.

The man on the job needs certain equipment. Some items are basic, others help "sell" him on the program. Chambers Works electricians are provided potential testers, rubber gloves and blankets, "Blocking-Out tags and locks, ohmmeters, "Out-Of-Service" tags, clamp ammeters, and "Meggers". The equipment needed in other plants may vary according to their special requirements.

EDUCATION

Although the electrical phase has been left until last, it is probably the most important. The man on the job is the key figure in the success of any safety educational program. Since the electrician may resist changes in carrying out his job, he must be "sold" on the program. He was shown the "why," and in general worked in full compliance with the policy. His respect for the hazard was developed and a discussion of what can happen has been the subject of continuous review.

In addition, electrical supervisors responsible for carrying out the program were made to recognize hazards in "hot work". They learned the reason for the policy and helped develop every phase of the procedure. They learned how to plan, and shutdowns were held to a minimum, with all possible work done while the section was de-energized.

Under certain rare circumstances there may be a greater risk to de-energize equipment than to do the work "hot." On these occasions the work is reviewed by members of supervision (as set up in the procedure "Electrical Work on Circuits") so that proper safeguards will be established.

Supervision responsible for production and maintenance established a sound working relationship. Since the operating supervision had to adjust their thinking to the new policy, they were kept fully informed as the program took shape.

IS "HOT" ELECTRICAL WORK NECESSARY?

Chambers Works electricians have emphasized that the "No Hot Work" rule is one of the greatest improvements in work methods they ever experienced. The comprehensive coverage given the subject and the improvements in equipment and replacement of facilities, have brought a feeling of cooperative effort to make it fully effective.

Based on previous experience, the Chambers Works believes that "hot work" carries too high a price. Management has stated

that after seven years of the "No Hot Work" program, there was no notable loss in production and schedules had been maintained. In fact, Chambers Works has had less forced outages now that maintenance work is done during scheduled shutdowns.

As these results are history, we feel safe in answering our subject question. It is practical and profitable to maintain the electrical facilities on a large chemical plant without exposing personnel to energized circuits.▲

THE HAZARDS OF RADIO TRANSMITTERS AND THEIR CORRECTION

by READ H. CARD

methods engineer, Long Lines Dept., American Telephone & Telegraph co., New York city

When we think of the hazards of radio transmitters, our first thought is the danger of electric shock. The transmitter contains many bare conductors, bare terminals, bare parts of all kinds. There are many chances of shock from contact with, or arcing from, those conductors and parts that are energized with d-c or power frequency a-c. There are chances of shock from condenser discharge. There are also chances of burns due to contact with or arcing from conductors or parts that are energized at radio frequencies.

Radio transmitters are dangerous if not adequately safeguarded, because of the high voltages required for plate supply. Low voltage can be dangerous too when there are chances of low resistance contact with conductor and ground, or when one grasps a conductor and cannot release it because of muscular contractions caused by the shock.

One reason radio transmitters are hazardous is because they must be entered for adjustment and testing while power is on.

Some people think that as long as work is done by experienced personnel, aware of the hazards and careful to avoid them, there is no danger. But experience with radio transmitters as well as other electric equipment does not bear this out. Experienced as well as inexperienced men suffer electric shock all too frequently.

A relatively new hazard is radiation from microwave transmitters, such as radar and over-the-horizon (tropospheric-scatter) transmitters. This radiation in harmful quantities may be present at the open end of a waveguide, or in or near the beam of a parabolic reflector antenna.

Serious injury or death can result from exposure to this radiation. The distance from the antenna at which these effects are experienced depends on the transmitter power but, within the beam, it may be measured in thousands of feet.

Other hazards of radio frequency energy include the ignition of flammable liquids and the detonation of explosive materials, especially dynamite caps. Flammable liquids may be ignited by sparks such as at the openings of gasoline tanks. Dynamite caps can explode by energy picked up by leads arranged by chance in such a configuration as to stimulate a dipole with the cap at the center.

As an example, a recent test indicated that a dynamite cap at the center of a half-wave length dipole would explode in a 20 milliwatt per cm² field at 900 mc. The Institute of Makers of Explosives has published safety practices for using explosives in the vicinity of radio transmitters.

Besides electric shock and radiation hazards, there are many mechanical hazards. Prominent among these are burns from hot tubes and cuts from fan blades. Sometimes doors hinged from the top are not adequately protected against falling. In a transmitter designed for safety all such hazards are reduced to a minimum.

THE EFFECTS OF ELECTRIC SHOCK

The effects of electric shock on the human body must be understood to protect against electric shock hazards. The degree of hazard for different values of current and voltage and for different frequencies must be considered in determining the extent of protective measures employed.

Shock reaction varies greatly among individuals and the effects are sometimes complicated or not well known. Consequently, the values and effects discussed here should be regarded only as generally indicative of actual conditions.

At power frequencies we begin to feel currents in the range from about 0.3 to a few milliamperes. Currents just above this threshold of perception offer a degree of hazard, not because of direct effects, but because they might cause a man to draw back quickly and lose one's balance or strike some object.

The second level is the let-go current, the value beyond which one cannot release a conductor he is grasping. At power frequencies, this is around 10 to 20 milliamperes for men, for women, somewhat less.

Most people can stand currents in this range for a short time without serious effects. However, with currents above 25 milliamperes, the victim "freezes" to the circuit and severe muscular reactions make breathing difficult if not impossible. Death from asphyxiation may result if the circuit is not broken in a few minutes.

VENTRICULAR FIBRILLATION

The third level is an important current that can cause ventricular fibrillation. At values around 100 milliamperes to two or three amperes of power frequency current through the chest, the heart loses its rhythmic cadence and begins a quivering, uncontrolled motion that provides no pumping action. The minimum duration of shock causing fibrillation varies from a few seconds at 100 milliamperes to a few hundredths of a second at the higher currents.

The heart rarely recovers spontaneously from fibrillation. The normal beat can be restored by applying counter-shock: deliberate application of sufficient current to stop all heart action while the current is flowing.

This is a practicable procedure in the operating room where fibrillation often results from surgical shock. Much thought and research is being devoted to develop practical means of employing de-fibrillation in locations such as power and radio stations. But such means are not yet available. Therefore, once a radio operator suffers shock from currents in the fibrillation range, he usually cannot be saved.

LOW VOLTAGE IS DANGEROUS

With power frequency currents in excess of about six amperes, paralysis of nerve centers sets in stopping breathing and heart action. If artificial respiration is started promptly and continued until the nerve centers recover sufficiently to take over their normal functions, the victim may be saved, depending on other injuries such as hemorrhages or severe burning.

Volts of 120 at normal power frequencies can be dangerous causing asphyxiation or ventricular fibrillation. Normally the hand to foot resistance of the human body as measured with low voltages may be as low as about 1500 ohms. The corresponding current is 80 milliamperes.

A little moisture on the skin, as from perspiration, and a "no-let-go" grip on a conductor could cause a possible fibrillation fatality. Even with dry skin, if the victim freezes to a 120 volt conductor and no one is present to break the circuit, he could die from asphyxiation. With wet hands and feet, the resistance of the body may be as low as 600 ohms. The current then becomes 200 milliamperes and the chances of fibrillation are correspondingly increased.

Now, how do these effects vary with frequency? First let us consider d-c. For currents in the milliampere range, the tolerable d-c current is about four or five times as great as the corresponding rms a-c current. This applies to perception, let-go and the longer-duration low-value fibrillation currents.

SHOCKS VARY WITH CURRENTS

For shock durations of a fraction of a second, with currents of one ampere or more, the fibrillation threshold approaches the a-c crest value. For burns or internal damage from heat, the effects of d-c would be about the same as those of rms a-c.

Increasing frequency above the power frequency range increases the current one can

tolerate. For frequencies above 10 kc, currents of several amperes produce no muscle or nerve stimulation, only heat. Higher currents may cause severe injury or death from burns.

In dealing with high power microwave transmitters, an understanding of the effects of radiation on the human body is helpful to minimize hazards.

The harmful effects are due to internal heating of the body. There is no evidence of ionizing radiation, such as X-rays or gamma rays, from such exposures.

Damage may be done by localized exposure of the eyes and other parts of the body that are not efficiently temperature regulated by blood flow. Possible harmful effects include cataracts and damage to the gastro-intestinal and genito-urinary tracts.

Tests have indicated the threshold of field strength producing cataracts in the eyes of rabbits is around 100 milliwattts per cm² for an exposure of four hours to 12 cm waves. Similar figures for human eyes are not available but it is believed they have the same magnitude.

DEATH FROM RADIATION

Exposure of the entire body to radiation may result in injury or death from increasing bodily temperature. Ely and Goldman exposed animals to 10 cm (3,000 mc) waves. Their data indicate that, for dogs, the field strength corresponding to an increase in temperature of one degree C is around 20 to 30 milliwatts per cm². A further increase of five or 10 milliwatts resulted in several degrees additional increase in temperature and death to some animals.

Barron et al examined personnel experiencing incidental exposure to radiation from radar transmitters for varying intervals during the day for a six to nine month period. Field strengths ranged from four to 13 milliwatts per cm². Changes in the blood composition were noted but the significance is not known. No other effects were traceable to these exposures.

Many papers on radiation effects have been published. These three possibly establish, in order of magnitude, the upper and lower values between which the thresholds of this hazard may lie.

Considering only the formation of cataracts from localized single exposures, the magnitude of the threshold is 100 milliwatts per cm². But for exposure of the entire body, the danger level may be a small fraction of this figure.

Until further and more definite data on radiation effects are available, prudence dictates allowing liberal safety precautions in guarding against this hazard. It is proper in determining these safety factors to consider first, the lack of information on the pathological effects of the different field strengths and second, the possible inaccuracies in field strength measurements or estimates.

CORRECTION OF HAZARDS

Successful safety engineering of a radio transmitter is best accomplished by incorporating safety from the ground up as the transmitter is designed. To design without safety in mind and then backtrack and attempt to incorporate safety is wasteful in time and materials and may be ineffective.

For example, a transmitter designed for safety is arranged so that all necessary adjustments and voltage tests can be made without entering compartments containing conductors or parts energized at high voltages. Sometimes provision for reducing voltage energization is made for parts tested with power on.

For assembling cabinets, separate units in a high-power transmitter, such as transformers, rectifiers, power amplifiers, and throughout all transmitters in the same station, the same protective arrangements should be followed so far as practicable. Such uniformity engenders safety since operating forces can't confuse which cabinet has which type of protection.

SAFEGUARDS FOR EQUIPMENT

The most effective protection for a transmitter, except for lower power transmitters or low-power stages of large transmitters is a system of interlocks, supplemented by devices that automatically ground high voltage wiring when compartment doors are open.

In a well-supervised transmitter station the key-interlock is one of the most reliable systems of protection. Here's how it works: Before entering a compartment, the compartment door must be unlocked with a key from a lock on the power service switch supplying power to the compartment. Before this key is released from the switch lock, the switch must be opened. If the door is open, the key is seized in the compartment lock and cannot be obtained to close the power switch.

If more than one compartment is opened at the same time, there may be a key transfer box arranged so that inserting the power service switch key in this box releases several compartment keys. The transfer box seizes the power service switch key until all compartment keys are returned to this box. There are many variations of the key-interlock to perform more complicated functions.

A key-interlock can provide reliable protection if no master or spare keys are available and keys within or between systems in the same region are not duplicated.

DOOR-SWITCH INTERLOCK

Here's how the widely used door-switch interlock works: When a protected door to a compartment is opened, a switch in turn de-energizes power circuits controlled by the switch. In some cases all power circuits in the compartment may be de-energized; in other cases only the higher voltage circuits.

Assurance that the power circuits controlled by a door-switch interlock are off when a compartment is entered is qualified because a door switch can be easily violated. Also, this arrangement may be unreliable because it depends on the integrity of an electrical circuit and usually on the release of relays and contactors.

The door-switch interlock is often a secondary protection scheme to supplement a key-interlock system. This is good to protect against failure of the latter.

The door-switch interlock also may be used as the primary system of protection but its weaknesses must be recognized and guarded against. The door switch should open the primary power supply without the intervention of a contactor or circuit breaker unless the door movement is prevented by a locking device energized and actuated only after the contactor or circuit breaker is open.

As a supplementary measure to either the key or door-switch interlock, the automatic grounding system is widely used. An automatic grounding system is a mechanical arrangement to ground high voltage circuits within a compartment when the door is opened. In some instances all three systems, the key-interlock, door-switch interlock and automatic grounding system, are used in the same transmitter.

An interesting and effective mechanical interlock system employed in transmitters operated by the British Post Office was described by Wase and Sellwood. Here a flexible shaft interconnects power switch, grounding switch and door locks.

It is not unusual to find a transmitter with arrangements to turn off higher voltage circuits, but with no protection against lower voltage circuits. Men often lower their guard when working in an interlock protected transmitter. They develop a false sense of security engendered by the idea the power is off. Shock from contact with lower voltage circuits still energized may result unless these circuits are adequately guarded.

The well-designed transmitter has control circuits and fan circuits that are not de-energized by interlocks protected from contact by position, tape or plastic barriers.

OTHER PROTECTIONS

Some of the more important safeguards in addition to those already discussed are:

1. *Compartment sides or panels* not protected by a primary interlock system are often welded or bolted from the inside so they cannot be removed without obtaining access to the compartment through a protected door.

2. *Short-circuiting shunts* should be used to discharge high voltage capacitors, the shunts connected automatically when the compartment doors open. In addition, where feasible, permanently connected leakage resistors should be provided across such capacitors.

3. *Grounding sticks* should be provided at prominent safe locations inside compartment doors to make certain that high voltage parts are de-energized before working in compartments containing such parts.

4. Any protection system should be so designed that it will "fail safe." For instance, the electrical circuit of a door switch interlock should be arranged so that if the devices lose power the system will still be safe.

5. *Door switch circuits* should be simple, avoiding cascading of relays especially. Any relays required should be located or protected so they cannot inadvertently be operated by hand or other means while the compartment door is open.

6. *Wire-glass panels* in the compartment doors or walls enhance safety since they permit observation of meters, tubes and trouble conditions such as overheating and broken wires, without opening the compartments.

LOWER POWER TRANSMITTERS

Lower power transmitter or low power stages of high power transmitters can have optimum safety, with minimum effect on maintenance and service reliability by concentrating on positioning, insulating and guarding energized parts to minimize the chances of inadvertent contact. These measures often give better protection than door-switch interlocks alone, which are likely to be violated and the protection lost.

The use of one-half inch mesh rigid plastic screens to cover the energized parts is suggested. Sheet plastic with holes drilled in it is useful for guarding terminal strips and single equipment units. Such screens prevent inadvertent contact with the fingers yet permit insertion of insulated probes or tools for tests or adjustments. Any bare parts that cannot be protected in this manner should be insulated or provided with separate guards.

Adequate external controls and test points, permanently connected meters, effective warning signs, grounding sticks, and safe types of testing probes should be provided.

These measures should be supplemented by interlocks and grounding switches with certain voltages. Sometimes the main power switch is placed so that it is close by the person working on the exposed side of the transmitter. In other cases it may be placed out of view but arranged to lock in the open position, the key kept by the workman.

Antenna lead-ins, current meters, and other parts that might present a hazard from high frequency burning should be placed or guarded so that they cannot inadvertently be contacted or approached too closely by personnel.

It is also desirable to ground, directly or through static leaks, nearby fencing, guys, and wires that might be raised to hazardous potentials by induction. Also antennas and lead-ins that are out of service should be grounded to prevent burns due to high-frequency induction from nearby live antennas.

Arrangements should be provided for locking out and grounding high voltage antennas and associated equipment when being used.

When the antenna switch is opened the antenna is grounded with an operating stick. A warning sign is then locked in place over the switch blades to prevent closing the switch. The key to the lock is carried by the person performing the work.

Antennas and lead-ins should be placed and constructed according to the requirements of the National Electrical Safety Code or such local regulations as may be in force. In particular, crossing antennas and lead-ins with power lines, streets and railroads should be avoided except as permitted by the code.

To minimize the radiation hazard from the antennas at one over-the-horizon station, each antenna is surrounded by an eight foot fence of wire-mesh topped with barbed wire. The gate to each fence has a key-interlock so the gate must remain closed if the transmitter supplying that antenna is operating.

The fence prevents climbing the feedhorn tower and consequent exposure to the main beam. It also prevents recurring exposure of operating personnel to spill-over radiation in the area surrounding the antenna. Beyond the fence in front of the antennas the field strengths are within the safe range to heights well over a man's head. Swampy wasteland extends in the direction of the beam to such a distance that structures that might extend above the safe zone are not to be expected.

The most effective safety device is a careful, well-trained, safety-minded man. Station personnel must think and practice safety, not on occasion, but constantly. To achieve proper safety attitudes requires continual training, ever-present safety reminders, and management's day-by-day demonstration that it is sincerely interested in safety.

Only the very best in physical safeguards and the very best in safety performance by personnel will eliminate accidents.▲

CONTROL OF HEALTH HAZARDS OF ELECTRICAL INSULATING MATERIALS

by E. G. MEITER

director, Industrial Hygiene div., Employers Mutuals of Wausau, Milwaukee, Wis.

Electrical insulation is a design factor of great importance and engineering significance. It is absolutely essential to every electrical device and is the keystone to reliability of electrical equipment. Experience has shown that most failures in electrical devices are the result of insulation breakdown, caused by heat, oils, aging or the presence of voids, and by contributing mechanical fatigue of the insulation by scraping, bending or vibrational forces in rotating devices, such as motors and generators.

Resins of material or synthetic origin are the most widely used materials for electrical insulating purposes. The early insulating materials consisted of natural occurring film-forming gums dissolved in suitable solvents. These resins are relatively non-toxic and, therefore, introduced little or no health hazards into the electrical industry.

The material occurring resins, however, had insulation properties which left much to be desired. Consequently, there was a constant search for new and improved insulating materials. About 50 years ago, Dr. L. H. Baekeland announced a phenol-formaldihyde synthetic resin. This was the first synthetic resin used for insulating purposes and is still widely used.

SYNTHETIC RESINS

During the past 20 years, a variety of additional synthetic resins have been developed, which are used for insulating purposes, as well as many other purposes. The more important ones are: vinyl, polyester, polyethylene, fluorethane, silicone and epoxy. These resin materials are now available in a great variety of formulations, depending on the properties desired.

The published information available on the toxicology of plastics ranges from meager to quite complete. Adding to the meager side of the ledger is the fact that the plastics industry is progressive and its research chemists are constantly developing new formulations utilizing many chemicals for which the toxicity is not known.

Since there are several hundred plastic formulations and the health hazard information is incomplete, this paper will cover the health hazards of the electrical industry in fairly general terms. The materials discussed serve mainly as illustrations and it is not intended that only those mentioned require special handling. Likewise, it should be understood that those not mentioned should not necessarily be considered non-toxic.

Judging from published information, the health hazards resulting from the plastics as commonly used for insulating purposes are not of an extreme nature. They can be controlled, in most instances, by the ordinary environmental personal and mechanical protection methods used in industry today.

The principal problems encountered appear to be dermatitis and sensitization dermatitis.

It is the writer's experience that more difficulty is being experienced at present with dermatitis from the use of epoxy resins than any others, consequently, this group of resins will be discussed first.

Among the resins used for electrical applications, the epoxies, a relatively new type of plastic are showing great promise. These resins are being used for the encapulation of electrical components as potting compounds, adhesives, laminating coatings for cloth, and as surface coatings for metals and electrical equipment.

These resins are usually supplied in the form of two reactive components, the resin itself and the "hardener" or curing agent. Mixtures of these two are capable of transformation at room temperature or moderately elevated temperatures into solid infusible substances. In practice the resin is mixed with the hardener immediately before use and then applied to the desired point.

The potential health hazard from epoxy resins is direct skin contact which may cause skin irritation and contact with the vapor may cause irritation of the eyes, nose and throat. The uncured resin can cause skin sensitization in a small number of those individuals who come in contact with it, and dermatitis in others if the exposure is great enough.

The hardeners, which generally are amines, are irritating to the skin and the vapors are irritating to the eyes, nose and throat. They are both primary and sensitizing skin irritants. Everyone coming in contact with them will develop a skin reaction if the exposure is severe enough.

TYPES OF IRRITANT

Because these resins are both primary irritants and sensitizers, it may be desirable to define these terms at this point. A "primary irritant" causes dermatitis by direct action on the skin at the site of contact, if permitted to act in sufficient intensity and quantity for a sufficient time. Examples of skin irritants are strong acids and alkalies.

A "sensitizer," on the other hand, does not cause demonstrable skin changes on first contact but it may affect the skin so that after five to seven days or more further contact will cause dermatitis. Examples are poison ivy, formaldehyde and certain synthetic resins. Primary skin irritants may also sensitize persons exposed to them so that they may develop dermatitis from low concentration which would not have affected them before sensitization.

The matter of skin sensitizations by an epoxy resin is well illustrated by a dermatitis case that recently came to my attention. An employee applying the catalyzed resin broke out with a typical epoxy resin dermatitis. He admitted that he had been careless and contaminated his skin. In short, he had sensitized himself. He was treated by a doctor and returned to work. The superintendent of the plant was well aware of the dermatitis hazard due to epoxy resins and placed the man on another job away from further exposure.

His condition improved daily until he was nearly cured. The employee then became dissatisfied and wanted his old job back. The superintendent, against his own better judgment then gave in and returned the man to his original job. The story is short. He worked just one day and that very night his dermatitis broke out again. It now not only reacted on his hands, but spread, running up his forearms. The moral is obvious. Once one becomes sensitized to the amine catalyst he must stay away from further exposure until completely cured and then double his precautions thereafter.

PREVENTIVE MEASURES

Some bad practices which may cause or aggravate cases of dermatitis are: wiping contaminations from the skin with dirty rags impregnated with solvent and resin; wiping perspiration from the face and neck in hot weather with contaminated hands or rags; failure to wash hands before touching other parts of the body. Therefore, it is important to adopt preventive measures as outlined below.

Supervision

Close supervision is essential to make certain that the employees follow the necessary safety precautions. It is not enough to say we have provided the necessary control facilities, and let it go at that.

The individual worker should be trained by an experienced person to use these resins and hardeners and taught that traces of resin on work tables, floors, chairs, machines, door handles, pencils, clothes and shoes may be the source of skin inflammations.

Avoidance of Skin Contact

Direct skin contact especially should be avoided. The most positive means of preventing skin contact is through the process of mechanization. Mixing the components and pouring the uncured resin can be mechanized to the point where skin contact is minimized. In cases where manual handling is necessary, impervious gloves and/or barrier creams, aprons and sleeves should be worn.

Before work commences, paper or other disposal covering should be placed over all work surfaces to catch resin drippings. These disposal coverings should be placed in suitable containers as soon as the work is completed for the day. Contaminated rags should be handled with gloves.

Tools should also be cleaned. The solvents most effective for epoxy resin removal

are usually flammable, and should be stored in safety cans. It is important to avoid skin contact with these solvents as well as the resin.

Local Exhaust Ventilation

In general ventilation is secondary to the need of preventing direct skin contact of the skin with the resin, hardener or solvent. However, local exhaust ventilation should be provided wherever volatile components are present during weighing, mixing, pouring, and curing operations. The need for ventilation depends somewhat upon the type of hardener used, and its volatility. Some curing operations may not require local exhaust ventilation, provided they are performed in a large work area which has good general ventilation.

Washing Up

Solvents should rarely be used for removing resin stains from the skin. If in certain instances it is absolutely necessary, the solvent should be fresh, and not contaminated with resin. Thorough washing with soap and water at frequent intervals should be stressed. Several hand-cleaning compounds specially designed for epoxy resin removal are now on the market and should be of help in washing up and thereby avoiding the use of solvents.

Medical Treatment

If dermatitis does occur, a doctor's care is advised. The sources of a dermatologist is usually the most effective.

POLYESTER RESINS

The term *polyester* covers a wide range of materials that have one thing in common, the copolymerization agent employed. For electrical insulation monomeric styrene is sometimes used. This is commonly polymerized with organic peroxides.

Normally the polyester portion of this thermo-setting resin is not much of a problem. However, the styrene portion presents both a potential dermatitis and inhalation hazard.

Gloves and aprons of nonsoluble plastic should be worn where splashes or contact with the styrene monomer are likely to occur.

Both the styrene liquid and its vapor when in sufficient concentration are irritating to the eyes and respiratory tract. Prolonged exposure to high vapor concentration is capable of producing systemic effects.

Under certain conditions, therefore, downdraft ventilation is desirable for the taping operations following the impregnation of the coil with this resin. After the coils have been removed from the impregnating chambers local exhaust ventilation to the outside of the building should be installed for removing the styrene until the coils are cool enough to be stored in a cold chamber, which also needs to be ventilated.

Where catalysts, such as, methyl, ethyl ketone peroxide and benzoyl peroxide are used, skin contact must be avoided because those materials are also skin irritants. Due to the fact that these catalysts are active oxidizing agents they must be stored and handled with extreme caution to avoid fires and explosions.

Another word of caution—in no case should accelerators, such as, cobalt, naphthenate be mixed directly with the organic peroxides, since such mixtures may decompose violently.

PHENOL-FORMALDEHYDE RESIN

Although some of the polyester formulations are not considered classical dermatitis producers, we find that a potential hazard exists when employees remove the cured resin from the skin with a solvent such as acetone. As a preventative, it has been found helpful in many cases to provide a water soluble barrier cream for application before starting work. Since the cream is water soluble, the need for the solvent is nil and a potential secondary dermatitis hazard is eliminated.

Phenol and formaldehyde combine in the presence of a catalytic agent to produce phenolic resins. This resin is a non-conductor of electricity and widely used for electrical insulation purposes. It is available in both solid and liquid form.

The constituents of this resin either in liquid or powder form are loosely combined until the resin has been cured by heat into an insoluble state. The parent constituents of the resins phenol and formaldehyde, are capable of producing skin and respiratory irritation.

These resins give off more formaldehyde when heat is applied. In a poorly ventilated

area these fumes may have an irritating effect on the mucous, membrane and eyes.

Formaldehyde often acts as a sensitizer causing dermatitis after repeated exposures to the uncured resin or its vapor. As used in these resins it ordinarily does not cause systemic effects.

PREVENTIVE MEASURES

1. Suitable measuring containers, scoops, etc., should be provided so that the resins are handled without skin contact.
2. Where formaldehyde fumes are strong, suitable hoods and exhaust fans should be installed.
3. Workers who handle uncured resins should wash exposed skin surfaces frequently. The keynote of dermatitis prevention is personal cleanliness. Contaminated clothing should be removed immediately, and cleaned before using again.
4. Workers should be required to report skin rash so that they can be referred to a physician familiar with this type of condition for prompt treatment.

TETRAFLUOROETHYLENE RESIN

Because of the unique combinations of electrical, thermal, and mechanical properties, tetrafluorethylene resin (DuPont trade name Teflon) is used extensively by the electrical industry, particularly in insulation for use at high frequencies and high temperatures.

Teflon does not produce skin irritation. Dust, such as may arise from unheated molding powder is also innocuous. However, when Teflon is heated above 400° F small quantities of toxic compounds are given off. Consequently, adequate ventilation must be provided on operations where such temperatures are maintained. Cigarettes or tobacco should not be carried into areas where they could become contaminated with Teflon, because the polymer decomposes during smoking and the fumes would be inhaled.

Polyethylene Resins

High electrical resistivity and good dielectric characteristics, particularly at high frequencies, have made polyethylene an important material in electrical insulation; as far as I am able to determine these resins are inert physiologically.

Vinyl Resins

One of the initial uses of vinyl chloride resin was for electrical insulation. As a wire insulation it combines excellent electrical properties with fire resistance, abrasion resistance and ease of installation. The unplasticized material is free from any essential toxic hazard.

Silicone Resins

Silicones have good electrical properties which are maintained at elevated temperatures. Silicone rubber meets the requirement for extruded insulation and insulation tape, both supported and unsupported. Silicone resins used in combination with inorganic materials, such as, glass, mica, and asbestos provide operation of electrical equipment at high temperatures. Other uses in the electrical industry include dipping and impregnating varnishes and cloth-coating varnishes.

The silicones as a group have a low order of toxicity. They are essentially non-volatile and are physiologically inert and present no hazards.

Gases as Insulating Materials

The more important gases used for insulation against high voltages are the freons, sulfer-hexafluoride, and the fully fluorenated compounds, such as, octafluoropropane. They are reported to be non-flammable and non-toxic.

PUBLIC UTILITIES SECTION

REDUCING MOTOR VEHICLE ACCIDENTS IN PUBLIC UTILITIES THROUGH DRIVER CONTROL

by D. A. WEAVER

professor, Motor Fleet Training Program, Public Safety Institute, Purdue University, Lafayette, Ind.

At a National Safety Congress it is natural to expect new ideas and approaches. Yet the fundamental principles of increasing management control of driver performance have been taught for years. You all practice them. None of us operate without some measure of management control exerted over the actions of our drivers. We are concerned then, in this topic, not with new but with old ideas: we are concerned with re-evaluation and more sharply defined efforts along old and proven paths.

I shall isolate five basic fundamentals which make up management control of driver performance. I shall be concerned not with asking you to do something different, but rather with asking you to do the same things better. Have we in this past year improved our application of these basic ideas? Unless each year sees improvement in our use of these basic controls, we are not working at the driver aspect of our safety program.

Admittedly, our use of these five controls is imperfect. Driver control means that we deal with human factors—the greatest cause of all types of accidents, vehicle accidents and otherwise. We deal with factors as variable and unpredictable as human nature itself.

CONTROL DRIVER SELECTION

Despite this fact, the basic controls of these human factors are definite and tangible even though imperfect. Let's not be confused with the imperfections, but rather let's grasp that driver control does consist of definite and tangible pathways. Let us make each year yield a measurable improvement in the use of those pathways.

We all have some way of choosing drivers. Papers, speeches, and printed materials have been thrown at us on this subject. Rather than new knowledge, ask yourself a question: "Have I improved my techniques of choosing drivers in this past year?" Unless you have worked at sharply defined improvements, a specific and tangible tool of accident prevention has been ignored.

Has intelligent use been made of biographical data on the applicant? Are your physical exams based on standards and the use of physicians who know your need? Do your procedures permit the handiest man to operate your power equipment rather than those specifically authorized? Is driving competence evaluated in your service people who drive incidental to another job?

The topic of driver selection has distinctive features in Public Utility companies. In the first place, most public utilities have a low turnover rate, a helpful factor in any safety effort—if it is utilized. Second, you hire for a variety of jobs in which operating a vehicle is incidental to other work.

COMBINE DRIVING SKILL TO JOB

Your task is to incorporate driving competence into the job descriptions, job requirements, hiring procedures, and promotion practices of your company. And you have a third feature in a variety of power equipment—cranes, trenchers, trimmers, excavators, diggers, bull dozers and cats. Choosing operators for this equipment is a training task not a selection task.

In my contacts with public utilities, the opinion was unanimous that these jobs did not require extraordinary mental, or personality, or physical traits. Rather, you needed a man with proper driver qualifications and then give him experience and training on the specialized equipment he is to operate.

Choosing operators of specialized equipment is thus more a function of training.

So we have glanced at a pathway, a control, the control we call driver selection. My point is not new knowledge. My point is that we should recognize selection as a tangible and definite control, and our safety efforts each year should include sharply defined efforts to use that control more effectively. Unless we consciously assign ourself this task, we are ignoring one facet of our accident prevention program.

DRIVER TRAINING

We can glance at a second control of driver performance—training. This idea is old and deeply imbedded in our mind. Of all the tools of accident prevention, training is the least used and last undertaken. This is a pity for training can often yield dramatic reductions in accident frequency. I point to the U. S. Post Office department. Here is an operation of thousands of vehicles operating all over the nation.

Civil service procedures precluded any revolution in personnel or procedures. In a huge bureaucracy, fundamental safety controls could only be applied slowly. But training could be applied immediately. Their training program was not high powered; training was done by those persons most readily available, few with any background experience. But that training cut accidents in half and slashed accident repair costs by three-quarters.

Training holds a standard of performance before your driver's eyes, a standard which he is challenged to reach. Any man does better if he clearly knows what is expected of him. Training gives knowledge; it improves skills; it changes attitudes—but more important our people respond to an awareness that management is putting time and effort on safety instead of just finding new ways to scream, "My Goodness, be careful."

CUT OUT BACKING UP

Why don't we train more? Is it time, money, lack of competent supervisors, lack of skill? Yes, it is all of these, but the primary failure is intellectual. In the huge mass of things that can be taught, we fail to identify in our mind those one, two, or a dozen things that can actually be done in the present circumstances.

When was the last time you sharply defined an item of training and put the burden of training on your supervisors? You can't tell your supervisors to train all their men to drive, but you can tell them to teach their men to position their vehicles so that they never back up except when absolutely unavoidable. Perhaps as much as three-quarters of all backing is unnecessary. Cut down unnecessary backing and you cut out a lot of backing accidents.

If we ask for a training budget, or time on the clock for training, most of us will get little support for training from management. But we don't have to ask for money, at least not as a first step. We can start doing a better job of training without first getting approval of a budget. My favorite example is the brief and potent bit of training that can be done with a brake detonator. You can do a job of teaching and demonstrating in 20 minutes with 20 men, though it deserves more time. All safety men know of this device and know how quickly and interestingly it teaches facts of braking distance, speed control, and following distance. I've never met a safety man who wasn't impressed with the teaching quickly conveyed by a detonator, but I so seldom meet a safety man who took the time to use it on his drivers.

Yes, we can do a better job of training even in present circumstances—both training the new man and continued in-service training. The primary failure is intellectual—that we fail to define short and specific training projects to convey a specific training item—that we fail to seek a method, a medium, an opportunity to present it.

IMPROVE RECORDS

A third control is our record system. Each year conscious efforts should be made to get better data and get better guidance from it. Personnel records and accident records identify sore spots and give insight into cause and cure. In addition, those of us who can keep the same driver on the same piece of equipment can make tremendous use of vehicle records. In this case, the vehicle record can be pinpointed in driver responsibility and reveal wherein a specific driver needs certain specific training.

Records can be very simple or quite elaborate but each year should see conscious effort to use them better. We all have some means of keeping personnel facts and we all have some means of keeping accident information, and some of us have vehicle records that can be used in the driver control program. Perhaps we can improve the accuracy of our records?

GATHER, STUDY DATA

Do bangs and dents appear on vehicles—and even minor accidents—and no one knows who did it? In a large operation perhaps the problem is to gather the data, or to assemble it for summary and analysis. Or perhaps we can improve by studying our records and not permitting the collection of facts to become an end in itself. For example, a hasty glance at records in one large company revealed a driver with seventeen accidents in one year.

Records even in large operations are frequently misused, in that the facts of each accident are considered apart from the whole picture. Any one accident should produce a review of all aspects of our control program. Records can thus give us the means of constant re-evaluation of all the controls, methods, and procedures of our accident prevention program.

So far we have spoken of three old familiar ideas—selection, training, and records. These fundamentals are specific and tangible, even though imperfect. New ideas develop slowly and are applied even more slowly. Our work in safety consists in truth of constant improvement in these old and basic ideas.

MOTIVATION IDEAS

A fourth control is our use of motivation techniques. These are the teams, contests, posters, awards, bulletins, letters, prizes and numerous other gimmicks and techniques that have proven so effective. Do your motivation techniques need renewed imagination? Are they effectively administered? Is their cost consistent with the results you gain? Are they conducted with leadership with a true response of challenge, competition, better effort, and higher morale?

Are they regarded by your drivers as rewards of merit or rewards of luck? Are you stuck with an ineffective "give away" program that you have neither improved or abolished? Are your motivation techniques a mere collection of gimmicks, tricks of the trade, or have you reviewed in your mind a more sound philosophy of human nature and human motivation which is more deserving of desirable response from our drivers?

Motivation techniques are the oldest tool of accident prevention, but the need for conscious effort at improved use remains a constant challenge.

The fifth control is the whole area of improved management and supervision. This means all those things that enable us to do the other four things I have been speaking of. It is based on the cliche of our business that safety is an expression of good management. It is otherwise expressed that safety is not added on to company operations but is an integral part of company operation, or that safety is a by-product of correct operation, or bluntly, that you can't have safety in a sloppy operation.

IMPROVE MANAGEMENT

Anything that improves safety improves management and, vice versa, anything that improves management improves safety. That's why every study shows that effective safety efforts prove to be merely a part of efficient, "cost-conscious management. Improved management and supervision open an unending vista—job descriptions, safety analysis, job requirements, human relations, company organization, industrial relations policy—these and numerous other aspects of management are part of safety.

We find that safety, especially control of human factors, requires an alert eye on almost every aspect of the business. We must have an alert eye for policies or practices that are actually unfair, or are regarded by the men as unfair. We must spot supervisory practices that cause conflict or poor human relations.

UNLIMITED SAFETY FACTORS

Company policies and procedures relating to labor affairs, to discipline, wage administration programs, vacations, promotions—an almost unlimited list of factors which can lower efficiency anywhere in the organization come under consideration by the safety director.

Thus we see that control of driver performance is made up of basic and old ideas, that new applications and constant improvement must be the aim of the man dedicated

to safety. These fundamentals are things almost as tangible as checking and repairing a leaky valve or a set of brakes.

We at Purdue, in cooperation with the National Committee for Motor Fleet Supervisor Training, offer a five day short course based on these five fundamentals. The course is available at approximately 30 universities around the country. Improved driver control results from conscious effort to improve your methods and procedures in using these tools.

345 KV. HOT LINE MAINTENANCE

by W. P. CARTER
superintendent of transmission, Appalachian Electric Power co., Bluefield, W. Va.

In this country we have had to meet the obligation of ever increasing power demands by resorting to higher transmission voltages. Associated with the higher voltages is a greater demand to keep the transmission lines continuously energized if we hope to maintain a high standard of service. Since it is obviously necessary to perform work on these high-voltage lines from time to time because of damage that may be incurred by windstorm, lightning and other hazards, it is necessary as a part of maintenance work that these lines should not be de-energized to perform such maintenance work.

While hot line maintenance is not new, the problems associated with it are not so well standardized that we can apply the practices that are common at lower voltages to the higher transmission voltages. This involves not only electrical hazards but mechanical as well. Each time we adopt a voltage higher than that which has previously been maintained by hot line practices, we must proceed with caution, since mistakes or lack of recognition of the hazards may have fatal consequences.

CONSIDERED LIMITATIONS

In 1947 during construction and field testing of experimental lines, we, together with our associated companies, began considering the limitations of working the contemplated 345,000 volt lines and stations with wood-stick insulated tools. There are still many who feel that work of this nature is too hazardous for routine maintenance.

But we believe that we have not only developed methods feasible for routine work but that this work is probably less hazardous than is sometimes practiced at considerably lower voltages. Of course, extreme care is mandatory but by recognizing the hazards and with adequate equipment, hot line maintenance work at 345,000 volts is as commonplace with us as is the use of rubber gloves for distribution voltages.

Tools and equipment used for somewhat lower transmission voltages were not adaptable for working transmission line conductors of 1.75 inch diameter, weighing approximately 2.1 pounds per foot and requiring the added lengths to provide enough insulation to assure absolute safety to workmen when working on 345,000 volt lines. Longer and stronger sticks were necessary.

STICKS PROVIDE INSULATION

Twelve feet is now the minimum length for these tool sticks and workmen keep their hands within four feet from the end, allowing eight feet of stick between themselves and the metal tool. Sticks of this length become unwieldy and require skill to manipulate them; all the while the workmen must remain at a safe distance from the conductors while standing on steel frame structures 100 feet or more above the ground.

When replacing insulators, sticks are used both to provide insulation and to carry the load of whatever they are applied to. For this purpose lift and jack sticks have to be longer and of greater mechanical strength. Two lift sticks are used for holding the conductors on tangent towers and one jack stick on dead-ends to take the line tension. Lift sticks are designed for a breaking load of 6,500 lbs. each and the jack sticks for 16,500 lbs. each.

The electrical hazards are not difficult to surmount as long as these hazards are recognized. Obviously it is necessary for workmen to remain a safe distance away from the energized lines. We know that these voltages will flash over distances in air equivalent to about one inch for each 10,000 volts; thus the voltage will flash over a distance of nearly three feet between conductors.

POSSIBLE HAZARD OF LIGHTNING

Since the nominal voltage to ground is about 200 Kv., it will flash over about 20 inches to ground. To these distances must be added a safety factor because of switching surges and lightning which are much higher than the normal operating voltage.

We do not attempt hot line maintenance work in inclement weather; but if a sudden electrical storm catches you on the job protection may be required from fairly high voltages. If lightning strikes a line even though it may be some distance away from the work area, and causes a circuit breaker to operate, it is possible to get two to three times the normal line voltage, which could be a million volts phase to phase or about 600,000 volts to ground.

Hot sticks are normally rated 75,000 volts per foot as a top safe limit so that if a switching surge should occur having a voltage of more than 2½ times normal, the hot sticks would be stressed to the maximum limit of their rating. Switching surges rarely reach this magnitude, but we must be prepared for the worst.

An added precaution against the possibility of overvoltages occurring due to breaker operation while work is in progress consists of having these circuit breakers changed to manual control for reclosing.

If a line should drop out while work is in progress, there would be a five-minute delay for which a hold card is placed on the control switch before the line is re-energized. This provides enough time so that workmen can be in the clear before the line is re-energized.

Another hazard which is not so commonly recognized but which may be of equal importance is the fact that at the higher voltages the space between conductors and towers becomes charged with electricity. If a workman should be within this field, and adequate precautions are not taken, he could, by coming into contact with the tower, receive an electric shock that could so startle him that he might be in danger of falling.

This could happen if a man were standing on a dry wooden ladder which was suspended from a crossarm when he ascended the ladder and touched the tower. This hazard is eliminated by the use of aluminum ladders and by having workmen equipped with shoes having conductive soles.

The combination of the metal ladder and conductive soled shoes eliminates the static charge from the workman's body so that he feels no effect from the charged electric field. Thus, the use of metal ladders is mandatory at the higher voltages whereas a few years ago at lower voltages, their use was prohibited.

PLATFORMS USED

In the performance of replacing defective suspension insulators in a tangent assembly, platforms are a convenient aid for pulling and driving the cotter keys. We, therefore, provide wooden platforms that are attached to the tower at such a point that the workman standing thereon will be within working range of the conductor end of the assembly.

Since in this position a man is in the charged electric field, the platform is equipped with copper braid tacked on to the standing surface and bonded with the hardware of the platform so that it is grounded to the tower. In performing this work conductive soled shoes also are mandatory.

Additional safety precautions must be observed prior to performing 345 Kv. hot-line work. Moisture on hot sticks renders them semi-conducting and therefore no hot-line work can be done in inclement weather.

The weather conditions must be checked not only in the vicinity in which the work is to be done but also in the whole area through which the line extends. A sudden rain or lightning storm could require abandonment of work that is in progress in order to protect the workmen.

In addition to stick work on 345 Kv., we are successfully washing and cleaning insulators on voltages up to and including

345 Kv., with a high pressure water jet. Safety precautions necessary in such operations are as follows and must not be overlooked.

First, the water must be of a high resistance, *sufficient* to avoid electric current leakage into the stream once it is directed against the insulator.

Second, the nozzle and all other necessary equipment such as the pumper, pump truck, ladder truck, tank truck, etc., must be securely grounded at all times.

Third, the nozzle operators must stay and remain a safe distance away from energized equipment.

Fourth, prior to actual washing, a test should be made to determine the resistivity of the water you propose to use. We consider 1200 ohms per cubic inch as a minimum resistance for washing insulators hot.

To double check this test and to be doubly sure there is no current leakage in the stream, taking a bit of additional time, you mount a piece of sheet metal 12 inches x 12 inches at a convenient point on a de-energized bus with a hot clamp arrangement. Then, place the nozzle in a fixed position ungrounded with the stream directed against the plate; then, energize the bus.

The leaking current is measured with a milli-ampere across from the nozzle to ground. If the current in the stream exceeds 3 milli-amperes, we consider the water too low in resistance and unsuitable for washing insulators hot.

THE DEVELOPMENTAL METHOD OF TRAINING FOR SAFE POLE CLIMBING "YOU LEARN BEFORE YOU GO ALOFT"

by LOWELL S. ORTH

area installation supervisor, Southwestern Bell Telephone co., Dallas, Tex.

Some of us believe safe pole climbing equipment has kept better pace than safe pole climbing training technique or safe pole climbing supervision. The pole climbing learner has problems. Men are fearful of learning and fearful while learning. Consequently, learning progress is sometimes slow because of such fears. Their legs do not act right. Some get off the ground before they are prepared. Fatigue, lack of physical development, cause accidents. New men have questions. Gaff cut-out often cannot be accounted for.

The instructor has problems. Men who climb acceptably have had difficulty in safely sharing their skill with others. The trainer finds as many methods being used as there are trainers. Sometimes instructors of pole climbing change methods between men. Others change approaches during the course of training a single man.

We were asking the men to leave the ground before they were prepared to do so. Leg control was uncertain. They were not sure what we wanted them to do, or how they should do it. They would try to climb like the instructor, but it didn't work. Some were fearful. Others fatigued easily, and cut-outs occurred. I became concerned, because the training approaches were getting out of control at times, and responsibility for the safety of the trainees was causing considerable personal concern.

LEARNING TO CLIMB ON GROUND

One of my hobbies was pistol shooting. I knew that a pistol shooter could teach another to hold a pistol, to aim a pistol, to squeeze the trigger properly *without firing a shot;* and when live ammunition was placed in the gun, a creditable job of shooting was done *from the very start.*

If men can learn to shoot creditably *without firing a shot,* why couldn't pole climbing be taught *before* leaving the ground? Why not tell the trainee about climbing before he

starts? Give him the basic detail—permit him to practice. Develop muscle, develop leg control, strengthen the wrists and hands. Loosen the hips. Know exactly what must be done and do it before leaving the ground.

Also, why not permit some over-learning—develop habits through repetition, fortify and discipline the trainee on the ground so pole climbing would be easy when he leaves the ground.

For pistol shooting, we picked up empty milk bottles before matches—sometimes beginning two weeks before shooting. We extended the shooting arm out straight for several minutes. The next day we added water to the bottle. The third day, we added more water, and so on until the bottle was *full of water.* When the heavy target pistols were picked up in matches, they felt light.

Baseball players pick up two and three baseball bats to swing before they go to the plate and then the bat they use seems light.

In keeping with this same idea, leg stroking is carefully and repeatedly done until the trainee moves his legs from *habit.* It becomes difficult to do wrong.

At first, we had difficulty selling the idea of learning to climb poles on the ground. But we have seen an expert swimmer, stomach-down on a kitchen chair perfecting a stroke. Expert golfers get out in the *back yard with cotton balls.* Fighters, boxers—*men who do not fear other men,* spend days with a *punching bag.* Dummies and false lines of stuffing and wood are found on football fields. Flying is taught in the link trainer *on the ground.* It should not seem unusual to anyone if we choose to teach safe pole climbing *on the ground.*

Most new men have difficulty learning where each gaff should go into a pole. Also, a question usually is asked concerning the proper distance or angle between the gaffs or feet. There is a definite target, no matter what size the pole, and the distance or angle between the feet can be forgotten. We explain what and why.

The emphasis is on descent. We do *not* descend in the same manner as we climb. Descent is an altogether different procedure. Men have often experienced gaff cut-out and accidents on taking the first step down. The very first step in descent gives trouble because descent has not been taught. Teach proper descent, and the problem no longer exists. Fail to teach descent, and the trainee is in trouble, when the first step down is taken.

You have seen men *freeze* after climbing. They can't move. Why? They have never been taught to go any direction but up. An extension ladder has often assisted in getting men, who have not been taught descent, back down to the ground. If descent is not taught, leg stroking instead of dropping will be done during descent—leaving an opening for an accident at any time because of lack of leg control and tendency for the gaff to miss the pole completely.

EXPERT SUPERVISION NEEDED

Often unsafe procedure results *in* gaff cut-out—whether or not there is personal injury. When these cut-outs occur, no-one seems to know what happened. Ask the trainee or experienced lineman what happened. He will say "My gaff cut-out." Ask what made it cut-out. He will reply "I don't know." Ask a fellow workman who may have seen the gaff cut-out. He will say "I don't know." Ask instructors or foremen what happened, and the reply will often be "I don't know."

We need foremen, who supervise climbing employees, who know what can and does cause cut-out. We need foremen who can see, in a split second, what can cause cut-out. We need foremen who can spot an unsafe habit in a moment's observation. We should be able to ask what happened and get a real answer. A foreman who is familiar with the necessary detail can tell all about a lineman's basic habit in a very small climbing sample. A few steps up—a few steps down.

Some foremen do a fair job of noticing unsafe procedure, but do not seem to know what to do about it when it is observed. A lineman may not be *at home* on a pole, or moves as if he *is afraid.* Something is wrong about *the* leg stroking. *The whole job is* done questionably and awkwardly. Cut-outs sometime occur. Ask these foremen what they intend to do, or are doing, about the nonstandard procedure. They don't know what to do. Perhaps a poor habit could be corrected in fifteen minutes. Why postpone correction until after the accident occurs?

You can begin as soon as unsafe procedure is noticed.

Approximately 18 hours of training are spread over a five-day week. If schedules are followed, as much can be done in 18 hours as is sometimes accomplished in 40 hours, and more safely. Do not be tempted to cut the recommended schedule short to get men off the ground more rapidly. It takes time to develop what is required to climb poles safely.

Before going aloft, important ideas about *climbing and descent must be understood.* Leg muscles require development. The wrists and hands require development. Leg control must be developed. For these reasons, the approach is called: "the developmental *method* of training for safe pole climbing."

A SUGGESTED TRAINING SCHEDULE

		Hours
First Day (Practice WITHOUT climbers)	1 hr. A.M. 1 hr. P.M.	2
Second and Third Days (Practice on the ground WITH climbers)	1 hr. A.M. 1 hr. P.M.	4
Fourth Day (Climb to five or six Feet)	2 hrs. A.M. 2 hrs. P.M.	4
Fifth Day (GRADUALLY progress to top of 25-30 foot poles)	up to 8 hrs.	8
		18

After the fifth day, most men will be at home on poles and will have acquired the basic conditioning and technique to fortify them against cut-out—permitting them to learn and continue to climb without an accident.

Knowledge of the detail described in the instructor's manual will equip line foremen to observe readily unsafe climbing habits, and to correct them effectively.

Foremen will be equipped to do observing and correcting. The success in these two *abilities makes the approach exceedingly valuable* to men supervising safe pole climbing activity.

The developmental method of training for safe pole climbing is:

Safe—

Gaff cut-out while learning is nearly unheard of. Most training is done on the ground—all within five or six feet of the ground. No fear exists OF LEARNING or fear WHILE LEARNING. The confidence that prevails from the very beginning of training encourages progress. Muscular conditioning and climbing skill is developed BEFORE going aloft.

Efficient—

Now, 18 hours can do what used to be done in 40 hours. Less physical exertion is required when proper technique is used.

Training in Descent—

Men are not only trained to "climb" poles, but are *given adequate instruction as to how* to come down safely.

Anticipates Problems—

Difficulties of men who have never climbed poles before are explained. The ideas and the reasons for operations which give learners the most difficulty are given trainees *in advance of the time they are needed.*

Objective—

The technique makes allowance for the normal physical and emotional differences in men: Often men are observed to climb exactly like the instructor who taught them. The developmental method is objective in *that it is generally impossible to tell WHO* taught them. The basic climbing habit they have learned is not related to the personal and sometimes peculiar climbing habit of the instructor. Each man climbs as he should *climb.*

Scientific—

At first glance, the thought of teaching another to climb poles "without leaving the ground" might not appeal. However, more than 90 per cent of pole climbing training can be given with the learner on the ground, and *the balance with the learner within* five or six feet from the ground.

Whenever physical development and a high degree of physical and mental coordination must be realized, a large per cent of *the training necessary can be most efficiently* accomplished through the aid of "processes" and "apparatus" sometimes remotely related

to the performance of the specific skill sought after. On the ground stroking develops the necessary physical equipment and leg control.

Detailed—

It gives attention to the necessary detail which enables instructors to "spot" unsafe climbing habits in those already climbing poles:

Wrong habits are *those basic climbing* habits that affect efficiency and safety and which should not be allowed to continue.

The effective remedy for unsafe climbing habits readily suggests itself. The approach permits locating with certainty and without delay those few individuals (one in 150 to 200 men) who may be constitutionally fearful of being aloft or have basic difficulty in coordinating movements.

Economical—

The method is economical in both trainee's and instructor's time. What is often accomplished with questionable results in 40 hours is accomplished with more certain results in 18 hours. The time saved is available for other training or for productive work.

The procedure is also economical in timber because of:

1. *No* pole gaffing the first day.
2. Gaffing in only two spots the second and third day.
3. Gaffing up to five feet the fourth day.
4. Minimum gaffing the final day because gaffing is normal.

There is absence of anxiety on the part of the instructor concerning the safety of trainees.

Pole climbing with climbers becomes easy to teach and just as easy to learn.

The simplicity of the development training approach is in marked contrast to the many satisfying results obtainable through its use.

SAFETY IN THE USES OF CYLINDER GASES IN OXY-FUEL GAS WELDING AND CUTTING

by F. C. SAACKE
safety director, Air Reduction co., Inc., New York city

Despite the use of welding and cutting torches involving flammable fuel gases, oxygen, high temperatures and flames, and high pressures, there is no justification for an accident with this equipment.

The characteristics of these materials and processes are well known so these processes can be and are being handled daily with complete freedom from accident or injury. Then why do we have accidents involving these processes? We don't have *many, but the few that occur cause unnecessary* damage yearly and are always capable, as is any fire, of becoming catastrophic in scope.

Do these fires and accidents occur because of a lack of understanding of what constitutes safe practices? Possibly some of them do! But there is a greater probability that the welders and cutters and their *supervisors do not understand their joint* responsibilities for the prevention of accidents.

A man wearing goggles cannot see where his sparks are flying. His whole interest is centered in making a workman-like weld or cut. Protecting the surrounding exposure from fire cannot be solely the welder's responsibility. The supervisor must also know the risks involved and take appropriate *preventive measures* before instructing the welder or cutter to work in an area or before permitting hot work in the area.

Even where the only exposure is possible injury to the operator, the supervisor can *still help. Certainly the welder should* know how to protect himself. But the supervisor still has a partial responsibility!

Whenever conditions differ from the normal, the supervisor should instruct the welder in how to cope with such situations and why they are hazardous. A man will not knowingly weld in or near an explosive atmosphere, or in a room filled with oxygen where a spark may cause his death. But unless the supervisor has specifically trained the welder to recognize these conditions and avoid them, the welder is liable to assume the work area is safe because he was told to weld or cut in that area.

SUPERVISOR MUST HELP

Naturally, the better the workman is trained, the less supervision by his boss is necessary. Unnecessary supervision when the workman knows his job can be resented as readily as it is missed when it is needed. The correct approach must strike a happy medium and is accomplished when the supervisor has recognized his joint responsibility and permits the welder or cutter to operate alone only within the scope of his limitations.

The safe practices needed to guide a welder or cutter and his supervisor past the risks involved in his work are readily available and quite readable. The following list of *organizations publicizing safe practices* for handling compressed gases in welding or cutting is given alphabetically together with some of their publications. The most comprehensive is the ASA Standard Z49.1. However, for oxy-acetylene welders and cutters, the IAA pamphlet will be the most applicable.

*AWS—ASA—Z49.1—"Safety in Electric and Gas Welding and Cutting Operations"

CGA—G1—Acetylene Data Sheet
G4—Oxygen Data Sheet
P1—Safe Handling of Compressed Gases

Equipment Supplier—Recommended Safe Practices in Cutting and Welding (See Airco)

**IAA—"Safe Practices for Installation and Operation of Oxy-Acetylene Welding and Cutting Equipment"

ICC—Interstate Commerce Commission Specification and Regulations—Freight Tariff No. 10

Insurance Company—Safety Data Sheets

City Codes and Ordinances

MCA—SD7—Acetylene

NBFU—#51—"Standards for Installation and Operation of Gas Systems for Welding and Cutting"

NFPA—#51—"Standards for Installation and Operation of Gas Systems for Welding and Cutting"
—#58—"Standards for Storage and Handling of Liquefied Petroleum Gases"
—#566—"Standards for Bulk Oxygen Systems on Consumer Sites."

NSC—#95—Safe Practices Pamphlet on "Compressed Gases"

State Regulations

USAEC—#2—Safety and Fire Protection Bulletin—"Hydrogen"

*American Welding Society Inc.
33 West 39th St.
New York 18, N. Y.

**International Acetylene Assn.
205 East 42nd St.
New York 17, N. Y.

However, these publications are too long for an effective discussion. Instead, I would like to touch briefly on the compressed gas containers into which these gases are packaged, describe briefly the gas properties in which we are most concerned, and explain the reasons behind five recommended safe practices which, in my experience, would prevent the large majority of accidents and injuries caused by improper handling of these materials.

TEST EACH CYLINDER

The cylinders are manufactured under ICC Specifications and given rather complete individual inspection and tests. The high pressure (over 500 psi service pressure) cylinders are of seamless construction; the low pressure (under 500 psi service pressure) are usually of welded construction.

Each individual cylinder is tested to make certain that it is tough, ductile, strong, tight and will act elastically under service pressure filling at temperatures as high as 130°F. In addition, safety devices consisting of relief valves, fusible plugs, frangible discs or combinations of these devices, are used to protect the cylinder from exposure to temperatures above 130°F.

In general, the weakest part of a cylinder is the valve so that it is important to keep the valve protection cap in place when the cylinder is not in use.

I don't believe that people need be reminded that pressure vessels should not become exposed to fires. If they need advice, it should be to the effect that the "safety" relief valves can limit the maximum pressure to which the vessel may be exposed, but that this maximum pressure may be more than the vessel can withstand at excessively high temperatures.

When transferring gas from one cylinder to another, the possibility of overfilling is a constant one. Pressure gauges must be accurate, pressure regulation reliable, and the state of the gas under operating pressures understood.

For instance, gases such as propane or carbon dioxide are partially liquid at charging pressures. However, the vapor space over the liquid should be the result of precise control and not chance. Liquids, even water, expand faster than steel shells when heated—and unless a vapor space is present to permit the liquid to expand freely, the cylinder is likely to rupture if it is filled "liquid full" and subsequently warms up. If the cylinder is filled "liquid full" while chilled, the cylinder may fail before it warms up to room temperature. For these reasons, the industry ordinarily recommends against transfilling by other than charging plants.

PROPERTIES OF GASES

Some of the properties of the compressed gases in which we might become interested are:

Density—Does the gas rise or sink when released in the atmosphere according to whether its molecular weight is lower than, or greater than approximately 29 for air?

Flammable range—Will the gas burn over a wide range of concentrations in air?
Hydrogen 4—75 per cent
Acetylene 2.5—81 per cent
Propane 2.2—9.5 per cent
Heptane 1.2—6.7 per cent
Is the lower limit of flammability (LEL) so low that small leaks can sustain greater volumes of air to ignition and explosion?

Phase—Does the compressed gas liquefy under cylinder pressure so that a vapor space must always be present in the cylinder to avoid the high pressures which will follow when a "liquid" full cylinder is warmed?

Pressure—How high is the pressure in the cylinder and do we have adequate pressure reducing regulators and over pressure valve protection?

Oxidizing—How clean must we keep oxygen metering equipment?

But where should a safety engineer begin in his approach to educating the welders and cutters and their supervisors?

JOINT RESPONSIBILITY

First, I believe both the individuals performing hot work and their supervisors should be taught to recognize a joint responsibility for the protection of the individuals performing the hot work and for the protection of the surrounding property.

Where a man's life or well-being is involved, the workman should be in a position to satisfy himself that the job can be safely performed. Where the building, equipment, or property can be jeopardized, and regardless of the training of the workman doing hot work, the supervisor should feel a special responsibility to see that the workman cannot cause severe damage.

My personal feeling is that the failure to recognize joint responsibilities has permitted so many fires to occur, particularly where construction, repair, maintenance, or demolition operations involving hot work have been performed in areas not customarily exposed to hot work. Not only have the workmen and their immediate supervisors often failed to recognize their joint responsibilities—but too often the management personnel on the premises involved have also failed.

Where an outside contractor is involved, a misguided effort to economize can overemphasize the need for speed with insufficient attention to preventive measures. When this happens with building and maintenance crews, the lack of adequate preventive measures cannot be justified. The excuse that one is covered by insurance collapses under experience rating practices.

Next, in order to discharge their responsibilities properly, I would suggest that a suitable reference source of safe practices be chosen, studied, and followed.

USE SAFETY REFERENCE FORMS

The most comprehensive of the pamphlets listed heretofore is the ASA Standard Z49.1. This should be the supervisor's reference. He may also avail himself of any or all of the other pamphlets listed—but the ASA Standard has been compiled by all interested technical groups.

For the welder or cutter, I would suggest the IAA pamphlet: "Safe Practices for Installation and Operation of Oxy-Acetylene Welding and Cutting Equipment." This covers the best way to handle compressed gases and should be supplemented by whatever recommendations are provided by the supplier of the equipment he is using.

Finally, I would suggest that every effort be made to sell your supervisors on the value of all the safe practices listed. Everyone of them is the result of a past history of accidents or injuries. Sometimes the reasons for the recommended safe practices may not be apparent, but ordinarily they need little explanation. What is most important is having the supervisor start his men off on the right foot and correct them the first time anyone gets out of step.

Since there is not sufficient time to explain the accident experience behind all the recommended safe practices listed in these pamphlets, I would like to take the remaining time available and describe, from my own experience, the results of failure to follow several of the more frequently violated safe practices.

SAFETY VIOLATIONS

These five safe practices, based upon the use of equipment and gases furnished by reputable manufacturers, are believed to be the most frequently violated safe practices and responsible for the major number of accidents, fires, and injuries. Because they are so frequently violated, it should be of equal importance to consider the individual's reasons for these violations.

1. KEEP EQUIPMENT IN GOOD CONDITION AND CLEAN particularly with oxygen where oil is hazardous.

The results of a study of accident reports last year involving compressed gases in welding and cutting where sufficient information was available to justify a conclusion as to the cause indicated that 31 per cent were caused by poor maintenance.

In one case, a check valve element had been removed to permit a slight increase in flow capacity. Two inlet screens had been removed from oxygen regulators after they became clogged, and were not replaced. An oxygen recording gauge was tested with oil. In another case, an oxygen regulator had become oily from careless handling and storage. The final accident in this group was the result of a corroded pipe line caused by burying in cinders.

2. AVOID GAS LEAKS

During this same year, 38 per cent of all accidents reported were traced to gas leaks —usually of the flammable gas. I wonder how many of the welders or cutters in your company operations can be seen with a bottle of soap suds and a brush? Some typical accident reports are reproduced verbatim:

> "Fuse plug leaking at threads. Ignited by cutting sparks. Smothered by glove. Plug showed evidence of damage from blow."
>
> "Arc welding overhead and sparks ignited acetylene leak at regulator connection."
>
> "Operator burning overhead. Sparks ignited leaking acetylene—causing fuse plugs to release. Operator stated after hook-up of regulators and hose, noted odor of acetylene gas. Turned valve all the way out to limit—thinking to force bottom of stem against packing. Operator believed leak to be stopped. Attempted burning operation which resulted in fire."

Do not let your workmen sell you idea that they can see any leak that may ignite while they are present. Consider the following report:

> "A welder was using steel electrodes about six feet away.— (someone) saw flames near the arc welder. He shouted to him and made welder aware of danger. Shop personnel could not put out fire and called fire department. Firemen confined fire to cylinder and let it burn itself out in about half hour."

Besides the risk of property damage from fire due to leakage of fuel gases, there is the additional danger to personnel from leakage of oxygen. Consider the following:

> " . . . a fatal accident occurred aboard the . . . ship while under construction. A pipe fitter, working in a tank on the 4th deck, struck a match, lit a cigarette and threw the burning match to the deck. His clothing was almost instantaneously enveloped in flame." The accident investigation indicated that both the tank and the victim's clothing had become saturated from a hose line that had been inadvertently turned on."
>
> " . . . a fatal accident occurred aboard the . . . ship while installing sprinkler piping . . . when the welder first struck the arc, a flash fire resulted and ignited his hair and then spread to his clothing."

MATERIALS IGNITE RAPIDLY

Most people, because of their familiarity with an oxygen cutting torch, appreciate the rapidity with which combustible materials burn in contact with oxygen. What they may not be familiar with is the rapidity with which materials ignite in oxygen.

When a workman's clothes are soaked with oxygen or when standing in a room with the oxygen content up to 30 to 40 per cent, a spark coming in contact with cotton, wool, denim, corduroy, or even asphalt tile and wood may break into flame immediately and sweep over the entire surface of the clothing in a second.

Prevention starts by preventing high oxygen concentrations in work areas. If welding is to be done in a small compartment, the cylinders and regulator are left outside and the torch kept inside only during the work period. It is preferable to purge and light outside and then bring the lighted torch into the compartment for as long as the welding or cutting is in progress.

3. PURGE OXYGEN AND FUEL GAS LINES BEFORE LIGHTING

About nine per cent of the accident reports in this group were the result of failure to purge gas lines before lighting. Typical accident reports always mention the gas being lit at the time:

> "Operator was lighting up a cutting torch—As he lit the torch, it backfired and set the acetylene hose on fire approximately 12 inches behind the torch."
>
> " . . . Operator was adjusting torch in preparation to start flame cleaning. Torch backfired and attempt was made to relight. A popping noise was heard and fire started burning at the acetylene regulator."
>
> " . . . Started to light cutting attachment with spark lighter and as he used the flint—the torch backfired and ignited the hose."

FLASHBACK CAUSES

These flashbacks occur when the gas lines feeding the mixer have been contaminated. Not only can the two gases being used be found mixed in either line by feedback through the mixer, but air can contaminate the fuel gas line. This condition is quite unusual but operating mistakes do occur. For instance, air will be found in acetylene hoses if the torch valves have been left open over a weekend shut down.

To take care of the occasional failure to keep torch valves closed while not in use, it has become established practice to purge each line for several seconds (or longer depending upon the hose capacity) before lighting. When purging before lighting becomes automatic, the possibility of flashbacks traveling back past the mixer and into the hose and regulators and even the cylinders will be eliminated.

4. OPEN CYLINDER VALVES SLOWLY

Despite the fact that no accidents were reported on this category during the period being summarized, the precaution is being repeated since we cannot afford to forget it.

The sudden application of 1800 to 2400 psi of oxygen to regulators can develop fires if the equipment has not been kept clean, if worn and leaking seats have not been replaced and if the inlet filter screens are damaged or missing.

While our main concern may be fire, we still should not forget that these gases are under high pressure and that the pressures should be applied slowly to the equipment for most reliable operation.

5. KEEP HEAT, FLAME, AND SPARKS AWAY FROM COMBUSTIBLES

Of the accidents summarized, six per cent were caused by doing hot work near combustibles (other than the fuel-gas supply). Nationwide, only one-half of one per cent of all fires were caused by welding and cutting. In 1956, the one-half per cent ac-

counted for 4,300 building fires costing eleven million dollars.

The need to separate combustibles from hot work or to protect by tarpaulins or screens is usually understood but I am afraid what is not understood is who should have anticipated a fire and acted to prevent it.

PERMIT SYSTEMS

Hot work permit systems are in use by all safety-minded organizations to cover areas not ordinarily subject to the hot work proposed and are doing an effective job—particularly where the individual issuing the permits knows fire prevention and extinguishment techniques, applies them in accordance with the risk involved, and maintains the respect of the personnel performing the hot work.

The fire permit must take into account the type of work, its location in the plant or building, the degree of hazard from the surrounding exposure, the adequacy of accessible fire extinguisher equipment and trained firefighters available, and the need for fire watchers after the job.

Wherever the hot work permit system is established, the first major step in the prevention of welding and cutting fires has been taken.

Safe working practices are available covering all possible situations. The problem is to make personnel who are responsible for supervising welding and cutting operations aware of the probabilities of an accident (not just the possibilities) without overemphasizing the hazard involved.

Safety engineers interested in safety in welding and cutting should familiarize themselves with the ASA pamphlet Z49.1. Supervisors also should be familiar with the IAA pamphlet: "Safe Practices for Installation and Operation of Oxy-Acetylene Welding and Cutting Equipment." Welders and cutters should not only be familiar with the IAA pamphlet but should also have studied the recommendations of the manufacturers who have supplied the equipment being used.

Wherever hot work is done in areas in which welding and cutting are not ordinarily performed, the hot work permit system should be followed with particular emphasis on outside contractors.

Finally, accident prevention activities should be based upon training of welders and education of their supervisors not only in the techniques of safe operation but in their joint responsibilities to see that these techniques are followed.

HOW TO SET UP AND MAINTAIN A GAS UTILITY SAFETY PROGRAM

by MARK FLAD

director of safety, Dayton Power & Light Co., Dayton, Ohio

You cannot be concerned with just the mechanics of setting up a safety program. Accidents will develop unless we work at preventing them. We must believe:

- Accidents can be prevented.
- It is good business as well as humane to prevent accidents.
- Accidents are symptoms of something wrong.
- The development of most accidents reflect back to supervisory and executive forces.
- Safety must be an integral part of every job.
- Certain responsibilities must be assumed by executives and supervisory forces before a safety program can really be effective.

Three groups of people who must assume responsibility before any safety program can achieve results: the executive, the supervisor and the employee.

First, the executive must recognize the need and authorize the cost of a safety program. He has to follow up and check results of the program, and actively support the safety program. Lastly, the executive must subscribe to a written safety policy, such as:

a. "There is a safe way to perform every job in the conduct of our business."

b. "There is no job so important or pressing that safety can be by-passed in any way."

He must sign this policy and back it up without exception.

Second, the supervisor must provide adequate tools, equipment and materials for the job, and protective equipment whenever necessary. He should offer adequate training necessary for safe, efficient job operation and give job demonstrations that convince.

In addition, the supervisor must be tolerant, understanding and impartial in dealings with workers. He must be a real salesman of safety.

The role of supervisor is a difficult one. He must sell his program by generous portions of sincerity, accompanied by a good, wholesome sense of humor. He must demonstrate a point so clearly that each employee will completely understand.

For example, have you had difficulty selling your gas workers on the idea that a dead-end must be securely anchored for a leak test before letting the pipe down in the ditch? Here is a simple convincing demonstration:

A short piece of pipe is placed in a vise with a coupling and dead-end on one end; the other end is open. Several men are handed 1-inch square sticks and asked to insert the sticks in the open end of the pipe against the dead-end and push to the pressure of approximately 90 pounds. (A bathroom scale is provided to get the feel of 90 pounds pressure.)

As more sticks of varying length are provided the increased pressure starts to move the dead-end off the coupling. The participants and observers are definitely sold on the extreme pressure of 90 pounds per square inch acting against the dead-end. Figuring the area of the head of the dead-end multiplied by the pounds per square inch applied, now takes on a very practical meaning in the minds of crews.

Here are some additional helpful hints for the supervisor:

He should have first aid training and urge all employees to do the same. His group safety meetings should be short, crisp and interesting. Contacting at least one individual each day about safety is effective and conducting regular inspections and occasionally a surprise inspection by a special committee is most effective.

The supervisor should delegate part of the job to employees, and never hesitate to spend money to eliminate a hazard or unsafe procedure. He should have a safety committee representing executive, supervisory and employee groups, and consider all suggestions and take action.

He must make it easy for employees to report all accidents regardless of how minor the injury, and then he, himself should investigate all accidents and act on the basis of facts to prevent reoccurrence. When the supervisor needs help, he can share the problem with:

a. the boss.
b. fellow supervisors.
c. employees.
d. local safety council.
e. National Safety Council.
f. American Gas Association.
g. any safety man in area—there are no secrets in accident prevention work. Every safety man is eager to give time and apply his knowledge and experience to the problem.

Each employee must be made to feel that he has a personal responsibility for working safely. This is the specific selling job of first line supervision.

Whether you are an executive, supervisor, or safety man, for any gas utility, regardless of size, here is what you personally need in order to set up and maintain a really effective safety program:

- Courage to stand by your convictions and an honest fear of real hazards.
- Tact enough to disagree without being disagreeable and brass enough to command attention.

- Dedication to work constantly toward the objective and humor enough to laugh at yourself when the joke is on you.
- Drive to overcome obstacles and patience to get results before being discouraged.

This is a personal challenge. We know it isn't easy, but we all agree—"It will work."

Water Utility Safety

WHAT'S NEW IN WATER SAFETY—1957?

by RAYMOND J. FAUST

executive assistant secretary, American Water Works Association, Inc., New York city

I am pleased to report the water works industry is rapidly becoming safety conscious. We know this because of the number of letters we receive on the subject; the continued popularity of the "Safety Practice for Water Utilities" manual and the decrease in both the frequency and severity rates for the industry.

Last year I reviewed the safety award plan which the American Water Works Association Committee on Safety Practices developed. In January 1957 the award plan was presented to the Board of Directors of AWWA, and was approved. Since then the committee has implemented the Board's action. For example, section committees on safety were established. To date 22 of the 30 sections have safety committees, and the remaining will establish committees in the near future.

Section safety committees are important because they have direct contact with the management of the local water utilities, and are in a favorable position to "sell" the safety program. In addition, the section safety committee gathers all the statistical evidence to determine the utility section award winners; it promotes and selects program material on safety for the annual section meeting; it also chooses the section candidates for the AWWA Wendell R. La Due Safety Award. Thus the section safety committee is an important cog in the safety program in the water industry. Its activity can make or break the whole program. Fortunately, the section committees are doing a splendid job. Several bold regional safety meetings for utility operators to familiarize them with the rudiments of the program. Work of this character can only produce favorable results.

A special report form for submitting information on utility safety was prepared and sent to all section committees. The form is short, with only seven questions. It is hoped that each section will obtain a good response to the questionnaire, and can select winners.

SECTIONS COMPETE FOR AWARDS

Section awards will be announced and presented at the annual Section banquet. The presentation will be dignified and impressive, and we hope the recipients will have them framed and hung in a prominent position in the utility office. By giving publicity to all awardees, competition should soon develop among the utilities for top honors.

Although it is an honor for a utility to win an award, the big winners are the employee, the utility, and the public. The employee wins because he is well and on the job, earning a full pay check; the utility wins because it has its trained employees on the job doing superior work; the public wins because it is receiving better service from trained personnel.

Everyone wins when the services of trained workers are available for the day, the week, or the year. The answer to good utility operation is quite simple—work safely and have the trained personnel stay on the job—it pays! Water works management is learning this fact, and is starting to do something about it.

One obstruction delaying a safety program adoption in some water utilities is the slow acceptance of safety equipment as a necessary part of utility operation. For example, the simple act of providing safety hats for a water main construction job is resisted in our industry.

ADVERTISING CAN SPEED UP PROGRAM

To overcome precedent in safety in our industry, the committee on safety practices is enlisting the aid of manufacturers who advertise in the Journal of AWWA, as well as trade journals. A review of the present advertisements shows that few, if any, include safety features. For example, a manufacturer of pipe often shows in his advertisements an open trench with pipe being installed. The workmen in the trench laying the pipe are wearing ordinary headgear.

Water works employees not trained in safety see these advertisements but are unaware the picture represents an unsafe practice. However, trained and alert executives and employees notice the omission immediately. If advertisements do not show employee safety features they may inadvertently discredit the manufacturer and his product as not being up-to-date.

The number of advertisements that can show safety features is limited to a small percentage of the total. The majority of advertisements could not normally aid in promoting a safety program. To overcome this deficiency and give all advertisers an equal opportunity to support the program, one manufacturer suggested AWWA provide advertisers with a small cut calling attention to the safety program. This idea has been considered carefully, with the result that the committee is now developing one for manufacturers in their advertisements.

Instead of trying to promote the regular use of these cuts on a monthly basis, it is presently considered advantageous to have the Board of Directors of AWWA establish by declaration, a *Water Works Safety Month* each year, at which time the safety program would be featured. The AWWA Journal would carry papers on safety, while the manufacturers might feature in their advertisements the safety device built into their equipment, and also use the safety cut AWWA would supply to them.

By concentrating our efforts, the safety program could be given added impetus and brought to the attention of the executives of the water utilities. Such a program would have a far-reaching effect.

HOW AND WHERE TO GET STARTED

by V. A. APPLEYARD

chief, Water Operations, Philadelphia Water Department, Philadelphia, Pa.

In 1952—our city started operating under a new charter—which set up water and sewer utilities under one department. The revenue received for these services can only be used to operate our department, and the commissioner operates the department as a self-sufficient unit, that is — revenue must equal expenses. This reorganization started us off on a sound basis. By this time—the department had launched a large rehabilitation and new construction program costing $30,000,000 per year. However, during all this turmoil, employees' safety was ever present in our mind.

The department has four major segments —water operations, 1,140 personnel; sewer operations, 280 men; design and construction, 340 men; and administrative staff, 40 men—a total of about 1,800 people. The function of the safety engineer is in the administrative unit, under the commissioner's office.

With this setup the commissioner created a departmental safety committee of five members with water operations, sewer treatment, sewer maintenance, and the construction branch represented. We were to reorganize the safety and accident prevention program, recommend and standardize practices and procedures, work with National Safety Council to introduce current safety practices and set up safety sub-committees within the department units. We also reviewed all accident and safety reports, developed statistics, and utilized the information to reduce the accident rate.

ACCIDENT SURVEY TAKEN

This committee met regularly—but meetings were spaced too far apart. Most of the members were "line" supervisors, and the "growing pains" we were having left little time to devote to setting up the safety program in the department. The approach to the whole problem was to find out what our record was—particularly in the various operating units. A survey of accident reports reflected the following:

1. Reports not complete
2. Reports very late in processing
3. Not all accidents reported
4. Reports not followed up—no statistics compiled
5. No differentiation between chargeable and non-chargeable accidents.

In other words—we preached "safety"—but that was virtually all. Our conclusion was the need for a full time employee to head the program—so we created a safety engineer job classification then recruiting—examination—and placement.

RECORDS, HANDLING ACCIDENTS

In 1956, the personnel unit made a thorough review of motor vehicle accidents for the previous year—this area needed most immediate attention and these records were the most complete. An action program was developed requiring "accident prone" drivers to take a physical examination (particularly eyes) after two accidents occurred within 12 months. This program has been quite effective. Few people like to be cross-examined or physically examined—it seems to be easier to avoid an accident!!

Since we employed a safety engineer the committee pursued the problem with much more vigor. Records were systematized and showed that the ratio of lost time injuries to no-lost time injuries was grossly out of alignment compared to national figures. Investigations found that the clinics and the doctors were extremely liberal on permitting an injured employee off for a day or two for a very minor injury.

Also, the method of processing an employee on taking care of an injured employee enabled an employee to take time off without the supervisor checking and consequently spending excessive administrative time on the problem.

Those were two areas of getting started —accurate records and expeditious handling of accident cases—but, *that doesn't prevent accidents!* Step three was forming sub-committees in all operating units. A review was made of the safety committees in the three sewage treatment plants. They consisted of three men who make a plant inspection once a month—and reported to the supervisor in charge of all the plants. Our committee felt that similar sub-committees should be set up in water operations. There are six major divisions in the water works:

1. Pumping
2. Distribution
3. Filtration
4. Meters
5. Plant maintenance
6. Service section

"GRASS ROOTS" SUBCOMMITTEES

The safety engineer interviewed these division supervisors, and was received with varying degrees of welcome. The extremes were the prompt appointing of a three man committee to—"It can't be done by my shop." This was resolved when a higher level supervisor met the men and discussed the problem. Management is 100 per cent sold—a basic ingredient to a successful program.

The sub-committees have three skilled workers. The foreman can be a member—but, generally we encourage workmen to keep it at a "grass-roots" level. There are a chairman, vice-chairman and secretary—each serving two months in each capacity. The terms are staggered every two months

—the chairman goes off the committee, a secretary is appointed and the other two members slide up in position. This gives continuity as well as everyone a chance at the coveted position of chairman. With the right guidance they will continue to be safety exponents — preaching the gospel of safety.

Each month an inspection is made of the plants by the sub-committee. They are given a check-off sheet to guide them on points to inspect—plus room for comments. Their report is submitted to the area supervisor and to the safety engineer. They will take part in a safety meeting called by the supervisor—and their recommendations will be discussed. The safety engineer will follow-up these reports with the supervisor. If a policy decision must be made it is referred to the department safety committee. Although this program has just started, it has been well received.

This organization in safety will cost the department about 30 man days/month of non-productive work—.08 per cent of total man days worked. According to the department severity rate for the first three months of this year—we lost 160 man days/month.

So, if the record could be reduced by one-fifth—we certainly could justify this expense —plus accomplish the primary aim to reduce the "pain and suffering" of an employee—no disruptions created at time of accidents —no interrupted work schedules by less man-power and a higher morale of the whole working force. To work the safe way is also one of the most efficient ways—so, the gains are endless.

SAFETY EQUIPMENT USED

Safety equipment was installed in a number of areas—hard hats for ditch gangs, first-aid kits in plants and vehicles, inspections by the fire department and fire fighting equipment, working clothes, plus goggles, face shields and gloves were furnished by the department in various working areas. Traffic cones and barricades were furnished for street gangs, and a number of other safety practices were put into effect. This definitely was an indication that management and some of our men were thinking.

Our committee has asked our safety engineer to write up safety standards,—first a general one for any and all areas—then specific ones for individual divisions. This is a big job and will take time. In the meantime we are using the Council poster service liberally and distribute magazines and bulletins. We have instituted virtually a promotion campaign and use our *Water Department News*— monthly house organ—to publish statistics and other safety news.

Our committee decided to enter the National Safety Council's "Safe Driver Award" campaign, which should reduce and keep our vehicular accidents to a minimum.

To summarize "How and Where to Get Started," the following points must be accented:

1. Top management sold on "SAFETY"
2. Set up a safety committee
3. Appoint or employ a safety engineer
4. Set up accurate records
5. Set up expeditious handling of accident cases
6. Set up safety sub-committees in working organization
7. Plant inspections
8. Promotion compaign
9. Furnish safety equipment
10. Set up campaign and make awards to safe drivers

We have received invaluable help from other water utility safety engineers. This spirit of cooperation among the Water Works will bring our records down to where we can give the other utilities a "run for their money." If cooperation, active participation and application of good "SAFETY" principles is a criteria of success—IT WILL BE DONE!▲

A FIRST LINE SUPERVISOR'S SAFETY PROGRAM

by ALEXANDER C. RENER
district operations engineer, Department of Water and Power, Los Angeles, Calif.

Safety is an interesting subject with many sidelights that defy explanation. We are constantly reminded of safety—when we leave home our wives tell us to be careful on the job—when the children leave for school or play we tell them to be careful. Many organizations develop and maintain safety programs with motion pictures, lectures and posters to remind employees of job hazards. In spite of all these reminders, accidents continue to happen.

The purpose of any safety program is to develop safe thinking among the employees individually and collectively to maintain the accident frequency and severity rates at a low level. Without a safety program every individual acts on his own and safe thinking is a hit-or-miss proposition depending on the individual attitude.

There is no safe thinking by the group as a whole. In contrast to the safe thinking attitude there is the negative attitude toward safety. The fatalistic attitude is the most common—"Be reasonably careful but when your number is up, you'll be hurt." Another dangerous attitude is that "Someone will get hurt but it won't be me." Then, of course, there is the attitude called forgetfulness.

Safety in a water utility is no different than safety in a factory, railroad or a construction project. For an effective safety program, the basic requirements must be fulfilled. A safety program must have the complete and enthusiastic support of management and all supervisors. The first level supervisor must direct the safety program because top management cannot be aware of detailed problems involved in reaching employees.

Accidents are not reduced by bulletins urging safe thinking. They are reduced by continuous contact of the first level supervisor with the employees. In a large organization, the safety engineer is a great value in organizing a safety program, preparing safety material and developing safe methods. But the first level supervisor must be the contact with the employees.

The distribution division of the Water System of the Department of Water and Power constructs, maintains and operates the water system in Los Angeles. This includes installation, maintenance and operation of all water mains, trunk lines, fire hydrants, meters, services, pressure regulating stations, tanks, some of the reservoirs and all other appurtenances dealing with the distribution of water. These functions require 1,200 personnel, of which 1,000 are field employees ranging from district superintendents to laborers. The Water System, 44 miles by 28 miles, is divided into five self-sufficient districts.

For the past 10 years, the distribution division has had an assigned safety engineer from the accident prevention section. He visited the various districts with a field superintendent to inspect construction projects. He had no authority to enforce safe methods but his advice on safety was generally followed. On his recommendation, safety equipment such as toe guards, goggles, respirators, hard hats and gloves were purchased and their use encouraged. His position and title promoted safety; however, no one else took the same interest in the problem.

The foreman respected his comments but only saw him once every two or three months. With 110 crews in the field, he couldn't devote much time to any particular foreman or construction project. Every two months a district safety meeting was held after work on an overtime basis, and was attended by all superintendents, foremen and lead men. A lecture on safety with demonstrations and motion pictures followed by a general discussion constituted the meeting. The men were expected to practice the lessons they had learned at the meeting. The safety engineer was doing everything within his power to promote safety and reduce accidents.

After operating in this manner for years, it became apparent something was missing. Our accident frequency and severity rates were static. In spite of the support by management and the purchasing of safety equipment and the personal contact of the safety engineer, people were still injured at the same rate. In analyzing our safety program, we found the source of our trouble was that the entire program was the personal activity of one man, the safety engineer. He did all the talking and everyone else listened.

But with 1,000 men, his contacts were necessarily infrequent. We had to find a way for his effort and enthusiasm to be utilized and transferred to the first line supervisor. Our foremen and lead men were not neglectful. They just didn't get enough material from bi-monthly safety meetings for the next two-month period.

After considerable discussion with safety engineers, other utilities and management, a new safety program was developed. The new program was announced at a safety meeting attended by top management so that the personnel would realize the support this program was receiving. Essentially, it consists of seven major points which I will describe in detail.

WEEKLY MEETINGS ON THE JOB

The foreman will conduct weekly trench-side or yard meetings on safety subjects. The meetings, held every Monday, will last from five to 15 minutes. The Accident Prevention Section will furnish topics and the necessary information to the foreman.

This is most important in the safety program because it gives the first level supervisor the entire responsibility of getting the message to the employee. The safety engineer prepares the material and mimeographs copies for all foremen to use. The safety engineer must provide interesting safety material written in a form readily understood by the field personnel. Here is a typical weekly safety talk to illustrate the type of subjects used:

The Subject for this week is "Hoists and Cranes."

1. "If we're using a hoist, we'll have *one* man give the signals. Nothing confuses an operator as having two or three men telling him what to do.

2. "If it's your job to hook pipe, be sure your slings are in good condition and strong enough to do the job.

3. "If you are using a clamp, be sure it is free from grease and dirt and in good working order. Make sure it is fastened securely on the pipe and then fasten the safety so that the pipe won't scissor out.

4. "Never swing a load over another man. Stop the operator until every man is in the clear. If men are in the trench, do not bring the load to the edge of the excavation until the men are beyond all danger.

5. "Never attempt to catch or hold a length of pipe that appears to be slipping. It's better to have a cracked pipe than a cracked back.

6. "If pipe is stored along a roadway or street, securely block each length separately. Not only our own men but children at play have been injured because we did not securely block our pipe to keep it from rolling.

7. "If in lowering we knock out some of our timber, stop proceedings at once and replace the timber. Remember, the man in the ditch must be protected at all times.

8. "When lining up pipe in trench, keep your hands away from the ends. *Never* attempt to remove dirt from the pipe until you are *positive* that the hoist man knows what you are going to do.

9. "Never stand directly in line with a suspended pipe. It may slide in the clamp or sling.

10. "Never take hold of a hoisting cable. You may have your fingers cut off between the cable and the block.

"Any comments?"

That concludes the lesson for the week. The language and the sentence structure are plain and to the point. The subject "Hoists and Cranes" is one from an almost inexhaustible source. Many of the foremen read the lessons; others talk extemporaneously on the subject. Both methods have proven effective.

The districts will hold five safety meetings a year, devoted to a review of the accidents in the past two months. A discussion of the weekly topics for the trench-side or yard meetings to be held during the following eight or nine weeks is included. The discussions will be led by a field super-

intendent with the safety engineer as advisor to enter discussions only when specifically requested.

The entire proceedings are directed by the line organization rather than the safety engineer who is a member of the staff organization. Taking the meetings away from the safety engineer and having a field superintendent take charge made the foremen and lead men aware that promoting the safety program was their problem. Upon the request of the field superintendent, the safety engineer advises the foremen on the most effective presentation of the material for the weekly meetings.

NEW EMPLOYEES EDUCATION

The foreman or the lead man will instruct every new employee assigned to his crew. This instruction will include: handling shovels and pneumatic tools, correct methods of lifting and other crew functions. A check list to indicate the instruction given will be filled out and signed by the new employee and the foreman.

This eliminated a great source of trouble of new men injured on the job claiming they had never been instructed.

As soon as possible after an accident on the job, the foreman will assemble his crew describe the accident, explaining why it happened and how it could have been avoided. The foreman will use these opportunities to develop a safety-conscious crew.

This idea is effective because a discussion of the accident immediately after it happens always impresses the crew. Safety consciousness in the crews has made the men suggest safety gadgets and equipment such as heat-resistant sleeves for use when pouring lead, and cutting holes in shovels for handling wet adobe.

ACCIDENT INVESTIGATIONS

A committee in each district will review each lost-time accident. The committee will consist of the district superintendent, the field superintendent, the foreman, the man involved in the accident and the safety engineer. The purpose is to determine, if possible, why the accident happened and how it could have been prevented. The findings of the committee meeting will be reported on the "Foreman's Report of Investigation of Accident" form.

This point has also made quite an impression on the foreman and his crew. Although the committee only determines causes and cures, the foreman and his men do not like being included because it is their lost-time injury being investigated.

LOST TIME CHARTS

Each crew of four or more men will have a safety board mounted on the truck showing the number of man-days worked without a lost-time injury. The foreman or truck supervisor will change the totals every day.

Each crew has a group pride in this ever-changing number posted on the safety board on the curb side of the truck. As the man-day figure increases, a rivalry develops between the various crews and a lost-time injury upsets the crew. Teamwork has developed and the men take care of each other, watching, advising and helping to prevent accidents.

A safety plaque will be awarded to each crew working without a lost-time injury one year. These plaques will be mounted above the safety board on the trucks.

AWARD SAFETY PLAQUE

At the end of the first year, our top management appeared at the safety meetings and presented plaques and certificates to the foremen. The impression on the men was very favorable and they appreciated the compliments and pats on the back. Their presence at the meeting assured the foremen of the continued enthusiasm and support of management.

This new safety program has operated for more than a year. From the start the first line supervisors were cooperative and enthusiastic because they felt this plan would produce results. In a very short time there was a decided downward change in accident frequency and severity rates, and with management voicing its approval, the first line supervisors redoubled their efforts. The results were gratifying and the record of the first year shows a 30 per cent drop in accident frequency and a 52 per cent drop in accident severity. Now in our second year, we are continuing to reduce our accident rates even further.

This seven-point safety program excludes records and reports because they have been in operation for years. An organization

starting a safety program should have an eighth point dealing with active records and reports to determine the effectiveness of the program.

A system of bulletins on repetitive accidents such as strains, sprains and lead burns reminds employees of injuries from carelessness or neglect in using safety equipment. Continual repetition by an employee of the same type of accident brings a warning of disciplinary action.

In this program promoting safety is the first line supervisor's direct responsibility and gives him experience in leading group discussions. The "tail gate" meeting is not new but is successful in our distribution division because the foremen receive the necessary material at the district safety meetings and are coached by the safety engineer. The cost of maintaining this type of program is no greater, since it just rearranged our responsibilities.

The ideas developed in this safety program may be used in any size organization. Many water utilities are small and do not have enough employees for a full-time safety engineer. However, the material necessary for first level supervisor meetings is readily available. The American Water Works Association recently published a manual *Safety Practices for Water Utilities* containing safety information and program material. By using the manual at foreman discussion meetings, an adequate safety program can be organized and maintained. The benefits of safe practices—both humanitarian and monetary—are derived by a small as well as a large water utility.

If the first line supervisor feels that promoting safety is his responsibility, and if he is backed and encouraged by management, safety consciousness will become a definite part of every employee's thinking. With that positive attitude, accident frequency and severity rates will be reduced.

SAFETY PAYS OFF

by ARTHUR J. WEBB
safety coordinator, East Bay Municipal Utility District, Oakland, Calif.

Have you ever been in a busy railroad station and watched the trains come in? Have you noticed the joyous looks on the faces of the men and women and children as they meet one another at the station after a trip? When these people are protected and helped to go home at night through your assistance, we have had the big payoff.

This is one type of a payoff. In addition to the human side of the accident picture there is the cost side. Dollars and cents are important. There is no better way for a businessman to make a dollar than to have a good safety program. Safety pays off! It not only gives the business the margin of profit it needs but it gives men the chance to arrive home each night safely to the ones they love.

An important study of injury frequency rates in the water-works industry was conducted by the United States Bureau of Labor Statistics. The industry, one of the worst in the nation, was selected for the special survey in 1953. The industry had a frequency of 24.8 lost time injuries per million man hours compared to an all industry frequency of 8.4. This is almost three times the national average. Since then the frequency has been 25.3 in 1957 and 24.1 in 1955. The industry had not changed much since 1946. However, it will and can change as more utilities begin safety programs.

HOW COSTS ARE REDUCED

One easy way to save money through a safety program, especially if the injuries are high or if the utility has not had a safety program, is the insurance dollar. Company insurance rates are figured on the experience rate of the industry. As the industry lowers its number of injuries, the insurance rate decreases for all companies whether or not they have an injury prevention program.

Secondly, not all the insurance rates are set by state law. If your experience is bad, the insurance company can either raise rates or cancel the insurance. All states do set basic rates for different industries but the insurance companies can charge more than 100 per cent of the basic rate. In fact there was a time when our company was paying 125 per cent of the basic rate.

To compute your rate, the insurance company will average your previous three year accident costs and frequency. It considers whether you have a planned program to reduce injuries and sets the next year's rate from that. Deaths or amputations reflect for a three year period in insurance rates.

Some insurance companies have a refund system. The company reviews your actual compensation and medical costs at the end of the year and refunds money on the per cent of actual costs below the premium you were charged. In the East Bay Municipal Utility District we recovered more than $213,000 since 1949, saving about half the premium. In addition, our premium rate went from 125 per cent of the basic rate set by California to the 71 per cent we are now paying. This is a direct dollar saving to the people of the district.

The National Safety Council reports that for every compensation dollar saved, you save four to six more dollars in indirect or uninsurable dollars.

INDIRECT AND UNINSURABLE COSTS

1. Worker costs—those not injured. These are observers, people who helped the injured party, time to take them to the doctor or hospital, time to describe the injury to other employees. If ten men take 15 minutes each at $1.50 per hour, this will be $3.75.
2. Supervisors time—helping the injured man, home calls, doctor visits, insurance interviews, telephone calls within the company, report making, investigations. This could easily take one to two hours or more at $2.50 an hour. Possible cost could be $2.50 to $10.00.
3. Loss of working time when the employee received pay. If an employee is injured during the day, he is usually paid for the whole day. This could amount to approximately $1.50 to $12.00.
4. Many times the loss of time from an injury causes other men to work an hour overtime. The cost for three men for one hour would be about $4.50.
5. Decreased production results from the injured man when he returns to work.
6. Cost of training a new man.
7. Clerical costs for processing report forms through the insurance company and accounting.
8. Repairs to equipment damaged—includes costs of tractors rolled over, cables broken, doors to trucks damaged.
9. Rental costs for equipment while repairs are made, and other expenses such as liability costs for damages to property.

These are the main elements of the cost picture of accidents. Now—the methods we use to combat costs, our safety program.

We aim to operate the safety program so that the man on the job and his foreman make a team of accident prevention. The program operates through them as much as possible. The safety unit functions by coordinating the information and stimulating the program.

LEVELS OF SAFETY ACTIVITY

There are three levels of action taken by the district. The first is the basic one in which the facts are determined. Then comes a plan for teaching the facts. Finally there is learning the facts to develop teamwork.

To show how effective this approach has been the five year accident frequency of 24 reduced to a three year accident average of 3.4 in four years. When a person realizes that the lost time accidents cost money, the curve is more significant.

In addition, the premium lowered with the continued reduction of accidents. It dropped from 125 per cent in 1949 to around 70 per cent in 1956.

A great impact on the morale of the employees results from a good accident prevention program and is another reason why safety pays off.▲

OFF-THE-JOB ACCIDENTS

Statistics are such boresome things
And figures rather dull.
It's hundreds, millions, billions, trillions,
Over which we mull.

But facts are facts where'er we go
Regardless of amounts,
So here's some facts on accidents,
And that's what really counts.

It isn't always big machines
With blades of sharpened steel
That rob a man of arm or leg
And make his senses reel.

Nor is it always "on the job"
Most accidents take place,
But just the opposite is true
And figures prove our case.

It's carelessness in little things
At home and on the street
Neglect in moving objects small
Away from running feet.

A makeshift ladder, sliding rugs,
Electric cords that spark
A disregard for cellar stairs
And stumbling in the dark.

Crossing where no crossings are
While looking at the sky,
Driving on a slippery road
With milestones whizzing by.

These are the things that take a toll
We all should frown upon
So watch for them when off the job,
As well as when you're on.

—Humble Pipe Line Company, Houston, Texas

OFFICERS OF THE

ELECTRICAL EQUIPMENT SECTION

NATIONAL SAFETY COUNCIL 1957-58

General Chairman—E. E. GEBHART, supervisor of safety, Frigidaire Div., General Motors corp., Dayton, Ohio.

Secretary—G. W. KOCH, supervisor of safety, Western Electric co., Kearney Works, Kearney, N. J.

Staff Representative—PAUL E. SHEPPARD, National Safety Council, Chicago, Ill.

Vice-Chairman for Electronics Division—FRANK J. STORMER, Mgr., Safety & Plant Protection, Hotpoint Co., Chicago, Ill.

Vice-Chairman for Heavy Apparatus Division—E. J. TURTON, supervisor of safety, Westinghouse corp., Buffalo, N. Y.

Vice-Chairman for Light Apparatus Division—E. L. GERDING, Leeds & Northrup co., Philadelphia, Pa.

Vice-Chairman for Electrical Wire and Cable Division—H. E. YOUNG, safety director, Rome Cable Co., Rome, N. Y.

Newsletter Committee: J. J. MARINER (Chairman), safety director, Federal Telephone & Radio co., Clifton, N. J.; M. I. GJERDE, senior engineer, American Mutual Liability Ins. co., Hackensack, N. J.; F. G. COFFEY, safety director, I.T.E. Circuit Breaker co., Philadelphia, Pa.; M. M. RHULAND, safety director, Landers, Frary & Clark, New Britain, Conn.; R. P. SNYDER, safety engineer, Sylvania Electric Products Inc., Altoona, Pa.

Research and Engineering Committee: W. F. McCHESNEY, Chairman, safety director, Airborne Computer Laboratory, International Business Machines corp., Vestal, N. Y.; M. E. KULBERG, division safety engineer, Sylvania Electric Products Inc., Woburn, Mass.; C. A. SLAUGHTER, supervisor, Plant Protection & Safety, Jack & Heintz, Inc., Cleveland, Ohio; W. G. MOORHEAD, Administrator, Safety & Health Dept., Aircraft-Marine Products, Harrisburg, Pa.; C. H. BOWLIN, safety director, Anaconda Wire & Cable co., Anderson, Ind.; F. G. PEREGOY, supervisor of safety, Air-Arm Div., Westinghouse Electric corp., Baltimore, Md.

Program Committee: R. B. MARSHALL, Chairman, safety director, Trailmobile, Inc., Cincinnati, Ohio; G. MacDONALD, Self Insurers Services, Inc., Chicago, Ill.; S. J. CURTIS, safety director, Burroughs Corp., Detroit, Mich.; R. A. WRIGHT, manager, Safety & Security Dept., Farnsworth Electronics co., Fort Wayne, Ind.; R. L. BARTLETT, supervisor of safety, Allis-Chalmers Mfg. Co., Pittsburgh, Pa.

Membership Committee: G. R. SMITH, Chairman, safety director, Champion Lamp Works, Lynn, Mass.; H. J. JENNINGS, supervisor of safety, General Electric co., Lynn, Mass.; E. T. SCHRECK, safety director, Sunbeam corp., Chicago, Ill.; D. LEONARD, safety engineer, Simplex Wire & Cable co., Cambridge, Mass.; R. J. FERRARI, sales manager & engineer, Excel Electric Service co., Chicago, Ill.

Training and Publications Committee: K. STANAT, Chairman, safety director, Magnetics, Inc., Butler, Pa.; J. R. DAVIS, chief of plant protection, The Hallicrafters co., Chicago, Ill.; L. J. LACKNER, director of personnel & safety, White Sewing Machine co., Cleveland, Ohio; C. LANG, supervisor of safety, Westinghouse Electric corp., Meter Div., Newark, N. J.; J. V. BEECHER, chairman, Industrial Relations Staff, Stromberg-Carlson Co., Div. of General Dynamics Corp., Rochester, N. Y.

Counselors and Association Committee: Past Chairmen—J. M. TRANSUE, Chairman, Security director, Philco corp., Philadelphia, Pa.; M. L. MILLER, supervisor of safety, Westinghouse Electric corp., Pittsburgh, Pa.; E. K. TAYLOR, safety director, Zenith Radio corp., Chicago, Ill.; H. B. DUFFUS, administrator, accident prevention, Westinghouse Electric corp., Pittsburgh, Pa.; C. F. SCHLUETER, accident prevention manager, Employers Mutual of Wausau, Wausau, Wis.; M. F. BIANCARDI, manager, Safety Services dept., Allis-Chalmers Mfg. co., Milwaukee, Wis.; C. N. FOGG, safety director, Simplex Wire & Cable co., Cambridge, Mass.; J. A. EDMONDS, vice-president, Daniel Woodhead co., Chicago, Ill.; J. J. LAWLER, division safety engineer, Radio Tube div., Sylvania Electric Products Inc., Emporium, Pa.

OFFICERS OF THE

PUBLIC UTILITIES SECTION

NATIONAL SAFETY COUNCIL 1957-58

General Chairman—J. E. APPEL, safety engineer, Commonwealth Edison co., Chicago, Ill.

Vice-Chairman—E. M. CHASE, safety director, Central Vermont Public Service corp., Rutland, Vt.

Second Vice-Chairman—R. S. LOWE, plant training & safety supervisor, Northwestern Bell Telephone co., Omaha, Neb.

Secretary—R. E. McELDOWNEY, JR., safety director, United Fuel Gas co., Charleston, W. Va.

Program Committee

Chairman—L. CLANCY NANRY, director of safety, The Detroit Edison co., Detroit, Mich.

Vice-Chairman—Electric—M. M. MEHRING, safety supervisor, Consumers Public Power District, Columbus, Neb.

Vice-Chairman—Gas—F. P. MUELLER, assistant director of safety, The Peoples Gas, Light and Coke co., Chicago, Ill.

Vice-Chairman—Water—W. R. LaDUE, superintendent & chief engineer city of Akron, Bureau of Water, Akron, Ohio.

Vice-Chairman—Communications—SAMUEL McKAY, JR., area safety supervisor, The Bell Telephone co. of Penna., Philadelphia, Pa.

Engineering Committee

Chairman—V. L. WOMELDORFF, safety director, Illinois Power co., Decatur, Ill.

Vice-Chairman—Electric—W. F. BACHMAN, safety director, Omaha Public Power District, Omaha, Neb.; ROY BEITH, manager & secretary-treasurer, Electrical Employers assn., Toronto, Canada; I. L. RIPLEY, director of safety, Central Maine Power co., Augusta, Maine; D. B. MOORE, safety director, Duke Power co., Charlotte, N. C.

Vice-Chairman—Gas—W. J. EASTON, director of accident prevention, The Cincinnati Gas & Electric co., Cincinnati, Ohio; R. G. CLAAR, safety director, The Ohio Fuel Gas co., Columbus, Ohio; E. D. JONES, safety director, City Utilities of Springfield, Mfksouri, Springfield, Mo.; W. D. COLLINS, safety director, Rockland Light & Power co., Boston, Mass.

Vice-Chairman—Water—T. F. ALLEN, safety engineer, Department of Water & Sewers, Commissioner's Office, City of Chicago, Chicago, Ill.; V. A. APPLEYARD, chief of water operations, City of Philadelphia, Water Department, Philadelphia, Pa.; O. V. BROCKWAY, safety inspector, Board of Water Commissioners, Denver, Colo.

Vice-Chairman—Communications—N. W. TEMPLE, plant safety supervisor, Pacific Telephone & Telegraph co., Seattle, Wash.; JOHN BIRD, administrative supervisor, The Western Union Telegraph co., New York, N. Y.

Vice-Chairman—Special Projects—J. M. FALLS, assistant to manager of industrial relations, Northern Indiana Public Service co., Hammond, Ind.; CHARLES SCHWEICKART, safety director, Hoosier Engineering co., Columbus, Ohio.

Education and Training Committee

Chairman—ERROLL DUNBAR, safety engineer, Potomac Electric Power co., Washington, D. C.

Vice-Chairman—Posters—F. D. NORBERG, safety director, Utah Power & Light co., Salt Lake City, Utah; M. J. BENDEKOVIC, manager of safety claims, Public Service co. of Colorado, Denver, Colo.; J. B. SCHEERER, supervisor, inspections, safety department, Philadelphia Electric co., Philadelphia, Pa.

Vice-Chairman—Visual Aids—H. C. POTTHAST, supervising instructor, Wisconsin Rural Electric, job training & safety, Menomonie, Wis.; C. H. GUM, safety supervisor, City of Jacksonville Utilities, Jacksonville, Fla.; K. G. CREGAR, safety director, Metropolitan Edison co., Reading, Pa.

Vice-Chairman—Training Plans—A. B. LARSEN, supervisor, construction training, Commonwealth Edison co., Chicago, Ill.; W. L. CLIFTON, technical assistant, accident prevention div., The Hydro-Electric Power Comm. of Ontario, Toronto, Canada; J. G. DALTON, general safety engineer, Southern Bell Telephone & Telegraph co., Atlanta, Ga.; HERBERT HOLMES, safety director, Michigan Wisconsin Pipe Line co., Detroit, Mich.; R. N. PAPICH, safety consultant, American Gas Assn., New York, N. Y.; C. E. HAMMON, safety director, Columbus & Southern Ohio Electric co., Columbus, Ohio.

Publicity Committee

Chairman—T. F. WICKFORD, safety supervisor, Commonwealth Edison co., Chicago, Ill.

Vice-Chairman—Public Relations—R. R. CONN, supervisor of training & safety, Power Station Department, Duquesne Light co., Pittsburgh, Pa.

Vice-Chairman—Newsletter—PAUL WINDSOR, safety director, Bureau of Safety, Inc., Chicago, Ill.; R. M. CLARK, safety director, Atlantic City Electric co., Atlantic City, N. J.; J. G. LAMBERT, safety supervisor, Northern Illinois Gas co., Wheaton, Ill.; A. B. SHEHEE, safety engineer, R. E. A., Electric Engineering div., U. S. Department of Agriculture, Washington, D C.

Statistics & Contests Committee

Chairman—C. A. FISCHBACK, safety supervisor, Southern California Edison co., Los Angeles, Calif.

Vice-Chairman—D. E. HUSK, safety director, New Jersey Power & Light co., Dover, N. J.; J. W. GRONBECK, safety manager, New England Electric System, Boston, Mass.

Membership Committee

Chairman—S. T. ROBESON, safety supervisor, Carolina Telephone & Telegraph co., Tarboro, N. C.

Vice-Chairman—H. W. MASTERS, safety director, Asplundh Tree Expert co. & Utilities Line Const. co., Inc., Jenkintown, Pa.; J. E. HICKMAN, safety engineer, Los Angeles Department of Water & Power, Los Angeles, Calif.; J. R. HEIM, safety director, Monongahela Power co., Fairmont, W. Va.; E. B. BELL, assistant safety director, The Ohio Power co., Canton, Ohio.

Projects Committee

Chairman—J. O. LESLIE, safety director, Gilbert Associates, Inc., Reading, Pa.

Vice-Chairman—E. S. HANNAFORD, safety engineer, Long Lines Department, American Telephone & Telegraph co., New York, N. Y.; W. S. KITCHEN, system safety supervisor, Appalachian Electric Power co., Roanoke, Va.; J. E. HICKMAN, safety engineer, Los Angeles Department of Water & Power, Los Angeles, Calif.; HOWARD COOK, assistant manager, safety department, Philadelphia Electric co., Philadelphia, Pa.

Nominating Committee

General Chairman—W. S. KITCHEN, system safety supervisor, Appalachian Electric Power co., Roanoke, Va.

Special Representatives:

R. J. FAUST, assistant executive secretary, American Water Works Association, New York, N. Y.; E. C. BAUMANN (chairman, Accident Prevention Committee, A.G.A.), safety engineer, Gas Department, Public Service Electric & Gas co., Newark, N. J.; I. R. DOHR (chairman, Accident Prevention Committee, Edison Electric Institute), general safety supervisor, Consumers Power co., Jackson, Mich.

Staff Representative—PAUL E. SHEPPARD, National Safety Council, Chicago, Ill.

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscr[illegible]ith any charts or illustrations used, are available in the National [illegible]ty Council files. Views expressed at the Congress or in any volum[illegible] Current Safety Topics are those of the Congress participants, and not n[illegible]arily those of the National Safety Council.

THE FARM CONFERENCE

This volume is a record of the sessions held at the 1957 National Safety Congress by the Farm Conference. The conduct of these Congress sessions each year is only one of the many cooperative activities which the conference carries on in behalf of its members, and for the benefit of accident prevention work on the farm.

The activities of the conference are under the direction of its executive committee, the members of which are listed at the close of this volume.

SAFETY MAKES SENSE

by EARL L. BUTZ
dean of agriculture, Purdue University, Lafayette, Ind.

Safety makes sense in any occupation. It certainly makes sense to farm residents, where there is a potential saving of nearly 13,000 lives annually. Add to this the more than one million non-fatal farm accidents each year, and you have a substantial accident toll on the farms and in the farm homes of America.

More farm workers have fatal accidents than in any other major occupation. Last year's toll was 3,600 farm workers killed. The total number of farm residents—men, women, and children—killed accidentally last year was 12,800, and 1,050,000 others were disabled. Among farm workers themselves, 300,000 suffered disabling injuries. The farm death rate per person employed was exceeded only by the mining and construction industries.

The National Safety Council estimates that the accidental death rate of farm residents declined from 58.7 deaths per 100,000 population in 1955 to 57.5 in 1956. This was only a one per cent reduction in the accident rate in the one-year period. One per cent reduction per year is far too slow. We must do better than that.

The financial loss from farm accidents is appalling. This has been estimated at approximately $1.5 billion annually. This is one-seventh of total realized net farm income in recent years. Substantial reduction of this figure would be a wonderful way to raise net farm income.

STATISTICS HAVE MEANINGS

Figures and loss ratios like those cited above are cold and impersonal. Losses are just a number. But these figures take on concrete meaning at the place where they have their beginning—with the family of the accident victim. The measurable loss from accidents and fires is tremendous, but the part that can't be measured is even greater. It encompasses all those things that are not replaceable—including human life itself. And who can place a monetary value on a human life snuffed out at the beginning of its productive period?

The really heartbreaking thing about all this is that most of the accidents that kill some 13,000 farm people each year and injure another million are caused by unsafe practices and hazardous conditions that could be corrected. That's something to think about, isn't it?

DON'T KNOW HOW SERIOUS

Yes, the farm accident situation is really serious. However, many farmers and farm leaders have had their attention directed elsewhere by newspaper headlines telling about airplane crashes, train wrecks, and similar calamities in various parts of the world. At the same time, farm people are being killed at the rate of 38 a day in the United States alone. But these deaths happen at different times and in scattered places, and never make the headlines on a national scale.

Our first need, then, is to make people aware of the situation. In general, progress is being made in this area. Fourteen annual National Farm Safety Weeks have helped greatly in calling attention to this need. National leadership for this event is provided by the Safety Council and the U.S.D.A. Farm Safety Week and the continuous efforts of local, state, and national groups have combined to make people more aware of the problem. Needless to say, the excellent cooperation of press, radio, and TV has been a major factor.

Unfortunately, awareness alone does not prevent accidents. People must act. There has been improvement in this respect too. However, action might be more plentiful if we could only convince more farm people that something can be done to prevent accidents. Many still seem to believe the situation is hopeless. We have positive evidence that something can be done merely by looking at the lower and lower accident rates in states and communities which have had active safety programs and where accurate records have been kept. We need to tell this story to those communities where safety is still an accident.

TEACH THE ADULTS TOO

One of the things at which we excel in the United States is all kinds of programs to "teach the youngsters." We do it in the schools, 4-H organizations, Boy Scouts, church organizations, and a dozen other places. We frequently overlook the necessity to teach the adults too. And that includes ourselves.

In many cases our teaching the youngsters takes the form of preaching rather than teaching. Our group leaders will tell them how to do it or how not to do it, but frequently will not follow through by practicing what they preach."

Many parents openly violate safety rules and, at the same time, warn their children, "Don't let me catch you doing it this way." They might as well add—"Wait until you become an adult, then you can do it." Some of those youngsters just can't wait until they reach adulthood to imitate the people who tried to teach them to do otherwise.

HAVE NO TRAINING

Most farm leaders have received practically no formal training in safety. It's no wonder they so seldom consider it as part of their job. However, they are often in an excellent position to teach safety on a practical basis. In one state, a subject matter extension specialist remarked that if his state wanted safety taught, it should hire a safety specialist because he had enough to do without pointing out the safety aspects of his specialty. Obviously, he was overlooking the fact that safety should be a part of every job. The reason for establishing educational programs is "to make living better" for people, but without safety, "*we may not live at all.*"

People who are worth teaching "how to live better" certainly should be worth teaching "how to live!"

Some stories fit so many situations that they are used over and over again. For example, many times we've all heard about the house that had the leaky roof. Someone asked the owner why he didn't fix it. He explained that he couldn't work up there when it was raining and when it wasn't raining, the roof didn't leak.

In many ways, safety is just the same. People seldom see a need for it until the accident happens, and then it's too late.

American agriculture is in the middle of a far-reaching scientific and technological revolution. It is changing from an industry of "arts and crafts" to an industry undergirded by science and technology. Adjustments which have occurred in agricultural production and marketing during the past 10 years have been phenomenal. Still greater changes lie ahead.

The rapidity of change is greater now than ever before in our history. Research and education are shortening the time span of progress.

Adjustments have always had to be made in American agriculture. But because these adjustments in previous generations were spread through several decades, farm families were pretty well able to "take them in their stride." Today the agricultural revolution is advancing with such rapidity that farm families and rural communities often find it difficult to make the kind of economic and sociological adjustment required.

In any period of rapid change like this it is doubly important that we be safety conscious. New machines, new techniques, new ways of doing things, and expanded scales of operation create unfamiliarity and breed new hazards. This will be increasingly true as our farms continue to grow in size, in capital investment, and in technology. Some of the old hazards may be eliminated by these advances, only at the expense of introducing newer and more perilous ones.

RESEARCH IN FARM SAFETY

Why all this talk about changes in safety problems? What does it mean to people like you who are promoting farm safety? Today's safety facts may not be true at all tomorrow. Certainly, the relative importance of many farm hazards will be changing almost constantly. Obviously, this makes up-to-date research important. Without it no program can operate effectively. Farm safety is no exception.

While commending those who have helped provide farm safety research, I would quickly point out the need for much more help in this particular field. Some of this help will come from highly trained engineers and other professional research specialists. On the other hand, every farm family can help in the important job of accident reporting and other phases of research.

Through constant, well planned research, farm life can be made safer. Much progress has already been made. In the farm machinery field, for example, we have had improved shielding, safety decals, self-starters, standardized hitch point, and other features that have some safety in their background. The fact that some farmers do not use all the safety divices that are now provided should not be used as an excuse by manufacturers for not providing more and better safety features as fast as they can be developed by competent research.

In past years there has been a tendency for some farm equipment manufacturers to "let the sales manager design the equipment." Although this obviously may be good business from a short time point of view, the design engineer cannot ignore safety features if he wants to stay in business over a period of years.

Moreover, it is our public responsibility to include every possible safety feature, even though the sales manager might contend that the added cost will not be recoverable in increased sales. Then again, some sales managers might be surprised if they tried to "sell the safety features" on their equipment. With the broad educational programs in safety going forward among farm people, farmers will increasingly look for those equipment items with the best built-in safety features.

PUSH SAFETY EVERYWHERE

Let's not be so satisfied with the progress we've made in few isolated cases that we overlook the need that still exists in many other situations. Outstanding safety programs by a few 4-H Clubs or Future Farmer Chapters or adult farm organizations should be commended and used as examples for other less active groups. They should not lead us to think the entire job is practically solved. We can't expect much progress from anyone who is not reached in some way by our safety educational programs.

Careful planning is necessary to reach the most people with a convincing program. I undestand the *1958 National Institute* for Farm Safety will be conducted on a workshop basis in a special effort to pool the best ideas from many different sources. But ideas are of no value unless they are put into action.

Therefore, it will be up to each state, each county, and each local organization to see that ideas for action reach farm families and individuals in a way that will inspire them to eliminate hazards to their life and property. To do this, planning must not be limited to the Farm division of the National Safety Council or the various state farm safety committees. Planning must be evident all along the line until safe conditions and safe habits are thoroughly a part of farm life everywhere.

By definition, an accident is unplanned. Safety can result only from planning and good luck. We must not depend entirely upon good luck.

THREE T'S OF SAFETY

An effective program in farm safety should be built around "The Three T's of Safety." There are:

1. *Training.* Everyone working in farm safety must constantly train himself regarding incidence and causes of accidents, new hazards that come with changed agriculture and rural living, more effective ways of *motivating people to "live safely," and methods* of mobilizing communities for action programs. Training of both self and others must be a never-ending process.

2. *Teamwork.* Safety is a job everyone. It can't be left to the so-called safety expert, to the teacher, to the county agent, to the farm organization, or to the farm editor. It's a job for all of us. To the extent that we get full teamwork in the attack on accidents, success will be achieved.

3. *Tenacity.* This is a job that calls for a lot of "stick-to-itive-ness." Progress will be slow. Discouragements will be many. Frequently accidents will occur in spite of everything we can do. There will be times when all of us will be tempted to throw in the sponge. But farm safety education is a job that calls for the highest degree of tenacity. If each of us sticks to it, then the community program will be advanced.

We who promote farm safety deal with one of the most precious resources we have —*human life itself. The Lord* gave each of us three precious and irreplaceable gifts. He endowed each of us with a human life, a human mind, and a span of years in

which to use that life and that mind. These gifts constitute the ultimate scarce resource we have on this earth. When they are taken from us, they can never be duplicated. They are irreplaceable.

GIFT OF HUMAN LIFE

Our real goal in farm safety promotion is to preserve those three divine gifts a little longer for some of the 13,000 farm people who otherwise will be killed this year in farm accidents, and to make life more meaningful and more productive for some of the one million non-fatal accident victims on our farms this year.

Our real goal is to make it possible for an increasing number of these people to be spared death and accident so that they may continue to make a lasting contribution to the service and growth of the America we love so much.

Our basic goal in farm safety, therefore, is the advancement of human welfare and human happiness in our time. This is a goal worthy of the best efforts and highest talents of all of us.▲

RESEARCH—A KEY TO SAFER FARMING

(A Panel Discussion)

V. S. PETERSON, (Discussion Leader) E. I. du Pont de Nemours & Co., Ames, Iowa; FRANK B. LANHAM, head, Agricultural Engineering dept., University of Illinois, Urbana, Ill.; G. H. LARSON, head, Agricultural Engineering dept., Kansas State College, Manhattan, Kan.; CHARLES LOGAN, superintendent, Beltsville Research Center, U. S. Department of Agriculture, Washington, D. C.; E. W. TANQUARY, International Harvester Co., Chicago, Ill.

Research is an "organized quest for knowledge," and is generally divided into two areas: applied and fundamental. Research, the panel emphasized, must be based on facts.

Farm accident research now in progress continues to search into the underlying causes of accidents. Standardization of safety equipment and operating principles are being applied to farm equipment to reduce confusion and to safeguard operators.

In regard to cornpickers, the best safeguard for the operator is to make sure his machine is maintained in the most efficient operating condition.

A question and answer period designed to bring out important research subjects produced the following proposed areas for study:

1. The effect of vibration on the machine operator
2. The effect of dust on the health of the farmer
3. Insecticides and their effect on humans
4. Basic research on human behavior in relation to accidents
5. Causes of accidents from the view point of human tolerance and behavior
6. Research into the causes of hay baler accidents
7. The effect of nutrition in relationship to fatigue and accident rate

Four factors stand in the way of expanded research. They are: 1. lack of manpower. 2. lack of funds, 3. lack of facilities, and 4. lack of administrative support.

The way to overcome these obstacles is to do a complete study of the present research situation and on the basis of it present a strong case for the need.

In his closing remarks Lanham stated that technical societies should play up safety factors in technical papers. Others stated that there should be further use of commercial institutions in furthering safety research and that the Farm Conferences of the National Safety Council take the leadership in accelerating such programs.▲

THE OHIO STORY—A RURAL ACCIDENT SURVEY

PROGRAM MEMBERS:

W. E. STUCKEY, farm safety specialist, Ohio State University, Columbus, Ohio.

W. B. WOOD, director of extension, Ohio State University, Columbus, Ohio.

R. H. BAKER, associate professor, agricultural economics, Ohio State University, Columbus, Ohio.

DAVID GERBER, associate agricultural extension agent, Ottawa, Ohio.

LITTA ROBERSON, director, Women's activities, Ohio Farm Bureau Federation, Columbus, Ohio.

The Ohio rural accident survey, conducted during the 1957 calendar year, was a stratified random sample survey to ascertain the frequency, severity, types, causes, time and places of accidents occurring to farm people in Ohio.

The survey was launched because "A program in safety education, to be most effective, must be based on the needs and interests of the people involved. It is imperative that we have the facts pertaining to a problem before we program to improve the situation. This survey is an attempt to collect the facts pertaining to the accident problem affecting farm people in Ohio. In the process of collecting these facts we are actively involving thousands of people in a safety program—this fact alone, justifies the work and expense involved."

Four hundred forty voluntary, trained interviewers contacting 4,300 families in eight counties in Ohio are the survey work force. Counties included in the study are Putnam, Hancock, Clinton, Fayette, Perry, Carroll, Medina and Lake.

Results of the study will be scrutinized at both the county and state levels to determine further safety education programs.

The following is the letter sent to the voluntary interviewers:

Subject: Accident Study

Dear Friend:

Welcome aboard! We are delighted to have your help in this splendid public service project.

Will you please visit the 10 farms in your sample area as soon as you can, preferably this next week.

Your sample is the 10 farms that lie between your farm and your usual shopping center. They should be the farms on both sides of the road you usually travel going to town.

If you live in town, a sample area will be selected for you.

If two interviewers live too close together to get a full quota, let the one closer to town choose an alternate area, usually the road that parallels your road on the right as you face town.

Even though these samples contain only 600 to 800 families, we expect to have enough representative information to estimate accurately the nature, cause and extent of all accidents that took place in the county in 1957. The eight counties that are carrying on this study will provide enough information to do the same for the state.

Visit 10 farms. What is a farm? Any tract of land of three acres or more on which agricultural operations are performed by the operator, either alone or with the assistance of his family and hired labor (or even a tract of less than three acres producing $150 worth or more of agricultural products for sale), is considered a farm. As you see, this includes part-time farmers, even a farm if all of it was in the soil bank. A farm may be one tract or several, provided it is handled by the same operator.

Report all accidents. What is an *accident?* For this study let us define an accident as any injury to any person living or working on a farm, that requires professional medical care—doctor, hospital, nurse, X-ray, or loss of ½ day or more of time from work or play.

Report all accidents to farm people, regardless of where they occurred.

Any information that you receive should be treated confidentially. Assure the persons being interviewed that no names will be used in any reports, news stories or even in your conversation with others.

All of us thank you for what you are about to do. Good luck!

FARM ACCIDENT STUDY SHEET

☐ No accident this farm or family this period.

A. *WHO* was injured? Husband, wife, son, daughter, hired help. Age, M, F.

B. *WHEN?* Month, day, hour, A.M., P.M.

C. *WHERE* did it occur? In home or dooryard, in field, building or barnyard, while away from farm.

D. *WHAT* were they doing when injured? Working, playing.

E. *WHAT TYPE* of injury? Cut, bruise, sprain, burn, fracture, infection, poison.

F. *HOW SERIOUS* was the injury? Slight, severe, permanent, fatal.

G. *WHAT THING* was involved? Tractor, machinery, tool, animal, knife, chair, bed, ax, auto, truck, tree, gun, lightning, nail, ice.

H. *WHAT KIND* of accident? Fall, same level; fall, different level; slip; caught in or between; struck against; struck by falling or flying object; burn; electric; inhalation.

I. *TIME LOST* from work (or play)—days at home, days in hospital.

J. *COST.* Doctor bills, drugs and medicine, hospital, help hired to replace person injured.

K. Give any other pertinent facts about the accident.

COWBOY HIGHWAY SAFETY

by CALVERT R. DODGE

executive secretary, Wyoming State Farm Safety committee, Laramie, Wyo.

The cowboy state of Wyoming is known for its wide open space, friendly people, wonderful hunting and fishing and its wide highways enabling all comers to get where they're going easily and with a fairly good measure of safety. Yet, with all these attractions 7,707 people were involved in accidents in 1956. During June, July and August, when the fish run to bite the visitor's hook, the visitor is getting himself hooked on the highway.

The driver of the car, truck or other vehicle in Wyoming gets so excited or anxious about this great state that he speeds; he fails to grant the right of way; he drives on the wrong side of the road and he engages in the consummation of toxic liquids that not only dull his sense of beauty in the west, but in many cases plant him within six feet of the top of this wonderful earth.

Twenty-six per cent of these folks that kill themselves in Wyoming do so by ramming into the rear end of someone else's car. Another twenty-two per cent are so anxious to die in Wyoming they sideswipe other cars. An additional four per cent ram head-on to cure their desire for speed and thrill. Our Chamber of Commerce presents the inquiring traveler within Wyoming a brochure, which, among other suggestions, asks the driver to pull off the road occasionally and take in the sights. But this suggestion didn't imply that they should jet propel themselves off the road and into eternity. Yet 80 per cent of Wyoming's noncollision type accidents resulting in fatalities are caused by people driving off the road.

Since Wyoming has some outstanding state highways, 80 per cent of the folks killing themselves use these highways, while five per cent use the county roads.

WYOMING RACES

One race you probably haven't heard too much about is the chuck wagon race held at our famous frontier days in Cheyenne. It's thrill-packed and exciting. Someone usually gets hurt each year but he recovers. Then, we have what is known as the potato race at many of our rodeos. Cowboys on horseback race with a javelin to see who can stab the most potatoes in a box. Once in a while someone gets hurt. But, perhaps the strangest race we have in Wyoming is the race between residents and non-residents to get killed.

In the past five years, for example, the residents have won the race almost two to one which proves that home is where you find most, the kids and the crazy drivers. In 1956 the race ended something like this —119 residents killed and 54 non-residents killed on the highways. Twenty-six per cent of the racers were between 25 and 34 years of age. Sixty-three per cent of all fatal accidents involved Wyoming licensed drivers.

Now, our ranchers and farmers ever since the days of the Oregon Trail and the Lewis and Clark expeditions, have never been outdone. They boast the most of everything and the biggest of anything that's left. We've got the most antelope, the most deer, the most hot springs, and the most scenery—and we're bigger than Texas when you flatten us out. Well, by some poor luck only 49 per cent of instate drivers are rural residents. That's less than half . . . but not by much.

Which proves only this . . . that the slow drawl and easy going way of the 'ole cowhand generally turns into a blood curdling scream and a tense, eager highway hunter when he mounts the 'ole Ford or Chevie for a run to the market. Now, this is a slight exaggeration and we don't want to imply the Wyoming resident has no regard for others, because he certainly has. It just seems like a few of them want to paste up some sort of record, and it just happens that the highway is generally where they get pasted up.

COWBOY HIGHWAY ILLS

But all this preliminary is nothing short of a buildup to point to the true picture of the cowboy and his car in Wyoming. Some years ago, 1949 to be exact, we organized a Wyoming State Farm safety committee. It was reorganized in 1955 and we believe that in the near future it will change its name to Wyoming Rural safety committee so as not to leave out a single cowboy, rancher or sheepherder.

The Committee isn't going to attempt to cure the state of all its ills along highway safety lines, but its members feel that by using constant reminders, working on local levels, creating interest and setting up challenges . . . the 'ole cowboy will become interested enough in himself and his family to want to keep them alive just to see if the committee succeeds.

On the state level the committee developed a state-wide highway safety program. It helped organize 23 (that's all the counties we have) county safety committees. Each of these committees (in 1956) worked out plans for Highway "Slow Down and Live" signs six feet by three feet and placed them along the highway right of way with the help of the highway department. News releases are made to appeal to local residents once a week. Radio releases are also prepared.

DIVIDED UP STATE

To get the program on a surer footing the committee developed an intensive training program for local committees. Each member of the state committee had a district of three to four counties which were his or her responsibility. Safety materials were purchased from the National Safety Council for distribution to local committees. As an example of the result of this seeding process, we'd like to tell you about the Lee Cummins' safety committee story.

One exceptionally bright morning (you must remember that in Wyoming every morning is bright, but some are exceptionally bright) a state committee member went to the county agent's office in Johnson county, Wyoming. In case you don't know where Johnson county is, remember that Buffalo is the county seat and that it is the gateway to the Big Horn Mountains which in turn form the gateway to Yellowstone Park.

Now, in the county agent's office it was suggested that someone call someone to help get a safety committee organized. In another three-quarters of an hour on the same exceptionally bright, morning five safety-minded citizens met for coffee. One of them happend to be Lee Cummins. Lee is manager of a local co-op. The others included an auto dealer, an electrician, a hardware dealer and the county agent.

COMMITTEE'S ACTIVITIES

Six weeks later the Johnson county safety committee, which was formed that morning over coffee, had:

1. Helped complete the highway sign project.
2. Set up a regular series of radio broadcasts.
3. Set up a program for regular news articles on safety.

4. Started a safety message insert program for mailing with regular monthly statements of all business concerns.
5. Prepared safety window displays.
6. Started gimmick program. (with pencils)

This doesn't end their story, however, for they are now planning a whole new year's worth of ideas and they plan to carry it out with gusto. People in Johnson county are becoming fully aware that they themselves are responsible for being alert and for being careful.

Again we at the state level find ourselves in some sort of a race. This time it's a race to keep ahead of Johnson county. So, we have now thrown into the hopper of ideas such items as:

1. A welcome arch at all main highways entering the state. Here a patrolman would stop each visitor's car and issue a welcome ticket, which tells of the wonderful cowboy state and also lists a last chance warning to slow down and live and be careful or else!

2. Stimulate the auto testing program handled in many towns by the Junior Chamber of Commerce.

3. Support and promote pay increases and increase in numbers of highway patrolmen.

4. Promote an improved Justice of the Peace program.

5. Increase our efforts on local safety programs, including the Scout Good Turn Program for 1958, the 4-H and FFA programs and others.

6. Develop an incentive awards program for participants.

These are just a few of the ways in which we believe we can keep reminding people to be safety-minded.

We hope you will come to see us and our program in action. We know you will enjoy Wyoming more than ever because you can be confident we are going to help you help yourself to safety and pleasure in the Cowboy State.▲

BOY SCOUTS OF AMERICA 1958 NATIONAL SAFETY GOOD TURN PROGRAM

DONALD M. HIGGINS, director, health & safety service, Boy Scouts of America, New Brunswick, N. J.

EDWARD WATSON, Explorer Post 2604, Chicago.

JOHN HAYES, Sea Explorer 5733, Chicago.

STEVE SCHOOLMAN, Boy Scout Troop 599, Chicago.

Higgins: I've had the chance for the last two or three days of going around and meeting with various groups to tell them about the National Service Project being planned by the Boy Scouts of America for next year. However, the two finest presentations have been the ones that have been made by boys themselves.

One of those happened Monday morning when, at the annual meeting of the National Safety Council, Scout Warren Meland had the privilege of giving one of the principal talks at the opening meeting of this National Safety Congress. Scout Meland explained the three different phases of the 1958 program which will emphasize traffic safety in the spring, outdoor safety in the summer and home safety in the fall.

This morning I have the privilege of presenting not one but three young men who are going to tell you briefly about the different phases. The first speaker who will tell you something about the Safety Good Turn and the traffic safety phase of the program. I introduce Scout Steve Schoolman of Troop 599, Chicago.

Schoolman: The slogan of the Boy Scouts of America is do a good turn daily, but this concept of personal good turn has been expanded to something bigger. We are ready to announce our 1958 national project. It will be a Safety Good Turn. Safety has long been a part of Scouting.

It will be the job of the Senior Scouts and the adult leaders to impress upon the boys the need for safety practices. We have a membership of nearly four and one-half million Scouts and Scouters. If we do our job properly we have four and one-half million safety conscious young men. Remember, too, that a Scout's activities are apt to rub off on the members of his family, thus expanding the program's effectiveness.

I would like especially to discuss our contribution to the traffic safety program. We will have to function in terms of Scouting tools. Our basic tools are our Scout oath and laws. By applying these laws, particularly alertness, courtesy and obedience, to the traffic problem we can best make our point. We must make our point that alertness is absolutely necessary to traffic safety for motorists and pedestrians. Even a momentary lapse can mean injury, suffering and even death. Neither drivers or pedestrians can afford to daydream in our streets.

The young boy gets the impression that courtesy means tipping his hat to his neighbors on his way to church, or giving his seat to a woman should he happen to be on a crowded bus. We must make the young boy realize that it is more than that. It is the difference between being a civilized human being or the pack of the jungle. To give way to another, regardless of right of way, is a small gesture that will often avert an accident. The small kindnesses cost so little in time, but pay big dividends in good will and safety.

Obedience, as courtesy, is taken from the Scout law. Our country is based on law. Our laws are made for the good of the majority. They must be obeyed to avert chaos. No laws are more important than those concerning traffic. For safety's sake the Boy Scout must learn that he must obey both the written law and the laws of common sense.

If our program can prevent one accident during 1958 it has been successful. We hope, however, to have our achievements surpass this.

Higgins: To speak on the outdoor safety part of this program I present Sea Explorer John Hayes of Ship No. 5733 of Chicago.

Hayes: The summer months offer a great deal of activities for the average boy. He may go camping, sailing, or fishing. He will have a great deal of fun if safety is applied, that is if he uses common sense. It is only good sense to do things as they should be done.

I am most interested in sailing, but sailing can be extremely dangerous if proper precautions are not observed. The same applies to a good many other outdoor sports. Our outdoor activities are designed chiefly for fun, and there is very little sense in marring these occasions with accident tragedies.

HOME SAFETY PROMOTED

Higgins: I like to present the third of our group of speakers who will emphasize the home safety phase which is what we will emphasize in the fall of 1958. This is Ed Watson of Explorer Post 2604 of Chicago.

Watson: The 1955 statistics of the National Safety Council show that some 9,450,000 people were injured in accidents. The home is not safe because more than half of these accidents which occur every year, occur in the home. This is more than 4,000,000. More than 200,000 of these accidents result in death. The financial loss is also great. About $600,000,000 a year in wages are lost just because of home accidents.

I will explain just approximately what will be done in my own council so that you will see what kind of a job will be done. Here in Chicago, in February the program will be kicked off. The first thing will be pamphlets distributed and parades and the whole safety program will be highlighted. There will be individual and unit projects and demonstrations given by each unit. We will also use the help of public officials, the fire department and other local safety organizations.

We will take the first three months of March, April and May for safety on the highways. We will take June, July and August and safety in the outdoor will be our theme. In the last three months September, October and November, we will stress the home safety phase of our program. In these months there will be home safety projects by each unit and there will be a booklet distributed to some 40,000,000 homes to facilitate our campaign and to help reduce and correct danger spots in the home.

The American public will receive the most concentrated dose of safety education which we can give them. Let us all hope that it takes.▲

SAFETY WITH FIREARMS

by ROBERT J. CLAVIN

field representative, Remington Arms co., Inc.,

It has been said that at least 95 per cent of all hunting accidents due to firearms can be avoided if every gunner will acquaint himself with the fundamentals of gun handling and constantly practice them. These fundamentals are simple and serve a dual purpose. First, they help keep hunting a safe sport and second, they make for better marksmanship. There is no excuse for carelessness in gun handling, whether the weapon is loaded or not. The cardinal rule of gun safety is "treat your gun with the respect due a loaded gun."

Here are some simple, *easy-to-follow* suggestions that, if made a definite must on every hunting trip, will assure the hunter and his companions a safe return:

Carry only empty guns, taken down or with the action open into your automobile, camp or home. Whenever you pick up a gun, whether you are indoors or outdoors, always first point the muzzle of the gun in a safe direction and examine the piece carefully to make sure it is not loaded.

The pointing of a loaded or unloaded gun toward a companion is a violation of every principle of good sportsmanship. It is the unpardonable sin of shooting ethics. Do it just once and you have lost the respect and comradeship of your companion, and branded

yourself as either a thoughtless novice or a careless, dangerous shooter with whom it is unsafe to go afield. *Watch that muzzle!* Never indulge in horseplay with firearms. This fool-hardy practice has caused many fatal and near fatal accidents.

Leaving loaded guns unattended is extremely dangerous. A companion may pick one up thinking it unloaded. If it is propped against a tree, car or post, a frisking hunting dog may bump against it, knocking off the safety and stepping on the trigger. These things have happened!

When you are resting in the field or woods, always lay your gun down flat, preferably unloading it first, with the muzzle pointing away from everybody. No one can enjoy a lunch looking down the muzzle of a gun, loaded or unloaded.

In climbing over fences or obstructions, always first pass your gun over to your companion, or pass it through the fence and lay it on the ground. A stumble or a fall might prove disastrous.

CHECK GUN'S BARREL

Before loading your gun, always make sure that the barrel and action are free from obstructions. Foreign matter in the barrel causes more "blow up" guns than any other factor. Should you stumble badly or fall and your gun muzzle touches the ground, always unload and look through the bore to be sure that it is not clogged with mud, snow or other substance.

If you are walking single file, keep your muzzle pointed forward. If you are walking behind your companion, see that your gun points away from him at all times. It is best to walk abreast in the fields or woods, but in doing so, see that your muzzle is always pointing away from him. Never crowd your companion in the duck blind. Be sure that each of you have plenty of room in which to shoot safely.

Never, never pull a gun, loaded or unloaded, toward you from a boat, car or through a fence. You are flirting with a date with the undertaker when you do this.

Always see that your safety is *on* until you are ready to shoot. Sudden jars and brushing against twigs or brush can release the safety catch without your knowing it. Examine it frequently.

When you approach camp or your automobile, always unload your gun. Take it down or open the action before putting it away or setting it aside.

Always make sure of your target before pulling the trigger. Take a good look . . . and then look again! Never fire in the direction of a sudden sound. It may be caused by some farmer's livestock, or, worse still, another hunter. And this has happened, too!

When you are in the woods or close cover, it is best to wear some article of bright color, preferably yellow. No deer goes prancing around wearing a bright colored bandana.

Be careful of shooting at flat, hard surfaces or the surface of water. Dangerous ricochets may result from such shooting.

Don't be afraid of being accused of having "old maidish" ideas in the practice of these simple principles of gun safety. By observing them, you will gain the respect and admiration of your fellow sportsmen and by example, encourage them to do likewise.

Be on the alert always. This will avoid confusion and allow you to bring your gun into action quickly. Alertness makes for good marksmanship. Carry your gun at the "ready" position, hands on the fore-end and grip, muzzle elevated at an angle about in line with your eye. Adopt a free and easy attitude. This will allow you to bring your gun up to your shoulder quickly, get your cheek down on the stock easily and permit the free swing which gets results.

Watch your footing carefully. Try always to be in position to gain solid, comfortable shooting stance which will allow quick coordination of mind and muscle.

Always go comfortably shod. Pinched or blistered feet will spoil any day's hunt. Dress as lightly as possible. If the weather is cold, a couple of light sweaters under your hunting jacket will keep you warm, and if they become uncomfortable, one or both can be removed and carried in the game pocket.

It is a compliment to be invited to go hunting with an experienced gunner. It means he believes you will observe all the rules of safety and practice good sportsmanship. Don't let him down by taking chances and you'll help make hunting a safer sport.▲

HAVE YOU MET OTTO?

by ELAINE PETERS

winner, 1957 State 4-H speaking contest, West Bend, Wis.

Have you ever met Otto? He can be seen most anywhere, on streets and highways, in parking lots and garages, in the city as well as in the country. He comes in assorted sizes, shapes, and colors. He is most happy when filled with sufficient amounts of gas and oil, washed occasionally, and always kept in repair. I think by now you have guessed that Otto is an auto. Yes, Otto is an automobile.

He probably has some of the same characteristics of your own car, because all cars have something in common with Otto. I think Otto knows you pretty well. He knows how you react to certain situations. He knows how long it takes for you to get disgusted with other drivers on the highway.

I wonder what Otto would say if he could talk? He would probably say, "Listen here. The next time we go around a corner you better slow down, because I can't go around the corner at such a speed and still stay on all four wheels." Or he might say, "The next time we come to a railroad track, let's wait for the train instead of getting across in the nick of time." Yes, I guess Otto knows you pretty well.

OTTO FEARS ACCIDENTS

Otto has talked to many of his friends and relatives who have been close to dangerous, yes, even fatal accidents. I wonder what he is thinking as he's waiting for you to drive him? He's probably thinking "If it's happened to them, it could happen to me; if it's happened to their drivers, it could happen to mine." Yes, it could happen to you.

Nine hundred thirty-seven people thought it couldn't happen to them in 1956. Nine hundred thirty-seven people were killed on Wisconsin highways because someone was in too much of a hurry, careless, or didn't use common sense.

Directly or indirectly there is a cause or reason for every accident. We as human beings, like to pass the blame on someone else. I wonder who we can pass the blame on this time. Let's see—could it be the sign's fault? The sign reads "Slow—Watch Out for Cars," but still the driver tries to get across but doesn't make it. It isn't the sign's fault. Well then, maybe it is the road's fault. Yet, the road with its many hills and hollows and sharp turns and curves. No, it is not the road's fault. Oh, maybe it is the weather's fault—the rain, sleet, and fog that make it hard to see.

You have all heard drivers say, "Why, I can handle my car under any condition." Sometimes they can't. No, it is not the weather's fault. How about the car? Is it Otto's fault that his brakes weren't adequately adjusted the last time he was in the garage? No, we can't blame Otto. Then there is only one place we can put the blame—that's on the driver. Every man and woman who attempts to get behind the wheel of an automobile can directly or indirectly be to blame for an accident.

I don't have to list a book of facts or a roll of statistics to prove that there are accidents. You are all aware of them. The most important thing is how they can be prevented. Four-H Clubs, Boy Scouts, Girl Scouts, safety councils, yes, and even motor corporations put out posters, signs, and slogans urging the American people to drive safely.

You have heard them all: "Drive With Care Everywhere," "Drive to Arrive," "The Best Safety Device Is You," "Look Out For the Car Behind the Car in Front of You." Don't the American people know that when they are behind the wheel of an automobile, they are behind the wheel of potential death? What do we have to do to convince the American people to drive safely?

SHOULD WE THREATEN?

Do we have to put out signs and posters that say "Let's See How Many People We Can Slaughter in 1957," "Let's Make It an All-Time High This Week End," "Can You Come Home Minus a Leg or Arm After This Motor Trip?" I don't think it would help. The American people read, and

that's as far as it goes. They don't take it to heart and they don't take it to head.

What is my advice, my opinion? I think we should educate the American people—educate them to use their common sense, to use their God-given ability to use their mind. If there is any doubt that everything will turn out safe, they shouldn't attempt to try it. When driving down the road, a driver should make sure there isn't a car in the other lane when he attempts to pass. In this way he will be using his common sense.

We don't have to let our buttons pop just because the death toll stands at 345 today—much lower than last year's death total through June. We won't let our buttons pop until that death toll stands so low that every state in the Union will look at us and admire Wisconsin. They will wonder what we did to convince the people to drive safely.

BLAME DRIVER ONLY

We must put the blame on the driver because we can't blame the car, the road, the weather, or the signs. Along with signs, slogans, and posters, as well as articles written, we must educate the American people to use their common sense.

I wonder what Otto would say if we asked him. He would probably smile, blink his headlights and say, "I think the American people should invent a car with common sense—a car that wouldn't let you go 75 mph in a 65 mile speed zone because the car, not the driver, has common sense—a car that wouldn't let you cross the railroad track because the car, not the driver, sensed the danger." It certainly would be wonderful, but most impossible.

I would like to leave you with this final thought. The only way we can equip a car with common sense is if we equip you—the driver—to drive with common sense.

PEACEFUL AND SAFE USES OF ATOMIC ENERGY

by COL. WILLIAM D. JACKSON

chief, office of research & engineering, Dept. of Army, Washington, D. C.

The generation before you progressed from the horse-and buggy age to the automobile age. You are witnessing and will actively participate in the beginning of the atomic age. My subject is the Peaceful and Safe Uses of Atomic Energy. My generation failed to make the use of the automobile safely and the pathetic part is that we seem to have become accustomed to the high death, injury, and destruction figures from the automobile. I'm glad to see that you people are trying to do something about it.

Regarding the safety of the use of atomic energy, I honestly believe that the nonmilitary use of atomic energy will be one of the safest forms of energy we have. After all, fire and gasoline are certainly not safe, unless handled properly.

The factor that contributes to the additional hazard of atomic energy is the radiation effect. The Atomic Commission and the other agencies engaged in this work are mindful of the problems and every indication points toward the careful and systematic solution of these problems. May I quote from an article entitled "Reactor Safety" in the September 1957 issue of the magazine *Nucleonics:*

"Since its formation, the Atomic Energy Commission has been concerned with the reactor safety problem. It first set up the reactor safeguard committee, then the industrial committee on reactor location problems, and now the advisory committee on reactor safeguards. AEC has established a technical staff to deal with the evaluation of reactor hazards. It has sponsored the development of more reliable and safer reactors and has invested and is investing large sums in research on the many unsolved problems related to reactor safety.

"Regulations are in effect now requiring a complete description of proposed reactors, their site, and proposed operation. The regu-

lations also require that the applicant make a study of the possible and probable accidents and show that all reasonable precautions have been taken to protect the public and employees. All applications, including the applicant's hazards summary report, are available to the public as are the evaluations and actions of the AEC."

You can see that the excellent safety record, to date, is the result of a concerted effort to proceed with caution during this development period.

Background of the Peaceful Use of the Atom

During World War II, much was learned about nuclear technology. The practical application was toward the developing of a weapon. After the War, the effort was to develop further nuclear weapons; but, in addition, a whole new era has begun. We refer to it as the peaceful uses of atomic energy as contrasted with the military application. We should not refer to it as a new industry because it is much more widespread. Actually, nuclear energy has a potential of spreading across almost every type of industry that we know.

Until 1953, most of the investigations of the potential of atomic energy were sponsored by the Atomic Energy Commission. The address of President Eisenhower before the General Assembly of the United Nations on December 8, 1953, entitled: "The Atom for Progress and Peace" was the real "kick-off" for nuclear applications. It put this challenging program on a world-wide, inter-national basis rather than being limited classification. It is less than four years since this expansion began and the progress is actually unbelievable.

PEACEFUL USES OF ATOMIC ENERGY

Thermal energy for the production of heat and power is only a small part of the potential we have in this field. When coal or oil burns, energy is released during the process of molecular rearrangement. When uranium fissions, the weight of the fission products is less than the original atom. The weight is not lost, but is converted into energy and mostly thermal energy; and it is a potent source of energy, indeed. A many times greater source of energy is the fusion process which is the principle of the H-bomb.

The successful harnessing of this energy is at present limited to the fission principle. It is interesting that with all the advancement we still must rely on water being heated to steam and the turbine-generator to generate electricity. The use of atomic energy has been visualized for the various forms of transportation and, of course, is a reality with the submarine.

The phenomenom of radioactivity has certainly opened up a big field in the form of the use of tracer elements. Radioactive elements can be fed to humans, animals, and plants. The path of the element as it journeys through the life cycle can be traced. Much has been learned about the metabolic processes of the body and much valuable information has been gained on the action of fertilizers in plant life.

RADIOISOTOPES

A widespread application of atomic energy in industry is the use of radioisotopes as gauges, for radiographic testing and as tracers. The basic principle is simple. Essentially a radioisotope with known radiation is placed on one side of the material to be measured and a calibrated detector on the other. Continuous measurements of mass per unit area can be made without contact with the material. The resulting data can then be fed back into the system to control the process. By use of shielding and continuous use of radiation monitoring instruments, these techniques are safe and free of health hazards to the plant personnel.

Wiggin, of the Atomic Industrial Forum, Inc. reported that a manufacturer of coated abrasives found that the installation of five radioactive thickness gauges on his production line paid for themselves in less than a year through a reduction in rejections, waste, machine down-time and inspection personnel and an increase in operating speeds.

The use of radioactive tracers in industry is also well known.

The Quartermaster General of the Army is charged with the problem of feeding the Army. Feeding soldiers in a garrison mess isn't too great a problem, but when large groups of men are fed in the field under adverse conditions, the problems multiply. Good food is one of the greatest morale builders we have. Food is not a luxury, it is a necessity, so we feel that if we can improve on its acceptability we will gain in many ways. For example, there will be less

discarding of food by the troops from the monotony. If all of the ration is consumed, we know the men are subsiding on a balanced diet, and of course, the men are happier and more contented.

Canned foods are acceptable to us in our homes. The main reason is that we can and do supplement our daily ration with fresh meat, fruit, and vegetables. In other words, we don't go to an extreme in eating a particular type of food and become tired of it.

In the field a long distance from base support, we must rely on a preserved food product. We feel that food preserved by radiation may greatly assist us in our problem.

NATURE OF THE PROCESS

As you are aware, the principal cause of food spoilage is the growth of insects and micro-organisms. In frozen foods, preservation and protection is affected by slowing the activities of these organisms. In the conventional canning methods, the food spoiling organisms are destroyed by heating. In this process the food is often subjected to high temperatures, under pressure, for periods in excess of an hour.

In radiation, there is almost no heating and the particular rays used can be either the beta or gamma type. The samples are exposed to these invisible penetrating rays and, through this penetration, the micro-organisms are either killed out-right, or their internal functions are so disrupted that they can no longer reproduce, and we eventually end up with a preserved product which can remain fresh for extended periods of time.

The entire process resembles that of taking an x-ray. Thus, if the food sample has been pre-wrapped before exposure to the rays, to prevent re-infestation by insects and micro-organisms, it will remain preserved in the fresh form—just as is now possible in your freezer. The principal distinction, however, is that with irradiation, foods will require only a minimum of refrigeration and many of them may not require any at all.

Let us examine where we are from the point of view of the two principal technologies involved. First, food—

There are four prerequisites that this method of preservation must satisfy:

1. The treatment must kill the germs in food.
2. The irradiated food must be wholesome.
3. The treatment must not adversely change the color, odor, taste or texture of foods.
4. The process must be economically feasible.

Let us see where we stand on these four points.

Killing Food Germs

There is no question but that radiation will in fact kill all the micro-organisms found in food, provided enough radiation is used. The amount of radiation required to produce an effect varies with the specie, with man being the most susceptible and bacteria the most resistant. For the same organism the lethal dose may depend upon the conditions of irradiation. In general we are fairly certain of the radiation requirements:

(rep—That amount of radiation that would be absorbed in tissue to the extent of approx 93 ergs/gm).

a. At 12,000 reps: potatoes and onions are inhibited from sprouting.
b. At 30,000 reps: trichina worms, insects are killed.
c. At 200,000 reps: Most micro-organisms are killed (Pasteurization).
d. At 2,000,000 reps: The most resistant of bacteria are killed (sterilization).

For comparison purposes only, at 500 reps, 50 per cent of exposed personnel would be killed. (Factor of 4,000).

Wholesome food

We are reserving final judgment on the wholesomeness of irradiated food until more information is accumulated. This conservative attitude is due to the potentially sizeable fraction of our diet which may be irradiated when the process becomes successful. From the data already available we can state that the treated foods do not become radioactive; they are not toxic or harmful, and are often more nutritious than foods treated by other preserving methods.

No adverse changes

We find that foods respond individually to radiation by changes in color, odor, taste and texture. Milk, for example, will develop undesirable flavor changes at 100,000 reps

while dried prunes will withstand 3,000,000 reps without change. For doses up to 30,000 reps needed to kill such things as trichina, insects or liver flukes, only few foods are adversely affected.

We have irradiated cheese. The flavor of the cheese is close to that of imported cheese. It may be possible to develop an acceptability for irradiated food, a method of developing an imported cheese domestically. These changes in flavor are departures from the accustomed flavors. Some of these may be acceptable departures. Other times they are not acceptable.

Process must be economically feasible.

Economic feasibility is somewhat a matter of conjecture at the present time. This is due to uncertainties surrounding the cost and capacity of radiation sources which will be required in commercial practice. There is at present no reliable experience upon which to base firm economic estimates. The best present estimates for different types of treatment techniques are as follows:

—To stop sprouting in potatoes or onions, .03 (plus or minus .02) cents per pound.

—To kill insects in grain, .06 (plus or minus .02) cents per pound.

—To sterilize meat, three (plus or minus two) cents per pound.

These costs will drop and the range rapidly reduce as we develop better methods for producing commercially acceptable radiation sources. This makes a fitting introduction to the next subject—radiation sources.

RADIATION SOURCES

The radiation sources may be of two kinds: reactors using nuclear fuel which produce gamma rays or electron generators which produce beams of electrons. The types of sources available are fairly clear to the food industry. What is uncertain are the respective speed of development, convenience of use, and economics.

The electron generator industry appears capable of constructing any number of machines at the desired operating ratings if orders were placed today. Electron generators have the advantage of portability, low operating cost, high efficiency, and do not use fissionable material. However, they are limited to treating foods processed in slabs such as bacon, steaks, fish fillets, cheese or grain. Electron generators appear to have the best application to foods which have a seasonal or transient processing cycle and relatively low volume at any one location but are not necessarily restricted to such use.

For gamma radiation it appears that reactors are the most feasible. It can be shown that specially designed reactors can be constructed to irradiate food and the heat thrown away and still prove to be a profitable venture. This need not be done since the surplus heat can be used for space heating and low pressure steam, both required in food processing plants.

Reactors for the food industry appear to have the strongest application for foods brought to central locations for processing in volume, such as meat, poultry, fish and possibly grain or for large packages such as roasts, or quarters of beef.

ACCOMPLISHING THE RESEARCH

At present we have contracts with approximately 50 academic, governmental, and industrial research laboratories. Within the quartermaster the main effort of the food program is centered at the QM Food and Container Institute for the Armed Forces, Chicago. Representatives of the Air Force and the Navy are on duty at the institute. Through these representatives, the needs and interest of the other services are considered and studied. Also, it is through these representatives that the other services are kept informed of the progress that is being made.

An interesting means of gaining assistance and creating interest on the part of industry in areas that may or may not be of direct benefit to the military is through "cooperative agreements" or "no cost to the government" type of contracts.

We will irradiate a firm's products in return for the firm's technical evaluation of the resultant product. Abstracts of all progress reports are compiled at the QM Food and Container Institute at Chicago and distributed to all interested and participating companies. We have approximately 30 of these agreements in effect now and negotiations are being made with five or six more organizations.

Let's take a few minutes to discuss the wholesomeness studies on irradiated foods. The work on toxicity, human feeding, and

wholesomeness is being conducted through the cooperation of the office of The Surgeon General, United States Army.

Since March 1954 short-term feeding experiments on irradiated foods have been conducted at three research institutions. After eight weeks feeding of these foods to rats and having obtained toxicity clearance on the basis of negative findings (based on growth of animals and food consumption) these foods are then tested by a palatability panel at the Quartermaster Food and Container Institute. Acceptance of irradiated foods by this palatability panel permits these foods to be actually tested on human test subjects at the Army Medical Nutrition Laboratory in Denver.

Irradiated foods have been fed to these human test subjects at levels of 35, 65, 80 and 100 per cent calories in the diet for as long as four weeks with no toxic effect.

RESULTS OF TESTS

Complete physical examinations were conducted periodically on the human test subjects with follow-up examinations for one year after they have been separated from the project. To obtain information on digestibility of such foods, complete analyses are conducted on the metabolic waste products from all test subjects on an unirradiated diet and irradiated diet. No significant differences have been observed in total energy value, utilization of protein, or digestibility for the untreated and irradiated diets.

For all the foods tested the human test subjects have found the irradiated foods nearly as acceptable as the non-irradiated foods. There are, of course, some exceptions such as irradiated powdered milk and strawberries which in first test were not as well received as the untreated products. Through all these tests no evidence of residual toxic effects from the consumption of irradiated foods has been reported. Work is continuing with future plans being concentrated upon longer term feeding of irradiated foods and the critical testing of irradiated foods that have been stored at 70 degrees F. for three to six months.

The Food and Drug Administration of the Department of Health, Education and Welfare has worked closely with the office of The Surgeon General in the design of certain experimental phases of the broad program. The Meat Inspection division of the U. S. Department of Agriculture has also been apprised of the progress in the program.

The long-term wholesomeness studies, which will carry the foods through to the point where the long-term human feeding can be started, are under way on the following foods:

Meat	*Vegetables*
Pork	White potatoes
Bacon	Sweet potatoes
Chicken	Green beans
Beef	Carrots
Sea Food	Corn
Codfish	Cole slaw
Shrimp	*Fruit*
Tuna	Peaches
Dairy Product	Oranges
Evaporated milk	Jam
Composite Food	Fruit compote
Beef stew	*Cereal Product*
Chicken stew	Flour

These are two-year studies and will be carried through four generations of two different species of animals on each food.

The foods will then be carried through the long term human feeding program, troop acceptance, plant production, and the specification phase.

CIVILIAN POTENTIAL

What the successful development of the process can do for:

a. *Farmer*

Food preservation will provide an important contribution to our agricultural economy since this treatment will result in the distribution of foods at the consumer level on a more economical basis.

The inhibition of sprouting of onions and potatoes may make possible a more orderly marketing of these products since the storage life may be significantly extended. Farmers cooperatives and other collection centers may have facilities for irradiating potatoes. This will minimize disposing of excess "overage" potatoes at distress prices because of the relatively short normal storage life.

Extended shelf life without refrigeration of some foods may expand foreign markets. Markets now closed because consumers do

not own the requisite refrigeration can be opened. This is particularly important in considering exports to lands less appliance-minded then the United States.

b. *Food Processing*

The expansion of markets cited for the farmer would also accrue to the food processor. Foods which now have a limited marketable life because of preservation difficulties may be more plentifully distributed. Oysters and shrimp for example, which are difficult to preserve even under refrigeration may be available to a widespread market.

Potato chip manufacturers, who are concerned about sugar concentration in potatoes will find that irradiated potatoes may be held longer and at higher temperatures without the formation of sugar from starch. A lighter chip will result which is more acceptable from the consumer standpoint.

Marketing of prepackaged meats might be simplified as refrigeration requirements will be greatly reduced.

c. *Public Health Officer*

The Public Health Officer's job of controlling food-borne diseases such as trichinosis, salmonellosis and liver fluke infestations can be facilitated.

d. *Grocer*

The grocer will of course share in the extended market possibilities that will accrue to the farmer and the food processor.

Overall extension of safe preservation time for many foodstuffs will reduce the grocer's losses. For example, the shelf life of luncheon meats, held under refrigeration, may be extended five to 10 times when irradiated. Irradiated tomatoes can be stored up to 14 days at room temperature. Cole slaw, stored at refrigeration temperature in perforated polyethylene or cellophane bags, is satisfactory at the end of 25 days.

Irradiated canned hams need not be kept under refrigeration. Many other meats now requiring refrigeration would be capable of being stored and displayed at room temperature when irradiated. Likewise some vegetables and fruits now requiring refrigeration will be held satisfactorily at room temperature when suitably packaged.

e. *Consumer and Housewife*

The consumer of irradiated foods would benefit in several ways: (a) an increase in the number of foods available; (b) improvements in the quality of certain foods; (c) economies due to lowered cost of refrigeration handling, and extended storage of perishables. Shelf life of items held under refrigeration will be extended reducing spoilage that may take place in the home. The storage life will begin when the package is broken rather than when packaged by food producers. In other words, the food will react to the influences of spoilage similar to that of fresh foods or canned foods after the sealed container is opened.

Future Outlook of the Industrial Applications of Atomic Energy

In research with glass, for instance, the reports are that irradiation experts in this field are within striking distance of producing a glass which is not brittle and which will withstand extremely high temperatures. Standard Oil has already reported that its researchers have produced gasoline by direct irradiation.

In Dun's Review and Modern Industry (a Dun and Bradstreet Publication) of August 1957 it is reported that the General Electric company is producing an irradiated polyethylene tape that has special sealing and protecting qualities. The Upjohn company are sterilizing heat sensitive drugs; such as antibiotics, by radiation. In the Atomic Energy Guideletter of August 7, 1956, it is reported that Westinghouse developed a process to produce silicone rubber, a synthetic rubber, from silicone gum in a matter of seconds by electron irradiation. This rubber is on the market.

OTHER IRRADIATION PRODUCTS

Atlantic Refining is producing hydrazine, a powerful rocket fuel, by irradiating ammonia; experimentally sawdust has been produced which is edible by cattle as a food; a layer of plastics over wood makes a case-hardened product impervious to moisture and insects or fungi; sugars are changed into acids; paraffin can be converted into an insoluble rubber-like material; liquid hexane can be converted into formaldehyde; castor oil is changed into a solid; ordinary colorless glass burns brown; pure white diamonds turn pink or a light green.

A highly potent insecticide has been produced by using radiation to combine benzine and chlorine; new plastics, both hardened and flexible, such as squeeze bottles, are being produced conceivably which will withstand certain amounts of heat and corrosion.

Of course, we are familiar with the use of radioisotopes in medical therapy such as in the control of cancer.

These are only a few examples. One point should be made clear, ionizing radiation does not, just naturally, produce good in all cases. The process must be controlled and properly applied to obtain the desired results.

There has been much discussion about the health hazards from radioactive elements. It is a factor contributing to the anxiety of many people toward the use of any material that is radioactive. The objective approach you are taking to learn more about the developments of the peaceful uses of atomic energy is highly commendable.

I hope that I have been able to impart to you a feeling that every effort is being made to conduct these programs, with safety being one of the primary objectives. You will play the major role in the world's realization of the many benefits from this source of energy. I have every confidence that you will contribute to and witness more advancement in better and safer living conditions than we ever dream of today. I wish you every success in this worthy objective.

CAREERS IN SAFETY

by JAMES D. HILL
district director, field service dept., National Safety Council, Dallas, Tex.

A very prosaic—a very "safe" way—to start any speech is with a definition. So let's try to define safety.

Webster says it this way: Safety is the condition of being safe; the quality of being devoid of whatever exposes one to danger or harm. In the immediate sense in which we use the word here, he says safety is "of or pertaining to the safeguarding of the public, or of a group of employees, or the like, from accident."

Another way to describe it is to say that safety is doing things the right way—not the bush league way, but the big league way. It is keeping things in proper proportion. It is getting things done without "getting done in." It is accomplishing without risking the loss of more than we could possibly accomplish.

In Webster's definition—"of or pertaining to the safeguarding of the public, or of a group of employees, or the like, from accident"—is our first clue to the nature of a career in safety; safety is not something in and of itself, but always a quality of something else—always related to something. Among the world's most misguided souls are those who try to make safety stand alone—who try to make a career of safety in and of itself.

Safety is like a muscle: unless it is attached to something, it draws up in a knot and withers away. The more things it is connected to, the more things it can move, and the more useful and healthy it will be.

ACCIDENT COST $700

The economic basis of a career in safety is that accidents in our country cost more than $11 billion a year—about $70 for every man, woman and child. I could use my $70—couldn't you? If you doubt that it costs each individual $70 a year, find some individual who has one accident in 10 years and ask him if he got out for any less than $700. Even if we never have an accident, it still costs us; because money spent on an accident is just that much less to spend on something else—and all of us have something to spend money on.

The human basis of a career in safety is that accidents kill 95,000 people and injure nearly 10 million every year. This is about one in every 16 of our total population—every year. The 95,000 dead leave perhaps a quarter of a million widows, widowers and

orphans, and grief and hardship beyond measure.

The spiritual basis of a career in safety is our belief that human life and human well-being are the most important things in all creation—that the individual human being, be he high or humble, is the most precious of all values—that concern for our fellow man is second only to concern for our God—"Inasmuch as ye have done unto the least of these, ye have done it also unto Me." There can be no higher calling than serving the cause of life itself.

JOB IN SAFETY

Do you want a job in safety? No one can tell you that any more than can anyone tell you whether you prefer winter or summer; red or blue; tennis or canasta; blondes, brunettes or redheads; football heroes or "brains"; strawberry shortcake or rhubarb pie.

What you like or don't like—what you want or don't want—only you can decide to your satisfaction. If someone else makes decisions large or small for you, to the extent that they do you are courting unhappiness. For those who are deprived, or relieved, or incapable of making their own decisions never amount to quite as much as they would if they did—and they know it. They don't quite understand the full satisfaction, the full significance of life. In a certain sense they have never lived at all.

So don't expect anyone to tell you whether you want a career in safety, or in anything else.

On the other hand, the one thing that can be worse than no decision at all is the wrong decision. We never get the chance to make the same decision twice. So it is important to get the best facts and the best advice we can find upon which to base our decision—any decision.

Here are the facts, and the advice, as best we can compose them.

PIONEER TYPE CAREER

A career in safety? If you want to make a million dollars—don't. But if you would like to make a million friends, you might consider it. If you want an easy job, and someone offers you a job in safety—run the other way, as fast as you can. But if you don't mind putting in that extra hour, and getting back that extra bit of satisfaction in a challenge fully met—you might look into it.

If you like to tread a well-beaten path, where many have gone before and the way is well posted—get into something else. But if you still feel in your heart beat the blood of the pioneers, you might find safety interesting.

If you can take a beating for nine rounds and two minutes, then bring one up from the floor that has every ounce of you in it—it just might be that safety is for you.

If you can travel along through life with a little less of the material things than you know you could get if you went after them and nothing else; if you would like to look squarely into the eye of every man you meet and know you are doing him a service; if a declining accident rate can give you the vision of a child kept whole, a life lived out, a family circle unbroken; if you are willing to take your pay not only in the currency of the market place but part of it also in the currency of the heart and soul; if you want, when you leave this life, to bequeath a little that wasn't here when you came—then maybe you ought to look into this safety thing.

It is only fair to warn you, though, that in a way of speaking, safety is "against human nature." All of our legend, all of our fancy, lean to danger. The tradition is of adventure and derring-do; meeting and conquering superior force; overcoming obstacles; of courage, risk, conflict and victory. Our folklore is a folklore of slaying dragons.

Of course if we look closely and are uncommonly perceiving, we just might discern that the biggest dragon of all is inside man himself—in his tendency to destroy himself, to raise the bet when the cards are stacked, to sell his birthright for a mess of pottage. We might comprehend that educating man out of his foolhardy tendencies is the greatest challenge of all.

This is the challenge of a safety career. If your heart is not strong enough, your mind not supple enough for it, approach it with caution. But if you want a challenge bigger than you can ever be—try and turn your back on it!

Now for the practical side. What kinds of jobs are there in safety? The answer to this is, just about any kind you can imagine. There are safety jobs in industry, of course; and as our technology develops they will become more numerous and more varied. Yesterday, a safety job in a quarry was an oddity. It is no exaggeration to say that before you end your safety career, there will be safety jobs in celestial transportation.

KINDS OF SAFETY JOBS

There are safety jobs today in chemistry, mechanics, electronics, nucleonics, and many other fields. Tomorrow there will be safety jobs in the harnessing and transmission of solar energy, sea-water conversion and transportation, wireless power transmission, and in fields that today we can not even imagine.

There are safety jobs in teaching, construction, motor, rail, air and tubular transportation, traffic, recreation, home economics, civic affairs, agriculture, journalism, broadcasting, government, delving into the earth and sailing the seas—everywhere. Yes, even in garbage collection. Name any field of human endeavor, and there you will find a safety man or woman.

The pay? Average or slightly better than average for similar work in other fields, but never quite as much as you need.

VOLUNTEER, PROFESSIONAL JOBS

Of course, there are safety jobs in safety, too. Some people even work for the National Safety Council! Let me say in this regard that the volunteers—those who work for nothing—far outnumber the professionals. If it weren't for these volunteers, the efforts of the professionals would amount to nothing at all. So even if you don't follow a safety career for pay as you go through life, don't be surprised if you get put to work anyway—on a sort of "do it yourself" basis.

Speaking of experts—you know what a safety expert is, don't you? A safety expert is a person who, away from his native habitat, poses as an exacting professional on the basis of his being able to turn out, with prolific fortitude, infinite streams of incomprehensible formulae, calculated with micrometric precision, from vague assumptions which are based upon debatable figures taken from inconclusive experiments carried out by instruments of problematical accuracy by persons of doubtful reliability and questionable mentality, for the avowed purpose of annoying and confusing a hopelessly chimerical group of fanatics referred to altogether too frequently as being safety conscious.

The basic technique of a safety expert is to blow in, blow off, and blow out. He is sometimes described briefly as "X, an unknown quantity, a drip under pressure" expert.

We chide the idea of a safety expert for one simple reason—there aren't any. It doesn't take an expert to know the difference between right and wrong, sense and insanity—and that is yet another definition we can give to safety—the difference between right and wrong, sense and insanity. There are safety specialists, who work at it full time—but no "experts." All I know about safety you can know if you work at it and think about it and read on it as many years as I have. You should live so long!

BEGINNING SAFETY CAREER

This brings me to my next point: How do we "get there"—how do we get into a career on safety? This is really a good question.

Where do we get the education for it? The answer—everywhere. The only reliable basic course for a safety career is in "The University of Hard-Knox." It is the only school that offers a bachelor's degree—and by the time you finish it, you'll probably be married.

The unvarnished fact is that you can't start into college as a freshman and take a four-year course toward a career in safety. The reason is simple: just as safety to be safety at all must be a part of something else, so also you must be good at something else before you can do a job in safety. Every safety man or woman is an "ex" something else.

For instance, there are 20 other men like me working for the National Safety Council . . . well, not just like me, but working in the same kind of job. Four of them, and I, are ex-policemen. Five come from association work—chambers of commerce, trade groups and the like. Three are ex-school teachers and one a former school administrator.

Three come from journalism, one from professional fund raising, one from a state

motor vehicle department—this one was also once a shrimp fisherman—one used to be a city manager, and one is a former F.B.I. agent. In other divisions of the Council we have ex-miners, ex-farmers, ex-librarians, ex-engineers, ex-highway department employees, ex-statisticians, ex-college professors, ex-waiters, ex-butchers, ex-bakers, ex-candlestickmakers, and ex-experts.

NEVER STOP EDUCATION

These people all have one common characteristic: they have never stopped learning. Their education wasn't finished when they graduated from high school or college—it was only begun. They have had the curiosity to look behind the "how" and try to find the "why." They have tried to find a better way. They have put in the extra thought, the extra try, the extra bit of patience—and they haven't watched the clock.

The ones who are happy at it have enough love for their fellow man to be slapped down, misunderstood, misquoted, misapprehended and mistaken, time and again and still come back for more. Oh, yes—they have one more common qualification—their skulls are two inches thicker than normal, from butting them against brick walls. If you want to be a safety man or woman, this is something you can start practicing on now. Believe me, the experience will come in handy as your career develops.

So if you want a career in safety, first educate yourself well for something else. If you go into any branch of engineering, government, teaching, domestic law, journalism or business management, your chances are good. After you are well qualified in your chosen field, then broaden your experience, give a little more than you get paid for, think safety and keep your eyes open. An opportunity will come, never fear.

Now, at this point there is education available to you—highly specialized education, at places like the Center for Safety Education at New York University, Northwestern University Traffic Institute, Yale Bureau for Highway Traffic, Southern Police Institute, The National Safety Council, and a growing number of other institutions. This is specialized training to add to your qualifications once you have determined your heading.

I should retrace my steps just a bit and tell you that there are a number of things, actually, that you can and should take in your undergraduate college training that will better qualify you for a safety career.

If you go into teaching, by all means take all the safety education courses you can. As frequently as not, these are electives. There are courses in general safety education, special courses in traffic safety, driver education, visual education, and others. These are available to some extent in all good schools of education.

If you go into government, be sure it isn't all international. Take some municipal and state government and, if it is available, some training in police administration.

If you go into engineering, the most likely branch leading to traffic engineering is civil engineering. Just about every other branch of engineering has a strong safety aspect; and in many good engineering schools, special safety engineering courses are available. Look for them.

If you go into journalism, take pains to acquaint yourself with the part of the journalist in civic improvement programs and campaigns. Take some high-level advertising courses, some courses in newspaper and broadcast editorial planning.

If you go into statistics, accounting or business management, lend an eye to the economic aspects of accident prevention.

WHAT SAFETY MAN DOES

No matter what direction your college training takes, there is one critically important point to bear in mind—the basic nature of the safety professional's job. He has a technical job, yes; but fundamentally, his function is to get people to do what they should do and know they should do, but for some human reason don't do. He teaches—but more importantly, he persuades. He compiles information—but more importantly, he conveys the meaning of that information to people who wouldn't understand it but for him. He "sends"—but he accomplishes nothing until his target "receives." The most important thing he does is to communicate—information, understanding, spirit.

What does this mean, in terms of college training? It means, regardless of the area you study in, take all the courses you can manage in psychology, sociology, English and English literature, philosophy, logic, writing, public speaking, and the widest possible variety of courses, within scholastic requirements. Remember, no two people talk exactly the same language. To each the meaning of each word has a shade of a different meaning. The more peoples' languages you can speak, the more you can communicate with, make yourself understood to.

You know, anything I say can be any of four things: what I say, what I mean by what I say, what you hear me say, what you think I mean by what you hear me say. Only when all four are reasonably similar is a thought transmitted from one person to another.

This advice is especially important to those of you who will go into engineering training. The science of engineering is extremely well developed, and the work is heavy; but an engineer's usefulness is not only in what he knows, but also in how much of what he knows he can convey to others.

Regardless of his educational background, any safety professional has still more to learn, and needs to keep on learning as long as he lives. And having learned, simply to impart his knowledge is not enough—he must make it a part of the people he is dealing with. His merchandise is safety—but his business is human relations—communication, confidence, inspiration.

SPIRITUAL QUALIFICATIONS

Finally, the most important qualifications of all you won't learn from anywhere—they are already in you, right now. These are the qualifications of the human spirit. They were described well a good many years ago by a man who wasn't a professional safety man, but who had a deep and significant kind of safety in mind:

If you can keep your head when all about you
Are losing theirs and blaming it on you;
If you can trust yourself when all men doubt you,
But make allowance for their doubting too;
If you can wait and not be tired of waiting,
Or being lied about, don't deal in lies,
Or being hated, don't give way to hating,
And yet don't look too good, nor talk too wise;
If you can dream—and not make dreams your master;
If you can think—and not make thoughts your aim;
If you can meet with Triumph and Disaster
And treat those two imposters just the same;
If you can bear to hear the truth you've spoken
Twisted by knaves to make a trap for fools,
Or watch the things you gave your life to, broken,
And stoop and build 'em up with worn out tools:
If you can make one heap of all your earnings
And risk it on one turn of pitch-and-toss
And lose, and start again at your beginnings
And never breathe a word about your loss;
If you can force your heart and nerve and sinew
To serve your turn long after they are gone
And so hold on when there is nothing in you
Except the will which says to them: "Hold on";
If you can talk with crowds and keep your virtue;
Or walk with kings—nor lose the common touch;
If neither foes nor loving friends can hurt you;
If all men count with you—but none too much;
If you can fill the unforgiving minute
With sixty seconds' worth of distance run—
Yours is the Earth and everything that's in it,
And—which is more—you'll be a Man, my son!
—And you'll make a good *safety man*, too!

OFFICERS OF THE

FARM SECTION

NATIONAL SAFETY COUNCIL 1957-58

Vice President for Farms—KIRK FOX, editor, *Successful Farming*, Des Moines, Iowa.

Chairman—A. J. SCHWANTES, agricultural engineering dept., University of Minnesota, St. Paul, Minn.

Vice-Chairman—EDWARD HOLTER, lecturer, National Grange, Washington, D. C.

Secretary—MAYNARD H. COE, director, Farm division, National Safety Council, Chicago, Ill.

Members: EDWARD S. ADAMS, director of safety, Iowa Farm Bureau Federation, Des Moines, Iowa; MRS. VERNE ALDEN, National Home, Wellsville, Kan.; MRS. ALMER ARMSTRONG, Indiana Farm Bureau Cooperative assn., Indianapolis, Ind.; CLYDE N. BERRY, associate director, Institute of Agricultural Medicine, State University of Iowa, Iowa City, Iowa; THEO BROWN, Moline, Ill.; HARRY BRYSON, American Farm Bureau Federation, Chicago, Ill.; GRAHAM T. COULTER, Kraft Foods co., Chicago, Ill.; JOHN F. DANEKE, General Motors corp., Detroit, Mich.; MISS GERTRUDE DIEKEN, *The Farm Journal*, Philadelphia, Pa.; DONALD H. DUNHAM, manager, Retirement Saf. & Ins. dept., Nat'l. Rural Electric Coop. Assn., Washington, D. C.; JOHN M. EKLUND, director of education, National Farmers Union, Denver, Colo.;

T. A. ERICKSON, St. Paul, Minn.; C. M. FERGUSON, administrator, Extension Service, U. S. Dept. of Agriculture, Washington, D. C.; MRS. HOMER GREENE, health & safety chairman, National Home Demonstration Council, Tutwiler, Miss.; MISS EUNICE HEYWOOD, assistant director, div. home economic programs, Federal Extension Service, U. S. Dept. of Agriculture, Washington, D. C.; C. N. HINKLE, Standard Oil co. (Indiana), Chicago, Ill.; ROBERT HOWEY, National Vo.-Ag. Teachers assn., Sycamore, Ill.; MISS AMY KELLY, College of Agriculture, University of Missouri, Columbia, Mo.; MRS. DORSEY KIRK, Illinois State Grange, Oblong, Ill.; KEITH KIRKPATRICK, Radio Station WHO, Des Moines, Iowa; EDWARD R. KLAMM, Allstate Insurance co., Skokie, Ill.;

C. C. LANG, Extension Service, U. S. Dept. of Agriculture, Washington, D. C.; S. E. LARSEN, Michigan Farm Equipment assn., Grand Rapids, Mich.; E. W. LEHMANN, prof. Emeritus, Urbana, Ill.; S. P. LYLE, Extension Service, U. S. Dept. of Agriculture, Washington, D. C. EARL MERRILL, Republic Steel corp., Cleveland, Ohio; DONALD L. MILLER, National Agricultural Chems. assn. Washington, D. C.; PAUL MULLIKEN, National Retail Farm Equipment assn., St. Louis, Mo.; HERSCHEL NEWSOM, The National Grange, Washington, D. C.; G. L. NOBLE, National Comm. on Boys & Girls Club Work, Chicago, Ill.; V. S. PETERSON, E. I. Du Pont De Nemours, Ames, Iowa; HARRY PONTIOUS, Nationwide Insurance co., Columbus, Ohio;

HARRY L. POWELL, Goodyear Tire & Rubber co., Milwaukee, Wis.; FRANK REYNOLDS, manager, Agricultural Extension, U. S. Steel corp., Pittsburgh, Pa.; L. P. RICHIE, vice president & director of purchases, The Oliver corp., Chicago, Ill.; IRA ROGERS, Automotive Safety Foundation, Washington, D. C.; MARTIN RONNING, Minneapolis-Moline co., Minneapolis, Minn.; LOUISE ROSENFELD, assistant director home economics, Cooperative Extension Work, Ames, Iowa; C. G. SCRUGGS, Progressive Farmer, Dallas, Tex.; CHARLES SHUMAN, American Farm Bureau Federation, Chicago, Ill.; DR. W. T. SPANTON, Federal Security Administration, U. S. Office of Education, Washington, D. C.; ARTHUR STAPEL, Fox Valley Cooperative, Inc. Appleton, Wis.;

OTTO STEFFEY, president, Illinois Agricultural assn., Chicago, Ill.; RANDALL C. SWANSON, farm safety specialist, College of Agriculture, Madison, Wis.; E. W. TANQUARY, International Harvester co., Chicago, Ill.; F. R. WILLSEY, farm safety specialist, Dept. of Agricultural Eng. Ext., Purdue University, Lafayette, Ind.; W. B. WOOD, director, Extension Service, College of Agriculture, Ohio State University, Columbus, Ohio; CARLTON ZINK, products research dept., Deere & co., Moline, Ill.

Other Volumes in this Series

Users of this volume will find much value in its companion volumes. Here is the list:

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

THE FERTILIZER SECTION

This volume is a record of the sessions held at the 1957 National Safety Congress by the Fertilizer Section. The conduct of these Congress sessions each year is only one of the many cooperative activities which the Fertilizer Section carries on in behalf of its members, and for the benefit of accident prevention work in the fertilizer industry generally. The Section gives guidance in the preparation of a great variety of technical and educational material useful in the day-to-day safety programs of fertilizer companies.

The activities of the Section are under the direction of its executive committee, the members of which are listed at the close of this volume.

FRONT OFFICE SAFETY

by **FRANK A. GERARD**
safety manager, Olin Mathieson Chemical Corp., New York City

We all know that we must have the cooperation of top management for our Accident Prevention Program to succeed. Without this cooperation our program will collapse.

How many of you do have the cooperation of top management? What is your top management contributing to your Accident Prevention Program? It's the same question with a different twist—Are your answers the same? Sometimes I think we get all mixed up on the question of cooperation and become complacent in thinking that we have it. Yet when we analyze it we find that we have *little* and *what* we do have is shallow and leaves a lot wanting.

Now I'm not telling you that your top management isn't cooperative. Ask them and they will be the first to tell you that they want a safe place for their workers to perform their jobs. They tell you "No sir, we don't want to hurt any of our people," and add, "I'm 100 per cent for this safety business." Sounds natural, doesn't it?

ARE SAFETY, PRODUCTION EQUAL?

And do you know that they really are sincere in their beliefs that they as top managers are doing everything they can and should do in this accident prevention business. Let me pose another question: does your management give the same attention to your problem as a safety man as they do to the guy who is in charge of getting out production? I doubt it.

Now that we have taken our top management for a ride, let's take a mirror-like look at ourselves. We are the safety men, hired to do the job. Too many of us use that old excuse of "lack of cooperation," to cover up our own shortcomings. Let me point out that if you don't have the cooperation of top management, you are not doing your complete job.

You as safety men, must in some way get *the cooperation of that guy in the front office*. I know this is sometimes difficult because the path to the front office is long and many times cluttered up with persons between us and the guy in the front office. However, somehow, someway, we must get to him. Believe me, when I tell you that the guy in the front office is a regular guy fully capable of understanding your problems and willing to help you with them.

But remember that he can't help you unless he is aware of your problems. If you have a problem bothering you, you will find that they can be solved a lot easier and quicker by having the guy in the front office on your side.

INJURY PROBLEM

Let's take a look at a few of these problems that are common to most of us. Did you ever analyze the injuries occurring in your plant and find that you were having a lot of eye injuries, toe and foot injuries, head injuries, and the type of injuries that protective equipment would eliminate?

Sure you have and you started a program to provide safety glasses to prevent eye injuries, safety shoes to protect the toes and feet and hard hats to prevent the cracked heads. It wasn't easy, was it? The glasses fogged up, the safety shoes pinched and the hard hats caused headaches.

Now suppose we take that guy in the front office into our confidence and point out to him the type of injuries we're having in our plant and how easy it would be to eliminate them, at least part of them, by the simple application of protective equipment. How much is this program going to cost? You know the answer to that one—much less than the injuries cost.

And do you know another thing—when the guy in the front office puts out the Bulletin announcing the program to his foremen, the safety glasses don't fog up nearly as much as they did before, the safety shoes become as comfortable as bedroom slippers and the hard hats worn at a rakish angle improve the looks and "We were only kidding when we said they gave us headaches."

Of course, there is a lot more to this accident prevention business than prevent-

ing injuries with protective equipment—job training, inspections, meetings, posters, injury statistics, contests, machine guarding and many others. But let me assure you—they will all come easier when the guy in the front office lends you his support.

Now let's get back to this subject of cooperation. Let's take a fresh look at it. What are we trying so hard to get from top management—cooperation? Let's give it another name, participation. Let me stop here a moment to illustrate what I mean by "participation" and tell you a story.

Several years ago one plant had a bad accident and injury record. A new plant manager and I were assigned to reduce the accidents and injuries. Production and all other operational phases of this plant were satisfactory. The one exception was the unfavorable injury rate.

PUSH FOR PARTICIPATION

On the train going out to this plant, the new manager and I decided on the plan that we thought would bring results and reduce the excessive injuries of this plant. The new manager called a meeting of the top supervisor of the plant, the plant engineer, the production manager, the projects and planning supervisor and all the others. This is about what he said to them:

"Gentlemen, Gerard and I have been given the job to improve the injury record of this plant. Production and other phases of the operations are satisfactory so our immediate and most important job is to attack this injury problem. This is the way we propose to do it.

"I want each of you men sitting around this table to put your assistant in charge of what you are now doing. I want each of you to do nothing else but work toward improving the injury record of your particular division or department. You will continue to do this until I relieve you of the assignment."

"Now," he said, "Gerard and I have six months to improve the injury record of this plant. If at the end of that period the injury rate is as high as it is now, Gerard and I won't be here." Then he added, "But gentlemen, you won't be here to see us leave."

MANAGEMENT BECAME SAFETY ENGINEERS

I don't have to tell you what happened. Immediately accident prevention became of prime importance—everything else was secondary. Top management men were the safety engineers of this plant and, incidentally, good safety engineers. So good in fact that I had little to do. They did everything that was to be done. The results? This plant of 13,000 people operated a complete year with only one serious injury; that being the loss of an index finger.

The gratifying part of this entire program was the continuing interest these top management people displayed long after they had been restored to their original assignments. Accident and injuries were no longer a problem in this plant.

I think that about tells the story—cooperation, participation—call it what you wish. Top management—front office management must be a part of your program. Without it you cannot have a successful accident prevention program.

SAFETY—A RETREAT OR A CHALLENGE

by DR. JOHN H. FOULGER

director, Medical Research, E. I. du Pont de Nemours & Co., Wilmington, Del.

During 1956, 40,000 persons were killed in highway accidents. Public announcement of this stark fact caused little comment. In the same year in Rome, a pathologist said many chemicals used to process or package food might cause cancer. He offered no proof. His purely speculative statement was repeated and magnified in the press and its repercussions are still with us in Congressional Committe hearings on new food laws.

In 1956, 28,000 persons were killed in their homes. In the same year, a presidential candidate raised the question of damage to health by "fall-out" from atom bomb tests. Again the facts received little attention, but the speculation resulted in acrid discussion, with petitions signed by "scientists" and others who frequently were ill informed.

These two attitudes: complete ignoring of data on needless loss of life and undue preoccupation with fears caused by pure speculation must appear irreconcilable to an impartial observer. They form a pattern of schizophrenia in which behavior is completely dissociated from reality. Just as a patient suffering from this mental disease can harm himself and others, so can a populace greatly harm itself if it willfully ignores facts and acts on pure speculation.

Those speculators raise fears in the name of "safety" and "public health." In the name of "safety," they demand that advances in food technology and radio activity should be prescribed unless shown to be "absolutely without harm" to the health of a single individual.

CAN'T GUARANTEE SAFE ACTIVITY

On the surface, this is an admirable demand. But analysis leads to an impossible situation. No human activity can be guaranteed absolutely harmless. I can not be sure that, as I rise from my bed after a sound sleep, I will not suffer circulatory collapse, because in sleep my muscles relaxed and cannot suddenly adjust themselves to the hydrostatic forces in moving from a horizontal to vertical position, and so cannot assist the flow of blood to my heart.

I cannot guarantee, as I step out of my doorway, that a roof tile, loosened by wind or rain, will not fall on my head.

I cannot guarantee that my neighbor's dog, usually very friendly, will not suddenly become aggressive.

Guaranteed, absolute safety is incompatible with any conceivable activity. The demand for guaranteed safety prohibits advancement in either the arts or the sciences. Safety has no meaning if divorced from activity.

This matter is of vital importance to those of us who attempt to prevent illness, or traumatic injury. The extremes of attitude shown by people are themselves unsafe—dangerously unsafe.

The rising loss of life and greater incidence of injury on our highways stem from indifference, carelessness or even contempt of both the harmful potentials of the automobile and the police powers of the state. But unfounded fear, aroused by propaganda based on pure speculation, can be an even greater enemy of safety than can contempt. Drastic action can sometimes convert contempt into respect. But what action can allay fear?

As a physician I deplore the "fear technique" employed by many national organizations in fund campaigns for medical research. The fear engendered by "scare headlines" might do more harm in a short time than research could nullify in years.

Not long after the report from the Rome meeting of the International Union Against Cancer said materials used to process or wrap foods might contain carcinogens, I received a letter from New York. The writer, about 60 years old, was much concerned if he could safely eat foods wrapped in modern synthetic films. His physician had told him not to purchase fruit or vegetables wrapped in plastic bags. They might cause cancer.

In France, Belgium and Germany, following the Rome statement, an organization was set up to oppose wrapping food in modern plastics. The fact that modern wrappings protect food and reduce the incidence of poisoning from bacterial contamination is apparently of minor importance compared with the pure speculation on the cause of cancer.

FEAR RESULTS IN IGNORANT ACTION

A few years ago, when a national organization started a campaign for medical examinations to detect cancer in women, two physicians told me their great concern about the mental state of their wives. Both were older women. Both had read the bulletins of that society and feared they had cancer. But both were afraid to have an examination because it might prove they did have cancer.

Fear, inevitably, leads to an attempt to hide. Its immediate results are either deliberate inactivity or aimless flight with uncontrollable, unpredictable results. Abject fear can lead to panic. A single individual suffering from fear can panic a whole crowd. Again, we have ample examples—the Cocoanut Grove fire in Boston, the

circus fire at Hartford, Connecticut. The possibility of fear and panic was the greatest problem of civilian defense workers during World War II, and it is a still greater problem in the present atomic era.

If both contempt and fear are enemies of safety, what mental attitude should be developed in our fight for safety?

First, what do we really mean by "safe?" A good working definition by the Food Protection Committee of the National Research Council is "'Safe' means the practical certainty that no harm to health will result" from a given activity. Note the "practical certainty" not the "absolute certainty." Webster's dictionary defines practical as "given or disposed to action as opposed to speculation."

In our application of the words "safe" and "safety" therefore, we cannot divorce them from action. That action must be orderly action, not misdirected action induced by fear, nor careless, nonchalant action accompanying contempt.

What is the basis for this action and, therefore, for safety? Obviously, there must be knowledge. To establish safety in any operation, whether it involves simple or complicated mechanical apparatus, the use of chemical agents, or physical forces such as heat, electricity or radio activity, we must know what we are doing. We must know much about the mechanisms we use to know their potentiality for good and for harm.

Obviously, we must respect these mechanisms or these agents. When we realize hazards are involved in our operations, we must develop continuing respect for them. With this respect, we can carefully study the hazards and devise methods of reducing them or protecting against them.

In our plant safety programs we must remember that often those closest to the hazard may not be as well informed as we who set up the program. Ignorance leads to fear rather than respect, and fear disregards common sense. Fear can convert a safe situation into a hazardous one. In our training, therefore, we must be diligent in allaying fear.

RESPECT HAZARDS

Finally, we must never forget that despite all our efforts for good operation and maintenance, physical equipment can break down and human error can enter. Fatigue, incipient illness, improper nutrition and family worries lead to inattention in even the best worker. Limited knowledge may render a good worker incompetent to handle a serious emergency. For this reason a properly designed disaster program must be set up.

Safety looked at from this standpoint offers a challenge to all of us; a challenge to acquire all the knowledge about our operations and their possible hazards; a challenge to devise safer ways of attaining our ends, or better protected procedures or devices for hazardous operations or materials.

If we let fear prevail, if we demand the unattainable—absolute safety—and use this demand as an excuse to retreat from reality, we can only be certain of one result—complete, stultifying inactivity and the drying up of all sources of new knowledge and all social progress.▲

HOW WE CAN PROFIT FROM THOROUGH ACCIDENT INVESTIGATION

by JAMES E. KAVANAUGH

supervising engineer, Engineering & Loss Control Div., The Travelers Insurance Co., Minneapolis, Minn.

We are here to consider the accident and how thorough investigation of the accident can, and does, lead to effective accident prevention activities, and so contribute in a real way toward an overall effective program. We do not expect to treat the accident problem as a whole, but rather to consider how one accident at a time will serve as a means to bring this problem into range, and maintain a program directed toward the real target.

A number of accidents may be selected for analysis and study as a group at any time. Such a study may indicate some patterns which lead to certain statistical conclusions upon which a program of training, education, publicity, or other accident prevention activity is based to meet a definite problem established through such analysis study. Such conclusions can be reached only by analysis of the factors involved in each accident.

COMPLETE FACTS REQUIRED

Thoughtful consideration will show that the conclusions reached will be justified and worthy of recognition only if they are based on true and complete data concerning each one of the accidents in that group. Anything less all the facts surrounding each accident in the group will lead to erroneous conclusions, the adoption of unjustified activities in the safety program, and consequently, disappointing results from many of the things we try in this field.

As we progress I plan to show that a weakness in the accident investigation procedure is not only a weakness in this one phase of the program, but also supplies the lack of sound information and false data that leads to false conclusions upon which we base the activities set up in our entire accident prevention program. No wonder that so many of our plans seem to fall through.

FALSE FACTS HAMPER PROGRAM

A short time ago I had occasion to review a plant accident file to establish the points of problem and to recommend a program for improvement. If the conclusion set down by the supervisors were accepted as thoughtful ones, based on analysis of the occurrence, we would conclude that the accidents occurred, at least 90 per cent of the time, because the man involved did a stupid thing, contrary to well known and established rules, for no apparent reason other than a complete disregard of all consequences.

Obviously such a conclusion, if a just one, would make prevention of accidents an impossibility. The control of any problem is predicated on the proposition that all, or at least a great majority of those involved want to eliminate the problem, and are ready to work to that end. This situation existed only because the data established for each accident was not true or complete, and the conclusions drawn were for some other purposes than to identify a problem and establish a remedy for that problem.

One specific example will demonstrate the results from an incomplete development of the accident facts as well as from erroneous data. In this case a man came to work one morning suffering greatly from the effects of a night on the town. It was reported in the first investigation that this man accidentally took a drink from a whiskey bottle containing carbon tetrachloride.

Following this, the man, not feeling quite well, went home to his bachelor quarters. Two days later he went to the hospital with a heavy cold, and he died shortly thereafter from the effects of his drink of carbon tetrachloride. Based on this, the conclusion reached as a result of investigation by the supervisor, was that a more suitable container be used for carbon tetrachloride, and with this correction the case was closed.

MORE FACTS REVEAL TRUTH

Because a fatality was involved in this case, a subsequent investigation was made on a more thorough basis. It was found that the man came to work on this morning with the hangover. As he joined the crew the supervisor chided him for his weakness saying, "If you must drink why don't you try some of that sometime and make a good job of it" (pointing to the whiskey bottle containing the carbon tetrachloride).

Before the man could be stopped he took the advice offered and drank some carbon tetrachloride. Following this the man did become ill, went home, finally reported to the hospital saying he had a bad cold, and he died.

With the new information developed in this investigation, there are several additional, worthwhile conclusions which can be used to correct some obvious weaknesses in the safety program at this particular place. Some of these would be as follows:

1. The matter of the supervisor's handling of the employee who reports to work in unsatisfactory condition should be given attention. Analysis may show this to be an order on a

plant wide basis and perhaps an instruction program would be in order.

2. The matter of prompt and adequate medical attention for injured employees needs clarification, and procedures for properly reporting such instances may need revision, or to be established.
3. The matter of follow up on an employee who leaves the job under questionable circumstances needs attention. Note that in this case medical attention was not arranged at the time of the occurrence, no report was made to any other person so that follow up attention could be given, and no attention was personally given by the supervisor involved.
4. Of course, a more suitable container should be provided for the carbon tetrachloride, but we now find that this was only a minor factor in this case, with other more widespread weaknesses evident as a result of a real investigation.

Consider here that the only reason an investigation was made that could lead to some intelligent and effective handling of the problem was because a fatality resulted. If this seems to violate the foundation principles on which we wish to build our accident prevention program, we have another good reason for giving this matter of accident investigation work more attention.

TRUTH AIDS ACCIDENT PROGRAM

This accident problem often seems insurmountable when viewed as a whole, and often ridiculous when considered in the light of the false and incomplete data available to us. This problem can be brought into focus if we will give enough attention to the digging into the specific problem to get the full and accurate actual information, and to reach conclusions through our best efforts at problem analysis. To this end I would now discuss the matter of accident investigation.

To begin with, this procedure is justified on the basis that practically all men are honest, interested in their own well-being and security, as well as the well-being of their fellow man. The fact that the job performance is not always up to this standard has its cause in some specific factor that can be found only through a complete investigation.

Perhaps this was best said by one of our outstanding men in the field of training, "Most accidents occur because someone did not know enough about something." If we identify the something which was not known with accuracy, and relate it to the person or persons who are involved or can be involved, we have started a chain of action that can lead to successful accident prevention work.

As a second consideration, each person and each firm or organization has established certain standards of performance which they attend to attain in all phases of their enterprise, including accident prevention work. Sometimes, especially in the accident prevention field, these standards are obscured even from themselves when they feel standards set might not meet general approval if set forth for examination.

ACCURACY CUTS ACCIDENTS

As a consequence you will often find men, even in high places, will assure you solemnly that they most certainly want to prevent all accidents. Yet, they will point helplessly to a man who bumped his arm against a building column and lost time when the arm became sore. With a set of true standards set up and acknowledged, it will be obvious that this accident defied control because the injury or potential for injury from this type of accident was so slight compared to the expense and inconvenience required to correct or eliminate this possible hazard.

The dividing line between accidents in this category and those which result in a serious injury, or have a potential for serious injury, is definitely set in each organization. I would strongly recommend that everyone resolves to find his dividing line, recognizing that experience tomorrow, or next year, may cause him to shift the line one way or the other. With a clear view of how far you are now ready and able to go, you will be in good position to apply your efforts to make them count, and get good results.

We must also be certain that we are not trying to identify a person guilty of some defection in this investigation, for the end result of this would be a criticism, rebuke, penalty, or punishment for that person.

This could be great deterrent, and may be a good way of handling criminals, but fortunately we are dealing with good substantial men and women who are trying to do a good job to earn the best living they can.

Investigation should deal entirely with the accidental occurrence, to identify the cause, or causes, of the occurrence, and to establish measures for control of the cause. The end result can be that some person will be required to make some change, adjustment, or undertake some other specific action designed to control or eliminate the cause of the accident as determined.

MATERIAL HANDLING PROBLEM

Perhaps an example in line with this last statement would be well in order. A loading elevator was used in one plant to raise sacked material from ground level to the floor level of the plant. The elevator was loaded at ground level, and then the men would enter the building through a regular doorway to raise the load and transfer the material into the plant area. One man was accidentally injured because, contrary to instructions and rules, he climbed over the loaded platform to the building floor, instead of using the doorway.

At first consideration, how easy to say that rules were violated and punishment was in order. A good investigation, however, showed that the doorway was 75 feet from the elevator location requiring a walk of at least 150 feet each time a load was handled. This was a great inconvenience and a waste of time. Therefore, not only this one but all men assigned to this particular job took the more direct route over the loaded platform as a matter of course.

WHO SHOULD INVESTIGATE?

Investigation of the cause of the unsafe method of gaining entrance to the building, if such were ever noted by a responsible supervisor, could have determined this same reason for the bad procedure long before the accident occurred. In any case installation of a door and proper steps adjacent to the elevator eliminated the inconvenience, waste of time, and made unnecessary attention to enforcing the rule against climbing over the loaded platform.

With this change, the safe method also became the easiest and the most convenient, thus making the safe way more desirable to all persons concerned.

With this, we come to consider the actual investigation procedure. Obviously the person best qualified to do the job should do it. In industry this is the supervisor in charge of the operation and the person involved in the accident who knows and understands this specific planned job in question.

The fact that this supervisor will usually be the person responsible for making at least some of the adjustments in procedure and other matters, also makes this a desirable place at which to start. This set-up would result in getting the best possible job started and in training the supervisor in investigation, analysis and self analysis, and other qualities to assist him in all phases of his work.

The findings of this investigation should be reviewed by the department head, superintendent, safety director, and others who have a responsibility in this work, each to make the correction complete, perhaps even to draw plant wide attention to the problems disclosed.

OUTLINE AIDS INVESTIGATION

Although an accident investigation may be made with no tools, we have found that a much better job can be secured by providing the supervisor with an outline to follow. A little imagination will show that this outline can be so arranged that it will guide him through an orderly investigation, serve as a form to record his findings concisely and orderly and result in enough standardization of the record material to make further analysis and consideration of this report much easier.

My suggestion here is not to recommend any specific form of outline, but rather to analyze the purpose for which this form should be used, and give attention to proper application of the investigating procedures. Any form of outline and report can be considered satisfactory if it incorporates at least the following major points.

- Provision for full identification of the incident under investigation, including date, time, specific location, person, machine, and equipment involved.

The purpose of this is only identification to aid in consideration of other factors that may be involved in the occurrence. Let us emphasize again we

investigate one accident at a time, not as a type, but as a very specific incident.

- A description of the injury or damage is recommended. This may give some idea as to the seriousness of the accident type, and will identify the evidence which motivates the investigation. In this connection the serious injury may have real value, but care must be taken to assess seriousness of a relatively minor injury for, in this case, it may be the potential for injury that should be considered as the guide to the seriousness of the accident.
- Description of the accident. This is the fact finding portion of the investigation upon which all of the conclusions to be made in following consideration finds its base. All factors involved in the accident should be established and recorded, beginning at the point with the men, tools and equipment are brought together, and continuing step by step to the point of accident. In other words, this should be a factual history of the job or task from its beginning to its conclusion in the accident.

  Perhaps a fall from a ladder might be said to occur when the man lost his balance and began to fall. The incident, however, also included the man who used the ladder, either under instructions or for some other named reason, to perform a specified job, and includes identifying the ladder, its set-up, and the progress of the work to the point of fall.

  All this must be factual and complete. Any tendency to alter, suppress, or otherwise depart from actual fact must result in false conclusions, and an inadequate corrective action.
- Name specific condition and/or acts which caused this accident. The condition and/or act which caused the accident may or may not be subject to control at this time. If the final conclusion is to be reasonable, the specific items named should indicate the exact point where the progress of the activity departed from the planned course of progress.

  In the case of the man falling from the ladder, it might be found that the man used both hands to carry an object up the ladder, and this could be identified as the specific cause of his losing balance on the ladder.
- The reason for the specific cause or causes named.

This item is often included with the above item, but I feel that it should be considered separately in this discussion. In many cases, the reason for the immediate cause of the accident is much closer to the remedy than the cause itself.

CAUSE DETERMINES CORRECTION

In the case of the man losing his balance and falling from the ladder because he tried to ascend the ladder with both hands full, effective corective action might well depend on the reason entirely. Consider a few things that could have served as reasons in this case.

1. The man had performed a like task in this manner as a matter of habit, and did not realize the possible consequences of his action. Perhaps an explanation of the proper use of ladders and the reasons for the rules of use is indicated. This might well be made the topic of discussion at a tool box safety meeting, followed by special supervisory attention to observation and correction.
2. The object handled might have required both hands to handle it. Here it might indicate a lack of job planning on the part of the supervisor or the workmen, and may require correction there.
3. The ladder may have been a substitute for some other arrangement. If so the substitute of a substandard arrangement as a matter of work procedure would be the problem in question.
4. This could be a two man job. Because of shortage of help, or some other reason, this one man was assigned to the job. Here the balance of how far to go in emergency situations may be subject for control action.

Each reason, and perhaps other, would point to a specific corrective action as the one in order. The selection of the correct factor would lead definitely to the most effective corrective or control action.

- **Remedy.** Each investigation should conclude with the specific action to be taken to prevent a similar occurrence. A man convinced that a similar accident shall not occur, will not find any remedy, even one involving effort and real attention, to be a burden. The remedy will be anticipated as an opportunity to improve the quality of the work performed under his responsible direction. The remedy selected must be adequate and carried to a conclusion.

STEPS IN REMEDY

A conscientious and thinking man will know that a remedy is often difficult and may, on occasion, require some temporizing. Then too, with full knowledge of what must be done, he may find it necessary to program the correction. Many times he must consider that a remedy must include at least three steps in progress.

1. *Immediate or temporary action to control.* In some cases a final and complete control or correction of an existing hazard may be both impractical and close to impossible. In such cases the supervisor should take temporary action to prevent a similar occurrence, even if the temporary action may require specific attention on the part of the supervisor, some inconvenience, or other undesirable situation. It is not enough to identify the problem and arrange for correction, but immediate action must also be considered.
2. *Permanent correction.* Permanent elimination of the hazard through revision of progress, guarding, replacement, or other action as soon as practical should not be overlooked. This is important, for until this permanent correction is realized, the temporary controls, or other action of some inconvenience must be maintained. It is important to return operations to normal as soon as possible.
3. *Planned control of future problem.* Control procedures to identify similar conditions before a point of failure or accident occurs should always be considered. This might require inspection, testing, schedule for reinstruction of workmen, changes in overall procedures or schedules, or other action to be undertaken on a planned basis.

   Particularly in this phase of the work, it should be recognized that once this control action is set up it should be considered no longer a matter of accident prevention consideration, but is a revision in operating procedures set up for the overall improvement of performance.

This, then, is an examination of the case for your serious consideration of accident investigation work. Once started on a course of action that leads to a study of this procedure, you will find your convictions that accident investigation procedures can form one of the cornerstones of an effective accident prevention program at least as strong as mine.

Our accident problem is made up of the individual problems involved in each specific accident which meets one qualification, that it lies in the area wherein you, as an individual, or as a responsible person in an organization, are ready and willing to act. Followed with patience, perseverance, and vigor, applying a common sense remedy to each of these problems as you are able to identify them specifically, will certainly bring the results you seek.

VISUALIZING AMMONIA HAZARDS

by E. V. ANDERSON
safety engineer, Johnson & Higgins, New York, N. Y.

Before discussing handling of ammonia, we should review some of its chemical and physical properties. Chemically, ammonia is somewhere between calcium and sodium. The union of ammonia with water gives ammonium hydroxide a caustic material

with hazards similar to those of calcium hydroxide and sodium hydroxide. This is the form in which most people have seen ammonia. Being a gas, it is constantly escaping from the solution at a rate determined by the temperature and pressure on the surface of the liquid. Concentrated ammonia water has about 25 per cent ammonia by weight and will start to boil off rapidly at a temperature under 100 degrees F.

Even for a one per cent ammonia solution, the vapor concentration at equilibrium will have one per cent ammonia vapor in the air space of the container at room temperature. Except for the slower rate of evaporation, ammonia water solutions are equivalent in hazard to liquid ammonia from a toxicity standpoint. To cite an extreme example, it would be possible for a fatality to occur in a closed tank which had held even a one or two per cent ammonia-water solution. Of course, an open tank at this concentration would present no appreciable hazard since natural room ventilation would dissipate the gas as fast as it came off.

DANGER: LIQUID EXPANSION

In the *anhydrous (dry) gas*, ammonia is a liquid at one atmosphere pressure and minus 28 F. temperature. With sufficient pressure, it will remain a liquid as the temperature is raised and an ordinary ammonia cylinder will have this liquid under an internal vapor pressure of 114 pounds gauge at 70 F. Raising the temperature to 140 F. triples the pressure to 364 pounds for a partly filled cylinder. At the boiling point of water the pressure is 900 pounds, while at 270 F., the pressure is 1600 pounds, equivalent to the normal pressures found on oxygen cylinders for example. However, the hazard of ammonia cylinders is more serious than that of other compressed gases for several reasons. *First*, the gas is a noxious or toxic material. Leakage of an oxygen cylinder aside from possible fire hazards presents no damage other than loss of material. However, one-third of a pound or about one glass full of liquid ammonia if vaporized in a 10 by 10 room would be quickly fatal.

A second hazard is the liquid expansion as the temperature is raised. Comparing ammonia with water, and taking one cubic foot of each material at zero temperature, there are two-tenths of one per cent expansion of the water up to room temperature but 10 per cent expansion in volume of the liquid ammonia. Going to a temperature of 140 F., which is considered to be the maximum reached in direct sunlight, water will have expanded by 2 per cent and ammonia by 20 per cent. Increasing the temperature to 270 degrees as might occur with steam heated equipment, and water has expanded by a total of 7 per cent while ammonia has almost tripled in volume. This is the expansion of the liquid not the gas. The pressures developed by liquid expansion are entirely different in magnitude. It takes almost 10,000 pounds or five tons per square inch to cause a ten per cent change in liquid volume. Because ordinary ammonia cylinders are hydrostatically tested at 700 pounds it is always necessary to leave sufficient outage or room for liquid expansion when filling a vessel with liquid ammonia.

The common filling density leaves 12 per cent of the space empty at room temperature, but due to expansion the cylinder will be completely filled with liquid at 145 degrees F. Filling densities commonly refer to the weight of ammonia over the weight of water, which would completely fill the cylinder. Maximum filling density is set by ICC at 54 per cent for the usual cylinder. However since water is a heavier liquid, a cylinder which has 54 pounds of ammonia and which could hold 100 pounds of water will actually be 88 per cent filled at 65 F. Ordinary ammonia cylinders have no safety devices of any type. Most of the other gases will have fusible plugs or similar devices to relieve the contents in event of fire exposure.

Because of the absence of a relief valve, it is obvious that any ammonia cylinder in a plant fire is bound to rupture and discharge its contents into the room. It is also obvious that cylinders of ammonia should never be warmed directly by water bath, steam or flame. For the same reason they should not be stored near sources of heat or near potential sources of heat, such as highly flammable substances. A maximum temperature recommended by the Compressed Gas Association for any cylinder is 125 F. This point cannot be stressed too much because there is a tendency on the part of the user to increase the flow of gas by applying heat to a cylinder. Under ordinary conditions, a cylinder will give a maximum of 50 cubic feet per hour since heat must flow in through the walls in order to vaporize the liquid inside.

In the literature you will find that 50 p.p.m. is normally detectible by odor, and 100 p.p.m., which is the same as one one-hundredth of one per cent, is the suggested maximum allowable concentration for continuous exposure. Since there would be a definite odor at this concentration, you should maintain less than 50 p.p.m. as a reasonable working condition. This would be about one-tenth of the first real hazard, which is found at about 500 p.p.m. where irritation will take place in less than one hour and definite scarring of eye tissue might occur.

To repeat, 500 p.p.m. is about 1/20 of one per cent of ammonia vapor in air. A concentration four times as great as this or 2000 p.p.m. will cause burning of the skin and can be fatal in a half hour exposure. This again is only one-fifth of 1 per cent ammonia. Concentrations of 5000 to 10,000 p.p.m. or still under 1 per cent ammonia are rapidly fatal.

BODILY INJURY HAZARD

For rescue work in such atmospheres, a cannister type gas mask approved for ammonia will last a very short time. Such gas masks are good for only about five minutes when new in concentrations of 3 per cent or 15 minutes for a concentration of 1 per cent if there is no deficiency in oxygen. Anyone who must work for more than a few minutes in these concentrations should be equipped with a one-piece rubber suit plus the full face gas mask. For higher concentrations or where the concentration is unknown, supplied air respirators or oxygen breathing apparatus should be worn.

There are no chronic affects from continuous exposure to small quantities of ammonia except that the gas is soluble in perspiration and may irritate any skin surface where moisture has accumulated. Discomfort in these areas may be minimized or prevented by the application of oil or vaseline in addition to wearing of protective clothing.

The MCA Bulletin on ammonia suggests wearing cotton shorts, trousers and undershirt, rubber boots, gloves, aprons and raincoats, rubber or felt hats and safety goggles of an approved type. For optimum protection, collars should be buttoned, glove gauntlet tucked inside sleeves and trouser legs left outside of boots.

As mentioned before, one glass of ammona evaporated in a 10 by 10 room could give a fatal concentration. This corresponds with 1 per cent gas or 10,000 p.p.m. At ordinary temperatures and pressures one molecular weight of any gas will occupy about 388 cubic feet. Thus, 32 pounds of oxygen, 28 pounds of nitrogen, 28 pounds of carbon monoxide, or 17 pounds of ammonia will give 388 cubic feet of gas. To calculate, use a table of atomic weights of the various elements. It follows that 1 pound of ammonia will give about 23 cubic feet of gas. With a weight of 5 pounds per gallon, one gallon will give 115 cubic feet. With 4 quarts to a gallon and four glasses to a quart, one glassful will produce 7 cubic feet of gas or produce a concentration of 1 per cent in 700 cubic feet of air, thus giving a fatal concentration in a room 7 by 10 by 10.

Since 50 p.p.m. of ammonia is detectible by odor, for this very reason ammonia poisoning as such is a rare event. However, emphasize the subject with all employees both old and new. For oldtimers, familiarity has bred contempt, while with new people the danger increases. One incident occurred in a chlorine plant where an employee smelled chlorine all night long and being a new man, assumed that was the normal situation. He ended up in the bospital. The ammonia hazard should not be considered an occupational disease hazard. It is rather an accidental exposure hazard.

SOME ACCIDENTS OCCURRED

Almost all accidents will result from breaking lines or similar incidents which discharge a high concentration in a small air volume. One accident occurred when an employee kicked a control lever to shut it off and fractured the connection. Another accident occurred when cleaning an oil separator without relieving ammonia pressure from that particular line. Again, dropping a load broke a half inch pipe, resulting in one death. Dropping a cylinder from a truck to the dock also caused a death when a cylinder ruptured.

A very unusual incident occurred in salvaging some scrap pipe in a yard. This pipe had been taken from the ammonia refrigeration system 13 years before and was thrown in the scrap pile to salvage the valves when needed. When taking the valve off workers discovered that the section of pipe between two valves had filled with liquid ammonia during this 13 year period. But they discovered too late, and a temporary eye injury resulted. Several years ago in New York an employee was killed while cleaning an ammonia tank, when the valve leaked and a blank inserted in the line failed.

As with most chemical hazards, the exposures will interest operators and more important, pipefitters and maintenance men. Actually preventing accidents is *half* the responsibility of the pipefitting department when they install and maintain equipment setups.

Another hazard of ammonia systems comes from the compressors or refrigeration equipment. Every year, explosions occur in compressors, separators and generating equipment. Articles in *Refrigeration Engineering* in November and December 1931 discuss this type of explosion.

BEWARE OF LEAKS

Once an ammonia explosion occurred when ammonia was used as a [illegible] to cool a large building. A watchman noticed the odor and shut off the refrigeration system in a separate building. However, before masks could be secured to enter the building and open windows, an explosion blew out the upper floors. No one was injured, but there was great property damage. It was decided that rupture of a fitting had permitted the entire floor area to be filled with ammonia vapor which is normally considered explosive in concentrations between 15 and 25 per cent.

You will note in the literature that an ignition temperature of 1200 degrees is cited. However, *this should never be taken to* mean that the whole mass of gas must be heated to that temperature. In theory, a single spark or match flame heating a fraction of an ounce of material could set off a chain reaction which would produce an explosion. Again, oil vapors introduced through compressors, for instance, may increase the fire hazards somewhat. The incident just mentioned of a massive leak in an unoccupied building is the only one in the writer's knowledge involving a flammable vapor explosion. However, the hazard should be considered whenever a process involves heating ammonia air mixtures or large volumes of ammonia gas vented into enclosed areas.

The hazards of ammonia are no greater than many other materials. Safe practices for the maintenance of pressure equipment, the handling of cylinders and training of employees are the same here as in any department or operation in your plant. If you are running a safe plant, you will handle ammonia safely. If you do not handle ammonia safely, you are not running a safe plant. One follows the other.

REDUCING THE HAZARDS OF USING NITROGEN SOLUTIONS AND ACIDS; CARELESSNESS CAN BE COSTLY

by ELMER C. PERRINE

technical representative, Nitrogen Div., Allied Chemical & Die Corp., New York City

Transition from the simple processes of past days to the complexities of modern industry is often neither simple nor pleasant. The fertilizer industry has successfully absorbed its personnel into the complicated activities of granulation and general modernization.

In most cases the transition was achieved with safety and efficiency. Where the transition has been attended with hazards, the

accusing fingers may be pointed at management and those who should know the hazards yet failed to carry the message through effective channels.

It is convenient, but certainly neither safe nor accurate, to believe granulation is merely an extension of the making of pulverized fertilizer. Several aspects of the use of sulfuric and phosphoric acid, largely confined to granulation, demand increased alertness.

Often, through misunderstanding principles or poor maintenance, the stage is set for trouble and the trained observer can possibly predict the outcome fairly accurately. Something can usually be done in time to bring the more happy results for which the plant is being operated.

More acid and nitrogen solutions are used in a ton of granulated fertilizer than in pulverized grades because the causing granulation, drying, and cooling will accommodate the products in large quantities and leave a fertilizer of good quality. Under some conditions pulverized fertilizers may also use large amounts of acid and nitrogen solutions, such as high analysis grades for bulk spreading and under other favorable conditions.

AMMONIA AND SUPERPHOSPHATES

The industry is now sufficiently advanced and formulation and analysis are no longer matters of chance. To be competent today an operator must know that superphosphate will readily hold large amounts of ammonia at high efficiency. But it can do this only if the ammonia is delivered to the superphosphates in direct proportions to the amount of superphosphates adjacent to the various regions of the distributor pipe.

He knows also that the ammonia should be mixing with the superphosphates as it enters the mass. Many operators are aware that ammonia gas is usually associated with high rates of ammoniation and this requires special consideration in design of equipment and in techniques of operation.

These are features developed ahead of granulation and have been adopted as originally developed, without many serious accidents.

However, only a few operators realize the sulfuric acid should be as uniformly matched against the ammonia as should be the superphosphates. The formula may be adjusted correctly as regards the maximum ammonia take-up by the superphosphates *and the sulfuric acid. But, through faulty* design of equipment or its maintenance, or some imbalance in the process, there may be local areas of varying sizes where excesses of acid exist.

BEWARE HEAVY CONCENTRATIONS

In some cases of fires in the mixers, certain conditions have been observed to exist. These same ones also exist in other cases where is is only "excessive fumes or the loss of nitrogen" concerning the operator.

The more conspicuous of these conditions permit heavy local concentrations of some ingredients. Fortunately, enough heat locally generated is usually dissipated throughout the mass by mixing, or by the evaporation of water, and the result may be only poor granulation or the loss of nitrogen.

The liquid phase favorable to granulation is achieved with less water if the temperature is raised. Since the heat of reaction of a pound of ammonia with sulfuric acid is *about twice that of the reaction with* normal superphosphate and the evaporation of water is cooling, the temptation is to react much sulfuric acid and to have a minimum of water present.

Correctly performed at fertilizer manufacturing rates this is recognized procedure and need cause little concern. Increased attention should be directed to all details, as such a schedule is advanced. Carelessness here can be costly.

Some operators apply the sulfuric acid in one large stream through an open pipe. Others through poor inspection or maintenance find an original good acid or ammonia distributor pipe corroded or worn so badly that nearly all of the material escapes through one hole.

MUST INSPECT PIPES

There is a very serious corrosion problem where the acid becomes hot and diluted with water. The abrasion on submerged *pipe is also severe. Close* daily inspection should be instituted. Some distributor pipes last no longer than three or four days before losing their good distribution pattern.

Stainless steels have often only about double the life of extra heavy carbon steel pipe. Various coatings have been tried and

some have a good promise of materially extending the life of these distributor pipes. Good distributor pipes are metering manifolds, meeting quite exacting requirements. To be effective, they should remain as originally designed.

PRESSURE CHANGES SERIOUS

The plugging of holes has been almost as serious as corrosion and abrasion in destroying the delivery pattern. Any inspection of the numerous acid and ammonia distribution pipes scrapped show they were used a great deal after they had become potential hazards. Any change on pressure requirements of acid, water, or ammoniating media should arouse immediate suspicion.

Failure of the distribution pattern of the ammoniating solution can have the same results as an erratic distribution of the acid. Both of these and any added water should be applied uniformly throughout the mass, allowance being made for the decreasing rate of ammonia take-up as the superphosphates approach saturation.

This applies to batch as well as to continuous operations. In the usual fertilizer plant, under no circumstances should the same distributor pipe be used for acid and ammoniating solutions. Mixing these two products in a chamber as they entered the mixer has resulted in serious troubles.

The interlock system in many continuous processes automatically arrests the flow of acid and nitrogen solutions when the flow of dry materials to the mixer is interrupted. In batching mixing, the hazards are greatly reduced by withholding the potassium chloride until after the acid has been neutralized by the ammonia. Where anhydrous ammonia is employed in addition to ammoniating solutions, the risks are also greatly reduced by adding the anhydrous ammonia to act on the acid before the ammoniating solution is added.

DISTRIBUTION IMPORTANT

Even with the large amounts of acid often used in some granulated fertilizer, where timely delivery and good distribution of the acid and the nitrogen solution are maintained, there need be very little ammonium nitrate present until after the ammonia has neutralized all of the sulfuric acid.

The problems are largely those of uniform distribution of both the acid and ammoniating solutions to the mass of the fertilizer.

Reference is made to the cost of carelessness. Barring the sudden breaking or plugging of the acid, water, or ammonia distributing pipes or an original design that was insufferable, some conditions associated with fires or explosions develop gradually from good or reasonably good conditions. Operating techniques, as well as equipment sometimes creep unnoticed from good to hazardous.

If the bookkeeper were looking over an operator's shoulder, observing the total cost of each ton, or even the last ton of the day, he could demand an investigation long before the operating conditions became a source of danger. He may still object only to the rapidly mounting costs of ingredients or poor working conditions, and may be totally unaware that the plant could be lost sometime later through reasons other than bankruptcy.

COSTS LOSSES

The loss of plant food through poor distribution and poor mixing of ingredients may reach a unit of nitrogen per ton of fertilizer. Add to this the cost of the extra acid that usually accompanies these cases and the total cost could reach one dollar per ton of fertilizer, and is sometimes higher.

Acids and nitrogen solutions are used in great quantities per ton and in many tons of fertilizer without serious hazards. Although the operators may not realize it, just plain effective and efficient operations are good precautions against hazards that arise from using acids with nitrogen solutions.

The risks in using acids with nitrogen solutions could be materially reduced through the same means that achieve maximum granulation, while retaining the maximum amount of ammonia and using only the minimum amount of acid at its peak of effectiveness for ammonia take-up.

The interests of safety would be served without any reference to hazards from carelessness. Any fires are too many, but there are relatively few though conditions are present for many more. Even gross inattention to techniques and equipment is rarely attended with fires or explosions.

Operations have been so poor in plants that personnel were driven from their operating stations by fumes. Such fumes should warn of impending trouble, without having fires in many plants from using acids with nitrogen solutions.

If there are potential hazards in using several ingredients, it is often believed that greater quantities create greater hazards. People active in safety in industries believe that a plant run with great industrial efficiency is also run quite safely.

CONTINUOUS MIXERS

There have been fires in the conventional continuous ammoniator when all equipment passed careful inspection. It was found that the mass was permitted to reach such a physical condition that it simply rocked in the mixer as one inert mass. Although all formula ingredients were present and equipment considered to be of good design—in good condition, the mixing ability of the mixer was handicapped.

Most continuous mixers, particularly those equipped with a good interlocking system and with dry ingredients reasonably well pre-mixed, can handle the problems of high analysis fertilizer manufacturing efficiently and with reasonable safety. The same is true with most rotary batch mixing installations that are well maintained and operated with skill.

As this condition adversely effects granulation and ammonia take-up, at least in the superphosphate, every effort should be and usually is made to prevent or correct it as soon as detected. This condition is not necessarily the result of poor equipment nor of any form of carelessness and some fires may result from causes other than carelessness or faulty equipment.

With present conditions it may not be possible or practical to offset completely by using the best present equipment and techniques, all existing factors in fires. These may even be increasing with the trends of fertilizer manufacturing because not all factors may be known.

However, those practices which generally result in good fertilizer, through efficient use of materials and equipment, have reduced fires in enough cases to be worthy of the most serious consideration. In no case has a switch to these more efficient practices increased fires with a given formula.

Many tons of fertilizer have been made with substantial amounts of acid and nitrogen solutions without fires, and much of this has been made under conditions that violate the general principles of operation suggested here to lessen the hazards.

Several conditions are required for acids with nitrogen solutions to be hazardous. It is possible for these conditions to exist at the required time and to the required degree in some fertilizer manufacturing. Enough of these conditions are known and enough of them can be controlled so that, in many plants, the risks can be and are being consciously held to a level that management deem the over-all operation to be satisfactory and practical. These operators are usually aware that carelessness can be costly.

The development of this theme became quite involved, but the summary can be brief:—

The technical properties of some of the ingredients used in large quantities in modern fertilizer making are such that indiscriminate use of poor equipment can result in fires or explosions in extreme cases. Some of the conditions have been exposed; there may be others as yet not isolated, but a high degree of control has been effected when the conditions revealed are respected in operations.

Although they are no guarantee of immunity, the practices and equipment that use the ingredients most effectively are good precautions against hazards.

The requirements are generally that all ingredients, liquid and dry, be uniformly mixed throughout the entire mass, the acid and ammoniating medium particularly being so delivered that they are mixing uniformly as they enter the mass. These are also good operating techniques.

OFFICERS OF THE

FERTILIZER SECTION

NATIONAL SAFETY COUNCIL 1957-58

General Chairman—GEORGE F. DIETZ, safety director, Fertilizer Manufacturing Co-operative, Inc., Baltimore, Md.

Vice-Chairman—GEORGE L. PELTON, personnel manager, The Smith Agricultural Chemical Co., Columbus, Ohio.

Secretary—ELMER PERRINE, technical representative, Nitrogen Div., Allied Chemical & Dye Corp., New York, N. Y.

Engineering Committee Chairman—A. B. PETTIT, director, Industrial Health & Safety, W. R. Grace & Co., New York, N. Y.

Engineering Sub-Committees—

Statistical and Contest Chairman—F. WAYNE HIGH, manager of Operations, The Baugh Chemical Co., Baltimore, Md.

Data Sheet Chairman—JOHN S. MARK, production manager, Farm Bureau Co-op Association, Columbus, Ohio.

Public Relations Chairman—J. LAUREN SHOPEN, safety director, Consumer Co-op Association, Kansas City, Mo.

Membership and By-Laws Chairman—C. S. GRIFFITH, superintendent, Virginia Carolina Chemical Corp., Cincinnati, Ohio.

Visual Aid Committee Chairman—O. E. PERRY, superintendent, C. O. Smith Guano Co., Moultrie, Ga.

Insurance and Legislative Committee Chairman—E. O. BURROUGHS, JR., manager, Insurance Dept., F. S. Royster Guano Co., Norfolk, Va.

Research Committee Chairman—JOHN E. SMITH, safety director, Spencer Chemical Co., Pittsburg, Kan.

Nominating Committee Chairman—E. O. BURROUGHS, JR., manager, Insurance Dept., F. S. Royster Guano Co., Norfolk, Va.

Supervisory Training Committee Chairman—W. C. CREEL, safety director, State of North Carolina, Dept. of Labor, Raleigh, N. C.

Members-at-Large

S. COTTRELL, director of Operations, Olin-Mathieson Chemical Corp., Little Rock, Ark.

EARL DAY, president, Ark-Mo Plant Food Co., Inc., Corning, Ark.

MIKE C. ELLISON, safety director, Mississippi Chemical Co., Yazoo City, Miss.

ROD MARTINET, vice president, E. Rauh & Sons, Indianapolis, Ind.

GRAYSON B. MORRIS, assistant production manager, Southern States Cooperative, Richmond, Va.

GORDON W. PITTOCK, works manager, William Stone Sons, Ltd., Ingersoll, Ont., Canada.

HARWOOD T. RICE, safety director, Southwest Potash Corp., Carlsbad, N. M.

YEN SHEN, Taiwan Fertilizer Co., Ltd., Taipei, Teivan, China.

W. A. STONE, plant manager, Wilson & Toomer Fertilizer Co., Jacksonville, Fla.

J. R. TERRY, personnel safety engineer, Davison Chemical Corp., Div. of W. R. Grace & Co., Bartow, Fla.

A. A. WAUGH, safety engineer, International Minerals & Chemical Corp., Bartow, Fla.

M. F. WHARTON, treasurer, Arizona Fertilizer Inc., Phoenix, Ariz.

ROY WHITE, Lion Oil Co., El Dorado, Ark.

C. K. BRUTCHER, superintendent, Davison Chemical Co., Div. of W. R. Grace & Co., New Albany, Ind.

STRATTON McCARGO, personnel supervisor, G.L.F. Soil Building Service, Terrace Hill, Ithaca, N. Y.

R. A. FISCHER, general manager, Milford Fertilizer Co., Milford, Del.

V. A. FRIZZELL, vice president, The Triangle Co., Salinas, Calif.

ROGER HUGG, personnel supervisor, International Minerals & Chemical Corp., Chicago, Ill.

N. NICHOLS, Nichols Fertilizer & Chemical Co., Oklahoma City, Okla.

B. A. SCHLAGENHAUFF, supervisor, Fire Protection & Safety, Brea Chemicals Inc., Brea, Calif.

QUENTIN S. LEE, The Cotton Producers Assn., Atlanta, Ga.

EDWARD J. LARGENT, M.D., assistant professor, Ohio State University, Columbus, Ohio.

A. I. RANEY, safety director, Phillips Chemical Co., Bartlesville, Okla.

GAITHER T. NEWMAN, manager, Insurance Dept., Smith-Douglass Co., Inc., Norfolk, Va.

Honorary Members

SIDNEY H. BIERLY, general manager, California Fertilizer Assn., San Marino, Calif.

PAUL T. TRUITT, executive vice president, National Plant Food Institute, Washington, D. C.

HENNING WALTERSDORPH, Magnolia Fertilizer Co., Seattle, Wash.

Staff Representative

J. C. KATO, National Safety Council, Chicago, Ill.

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

THE FOOD, MEAT PACKING, TANNING AND LEATHER PRODUCTS, TRADES AND SERVICES SECTIONS

This volume is a record of the sessions held at the 1957 National Safety Congress by the Food Section and Meat Packing, Tanning and Leather Products and Trades and Services sections. The conduct of these Congress sessions each year is only one of the many cooperative activities which the Food section and the Meat Packing, Tanning and Leather Products and Trades and Services sections carry on in behalf of their members, and for the benefit of accident prevention work in the Food and Packing, Tanning and Leather Products and Trades and Services industries generally. These sections give guidance in the preparation of a great variety of technical and educational material useful in the day-to-day plant safety programs.

The activities of these sections are under the direction of their executive committees, the members of which are listed at the close of this volume.

FOOD SECTION

CHANGES IN THE N. F. P. A. CODE FOR THE PREVENTION OF DUST EXPLOSIONS IN STARCH FACTORIES

by EARL GOMOLL

safety supervisor, Clinton Corn Processing co., Inc., Clinton, Iowa

The explanation of changes in the code for the prevention of dust explosion in the manufacture of dry starches would be difficult without a few words of explanation on what the National Fire Prevention Association really is.

This association is a non-profit technical and educational organization devoted to the reduction of loss of life and property by fire. Its efforts have been directed toward establishing standards recognized by industries throughout the country. I will summarize the recommended changes in the present code to meet the needs of industries manufacturing starch products today.

The code for the prevention of dust explosion in the starch manufacturing industries is set forth in 10 sections, preceded by an introduction explaining its purpose. In the introduction, the changes have been expanded to point out that starch can be manufactured from corn, sorghum (milo), wheat and other starch bearing cereals or vegetables. The starch, through conversion, can be made into sugar, syrups and dry starches, including chemically modified starches and dextrins.

EXPLOSION POSSIBILITIES

Explosion hazards are prominent in four specific points in the operation of starch manufacturing and the new code points out that they appear (1) in grain and receiving and starch departments in the form of grain elevator dust, (2) in the handling of bulk sulfur used for wet processing of grain, (3) in dust from conveying, milling, and storage and packaging of feeds, germ gluten, and gluten meal, (4) in dust arising from drying, grinding, conveying, storage, and packing of starches and sugar.

The handling of sugar should conform to the N.F.P.A. code for pulverizing systems of sugar and coke. In the manufacture of by-products in the feed departments, equipment layout should conform to the code for dust explosions.

BUILDING CONSTRUCTION, ARRANGEMENT

Under general standards listed in the N.F.P.A. code the wording has been clarified as follows:

11. The operation of starch drying, grinding, grading and packing dextrin cooking or conversion and packing will be permitted in the same building, provided the various operations are suitably isolated by proper sanitation and fire and explosion resistive walls.
12. Buildings housing operations where dust hazards exist shall have at least 50 per cent of the exterior wall space constructed of thin glass or similar material. Windows shall be equipped with explosion vent hardware.
14. The transfer of starch between buildings shall be by cart over tramway, enclosed spiral conveyors with positive choke cells, or approved pneumatic or mass flow systems.
15. Walls shall be finished smooth and irregularities brought flush with the surface to reduce the accumulation of dust.
17. There shall be no locker and change rooms within these departments except where rooms are separated by adequate fire and explosion resistive walls. Doorways are to be protected by self-closing exit doors conforming to N.F.P.A. code.

II. SPECIFIC STANDARDS

21. In this section of the code the recommended changes were modified to include the new type of drying equipment. It is recommended that dryers be designed to eliminate surfaces where dust might accumulate inside. Where air space exceeds the space occupied by the starch, steam vats or other effective fire extinguishing media shall be installed. All direct fired flash dryers shall be located in a separate detached building. Dryer cyclones should be provided with explosion vents. All cyclone product discharge outlets should be equipped with standard explosion choke and drives shall be interlocked with the combustion safety controls. Drying units located within all enclosures shall be equipped with power cut-off switches located outside the building.

III. DRY STARCH GRINDING, GRADING

31. Primary collecting systems for equipment ahead of the mills shall be separate from the collecting systems used for the grading, grinding, and packing stations.

32. Hoppers for bulk starch shall be constructed to minimize arching of the material. Interior shall be finished smooth. Maximum explosion relief venting should be provided as recommended in N.F.P.A. code number 68 for pearl and powdered starch bulk packing.

42. All packing equipment shall be equipped with an adequate dust collecting system. Electrical controls shall be of the class 2—group G type.

V. LUMP STARCH COOKING, PRESSING, GRADING, AND PACKING—No new changes in this section of the code.

VI. CONTROL AND REMOVAL OF SUSPENDED DUST—No new changes in this section of the code.

VII. REMOVAL OF STATIC DUST

72. The cleaning of surfaces shall be by vacuum sweeping if feasibly applied. This equipment including the hoses shall be properly grounded and regularly checked for electrical continuity for pick-up nozzle to piping system. This equipment should also be approved for class 2—group 2—group G locations.

73. Removal of dust from motors by a stationary compressed air system. Cleaning of this kind shall not be undertaken while the department is operating. If portable electrical blowers are used, electrical controls and motors should be of the class 2—group G type.

74. Repairs to starch drying equipment should not be done unless adequate precaution is taken to prevent fire. All departments in the repair area shall be shut down which involves the operation of welding torches, grinders or portable hand electric tools.

VIII. PREVENTION OF IGNITION

82. Smoking and the carrying of matches and lighters shall not be permitted.

84. Static electricity shall be removed from such machines as it accumulates by permanent ground wires, from joints by grounded metal cones, or other equally efficient systems. The use of bent type drives for equipment shall not be permitted for starting type machines which will cause the joints to slip and heat up unless other drives are impractical or more hazardous.

IX. MECHANICAL PRECAUTIONS

91. Unless ball or roller bearings are employed, the speed of revolution of spiral conveyors shall not exceed 100 revolutions per minute. The speed of drag type conveyors or elevators, unless made of completely non-sparking metals, should be limited to 50 feet per minute.

93. All elevator legs shall be equipped with automatic over-load releases or similar systems which will warn the operator of the possibility of a choke up. Faster type elevators employing a bend should be equipped with motion switches. Elevator housing be installed with a rupture type diaphragm to prevent equipment damage in case of an explosion.

X. HOUSEKEEPING—No recommendations to present code.

Our modern civilization, which has made it possible for us to enjoy life to a fuller extent, is based upon many many standards. The units of measure for instance guarantee that the things we buy, those necessities of life, are delivered to us in full measure. Homes, offices, and factory buildings are made possible by the acceptance of standards.

Yes, everything in our life is made safer and more comfortable by the formulation and acceptance of many many standards put forth in the form of codes.

BREWERS DIVISION

by WILLIAM A. MULVENNA
director, Safety & Fire Prevention, C. Schmidt & Sons co., Inc., Philadelphia, Pa.

During the week of the National Safety Council Congress, the National Safety Council Brewers Division and the United States Brewers Foundation conducted several sessions for safety personnel related to the brewing industry. It was felt that some of this material was of sufficient interest to the brewers unable to attend that it has been included as a part of the transactions. On Monday, October 21, 1957, Jack Cantrell, safety director of the Miller Brewing company spoke on, "Suitable Work Assignments."

BASIC SAFETY FUNCTIONS

Cantrell went into great detail explaining Miller's comprehensive program. Employees who lose time because of injury or illness must have releases from their attending physician. This release is more than a simple form as it contains the type of work the employee is able to perform in great detail. The form requires only check marks by the doctor in the proper squares designating physical qualifications.

If the department to which he is assigned cannot provide work as prescribed by his physician, other departments are surveyed for possible work assignment until the employee is able to return to his regular job. Cantrell stated that the progr m served its purpose well as the employees, department heads and the union are all satisfied.

On Tuesday, October 22, 1957, William Mulvenna, chairman of the Brewers Division introduced Mike Aicher of the United States Brewers Foundation and Nixon de Tarnowsky who portrayed a supervisor and safety engineer or director, respectively. The safety director was informing the supervisor that the company was implementing a safety program which required the wholehearted participation of all supervisory personnel.

The supervisor, quite skeptical and very candid, questioned the purpose and sincerity of the program. The following pertinent items resulted from the presentation and group discussion; supervisory training every two weeks on Saturdays for a total of seven sessions. Flannel board and films will supplement talks on basic safety functions. (This permits special training; even though it is on an overtime basis).

The following items were presented during the discussion period:

Accidents result in unnecessary waste and cost. It was emphasized that the fixed price structure on beer necessitated stoppage of waste; and higher efficiency in operation and prevention of accidents and injuries is an important step toward that goal.

INCENTIVES USED

Incentives for supervisors included dinners, passes to althletic contests, and other inexpensive yet effective awards. Incentives for employees included team awards of pencils, billfolds, etc. Emphasis was made for an immediate and thorough investigation of all back injuries in order to discourage malingering.

On Wednesday, October 23, 1957 the following panel participated in a special

presentation—Hebert Naegele, Carling Brewing company; Nixon de Tarnowsky, F. M. Schaefer Brewing company; M. B. Macaulay, Interboro Mutual Insurance company; and John Miskelly National Brewing company. Discussion by the panel and audience covered the followed items:

1. Providing eye protection for all employees and visitors in the bottle shop is a good investment.
2. Eye protection is provided in many breweries to maintenance employees, handlers of caustic, drivers and helpers handling open cases and others.
3. Safety work orders have priority over production and maintenance work orders when the safety problem is more acute. Safety personnel through proper evaluation must be practical in their demands for priority. Safety work orders should be followed through by checking for completion.

BLOCK TRAILER WHEELS

4. One solution to fork-lift truck accidents when loading trailers at docks —wooden chocks chained to docks must be used by truck drivers to block both back wheels of trailer. It is lift-truck operator's responsibility to check and see that these chocks have been properly placed and also to see that the chocks are hung on the dock by the driver after they have been used.
5. Employees are "sold" on reporting of minor injuries through education by a constant repetition of instructions, posters and signs. Prevention of infection and eliminating hazards or unsafe practices are two important points to stress.
6. Back complaints should be investigated promptly and thoroughly to learn facts and discourage malingering. "Back cases" diagnosed by nurse or physician as minor or non-existent may be alleviated by the simple pill treatment or heat lamp. Some of the "pains" may only be mental but exist in the minds of "injured" and should be "treated."

FIRST AID TRAINING

7. First aid training is given to all supervisors and employees who volunteer in many organizations. Many classes are conducted after working hours on supervisors' and employees' own time.
8. Approved masks for use in atmospheres contaminated with ammonia or CO_2 should be provided. Limitations of these masks must be taught and proper maintenance by periodic inspections of equipment. Used cartridges should be replaced immediately. In heavy ammonia concentrations a self-contained breathing apparatus should be supplemented with proper rubberized clothing to prevent burns to otherwise exposed skin.
9. Testing tank for CO_2 before entering—there are instruments for testing same but there was controversy as to the efficiency of these instruments. Proper ventilation and experienced personnel were stressed as major points in this regard.▲

THE NEW SOLVENT EXTRACTION PLANT CODE NO. 36-T

by GEORGE H. STEEL

safety director, Ralston Purina co., St. Louis, Mo.

Dick Hopkins of A. E. Staley Manufacturing co. and Paul Sheffer of Corn Products Refining co. related to the group many things about the new NFPA code 36-T that might be objectionable as far as some industrial applications were concerned. Many of these objections were discussed the week previous by the NFPA committee. This report gives those changes related which the committee recommended for adoption. The following is a resume of these changes:

1012 has been changed to emphasize management's responsibility by now reading "provide a means by which fire protection directors and supervisory personnel may evaluate the operations under their authority."

111 has been made to apply to commercial scale solvent extraction of animal and vegetable oils and fats. This alleviates criticism that our standard would apply to experimental units, laboratories, and pilot plants.

121 has been changed to read "the provisions of these standards pertaining to design, layout and construction do not apply to existing plants." However, modifications to existing plants shall comply with these standards.

FIRE STANDARDS

Old paragraph 131 has been eliminated and old paragraph 132 has been changed to read "the authority having jurisdiction shall follow nationally recognized standards for fire prevention and fire protection which have been prepared in such a way that they may be taken to represent the best informed judgment available on the subject and which are in such published form as to be available for a reference."

A new paragraph 2051 has been added which reads "electrical equipment and installations shall comply with the requirements of the National Electrical Code as herein after specified."

Paragraph 2051 is now 2054 and reads "There shall be no smoking within the fenced areas. Sources of spark or flame including matches, lighters, as well as smoking materials, shall not be permitted in the fenced area."

FENCED-IN AREAS

In several places through the standard, we have changed these requirements from within the restricted area to within the fenced area. There was quite a bit of criticism about the distances used in defining the fenced area and the restricted area and the point was well brought out that it would be possible to build the boiler room right in the extraction building and that sometimes 300 feet is not enough distance in case of severe trouble.

However, the committee felt that some distances should be used as a minimum and while we didn't think that anyone would want to spend the money to make boilers within the extraction building safe, it is a possibility. The members of the committee are fully aware of the limitations in using distances but we felt that if we could get 100 feet clear distance in every direction from the plant we'd be a lot better off than many of the installations that are now in existance.

We knew that from a practical standpoint that if we put that at 300 feet or 500 feet we would make it almost prohibitive to build plants and comply with the standard.

Paragraph 221 on hand tools and paragraph 223 on miscellaneous equipment has been eliminated. There was such an objection raised by the American Petroleum Institute to this statement that we felt that the standard would not be approved at the annual meeting if it was left in.

Paragraph #232 on purging was completely rewritten. The script for this was lifted mostly from pamphlet 327 of the N.F.P.A. on "Purging Small Vessels and

Tanks." As it is now written it describes the various methods including the use of steam, air, and inert gas.

Paragraphs #2544 and 2546 have been eliminated. One of these was providing for sleeves when going through floors or walls with pipes and the other was for all pipes entering vessels to enter from the top. Paragraph #263 about providing level, pressure, and temperature controls has been eliminated.

AUTOMATIC WATER SPRAY

Paragraph #281 about fire protection has been changed to read "an approved, acceptable automatic water spray or deluge system or equivalent shall be provided to protect the extraction process, equipment, or structure."

Paragraph #284 has been changed to read, 'approved first aid fire protection of appropriate size and type shall be provided."

The last sentence of paragraph 3122 has been changed to read "normal breathing vents with approved type flame arresters or pressure—vacuum relief valves shall be provided."

Paragraph #341 which read "tank cars shall be unloaded from the top only" has been deleted.

Paragraph #351 has been changed to comply with N.F.P.A. pamphlet #30 on the testing of tanks. As originally written, the method could not be used on such tanks as finished product storage tanks, etc.

Paragraph #421 has been changed to read "in buildings where explosive or flamable dusts occur, all electrical wiring and equipment shall conform to the requirements of class 2 group G division 1 locations. As this was originally written, it required the use of 2G equipment in such occupancies as a packing house where meat scrap was being prepared for extraction.

Paragraph #514 was changed so that solid floors may be used at upper levels in the extraction building.

It was decided to eliminate any drawing of the separation sump but to leave the details of the design up to the engineers and the insurance companies and the inspection authorities that will have this say at the time the plant is built. In this connection, I know that several objected to that wording "authority having jurisdiction" but from a practical standpoint the local fire marshal, building commissioner, or inspection bureau have the authority anyway so we're only spelling out what their duties are.

The Committee had quite a bit of discussion over the flammable vapor detection section but finally agreed that permanent detecters should be required.

GRAIN HANDLING AND PROCESSING DIVISION REPORT

DISCIPLINING FOR A SAFETY

by WARREN RINDERKNECHT
safety director, Penick and Ford, Ltd., Cedar Rapids, Iowa

How can you justify discipline in a safety program when you need the cooperation of all the employees in the organization?

When you feel you have a good safety program and have done all that is possible and practical to have safe working conditions but you continue to have unsafe workers, then it is time to consider your responsibility to the employee's family. This will be your conclusion after you have met several individual families after accidents—then you realize that if the employee will not voluntarily work safely you are going to have to do something about it.

How do you introduce discipline into a program?

First, discuss your program with your supervisors and then with your union labor committee and emphasize that your reason for the disciplining of the employees who fail to work safely, is to insure the economic future of the employee's family, the safety and welfare of his fellow workers, and that the goal of your safety program is to make certain that your employees go home to their families the way they came in that morning.

SORRY ENFORCEMENT

Who can argue with this reasoning? If a supervisor shows little interest in correcting his employees who work unsafely—invite him to go with the safety supervisor the next time you have to inform a family that their husband or father has been hospitalized due to an accident. This same invitation should be issued to any union steward who resists this part of your program.

What kind of plant safety rules and discipline for the violation of these should be considered?

- —Rules should be justifiable and reasonable because unnecessary or harsh rules cause bad morale.
- —Rules must be known by all employees and supervisors.
- —The rules must be uniformly enforced throughout the plant.
- —Don't have too many rules. It is better to have a few basic rules thoroughly understood than detailed rules not too well known or understood.
- —The discipline handed out must be in proportion to the offense committed which means repeated offenses justify increased penalties.

Discipline in a safety program must fit into the discipline procedure set up for the entire plant. If the plant uses steps in discipline, then increased penalties are in order for subsequent offenses of the same nature—such as one day for the first unsafe practice, three days, 10 days for subsequent offenses and discharge for the fourth offense. Some plants treat each rule violation separately and affix a penalty according to the seriousness of the offense also taking into consideration the past deportment of the employee.

In either system the result of any discipline should be that fellow employees will feel the penalty was justified and the individual will understand that its purpose was to correct him and make him a good employee.

BORDER CASES EXCUSED

There is a disadvantage in treating each offense separately and fixing a penalty for each individual case. Borderline cases will cause management to back away from a penalty or if a penalty is applied, cause the plant to feel that the man was unjustly treated. Therefore a minimum penalty must be decided upon and then you only have to decide whether or not an unsafe practice was actually committed.

Our system is to use steps as mentioned before, of one day, three days, 10 days and discharge for consecutive unsafe practices, for those cases written up by the foreman and handled by the safety department through the usual channels set up for handling violation of plant rules. On borderline cases it is left in the hands of the foreman to handle. If the man continues to work unsafely then the foreman warns him that he will be written up and steps taken if he does not correct his work habits.

Obvious and deliberate unsafe practices are written up immediately. Any case written up is followed through the entire procedure resulting in the man being called to the Labor Relations department with a steward and the proper penalty imposed. A foreman will not write up a case he cannot prove because he knows his writeup will be respected and followed through. At the same time the men in the department know that if they do not heed the warning of the foreman, they will be written up.

We have a form for the foreman's use with the heading "Personal Safety Report." This is to be used to record unsafe practices by employees. On this form is a definition "An unsafe practice is performance of work in a manner which might result in injury to the employee or to other employees." If a department continues to have accidents as a result of unsafe activities and a foreman has not been writing reports, the obvious conclusion is that he does not know an unsafe practice when he sees one. That, of

course, would be a reflection on his selection as a foreman and your safety training.

Before you again face the responsibility of knocking on the door of an employee's family to inform them of a fatality or a serious injury, you will convince yourself that rules and discipline for the violation of these rules, should be made a part of your overall safety program.

The following plant rules concerning the problem of discipline as it relates to safety, have been developed by Penick and Ford, Ltd., Cedar Rapids, Iowa in their Joint Labor Relations committee. The material and comments are quoted, with permission of the corporation, from a letter written by Warren G. Rinderknecht, safety director, on April 8, 1957 to a special committee of the Grain Handling and Processing division, Food Section, National Safety Council.

Unsafe Practice or Act by an Employee

One day disciplinary layoff for the first offense

Three day disciplinary layoff for the second offense

Ten day disciplinary layoff for the third offense

Discharge for a fourth offense

However, in addition to the above we set forth the following steps in regard to discipline for violation of plant rules—the following being excerpts of those that apply to safety.

Four step procedure:
(1) Warning
(2) 3 days off
(3) 10 days off
(4) Discharge

1. Threatening to do bodily harm or use abusive language to fellow employee.
2. Failure to report injury incurred in plant.

Except where specially noted, the above four step violations are the only violations to plant rules which will revert to first step discipline if subsequent offense does not occur within 12 months of previous offense.

Three step procedure:
(1) 3 days off
(2) 10 days off
(3) Discharge

1. Reporting to work under the influence of intoxicants.
2. Horseplay involving definite possibility of injury to himself or others.
3. Use of abusive or threatening language to a member of supervision.
4. Fighting with other employees. Subsequent offense must occur within five years or penalty reverts to first step.

Two step procedure:
(1) 10 days off
(2) Discharge

1. Smoking in plant area other than critical areas, as shown in one-step procedure except in cafeteria, time office, railroad gate, watchman shanty, pump house and laboratories (not including storage or sample preparing room).
2. Leaving plant and drinking intoxicating beverages during his scheduled time to work.

One step procedure:
(1) Immediate discharge

The following violations call for immediate discharge:

1. Smoking in critical areas which are defined as follows:
   Tank car washing shed
   Extraction plant
   Dextrine department
   All dry starch departments
   Feed house and feed grinding and loading
   Oil department
   Pregelatinized starch
   Corn unloading department, inclusive of elevators, sewing room, bag room, carbon storage, and all areas used for warehousing of starch or supplies and combustible materials.
2. Violation of safety rule regarding the carrying of non-safety matches.
3. Possession of, or partaking of intoxicating liquor or narcotics in the plant, whether brought in by that individual or not.
4. Fighting which results in serious injury to another employee, while on company premises or in area where workmen's compensation would consider company liable for injuries sustained.
5. Any fighting or assault on any member of supervision at any location, or at any time, if issue relates to job or company.
6. Deliberate damage to fire extinguishing equipment or tampering with any fire equipment or system.

The discussion on the above disciplinary steps resulted in the company and union agreeing that each discipline case should be handled as an individual matter and the framework of steps shown above used as a general guide.▲

PANEL QUESTIONS AND ANSWERS:

Q. Does the Industrial Relations department within your plant impose penalties for safety rule violations?

A. Not entirely. Warnings may be issued by a shift superintendent, but time off is given only by the plant superintendent, master mechanic, or the director of industrial relations.

Q. Can you give some examples of the types of safety rule violations and penalties imposed within the past year at your plant?

A. Since January 1, 1957, seven penalties have been imposed for safety rule violations. Some of these were:
   February—10 days off—fighting on the job
   February—three days off—abusive language to supervisor.
   February—dismissal—bringing liquor into the plant
   July—three days off—intoxicated on the job

Q. How do you determine whether or not an employee is intoxicated?

A. The shift superintendent charges the man with being intoxicated in the presence of a shift steward using his judgment based on the man's behavior.

Q. You say that repeating offenders are subject to more severe disciplinary action. How do you keep track of this?

A. A card record is kept on all disciplinary action in the personnel department.

Q. Are these penalties for violations a part of your union contract?

A. Only the penalties involving coming on duty when under the influence of intoxicating liquors.

Q. Have you ever found that foremen allow personalities to influence their reporting safety rule violations?

A. Occasionally, but not as a rule. To circumvent this, we use a cooling off period of one day before any disciplinary action is taken.

Q. Can the plant's safety director discipline plant employees for safety rule violations?

A. No, not directly.

Q. What training did you give your supervisors before this program of safety rule enforcement went into effect?

A. We had a series of meetings with all supervisors discussing the program and the form to be used before it was put into effect.

Q. Have you had experience with outsiders (truckers making plant deliveries) violating company safety rules?

A. Very little.

Q. Do you feel that it would be helpful to have union representatives on the development of safety rules?

A. It would lead to a better understanding but the company should retain the perogative of establishing the rules.

Q. You mentioned a penalty imposed for failure to report an injury. Will you explain this?

A. We believe it is good safety practice to insist employees report accidents promptly.▲

FIRE PREVENTION AND FIRE CONTROL (A Symposium)

WHAT MAKES A GOOD PLANT INSPECTION?

by CLAUDE C. STUBBE

Fire Prevention engineer, Mutual Service Insurance co., St. Paul, Minn.

Fire prevention and fire control in plants is our concern. People living in peaceful communities go to work daily with little thought that fire can destroy their plants. Superintendents, supervisors and management personnel must be concerned with preventing fire in these plants.

We can never be 100 per cent sure that we will not have a fire. If we could, then fire insurance and fire departments would not be needed. We would not have fire drills which take a lot of time. Often we cannot get management to have fire drills because " it can't happen to our plant."

We cannot eliminate chances of fire even if the building is so-called fire proof. There is no "fire proof" building even if it is constructed of steel, concrete, brick or other "fire proof" material. A structure is only as "fire proof" as its contents, occupancy, and the housekeeping in that building. A blazing interior fire developing up to 1800 degrees Fahrenheit heat will reduce any structure to shambles of twisted steel and broken masonry. From here on, we shall refer to so-called fire proof buildings as fire resistive buildings.

We are interested in two things—fire prevention and fire control in our plants. We make periodical plant inspections to save lives and property. The saving of lives is our first concern, and saving property and fire prevention our second.

FIRE PREVENTION

Fire prevention is most important to all fire prevention engineers because where there is no fire, there is no loss of life or property. *Fire prevention and control is a* complete fire wall from the basement to the roof with Class A fire doors for the openings. This in most cases, saves half of the building or whatever is cut off by the fire wall. Good housekeeping and good plant maintenance are fire prevention. A sprinkler system, fire extinguisher, and hoses and standpipes are fire control.

A fire prevention program depends upon how well you get everyone in the plant to heed your suggestions and ideas. You are no fire marshal, you have no governmental authority. You are a detective without a badge. You have no more authority than management gives you. A good plant inspection depends on how well you sell the plant manager or company president on your ideas. Therefore, you must be a good salesman. Fire prevention engineers with insurance companies must also have salesmanship qualifications.

You first must know a plant's construction. There are very few plants alike in construction. Therefore, a good plant inspection in one firm may not be so good in another. However, there are basic principles that are the same.

Fire resistive buildings are most desirable. However, there are many wood constructed plants, or half masonry and half wood. Heavy wood constructed plants are usually termed mill construction. The roof of such a building should have three inch planks nailed to heavy roof cross beams and covered with a good grade five ply tar and gravel. If a good coating of gravel is missing, this should be done immediately to protect the roof from burning embers carried by wind from another building.

Check your elevator pent house to see that all window lights are in and screened so birds cannot build nests and create fire hazards. Pent house door must be kept closed and locked. Check all sky lights. The glass in sky lights should be a light type glass with screen above to protect it from falling articles.

You should have scuppers on your roof to carry off surplus water quickly, especially snow water, and the roof should slope towards scuppers. If any high voltage wires cross your building roof check that wires and supports are in good condition. Also check the condition of parapets and chimneys.

Inside the building support posts and cross beams of wood should be as heavy as possible. A cross beam 8"x8" will withstand a fire better than a 6"x10". Check for dry rot. The cross beams of this construction should rest on cast iron plates or beam boxes.

Provide a 4"x4" drain scupper for each 1,000 feet of floor space. If you have a fire, a lot of water will be used and your drain scupper will drain this off and reduce damage to stock.

VERTICAL FIRE SPREADS

There should be no *unenclosed openings* from floor to floor. Your biggest concern must be the vertical spread of fire. When heat gets up to 1,000 degrees or more everything starts to burn. Fires in large areas are worse to control than in smaller areas. If an area is larger than 10,000 square feet, put in a cut off. Make sure all stairways, beltways, elevator shafts and other openings are enclosed. Any floor opening makes the construction deficient and aids to the vertical spread of fire.

Even in fire resistive buildings, you must be concerned with these things. In addition, if support posts and cross beams are steel "I" beams and unprotected, coat them with two to four inches of gypsum plaster—good insulation against fire.

Steel beams and other iron supports must be protected since Steel "I" beams weaken at 600 degrees Fahrenheit. The numerous buildings going up today without sprinkler protection or steel beam protection are potential hazards.

You must know the exposure to your plant, the types of buildings and their occupancy that surround or adjacent to your plant. Fire hazards come from other plants in your neighborhood. If there is a serious threat of conflagration from buildings near you discuss the situation with your city fire department. Or, go directly to the people who occupy the building and discuss the need for changes.

One thing you can do is close all openings next to the bad exposure. Check that you have an adequate water supply and good equipment to fight any roof fire that might occur. Water pipes to the roof are very important and be sure these connections are the same as fire department connections.

HOUSEKEEPING! MAINTENANCE!

Fire prevention engineers agree that many fires are caused because of poor housekeeping and poor maintenance. *With* good housekeeping and good maintenance, fire insurance rates would be much lower.

On an inspection tour housekeeping and maintenance should top the list.

Some plants do all their own maintenance work. Others do part and sublet the larger jobs, and still others hire everything done.

Plant fire protection engineers must be vitally concerned, especially with people who do your plants repair work, remodel or change your production lines.

In many cases, welding is performed when repair work or remodeling is done. This constitutes a serious hazard. It is your job to discuss with contractors how they will do the work and what protection they will provide.

When checking your plant for possible repairs, you are doing preventive maintenance. Preventive maintenance goes hand in hand with fire prevention. Preventive maintenance establishes means to reduce maintenance costs through necessary repairs. Therefore, the real instrument to meet this condition is inspection.

Your responsibility is great; you must know and understand all the machines in your plant, how they operate, and their potential hazards.

You must know all the electrical installations and whether or not they are overloaded. You must understand ventilating systems or blower and exhaust systems which extract dust and vapor. You must check for dust, grease residue in hoods, ducts or fans and provide a safe method for removal.

Feed mills or flour mills have special hazards such as dust explosions. These inspectors must understand driers, and there are many on the market. As the plant fire protection engineer, make certain the employees know how to operate driers. Be

sure employees will not create a hazard if a drier does not start.

Operators should know where the main valve manual shut off on the gas line is. One operator ran to the gas tank 300 feet and climbed over a cyclone fence to shut off the main valve by the tank. The result was 370 feet of three inch pipe filled with liquid gas went uncontrolled into the burner and burned out 300 tubes in a new boiler, burner and all. The plant was closed for several days.

Do you know and understand whether your milling grinders have good magnets?

Do you understand your heating plant? This is important because heating plant failures cause many fires. Can you enclose your heating plant with a masonry wall without too much expense? It pays off!!

Do you understand the boiler and all its controls? Check the controls every six months to see that they operate. The heating plant may be all automatic but it still needs attention.

Be sure your boiler burners are properly installed. Boiler operators should check water glasses, safety valves and burner combustion regularly, and clean the boilers when needed. High pressure boilers should have two ways of getting water into such a boiler. This is all a part of a plant fire prevention inspection.

FIRE CONTROL AND EMPLOYEE SAFETY

Two primary concerns when inspecting your plant are protection of life and fire control. Your sprinkler system must be in good order and working properly. Sprinkler systems cut insurance costs and give good protection if the main valve is not closed. The main valve when open looks like it is closed. Be sure to have a "DO NOT TOUCH" tag on the main valve.

The same is true with the automatic alarm system. A good plant inspection includes checking the automatic alarm system. If out of order, lose no time in calling the serviceman. Most plants have automatic service. However, you must know if that service is being performed properly. If you have time, go with the serviceman and learn all you can about the alarm system. Also make certain all fire extinguishers are in good operating condition and the right type for the fire to be put out.

The plant fire protection engineer must also be concerned with flammable liquids. If you are using gasoline, propane gas, butane gas, hexane or other volatile products of nature, you must know and understand their characteristics, and be sure the people using them do also.

Obeying the safe handling rules of volatile liquids is a must! If you do not understand the proper use of volatile liquids before a fire, it is too late afterwards. A lot of property is lost all because people do not know how to fight and control volatile liquid fires.

On many occasions when checking a plant, I find that fire doors do not operate properly. They are out of order, off their track, blocked by materials, fusible links are broken or the door does not close properly with the weights provided. Get your campaign going now and see that all fire doors are in good operating condition.

GUARD LIFE OF EMPLOYEES

The most important part of our jobs is safe guarding the lives in your plant. You are responsible for employees—old and new, visitors, and salesmen, who come into your plant.

The first protective device is good, visible EXIT signs. Arrows should point the way out of building and to fire escapes. Exit stairways which lead to outside doors must be so marked. Mark blind hallways and doors with no outside exit. This can cause the needless loss of life. Do your exit doors open out or in? Are your exit doors provided with panic hardware?

Check for overcrowded floors and provisions for orderly evacuation of employees on each floor. Be sure each floor has provisions of what to do in case of fire.

How about knowing that the fire alarm will be given and done so in understandable language? Is the switchboard operator in your plant designated to do this? When fire is discovered in your plant is the whole group trying to extinguish it and forgetting to call the fire department? Delayed fire calls are a sad story.

Even if you are organized there will be confusion if a fire begins with a flash or explosion.

In one plant when a drill took place some superintendents and management personnel

were usually too busy to take part. They told their personnel to leave the plant but they kept right on with their work. This is a very dangerous situation.

After one of these drills was completed, I spoke over the loud speaker system for three or four minutes. I commented on the excellent job everyone did and said I regreted there were some who felt too busy to take part in the drill. I stated that they have been orientated to a fire drill and know what to do. Therefore, I said, there will be no more fire drills in the organization. Hereafter when and if the alarm should sound—it's a fire! I hasten to say, let's get away from the fire drill idea as much as possible. There is no such thing in my book as a fire drill. All fire alarms are the real McCoy!

Let's assume you have made the plant inspection. When should you repeat the performance? Only as often as you deem it necessary. But I warn you do not inspect on a certain day of the month and a certain time of the day. Checking your plant for fire prevention and fire control should vary. Come when no one expects you.

After inspecting, write a report of the results of your work in good clear understandable language and not too technical.

Report to top management, outlining how the corrective measure can be put into effect. This is very important and you must also be a public relations man in many respects. This particular one is on security for your community. The symbols of security against fires are water systems, fire alarm systems and fire departments.

Whenever a bond issue is needed to get new fire department equipment or extension of present water mains, it is your duty as a fire prevention engineer to take an active lead and help obtain better fire protection for your city and community.

Fire protection engineering is one of the biggest jobs in all engineering phases. The challenge is yours!

CAN YOU WAIT FOR THE FIRE DEPARTMENT?

by JAMES H. SNYDER

manager, Safety & Plant Protection, Hiram Walker & Sons, Inc., Peoria, Ill.

The topic is in the form of a question, entitled, Can you wait for the Fire Department? One good question deserves many others, and to justify posing these questions, I would first tell you that there is more than one good reason why safety men should be concerned with fire.

Fire is an accident, an unexpected occurrence usually occasioned by loss and often accompanied by personal injury.

Of major concern to all in preventive work is, of course, preservation of human life. Of equal concern is the ability of our employers to continue their business. The preservation of property, physical assets and work places of the employees follows as an obvious necessity.

Because of the multiplicities of kinds of businesses represented by this group, I can only hope to stimulate your thinking by asking questions and hope as you think about it, you may be able to do for fire prevention and protection what you have been doing these many years for accident prevention.

FIRE DEPARTMENT SERVICES

What are the availabilities of your fire department? How fast can they come to your plant? What can you do with them assuming that they come when called? There may be a multiple fire situation, for example, attendance at a school or hotel fire to the detriment of the preservation of your property. Accordingly, what can you do without them?

What have you in your plant, already established by the way of sound procedures and good relationship?

Please have in mind that your fire department will not of necessity be familiar with:

Plant layout

Plant processes
Properties of products
Properties of raw materials
Built-in fire system
Its location
Effectiveness
Limitation

It is therefore necessary to establish an in-plant guidance group to work with public fire officials.

To switch over to the positive, you know what to do when a fire starts, and these topics will refresh your thinking:

EVACUATION
Building on fire
Nearby buildings

DIRECTION OF FIRE DEPARTMENT
To proper building
Nearness to scene for preservation of fire department's apparatus

PATHS OF EVACUATION
For safety of personnel
To minimize confusion of arriving fire dept.

USE OF VOLUNTEER FIRE DEPARTMENT
Lights
Portable intercommunication system
Proper rescue apparatus—masks, etc.,

USE OF SEARCH PARTIES
Rest rooms
Isolated offices
Showers and lockers
Janitor closets

COMMUNICATIONS
Call in volunteer fire department
Call in key personnel
Call in executives
Call in public press, radio & TV

TELEPHONE SERVICES
Incoming calls block switchboard
Coins for public telephone
Private wire

NEED FOR SPECIALISTS SERVICES
Craftmen
Doctors
Nurses
Ambulance
Engineers

NEED FOR SALVAGE
Vital records, formulae, cash, tax stamps

From the above you have possibly concluded that pre-planning for prevention is equally as vital as knowing what to do when trouble strikes.

What do you know about properties of raw materials and products:
When subjected to heat?
When subjected to burning?
When subjected to water?

What is the condition of sewers and drains:
Where ultimately exhausted?
Interconnected
Possibility of siphoning?

How about your fire pump:
Standards for starting?

What is the result of possible diversion:
Boilers
Process coaling—possible vacuum and implosion situations.

You have considered the results of interruptions in electrical services, for example: What else will it effect? Where is immediate location? What is ultimate location?
Does it effect:
Sump pumps
Other lines
Well pumps connected to fire system
Desirable ventilation
Elevators

How about movement of freight cars or trucks:
Containing flammable liquids or combustible materials.

What about pumping procedures:
Between buildings
To tanks—inside, outside
To and from tank cars

What is the effect of natural draft:
Favorable
Unfavorable

Are you aided by floors serving as fire stops:
Processes, piping or equipment passing through floors

Scuppered areas:
Piping and openings caulked
Capacity sufficient

Do you have container hazards:
Full, partially full, empty tanks and drums
Need to cool

Do you know about your illuminating gas lines:
Where terminated?
How shut off?

Consider airveyors and vacuum systems:
Transmission of burning material.
Shut off or operate.

How about windows, doors and monitors:
Open
Shut
Desirability
Undesirability

What about the operation of fire curtains:
Where?
What effect?

Do you have obstructed access:
Bridges
Railroad tracks
locked gates
locked buildings (Particularly bonded premises)

No safety man has been so thoughtless in his reasoning as to fail in the planning so necessary in actual fire or explosion. But the definition of pre-planning should take us in our thinking so far back in the basics of prevention to force us to conclude that if proper and productive pre-planning has been done, you may never need the assistance of the fire department.

The odds are all favorable, that if you are ready, and do need assistance, the occurrence will be small; it will be easy to control; and the loss will be at a minimum.

WHY INDUSTRIAL PLANTS BURN

REMARKS OF CHIEF EDWARD E. NEWELL, JR.

Chicago Fire Department, Chicago

Fire! ! Fire—one of the most thrilling words of our American vocabulary; thrilling to the kids who chase red fire engines down the street—but tragic to the home owner or business man who stands in front of his home or place of business, watching the savings of a life time being consumed in a few minutes.

Fire is only of general interest to the average person. He reads of fires in the daily papers, hears of them on radio and television. This is a natural condition, as the average person may live his allotted time with never an actual fire experience. The average man or woman has little knowledge of fire, or fire causes.

There is no doubt that management, responsible for protecting its company's assets, is concerned over the mounting, staggering losses in industrial fires. Recent disasters point up the need for constant vigilance and planning to minimize the results of destructive fires.

We preach fire prevention and fire protection almost constantly; yet fires continue to start.

DON'T DELAY ALARM

However if "Pre-Emergency" planning such as fire brigade training, monitoring of the area involved and the areas immediately adjacent is sufficiently active, automatic detection, either of local or central station

design will improve the program by minimizing the possibility of delayed alarms.

Automatic sprinklers are the best protection against delayed alarms; and to be equipped with local or central station alarms greatly improves their efficiency.

However, not all buildings are sprinklered so we find the need for proper instruction and training of fire brigade members. Employees should be thoroughly instructed and impressed that their first duty, upon discovering a fire, is to sound an alarm and then try to control the fire, using the proper type fire extinguisher.

There have been many instances where first aid fire appliances were used until the supply was exhausted and then the fire burned uncontrolled while someone called for help and larger equipment arrived.

Fire extinguishers should be considered as first aid appliances. They are important and when used properly extinguish many fires but we should understand the limits of their effectiveness and back them up by having the fire department on the way.

It has often been said, with relation to fire control, that the "first five minutes" after a fire starts is more important than the next five hours.

All fires start small but with sufficient fuel to feed on they grow rapidly and many require hours of labor and tons of water to control and finally extinguish. Each of the varied industries have their own specific fire problems. You must understand the hazards of your industry, and to reiterate, practice fire prevention and step up your Pre-Emergency planning.

Practice fire prevention always but also be prepared.▲

REMARKS OF CHIEF RAYMOND KOLZE

Fire Department, Des Plaines, Ill.

Why do industrial plants burn?

There are many reasons: first consider the construction of a modern industrial plant. In most cases it will cover from 25,000 square feet to six to ten acres. It is built of unprotected steel with a metal deck and a tar and gravel roofing. Unprotected steel stands up poorly under fire conditions. Firemen are thankful that larger plants have sprinkler systems if not in total area at least in part. There is a minimum of doors, few if any windows and sometimes a few skylights. This is what a fireman sees when he views this building from the outside.

Inside the building stock is piled to the legal limit in shipping and receiving areas. As if this were not enough the shipping and receiving platforms are inside the main building so all work can be done with a minimum of effort even if it means backing six or seven freight cars in the building.

Further examination of the building may reveal few fire walls or cut off walls. The reason for this, a supervisor said, was a plant cannot operate efficiently with division walls in the building because they interfere with production lines. In one plant nine fire doors had been removed to accommodate these lines. You can well imagine the danger when firemen have to drag 1000 to 1500 feet of hose into a building before they can reach the fire.

WORK OF FIRE BRIGADES

Training of fire brigades in any plant is a very important job. It makes all the men fire conscious and in this way always on the lookout for fire hazards and careless fellow workers. In the event of a small fire they usually have it under control before the local fire department arrives. In a major fire they certainly are a big help to the local department.

The city of Des Plaines has an industrial school each year to which industry sends men. The morning session is devoted to movies and talks on fire prevention with the afternoon session on fighting actual fires by the plant fire brigades. These fires are built of materials used in the various manufacturing plants. We find when they know what their products will do under adverse conditions and the limitations of the extinguishing agent they are using, they lose their fear of fires and really do a good job.

Once a plant superintendent called me and said "Chief I want you to see how well we have our men trained. We will go over to M section and I will turn in the alarm." My reply to him was I would rather go to section D with the dip tanks and see the response in that area. "Well, Chief," he said, "the boys don't know the fire is supposed to be there."

Many times it's hard to sell management on the idea of training fire brigades because of the additional cost for non-productive work. But I believe with the right approach it can be done and it must be done.

In most cases a watchman is an elderly man who walks about punching a time clock at various stations in the plant. He also has knowledge of how to operate a fire extinguisher. He should know how to contact the local fire department and should do this immediately when discovering a fire, not after it is out of control because he tried to extinguish it first.

Just remember, a lifetime of effort has gone into establishing your plant and certainly no one wants to burn it down in a few hours because someone neglected to do the right thing at the right time.▲

REMARKS OF E. K. CROSBY

fire prevention engineer, Pabst Brewing co., Milwaukee

A large loss fire is one that results in a quarter of a million or more dollars in damage. In 1956, there were 430 in the United States and Canada. Only one out of every 1,860 fires could be classified as a large loss one, but these fires accounted for 24 per cent of all property damage.

Hardest hit of any type of building was the industrial plant. Industrial fire damage was 50 per cent higher than in 1955. This fact contributes substantially to the over-all rising trend in fire losses. Half of all large loss fires go undetected or unreported until they grow to uncontrollable proportions. This is because most industrial fires occur when a plant is closed. About 83 per cent of fire damage occurs in idle hours.

Reports by the National Fire Protection association show that in many cases there is little or no watchman service. That is why I believe that all food industries should have good guard training at all times so that they are familiar with every phase of the industry. They should cooperate with the local fire and police departments and have full knowledge of sprinkler valves and water supply. Since many food industries have refrigeration systems, it is good to know where all ammonia shut-offs are. This applies to gas and flammable liquid storage.

One of the things I'd like to mention is welding and cutting. Many large industrial fires were caused by careless handling of torches. In my own experience I have encountered several large industrial fires where dust explosions were set off because of this careless act.

Poor housekeeping and failure to thoroughly " change-over" the facilities resulted in a large food warehouse fire where $960,000 of food were damaged by fire. No one paid much attention to the fact that the warehouse was formerly used to store nitrates, and a cutting torch did the rest. Watchman service in this case was also poor.

Management of course must stand behind a good program of fire prevention, such as a well-trained fire brigade. Why install expensive explosion-proof equipment in grain elevators, and flammable liquid storage vaults if a mechanic carries an ordinary light cord and naked light bulb and uses portable electric drills in a location where such equipment might cause an explosion?

Instead of using non-sparking tools around starches, grain dust and flammable liquids, regular steel tools are often used. They should be made of aluminum, bronze, brass and beryllium copper.

Fires in warehouse storage with and without sprinkler service resulted in 50 "large loss" fires during 1956. In 43 fires, there was a delay in detection with serious consequences. A further problem is lack of division walls. Fire damage might have been minimized in one where a back-fire from a truck caused a $265,000 fire. In many cases temporary wiring is used in a

factory and warehouse but forgotten in a short time—this too is dangerous.

Using an open flame near a vacuum system which sucked sparks into cyclone and set it afire is another example of the need for a thorough fire prevention program in every industrial location. Another example is stealing a smoke in warehouses loaded with combustibles. This indicates a complete lack of discipline in that organization.

I personally believe in the silent watchman i.e. automatic detection and sprinkler systems, maintained in working condition at all times. Here are some of the various fires around the nation that reflect the tremendous costs to industry in failing to develop an effective fire prevention program:

Montreal, Quebec, Canada (Brewery) $1,250,000. One killed on May 18th, 1957 in a fire caused by an ammonia explosion. Possible ignition sources were an ordinary light bulb at ceiling or static discharge generated by rapid escape of ammonia, no explosion venting.

OTHER BIG FIRE LOSSES

A cannery fire on April 29th, in Portland, Oregon resulted in $1,286,500 damage. Green beans and strawberries, spontaneous ignition. Plant was not sprinklered and no watchman was on duty over week-end.

A Super market fire in East Paterson, New York left $500,000 damage. No sprinklers were in the building. The fire started in the basement and was discovered at 2 P.M. Eight extinguishers were used but the fire could not be controlled due to congested stock piling. There was a delay in calling fire department.

Another fire—a grain elevator on March 28th, in Philadelphia, Pa. had $2,593,000 damage. Three people were killed. Cause of explosion was undetermined.

A food and grocery warehouse burned on October 21st, 1957 with $1,065,000 damage. Poor stock piling hindered the fire department. A watchman saw smoke at ceiling level at 8:30 A.M. and after determining that it was not coming from the coal furnace telephoned the fire department. As he was giving the alarm the flames shot through the ceiling.

There are many more major fires and disasters. However we can prevent all this by being on guard at all times.

WHY A FOOD PLANT BURNS

Here are some causes for fires in breweries, grain elevators, cereal processors, bakeries, distilleries, canneries, dairies and confectioners:

1. Ammonia—many have refrigeration
2. Poor housekeeping
3. Dust
4. Welding and cutting
5. Flammable liquids
6. Powdered milk and yeast—explosion hazards
7. Garage fire hazards
8. No sprinklers—fire extinguishing equipment inadequate or improperly used—watchmen service lacking
9. Vacuum systems—inadequate, or lack emergency cut-off to reduce spread of fire
10. Electrical hazards

Many plant managers don't give enough attention to fire prevention. They don't realize that fires can be prevented by adequate watchmen service—an alert fire prevention engineer whose only duty is to eliminate fire hazards. They don't have adequate sprinkler lines, fire extinguishers, or hose lines which are essential for any fire prevention program.

REMARKS OF C. F. MAROTZKE

Summit Volunteer Fire Department, Summit, Ill.

On the question: "Why Industrial Plants Burn," my answer is Carelessness. You will find that most plant owners or executives know little about first aid fire fighting equipment. They in turn appoint a man in charge of Plant Protection, but they also tie his hands and if his suggestions cost much they are turned down. In other words they are afraid to spend a buck for fear some moths will get out of the purse.

The average small business man will spend thousands of dollars for a new building, put in up-to-date fixtures and merchandise, but when it comes to first aid fire fighting equipment, he becomes penny-wise and dollar foolish, so he either installs inadequate equipment or no equipment at all.

If fire equipment is installed, it is not a question of how much protection I get, but how much will I save on my insurance premium?

The Volunteer Fire departments are interested in, and usually have some kind of fire prevention program. This naturally involves a lot of time and effort, with no pay. After the statement is made, "you fellows must be crazy to spend all that time and effort for nothing," I in turn ask if they realized how much fun we have being crazy. We look for no glory, but it is indeed gratifying to see the fruit of your efforts as in these examples:

The scout troop was meeting in a school house and one of the boys coming in late noticed a fire in a container near the basement door. He notified the scoutmaster and while he called the fire department, one of the boys took an extinguisher and put out the fire. He was asked, how did you know what to do and he stated, "that is what the Firemen teach us in school."

In another case a young boy came home from school and contrary to instructions started to get his own dinner. While doing this his hair caught fire and he suffered 2nd and 3rd degree burns. When his mother arrived she found him with a large towel wrapped around his head and she asked how he knew what to do. He said, "That is one of the things the Firemen teach us at school."

The Volunteer Fire departments realize that fire prevention goes hand in hand with fire fighting. They have accepted the challenge and are doing their share.

BRAINSTORMING FOR SAFETY

by A. C. STUDT

manager, Training & Education, The Hotpoint co., Chicago

Let's take a look at what thinking really is.

Thinking is a considering of alternatives—a rejection of many, and a choice, at last, of one.

Thinking is the exact opposite of routine action. If ideas which pass through our mind influence our actions, we are thinking. If our actions are not influenced by these ideas, we are daydreaming.

Thinking is invention. When a way of action has been blocked, when a routine has broken down, some other means must be discovered. Animals can be trained to follow routine, but humans must think—they must consider. For animals adjustment means conforming. For humans adjustment means readiness and ability to meet and cope with problems. Human adjustment must be logical and creative. We, therefore, have two kinds of thinking:

1. Logical.
2. Creative.

The ability to think creatively is not a gift—it's not something that some people have and others do not have and cannot get. Creative thinking can be taught. We are going to explore methods we can use to help us think about problems creatively.

Before we talk about how we're going to learn creative thinking, however, let's see just what creative thinking is and how it differs from logical thinking. Logical thinking starts at a given point and moves step by step to an incontestable solution. Creative thinking, on the other hand, has many possible starting points—imagination rules over logic—we may reach a conclusion on a problem without knowing how it was reached, and we may reach a conclusion on an idea or a problem which actually had no connection with the original problem.

BRAINSTORMING SESSION

We call this type of meeting a "Group Brainstorming Session" and it is based on the principle that one thought leads to another.

This is commonly called "chain thinking." In order to show how one thought leads to another or how one idea grows out of another idea, one can try a little experiment.

You whisper a word to one man in the room who in turn will whisper to the second man the first thing he thinks of after hearing the word you whispered to him. The third man carries on to the fourth and so on until you have gone all around the room. Then you mention aloud the word you started with, the second man tells what idea he got from it and why he stated the word he did and so on around the room until everyone has stated aloud the words they thought of originally and why they thought of them.

This is done to show how one thought leads to another and how, when a person mentions a certain idea or thought or word, we get an idea from it that may seem to have no connection with the first word, but which does have a connection when we hear the explanation.

We have now seen how, when we hear a word or idea, it reminds us of something which actually has a connection with the word we heard. This is the basis for what we call the "that reminds me" principle.

ORIGINS OF IDEAS

There are four basic reasons for getting an idea from what we hear:

1. *NEARNESS*—Something is near you which you feel or see or hear that reminds you of something which is not near you. For example, you see a baby's shoe and it reminds you of an infant—maybe your own child or a niece or nephew who may be miles and miles away. The fact that you saw the shoe which was near you reminded you of someone who was not near you.

2. *SIMILARITY*—Something you see or hear reminds you of something which is similar to it, although they are not the same. A picture of a lion reminds you of a cat, because there is a similarity between the two.

3. *CONTRAST*—Something you see or hear which reminds you of the exact opposite. For example, we see a midget and are reminded of a giant.

4. *CAUSE AND EFFECT*—Something happens which reminds us of an action to be taken or something to be done. For example, there were two men in a creative thinking class not so long ago who were standing in the hall discussing some of the ideas and a third man named Ted happened to walk by. One of the men said, Gosh, Ted, you seem to be in a hurry." Ted turned around and said, "Oh, that reminds me, I left my hat in the restaurant." Now, apparently there was no connection between being in a hurry and leaving a hat in a restaurant, but off Ted went to get his hat.

Later in the afternoon the two men checked with Ted to see just what it was that had reminded him of leaving his hat in the restaurant and he explained that he had gone to lunch with three other men that noon and while he was at lunch remembered an important appointment he should have kept. He dashed off to keep the appointment, explaining to the men that he would see them later in the day.

He kept his appointment and was walking down the corridor when one of these men happened to say, "You seem to be in a hurry." When he heard "being in a hurry" he was reminded of the last time he was in a hurry, which was in the restaurant, and he then remembered he had left the restaurant so quickly that he had forgotten his hat. All very simple and very clear when the whole story is known.

These ideas we get from other ideas can either happen by accident or they can happen on purpose. If they happen by accident, as in the case of Ted and his hat, we can get some good results from them. However, we can't just hope these accidents will happen; therefore, we make them happen. We make them happen on purpose in a "Group Brainstorming Meeting" by making people come up with ideas and talk of ideas and bring out many ideas. This is the only time, by the way, when we wish to make accidents happen.

There are certain ground rules for a "Group Brainstorming Session" that are best to follow. One is that logical judgment is more or less ruled out, at least at the beginning. Wildness of ideas is wanted because in that way we get many ideas. And even though your idea may sound very silly when you mention it and not practical or logical, that doesn't matter. The more ideas we get, the more ideas someone else will get from what we say.

MOTIVATION FOR THOUGHT

We must remember one thought leads to another. We can never tell when one man will get a good idea even though the idea that gave it to him may have sounded rather silly. When we do hear an idea that begins to make sense, and even though it may leave us up on "Cloud Nine," if it has a glimmer of sense to it, we then begin to engineer it down to earth and make it practical.

Now, while beginning this you will find that automatically our minds are going to go through certain stages of thinking. The first stage is motivation. An impetus of some kind is needed because old concepts have started to conflict with data and the conditions have changed to such an extent that our logical thinking has failed us—our backs are to the wall and we now realize that we are going to have to do some creative thinking to solve the problem.

The second step is: define the problem to find out just exactly what the problem really is. We had a case one time where we were working on the problem of: Eliminate poor morale. We had worked on the problem for some time and hadn't gotten very far.

We finally discovered that the reason we hadn't made much progress was because we had not defined our problem properly. We had men in the room who disagreed on just exactly what morale really is and we had several men in the room who thought that the morale in that department was not poor. Therefore, we had disagreement on the word "poor" and we had disagreement on the word "morale."

Naturally we couldn't solve the problem of how to eliminate poor morale until we could define the problem and agree on what we were trying to solve. Then we were prepared to collect information and really become immersed in that problem.

The third step: the collecting of all the information is what we call preparation—just getting ready to solve it. We must learn all we can about it. We must live with it. We sleep with it and eat with it and when we have collected all possible information we are ready to brainstorm the idea, which is step four.

In a brainstorming session we forget convention. We go wild; we let our imaginations run loose, mentioning many ideas which we hope will give someone else an idea as to the solution of our problem. If we do not come up with an answer to our problem, we're very likely to run into the next step which is frustration.

The only thing we can say about frustration is that it is at this point that we must learn the greatest of all virtues—patience. If we recognize that feeling of frustration as being natural, we will be able to go along to the next step and purposely divert our attention from the problem. In other words, forget it. Put it out of your mind; don't even think about it.

CAN'T STOP THINKING

The only reason we can say that, is because actually it's impossible to do, because our mind will unconsciously continue to operate on that subject. In the back of our mind we will be thinking about it whether we realize it or not. And then all of a sudden we will hear a word, we will see something or get an idea from someone and the next step of insight (Step Seven) will take place.

The sudden illumination will come and we will realize then that we have begun to

solve our problem just as Archimedes did when he stepped into the bathtub one day and solved a problem he had been working on for years. All of a sudden, after putting this idea out of his mind, that moment of insight came and he had solved his problem. It's happened to you—it's happened to me—it's happened many times, and it will happen many more times in the future.

Then, comes an important step: that of verification. (Step Eight). Now our idea must be engineered down to earth. This is where the creative thinker distinguishes himself from the crackpot. The crackpot leaves the idea on "Cloud Nine," the creative thinker engineers the idea down to earth and makes it practical and usable.

He assesses the idea, he evaluates it, and then analyzes the idea in the light of the problem and comes up with a solution. It may be in many cases that modification will have to take place. (Step Nine). There may be details of the idea which have to be worked out and they may involve some creative thinking too.

AWAKENING IMAGINATIONS

"Group Brainstorming Sessions" are based almost entirely on imagination. Now, that isn't quite as easy as it sounds because in most cases our imaginations have been stifled. In most cases we haven't deliberately used our imaginations for many years.

So we have to revive these imaginations. The first thing we are going to do is to reawaken our imaginations and as we start, the first thing I'll do is tell you a story—a story about an old friend of mine Pete Smith.

Pete Smith is driving down a road on Long Island and he's in a battered, worn out, 1937 model automobile that is chugging along as though each mile will be the last mile. Pete is wearing a suit that must have cost $300 new, but now it is dirty and has many grease spots and a few holes in it. As we get a little closer to Pete and take a look at him we discover that he has a very strange expression on his face.

The first time we look at it, we think it is a rather grim expression, but then as we look at him a little more, we decide that maybe he's smiling and we're a little puzzled as to just what's going through his mind. Just about that time, Pete turns into a driveway of a beautiful house, practically a mansion.

He drives the car to the front door, gets out of the car and stands and looks over the house for 30 seconds, and then with what we think could be a chuckle, walks up the front stairs and rings the bell. There is a short pause, the door is opened by a butler who is about to tell Pete Smith to go away, when he takes a second look at him, claps his hand to his forehead and says, "Oh, my God . . ."

UNFINISHED STORY

Now—we could finish the story. If time would permit, we would stop and write a conclusion to that story. In finishing the story one would begin to use the imagination. It doesn't matter what the answer is or what is written. The only reason for having this story completed is to get the group back into the habit of using their imaginations.

After your brainstorming group has worked on this story, give them an actual problem.

The problem we are going to describe is one we use at Hotpoint and probably could not be used any place else. We distribute to each participant a small paper tube, approximately one inch long and a half inch in diameter, sealed at one end. We explain that we have 13,000 of these paper tubes which are thrown out every week. We have decided to form a company and sell them. Our product is already made for us: it doesn't cost us anything.

All we have to do is to sell it. But before we can do that we must find a use for the paper tube. So, who has an idea as to what this paper tube can be used for? The ideas are listed. Even though they might sound silly in some cases, that's perfectly all right because even though it's a silly idea, it may give someone a good idea. After we have exhausted the possibilities of what this paper tube can be used for, we close the meeting by introducing another idea which will help reawaken their imaginations.

You might find that the group occasionally has reached the stage of frustration. The instructor should then have them forget the problem until someone in the group brings it up again because he thinks he has reached the next step of insight.

However, for these practice sessions it is suggested that the problems presented be simple ones. It is better to solve a simple problem than to confuse the issue by presenting a complicated one. The tougher, more complicated problems can be brought up later when the group has had some practice and is more familiar with brainstorming.

I'd like to tell you a story—a story about a friend of mine, John Jones. John Jones was a fairly good salesman making a fair average living. There was, however, one man John Jones wanted to sell. If he could get this one account, he knew that it could put him on top of the heap.

The man he called on, Mr. Brown, was always nice to him. He had never definitely said, "I will never give you an order." On the other hand, he had never yet given John any business. On the day when we come into contact with John, he's sitting at his desk in his office and the phone rings. Mr. Brown is on the other end of the wire and he says to him, "John, I was wondering if you could have lunch with me because there is something I'd like to talk to you about."

Naturally, John gets down to the hotel as fast as he can. He meets Mr. Brown in the lobby and they go into the restaurant to have lunch. Mr. Brown says, "John, before we start to talk, let's order. I think I'll have some roast beef, mashed potatoes and gravy," and John says, "That's fine. I'll have the same thing." The waitress brings the order. Mr. Brown puts a little salt on his roast beef, mashed potatoes and gravy, and hands the salt shaker to John.

COMPLICATIONS ARISE

John begins to put some salt on his potatoes when Mr. Brown starts to talk to him. As Mr. Brown is talking, John doesn't realize it but the salt keeps pouring out of the salt shaker, and quite a little mound gathers in the gravy. John, thinking it is a little mound of mashed potatoes with gravy, picks up this mound of salt and places it in his mouth just as Mr. Brown says to him, "Well, John, what do you think of that idea? . . . That's right. You finish the story.

However, before you finish that story, let me tell you of a little experiment I conducted. I went home, got a little gravy, poured a mound of salt into it, placed it in my mouth and I found that I could not get rid of the salt using a napkin. I found that I could not wash it down with a glass of water because it made me sick and I found that I could not say, "Pardon me, I'm going to rinse out my mouth," because I couldn't talk. Now, finish the story.

You will note that we have tried to eliminate the obvious ways of getting John out of his trouble so that the group will have to do a little more thinking to finish this story. You will also note that we do not tell what Mr. Brown said to John. He did not necessarily talk business. This is the big loophole for the group. If they ask you what Mr. Brown said, or ask if he discussed business your answer should be, "It doesn't say in the book. You'll just have to use your imagination."

BRAINSTORMING RULES

Now, let's add some ground rules for "brainstorming."

Appoint someone to record your ideas. Preferably someone capable of speed-writing or shorthand. Record all ideas. Any ideas are acceptable but—no logical thinking allowed! Review and analyze,—establishing a difference between creative thinking and day-dreaming. If it leads to action of some kind, it's creative thinking, otherwise—just day-dreaming.

Ten people sit around a table and the problem is posed. Write all the answers as rapidly as they are given. You can't say, "I don't think it will work!"

There are many people who claim they are logical thinkers and that creative thinking is not for them. Too many times, however, you will find that their logic is something like the Eskimo's thinking when he says, "A lighthouse is no good. The light shines—the bell rings—the whistle blows—but the fog comes in just the same." Or, like the Burmese who were astonished to find that Americans made sidewalks out of water. All they did was add a little sand and cement.

It is obvious that anyone who reasons along any of these lines needs help, and it is the duty of the training man to give it to him. Should you encounter anyone as described above, the following may be useful.

Often a person has trouble getting an original idea. It may be that he can expand

on an idea he has heard. He may be able to improve an idea, but the start is what stymies him. In those cases, this formula has been found successful. It is the method of solving the problem first. In this method of teaching creative thinking, we present the problem to a group and immediately produce a solution to the problem.

However, in spite of the fact that our solution is actually a solution to the problem, it is so ridiculous and far-fetched that improvements are obvious. With this method, however, we get their thinking started and get them over the first hurdle, although we are not doing their thinking for them.

IMPROVING A ROOM

Now suppose I tell you that I think a group should have a room in which to rest and relax during the day. I have decided that this very room would serve our purpose. However, it would be improved considerably if it was cleaned up a bit, so I'm going to have it painted. I think the west wall should be a bright yellow—the ceiling, Chinese Red—the east wall, light green with purple polka dots. How does that sound to you?

Your group will undoubtedly agree that a "relaxation room" is a fine idea. They will also agree that it should be painted, but they certainly cannot agree with the color scheme you have outlined for a room in which to relax.

Our solution, however, meets the requirements of the method. It is a solution to the problem, but the improvements to be made in color selection are obvious.

REMOVING A POST

Now here's another example. This meeting room is convenient for all participants of these sessions and comfortable. We have in this room everything we need to conduct a successful conference. The room, however, has one serious drawback. As you can see, there is a post about four feet in front of the door.

Now, this post does not interfere with coming in or going out of the door, but it is inconvenient, and we would be better off if the post was not there. Now, I'm smart enough to know we just can't remove the post and let it go at that, because the ceiling would fall down. The post now holds it up. However, I'm not too concerned about this problem because I have a solution to it.

What I purpose is to measure up from the floor seven feet and cut through the post at that point. Then we will remove the bottom seven feet, allowing us to pass in and out of the door and not be bothered by the post. The three feet of the post above the seven foot mark we will leave there because that is the part that supports the ceiling in the first place.

So my solution is to remove the bottom part of the post, which is in our way, and leave the top part where it is, to support the ceiling. What do you think of my idea? Can you think of any improvements on it? Again the improvements are obvious and the group will undoubtedly have many suggestions.

You can now introduce a real company problem, and at the same time a solution to the problem. Just be sure your solution is really a solution to the problem and can be improved upon easily. In other words, be sure you have a solution that the group must agree with in principle but must disagree with in detail.

THREE WAYS TO CREATE IDEAS

There are several other techniques that can be effective if your group is confronted by an inability to continue the process of creating thinking. There are three which should be considered:

The Tear-Down Method in which a product, part of a product, or a method of operation is selected for discussion by two men. One man takes the attitude that everything about the product or method is wrong and suggests a different, and not necessarily a better way of doing or making it. The other cannot agree with him and suggests another way of doing it.

The first disagrees and suggests another way, and so on. When one man makes a suggestion that makes sense both men get together and engineer it down to earth, making it practical and useable.

A second approach is called the *"And-Also Method."* Again two men work together and make suggestions but do not disagree. One suggests a different method and the other says "That's good, and also we could . . ." and he adds to the idea. This elicits additional ideas and thinking. Again, eventually a good idea is worked out.

Finally there is the *37 Solutions Method.* All interested parties are told about a problem and asked to write down 37 solutions to the problem. A week later they attend a meeting and their ticket of admission is their list of 37 solutions. After duplicates and the obviously impossible solutions are eliminated you may have only five or six good ideas left. But you are in the position of starting a meeting to solve a problem to which you already have five or six good solutions.

BRAINSTORMING ANSWERS

You confront many problems in your safety responsibilities. In finding some answers to the question, "How to get supervisors to accept their safety responsibilities," the following list of unedited replies were given as a possible answer to this problem.

Sell idea of safety as part of production.
Fire all and get new ones.
Make them give detailed reports with recommendation on all accidents.
Let supervisors know that they have 100 per cent management support.
Make foremen act out accident.
Get supervisor into every safety activity.
Add accident costs to supervisor's report or take out of his pay.
Send to NSC school.
Penalize foreman by shift to night work or to more disagreeable job.
Integrate safety record with annual merit rating.
Have all reports routed through immediate and "top" boss.
Make supervisor announce and explain accident to family of worker.
Hold them responsible for reporting and requesting correction on unsafe conditions.
If an accident occurs, the foreman must treat safety director to a dinner.
Awards and recognition.
Management must demand it.
Sell safety to management.
Charge back of compensation costs to the department.
Publicity for bad performance.
Educate them.
Include supervisors on safety committees.
Dramatize the problem.
Have supervisors investigate and explain accidents to their bosses.
Get tough.
Bonus system to supervisors with good safety records.
Promote employee suggestion system. Pay for suggestions that are adopted.
Have supervisors accompany inspection committee.
Publicize workers' safety suggestions.
Write safety into job specifications.
Enforce safety as written into job specifications.
Emphasize safety on staff meetings agenda, and in actual session. Introduce at all staff meetings—supervisory, middle and top management.
Get managers "off their duffs" and out in the plant to check the job that is being done.
Be sure that management is properly advised by adequate reports as to what is going on.
Proper selection of safety personnel—man in charge must have know-how, personality and dedication to the job. He must be able to win the cooperation of the line organization.
Understandable rules.
Explain "why" to supervisor.
Annual dinners for no lost time injuries.
Supervisors investigate safety suggestions.
Supervisors in charge of safety suggestions.
Hold responsible for accidents.
Threaten.
Discipline.
Promise a trip to Sputnik.
Evening meetings on overtime.
De-merits—counts against bonus.
Give him your job, and you take his.
Make out all necessary reports.
Department competition.
Incentive awards.
Pride in plant safety achievement.
Badge.
Put in pillory.

Put on first aid for a time.
Visit hospital injuries.
Consciousness of safety.
Impress him that safety is part of his job.
Have supervisor explain to top management why the accident occurred and what he is doing to prevent accidents in the future.
Have superintendents grade each foreman.
Give S&H stamps.
Demote foremen to assistant.
Discuss safety responsibilties with foreman's wife and family.
Have top management get foremen together weekly — rotate chairmanship among foremen.
Joint safety and health meetings with union personnel represented.
Penalize foreman by putting red sign on his back, "I goofed."
Use National Safety Council material.
Think safety and make it a habit.
Completely train them.
Have program where supervisor is directly involved—like contact system.
Accident cost budget.
Accident cost budget with savings on estimated costs returned to the department.
Pay sufficiently to insure acceptance of responsibility.
Fire them—set examples.
Interview with top management.
House organ on safety—supervisory level.
Supervisor as "Safety Man of the Month."
Have vice presidents visit with all levels of supervision on safety.
Have supervisors investigate all accidents, serious or minor, actual or potential.
Safety Director take problem to top management.
Make safety a line function instead of staff.
Negotiate so that labor contract does not hamper foremen's position with respect to safety.
Hypnotize him so he will accept responsibility.
Organize good supervisors' safety training program.
Use them as assistant safety supervisors for a time.
Send top supervisor to NSC Congress as a reward.
Select winner (as in above) through departmental contest.
Have him address next safety meeting if his safety record is poor.
Let him defend safety record before his boss.
Safety scoreboard by departments.
Invite supervisor's wife to visit his job area during working hours.
Break down supervisor's work—see if he has time to do safety. Review his "red tape."
Supervisor analyze each job with his men. Offer supervisor help from the safety and engineering department for four weeks.
Place white elephant in department of supervisor with poorest safety record. Also, award department with the best standing.
List uncompleted recommendations in a department and dates on which they were made.
Take photographs of conditions in need of correction and submit to company officials.
Bring all supervisors to NSC Congress.
Take supervisor to supper.
Extra incentive wage for accident free year.
Films.▲

HOW I TRAIN MY EMPLOYEES FOR JOB SAFETY

INTRODUCTORY REMARKS

by E. G. HUTZLEY
senior safety engineer, Campbell Soup co., Camden, N. J.

Next to the backing of plant management, a supervisor's understanding of why accident prevention is a part of their daily duties is, without a doubt, the most important.

Without such understanding and knowledge of how consistent use of understandable techniques will reduce accidents and costs, the incentive to take active part in accident prevention educational training of people they supervise is entirely lacking.

Sincere supervision of every degree will use his powers of observation, administration and human relations knowledge to have people he directs do their work with the least hazard possible.

Everyone has their own pet theory concerning the best way of putting a story across. The five gentlemen we have here on our panel can provide us all with down to earth information, methods and procedures which we can take back and use in our own plants. Each panel member will present his method of training employees in job safety.▲

REMARKS OF LEO D. BAUER

maintenance foreman, Brown-Forman Distillers corp., Louisville, Ky.

Since my work is confined mostly to the main plant, my remarks will pertain chiefly to that operation. Of a total of 1,650 people employed by Brown-Forman 1,140 are located at the main plant, called the Old Forester Plant, 300 in the general and sales offices and 830 in production, working in the distillery, warehouses, bottling house, shipping department, maintenance and power plant.

My job as general maintenance foreman involves the supervision of 45 men whose duties are to maintain buildings, grounds and all equipment, except bottling machinery. Bottling machinery is maintained by a separate group. We also maintain all heating and air conditioning equipment.

Most of our work is done on the day shift, although there are two maintenance men on duty during each production shift. Our present schedule consists of 24 hour operation, five days in the distillery, and eight hours, five days in bottling.

The maintenance crew is made up of electricians, pipefitters, mechanics, carpenters, painters, gardeners, a brick mason, apprentices, helpers and laborers. All except electricians are members of Local #39 of the Distillery and Wine Workers Union. Electricians are members of International Brotherhood of Electrical Workers. During the day shift, there is a trained nurse on duty in a well-equipped dispensary.

WHISKY PROCESSES

Bourbon whiskey is made by grinding grain, consisting of corn, rye, and barley malt into meal. The corn meal is added to water in a cooker. Here the starch in the corn is broken down by a process called Pastification. The pastified meal is then pumped into mash tubs where rye and malt are added. The malt converts the grain starches into fermentable sugars.

The finished wash is pumped through coolers into fermenter vats where yeast is added to convert the grain sugars into whisky. The fermented "beer," as it is now called, is then pumped into the "beer still" where the whisky is removed by distillation. The new whisky is then put in new white oak barrels and stored in warehouses for at least four years before it is bottled.

The by-products of the beer still are called spirit stillage. It is processed in driers and evaporators to produce distillers light grains and solubles, which are used as feed supplements in the feeding of poultry, cattle and swine. Our bottling house consists of 10 bottling lines capable of bottling 90 bottles per minute each.

HAZARDS IN DISTILLERIES

In a distillery, hazards are created by the handling, storage and milling of grain, the distillation of alcohol, and the handling and storage of alcohol in tanks, vessels, and barrels.

The principal equipment used in the production of whisky are mills, conveyors, pumps, stills, and various types of heat exchanger equipment. The major hazards in the distilling industry are fire and explosion from grain or meal dust, and from vapors of volatile liquids.

The danger from fire and explosion are probably the easiest to recognize, and, therefore, are the ones which we guard against the most. As in all distilleries, we have definite rules and precautions which must be observed in the routine production and maintenance jobs connected with these hazards.

In addition to the fire and explosion hazards, we have the hazards found around power transmission equipment, materials handling equipment, tools, electrical apparatus, steam and gas lines. Perhaps, we are less aware of these hazards because they are aids to the production of the product, and do not necessarily involve the product or any raw material. It is in this field that we must be most cautious.

ALL AID SAFETY PROGRAM

At Brown-Forman, the safety program is under the direction of Joe Redelberger, the Director of Safety. Redelberger organizes the program and it is carried out by the department heads, foremen, and the men and women on the job. He maintains the records and provides all the material and help necessary for a good safety program, but he depends on the foremen and workers to carry it out. Each foreman is responsible for the safety program in his department. All contacts from the safety department are made through the foremen and not through the safety department itself.

There is an annual company-wide safety contest. The division which wins each contest is treated to an open house, where the families of the workers are invited to witness the presentation of awards and enjoy a buffet lunch.

In the maintenance department, we have *many men who are quite skilled at their* trades, and who have learned that a good job is one which has been done safely. These men believe in safety and are a great influence in teaching safety to the younger men.

When a new man reports to the maintenance department, he is made familiar with the safety rules of the department. The rules are posted conspicuously, and are reviewed frequently. The new man is assigned to work with older employees if this is at all possible, and the older employee, as well as the foreman, is expected to see to it that the new man learns what is expected of him from a safety standpoint.

TRAINING, SAFETY MEETINGS

We also have an apprentice program, consisting of on-the-job training, and off-the-job class work. Safe working practices are an important part of this program. Monthly safety meetings are held. These *meetings are carefully planned so that the* workers take part in them and so that they will be of interest to the maintenance men. We discuss accidents and near accidents and the ways and means by which they were, or may have been avoided. We discuss hazards *and request safety suggestions. We try to* limit these meetings to 45 minutes and we've found that they're well received. At these safety meetings, typical distillery jobs are reviewed and safe methods for carrying out the jobs are discussed.

There are several rules which apply to hazardous work and jobs which involve welding, cutting, or sprinkler tests and repair. We try to make these rules as ironclad as possible. The rules involve the use of Welding & Cutting Permits, and Sprinkler Maintenance Permits. When these permits are issued, permission is received from the department head, the safety department, and the maintenance foreman in writing. Fire watches are assigned and explosion meter readings made, if necessary.

When a fire watch is assigned, he is a member of the Guard Force. He is not interested in the maintenance job, itself, but only in seeing that a fire does not start. He maintains his watch for one hour after the job is completed. The proper handling of these permits insures the worker that the area or equipment he is to work on is reasonably safe. We've found that the *maintenance* men are enthusiastic about the permit system. They try to make it work, and that's the item which determines the success or failure of a program.

Other rules involve locking out power equipment, methods of purging tanks, use of ladders, blocking off areas where work is going on overhead. We try to remind the men of these regulations constantly.

Formal training programs, regular meetings, safety rules and regulations—these are important and necessary parts of a foreman's safety program. The most important part of the foreman's safety job, however, is the person to person contact on the job. While we must learn to deal with a group—be impartial—award jobs and overtime by seniority, we must not forget that every human being is a different person. A foreman must learn to know each man. He must learn to know what to expect from each. He must be where he can help if help is needed. He must be diplomatic and inspire cooperation. The success of a safety program depends on people wanting to work safely.

REMARKS OF DEAN McCLURE

Albers Milling Div. of Carnation co., Kansas City, Mo.

I have a safety story I'd like to relate. It is a letter written as a gripe to the insurance company, and reads as follows:

"Gentlemen:

The soullessness of corporations such as yours is astounding. Let me review my case. I carry an accident policy DX 567843 in your company, by the terms of which you agreed to pay me $25.00 a week during such time as I was prevented from working because of an accident.

"A week ago I was inspecting a new apartment house that is being built for me. I climbed the stairs, or rather the ladder, now located where the stairs will be when the house is finished, and on the top floor I located a pile of bricks which were not needed there. Feeling industrious I decided to remove the bricks. In the elevator shaft was a rope and pulley and on one end of the rope was a barrel. I pulled the barrel up to the top and fastened the rope firmly to the bottom of the shaft. Then I climbed the ladder again, and filled the barrel with bricks.

"Down the ladder I want again-five stories, mind you—and untied the rope to let the barrel down. The barrel was heavier than I, *and before I had time to* study the proposition I was going up the shaft with my speed increasing every second. I thought of letting go of the rope, but before I had decided to do so, I was so high up that it seemed more dangerous to let go than to hang on. So, I held on.

"Half way up the elevator shaft I met the barrel of bricks coming down. The encounter was brief but spirited. I got the worst of it and continued on my way upward toward the roof. I struck the roof at the same time that the barrel struck the cellar. The shock knocked the breath out of me and the bottom out of the barrel. I was heavier than the empty barrel, and I started down the shaft while the barrel started up. We met in the middle of our journey and the barrel pounded my solar plexus, barked my *shins, bruised my body, and skinned my* face.

"When we became disentangled, I resumed my journey downward, and the barrel went higher. When I hit the bottom, I stopped so suddenly I lost my remarkable presence of mind and let go of the rope. This released the barrel which had reached the top of the shaft, and it fell five stories landing squarely on top of me.

"Consider the heartlessness of your company. I sustained five separate and distinct accidents within one minute. One,

on my journey up the shaft; two, when I struck the roof; three, when I met the empty barrel; four, when I struck the bottom; five, when the barrel struck me. Now, your agent states that it was only one accident, not five, and instead of receiving $125.00, I am only entitled to one accident settlement at the rate of $25.00."

SOME ACCIDENT FACTS

To me, while the story is comical at first, it also points out several things from a safety standpoint.

1. How quickly accidents can happen.
2. How a chain reaction of events can come about before you have had time to reason out or evaluate the situation.
3. Accidents may be caused by someone doing something he should not have been doing.
4. The logic of some people concerning an accident after it has happened.

Certainly, we all realize a company cannot suddenly decide that all of their employees will work safely and make their wishes come true. It requires a good safety educational program to develop good teamwork between management, supervisors, and employees. A positive attitude by all concerned toward working safely is very desirable.

MUST STRESS SAFETY

This safety consciousness can be greatly stressed if management and supervisors practice safety themselves; remind others of safety practices while they work, give credit where credit is due; and always be willing to supply and maintain any safety equipment needed.

At our Kansas City plant, we like to introduce new employees to our plant safety program by letting them know how proud we are of our safety record at the plant, and explaining some of the reasons for safety. For instance:

- From the employee's point of view, if he is injured:
  - (a) He must suffer.
  - (b) He stands a chance to lose his life or limb.
  - (c) He and his family may have financial hardships due to partial or permanent loss of pay.
  - (d) He must stand partial medical expenses even though covered by insurance.
- From the company's point of view:
  - (a) A safe worker is an alert worker.
  - (b) Employee's attitude to the company is better when they know the company is concerned with their family's welfare.
  - (c) It is costly to replace a trained man while he is temporarily or permanently disabled.

Next we like to discuss our safety committee, its functions and the authority of the committee members. We also explain that he should not take offense if someone points out his unsafe practices, but to accept these suggestions as a personal favor to himself and his family.

SAFETY COMMITTEE'S DUTIES

To me it is gratifying to overhear an employee—committee man or not—remind a fellow employee when he sees something he considers unsafe. Teamwork such as this is desirable and necessary to help maintain interest and alertness toward plant safety at all times.

Our safety committee meets monthly. It is composed of management, all of the supervisors, and at least one man from each division of the plant. We try to select key men from each group who rotate each year. Eventually, we hope to have every employee serve on the committee at least one year or more.

SAFETY MEETING AGENDA

A typical safety meeting program is as follows:

—Since our plant safety contest standing is comparable in interest to a football or baseball score, we discuss it first.

—Then we discuss safety posters and any other safety material presented by the members.

—Members make mechanical and non-mechanical recommendations which are noted in our minutes of the meeting. These recommendations are all logical and well planned and we always try to have them completed by the next meeting. Thus, the individual feels it is worthwhile to watch for things that need attention.

—Selection is made by the committee of the "Safety Man of the Month." The men are divided into groups that are exposed to similar risks. Each month we pick a different group, and from that group is chosen the most outstanding, safety-minded individual according to his attitude, past record, etc. This employee receives a $5.00 award, and his name goes on our "Safety Man of the Month" board. Also, a nice letter is sent to his family to tell them of the honors bestowed on him.

Our meetings are generally closed with a film on safety, or a talk concerning industrial or home safety.

REMARKS OF HENRY NUTI

foreman, Mars, Inc., Chicago

The successful training of employees for job safety depends on many things. Primarily it is necessary that the fundamental principles of a safety program be backed by the owners and executives of the company. Their sincerity is demonstrated by the employment of a safety director, the installation of a medical department complete with doctor, registered nurses, and full equipment for handling minor accidents. In many other ways they must set the example by safe practices.

When a new employee is placed in the hands of the foreman he has already received some general instructions on safety. From that point, after the preliminary introduction, we try to find out what qualifications the employee has for the task to be undertaken. To the best of our ability we try to determine if the employee is suited physically and temperamentally for the work.

Although it is difficult to determine much from the initial interview it does sometimes save us from unwittingly exposing a workman to hazards which may aggravate a pre-existing condition or place him at work which he cannot be expected to perform efficiently.

For example, we have jobs on our roll wrappers which require a rather tall girl because she must reach up and guide pieces into the wrapper. Five feet, four inches is a minimum. To put anyone shorter on the job would require supplying her with a platform to stand on. This would aggravate a pre-existing condition by putting her in a job which she cannot perform efficiently. If we feel the employees qualify then we instruct them in the safe methods of a specific task.

From there on he is watched frequently until he has demonstrated his aptitude for the work and has formed safe and efficient habits. Older employees also must be reminded of safe performance because they often form unsafe habits without realizing it.

FOLLOW-UP INSTRUCTION

Any instance of non-compliance with safety regulation and practice is dealt with firmly and positively just as it would be with poor workmanship. Here is where we foremen sometimes fail. In the interests of expediency and continuity of live performance we are perforce to look toward the ceiling while the unsafe act is being performed.

We excuse ourselves by saying we will take care of it when the right time comes. This is tantamount to approving the action and the employee feels assured that it is alright until he is hurt; then he condemns you for not stopping him.

Since it is physically impossible for any foreman to be in enough places at the right time to verify safe conditions and behavior, each employee is required to verify the proper condition of his workplace and equipment. He is also required to keep equipment and workplace in first class condition. Obviously this is necessary in a food plant for more reasons than one. Here of course he is supplemented by an adequate maintenance force.

Every accident, no matter how minor must be reported to the medical department

for attention. The report is turned back to the foreman who investigates and corrects the cause to prevent recurrence. Sometimes it is difficult to get quick response to some necessary action to remove or guard a hazard.

If this occurs, the foreman's responsibility does not end by merely requestioning. He cannot be relieved until the correction has been made. Moreover the cooperation of the employees is discouraged when correction is delayed.

EDUCATING EMPLOYEES

To assist us to determine the effectiveness of our program we receive monthly, semi-annually and annual reports from the safety department as to the number and types of accidents that occur in ours and other departments. This information assists us by focusing attention and corrective action upon the more urgent situations. Long operating periods without lost time injuries are recognized by publication on a bulletin board. So is the injury which stopped the period.

No one person or small group of persons can carry on safety work alone. All employees must feel they are essential partners in the program. To accomplish this it is necessary to create a guard in each employee so he will habitually think and look before acting. Only through sustained education can this guard be created and maintained. Ours is a never ending task because each accident is evidence of failure and therefore a signal for prompt remedial action. Persistent supervising, patient but firm and positive handling in cases of non-compliance with safety regulation, instilling a feeling of partnership in the employees because the job is too big to do alone and most important, sustained education to make it a habit to think and look before acting are our complete responsibility. This is our part in halting the widespread human misery and economic waste that follow accidents. ▲

REMARKS OF GEORGE E. SHUMAN

assistant plant superintendent, Libby, McNeill & Libby, Janesville, Wis.

Being in the seasonal canning industry, I often train a great number of seasonal employees in a short time. In addition, I continuously train new employees at a rapid rate because of the high turnover of labor. To do the job adequately, it takes the combined effort of all departments and all supervisory personnel.

In order to do this, we must approach safety training from many directions. I start this training when the employee first reports to work. Even before he reports on the job the personnel office spends from 20 to 30 minutes with the employee, explaining how the company feels about safety and what it is attempting to do. Second, the employee gets another reminder of safety precautions and has explained to him the particular safety precautions and hazards of his job.

This training is not adequate, however, and we go to even greater extents to keep every employee constantly aware of safety. Once each week, during brief pauses in production, my foremen and supervisors take the employees aside in small groups and remind them of safety. During this time, they ask for suggestions on improvements that could be made or criticism on our present safety precautions.

Each week, I hold a meeting of the safety committee to discuss these suggestions and recommendations. Several employees from different departments and different jobs attend and participate in the discussions. In this way, I obtain a different point of view which often brings up things that I had overlooked completely myself.

Finally, I conduct a continual safety campaign with posters, contests, and awards to keep safety foremost in the mind of all. ▲

WHAT'S MY LINE IN SAFETY

REMARKS OF A NURSE

by BERNICE McDERMOTT, R. N.*
I. Miller & Sons co., Long Island City, N. Y.

The working basis of an accident prevention program includes:

a. A statement of policy by top management which emphasizes the importance of safety and assures enthusiastic support of all responsible for reducing accidents and occupational illness.
b. Safety education of all supervisors and workers.
c. The discovery of all hazards by point of operation guarding.
d. Physical safeguards for all hazards discovered by regular inspection and reports.
e. First aid facilities to minimize the severity of the accidents.
f. Assignment of responsibility for safety to line organization with the co-ordinating leadership specifically designated.
g. Assembly of data for control purposes.

CONTROL OF SAFE WORKING CONDITIONS

A monthly inspection of the plant is made by a team composed of: the maintenance superintendent, a personnel representative, the department chairmen (usually two), a nurse and the foreman of the department.

The monthly safety meeting includes the inspecting team plus a plant superintendent who conducts and moderates, employee representatives, one from each department, chairmen, from each department, foremen, (usually four), and an insurance representative.

Employees, chairmen and foremen who attend the safety meetings serve for three months. They are replaced by other members from the same groups thereby rotating active participation.

Before the safety meeting, the inspection team submits a report of its findings which includes the action taken from recommendations made at the preceding safety meeting. Additional reports, by specifically designated persons, are submitted for discussion and prevention control.

SELECTION, PLACEMENT AND TRAINING

Weekly conferences of supervisors are conducted by the plant superintendent. During these meetings accident control is considered from a viewpoint of cause and effect. The discussion material is provided in a summarized report of all injuries which occurred.

The selection and placement of employees is made by the personnel department. The experience and special skill of the applicant are the determining factors. Applicants are referred through agencies, however, some new employees are obtained through classified advertisement.

There is no question of the importance of pre-employment evaluation from a medical viewpoint. However, because of a union situation, there is no pre-placement program.

The training of all new employees is assigned to the supervisor of the respective department. The trainee learns first by observation with gradual participation in the immediate area of operation. The training

*Bernice McDermott was unable to attend the Congress. This manuscript was submitted previously for use in the transactions.

of the new employee may be delegated, by the supervisor, to an experienced, reliable and well skilled member of his department. Evaluation of the trainee's performance is made by the supervisor exclusively.

In promoting safety and maintaining interest the following practices are exercised: safety committee meetings are held, safety inspection teams are organized with workers participating, and training courses for all supervisors including the nurse. Awards are given to individuals for ideas and improved methods of operation, and safety literature is enclosed in pay envelope.

Messages on safety are included in the monthly communication to individuals by top management. Posters dealing with safety, bulletin board reminders and health literature promote safety awareness. Talks by the nurse to supervisors and employee groups and day by day instruction, by the nurse, when caring for individual injuries or illnesses make employees more safety conscious.

PERSONAL PROTECTION

By Management:

Protective equipment is available for general need with allowances for special requirements, e.g. refracted lens where goggles are essential. Management also installs safe machinery and equipment and provides first aid facilities.

By Supervisors:

The supervisors conduct fruitful training with observation of new employees, and then give objective evaluations of their adaptability, judgment and performance. Correction and prevention of physical hazards in their respective departments are their responsibility. They also supervise light and noise control and recognize any changes in the continuity of production. They detect unsafe practices, e.g. repairing of machines by operators.

By nurse:

Early detection of sensitivity to materials required in operation is a most important responsibility of the company nurse. In addition, early detection of fatigue factors, e.g. off balance at work position and spotting failure to employ protective equipment are her duties.

She gives instructions in using protective facilities when issuing them and recognizes inadequate clothing as related to seasonal demands, continued standing or type of operation. Of course, her main duty is administering first aid and instructing in hygienic practices relating to health in general.

CARE OF INJURED AND HEALTH PROGRAM

With no plant physician, the care of the injured in all emergencies, becomes the responsibility of the nurse. As a guide in carrying out routines and procedures, she is governed by the well known "standing orders." These orders clearly outline her limitations when administering first aid in either occupational or non-occupational emergencies. The physician who has written and signed the prescribed procedures has been approved by top management.

Occupational emergencies which arise and their treatment are:

1. Minor injuries receive first aid and follow-up care by the nurse.
2. More severe injuries receive first aid only and are referred to a physician, the injured person having 'free choice.' In the event of an eye injury, the patient is referred directly to the care of an ophthalmologist.
3. Injuries of apparent extreme severity, or where doubt exists, are attended at the site of the accident. The attending physician then assumes the responsibility for follow-up medical care.

The line of distinction between minor and severe injuries depends upon 1) the extent of the injury 2) part of body involved 3) the general condition of the injured and 4) the history of the accident. However, the required information on the cause of the accident sometimes involves painstaking investigation which in delaying is inadvisable. Contributing factors may escape attention.

Two purposes of early investigation are to determine compensation benefits of the injured person and aid as a guide to preventive effort. The nurse has a responsibility to obtain the cause of injury for the victim, and for preventing recurrence.

All occupational injuries or illnesses that require medical care are reported to the Workmen's Compensation Board, Department of Labor. Standard accepted forms are used and reports are submitted at the earliest possible date after the injury. The report includes any loss of time from the injury. The nurse is responsible for all such reports. Employees who lose time because of injury, resume work when authorized by their attending physician. When treatment has terminated, the doctor so indicates on his final report, and also reports factors of disability, such as scars or partial impairment.

Our health program is limited and informal being conducted and guided by the nurse. The primary essential in assisting individuals with their problems is the nurse's ability to gain confidence in her advice and recommendations. Encouragement and understanding by the nurse develops a sense of security and feeling of being welcomed, plus the reaction that no problem is "too small" for discussion.

Through voluntary consultations the nurse develops an awareness of varied health problems, such as dietary deficiencies, weight control, adequate and proper clothing, fatigue factors, emotional disturbances, detecting irritability, economical problems and personal hygiene.

AIDS FOR THE NURSE

Making use of numerous community services, with which the nurse keeps in touch, provides her a most beneficial aid. Also, through the co-operation of the family physician, and the employee's consent, many specific services are rendered by the nurse "in the plant," such as a series of injections or daily renewal of a surgical dressing.

In this area, the co-operation and the response of employees is most gratifying. Their interest in health literature and pamphlets is most encouraging and stimulates interest heretofore unchallenged.

Exclusion of employees from work, because of illness, is done on the judgment of the nurse.

Disability benefits for non-occupational illness are provided through group insurance and are facilitated through the personnel department. The nurse reports all known illnesses to this department and benefits are instituted. Employees resuming work after an extended illness do so with written authorization by the attending physician.

The extent of medical equipment is dictated by the program in practice. All medical supplies are ordered by the nurse with the approval of the general plant manager.

One of the greatest responsibilities of the industrial nurse is records and reports. The daily log is a day by day record of all persons advised or treated by the nurse, and serves as a working basis for all reports and analysis.

ACCIDENT REPORTS AND ANALYSIS

The personal record card is maintained by the nurse confidentially. These records are beneficial in accident control from repetitive standpoint. Reports submitted by the nurse include:

1. Monthly dispensary report, clarifying care of all injuries as differentiated from non-injuries, each designated under a heading, e.g. abrasion; headaches.
2. Monthly accident summary, giving all essential details of injury; cause, lost time, return to work.
3. Day to day report on accidents, showing cause, result and disposition of medical care; recommendations; lost time.
4. Reports on illnesses are made to personnel.

The above reports go to division management and the following to the HOME office:

1. Listing of individual accidents showing lost time.
2. Listing of individual accidents showing no lost time other than time spent receiving medical care.
3. Report of each individual who has lost time on how accident occurred, cause of injury including all contributing factors, e.g. part of machine, nature and extent of injury with diagnosis, classification of disability and supervisor's recommendation in preventing recurrence.

The purpose of these reports is for analysis and classification done by the HOME office. They are considered from the viewpoint of: type of accidents, cause of accidents, disability resulting from injury, assembly of data, control purposes, prevention of recurrence, comparison on competitive effort and costs in relation to production.

REMARKS OF A SAFETY DIRECTOR

by JAMES N. RUSSO
safety director, Newcastle Div., Allied Kid co., Wilmington, Del.

My company has plants in New Hampshire, Main, and Delaware employing about 2,000 persons, working about two and one-half million hours a year. In this talk, I want to discuss two things:

1. How to sell management on safety.
2. How we maintain interest in safety through a program of education.

In selling safety to people you must be sincere; you must be willing to spend some time and devote some effort to it. This is true whether you're selling it to an employee in the shop or to top management. However, there's one thing I've learned about selling safety to management: the best approach is on the basis of saving money.

Saving money is a tough thing to do in these days of increasing high costs. When one of our plants last year received a 50 per cent refund amounting to $25,000, our president looked on it as a windfall.

Because the president is pretty far removed from the men in the shop, and because such a thing was unusual in our company, I asked him to write a letter to the employees complimenting them for a job well done. I pointed out the savings that our accident prevention program had made possible and mentioned the highlights of the program.

The president's letter was well received by the employees, who had worked two and one-half million man-hours without a disabling injury. This letter from the president might not work in your shop, but it was different enough to be effective for us.

We have used all the gimmicks we could find to promote safety. These included visual aids of all kinds, inside speakers, outside speakers, contests, and five-minute talks by foremen.

Convinced that the key man in promoting safety is the supervisor, we decided to try something new last year: a human relations training program. This was new to us and new to the industry. We got the cooperation of the local board of education, which offered to supply qualified instructors free of charge in a list of 70 subjects.

We chose 20 subjects and set up a course for a selected group of supervisors and foremen. The course ran 20 weeks, with one two-hour session a week, for a total of 40 hours—all on company time.

Some of the subjects covered were cooperation and teamwork, giving orders, good housekeeping, the qualifications of a good supervisor, what the foreman should expect of management, what management should expect of the foreman, how to reduce costs and how to handle grievances. Safety was included for at least 20 minutes in each two-hour session.

INDIVIDUAL ATTENTION

Some of the men who attended have worked for 30 to 40 years with the company and we discovered that it is indeed hard to teach an old dog new tricks. Some of them were quick to say they thought it was a lot of baloney. But we made the course informal and let each man blow off steam and talk himself out. We handled each man as an individual and answered all of his rebuttals. In this way we convinced the men of the value of the course. Each man completing the course was awarded a certificate.

About a month later we sent each of the "graduates" a short questionnaire with about eight or nine questions. We asked them to fill it out and return it without signing their names. Some of the questions were: Was the course helpful in self-development? Helpful in your job? Helpful in handling men?

We received 80 per cent returns on the questionnaire and 65 per cent of those answering said they were helped by the course. We would have been happy if only 40 per cent would have agreed that the course helped them.

Courses like this one can be provided by universities for fees of $120-$150 per employee. At this rate, an outside course would have cost us $4,000 to $5,000. But our system, which we are sure will pay off, cost us only the employees' time.

TRADES AND SERVICES SECTION

ROUND TABLE DISCUSSION REPORTS

FOOD RETAILERS DIVISION

ROGER J. BEAR—Chairman
safety director, The Kroger co., Cincinnati, Ohio

by R. B. Norman, Secretary

THE FOOD RETAILERS DIVISION ROUNDTABLE

Roger J. Bear, chairman, outlined the start and progress of a safety program. It was indicated that a safety program, like a well kept garden, should be cultivated, weeded, pruned, dusted, and flowers would be picked and enjoyed by both management and employees.

Bear indicated he would be glad to send a Kroger Booklet on request. He further noted that he has two safety inspectors who report directly to him. Copies of their report go to divisional vice presidents. These inspectors visit each store and warehouse about once every eight months.

Harry Cochran reports that Safeway company has safety promoters in stores appointed by store managers. He emphasizes that managers are never relieved of their responsibility for safety in their stores.

Louis Amann reported that Colonial Stores, Inc. has a quarterly report submitted by regions and divisions indicating cause of falls for both employees and customers.

The Food Fair Stores—Miami Division—has committees composed of top men in various departments. They submit monthly reports which are broken down by causes, in detail.

WIRE MESH GLOVES

Phil Gray reporting for Stevens company of Miami, and Cochran speaking for Safeway of Los Angeles, both reported successful use of left hand gloves in their meat operation. Safeway of Los Angeles first tried it in eight stores. Meat managers and meat cutters were required to use them.

Productivity increased 12 per cent. Safeway uses these gloves in large markets only. One of the major problems encountered is in training meat personnel to remove glove when operating power saw. Cost of gloves, which is considerable, was reported as offset by increased production and reduced number of knife cuts.

Some companies permit their store managers to settle property damage claims at store levels. Others insist on submitting all claims to the insurance carrier. M. G. Jackson reporting for J. Weingarten, Inc. stated that his office gets a report on all accidents. His company feels that these reports have a public relations value.

FALLING MERCHANDISE

Some of the delegates felt that settlement of minor claims at store level eliminates much costly paper work. The majority of the delegates indicated that there should be a financial limit placed on the managers' authority to make spot settlements. There must be adequate cost control.

A new problem, that of mass display in aisles and on end floats was reported by delegates. The consensus was that the additional hazards involved more than offset any benefit derived from these displays in the aisle. It was felt that present day sales aisles are only wide enough to permit unobstructed movements of shopping carts, and that any obstructions placed in the aisles tend to create new hazards and are often the basis for sales-resistance.

It was felt that some of the end displays are too narrow and too high. Delegates present felt that no end displays should

be above eye level not only for safety reasons; but the best merchandising practice dictates this policy.

M. G. Jackson reported that Weingartens of Texas sends a letter to each injured employee's home immediately after the injury, with copies of this letter going to the store manager and district manager. Emmett Porter reported that Fisher Food Stores of Cleveland requires all meat cutters to receive medical treatment in neighborhood clinics after every laceration. Robert B. Norman reports that the ACF-Wrigley Stores of Detroit follow substantially the same policy on meat department injuries.

Delegates representing the majority of chains reported that their companies do not make a trip to the doctor mandatory after each employee injury; but leave this decision to the store manager. Kroger company requires managers to report every employee injury including those requiring first aid treatment only.

Stevens company of Miami which also sells drugs and has a registered pharmacist on duty during business hours has assigned the responsibility to that pharmacist for deciding whether an employee should go to the doctor or receive first aid treatment in the pharmacy. Food Fair of Philadelphia permits the manager to use his discretion about sending employees to the doctor. The Red Cross now has a 10 hour first aid course available.

Many of the companies report the use of liquid antiseptic soap which has reduced infections from minor cuts. Food Fair of Philadelphia and ACF-Wrigley of Detroit make use of follow-up forms as a part of investigation of accidents.

MERCANTILE AND WAREHOUSING DIVISION DISCUSSION

J. DONALD PRINCE—CHAIRMAN

insurance manager, The Hecht co., Baltimore, Md.

Under the chairmanship of J. Donald Prince, insurance manager, The Hecht company, Baltimore, Md., an informative and idea-producing discussion was held from 2 to 5 p.m., October 21, 1957, in the Morrison Hotel, Chicago, Illinois. The subjects discussed were under the following headings:

● *FALLS CAMPAIGN*

After some opening remarks welcoming the delegates to the National Safety Congress, Prince reviewed the program of The Hecht company for the National Safety Council's Falls Campaign. In the discussion, it was indicated that beneficial results were obtained by using "Falls" as a theme to call attention of the employees to these problems.

Ed Kryszak of Montgomery Ward reviewed that company's program and outlined a plan of close follow-up on all falls reports so that the causes of such accidents were revealed and remedies developed to insure a minimum of problems on this score.

Other ideas developed included Bill Smith's (Bowman Department store, Harrisburg, Pa.) use of building floor plans to record accidents with concentration of accident locations plus photos helping to identify problem areas. The whole program was also given widespread publicity through store magazines.

PINPOINT ACCIDENT LOCATIONS

It was agreed that concentrated attention to the use of the "Falls Campaign" theme pays off, especially when special emphasis is placed on:

a) Better housekeeping and floor maintenance procedures.

b) Physical facilities meeting local building code requirements and A.S.A. standards: i.e., handrails on stairs.

c) Accident investigation.

The key problem areas discussed were those of stairs, with their attendant hazards and possible solutions of safety problems,

and safety controls for areas which have particular problems of their own.

Mr. Paul Colson, Liberty Mutual Insurance company, outlined the development and use of a new "slip tester" which may prove to be a useful device in loss prevention and defense of negligence suits.

● *ESCALATORS*

A discussion of the safety problems involved in store escalators and motorstairs was supplemented by comments of a representative of a leading elevator and escalator manufacturer. Participants in this conference:

1. Reported on how to introduce the public to the proper use of escalators through open house activities, special newspaper publicity, instructional signs, attendants during peak periods, and training of sales personnel adjacent to escalators.
2. Reported new developments in escalator safety through mechanical improvements and use of various emergency stop devices and micro-switches.
3. Discussed individual case problems in retail stores with special comments by Harvey Siegel of Macy's and Paul Colson of Liberty Mutual.

● *MATERIALS HANDLING AND WAREHOUSING*

This discussion was led jointly by A. M. Lownsbury, vice-president, Edgar's Warehouses, Inc., Detroit, Michigan, and A. D. Walters, secretary, American Warehousemen's Association-Merchandise Division.

FAVORS "FIRE-STOPPED" PALLETS

Particular attention was given to a recent article entitled "Palletized Storage Fire Problems" by M. H. Nickerson, assistant director, Factory Mutual Laboratories, that appeared in the National Fire Protection Association Quarterly for July, 1957. This article advocated the use of "fire-stopped" pallets, stressing purported advantages in fire safety that could be achieved through the use of this type pallet.

The "fire-stopped" pallet is one in which a wooden pallet is modified by closing one end of the stringers to minimize air circulation. The ensuing discussion developed a considerable number of problems in the use of this type of pallet as against its purported advantages.

(1) The tests were limited in scope and do not reflect the great variety of storage conditions that might be found in general storage warehouses.

(2) In many instances it is essential that air circulation be allowed through and around stored goods. This is an absolute necessity in refrigerated storage.

(3) A sprinklered building was used in conducting the tests. There is no indication as to the results in unsprinklered buildings equipped with Aero Detection Alarm Systems connected with a central office. In such buildings the "fire-stopped" pallet might hinder fire fighting by stopping the flow of water from fire hose attempting to reach the source of combustion.

(4) In may instances the height of goods stored on pallets varies so that pallets in adjacent stacks would not line up, thus providing the "fire-stopped" effect without any change in existing practice.

(5) Fire-stopping allows only one entry, which is a serious disadvantage from an operating viewpoint. This is particularly true when using pallet jacks, since often the forks of this equipment of necessity protrude. Similar problems would be encountered in the present widespread use of four-way pallets, which can not be fire-stopped in any way.

(6) The "fire-stopped" pallet would be much more costly and involve higher maintenance.

(7) The "fire-stopped" pallet studies over-emphasize the degree of fire hazard in palletized storage, particularly when the same reasoning that characterized the Factory Mutual study is applied to the thousands of rack and open-shift storage installations throughout the country.

In general, it was agreed that the whole problem warranted a most careful and seri-

ous study *before* any recommendations could be made regarding the efficacy of the suggested "fire-stopped" pallet.

● *FORMS*

Mr. Walters discussed a warehouse safety *inspection form that had* been developed in cooperation with the safety committee of the American Warehousemen's Association-Merchandise division and the Trades and Services section of National Safety Council. This form is unusual in that it is divided into separate check lists for those factors that require monthly inspection, semi-annual inspection, and annual inspection.

It has found considerable acceptance in the public merchandise warehousing industry, particularly where the warehouseman *must conduct his* own safety program, since it provides a practical and useful guide for the warehouse superintendent. Copies of the form were distributed to participants in the conference, and are included at the end of *this report.*

● *"SAFETY AND THE RETAIL SUPERVISOR"*

Copies of the retail safety manual were *distributed* for review and comment. The National Safety Council will decide upon the proper presentation of *this material as a finished booklet with illustrations or in* some other form.

● *REPORTING CUSTOMER ACCIDENTS*

Copies of the accident report forms and *system* used by The Hecht company were distributed to those present for their information. (*Additional* copies are available by writing the Trades and Services Section, National Safety Council, 425 N. Michigan, Chicago, Ill.)

(*The following is the* information on the warehouse safety inspection form.)

CUSTOMER ACCIDENT REPORTING PROCEDURES

When a customer is injured in our stores, the following procedure will be *observed:*

DUTIES OF ALL CO-WORKERS: Immediately call the section manager or your supervisor. Assist the customer if *necessary.*

DUTIES OF THE SECTION MANAGER OR SUPERVISOR:

1. Instruct your co-workers in the necessity for promptly calling you in the event of a customer accident.
2. Call the store nurse to the scene of the accident. Do not ask the customer if she wants medical attention. You may have a co-worker telephone for you.
3. Assist the customer until the nurse arrives, and if necessary, assist the customer to the First Aid Room.
4. *Obtain the names & addresses of* one or two *customers who witnessed* accident.
5. Have at least two employees observe *the scene of the accident,* and have them fill out the employee section of the Report of Accident.
6. Fill in a Report of Accident, making one original and one carbon copy.
7. The section manager or supervisor is responsible for turning in to the nurse, as soon as possible and not later than store closing time of the date of the accident, his original and carbon *copy of* the Report of Accident.

DUTIES OF THE STORE NURSE:

1. After treating or attending to the needs of the injured customer, the nurse is to fill out the "Nurse's Report." A carbon copy may be made for file.
2. In the event of a customer "fall" accident, the nurse (or section manager) will call the person in charge of *maintenance* and have a Maintenance Report filled in.
3. The nurse is to mail to the insurance company the following reports:
   Original copy of the section manager's Report of Accident
   Original copy of Nurse's Report
   Two original copies of the Employees' Report of Accident (if separate forms)
   Original copy of the Maintenance Report if a customer fall accident is reported
4. In the event of a severe customer injury, the nurse is to notify immediately the Public Liability Claims Supervisor of *the insurance carrier by telephone, and to send the written reports later.*

NOTIFICATION OF THE STORE EXECUTIVES OF A CUSTOMER ACCIDENT:

1. Typewritten copies of the Report of Accident only, may be made from the carbon copy of the Section Manager's Report and distributed through store mail.

ALL BODILY INJURY CUSTOMER ACCIDENTS MUST BE REPORTED TO INSURANCE CARRIER

GET THE FACTS—GET WITNESSES—REPORT PROMPTLY

WAREHOUSE CHECK LISTS

For Annual Use

It is recommended that you include the following items on a regularly scheduled annual inspection of your warehouse property. Note those conditions where items are satisfactory and make special note where corrections should be made. If conditions on the check list do not apply to your particular unit, place an "O" in the "Good" column so as to indicate that it does not apply.

1. "No smoking" signs over doors into sections from loading and receiving docks and passenger elevators, and other designated smoking areas?
2. All electric circuits conform with National Electrical Code? All connections and insulation *in good repair?*
3. Appliance cords free of defects? Keep resisting cords on heating appliances?
4. Electrical outlets or heating devices provided with pilot lights?
5. Lighting arrestors on lead-ins from all outside aerials. Grounded?
6. Fire and exit doors in good repair and operating freely?
7. Ceiling high partitions bisect sprinkler lines?
8. Adequate supply of spare sprinkler heads on hand?
9. Fire extinguishers hung approximately five feet from floor to top of extinguisher?
10. Pressure vessels approved under local code before installation?

Comments:

For Semi-annual Inspection

It is suggested that you make a regular semi-annual inspection with this form as your guide. Note those conditions where items are satisfactory and make special note where corrections should be made. If conditions on the check list do not apply to your particular unit, place an "O" in the "Good" column so as to indicate that it does not apply.

1. Fuses exceed wire capacity? 15 amps. on no. 14 wire, 20 amps. on no. 12 wire?
2. Extension cords heavy rubber covered?
3. Interior of fuse and switch cabinets clean? Doors kept closed and in good repair?
4. Parts of wet sprinkler system exposed to low temperatures drained during freezing weather? Returned to service in spring? (Are adequate facilities available for fire protection during winter months?)
5. Stock on slatted pit racks more than six feet wide piled openly so water from sprinklers will reach stock piled below?
6. Sprinkler heads in good repair and free of paint or corrosion?
7. Sprinkler tanks in good repair?
8. Fire extinguisher for each 5,000 square feet of area? (Non-sprinklered outside warehouses each 2,500 feet?)
9. Home type extinguisher where open liquid volatiles are used?
10. Calcium chloride fire extinguishers in areas exposed to freezing temperature?
11. Fire hose free from defects and folded *in racks?*
12. Elevator pits clean?
13. Rip-saws provided with spreader fastened securely at rear? Automatic guard in place?
14. Swing-saws encased on both sides and equipped with limits chain or a positive stop?
15. Band-saw, band wheels completely encased and *blade enclosed* or guarded except portion between guide and table?
16. Gears and friction drives guarded?
17. Friction clutches less than six feet from floor guarded?
18. Sprockets and chains less than six feet from floor guarded?

19. Power transmission belts, chains and ropes less than eight feet from floor, guarded?
20. Vertical and incline shafts less than six feet from floor guarded?
21. Horizontal shafting less than eight feet from floor guarded?
22. Exposed shaft ends less than six feet from floor cut off or guarded?
23. Projections on shafting such as keys, bolts, pinions, etc. removed or guarded?
24. Sign reading "High Voltage" on all high voltage equipment?
25. Coping, building facing, and outdoor signs in good repair?
26. Gutters and down spouting in good repair?

Comments:

For Monthly Inspection

It is suggested that you make a regular monthly inspection with this form as a guide. Note those conditions where items are satisfactory and make special note where corrections should be made. If conditions on the check list do not apply to your particular unit, place an "O" in the "Good" column so as to indicate that it does not apply.

ACCIDENT PREVENTION STANDARDS

Pressure Appliances

1. Gasoline stoves and other equipment with fuel pressure tanks have pressure on tank released?

Miscellaneous

2. Elevator car top, door guides and guide rails cleaned?
3. Boiler, engine, pump, transformer and switchboard rooms clean and orderly? Metal receptacles provided for oily waste and rags? Receptacles properly covered?
4. Air compressors and adjacent area free of oil and cleaned at least weekly?
5. Elevator machinery free of greasy lint, oil, etc.? Penthouse or machine room clean?
6. Rubbish chutes cleared of materials frequently?
7. Chute doors in good repair; fused for automatic closing in event of fire; provided with stops and closed when not in use?
8. Paint spray booths conform with standards?
9. Exit lights lighted at all times?
10. Fire escapes in good repair?
11. Fire-brigade organized? Drilled during past month? Response to drill call satisfactory?

Stairways

12. Stair treads and nosings in safe condition?
13. Handrail provided on one side of enclosed stairways under 48 inches wide? Both sides at over 48 inches wide? Both sides of open stairways? In good repair?
14. Center handrail provided on stairs over eight feet wide?

Floors

15. Floors level, free of holes, cracks, and other defects?
16. Standard floor materials used and floors properly maintained?
17. Floor or deck loads not in excess of maximum posted capacity?
18. Openings in floors protected with railing or covers?
19. Structural floor or wall openings not made without review for compliance with local codes?
20. Pipe shafts with platforms at each floor and doors locked?
21. Certain floor openings equipped with toe boards?
22. All elevated runways and platforms (except one deck racks) more than six feet above floor, provided with railing?

Elevators

23. Hand cable control elevators have cable locks at each flood?
24. All interlocks, electric contacts and latches in good operating condition?
25. All shaftway gates and doors close and latch automatically when car leaves landing or have latches and electric contacts and interlocks?
26. Metal bi-parting doors equipped with pull-strap? Extra straps available?
27. Gates 66 inches high? If lower, warning chains attached?

28. Open car gates and elevator floor in contact if clearance between car floor and shaft wall is sub-standard? (through hinged plates if necessary)
29. Hinged car top where required? Closed except when moving long objects?
30. Gates and doors not blocked open? Latches, contacts and interlocks not blocked?
31. Elevator cars and landing areas adequately lighted?
32. Maximum capacity posted in each car?
33. Current state or city inspection certificates posted in cars?
34. "Safety Rules" posted in all freight and passenger cars?
35. No one less than 18 years old (or older if local law requires) operates elevators?
36. Only trained employees operating elevators and only authorized persons ride on freight elevators? (Cars posted to this effect?)
37. All elevator operators trained and provided with Operator's Cards?
38. Shear plates at shear hazards?
39. Defective elevator equipment reported immediately and prompt repairs made?
40. Elevator cables in safe condition?
41. Emergency release provided? Break glass cover in place?
42. Emergency elevator door keys kept under break glass?
43. Guards on car and gate counter weights kept in place and in good repair?
44. Car safeties inspected at least once each month and any necessary repairs made?

Entrances and Outside Areas

45. Swinging entrance doors stop swing at four inches past closed position?
46. Sidewalks, vestibules, docks, etc. free of holes, cracks, or other defects?
47. Entrance vestibules safe guarded against slipperiness during inclement weather?
48. Parking lots free of hazards, and lighted?

Boiler Rooms

49. Pressure gauges and water level columns well lighted?
50. Pressure gauges, water level columns and safety valves in good repair?
51. All safeguards for safe operation of power and heating plant in good repair?
52. Electric fans mounted seven feet above floor or guarded?
53. Racks for roll wrapping paper or cord properly assembled? Spindle ends securely clamped into place?
54. Proper ladders provided where needed, in safe conditions; and inspected; straight ladders have safety shoes?
55. Hand tools (hammers, wrenches, bars, etc.) free from dangerous defects (mushroomed heads, loose or defective handles, etc.)?
56. Grinding wheels in safe condition?
57. Compressed air receiver tank drained of oil and water weekly?
58. Safety valve on compressed air tank correctly set?
59. Cut-off air compressor correctly set?

Power Machinery

60. Power machinery and power supply guarded according to local or state codes?
61. Cross cut saws properly guarded?
62. Guards in good condition and used? Machinery stopped for repairs?
63. Signs posted and source of power locked off when machinery is repaired, adjusted or cleaned?
64. Generators, motors, switchboards, transformers, live wires, connections, starting boxes, etc. protected if within seven feet of floor?
65. Employees less than 18 years of age not permitted to operate power tractors?

Miscellaneous

66. Lugs and safety belts in good repair if outside window washing done?
67. Contract for window washing by outside cistern or individual approved by management or legal department in large organization?
68. Icicles, ice, snow, removed from window ledges, roofs, eaves, other parts of building?
69. Only trained electricians make electrical repairs?
70. Hand trucks and flat trucks in good repair?
71. Piling machines in good repair?

Property Damage and Burglary Prevention Standards

72. Basements, roofs and skylights leaky?
73. Waste water disposal pump in good repair?
74. Sewer check valves in good repair?
75. All windows, doors, skylights, roof fan exhausts or other means of ingress locked at closing time?
76. Windows guarded if not supervised by watch service and accessible from ground or adjoining roofs?
77. Merchandise stored outside building in open, unprotected areas?

Comments:

HOTEL DIVISION

by ROBERT C. NORDHAUSEN—Chairman
assistant to the director, Employer-Employee Relations Dept., American Hotel Assn., New York City

The hotel division round table discussion concerned itself with, "What Can We Do About Public Liability Claims?" Members of hotel organizations and insurance companies participated in this session. Those present questioned some of the methods and procedures used in handling public liability claims. Some of the hotel people felt that insurance carriers were settling too many claims under the classification of nuisance claims.

It was felt that this led to the creation of a claims-minded guest who takes advantage of the apparent tendency to handle claims on a basis. In reply to this charge the insurance representatives indicated that the reason for the increase in public liability claims and their treatment as nuisance claims is frequently related to lack of proper investigation and reporting on the part of hotels.

As a result of these discussions the following conclusions were made:

1. It is a pre-requisite that the hotels have a good sound safety program which affects the employees, and in turn, will reflect in the employees' dealings with the guests. The safety program should have a system whereby periodic investigations are made of the hotel property to ascertain the various existing physical hazards and also the improper safety habits exhibited by the employees. Immediate proper action should be initiated to correct either physical hazards or unsafe practices of employees. These solutions should receive support from top management.

IMMEDIATE INVESTIGATION

2. Investigation of an accident should be immediately conducted, determining the immediate cause of the accident, witnesses, etc. Pictures of accident areas should be obtained if at all possible.
3. If possible, obtain a signed statement from the guest as to his injury and as to how the accident occurred.
4. Supply the aforementioned information to the insurance carrier so that they, in turn, will be in a good position to handle and defend the claim on behalf of the hotel.
5. Work closely with the insurance carrier and discuss the case so as to decide together on the proper way of handling the case.
6. Keep in mind the cost of handling the case to its conclusion by either settling it immediately or permitting it to go to a court trial. All factors must be considered.

THE HOW OF ORGANIZING A SAFETY PROGRAM

FOOD RETAILERS DIVISION—SAFETY TO SELL

by EMMETT T. PORTER
safety engineer, The Fisher Bros. co., Cleveland, Ohio

In our business, as in all others, we have a product to sell. The measure of our success in the field of safety engineering is recorded in the profit and loss columns of the company which employs us.

The Fisher Foods Company of Northern Ohio has maintained an enviable safety record during the past five years. This record results from the cooperation of 3,000 employees in 92 stores, two warehouses, a bakery and 84 trucking units. This cooperation begins in the offices of the President, Chairman of the Board and Board of Directors, and terminates in the stock and service areas of the individual stores. No safety policy or safety measure can be effective without such large scale cooperation.

In order to enlist the personnel of the company in the safety campaign, the safety engineer must sell his product to every member of the company. He must convince management and labor that safety is good business, relatively as important to the welfare of the Fisher organization as selling itself. This, in my opinion, is the most important function of the safety engineer—to sell his company on the idea that time, energy and money spent on safety is well worth the expenditure. In short, safety is good business.

Fire and Accident Loss go into the debit column of the company's books. Merchandise, customers and a good location are the stuff from which profits are made. Fire consumes merchandise, often vacates location with consequent loss of trade.

Accidents mean dissatisfied customers, insurance settlements and altercations at law. Insurance protection covers some of this damage, the rest must be taken from sales profits. A chain like Fishers which operates on a small margin of profit, must increase sales to cover the difference.

This waste can be laid to the door of carelessness. Fire and accidents *don't just happen; they are caused!* Safety makes sense—business sense—and it is the job of the safety engineer to call attention to this cold fact. Watch for all the short cuts. We have them in the food business.

THE BIG FIRE

Fire destroys profit in volume. No company can afford to take chances with fire. For example, on February 19, 1949, The Fisher Bros. Master Market on Shaker Boulevard in Cleveland, Ohio, was burned to the ground from a fire in a bowling alley underneath. The merchandise stock worth $100,000 was lost, potential customers for that merchandise were lost, the employees had to be relocated, and finally, Fishers lost the location. This last loss is a continuing one which does not show on the books. Customers who patronized that store now take their purchasing dollars elsewhere. Fishers has not yet (8 years later) reclaimed that location or vicinity.

A picture of this fire-damaged site is posted in the service areas of 92 Fisher stores and throughout warehouses as a constant reminder that a little carelessness can burn up stock, store, job, and money.

THE SMALL ACCIDENT

The fire hazard makes a striking selling point. Everyone is impressed by the burning building and the consequent loss of business. The small accident has not the power to shock and therefore requires more emphasis from the safety engineer. The accident record at Fishers shows that for 1956 and 10 per cent of 1957, the accident average was one customer accident per store per year. Here is a small but constant loss to the company.

One of every three accidents is a fall and two-thirds of these are in the sales aisles. Mrs. Brown drops lettuce leaves, grapes, or beans on the floor. Mrs. Jones slips and

falls, breaking a hip. She has a grievance against the company, good will is lost, and money paid out.

Careless work habits can cause mishaps. Tommy, the stock boy, is setting up a display during customer hours. While wheeling his merchandise up the aisle, he runs over Mrs. White's foot. Her toenail is torn off: the company pays $750.00 damages.

Inadequate facilities aid and abet carelessness. Joe, the carryout boy, loads a car in a poorly lighted parking lot. His last contact with the customer is a severe shock. He slams the car door on her child's hand. This accident cost the company $1,000 in reparation.

Vegetable matter on the floor in the sales area, baskets and boxes in the aisle, stacking displays during customer hours, icy entrance and exit ways, slippery ramps—these conditions set the stage for accidents. The store must sell a lot of hamburger and potatoes to pay for the broken hip, the torn nail, the child's crushed hand. Thoughtlessness on the part of supervisors and employees cost the company profit and good will. Safety costs only a little time and effort.

STEPS TO SAFETY

The Fisher Bros. company recognizes that safety is good business. At Fishers, we have two safety committees. One represents the warehouse, office, meat commissary and transportation employees. The other represents store and operations personnel. Each committee meets regularly once each month, with two joint meetings annually—in May and October. These committees screen complaints and take measures against the big fire and the small accident.

Some of the steps towards safety we have taken are as follows:

EQUIPMENT & PERSONNEL:

In the field of fire and accident prevention, first aid kits, and fire extinguishers have been installed at key points in all sales, stock and service areas. Since many of our stores are located in outlying and rural districts where water and water pressure is often a problem and are protected by volunteer fire-fighting units, we have installed standpipe equipment within our service area.

Dome-top metal self-closing containers are supplied for floor sweepings and rubbish disposal. All excess cardboard is transported to a central disposal point. "No Smoking" signs are posted throughout service and restricted areas. Smoking areas are designated and adequate ashtrays and metal containers supplied. Bulletins are issued and posted during the holiday and high hazard shopping seasons.

Merely to have fire equipment on hand, of course, is not enough. Unless the personnel can operate it effectively, the fire extinguishers and hose will burn with the building. Very few people, on their own, will take the time to learn the proper operation of this equipment. It is the duty of the safety engineer to make sure they take the time.

Acquaintance and know-how with the different types of fire equipment reduces the chance of panic. At Fishers, we instruct the store and warehouse employees personally. Supervisors, superintendents, managers, assistant managers, cashiers, salesgirls, stock boys, directed by the safety engineer, fight an imaginary fire in a back alley.

If and when the fire crisis does occur, they will call the fire department, and calmly go about saving their store with reasonable effort until the fire department arrives. This sort of instruction takes time and effort, but the result may well be a store open for business tomorrow. Lack of instruction may well mean a gutted shell today.

A LITTLE FORETHOUGHT

Accident prevention means attention to details and a consciousness of small hazards. Many causes of action can be eliminated by focusing attention on safe practice. At Fishers, we are trying to insist on such "incidentals." To avoid vegetable matter falls, we move packaged goods to the outside of display racks with unpackaged fruits and vegetables placed on the inside. The product then can be handled without danger of excessive matter falling to the floor.

Scales should be placed near the unpackaged displays to prevent loose pieces dropping on the floor during transport. Stocking of display shelves should be done after store hours and avoided during high shopping periods. Then boxes and cartons will not clutter customer-choked aisles and collisions with stock trucks and carts avoided.

Parking lots should be well maintained, free of holes, well marked and lighted, and serviced with adequate permanent ramps.

I submit written safety reports of these details to the general superintendents responsible for store and warehouse operations. They process them to the supervisors, superintendents, and store managers. When the complaint is abated, it is signed by all supervisors and returned to the safety engineer within a 60-day period. This gives maintenance an adequate time to complete structural repairs, if necessary. These safety details make the difference. Their observance eliminates many accidents.

A semi-annual 12-page general safety questionnaire is sent to the stores and warehouses to be filled out within a two-week period by the store managers and warehouse superintendents and returned to the safety engineer under the general superintendent's signature.

BURDEN OF RESPONSIBILITY

As our record indicates, the supervisors and employees at Fishers have been very cooperative. Their response to the publicity campaigns conducted by the company, their newspaper, "The Champion," the safety bulletins, signs and pictures posted in the stores, and warehouses, have been very marked.

Once I was shown an ordinary box of paper napkins, charred on one side. The box was burned in the stock area of a Fishers store by a 60-watt electric light bulb. The superintendent in charge of that store called me and asked that I look at it. The manager, on my arrival, said "Look what nearly happened to me!" He did not want it to happen to anyone else. He showed me the excessively high stock pile where he had found the box smoldering at 2:30 in the afternoon. Had this occurred at closing time, the store would have been a heap of black rubble by morning. We would have had another Shaker Market on our hands.

What impressed me was that he accepted the burden of responsibility for the safety of his store and the stores of others. He did not shrug off the incident or destroy the box. He was interested enough to contact his superintendent and point out the hazard of high stacking. That manager is sold on safety and realizes he has a part to play in safe practices.

THE REST OF THE BATTLE

We still have a lot of selling to do. The old ways hang on. It was a struggle to install the covered metal trash containers. For years, cardboard boxes had been good enough. So why shouldn't they continue to be? For years, "No Smoking" signs had not been posted or had been utterly ignored. Now employees have to change their working habits. However, the record shows we have made progress at Fishers. Cooperation continues to increase under the stimulus of repetition and reminders.

Remember, you can never relax in supervision and, with the continued encouragement of the company officials, we can approach our ultimate objective—one hundred per cent observance of safety policy and practice!

Safety is as important to the welfare of the company as selling itself.

The officials at Fishers have recognized this fact and have cooperated with the safety engineer in selling their employees on safety.

Logic demands safe practices. When people think, they are bound to be safety-minded. The job of the safety engineer is to make them think, to put the facts before them and insist on safety measures, for the protection of stock, store, employee, and company.

Fires and accidents eat up profit and benefit no-one. This is the lesson the safety engineer must sell to every member of his company. Safety is as important as selling and safety must be sold!▲

HOTEL DIVISION

by ROBERT C. PETRIE
safety & training director, Hotel DuPont, Wilmington, Del.

Accident prevention is a major task of management. "The creation of a safe working shop and the creation of a safety minded, earnest, competent organization is our economic and social duty," stated a vice president of the Bethlehem Steel company recently.

Walter Carpenter, chairman of the board, briefly expressed this basic thinking: "We in the du Pont company long ago concluded that the safety of employees is of the greatest interest to management, ranking in importance with production, quality of product, and costs. We have found that maintenance of safe operating procedures in our plants is of benefit far beyond any resulting dollar savings, the human values involved being of greater importance to both employer and community. Also, the acceptance and practice of fundamental safety principles by management and men, with the reduction of personal injuries to a minimum, injects an element of team play which does much to foster a spirit of friendly cooperation throughout our company."

The successful application of a safety or accident prevention program is dependent on the following principles:

1. *All* personal injuries can be prevented.
2. Management, which includes all levels through the foreman, has the responsibility to prevent personal injuries.
3. It is reasonably possible to safeguard all operating exposures which may result in occupational personal injuries.
4. *It* is necessary to train all employees to work *safely* and to understand that it is to their advantage, as well as to the hotel's to work *safely*, and that they are expected to cooperate in doing so.
5. It is good business from the standpoint of both efficiency and economy to prevent personal injuries on the job and off the job.

Now how do you go about "organizing" a safety program? Actually, whether we are in a hotel or restaurant, or steel mill, or aircraft factory, the same basic principles apply.

Top management must be absolutely sold on safety. A considerable part of the work of a safety director should be slanted so that executives and employees find it to their interest to correct unsafe conditions and follow safe practices. You should submit evidence regularly to justify the program. A safety program is implemented largely through the efforts of foremen and supervisors.

MANAGEMENT'S RESPONSIBILITY

Therefore, it is essential that foremen find themselves in a position where their full cooperation will redound to their credit. They must see that safety measures will increase all-round efficiency rather than increase the cost and drag the production. They need to have safety continually brought to their attention and routines set up so that their part of the program will be a normal regular operation.

Presidents of some major corporations have found a good safety performance useful public relations material. We are constantly bringing it to the public's attention because our vital on-the-job and off-the-job programs are excellent "quality" advertising.

ORGANIZING FOR SAFETY

Top management should make clear to various department heads or staff specialists reporting to him their areas of responsibility in regard to accident prevention. He should appoint a safety coordinator, director, supervisor or whatever name is decided to act as his representative. A definite established allocation of time that is to be spent wholly on accident prevention is necessary.

A separate safety department established as a staff function and reporting directly to top management indicates the nature of its administrative position. It cuts across departmental lines and the direct channel to top management makes it clear to everyone that the safety program is a top-priority program with the authority of management behind it.

Now what authority should your safety specialist have? Generally speaking, as a staff function he has little of his own and must rely on education and persuasion. The most successful safety directors are "good fellows" who are greeted cheerily or good-humoredly around the hotel. If one is frequently engaged in a contest of authority, he is not likely to get the sincere cooperation he must have.

We have only power, including making initial recommendations. Before equipment is bought in the Hotel, particularly kitchen equipment, bread slicers and fat strainers, they ask for inspection and approval before purchase. Oftentimes, the seller will make modest changes for added safety features.

The requisites for a safety director should first be personal characteristics and then knowledge and experience. You must have:

1. *Ability to get along with people.* Good human relations are more important than dogmatic theories.
2. *Enthusiasm, drive, perseverance.* The results are so easy to see and so clearly of benefit to all, that the safety worker feels his is a humanitarian work. The safety man must, however, have the energy and push to keep continually after things. When he sees something wrong, he may have to give suggestions, write a report for so ..one, present the idea again in committee, and only eventually win the key people around to his thinking.
3. *Readiness for new ideas and approaches.* He should be a stimulator.

SAFETY COMMITTEE STRUCTURE

Committees are often an effective means of interesting or educating a large number of people in an activity. They are a good method for securing cooperation, coordination, and an exchange of ideas among people not otherwise thrown together. Basically, there are three main types of committees or functions they may serve on different levels. We use all three at our hotel with very good results.

Central Safety—This meets monthly and is basically a policy committee. The manager is the chairman, with department heads, the safety supervisor and physician as members. It periodically reviews the accident experience of the separate departments as reported by the safety supervisor. It investigates or acts upon reports of investigation of serious accidents or unusually hazardous conditions.

It makes safety regulations regarding wearing apparel, smoking, use of machine guards, maintenance, process design and layout of remodeling. It makes expenditures for major items for safety, approves employee training programs. It formulates incentive programs and allocates expenditures for prizes.

The second type of committee we use is one for inspection. This committee meets monthly on a one-hour inspection tour of the hotel with partial responsibility for correcting unsafe conditions or unsafe practices. The committee is made up of the safety supervisor and with four to six people rotating of wage-roll personnel—bellmen, maids, cooks, cafeteria.

This is extremely effective from one point of morale, in that it shows that management is interested in the brains as well as the brawn. The errors found are typed and the committee sends the report directly to the manager with copies to all departments for correction. We have had splendid results.

EDUCATION COMMITTEE

The third major type of committee is that for education. This committee promotes interest in and compliance with the safety program and develops a good safety attitude on the part of all employees. Oftentimes, the executive or employee who has "poohpoohed" safety becomes a strong backer after being on this committee. ..We have used this type of committee this year exclusively to get the same safety message to all of our employees.

A committee comprised of four supervisors from each of the areas or departments were appointed on a rotating basis in January. The monthly topics for the year were decided upon by the central safety supervisor. The topics this year are generally on off-the-job subjects, and include management's review and 1957 goals, on-

the-job hazards, falls-off and housekeeping. Six weeks in advance of the meeting date the committee begins work on the topic for a program including script, visual aids, handouts and giveaways.

This meeting is conducted by one of the committee members to all the supervision and the meeting leaders the first Wednesday of each month under the chairmanship of the manager and co-chairmanship of the safety supervisor.

This same meeting format or script is then given in each of the operating areas by the appointed meeting leaders and, in our case, the wage-roll employees, monthly. The length of these meetings are from 20 to 30 minutes. This type of program of actually using employees to do the instructing, has been very rewarding. Some of the instruction has been poor, by instruction or public speaking standards, but we made a lot of converts! !

One other auxiliary committee working partly on safety, is the suggestion system committees. This, of course, functions in all operative areas.

EFFICIENCY AND MORALE

I often hear other hotelmen complain of the poor class of help, high turnover, little interest in the job, and indifference of their employees. You might add all this up and call it morale. I certainly won't be so presumptuous as to say that a safety program is the Lydia Pinkham remedy.

But a high injury rate has a depressing effect on employee morale. Unsafe hotel conditions, poor housekeeping and poor supervision lead to dissatisfaction and poor job performance. Nobody can be proud to work in a place where mistakes are the order of the day and accidents are the usual thing.

On the other hand, real pride and enthusiasm for the job exist in hotels and departments which have outstanding safety records. Employees have a feeling of loyalty for the company and a sense of security on their jobs.

In further developing this "how" of organizing a safety program for hotels, might I also recommend orientation of new employees. We do this with a safety booklet containing general safety rules throughout the hotel. This is covered the first day of employment. (1) The foreman explains the hotel's philosophy of safety, both off-the-job as well as on-the-job. (2) He also discusses the importance of promptly reporting all injuries to the supervisor. (3) The new employee is given specific instructions in the area he will work—area safety rules, fire protective equipment, and a job breakdown for safety. (4) Lastly, constant follow up is taken for reviewing his safety performance, participation in the safety program and his knowledge of safety work procedures.

Just like a well-built house, a well-built safety program must have a framework, walls and a roof. Too many safety programs, and that term is often used loosely, begin and end with putting up signs in dark halls or on dirty bulletin boards.

REPORTING FROM DATA

One last recommendation on this "how to" angle is to have a well defined and developed reporting procedure form. I can't recommend this too highly. A foreman who accepts his full responsibility for safety has some things to learn and some things to do. He must learn work habits; he needs to see that every worker gets good safety job instruction; he must have their confidence and he also needs to investigate every accident whether or not personal injury results.

By making all injuries reportable and designing a form which makes the foreman investigate the accident, the effectiveness of your program will be improved immeasurably. These reports should be posted regularly and a friendly rivalry among departments maintained. A reporting form should include:

1. *Type of equipment* involved in accident
2. *Type of accident*—or the way person was injured
3. *Unsafe condition* of the tool, material or machine
4. *Unsafe act* or unsafe practice of person
5. *Reason*—lack of knowledge, disregard of instructions

I might add, however, merely filling in a form should not absolve the foreman of his responsibility. The safety supervisor should make sure the accident is well investigated, thoroughly investigated, and promptly investigated.

There are many, many points I haven't covered, such as publicity, promotion, costs and fire protection and I certainly am not minimizing any of these by leaving them out.

Accident prevention, like many other changes, has to be sold and we must be good salesmen to close the sale. I suppose our most important job is to show our customer, the employee, his need for safety.

MERCANTILE AND WAREHOUSING DIVISION

by PAUL M. COLSON
assistant division manager, Loss Prevention Dept.,
Liberty Mutual Insurance co., New York City

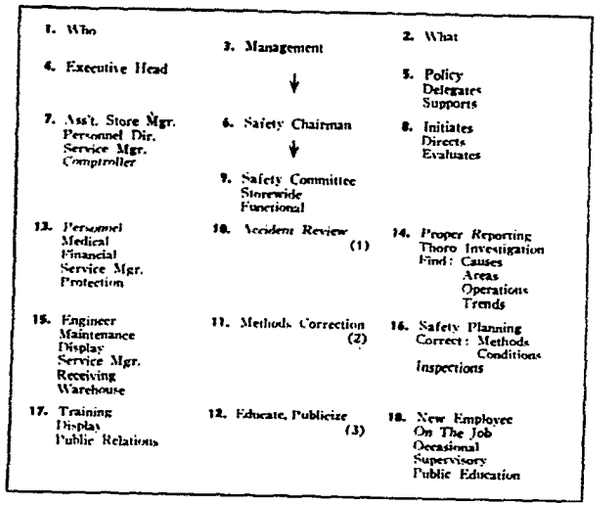
ORGANIZING EFFECTIVE SAFETY PROGRAMS IN DEPARTMENT STORES

Many safety programs are like good intentions; they are well meant but ineffectual. Considerable experience with safety committees in stores indicates a number of reasons for this situation:

1. Lack of management motivation (understanding of the urgency of store accident prevention problems and the importance of safety work in reducing losses).
2. Lack of qualified, authoritative direction of safety program
3. Lack of definite program for safety committee to carry out
4. Failure to assign specific responsibilities.
5. Lack of effective safety communication

The basic department store safety program I will outline eliminates these undesirable features and provides management with an effective safety organization with an effective program.

MANAGEMENT AND SAFETY



By means of the Flannel board display I will outline first the safety program. Note that I will consider only the problem of the stores that are not jumbo sized and do not have safety directors. The pressing problem lies in the large group of stores having no full time safety director. In the center panel I will build the program. On the left I will indicate who in the store organization should carry out the specific responsibilities outlined and on the right I will summarize what these people should accomplish (see table on next page).

The numbers refer to the individual box numbers on the diagram accompanying this article. The first and most important element in the entire program is (3) management—support and participation. Lacking this element you might just as well not have a safety program. Don't waste your time unless top management knows what the accident prevention problem amounts to, and gives positive indications of support through effective participation. By management I mean the (6) executive head of the store.

STORE SAFETY CHAIRMAN

In general he accomplishes the following (5) Sets safety policy—which indicates that management expects everyone in the store to cooperate to make the safety program work. He delegates by appointing an executive to act as (6) safety chairman and he provides support by giving the chairman and his safety committee authority to get things done, by attending occasional meetings, and by periodically reviewing results, to determine if executive action is required to expedite the work of the safety committee.

A safety program without a qualified coordinator is a ship without a rudder—it's aimless and powerless. Who should do the job? An executive—(7) such as an assistant store manager, comptroller, personnel director, service manager—someone important enough to command respect and attention. He need do little detail work, as you shall see.

His basic job which is (8) to initiate safety activity, direct the proper committee members to carry it out, coordinate their activities and evaluate their results to ascertain how effective they are and decide if added or modified activity is required.

SAFETY COMMITTEE

Part of management's function of delegation and support is to appoint a (9) safety committee to assist the safety chairman by actually carrying out the safety program throughout the store on a day to day basis at all levels.

To be effective, the committee must be store wide in its representation (without being unwieldy), and it must be functional i.e. assignment of specific safety activities should be made to members whose normal responsibilities fit them for such work. By "store wide" we mean that all operations will be represented so all basic operating hazards will thereby receive attention.

The membership of the committee is dictated by the nature of its work. Any safety committee has three major functions:

1. (10) Accident Review—to find accident causes.
2. (11) Correction of Methods—involved in accidents.
3. (12) Education & Publicity—to train and stimulate people to work safely.

Let's examine each of these functions more closely and see what is accomplished and who is best qualified to discharge these safety functions. In doing so, we'll outline a program and automatically define membership. Each of the three functions mentioned above could be the work of a subcommittee

composed of a number of persons whose normal store functions qualify them for the work involved.

These sub-committees should operate each as a unit but should meet monthly to form the store safety committee.

ACCIDENT REVIEW

Let's consider Accident Review. This group sees to it that:

1. Proper and effective employee and customer accident reporting and investigative procedures are set up and carried out.
2. Causes of all accidents are identified as to
   (a) Area
   (b) Causes
   (c) Operations involved, and
   (d) Frequency trends developing.

It is their function to gather this information, summarize and interpret it and, put it into writing and present it to the chairman for use in committee meetings so that specific action can be initiated to eliminate the accident causes defined. Obviously, the store people most qualified for this job are (13) personnel, medical, financial, protection, and service.

The very nature of this work brings them into contact with the accident at its inception and throughout the duration of the case. The nurse keeps many accident records. Store protection frequently is at the scene of the accident. The controller's office has statistical facilities essential to accident studies. The integration of these efforts produces the monthly accident report which tells where, why, and what kinds of accidents are happening, and, by extension, what corrective action is required.

METHODS CORRECTION

The next sub-committee to swing into action is the one responsible for the elimination of unsafe methods and conditions as indicated in the report prepared by the Accident Review group. This second group (11) Methods Correction has as its basic responsibilities the following major activities:

1. (14) Safety Planning i. e.: seeing that safety is built into new stores, plans for promotions or renovations or for special events, that safety is specified in the purchase of new operating equipment of all types.
2. Correction of unsafe operating methods or conditions that are revealed by the Accident Review committee or through
3. Periodic scheduled store wide safety surveys made by committee members, or through,
4. Safety recommendations submitted by insurance carrier engineers.

The very nature of these activities necessitates the following membership (15) store engineer maintenance, display, work rooms, receiving, warehouse and service management.

EDUCATION AND PUBLICITY

As the result of the efforts of these two sub-committees (10) Accident Review and (11) Methods Correction the work of the final sub-committee (12) Education is obvious to educate employees to avoid the hazards revealed by the work of those two committees.

The educational committee does the following educational work:

—(16) New employee safety orientation
—On the job safety education
—Supervisory safety training
—Customer safety stimulation

The wide variety of methods it uses are:

1. Safety bulletins or posters
2. Safety messages on P.A. system
3. Safety section in employee booklets
4. Store wide safety campaigns and contents etc.
5. Sound slide films
6. Floor or departmental meetings

Here again the sub-committee membership is dictated by the nature of the functions performed. In most stores the following departments are represented: training, display and public relations.

Each of these units can make a unique contribution to the sum total of safety education and propaganda throughout the store.

One aspect of safety activity remains uncovered by this safety program outlined,

namely, area safety efforts. However this gap is easily closed in an effective manner by the individual safety activities of committee members in their own areas of jurisdiction. They can hold brief scheduled periodic employee safety meetings, provide for limited area safety inspections and conduct other safety activities as the nature of their accident prevention problems dictate.

AREA SAFETY ACTIVITIES

Now let's see if this Organization and Program satisfies the five requirements mentioned in the beginning of my talk.

- Management motivation to support safety: The Accident Review committee keeps him informed of the costs of accidents and of its effect upon his merchandising activities; the Methods Correction Committee sees to it that he knows about the serious hazards that exist, and, finally, he too is subjected to the constant safety propaganda prepared by the Educational Group.
- Authoritative direction is implicit in the selection of a junior executive to serve as head of the safety committee, where in cooperation with the personnel director and the store engineer and service manager he can wield great safety influence, on a planned basis.
- A definite program is assured by the creation of the three sub-committees, each charged with an important function which lies well within their competence and the scope of their normal store activities.
- Specific responsibilities assigned—this characterizes each of the sub-committees outlined for us completely.
- Effective safety communication—you can readily see that effective safety communication is fully provided for by the operation of a sub-committee whose whole function is one of communication with employees at all levels, at all times, and through a great variety of media.

OFFICERS OF THE

FOOD SECTION

NATIONAL SAFETY COUNCIL 1957-58

General Chairman—STANLEY W. PARSONS, general safety director, Carnation co., Los Angeles, Calif.

First Vice-Chairman—I. W. SHUTT, safety engineer, Jos. E. Seagram & Sons, Inc., New York, N. Y.

Second Vice-Chairman—GREGG R. MEYERS, director of safety & security, Blatz Brewing co., Milwaukee, Wis.

Secretary—NORMAN L. HEUER, safety director, Anheuser-Busch, Inc., St. Louis, Mo.

Newsletter Editors—LESLIE J. QUINKER, director of safety, Schenley Distillers, Inc., Louisville, Ky.; L. H. GRETZER, director of safety and preventive maintenance, Cargill, Inc., Minneapolis, Minn.

Program Director—W. F. LEONARD, JR., vice-president, The Southland corp., Dallas, Tex.

Off-the Job Safety Chairman—WILLIAM A. MULVENNA, safety director, C. Schmidt & Sons, Inc., Philadelphia, Pa.

Membership Chairman—JAMES H. SNYDER, manager, Safety & Plant Protection Dept., Hiram Walker & Sons, Inc., Peoria, Ill.

Health Director—PAUL W. RUSH, M.D., medical director, Corn Products Refining co., Argo, Ill.

Trade Association Committee: Chairman, J. REDELBERGER, director of safety, Brown-Forman Distillers corp., Louisville, Ky.; *Vice-Chairman*, EARL F. GOMOLL, safety supervisor, Clinton Corn Processing co., Clinton, Iowa.

Visual Education Committee: Chairman, R. W. BLUNCK, The Quaker Maid Co., Inc., New York, N. Y.; *Vice-Chairman*, A. J. DEILE, training director, General Foods co., White Plains, N. Y.; *Secretary*, JOHN GROFF, safety engineer, American Maize Products co., Roby, Ind.

Engineering Committee: Chairman, EDWARD J. STEINKELLNER, safety director, Jos. Schlitz Brewing Co., Milwaukee, Wis.; *Vice-Chairman*, HARRY WEGEHOFT, employee service supervisor, Anderson, Clayton Co., Foods Div., Jacksonville, Ill.; *Secretary*, JACK CANTRELL, safety manager, Miller Brewing Co., Milwaukee, Wis.

Bakers Division: Chairman, W. C. MAHLSTEDT, safety engineer, Continental Baking Co., Rye, N. Y.; *Vice-Chairman*, EDWARD Z. BANKA, safety engineer, National Biscuit co., New York, N. Y.; *Secretary*, ARTHUR E. MARVIN, safety director, Long Island City, N. Y.

Breweries Division: Chairman, JOSEPH A. MENENDEZ, safety director, Falstaff Brewing corp., St. Louis, Mo.; *Vice-Chairman*, THOMAS J. WILKINSON, safety director, P. Ballantine & Sons, Inc., Newark, N. J.; *Secretary*, EDWARD J. ZABEL, safety director, International Breweries, Inc., Iroquois Div., Buffalo, N. Y.

Confectioners Division: Chairman, WILLIAM G. SMITH, director of safety, Nestle Co., Inc., Fulton, N. Y.; *Vice-Chairman*, GLENN W. RICHARDSON, personnel director, Bunte Bros. Chase Candy co., Chicago, Ill.; *Secretary*, WARREN G. RINDERKNECHT, safety director, Penick & Ford, Ltd., Inc., Cedar Rapids, Iowa.

Dairy Products Division: Chairman, VICTOR G. HENDRIES, manager, safety div., Land 'o Lakes Creameries, Inc., Minneapolis, Minn.; *Vice-Chairman,* PERRY R. ELLSWORTH, assistant to executive director, Milk Industry Foundation, Washington, D. C.; *Secretary,* ARTHUR S. FOUST, executive secretary—safety, The Borden co., Houston, Tex.

Distillers Division: Chairman, EDWARD BENNETT, Schenley Distillers, Inc., Frankfort, Ky.; *Vice-Chairman,* JOSEPH J. PRABULOS, safety director, National Distillers Products corp., New York, N. Y.; Secretary, G. WADE AMOS, supervisor, Safety Engineering Dept., Aetna Casualty & Surety co., Louisville, Ky.

Food Processors Division: Chairman, VICTOR R. JOHNSON, safety supervisor, Gerber Products co., Fremont, Mich.; *Vice-Chairman,* RICHARD CARTWRIGHT, personnel director, Haxton Foods, Inc., Oakfield, N. Y.; *Secretary,* ROY E. CAMPBELL, safety engineer, Campbell Soup co., Chicago, Ill.

Grain Handling & Processing Division: Chairman, JOHN M. JENSEN, director of safety, Corn Products Refining co., Chicago, Ill.; *Vice-Chairman,* J. R. McCANN, fire prevention manager, Ralston Purina co., St. Louis, Mo.; *Secretary,* GEORGE L. KITCHEN, director of safety, F. H. Peavey & co., Minneapolis, Minn.

Industrial Agriculture Division: Chairman, ROBERT P. ALDEN, safety & wage administrator, Castle & Cooke, Ltd., Honolulu, Hawaii.

Executive Advisory Committee: N. E. THIEL, director of safety, Sealtest Southern Dairies Div., Charlotte, N. C.; NIXON de TARNOWSKY, safety engineer, The F. & M. Schaefer Brewing co., Brooklyn, N. Y.; ROBERT C. LEITNER, supervisor of industrial relations, Libby, McNeill and Libby, Union Stock Yards, Chicago, Ill.; CLIFFORD P. McBRIDE, personnel manager, Pabst Brewing co., Milwaukee, Wis.; GORDON E. MORRISON, Employee Relations & Safety, Kellogg co., Battle Creek, Mich.; BURTON H. MAY, director of safety & health, Mars, Inc., Chicago, Ill.; E. G. HUTZLEY, senior safety engineer, Campbell Soup co., Camden, N. J.; GEORGE H. STEEL, safety director, Ralston Purina co., St. Louis, Mo.; DEAN M. CLARK, Grain and Elevator Processing Superintendent, Chicago, Ill.

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

THE GLASS AND CERAMICS, AND RUBBER SECTIONS

This volume is a record of sessions held at the 1957 National Safety Congress by the Glass and Ceramics section and the Rubber Section. The conduct of these Congress sessions each year is only one of the many cooperative activities which these sections carry on in behalf of their members, and for the benefit of accident prevention work in these industries generally. These sections give guidance in the preparation of a great variety of technical and educational material useful in the day-to-day safety programs of glass and ceramics, and rubber companies.

The activities of these sections are under the direction of their executive committees, the members of which are listed at the close of this volume.

GLASS AND CERAMICS SECTION

INVENTORY OF OCCUPATIONAL ACCIDENT PREVENTION ACTIVITIES

by J. EDWIN CROUSHORE
staff representative, National Safety Council, Chicago, Ill.

One of the functions of the National Safety Council is to serve as a clearing house for the exchange of information on industrial safety practices and techniques among Council members. This Inventory is designed to facilitate this function.

The object of this Inventory is to determine what types of accident prevention techniques are commonly used among the members of the Glass and Ceramics section. This information is provided for Council members to evaluate their own safety activities by comparing them with safety activities of others in their own field.

Experience shows that many managements in the small plant group are interested in learning of safety practices and policies of other plants. The Council feels that the material developed will be useful to small plant management in regard to their activities.

Because of the different types of accident prevention activities applicable in small and large plants, the information gathered is classified as to whether it originates in a small or large plant. Large plants are those with 1,000 or more employees, and small plants are those with less than 1,000 employees. One thousand was chosen as the dividing point because it is approximately the plant size at which there is a tendency towards designating the safety responsibility to a specific individual, and in beginning to think in terms of a formal safety program and organization.

Replies were received from 79 of the 164 questionnaires sent out to the key members and executive committee of the section. By size, the number of plants who returned completed questionnaires is as follows: Under 1,000 employees, 63 were returned; 1,000 or more employees, 15 were returned; one company sent back a questionnaire which represents 36 city area plants.

The Council appreciates cooperation shown by the 79 plants who completed and returned their questionnaires, and thereby made this report possible.

Due to the limited time, only those sections of the Inventory will be covered that are deemed to be of most importance to members of the section. All members will receive the completed report on or about January 1, 1958.

DEGREE OF SUPERVISION

Many phases of industry have been criticized from time to time because of spreading supervision too thin and not maintaining safe work practices. This spread of supervision has been especially prevalent on second and third shifts. However, from all the plants reporting this information for the section, the supervisory load does not appear to be unduly heavy on any other shifts. In this survey the average number employees per supervisor on each shift is as follows: on the first shift for large plants 20 employees, small plants 15 employees, the average number of employees covered on the second and third shifts are identical with those of the first.

It is contended that the supervisor will usually engage in greater safety activity if his employees' accident records are tied into his departmental operation cost. This is being done in four of the large plants, and in six of the small plants reporting. Another industrial section in which this inventory is being conducted reports 52 per cent of the large plants and 33 per cent of the small plants provide this safety incentive to their supervisory person.

In many operations it is important from the standpoint of safety and efficiency that the workers' experience, aptitude, skills, and their mental and physical makeup be matched

to requirements of the job. Failure to give this point the attention it deserves can result in serious work injuries.

Many organizations have developed job specifications which are used as a standard for hiring and placing workers according to the requirements of the job to accomplish this matching of the individual to the job.

JOB DESCRIPTION AND SPECIFICATION

Job descriptions are developed to specify the standard method of the job performance for individual jobs. These are used to guide foremen, supervisors, and workers in carrying out their work safely, and in accordance with approved standard methods.

Many plants recognize the importance of safety as an inherent factor in efficient production, and have their safety department review and check these job specifications and descriptions. This check insures that the job specification specifies the required characteristics of the individuals assigned to the work, and that the job description incorporates safe work methods and necessary safeguards and safety protective equipment for the workers' protection against injury.

CONSULTING SAFETY DEPARTMENTS

Reports indicate almost three-quarters of the large plants and more than half of the small plants consult the safety department when job requirements are developed. This means that safety considerations are incorporated in job specifications in the majority of the plants reporting. Plants that have the safety department check job requirements give the department an opportunity to recommend the use of proper safeguards, clothing, and equipment, as a part of the standard method of performing the job. The safety department can then point out the dangers, toxic, flammable materials, and hazards peculiar to each particular job, and recommend ways to correct these injury exposures in accordance with recognized safety practices.

The majority of reporting plants in the section realize the importance of written specifications and take advantage of their usefulness. But there still remains the good portion of the section who does not use written specifications. In many plants the institution of these practices may be beyond the control of the safety director, but where this is not true it seemed desirable to consider them as a standard procedure.

Once jobs have been studied and job specifications and descriptions written, it is important that they are reviewed from time to time. Further revisions or safeguards may be necessary, or new developments may have to be placed in effect on jobs and operations where they are applicable.

Many organizations hire and place new employees without first consulting the employees' foreman or supervisor. In such organizations the foreman sometimes complains about the quality of his workers. Foremen usually indicate they feel they could make a better selection of personnel if they had an opportunity to pass final judgment before applicants are put to work under their supervision.

Complaining foremen say the workers are not cooperative, that they are difficult to get along with, that they are not reliable, and that even when instructed properly they still fail to carry out their jobs in the manner desired. Although some of these may be an excuse for the supervisor's own failure to give adequate job instruction, or to follow through with adequate supervision, there is often some justification for such complaints.

Many plants try to eliminate this situation by sending job applicants to the foreman for an interview, and leaving final acceptances or rejections in his hands. Where the foreman exercises his prerogative of rejecting the applicant, the latter is often returned to the personnel or employment division for possible placement on another job in some other department.

A large proportion of both large and small plants do have job applicants interviewed by foremen. This is a good showing for the section as a whole, but there are still many plants who do not take advantage of the foreman interview.

APPLICANT'S ATTITUDE

Experience shows that work injuries sometimes result from the worker's not being properly machined to the requirements of the job, in terms of his personal attributes. The employee's attitude is perhaps the most important to the personal attributes he brings to his job. Foremen know that there is a great difference in the way a worker with a constructive attitude accepts and follows safety precautions and practices, and the way a person with an indifferent attitude accepts the same precautions and follows the same practices.

The foreman's interview gives him an opportunity to evaluate the applicant's experience, skill, physical qualifications, and especially his attitude. If a foreman feels that the man would not make a good and safe worker, the foreman can reject the man before he injures himself, decreases production in the department.

The fact that such a substantial portion of both large and small plants are following this policy indicates that they find it definitely worthwhile. In view of the advantages that can be gained from a safety standpoint, as well as from a standpoint of production, this is a practice which would seem to recommend itself to those plants not presently following it.

When a man is first hired, what he thinks and feels about the work he is doing, his company, his foreman, and the importance of safety in his new job, crystallize into his attitude toward his work. Since these attitudes influence his actions on the job, and are a basic factor in his cooperation and desire to follow the safe work procedures and safety rules, the time to start selling a man on safety is when he is hired.

SAFETY INDOCTRINATION

Because new employees are especially impressionable many companies include a general, but pointed emphasis on safety in their indoctrination of new men. One common means of doing this is to provide the new employee with the safety rule book at the time he is hired, and inform him that compliance with the safety rules, and participation in plant safety programs is an important part of his new job. Usually the new employee is told to read and become familiar with the safety rules, and told that the foreman will review some of the rules with him.

If the worker is to wear goggles, safety shoes, and other protective equipment, he is told about it at the indoctrination, and arrangements are made to draw this equipment. He is told that the supervisor will give him job instructions, will instruct him in the safe practices and safety precautions he is expected to follow on the job. He learns during indoctrination that his supervisor will teach him safety, and will expect him to follow the safety precautoins as a regular part of his day to day work.

The fact that only seven out of the 63 reporting plants do not have a safety indoctrination program indicates that this is one phase of our safety program that the seven plants should, if possible, include in their program. As might be expected, the proportion of plants giving indoctrination singularly is much greater for small plants than for large ones.

HANDLING ORIENTATION

Single employee indoctrination in the small plant is usually handled by the man's foreman or supervisor without any other assistance. A few plants report having the safety division handle single employee indoctrinations, and others have both the foreman and the safety department handle indoctrinations.

Small plants usually give employees their indoctrination program at the time of hiring, or during the first day on the job.

In the large plants single employee indoctrination is handled primarily by the man's foreman or supervisor, and in a few cases by the employment or personnel department. Group indoctrination, in the main, is handled by the safety department, the personnel department, and in a few instances by specially set up safety training programs for new employees.

Where the indoctrination combines single and group instruction, the man's foreman or supervisor usually is assisted by the safety department, or by the training or personnel department. The large plants give indoctrination either before hire, or within 30 days after the man starts on his job. In many cases the initial safety indoctrination is followed up at a later time. Follow-up on this phase is from one week to six months after hire.

An example of an indoctrination program is a large plant that gives new employees indoctrination singularly and in groups. Before starting work, a group of new employees meets with a member of the safety division, or a district safety coordinator, for basic instructions on safety and other procedures. When the new employee reports to work his foreman gives him single indoctrination showing him the particular hazards,

and ways of avoiding these hazards. At the group meeting a copy of the safety practices handbook is presented to each employee. The foreman then explains various rules to the employee who can question his foreman as they go along.

Some examples of plant safety rule books which are used in indoctrination in some plants have been provided by a number of large and small plant members. In those cases the booklets are devoted exclusively to safety rules and precautions, but sometimes the book incorporates safety and organizational material, personnel policies, and a brief company history. Usually such booklets are issued permanently to new employees who are expected to become fairly familiar with the safety rules, and to give the personnel department a written statement that they have done so. During the indoctrination attention is called to the booklet's importance, and its principal provisions are reviewed orally with the new employee.

Failure to carry out job instruction and good supervisory follow-up has been a causative factor in innumerable work injuries. Workers who are not well trained are apt to make mistakes or fail to follow correct safe practices, with the result that accidents occur. Good job safety instruction will point out to the worker what his specific job hazards are, and show him safe work practices that will help him avoid these hazards.

JOB INSTRUCTION, TRAINING

Job safety instruction is usually most effective when given to the employee on the job by his foreman, or by the supervisor who gives him his work assignments. The supervisor can evaluate the employee's attitude toward his job, his aptitude to absorb instruction correctly, and the extent to which he is familiar with the correct method of job performance when the instruction is completed. Since the supervisor is the one who gives him his work assignments, the supervisor's knowledge of the employee's job competence and know-how assists him in exercising good judgment in giving work assignments to the new employee.

A good method of job safety instruction is for the foreman to give individual instruction to new employees, and then have the personnel or safety department follow-up to check on the extent to which the new employee has absorbed the safety aspects of his instructions. If the employee is not adequately familiar with and currently following safe work methods and precautions, he will be given further instructions and follow-up by his supervisor. Such follow-up will disclose any deficiencies in the instruction given, or in the employee's absorbtion of the instruction.

Many plants in industry give workers instruction in production procedures, but no instructions on the hazards inherent in their operations, and the safe work methods and safety precautions for avoiding them. Lacking this specific knowledge, workers often commit acts which result in severe accidents.

USE CHECK LISTS

Poor job instruction, in many cases, has been traced directly to the instructor's failing to organize all the important points of the job clearly in his mind before giving the instruction. Consequently, the instructor overlooks certain safety features or other important points about the job. When this happens the employee being instructed fails to learn all the safe work methods and other safety precautions needed for his job. Training specialists recognize the importance of a checklist of safety items to be covered, or the use of a job instruction breakdown which incorporates all the safety features and precautions to be observed in connection with the job. In the latter case the safety instruction is an integral part of the regular job instruction.

Before job breakdown for instruction purposes is prepared, the job must first be reviewed and instructions listed according to safe procedure and standard work methods. The safe work method and safety precautions must be determined and these points entered into the breakdown. The result is a written breakdown which incorporates all the safe work methods and precautions which the worker should understand in order to avoid injury in performance of his job.

The breakdown provides the supervisor with a standard method of safe job performance. When this breakdown is followed each time a man is instructed in performance of his job, it insures that all men are uniformly instructed in the one best safe method of job performance. It also insures that the supervisor does not overlook any of the safety features of the job at the time of instruction.

The Inventory shows that the precautions of preparing job breakdown or lists the safety items to be covered during job instruction are ignored by a majority of the plants in the section. It seems apparent that this point deserves consideration from a number of plants in this section to make their job safety instruction more effective.

The usual practice in general industry is for the supervisor who actually gives job safety instruction to make his own breakdown on the jobs involved, and to use these as a reminder of the various points to be covered when he gives instruction. To be sure that the breakdowns, or list of safety items which should be covered are complete and effective, it is a good practice to review them with a representative of the safety department. Although many supervisors are qualified to do a good job in this respect, with the assistance of the safety department they can do an even better job.

The fact that slightly less than 50 per cent of all plants have the safety department check instruction breakdowns and safety checklists indicates that this checking is an important part of preparing job breakdowns. Any plants who adopt this policy in the future should adopt both parts of the procedure for maximum effectiveness.

TRAINING SUPERVISORS

The method of presentation is as important in job safety instruction as are job breakdowns or checklists. An effective instruction technique, such as the "J.I.T." for method of presentation should be used when giving instructions. The instructors should be taught a special technique that is easily understood and effective for the type of instruction they are to give.

One small plant indicates the use of outside help. It states that it sends its supervisors to a university extension course training. The large plants rely mainly on in-plant training, conducted by a training department, personnel department, or the safety department.

More important than who conducts the training is that the person doing it is well qualified to give the plant instructors a practical, useable knowledge of an effective instruction technique that can be applied to job instruction training.

Fifteen small plants and four large plants imply, or state definitely that instruction in job hazards and safe work practices is not adequately emphasized. In practically all of these plants all supervisors are not given special training in job safety instruction methods, nor are job breakdowns or checklists of safety items to be covered prepared.

Since good job safety instruction is an important factor in preventing work injuries it would appear that this is an area in which these 19 plants can make an important improvement, and add emphasis to their accident prevention efforts.

FIRE EQUIPMENT AND TRAINING

The fact that 78 per cent of the small and 95 per cent of the large plants reporting recognize the importance of having a well-organized fire prevention program, is very encouraging. Fire in the plant concerns everyone since it affects not only production but job security and steady income.

Among plants reporting, the method of training was almost identical, except that scheduled training periods vary from regularly scheduled meetings to periodic or as needed. Training in the larger plants is assigned almost exclusively to either the safety director or plant fire chief, augmented with assistance from the city fire chief or college extension service instructors. Small plants rely almost exclusively upon outside assistance.

The personnel instructed varied with the size of the plant, some plants using one department exclusively, others using personnel from all departments, while a few plants used only foremen and supervisors.

No attempt has been made to consider large or small plants individually in determining the use of employee publications for publicizing accident prevention material.

Sixty-six per cent or two-thirds of the plants reporting have some type of employee publication, however, only 48 per cent of the plants having publications devote space for safety items. This would indicate that many plants are not taking advantage of an excellent medium to publicize its activities, reaching not only the worker but his family as well.

Companies devoting space to safety vary space allocations to suit their needs on the

subject covered. Space varies from one inch to 20 inches per month.

In this section of the report we encountered a wide variation of opinions on the most effective types of employee material.

The largest percentage favored: written instructions, blackboard talks, films, posters and booklets from outside sources and their own publications. Publications for family distribution were also reported as being advantageous. However, in this category only a small percentage is using family contacts to improve accident prevention activities.

Reports all indicated that few plants are taking advantage of off-the-job safety material available through the National Safety Council.

Since companies not having safety awards or award limits are in a vast majority, large and small plants have been considered together in interpreting this section of the report.

Occasionally some type of personal award is given employees working on safety committees as a matter of recognition for a good report.

SAFETY AWARDS—LIMITS

Many companies feel that good performance in safety cannot be bought. However, the vast majority did agree that if awards were made they should be small, inexpensive personal items so the company could cover many more employees.

Only four per cent of the large and 16 per cent of the small plants include families of their employees in their safety promotion campaigns.

Companies using this family participation report good results and feel that the additional effort required for this type of promotional activity is worthwhile.

Mediums used are: house organs, special mailings of material and personal letters and payroll stuffers with safety slogans. A few companies make periodic calls to families, requesting the safety slogan, if known, and giving a small reward. Of the companies not having family participation, less than two per cent anticipate setting up any type of incentive award plan in the future.

Since only 12 per cent of the large plants and eight per cent of the small plants include any type of supervisory bonus or awards this indicates that such a practice is not general within the industry. Where it is a practice, bonuses are worked into and are a part of the regular department production bonus plan.

SUGGESTION PLANS

In this category 80 per cent of the large plants and 62 per cent of the small plants reported that they had a suggestion system in effect or just starting. This would indicate that a vast majority of companies favor this type of employee relations. The number of suggestions received during the period covered by this report varied from zero to 3,000 with 50 per cent being adopted.

Methods of compensation for suggestions adopted varied extensively, the most predominant being cash awards. Such awards in some instances were made arbitrarily, while others pay a set figure upon committee approval and then pay an additional award or bonus after the suggestion has been used for a set period of time. This additional bonus is based upon the elimination of the hazard and reduced production costs. In all instances a management committee passes judgment on all suggestions. In some cases the suggestor is requested to present additional facts to clarify his suggestion.

Compensation for suggestions ranged from merchandise to $100, with the majority of companies basing awards on the percentage of savings over a period of time, usually a the necessary training to alert employees period of one year.

GLASS FURNACE REPAIRS

by CLINTON BALLINGER
safety director, Owens-Illinois Glass co., Gas City, Ind.

A glass melting furnace is made of refractory and steel in different shapes. The area where the melting process takes place is shaped like a huge cave. The walls and floor are made of blocks of various refractory material, each block being 18 inches to 60 inches long and 12 inches thick. The roof is also brick.

On each side of the melting area and connected to it are the checkers which serve as the passage way for the various types of fuel to flow to the tank to melt the batch to make glass. The inside of the checkers are of brick laid to form a honey comb pattern. The checkers may be 30 feet high, 12 feet wide, and 25 feet long.

The plans to repair a tank evolve when the tank is built. The first step to repair a tank is to drain the tank of several hundred tons of molten glass. A special block is built in the tank for this purpose. A hole is knocked in this block and the molten glass runs into a stream of cold water which carries it several feet outside the building to a prepared bin for storage.

While the draining of the tank, the heat on the glass is about 2700° which insures a free flow of glass. About 12 hours are needed to drain a tank of 250 ton capacity. When empty all fires are turned off; the following day dismounting starts. But even then the tank proper is still very hot.

When a tank is out of operation for repairs, several men are out of their regular jobs. In our plant this means 20 to 30 men have to be placed on other jobs or laid off. Of course, these men have the least seniority and therefore are considered green help when put on a tank repair.

REASSIGNING CREWS

About one week before taking the tank out of operation, the plant engineer asks for 30 or 36 men to work with the regular maintenance crew. About three days before beginning work, we call a meeting to assign them to a shift and introduce their crew leader. Every type of safety equipment is shown, and when and where to wear it. They are also told if they can't wear this safety equipment someone will take their place.

One man of the group is designated as the safety and good housekeeping coordinator and reports directly to the plant engineer. This man has played a very important roll in our safety record for the past several years by making it an important job to himself. He has the responsibility of checking out all safety equipment and also seeing that it is used properly.

When the time comes for dismantling the furnace, the checkers have been opened up. They have had time to cool off but are still pretty warm. The first step is to throw out bricks by passing from one man to another. The first few hours result in a lot of horse play as the bricks are hot and a man only holds a brick long enough to toss it to the next man. Since this can result in cracked shins and broken toes, it is one feature that must be watched—for the first day—until the checkers are cleared out or the bricks have cooled down.

EARLY DISMANTLING JOBS

After about three days of dismantling in which the work is hot, dirty and dangerous, the brick masons are called in and the building up process begins. There is still much dismantling done, but enough is completed for construction to start.

While this work is going on (on the tank proper), there are several other crews working, such as the electricians, plumbers, steel workers, tinners and machine repair men. Although these craftsmen's work may be in different spots around the tank, they must know of the other work going on above them, below them and on either side of them. We are not too alarmed that a man throwing bricks will hurt himself but that someone else will catch the full force of a hastily tossed brick.

One of the big items on any repair is this thing called housekeeping. In every plant today it is stressed in many different ways to the employees. Many supervisors feel a

good housekeeping program is lots of janitors and lots of brooms. But it's not. It is pride in the worker who wants to work in a clean place, and will do his part to keep his work area clean. This is a job for the supervisor and only the supervisor.

GOOD HOUSEKEEPING ESSENTIAL

Many accidents are caused by poor housekeeping and little or nothing is done to correct the condition. When 50 to 75 men work in an area not much larger than a basketball floor, with many types of material and equipment, good housekeeping is a must. If you have a good housekeeping program you will likewise have a good safety program. Our last lost time accident on a tank repair was caused by poor housekeeping—a small piece of brick was lying on the floor (probably had been there for two or three days), a bricklayer stepped on it and broke his ankle.

To make safety more real to the average man, several methods or approaches can be used. Posters are the largest medium to preach safety. Supplementing the posters we have been using the give-away gimmick. After one full week of work on a tank repair, the names of all men working on the tank are put in a box. At the 3:00 p.m. coffee break, while the men are congregated in one area, one name is drawn out and this individual wins a small prize such as a jacket, pair of safety shoes or one of several items costing from $3 to $10 dollars. This gimmick has done more to promote safety on tank repairs in our plant than any other. Since the use of the give-away idea, we have not had a single serious accident.

Proper scaffolds are always a must and should be inspected before being used and very often after that. The use of high lift trucks to transport and elevate tank blocks certainly cuts the danger of smashed toes, fingers and back injuries. The payloader is a real asset in loading trucks of bricks torn out of the furnace.

Every safety device and gimmick available should be used on one of the toughest jobs in the glass industry.▲

HOW TO CONTROL OFF-THE-JOB ACCIDENTS IN THE GLASS AND CERAMICS INDUSTRIES (A Symposium)

OFF-THE-JOB ACCIDENT CONTROL IN A SINGLE LOCATION COMPANY

by JOHN NANFELDT
safety director, Harding Glass co., Fort Smith, Ark.

With the increased cost of group insurance plans and the increased specialization among employees, this is one field of accident prevention that is important to all industries regardless of what they manufacture, whether they are large or small, located in one city or spread over the entire nation.

I do not propose that we, at Harding Glass company, have the complete answer for controlling off-the-job accidents, but I do feel that our record indicates that we have made some progress in controlling this type accident during the past several years.

Before actually considering the features of our program, it might be well for us to describe our company. As you are probably aware, we manufacture flat drawn sheet glass. We are a member of the Fourco Glass company and are located in Fort Smith, Ark. a city of approximately 60,000.

During full production, we employ between 600 and 700 people. Our employees and their families number approximately 3,000 or close to five per cent of the city's population; therefore, it is easy to see the importance of an off-the-job safety program to our company.

Strictly speaking, the off-the-job accident control program at Harding Glass company may be divided into three sub-divisions. First are the activities of our Safety Council, composed of management, all supervisory personnel and foremen, and elected employee representatives from each department. This group meets once each month to discuss safety problems that affect the plant in its entirety.

Guest speakers are invited to discuss safety subjects of various types. The overall program for each month in a given year is set up by a program committee. It has been a policy of this program committee to include three or four monthly meetings of this group dealing with off-the-job accident control. For example, we have had meetings on such subjects as highway safety, at which time, a member of the Arkansas State Highway Patrol was our guest speaker.

COMPANY SAFETY COUNCIL

The members of the Safety Council are called upon in their regular monthly departmental meetings to report on the subjects discussed at the previous Safety Council meeting. In this way, this information is passed along to all the employees in the factory.

The second major division of our safety program that deals with off-the-job accident control is our departmental safety meetings. In my capacity as safety director, I meet once a month with every department in our plant. In these meetings, subjects pertaining to the safety of that particular department are discussed, along with an overall subject discussed in the meetings with all departments.

For the past few years, it has been a policy to devote three or four of these monthly meetings each year to subjects dealing with off-the-job safety. For example, subjects such as "Water and Boating Safety," "Home Fire Prevention" and others of this type have been discussed. Through these meetings and the discussion of subjects dealing with home safety, we feel that we can accomplish two things: (1) Impress upon the employees the company's genuine concern for their safety away from the job as well as on the job. (2) Educate all employees to recognize and correct hazards around their own home.

FAMILY NIGHT PROGRAM

The last feature of our program is what we call our Family Night Program. This is a program sponsored by the plant Safety Council for all of our employees, their families and guests. This is an idea which started seven or eight years ago to promote interest in the plant Safety Council. During the ensuing years, it has come to be one of the most looked forward to events in our safety program. This Family Night Program is primarily a chance for all employees and their families to get together for an evening of entertainment and safety education.

We have found that early in the spring, February or March, is the best time for a program of this type. In our part of the country, most of the bad weather is over and it is too early for any vacations to have started. We have used the auditorium of a grade school located near our plant to hold this event.

Since most of the employees will bring their children, we start our program at 6:30 p.m. and try to limit the entire program to about an hour and a half. We have also found it better to complete the safety educational portion of the program at the first of the program and not make this part any longer than absolutely necessary.

By doing this, we are able to get the safety message across and get into entertainment features of the program before the children get too noisy or restless. Another way we maintain the interest of the children is by using games or contests involving the children. For example, one year, we had the children pat on a prescribed amount of safety equipment and blow up a balloon. The first one finished in each age group won a prize.

The entertainment we have used in this program has been a variety of local talent, such as singing groups, dancing and instrumental groups. To stimulate interest and promote attendance, we award door prizes. We feel that our Family Night Program produces desirable results. It provides a

social contact for all employees and their families while pointing out to our employees' families the company's genuine desire to provide a safe place for the members of their families to work.

Through the brief educational portion of this program, we are able to get ideas across pertaining to the safety, not only of our employees while on the job, but also all the employees and members of their families while they are off the job.

These, then, are the three important features of our off-the-job accident program. The acid test of any program is "does it work and what results has it produced?"

We feel that our program is beneficial not only in a reducing the number of accidental injuries, but also in producing a savings in the company's group insurance program costs. To illustrate this, I have compiled the sickness and accident payments for accidental off-the-job injuries for the years of 1955, 1956 and through September, 1957.

COSTS OF ACCIDENTS

In 1955, employees of Harding Glass company suffered 13 injuries which caused loss of time from work and one accidental death. These injuries include lacerations, back injuries and fractures. The accidental death was caused by drowning. The lost time caused by these injuries amounted to 78 weeks and two days in the amount of $2,348.00 in S&A benefits.

In 1956, 11 employees lost time from their jobs. The total lost time was 20 weeks and three days for which $612.00 was paid in S&A benefits. For the first nine months of 1957, three employees have lost a total of 22 weeks and three days from their jobs and have been paid $672.00 in sickness and accident benefits.

The life insurance premium rate for our employees since 1948 has shown a decrease of .03c per thousand dollars while the average employee age has gone up. This does not represent a great drop, however, considering the relatively large number of employees involved and the period of time, this decrease represents a considerable saving to the company.

Similarly, the sickness and accident premium rate has remained constant since 1952, the amount of benefits has increased at no increase in premium rates. No summary of hospitalization costs have been used since there have been a number of benefit increases and changes of insurance carriers so that no accurate picture could be drawn.

In view of the results that have been reflected in the reduction of accidental off-the-job injuries and the reduction in group insurance costs, we feel that our program has been successful.

ALCOA'S APPROACH

To the Off-The-Job Safety Problem

by W. R. GILLILAND

assistant safety director, Aluminum Co. of America, Pittsburgh, Pa.

Alcoa has been concerned over this problem of off-the-job injuries for several years. However, we lacked concrete facts concerning the true dimensions of the problem, and didn't know the best way to obtain the necessary information.

When the National Safety Council announced their standard reporting form for off-the-job injuries in the fall of 1955, we asked our plants to use this form not only for reporting to the National Safety Council but also to our home office. We do not use the formula for Frequency and Severity rates but complete all other items.

Our procedure is generally as follows: All employees are covered by non-occupational disability benefits, medical, and surgical insurance program. The Insurance Department at each location, therefore, serves as an ideal accumulation point for all insurance claims of off-the-job injuries. Claims for employees' dependents can be accumulated in a similar fashion by each plant and reported to us on the National Safety Council form.

This arrangement has simplified the problem considerably. We probably miss some minor cases which result only in one or two days' absence from work or other minor incidents for which claims may not be filed. However, such cases constitute only a very small percentage of the total. Considering the foreman's or supervisor's time required to investigate every single absence for complete data, we believe our procedure is quite adequate for all practical purposes.

The data obtained from this reporting procedure during 1956 were:

1219 off-the-job injuries. Of these, 18 were fatalities—17 in traffic accidents and one at home. This amounted to 4.18 injuries off-the-job for every one occurring on the job and 9 off-the-job fatalities for every industrial fatality.

There were 23,497 days lost as a result of these injuries. This does not include any standard time charges for permanent partial disabilities and fatalities. The time lost is 3,335 man-weeks or 64 man-years of productive working time lost in a company of 50 thousand employees.

In addition to the loss of manpower and skills, the weekly disability benefits paid to employees for lost time due to off-the-job injuries in 1956 was 133,400 dollars plus life insurance benefits of 90,000 dollars for families of 18 deceased employees. This amounts to approximately $4.40 per employee a year. Although the insurance carrier pays these costs, our company pays the insurance premiums and we benefit by any reductions in payments.

This represents a substantial incentive for the company without including hospital and surgical expenses or any indirect costs. Needless to say, the cost to employees in lost wages and suffering is a considerable item, and should serve as an excellent point for rallying employee interest and support for off-the-job safety programming.

As I mentioned before, we do not have a complete program. As in industrial safety, there are a variety of different approaches with no single answer as the exclusive remedy. Education of employees and their families will undoubtedly be the major approach since supervision and other controls in industrial safety are absent.

RALLY LOCAL SUPPORT

Our principal approach to date is through locally conceived and sponsored programs hitting one or more phases of the problem at any given time. One example is a traffic safety program sponsored by one of our plants early this year.

This plant is located on a stretch of highway with the worst accident rate in the state. A 30-day campaign was launched with the cooperation and assistance of all industries located on the highway. Comprehensive publicity through plant and community newspapers and radio stations was arranged. "Back the Attack" bumper stickers and other reminders were distributed to all employees. Poster programs were keyed to this theme. Supervisory, safety committee, and employee meetings were held to discuss the problem and show traffic safety films. State police troopers participated in the meetings and campaign to warn motorists of highway hazards. Letters were sent to employees' homes. This same topic is being plugged this year to keep the topic fresh in the minds of employees.

While it is still too early to prove that this effort reduced injuries, we believe it has had quite an effect.

Another example of this local approach is in a small community where Alcoa is the principal employer. Here we use the services of all community organizations while the company acts as sponsor furnishing materials, lending guidance and support. Gaining participation by as many people as possible is a major objective of a successful off-the-job safety program the same as it is for an in-plant program.

In regard to the program at the home office, we make available all types of materials and services to the various plants. All plants receive the off-the-job materials published by the National Safety Council. The *Alcoa News*, our company house organ sent

to all employees, features articles and items pertaining to the subject. Reading rack booklets on off-the-job safety constitute a large percentage of the materials approved by our home office.

In addition, we are considering certain company-wide programs such as the Safe Drivers League as a continuing effort to superimpose the current one-shot type of campaign devoted to a specific hazard.

We feel that by constantly hammering away through the proven techniques of industrial safety programs, we can reduce the terrible toll of suffering and expense to our people resulting from accidents at home and on the highways.

ARE OFF-THE-JOB SAFETY PROGRAMS NEEDED IN INDUSTRY TODAY?

by R. P. HAMILTON

superintendent of safety, St. Louis-San Francisco Railway co., St. Louis, Mo.

During the past few years we have been brought face-to-face with startling facts. There has been an increase in school enrollment, in political activity, in the merger of great industries, in wages, in speed, and, according to statistics from the National Safety Council an increase in the number of persons killed and injured. There was an increase of two per cent in the number of persons killed in 1956, or a total of 95,000 killed and 9,500,000 injured.

Considering that approximately 81,000 of those 95,000 fatalities during 1956 occurred in off-the-job accidents, we realize that we should have off-the-job safety programs.

Although the cost of accidents, injuries and deaths is secondary, it amounted to $11,200,000,000 in 1956. This expense for loss of life, injuries, and destruction of property, would have clothed every man, woman, and child in the nation in 1956. It would have built 1,000,000 single-family homes, or 300,000 school rooms which are badly needed. It would have provided all three shots of Salk vaccine for every person in the world. The cost exceeded the net income of the nation's 135 largest railroads, utilities, and corporations. How nice it would have been to be able to spend that $11,200,000,000 for construction rather than destruction.

We feel that safety should be a family affair because it reaches through each man's job to his home, his family, his clubs, his schools, and his community.

The basic principles of off-the-job safety programs of railroads can be used in any organization—*make safety a family affair.*

During the latter part of 1947 I felt that we were not making sufficient progress in safety on our railroad and we should try something new. It was decided to hold some family safety meetings. On a cold, wet night in December, 1947, we held our first family group safety meeting with an attendance of 84—not too many, but at least a start. During 1956 we had two such meetings with an attendance of over 1,100 at each meeting. Last year 53 family group safety meetings with more than 29,000 in attendance were held over.

During April of this year there were over 5,800 at our Springfield, Mo., meeting. We had to turn away more than 500 people unable to get inside the building because the doors were closed by the city firemen for safety's sake. This clearly demonstrates that there is an interest in safety. We have always felt that if you can show the employee you are interested in the safety of his family as well as himself, he will be more responsive to the on-the-job safety program. If an employee is safety-minded at home and on the highway, he will also be safety-minded on the job.

The highlights of our safety program as summarized by "Railway Age" are:

- "Its ubiquitous energy (because it comes largely from within rather than from the top).
- "Its active—rather than passive—character for most employees (i.e., it is widely participated in, not just looked at or listened to).
- "Its sincerity, as evidenced by its volume of non-railroad public safety work.
- "Its corner-stoning the basic Frisco policy of building management potential from within the organization through widespread employee activities.
- "Its hand-in-glove fitting into Mr. Hungerford's philosophy of building up the individual and respect for his dignity.
- "Its knitting together the Frisco 'family' of 17,000 scattered employees by providing fellowship and a common goal reached through common experiences.
- "Its immeasurable public relations benefits derived through selfless efforts in community and home safety.
- "Its appeal to even non-railroad families through the continuing work with school children and family groups.
- "Its ability to save lives and suffering while at the same time boosting morale and pride in the company.
- "That the program has won over the Frisco rank and file is no better illustrated than in the remarks of a recently retired locomotive engineer. Spotting Mr. Hamilton one recent afternoon, he said: 'I thought this safety thing would die out when you first started it. It always had before. But I wish now that the company had started your program 10 years sooner.'"

We are confident that our off-the-job safety program helped save many lives and much needless suffering, and we feel the same way about the various programs carried on by industry today. The managements of a large number of railroads and industries of America feel we do need off-the-job safety programs, and we are confident that each year will see an increase in those participating in this worthwhile cause.

RUBBER SECTION

REPORT OF THE STATISTICS COMMITTEE

by RAY HART

safety director, The Dayton Rubber co., Dayton, Ohio

The records say that three people will die and 270 will be injured, while I am talking for 15 minutes. Approximately 95,000 are killed each year, accidentally, one way or another. About 40,000 die in traffic, 28,000 in their homes, and 14,500 on their jobs.

When we say 14,500 people died on their jobs and 28,000 in their homes that sounds good, and we hear it said that industry has a good safety record. Personally, I can't agree with this, because the record is not good as long as 14,500 people are losing their lives annually. It only looks good when we compare it with other causes that have a worse record than we do.

We are specifically concerned with the rubber industry. You want to know where we are in the standings and how we compare.

(1) First of all let's look at the frequency and severity record for the rubber industry from January 1, 1950, to the end of 1956, as reported to the National Safety Council.

FREQUENCY AND SEVERITY FOR RUBBER INDUSTRY—NATIONAL SAFETY COUNCIL

Year	Units	Total Injuries	Fatal Injuries	Permanent Partial	Temporary Total	Hours Worked	Frequency	Severity
1950	66	1196	5	86	1104	380,382,400	3.07	700
1951	107	2105	4	129	1972	555,537,500	5.91	380
1952	121	1896	6	143	1847	632,962,700	2.15	420
1953	126	1891	12	147	1641	390,382,400	4.61	490
1954	125	1411	8	105	1298	256,637,500	5.97	390
1955	136	2228	14	198	2016	633,962,700	3.51	390
1956	116	879	2	90	787	267,657,000	2.28	338

(2) Now, let's look at the frequency and severity for all industry, as reported to the U. S. Department of Labor for the same period.

FREQUENCY AND SEVERITY FOR ALL INDUSTRY—U.S. DEPARTMENT OF LABOR

Year	Units	Total Disabling Injuries	Fatal Injuries	Permanent Partial	Temporary Total	Hours Worked	Days Charged	Frequency	Severity
1950	6395	113,273	1,005	6,398	105,870	12,176,502,600	11,502,928	9.30	940
1951	7134	127,889	1,210	7,417	118,262	14,096,081,800	12,889,215	9.06	970
1952	7930	136,381	1,178	7,915	117,288	15,044,278,460	12,371,226	8.40	880
1953	8139	117,448	1,148	7,952	108,348	15,794,164,900	12,084,230	7.44	830
1954	8456	107,081	1,170	6,846	98,065	14,830,430,100	11,836,940	7.22	808
1955	9315	111,429	1,302	7,404	102,723	16,612,022,300	12,046,327	6.96	815
1956	9805	98,380	1,082	6,179	91,119	18,430,720,860	11,307,232	6.38	725

(3) Now, we have the frequency and severity for all industry, as reported to the National Safety Council for 1956.

The 1956 Injury Rates as reported to National Safety Council

FREQUENCY		SEVERITY RATE	
Communication	.98	Communication	58
Aircraft Mfg.	1.51	Tobacco	82
Electrical Equip.	2.01	Leather	121
Automobile	2.14	Electrical Equip.	156
Cement	2.26	Aircraft Mfg.	227
Tobacco	2.27	Automobile	280
Rubber	3.28	Rubber	338
Steel	3.52	Sheet Metal	554
Ship Building	4.84	Railroad Equip.	536
Railroad Equip.	5.29	Ship Building	667
All Industry	6.38	All Industry	732
Pulp & Paper	7.34	Iron & Steel	770
Lumber	7.56	Wood Prod.	818
Meat Packing	8.00	Steel	850
Iron & Steel Prod.	8.72	Foundry	976
Wood Prod.	9.88	Cement	1388
Foundry	10.22	Construction	2378
Construction	19.10	Lumber	2436
Lumber	22.52	Quarry	3134
Coal Mining	23.07		

(4) Last of all, let's see how the small plants compare with the large plants, as far as safety is concerned.

Injury Frequency Rates by Size of Reporting Units for the Rubber Industry—U.S. Department of Labor—1955

Size	Tires & Tubes	Rubber Footwear	Misc. Rubber Products
Less Than 20 Employees	——	——	10.12
20 to 49 Employees	——	——	12.0
100 to 249 Employees	——	——	21.0
250 to 499 Employees	14.4	——	14.2
500 to 999 Employees	3.7	12.5	10.7
1000 to 2499 Employees	4.2	6.5	8.1
2500 and over	2.6	0.5	5.0

Injury Frequency for This Year

January Thru August	Frequency
Under 300 Employees	6.02
300 to 500 Employees	4.46
500 to 1000 Employees	2.62
1000 to 2000 Employees	2.37
Over 2000 Employees	2.10
All Divisions 7-31-57	2.88

We can break down the injuries in the rubber industry and count the toes, fingers and hands that were affected, also the ones that were caused by machines, but what will that tell us? We still must deal with them individually—first find the cause and then the cure.

It has been said that more than 95 per cent of our injuries are caused by unguarded minds, and less than five per cent due to unguarded machines. I wish I could tell you exactly how to establish a better safety record, but I am afraid I don't have a sure cure. I am convinced that it is a job for supervision and no one else can do it. I can make it sound rather simple, because our work boils down to this—how do you make a supervisor want a good safety record? The desire must be there first.

It is not too difficult to provide ideas that will get good results, once we get them in the right frame of mind. Safety work reminds me so much of church work. We are all striving to do the same thing, but we use different methods to get the job done.

Perhaps this is a good approach to the problem. We try one idea and it appeals to some; another idea appeals to others, and so we continue on, and some day perhaps we will get everyone safety minded, if we can come up with enough new ideas.

ACCIDENT—CAUSE, INVESTIGATION AND PREVENTION

(Round Table Discussion)

ED TURNER, Conference Leader

I should like to preface my brief introductory remarks by establishing two simple propositions:

1. Only by a realistic analysis of the accidents occurring in our plants will we ever be in position to assess what we have accomplished in accident prevention, and what we hope to accomplish.

2. The objective of accident analysis is to establish the real causative factor, to carry out a thorough fact finding investigation of all history surrounding the case to set up workable preventive measures.

The factors of cause and investigation are relative. So as to clear our thinking, we shall look at it this way.

ESTABLISHING CAUSE

CAUSE is the actual agent, causing the injury. In essence, this may be the briefest part of our discussion; we really seek to establish who and what with the object of establishing fact and dissipating baseless rumor and possible panic. In establishing accident cause, in its simplest terms, we merely want to know whether the agent is human or mechanical.

Cause should never be confused with blame. It is a human failing it seems, that as soon as a tragedy occurs, a sacrificial goat is looked for on whom to pin the blame.

This resolves nothing, and merely turns the factor of shock and grief into mistrust or bitter recrimination.

Until such time as all the facts are established, management must assume full responsibility to give a full and proper account of what has occurred, and endeavor to offer a measure of calm assurance and reality at a time tempers are delicately triggered.

In this section we should consider (1) who should investigate and (2) what to investigate.

A representative of management is the best person to carry out a thorough investigation of all accidents or accident producing conditions.

The main purpose of an investigation is to find the fundamental error which caused the accident and correct it whether the error falls into the human or the engineering category.

The investigation should be made as soon as possible after an accident—before the conditions or machine can be changed.

PREVENTION

So long as management assumes the responsibility to manage the plant, then it must be the prerogative of management to act as the sole enforcing agency to—

(a) Correct defective working conditions.

(b) Put a stop to improper work practices.

I was much impressed last year when listening to a labor discussion when several workmen were insistent that their bargaining representatives incorporate into their agreements specific safety regulations, only to be told in no uncertain terms, something to this effect:

"Just keep this one thing in mind; that while we mutually subscribe to the need of safety measures in our plants, our local agreements will only deal with the subject in a very general manner.

"The sole responsibility for the safe welfare of the man in the plant is management's. Labor does not share in this responsibility as a management function; if and when we do that, then we must also expect to share the blame for accidents."

I do feel, however, that the management member should promptly inform the union safety representative of the actual history of the accident and the measures recommended to prevent its recurrence, in order that the union may have confidence in the impartiality and thoroughness of management's investigation.

Let me illustrate by two actual case histories:

ACCIDENT NO. 1

Six weeks ago a telephoned report came to my desk of a man having his arm caught in the spreader rolls of a machine.

Now long since, I have learned this cardinal rule—In any serious accident, get on the job immediately to establish as soon as possible (and certainly before rumor gets busy) the accident cause and extent of the injury.

In reaching over the top of a chain drive, this operator's sweater sleeve was caught, and it pulled his arm up against, but not into, a small idler sprocket. From the workman, who was well enough able to talk, we ascertained that he had followed a standard procedure, and was using a knife to free some loose threads adhering to a smooth rool. In picking off the threads he had to reach in further than normally, and came into contact with the chain.

This operator suffered severe lacerations and contusions to the lower arm. There were no broken bones and he was off the job for six to eight weeks.

Thus we had established the cause and the *whom* and *what* of the accident.

The investigation in this case,—which is always slow and involved—was done carefully, and verbal statements were shaken down from the supervisor, the man's workmate and other parties involved.

The supervisor submitted that the man had violated safety regulations and gone into an enclosed area alone when the rules specifically stated that he was not to do so.

His workmate was somewhat truculant in saying "Ah, I knew someone would be caught there someday. I've told 'em a dozen times the job isn't safe. There should be another man on the job."

Our investigation showed up two or three rather obvious errors.

- In doing the operation, which was quite essential, the safety cable was out of reach of the operator in an emergency.

- The safety rules did not specifically exclude him from going into the area alone —merely "that on all such cases a man must be on the platform of the machine, within call."

- The practice was admittedly hazardous, but no real thought had been given to taking specific preventive measures to meet an emergency. The safety and engineering departments did not even know that such a practice was regularly done.

Some recommended prevention measures are:

1. The safety cable is to be extended so it will be well within reach from any position.
2. The request by the union to have a third man placed on the job was partially met. An air whistle was installed so as to summon the third man whenever entry into the enclosed cabinet was required.
3. The rules were changed to read "in a less ambiguous manner." In other words, no entry into the enclosure is permitted unless a standby operator is first summoned.
4. A platform for easier access to the rolls was installed.
5. We made up a combination high air velocity rod and knife to remove the strips, thus obviating the need of the operator to reach into the rolls.

There you have it. The cause—to establish the facts and frustrate rumor.

The investigation—to establish the weak points of our safety measures.

The prevention—to set up the proper measures to eliminate further accidents.

ACCIDENT No. 2

The ambulance had called at the front door to remove an unconscious workman to the emergency ward of the hospital.

Rumor had it he was killed by poison gas. To add horror to the rumor—he was only one of several who had been exposed to the gas. Quickly then we must establish the cause factor, and dispel wrong impressions. This man was in shock so we could get little help here. We understood the operator had spilled some aniline oil and in attempting to clean it up had used some burlap bags to soak it up and had wrung the material out in a drum. This obviously resulted in the inhalation of fumes and in critical skin contact. Therefore a serious case of poisoning resulted.

Since the actual incident occurred about two hours previously, he was in shock and

immediate remedial measures were imperative; thus his prompt dispatch to the hospital.

It was all of five days (after complete blood transfusions to save his life) before we could complete the investigations with his help, and he admitted that he was involved only because he had tried to cover up an error. He had left the room to secure a cup of coffee contrary to regulations and had left a small valve open to fill a drum.

CAUSE AND ERROR

Our measures for ventilation were faulty and since the material being handled was hazardous, the margin for human error was too obvious. Thus we had to admit that our policy was as much the cause, as the error of the employee.

PREVENTIVE MEASURES for this hazard were:

(a) The liquid transfer was made automatic, both by a measuring device and by an automatic float shut-off.

(b) A retraining on the handling hazard of the chemical was undertaken for all employees of that department.

In taking corrective action after an accident, a great deal of skill and sound judgment needs to be exercised. In accident investigation there is no room for hot heads and unbridled tongues.

Even if there is a patent violation of a state code the interpretation as to whether the scope of that code covers the particular situation needs careful deliberation.

RECOMMEND CORRECTIONS

As mentioned before, corrective action can only assume the status of a strongly worded recommendation. we cannot enact legislation nor can we relegate any such action to the bargaining unit as a subject for negotiation. Accident prevention after all, can never be negotiated, if the safe welfare of any workman is at stake.

A skilled investigator will instill confidence in the minds of both management and men if he suggests a course of action, which, while not necessarily acceptable to both parties, will in the final analysis present a realistic solution to the accident problem.

The conference recorder of our discussion group was Mr. G. A. Miller, safety director of The Gates Rubber company, Denver, Colo.

The round table discussion was attended by 40 representatives of management and labor. Two phases of the subject took all the time alloted for discussion, i.e., cause and investigation.

Q. Should the cause of an injury and results of the investigation be posted on bulletin boards?

A. It was generally agreed that it would not be best to publicize this plant-wide on bulletin boards. Workers in the department involved should be fully informed by the department head after the investigation was completed.

Q. How soon should investigation be made after the injury?

A. As much as possible of the investigation should be made immediately after the accident, especially of the machine or whatever other agent was the cause. The injured man may not be in a condition for an investigation, but definitely his side of the story should be taken as soon as possible.

FINDING GUILTY PERSON

Q. Should investigation be made to find individual at fault?

A. The primary purpose of an accident investigation is to ascertain the unsafe act or condition involved. The only purpose served to interrogate an individual would be to get information on these particular aspects of the case.

It would definitely never be within the jurisdiction of the investigating man or group to prescribe any course of action against any one.

Q. Is an investigation best undertaken by an individual or a group?

A. This would depend entirely upon circumstances. It would seem obvious that the findings of any large group would have to be submitted or presented by an individual in order to get an accurate estimate of the injury.

Q. Should a joint labor-management safety committee assume the status of the official investigating party?

A. Labor feels strongly that this should be the case, or if not the whole committee, certainly representatives from both sides should take part in the investigation.

As a matter of interest, a poll showed that 50 per cent of the companies represented have joint labor-management safety committees. Local differences of policy were evident as to whether the nominees for the Union should be appointed by management or by the Union.

It is to be noted that the whole object of our meetings is merely to observe and record our findings as to the generally accepted policies governing these situations.

Depending upon the communications within the separate plants, a wide variation of company policy is evident. However, we have one common object, and that is to prevent accidents and have a workable program for the safe welfare of the workmen on the job. His livelihood must never be jeopardized by what he feels to be reluctance of management to set up safe working procedures.

As one listens to these discussions, one thing is obvious—the sincerity of both labor and management to agree on a commonly acceptable basis of mutual trust for the well being of all concerned.

HEART DISEASE IN INDUSTRY

by W. A. McCAUSLAND, M. D.

medical director, The B. F. Goodrich Footwear & Flooring co., a division of the B. F. Goodrich co., Watertown, Mass.

It has become increasingly difficult in industry to find employment for people suffering from heart disease. There are 280,000 persons afflicted with some form of heart disease in Massachusetts alone. Some 60 to 70 per cent of these are employable. Many of these are young people with families. Realizing that many of our own employees who are now in good health will, as they grow older, develop some form of heart disease, we are compelled by loyalty to save our medical jobs for our own people.

There are various types of heart disease. First, we have the congenital anomalies due to embryonic defects in development during the period when the heart and great vessels are formed from the primitive vascular tube. Briefly by name they are the acyonotic group, the cyanotic group, the tetralogy of Fallot, Eisenmenger's complex, coarctation of the Aorta, Patent Ductus Arteriosus, ventricular septal defects, auricular septal defects and Valvular Pulmonic stenosis. For some of these congenital conditions we can do nothing; whereas many can be corrected by new forms of heart surgery.

We have another big group of heart diseases caused by arteriosclerosis, rheumatic fever, syphilis, thyroid disease, diptheria, certain types of anemia, certain vitamin diffciencies, bacterial infections, aneurysms, arterial hypertension. This group is the more common of the heart diseases and usually can be treated by the physician over a long period of years. These acute and chronic congestive heart failures occur at any time of life. They may be said to constitute the bulk of the every day run of the mill heart disease.

CORONARY ARTERY DISEASE

The most dramatic of the heart diseases is Coronary Artery Disease, which is a narrowing or occlusion of the coronary arteries usually due to arteriosclerosis with the resultant imbalance between blood supply and cardiac muscle demands giving rise to anemia or damage to the heart muscle. Arteriosclerosis is the most common cause of coronary artery disease.

The etiology of arteriosclerosis is unknown but is frequently associated with high blood pressure, sugar diabetes, thyroid disease, high blood cholesterol levels, overweight and old age. Arteriosclerosis may be localized to the coronary arteries or may be a part of generalized arteriosclerosis.

Coronary artery disease is essentially a disease of middle life and old age. It is four times as frequent in males as in females and has an occasional family tendency. Approximately 90 per cent of cases occur

in the 60 to 80 year age group. It has been found in infants and children.

Coronary artery disease may produce no clinical symptoms. Only when damage becomes severe enough to cause a critical deficit of blood supply in proportion to myocardial demand do symptoms occur. The clinical picture depends upon the size and location of the myocardial region inadequately supplied with blood, the severity of the deficiency, its rate of development and its duration.

Angina pectoris or chest pain results from a short period of relatively mild ischemia. Myocardial infarction results from severe and prolonged ischemia in a more localized portion of the heart muscle often from an occlusion of one of the larger coronary arteries.

With coronary insufficiency we try to dilate the blood vessels and make them carry more blood—these people may live for 20 years under proper treatment. Myocardial infarction may occur with coronary occlusion and coronary thrombosis or without them. Small vessels may become occluded without myocardial infarction, because of a good collateral circulation.

Myocardial infarction is usually produced by thrombotic occlusion of one of the larger branches of the coronary arteries. The thrombus usually occurs in the narrowed channel of a sclerosed vessel often in the bed of an atheromatus ulcer or calcified plaque. It may form slowly or rapidly producing a thrombus which cuts off the blood supply to the area of heart muscle supplied by that particular arterial branch.

INDUSTRY'S PROBLEM

This may result in sudden death or hospitalization and slow recovery having various complications. The physician in industry is primarily interested in coronary artery disease. The majority of heart conditions can be easily detected by the stethoscope and the electrocardiogram. With these people we know just how much of a work load their hearts can sustain.

With coronary artery disease, it is a different story—as yet there is no medical test which indicates a man has this type of disease with no apparent symptom. I can take a cardiogram of an apparently healthy individual, find a normal reading, have him walk out of my office, and drop dead from a coronary.

Coronary disease is a relative newcomer to the field of medicine. Autopsies done before 1910 do not reveal this type of disease of the coronary arteries. We can blame civilization with our higher standards of living. Our full refrigerators containing foods which raise our blood cholesterol play a part in the whole general picture.

Lack of exercise, since we tend to use our automobiles to go to the next block rather than walk, is also part of the picture. Smoking, drinking and worry don't seem to have any effect. Hard work does not play a part unless there is some previously existing disease. The real criminals seem to be diet and lack of exercise. One of the most interesting proofs of these facts is that among Detroit automobile workers coronary disease was almost unknown in earlier years.

PLAIN FOOD HEALTHIEST

With improved working conditions and better pay there has been a tremendous increase in coronary disease. Our plain foods of earlier times seemed to give us protection against coronary disease. A program for control in industry is rather difficult because we have no tests which will indicate whether arteries are diseased or not.

Thorough physical examination including an electrocardiogram should be periodically made. If an employee indicates an elevated blood pressure, we should make sure that he undergoes treatment. Any underlying disease should receive prompt attention. Overweight must be controlled. Plant jobs must be inspected to make sure that the work is not too hard for the individual.

Many individuals will keep on working at a job which may be too difficult because of age or some other underlying disease. The pay check is too good to pass for an easier job with probably less money. These people we never see until the damage is done.

The returning coronary patient is always a problem—his physician's note simply states the employee is ready to return to work and we must determine if the job is going to be satisfactory from a physical standpoint.

The industrial physician must rely on adequate physical examination to control coronary artery disease.

RADIATION EXPOSURE IN THE RUBBER INDUSTRY AND CONTROL MEASURES

by R. A. MANNING
The Goodyear Tire & Rubber co., Akron, Ohio

Man in his search for an ever increasing standard of living resorts to an expanding technology that often advances the boundaries of knowledge and productive capacity, but also generates potential problems and requires adjustment to additional stresses in our environment. One such tool, from which we have not yet realized the full impact or benefits, is nuclear energy.

One must not feel that man's exposure to nuclear radiation is a new innovation—commencing near the end of World War II or with the formation of the Atomic Energy Commission. Man's environment has included exposure since time began because wherever one goes, there is always a small amount of so-called "background" radiation. This "background" radiation arises from naturally radioactive substances; uranium and radium and others found in rocks and soils as well as the radon and thoron that are given off into the atmosphere.

In addition, cosmic radiation from space is present everywhere and of course, like the natural deposits of ores, the exposure varies from one location to another, depending on altitude. For 60 years, man has been exposed to man-made radiation in the form of medical and dental X-rays. In fact, many U. S. citizens, today receive approximately the same amount of whole body radiation from the average X-ray fluoroscopic examination as from natural background.

Therefore, it is obvious that the mechanism of radiation exposure is not new. Only the increase in use and subsequent increase in potential exposure is new. As an illustration, on May 31, 1957, the AEC had licensed a total of 4,041 employers to use radioactive isotopes, of which approximately 40 per cent of these licenses are industrial firms.

In hopes of dispensing with one of the more controversial issues, it can be stated that the average exposure to "fall-out" from weapons testing, if continued at the average rate of the past several years, would be only 1/40 of the genetically important exposure due to background alone.

With respect to weather there has been no evidence that nuclear energy or nuclear explosions have contributed to any changes in weather or climate. In fact, one comment heard recently probably explains the situation adequately; the early caveman felt sure that they had never had such strange weather until they started using the bow and arrow.

Medical X-ray facilities as used in industry today are familiar to all of us and everyone will agree that their diagnostic value far outweighs any detrimental effect that might possibly exist. The radiation received from a chest film is higher than any other exposure that might be received under normal operating conditions from other uses of radiation in industrial operations.

X-RAY INSPECTION TOOLS

Industrial X-ray facilities and fluoroscopes are generally of higher peak voltages and are utilized to examine or inspect equipment or manufactured items, such as belts or tires, for internal flaws or specification quality that cannot be determined visually or by other conventional inspection methods. Exposures with this equipment can be high unless adequate control procedures are employed.

Radiographic techniques are used for essentially the same purpose as industrial X-ray facilities, but are usually somewhat more mobile and are moved to the item under inspection rather than moving the item. These are high energy radioactive, gamma emitting, sources requiring no electrical power; radium and cobalt-60 being two of the more popular isotopes used. Care must be exercised with such usage to prevent exposure to operating personnel and others in adjacent areas. Distance factors and shielding are usually mandatory.

One of the outstanding applications currently in use in the rubber industry is beta gauges for determination of weight of films and thickness of items such as films, treads and calendared stock. Beta gauges usually use carbon-14 or strontium-90 as source materials with a measuring head that detects the scattered radiation and reads directly on a calibrated dial in the units in which interested.

Through proper circuitry this measurement may be electronicly coupled with the process to provide control and make necessary adjustments with better accuracy and less effort on the part of the operator. As customarily used, such devices while operating present no hazard to personnel in the area.

MAINTENANCE HAZARDS

During maintenance procedures on the gauge some consideration must be given to prevent unnecessary exposure. If an emergency arises, such as a fire, it might be possible for the source to be vaporized by the heat and contamination spread over a large area. It is recommended that periodic air samples and area surveys be conducted in the vicinity of such gauges to insure that the integrity of the source container is being maintained.

Tracer techniques are being used extensively in the research laboratories to study the physical and chemical reactions in rubber chemistry, particularly with regard to accelerators and anti-oxidants. "Tagged" compounds are made up containing various radioisotopes of carbon, sulphur and zinc.

These materials are handled in laboratory quantities and have contributed a great deal to understanding some of the basic processes involved in rubber compounding and technology. Their use is confined to individual laboratories where stringent cleanliness standards are maintained to prevent the spread of contamination. Waste disposal is monitored carefully so that radioactive materials are not released into public sewage or water systems.

IRRADIATION FACILITIES

Various irradiation facilities for research and development purposes are used in some companies and projects in conjunction with governmental reactors are popular. These facilities are used for testing properties of materials under the stress of high radiation density. Another promising application is to promote polymerization of various monomers and tires have even been cured by this method.

Sources range from multi-currier cobolt-60 sources to fission products from reactors. Extreme operating precautions are necessary for experimental work of this type including heavy structural shielding, safety interlocks and a full complement of personnel protective devices.

Anti-static bars employing alpha particle emitters such as prolomium are commercially available, and although not used extensively in the Rubber Industry, may have applications in some of the diversified operations conducted by rubber companies.

Future applications are numerous and undoubtedly many still beyond our present comprehension. Subsequent applications will necessitate that sufficient thought and planning be given during process development, engineering design and production use.

In order to receive radioactive materials legally in sufficient quantities to be potentially hazardous, it is necessary to be licensed by the AEC and meet the health and safety standards as outlined by Federal regulation. Furthermore, nine states at the present time have additional state registration requirements as a further safeguard. This means that an original installation then is a safe installation for the employee.

FEDERAL, STATE REGULATIONS

By the use of design criteria and operating procedures, audited by AEC inspection teams, the installation or use is kept safe. Personnel protective devices are utilized extensively, where needed, and include film badges, monitoring chambers, and dosimeters. Area surveys and air samples are performed by regulation to maintain the license, and at other intervals as indicated by operating difficulties.

Radiation exposure to personnel in the rubber industry is not a new environmental condition. The application of nuclear techniques to product development and process control can be adequately controlled so as not to present a hazard to personnel. The employee in this industry is not receiving significant radiation exposures at this time and the knowledge for prevention of undue exposure is available so that emergency planning can reduce or alleviate potential exposures that might arise from catastrophes such as fires or explosions.

The benefits to be derived from the use of nuclear energy techniques are tremendously greater than the risk of occupational injury with our present standards.▲

OFF-THE-JOB SAFETY

(Round Table Discussion)

EARLE R. GARDNER, Conference Chairman

We are having a lot of off the job injuries via the power lawn mower, hunting and home workshop. Statistics have proven we are losing a lot more production and causing human suffering by off the job injuries than we are by on the job injuries.

It is recommended that those of you who are not keeping records regarding off the job injuries should do so for you will be amazed at the amount of time your employees are losing due to off the job injuries.

One question asked was: What civic organizations as safety men or representatives of your local unions can you obtain help from?

Answer:

1. PTA
2. American Automobile Association (AAA)
3. Automobile traffic associations.
4. The garage associations.
5. The mayor's traffic committees.
6. Church groups.
7. From the ladies.
8. House organs.
9. Newspapers.
10. State Departments of Safety and Hygiene.
11. Union locals

Following is one of the suggestions on how to start an effective off the job safety campaign.

—An analysis of your experiences for one year.

—Disseminate information through your regular line of communications as you do on the job safety campaigns.

—Form on off-the-job safety committee.

—Form a family safety committee consisting of the wives and children of your employees.

—Hold a family safety month in your community and ask all the civic organizations to participate.

It was brought out that the automobile manufacturers are now putting the emphasis on safety and comfort in their products, rather than on horsepower.

The formula for measuring the frequency and severity was the subject of considerable discussion and it was found that there was a wide difference of opinion as to how this should be figured. However, it was generally agreed that the National Safety Council's formula was at least basic.

Suggestions of ways to reach the home with safety messages were:

1. Post the answers to safety questions on the bulletin boards in the shop and make phone calls to the homes with a cash incentive for the wife having the correct answers.
2. Mail the house organ direct to the homes.
3. Draw a comparison for the employees between plant safety and off the job safety, such as in plant trucking and traffic safety, machine shop safety, to the home workshop.

"Off the job" safety will keep the production lines rolling and families united and happy!▲

COMMUNICATIONS IN SAFETY

(Round Table Discussion)

T. J. CAIN, JR., Conference Leader

Report on Round Table No. 4—*"Communications in Safety"* by T. J. Cain, Jr.

Conference Leader: T. J. Cain, Jr., Director of Safety, The B. F. Goodrich Co., Akron, Ohio.

Conference Recorder: *N. C. Longee, Safety Supervisor, Passaic Plant United States Rubber Co., Passaic, N. J.*

T. J. Cain pointed out that we get from a conference what we put into it. In a few brief words he stressed the importance of effective communications and laid the groundwork for our work. He announced a prize of one dollar to be paid to the first one to utter the "magic word" which he felt was the real key to communications in safety. Each person was asked to stand, identify himself and name one communication medium he thought important:

—A weekly newsletter.
—Word of Mouth.
—Messages in the plant publication.
—Personal contacts.
—Daily memos.
—Daily reports of conditions, and follow up.
—Following established lines.
—Bulletin boards.
—Monthly meetings.
—Reports from line supervision to superintendents.
—Weekly meetings—use key men.
—Written reports to the top, sent back down the line as directives.
—Daily contacts—even by telephone.
—Boards showing comparative standings.
—Five-minute safety meetings.
—Post rules in departments, issue rule books.
—Contests.
—Direct communication with the worker.
—Direct communications, but through supervisor.

At this point the ideas began to emerge, and the following were added to the list: Safety book racks, slogan contests, letters to homes, cards to homes on special occasion, visual presentations, such as movies, sound slides, photo projection and safety workshops, a device the Union is beginning to use.

Glenn Gross of Firestone Co. used the magic word when he stressed the importance of listening to the other fellow, and getting his ideas. Cain was delighted to hand over the dollar prize.

John Kumpel AFL-CIO urged that material be presented in a clear, dignified, forceful and attention-compelling way. Mobile displays and message tapes were suggested. Cain reported briefly a contest that ended in the low man serving as valet for the winner at the Congress.

Kumpel said the URW has a film library in great demand. He commended the film, "It's In The Cards." It was noted that the National Safety Council is a good source of safety films. Among other visual aids to communications, Cross uses a 16 mm camera and makes his own films; some plants are using Polaroid cameras, equipped to deliver slides; Dale Knox of Dayton Rubber, uses a display of safety shoes that have saved toes.

Some plants hold meetings on company time; others have special arrangements. J. M. Papp, of Goodrich, suggests that at *any meeting, you will learn more by listening* while the men talk. Cain noted that an intentional error checks on whether or not a report has been read. Cain also recommended that symbols used in a report be explained, in case the message doesn't get through.

Cain stressed the importance of a plan for use to combat rumors, in case of disaster. Public relation is extremely important.

Cain read off a number of ideas represented by various displays and recommended we look over the NSC exhibits for more. Although ideas were still coming in, time ran out and Cain closed with the point that "what we do is more important than what we say" when we are trying to communicate with people, and that one of the best things to do is—listen to the other fellow.

THE HUMAN FACTORS IN SAFETY

by ROBERT L. CRANE

manager, Supervisional Training, The Goodyear Tire & Rubber co., Akron, Ohio

Goodyear Tire and Rubber company emphasizes safety through programs in supervisional training conferences, and the safety department.

A program, entitled "The Human Factors in Safety," was presented to approximately 3,000 supervisors in 15 Goodyear plants. The program consisted of four, one-hour sessions and stressed the importance of supervisors' using good *human* relations in accident prevention. We have had programs on human relations, and many on safety. But this was the first attempt to tie them together in one program.

The three objectives in putting on the program were:

1. To help supervision recognize the types of behavior that frequently lead to accidents.
2. To help supervision analyze daily reports for accident prevention.
3. To emphasize that good human relations plays an important part in accident prevention.

We started the program with a review of the four foundations for good relations which we and a good many other companies have stressed in human relations programs:

- Let each person know how he is getting along.
- Give credit when due.
- Tell him in advance about changes that will affect him.
- Make the best use of each person's ability.

LEARN EMPLOYEES' PROGRESS

In session one, we concentrated on the first foundation. Let each person know how he is getting along—safety-wise. But first we must know how our people are doing safety-wise. There are two major sources of information that can help supervision *find out how their people are doing:*

1. REPORTS

The reports available to supervision are:

1. Foreman's reports of injury
2. Hospital or first aid reports
3. Attendance reports
4. Production reports
5. Quality reports

In our sessions we discussed how each of these reports can help us prevent accidents. For example, foreman's reports point out: accident repeaters, hazardous operations and violations of safety rules.

Attendance reports reveal conditions of health that lead to accidents, or that people are having difficulties at home. Production and quality reports may point out poor job conditions or personal problems of the employee. These reports can give us a lot of information *that will help us to build* a road to a better safety record.

2. BEHAVIOR

However, reports are not the entire answer to accident prevention. The other source of information is the behavior of our people. There are seven types of behavior which are accident hazards:

1. Anger
2. Indifference
3. Confusion
4. Fatigue
5. Carelessness
6. Daydreaming
7. Worry

We ended the first session with a discussion of what action can be taken when these types of behavior are observed.

Session two was devoted to the 16 safety rules of our company, because to let a person know he is breaking a safety rule we ourselves must know what the rules are.

To give credit to our people for following the safety rules we must know what the rules are. So we attempted to get our supervision thoroughly familiar with the rules.

We used this technique: We picked the key word out of each safety rule and put it on a three by five inch card. One safety

rule says *not to use air hoses to blow off our clothes,* so we put the words *air hose* on a card.

We distributed these 16 cards to the conferees, and in discussion asked "Who has the card that says "*air hose*?" when somebody raised his hand, we asked what the safety rule was about air hoses. Normally they came pretty close to the rule, and we discussed each rule and its importance. The conferees brought out many examples of accidents that happened because the rules were broken.

LOCKING-OUT RULE

Session three was devoted to one of the safety rules: "The zone engineer or engineering supervisor is responsible for properly safeguarding against dangerous conditions developing during the progress of a repair job." The area of safeguarding machines from being started when being repaired is potentially very dangerous.

In our company some machines are quite large, extending three to five stories high. It would be easy for a worker to start such a machine when someone was working on it, if proper precautions weren't taken.

To drive home the necessity for "locking out" a machine *every* time it is worked on, we showed a film, "It's in the Cards," produced by the Abitibi Paper co. of Canada. In our conferences we asked the conferees to note the behavior of the people to see if they could pick any of the seven types we discussed in session one.

We concluded the session agreeing that it is important to observe the behavior of our people to prevent accidents.

PERSONAL TRAITS EMPHASIZED

In our last session, we discussed how people are both different and alike. Sometimes we overlook that people are so different, one from the other. To demonstrate this the conferees participated in a little experiment. We gave them a number and asked them to double the number and then re-double as far as they could go in 60 seconds.

After the minute was up, we read correct answers and asked them to mark on their paper how many times they had doubled the number correctly. In every class there was a terrific range from a low of two or three times up to 20 or 21 times. It was pointed out that this large range of differences was true in any group of people for any ability trait or characteristic.

We discussed the people who would most likely cause problems, and concluded that most problems would come from those at either extreme of the range. Then we said that although every one is different, there are distinct and similar types of personalities.

Five of the common types of personality that can cause difficulties are:

1. The fellow who is sloppy
2. The tough guy
3. The show off
4. The loud mouth
5. The practical joker

The ***sloppy man*** is frequently lazy, leaves things lying around. *The tough guy* thinks safety is for sissies. He's the fellow who runs the machine with the guard off. He's much too tough to get hurt! The *show off* is interested in calling attention to himself. He will take chances to get people to notice him. The *loud mouth* attracts attention to himself by telling others how to do their job. He's the authority on everything. The last one, the *practical joker* can give us a pretty rough time.

The problem is not how to recognize them but how to handle them. The session ended with a summary of the four sessions and the four foundations for good relations. Any house of safety would have to be built on these four foundations:

1. To let each person know how he is getting along, supervisors must know the accident, hospital, attendance, production and quality reports with an understanding through observation of the behavior of our people.

2. To give credit when due, supervisors should have an attitude of fairness and sincerity.

3. To tell people in advance about things that will affect them "safety wise" they must know the safety rules.

4. To make the best use of each person's ability they need skill in leadership remembering that everybody's different and recognizing that people must be treated as individuals.

These are the foundations upon which any house of safety must be built.

OFFICERS OF THE
GLASS AND CERAMICS SECTION
NATIONAL SAFETY COUNCIL 1957-58

General Chairman—RUSSELL FRANK, Ferro corp., Cleveland, Ohio.

First Vice-Chairman—CLYDE C. RUDDICK, Pittsburgh Plate Glass co., Pittsburgh, Pa.

Second Vice-Chairman—JOHN V. SKENDALL, Harbison-Walker Refractories co., Pittsburgh, Pa.

Secretary—EDWIN L. WRAY—Ball Brothers co., Inc., Muncie, Ind.

Program Committee Chairman—THOMAS R. DONOGHUE, Pittsburgh Plate Glass co., Pittsburgh, Pa.

Membership Committee Chairman—A. H. BURKETT, Owens-Illinois Glass co., Libby Glass div., Toledo, Ohio.

Engineering & Health Committee Chairman—W. G. HAZARD, Owens-Illinois Glass co., Toledo, Ohio.

Newsletter Editor—RUSSELL FRANK, Ferro corp., Cleveland, Ohio.

Safety Promotions Committee Chairman—JAMES L. MORRIS, The Federal Glass Co., Columbus, Ohio.

Safety Contest Committee Chairman—JOHN V. SKENDALL, Harbison-Walker Refractories co., Pittsburgh, Pa.

Associations Committee Chairman—WILLIAM KOPPUT, Owens-Corning Fiberglas co., Newark, Ohio.

Off-The-Job Safety Committee Chairman—KARL STEINKRAUS, Owens-Illinois Glass co., Alton, Ill.

Staff Representative—J. E. CROUSHORE, National Safety Council, Chicago, Ill.

OFFICERS OF THE

RUBBER SECTION

NATIONAL SAFETY COUNCIL 1957-58

General Chairman—C. E. BECK, St. Clair Rubber co., Marysville, Mich.

Vice-Chairman in Charge of Program—M. R. BATCHE, Firestone Tire & Rubber co., Akron, Ohio.

Secretary—W. J. DOOLING, B. F. Goodrich Footwear and Flooring co., A div. of The B. F. Goodrich co., Watertown, Mass.

Newsletter Editor—A. R. POMEROY, The Ohio Rubber co., Willoughby, Ohio.

Engineering Committee: Chairman, N. C. LONGEE, U. S. Rubber co., Passaic, N. J.; ED TURNER, The Goodyear Tire & Rubber co. of Canada, Ltd., Toronto, Canada; A. B. MAINES, Republic Rubber div. of the Lee Rubber & Tire corp., Youngstown, Ohio.

Health Committee: Chairman, R. H. WILSON, M.D., The B. F. Goodrich co., Akron, Ohio; W. L. HOGUE, M.D., The Firestone Tire & Rubber co., Akron, Ohio; W. A. McCAUSLAND, M.D., B. F. Goodrich Footwear and Flooring co., A div. of The B. F. Goodrich co., Watertown, Mass.; F. W. SANDS, U. S. Rubber co., New York, N. Y.

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

THE HOME SAFETY CONFERENCE

This volume is a record of the sessions held at the 1957 National Safety Congress by the Home Safety Conference. The conduct of these Congress sessions each year is only one of the many cooperative activities which the Conference carries on in behalf of its members, and for the benefit of accident prevention work in the home. The Conference gives guidance in the preparation of a great variety of technical and educational material useful in the day-to-day safety programs of the home.

The activities of the Conference are under the direction of its executive committee, the members of which are listed at the close of this volume.

HOW TO INTEREST PEOPLE IN WHAT THEY DON'T WANT TO KNOW

REMARKS OF FAIRFAX M. CONE

chairman, Executive committee, Foote, Cone & Belding, Chicago

I know almost nothing about the organization of your work for safety. I can only talk to you a little but out of a fairly long experience in selling, and most of this through advertising.

But it just may be that advertising, properly planned—with the right appeals, and done according to certain standards, can be important in reaching certain objectives.

The thing here, as everywhere, of course, is how advertising is used. For advertising without a plan is no better in most cases than no advertising at all. I am not at all sure that advertising of the means and the rewards of safety—in any of its areas of interest, can ever be wholly planned.

There may simply be too many well-meaning people and dedicated organizations at work in the field—each going his own way or its own way, to make possible the unified planning that makes good advertising effective.

On the other hand, advertising may be helpful. For advertising is one of *our* most powerful means of communication. And it is our only controllable one. It is the only one where you or I can say what we want to say, when and where we want to say it—without change and without interference. The great problem is to make advertising, in cases like this one, a part of a plan. When you can, few means are more productive.

PLAN ADVERTISING

Over a long period of years, ever since I was a little boy, the press and the periodical press, and later the radio—and, still later, television, and pastors and priests and rabbis, all worked at the problem of voting. And all that happened was: the percentage of eligible voters who went to the polls declined —steadily and drastically.

The best selfish reasons that could be presented were of no avail. The trouble was that there actually were too many arguments. No one could hear any of them, or see any of them, because of the din of the sounds and the confusion of all of them.

There was nothing wrong with those arguments; in fact, they were very good ones. But no *one* stood out. There was no voice of authority; no single command. And I think this is a little bit like our current campaigning, for instance, for traffic safety.

It needs not more money to be spent or more people to be interested in it; but only more planning.

This is what happened to getting out the vote.

One simple idea—"See you at the polls," became the slogan and the selling idea for everyone who was interested: radio, television, press and pulpit, and millions of school children working on their mothers and fathers—did it.

CAMPAIGN GOT VOTERS

A single campaign turned the tide; voting increased everywhere in the country in 1952. A repeat of that campaign, that single theme, further increased the vote in 1956.

Now, I certainly cannot tell you what the theme of an advertising campaign for traffic safety should be; or how much or what kind of an organization would be required to successfully back it up. But I can tell you that various efforts under a variety of auspices at varying levels of intensity are not the best way to sell anything.

There are right ways and there are wrong ways and, in between there are indifferent ways. What is worst of all are the misguided ways; and these, more often than not are the uneducated ways; the amateur ways.

The men and women of the National Safety Council are professionals. I think they can do no better as a starter than to try to rule out the amateurs.

Sticking to traffic, as an example, I would hope that you could regulate signs and no-

tices, and establish professional standards. Here are two examples of what I mean.

Anyone who has driven on Chicago's Outer Drive has seen what is surely one of the most oversigned roadways in the world. Almost every lamp post carries some kind of message. Highway numbers are easily confused with speed limit signs. And almost every overpass is decorated with highly embellished warnings to drive carefully.

So highly embellished are these, with so many different messages, in so many kinds and sizes of type, that to read them surely must create a traffic hazard in itself.

SIGNS CAN BE HAZARDS

Every time I see one of these I am reminded of another traffic safety sign that I saw on a narrow, twisting road in Sonoma county, California, between Petaluma and Rio Nido, on the Russian River. This was on the back of a billboard structure that faced north.

Coming from the south I saw a line of white letters on the dark back of the structure, letters about five inches high, and when I got right even with them, peering across the road, I was just able to read—in the face of oncoming traffic:

"Drive safely, the life you save
may be your own!"

I have no doubt of the good intentions of the man who painted those words on the back of that billboard structure. But I also have no doubt that the result could be awful.

Incidentally, on that same drive, crossing the Golden Gate Bridge from San Francisco to Marin County, I saw what I believe is an example of very good signing. There are exactly three signs on that span; three each way, that is.

—One large one posts the speed limit.
—One medium-size one marks the county line.
—One other large one says: stay alert.

And there isn't any picture to distract you from the words.

Let me say again that I don't know whether any standardization is possible, either in the design of highway signs or in their wording.

But if there could be generally (much as there is beginning to be on the toll roads) the results would be startling. They could have some of the effect there that consistent advertising has for products and services whose worth is nothing compared to human lives.

I believe the same kind of planning of factory and plant signs—and perhaps even home safety instructions, backing up your best educational efforts would be no less effective.

STANDARDIZE ADS

The thing is to standardize—on professional standards.

I can give you no better example of what this may mean than the campaigning against forest fires since 1941. My own company happens to have made the very first outdoor posters with Smokey Bear. We also made the school posters, the radio warnings and the television films.

And we've made them to a single standard, for a single integrated plan, mapped out with the forest service of the U. S. Department of the Interior.

Last month I heard Richard E. McArdle, chief of the U. S. Forest Service, tell the story of results. Up to 1942 the number of forest fires was increasing rapidly. Then there was a sharp decrease. During the war years there were many fewer people in the forests. However, at the end of the war there began a greatly stepped-up activity—more visitors, more timber-cutting, more land-clearing and road-building; and the number of fires increased sharply.

SMOKEY CUT FIRES

Now the Forest Fire Prevention campaign took hold. Approximately 350,000 fires a year were expected at the time and there were less than half of that number. In 1942 fires blackened 30 million acres of forest land. By 1956 this figure was down to six million.

During the 15-year period of this campaign, McArdle said there was a total of 600,000 fires expected that did not start. There were 260 million acres of forest land that did not burn according to schedule; and there was 10 billion dollars of forecast damage that did not occur.

The timber and water and wild life saved and soil preserved passes any possible dollar estimate. This was the savings through the kind of planned warnings and planned national campaign that I hope may some day be yours.

REMARKS OF PIERRE MARTINEAU

manager, Research & Presentation Division, Chicago Tribune, Chicago

One of the most battered cliches in the world of the social sciences is "the individual as a whole." Educators talk of "teaching the *whole* child"; psychologists mention the "personality as a *whole*"; and sociologists stress "the relationship of groups to the *whole* person."

In talking about the individual as a *whole*, however, the exigencies of language force us to talk of sections of the personality—we speak of "knowledge," "information," "interests," "needs," "predispositions," "beliefs" and "attitudes." As men have sought to understand personality and the reasons why other men behave the way that they do, there has been a compartmentalization due to these words—an isolation of "factors of the mind."

TERMS ARE THEORETICAL

To be sure, writers always add a preface or foreword that states something about the dynamic interaction of various factors, but when the chips are down, the conversation usually turns to a description of how a particular "belief" or attitude," by itself, influences what somebody or some group does.

Just as there is no such thing as an ego, so too is there no such thing as a need. All our terms are only theoretical guesses about what exists within the churning mass of a man's brain. We shuffle explanations and regroup hunches; we alter relationships and construct systems of behavior that we think does a better job of explanation.

But we always have to remember that there is no surety that we are correct. The responsible social scientist is always sensitive that it is a dull knife with which he is cutting the pie of personality and the explanation of behavior.

The great contribution of Freud to the social sciences was that he sharpened the knife, and by so doing, changed the distribution of slices. But many of Freud's followers have been overly rigid in their view of behavior—just as the more "scientific" camp has been overly rigid in so precisely looking at factors that they have forgotten where the factors came from.

CONSIDER THOUGHTS, BEHAVIOR

I suggest that we take the largest possible overview of behavior. Men's thoughts and their behavior—and change in their thoughts and behavior—have two major influences on them. The first of these is what the individual man wants to do. At the simplest level, when he gets hungry, he wants to eat—no nonsense about it. But every time a man is hungry, he doesn't eat. And when he doesn't eat, it is because of the way that he sees the world around him.

A man having a job interview doesn't pull a candy bar from his pocket in the middle of the interview—even though his stomach may be growling away; it isn't the thing to do at this time or in this place. The world outside the individual brings pressures to bear on him—pressures that modify what he can do, the ways he can do it, and when he can do it.

If we want to change behavior—that is, to influence people to do something they are not doing, and to tell them things their ears are closed to—we should try to understand how the two considerations of individual wants and group pressures relate to each other.

INTERPRETING COMMUNICATION

Take a common piece of behavior and communication—a friendly face to face conversation. Going into the conversation, each member already has ideas about the other—his habits of speech, his status position and power, an evaluation of him as a man.

When A says to B "nice job you did," B immediately interprets the message. Is he really giving out congratulations, is he being patronizing, or is he saying "It's about time you did something good"? The past experience of the two men will give the listener the cues to interpret the message.

A's meaning may be greatly distorted, but it is the interpreted meaning that B will act on—not the intended meaning. With the interpreted meaning now serving as the "motivator to action"—the listener will come up with a reply. He might say to himself "of course," or "Thank goodness" but this will not be his reply. Just as the message

was altered in meaning, so too will the reply be altered.

If A was president of the firm, the answer might be "thank you, oh sir." If A is a mailboy, the reply might be an impatient nod. The output will be modified and distorted just as the input was. The *effect* of behaving the way that you *want* to behave to the answer will be weighed, and your reply will depend at least on these two levels of interpretation.

This is a theoretical example of a situation in the smallest possible group. Let's look now at an experiment which shows the same skeleton form of behavior in a larger group and with a message that had little appeal to the audience.

GROUP BEHAVIOR

During World War II, there was a strong movement urging housewives to serve cheaper cuts of meat. For the most part, the early parts of this campaign were a flop; housewives did not want to, and did not serve kidneys and beef hearts—these foods did not fit into their image of the good housewife. In order to convince housewives—to tell them something they didn't want to know or do, a social psychologist experimented with two different approaches to selling the idea of serving sweetbreads, kidneys and beefhearts.

With one group, he had an authority—a sweet, motherly home economist—lecture a group of housewives about all the advantages of these foods. The economy, the nutrition, savory methods of preparation, and the contribution to the defense effort were all mentioned. This home economist talked, and the housewives listened. The end result was that 4 per cent of the housewives served the foods that they were informed about in a convivial lecture.

DISCUSSION GROUP EFFECTIVE

Another group, very similar to the first, had the same information presented to them —price, economy and so on. But the technique was to give them a short talk first and then a discussion period about how husbands would react to the foods, cooking odors, and any other questions that the housewives felt were important.

This group—the discussion group— had *eight times* as many housewives go out and serve the food to their families as the group that was just told about all the benefits of sweetbreads.

The information communicated was the same in both cases—the knowledge that the women had was the same—but this startling difference came about. The explanation that has been given centers about the interpretation that the housewife gave to the *results* of serving the food. No matter how "right" she felt serving brains, or how "good" it *would be for her family*, the basic consideration was the acceptance of the food by the family.

In the group discussion situation, the sharing of the problem with other housewives showed up the individual housewife's concern—and the group gave her the confidence that she would not look worse in her family's eyes for serving the food; at *least, she would be no worse off than other* women in her same position.

The same man, Kurt Lewin, showed that the same results could be obtained with as important an area as a mother's wish to take good care of her child. The value of serving orange juice to infants was presented in the same two methods and the same findings occurred. Those who just *heard* about how good orange juice was for babies did little about it; those who discussed serving orange juice actually did do something—they were positively influenced to serve orange juice to their children.

FEAR MOTIVATES SAFETY

These are both examples of how relating the knowledge to a group situation activated *the knowledge—made it a stimulus to* behavior instead of idle thought. Information alone never sells a thing—information must have with it a catalyst that will produce action, which, directly or indirectly, is the goal of most communication.

Safety is centered around fear; we don't take safety measures because there is some inherent value in being safe; we are safe because we are afraid of being hurt or hurting others.

Advertising and promotion in prior safety campaigns have played on the fear element and "you can't afford not to be" has been an outstanding example of this.

Fear is a necessary part in the selling of safety ideas, but to be effective, the proper

amount of fear has to be injected into the communication process. If there is too much fear, the listener will be repelled by the whole business. If there is negligible fear, he won't be disturbed enough to do something about the threat that you present to him.

To be most effective, the appeal must first arouse anxiety and then present a believable solution to the problem.

One of the major advantages of using fear is that it is an emotional *rather than* an intellectual or rational approach, and is thereby more powerful in stirring up feelings.

EMOTIONAL APPEAL BEST

Lewin's studies, and the experience of many advertisers, shows that information alone is not enough. The cancer threat in cigarettes has not harmed long term sales; in politics a study has shown that an emotional appeal produced a 15 per cent greater vote for a party than an identical appeal which was rationally based. Information is necessary, but it can never be relied on to carry singly the burden of influencing others.

A famous study in dental hygiene shows how the strong emotional approach of fear and various intensities of fear influence the receivers of a message.

The same dental health information was presented to three different groups. The first group was given a strong fear approach —the showing of gory pictures, dire threats and the like. The second group was given a more moderate dose of the same treatment. The third group was presented with material in a low fear setting. The result? The low fear group showed a 36 per cent improvement toward better hygiene, the moderate fear group a 22 per cent improvement, and the appeal in a powerful fear setting produced an 8 per cent improvement. Four times as much success with the low fear approach as the high fear approach.

But this was not all. The three groups were followed up and all were exposed to information that belied everything they had been told about dental hygiene. Despite this contrary evidence, the low fear group still believed what they had been told first. But, the moderate and high fear groups switched their allegiances to the last message.

Thus, in terms of both long and short term results from the message, the low fear setting was far superior to the other two treatments. Powerful tool that it is, fear cannot be used indiscriminately.

COMBINE GROUP, FEAR FACTORS

Both the group and fear can be effectively united in a campaign to further safety. We know that fear is powerful if used properly, and we know from observation how important others are to an individual's ideas about safety.

Consider a man driving. It is quite likely that if his wife and children are with him, he will be more careful—and not just because of the wife's nagging. He may be devil-may-care and ignore the skull and crossbones signs, when he is alone, but the presence of his family forces him into a responsible role.

To some degree, all of us have a sense of "personal invulnerability." But the sense that nothing is going to happen to me—the sense that makes for carelessness and accidents—can be short-circuited by arousing the important image of the family.

Now, this won't be easy. The home particularly is a haven from the struggles of the world—a safe place to retire to at the end of the day. If too strong a campaign were used, the campaign ideas run headon into this idea of the comfortable retreat.

EXPLAIN JOB, HAZARDS

Better to state positively to the man his job—that of providing a safe place to live for his family. Shore up his confidence in *this*. Then inject a little fear by pointing out the common accidents in the home and on the road.

After he is slightly concerned, offer solutions that will eliminate the concern. The safest (psychologically) of all places—the home—can be made even more safe.

The feeling of safety can be sold at the same time that responsibility can be sold. The *individual is reached on two levels*— his own personal, and individual state of well being and his job to the group, his family.

It is more difficult to communicate via one of the mass media than it is on a face to face basis. But practical considerations force us to think in terms of the mass media.

SELECT RIGHT MEDIA

Use media that have high prestige. It has been found that a message gains a great deal from the "ruboff" or association with the media in which it appears. To increase believability and impact in your message, a solid and serious television show would be better than situation comedy; the major newspaper in a city would probably be good, as would be association with a high status commentator—say Edward R. Murrow.

There is a greater risk in television than in other media of arousing too great a fear. Go soft on the more blatant results of carelessness; imply them, but don't show a distorted man hanging from a car.

The running media of radio and television can offer a good deal in sequential development of the "fear then resolution" idea. The print media (magazines and newspapers) can give more weight to your message by nature of the public's perception of them. The broadcast media are primarily light; the print media are primarily heavy.

Basic to every man is his allegiance to himself and to his group (be it family or friends or community). The most successful communications will be those that play on both allegiances; communications that offer to the man as individual greater happiness and to the man as group member a more adequate filling of his responsibility.

REMARKS OF VICTOR M. RATNER

vice-president, Benton & Bowles, New York city

Let's start with some specific questions, for example: "Is it possible to interest people in what they don't want to know?" Or:

"In order of importance, which of the following have the greatest positive reaction, from the standpoint of safety precautions: pictures, the written word, the spoken word or personal experience?"

And just one more, of the many questions received: "Are mass media effective in influencing a change in people's habits, to the same degree as in the purchase of something which gives immediate satisfaction?"

"Is it possible to interest people in something they don't want to know?" The answer is "*Yes*"—in almost every case.

"What creates the greatest positive reaction . . .?" I would place "personal experience" and "face-to-face" communication so far ahead of the "written word" and "pictures" as to put them into separate categories.

Furthermore, I would suggest that—in such a complex area as safety precautions—you cannot begin to move people very much or very far with the "written word" and "pictures" alone, unless these are somehow used *together with* "personal experience" and "face-to-face" speech.

As for our third question: "Are mass media as effective in changing people's habits, as they seem to be in getting people to buy specific merchandise . . .", my answer, here, would be a large and flat "*No.*"

EVERYONE WANTS TO KNOW

These may guide us toward answering almost any question. Let's look, then, at the first question again: "Can we really interest people in anything they don't want to know?"

If we stopped at that, the answer, of course, would be that we cannot. But this needn't be discouraging. For Aristotle pointed out, a long time ago, that *"all men have the desire to know"*—and this is true, even if it be only a desire to know who is going to win next Saturday's football game.

Certainly, every normal human being *is* interested in many things. Certainly, he is interested in himself and in his family. And just as certainly, the real question you face is, "How can I best relate what *I* want to say to something he is already interested in?"

If you can, you can reach him, and you can teach him. But you must realize that this is a two-step process. You must first take the trouble to interest your man. And then, you do your teaching.

Putting this another way—one of the axioms of effective communication says that: "You must start with where your audience is, not with where you are." And surely, anyone you are trying to reach has some interest, some need, some desire, to which you can relate yourself and your message; something in which he is interested, rather than something in which you are interested.

RELATE TO NEEDS

You must find this need or desire, and use it to anchor an emotional or intellectual "bridge" between you and your audience. You then send your message to them over this "bridge." If you don't, it's as though you are shouting from bank to bank across a wide river. This is fundamental to all teaching and all selling, whether you're selling a man a new house, a new car, a new hat . . . or a new idea.

The basic act of selling is to try to relate something to someone else's need or desire. You must make him feel that this something will serve one of his needs or desires—or why should he buy what you have to sell, whether it be "better schools" for his community, or a brand of beer, or even the Brooklyn Bridge?

You see, I am not discussing the morality of selling but the act of selling. Until you *have figured out what need or desire* you can serve in someone else—and until you state it convincing to him—you cannot begin to sell a person, or even interest him, in anything.

This reminds me of something I once said while discussing a curious prejudice about the power of advertising. Oddly enough, it is a prejudice in favor of advertising, in the minds of its friends, and simultaneously, a prejudice against advertising, in the minds of its critics. It is the often-repeated claim that *"advertising creates desires."* Or, stated negatively, *"advertising makes people buy things they don't want."*

ADS DON'T CREATE

I think both the friends and critics of advertising are repeating a myth which has no substantiating data behind it. They have only hunches and opinions about it.

Advertising, I am convinced, cannot create a desire. It can only capitalize on an existing one. Thus, advertising which sold orange juice to mothers, derived its inherent power out of the desires mothers have to feed their children well. That desire was there, long before advertising or orange juice.

Such advertising told mothers about a new and healthier way to feed their children—a useful educational function, but not the creation of desire.

Does anyone think advertising "creates the desire" in women to look more beautiful or to wear new clothes?

This is something which started, I believe, in the Garden of Eden. And I refuse to think of the serpent there, as the first advertising man!

It's much the same with automobiles and washing machines, and even beer. People have basic desires for such things. That's the only reason advertising can help to sell them.

Similarly, you must effectively relate the important story you have to tell to some *basic desire* of people—in their terms, not your terms—and then you can hope to move them.

But let's try to get even more fundamental than this, in analyzing just what it is your communications must try to do. Where do you start, when you're planning any type of communication? If you want it to be effective, you must begin (either consciously or unconsciously) with a full realization of the fact that all communication has something very like the structure of a sentence.

ELEMENTS OF COMMUNICATION

A sentence, as you know, always has a subject, a verb, and an object.

And the meaning of each of these influences and modifies the meaning of the others; and of the sentence as a whole. Therefore, even a slight change in any one of these can make quite a drastic change in the meaning of the sentence.

Consider, for example, a sentence as simple as "John loves Mary." You could probably write a whole novel about changing just one word here: "John loves Sally." You see, Mary is John's wife. And Sally is her sister! Or change it to: "Jim loves Mary."

The confusion is compounded. Jim is Sally's husband! You see how intimate the relation between the subject and object can be? What does this suggest about "communication"? Well, like every sentence,

every communication has three elements—each of which determines the meaning and values of the other two.

There is a subject—which is the "content" of your communication, what it is you want to say.

There is the "form" in which you say it—how you express and transmit the "content," which includes both the medium and the words you use.

And then there is your "audience"—the object of your communication.

RELATE THE ELEMENTS

Obviously, until all three of these—"content," "form" and "audience"—are carefully and successfully related to each other, your communication is not likely to have the result you want it to have.

What you have to say must be properly and precisely related to your "audience."

How you say it must be properly and precisely related to both your "content" and your "audience."

When these three are not effectively related the communications fail tragically short of communicating. It is here, I think, that we find the fundamental differences between an amateur communicator and a good professional communicator.

The amateur is generally in love with his message. He tells it in his own way, in media of his personal preference. He is known as "message-oriented." He feels that what he has to say is so fascinating and important that everyone will drop everything to listen to it and absorb it. Your children are such amateur communicators.

The professional communicator, on the other hand, tends to be as much "audience-oriented" as "message-oriented." He is always conscious of whom he is trying to reach, of how that person thinks and feels, and he directs his efforts, shapes his message and his media as best he can to fit his audience.

To do this, he must start with his audience in mind. That, I think, is where all persuasive communication must start. You, too, can start with rather precise definitions of just whom you can realistically expect to reach. This is never the "many" people you would like to reach. It should be, rather, the "few" people you can really hope to reach.

AIM FOR SMALL AUDIENCE

I would earnestly suggest that, in your communication efforts, you aim for a small success rather than for a glorious failure. The small success will be hard enough to come by!

To do this, you should start with defining some small audience on whom you can hope to make a significant impact. The smaller the better! For, then, you can more specifically define your audience and its interests. You can learn, or guess, what is particular to these people—and you can then relate your message to their particular feelings, rather than your own.

This brings us to the question of the best media for reaching them—and here you run into all sorts of myths and fantasies about our modern communication media.

What I am about to say, now, may sound unorthodox to some of you. And it may sound paradoxical, coming from the vice-president of a large New York advertising agency, who also spent 14 years working for a major network.

All I can say is that I am serious; and that I am prepared to debate the validity of my observations until all our citizens really learn how to avoid having accidents at home.

Our mass media—our so-called "major media of communication"—are relatively minor media, when it comes to moving serious ideas into the heads of people.

They have, I believe, only a secondary role to play in helping you with your problems; and it is important that you do not divert too much of your limited resources, chasing after these media. They are not the first or second or even third media you should think of, to reach people, and to teach them serious things for their own good.

PURPOSES OF MEDIA

The basic reason I say this can be summed up very simply. Our mass media are busily at work doing three different things:

They move entertainment.

They move merchandise.

They move ideas.

I place them in that order because this is the order in which we are successful with them.

Our mass media are most effective, today, in distributing entertainment across the nation; whether in the form of popular programs on the air, or by comic-strips in the newspapers—the most widely-read features of any newspaper.

They are next most effective in moving merchandise into people's heads and homes. And our mass media, in themselves, are least effective in moving serious ideas to the public. The evidence for this is overwhelming.

This should not suggest to you I am criticizing our mass media. I am not. Like everything else, they are designed to do some jobs very much better than others.

We will not try to examine the reasons why I am sure that mass media are intrinsically weak media for moving serious ideas into people's heads, deeply enough to change people's behavior.

PERSONAL CONTACT BETTER

While they have a role to play, in this area, it is a secondary role, not a primary one. And it will be far more useful to you to direct your attention to what really is your primary medium for the work you want to do.

It happens to be the most powerful and most effective communication medium at anyone's disposal. If I were to try to wrap it all up into one phrase, it would be:

Face-to-face communication

All of you live and work in communities. You all live locally. Because you live and work in communities, you can all participate in, create and further "community action" programs of one sort or another.

In these, you can all use "face-to-face communications," with small groups of people, who are gathered together in one room, where they can see and hear each other talk.

The only hope of moving serious ideas into people's heads effectively, is for us to set aside the seduction of our modern, technologically-advanced, mechanical media—and to refocus our attention on the basic, old-fashioned methods of "face-to-face communication." This is still the only way most people get most of the ideas which move them!

Therefore, my basic recommendation is this:

- If you really want to teach people something, you cannot take "short-cuts" in doing so. The results we get from the "short-cuts" don't seem to warrant the time, effort and expense we put into them.
- If you want to take your efforts seriously, you must figure out ways to communicate with people in small groups, where there is a "live" discussion, among people gathered together in one room.

I know you can only reach a relatively few people this way, compared to the thousands and the millions you think you might reach by television or newspapers or magazines. And I know it is very difficult to develop such programs, and that they have little glamour about them.

It would, indeed, be nice if we could take the "short-cuts" to reaching lots of people, in lots of places, all at the same time. But even if you could get enough time and space in the mass media, beyond your wildest dreams, there is really no good evidence I have ever seen that such "short-cuts" to the people would work for you.

THE NEED FOR RESEARCH IN HOME ACCIDENT PREVENTION

REMARKS OF FAY M. HEMPHILL

associate professor, School of Public Health,
University of Michigan, Ann Arbor, Mich.

Many constructions and connotations might be attached to this topic. As long as 28,000 deaths a year in the United States are attributed to accidental circumstances which terminate in home injuries, there is need for research in the prevention of home accidents. Therefore, rather than discuss an obvious topic, I will present the needs which must be filled to have fruitful rewards from research in this domain.

I shall use the word *research* as defined in the dictionary, that is "studious inquiry or examination, critical and exhaustive investigation or experimentation having for its aim the discovery of new facts and their correct interpretation."

MUST DEFINE TERMS

The word *survey* will be used in its dictionary context also, namely "to take a general or comprehensive view of" or "to view in detail." I will use the words *studies* and *investigations* when I wish to refer to surveys and/or research and thus to generalize.

Clearly the mere enumeration of items and/or events does not constitute research; a survey may have objectives but rarely, if ever, does this objective deal with the test of an hypothesis. Experiments traditionally test hypotheses. I point out these concepts to call attention to the necessity for clear and concise terminology in any discussion of the needs for research.

The needs for research in preventing home accidents are not basically different from those for research in any other field. The problems of research in accident prevention are not as complex as those of nuclear physics or in making a vaccine against poliomyelitis. Only a few years ago the suggestion of releasing the energy of the atom was considered an impracticability and only five years ago there was little real hope of producing an effective vaccine against polio.

While both accomplishments have occurred through research efforts, each resulted from compilations of many items, experiments, survey efforts and observations. Within a general frame of reference, the needs for research fall under the following four categories:

1. A framework of terms, definitions, and concepts within which hypotheses and objectives may be developed.
2. A background of observations and experience from which opportunities for research may be fabricated.
3. Persons skilled in techniques and methods of research and motivated to organize and administer these skills.
4. An environment conducive to pursuing research activities, encompassing physical facilities, equipment, and financial support for continuing investigations.

This is only an attempt to suggest the needs which must be met for success in research. These suggestions are neither meant to be exhaustive nor detailed. The details must be spelled out by research persons.

NEED SPECIFIC CONCEPTS

Until quite recently there was no coordinated effort to develop a framework of definitions and specific concepts in accident prevention. However, there were satisfactory definitions and concepts of injury. The Committee on Standard Nomenclature for Home Accident Prevention prepared its first report on definitions and terms which should be helpful.

Definitions and specified concepts are prerequisites to any organized research or survey work, specific hypotheses being essential to experimentation and definitive objectives mandatory in planning surveys. Essentially, basic definitions and statements of underlying concepts must be established before studying a science.

Passing on to the background of observations and experience in accident prevention from which research undertakings may be fabricated, one is amazed at the quantities of data on injuries and at the paucity of compilations dealing with accident circumstances and conditions. This is not amazing in view of the lack of definition and specific language applicable to investigations of accidental occurrences.

I do not intend to belittle the enormous amount of background work accumulated, but relatively little benefit will accrue from these to investigators who try to understand events associated with accidental occurrences. Much can be accomplished in such compilations through studies and surveys before those specifically planned steps are taken and can be dignified by the term *research*. There are so few persons skilled in the exacting methodology of research or sufficiently motivated to investigate home accident prevention that all one can do at this time is decry the dilemma. Furthermore, I am not optimistic that this situation will be improved in the near future.

MUST MOTIVATE RESEARCHERS

Professional researchers are not and have not been attracted to accident prevention. I doubt if they will be until the terminology is specific and some gallant, brave surveys have been completed. All the attempts at describing the loss of life, human suffering and destruction of property through accidents has not motivated research in accident prevention.

Researchers are motivated by demonstrating procedures and devices used for measuring, calibrating or evaluating observations or other manifestations, usually in understandable objective units. Professional researchers are not convinced that there is a well defined area of research in home accident prevention or, to go all-out, in any other field of accident prevention. Relatively few research undertakings are found in the field of injury prevention. However, progress along these lines is showing a modest spurt in recent years and there is some reason for cautious optimism in this domain.

CONDUCIVE ENVIRONMENT

The fourth requirement for research is that of an environment conducive to the researcher. Certainly if there be concurrence with the opinions I have expressed on the previous three phases of research in prevention of home accidents, there is no reason to suppose that there currently exists such a situation. However, when and if such a situation is demanded, an imaginative and dynamic administrative leadership will be needed.

In addition, sufficient and continuing sources of economic support must exist for researchers to settle to their exacting tasks with confidence. Thus they may be assured their struggles will not be unduly drenched in administrative restraints, will be guaranteed opportunity for continuity of effort and equipped with sufficient facilities, equipment and supplies to pursue the steps involved.

These are my own biased opinions of the needs to be met for profitable results from research in home accident prevention, and my evaluation of where we now stand in fulfilling these needs. Let me assure you I consider my experiences on which I base these evaluations quite limited.

Furthermore, even though I may sound pessimistic in evaluating where we now stand, I am quite optimistic that these situations can and are being improved, and that great gains will be made in the future. I believe that gains toward this goal will be made in step-wise progression and that "Heaven is not reached at a single bound . . ." but that "We build a ladder by which we rise from the lowly earth to the vaulted skies."

I have ventured my description of the "lowly earth" on which I now believe we are with respect to research toward accident prevention, and I have depicted my opinion of the framework of the ladder by which we might rise. Let's look upward, build, and climb!

REMARKS OF ALBERT P. ISKRANT

chief, Operational Research, Accident Prevention Program,
U. S. Public Health Service, Washington, D. C.

Research into the causes of accidental injuries is one of the most vital needs in public health today. We talk about the 90,000 deaths from accidents each year, the increasing proportion of deaths due to accidents and the fact that from ages one to 35, accidents are the leading cause of death.

We talk about the "epidemiologic approach," about "accident proneness," about emotional factors accounting for 80 per cent of accidents and about the medical aspects of accident prevention. We talk of the 28,000 deaths, the 800,000 lost man years of life, the four million injuries and the almost billion dollars cost resulting from home accidents. We recognize in a vague kind of way that the home accident is the leading cause of death of young children, and so we talk of slippery rugs and insecure ladders, and we decide to do a survey.

We organize the commuity, do a survey, and it is forgotten before the results are known. There is nothing wrong with a survey; it is an excellent method for determining the extent and nature of the problem. All praise is due to the Kellogg Foundation or the National Safety Council or the health departments and others that struggled so manfully in uncharted waters. Also the work of the national office of Vital Statistics and the Vital Statistics Bureaus of the 14 states that cooperated in the preparation of special forms for data on deaths from home accidents—all this deserves mention. Much invaluable data are contained in the report of this cooperative effort.

If we wish to apply to home accidents the same epidemiologic methods we used in combating the communicable disease we shall have to extend our efforts beyond the "survey." Tabulations regarding the who, when, and where of home accident injuries and deaths help identify problem areas and the need for control measures, but they *do not* provide solutions or identify causal relationships.

RESEARCH PINPOINTS PROBLEMS

Much research has been done in the field of home accidents, especially in children. In poisoning, in particular, a great deal of practical knowledge has been obtained. And the subject of "accident proneness," and the personality traits of accident repeaters, has been dealt with widely, though sporadically. But the findings don't "hang together," and there is no organized research expected to come to fruition within a definite time.

In spite of the repeated declarations that we must apply to home accidental injuries the same epidemiologic techniques used in determining the etiology and control measures for communicable diseases, we have not gone past the stage of the survey. If we really believe home accident injury, disability and death constitute the health problem, and that we need to know more about the circumstances surrounding them to develop preventive efforts, then it is high time we started a research program commensurate with the problem.

The immediate goal of a research program for home accident injury prevention is to identify and eliminate the basic causes to reduce accident frequency and/or severity, save human life and decrease disability.

Ordinarily we consider epidemiologic studies as being concerned with the host (person who has the accident), agent (physical, chemical, or biologic), the environment (physical, biologic or socio-economic), and their interaction. Hypotheses developed from studies should be tested by the most stringent statistical tests possible, and through controlled experiments whenever feasible. The team approach should be used in these epidemiologic studies to give the investigations the maximum talent available, and to exploit to the fullest the opportunities presented. Physicians, engineers, nurses, psychologists and investigators can all contribute. In addition to a statistician and clerical help, the composition of a team would depend on the type of investigation. Poisoning investigations of children take different talents from one of falls from ladders in young adult men.

ACCIDENT PRONENESS UNREVEALING

The subject of "accident proneness" should be explored. To date the term describes a series of personality traits not yet identified. Scattered studies have identified various traits which might be the product of the author's imagination, or his pet belief, or else traits found in most people. Characteristics suggested by epidemiologic studies should be subjected to the most vigorous tests under controlled conditions.

Apart from any inherent "accident proneness" which may exist in individuals, attitudes developed because of social or environmental forces affect human behavior and safety. Workers who are extremely careful on the job may be careless around the house. A person cautious around the house may drive like a lunatic. While many authors feel the key to the accident problem lies in this area, virtually nothing is known, although much is speculated. There is great need for developing and using methods of assessing attitudes, to identify those which predispose unsafe behavior, and to modify or change attitudes and behavior.

A particular problem in home accidents concerns older people, which account for more than half of the home accident deaths. We must convince older persons they are not as young as they used to be, and modify their behavior pattern for greater safety. Very young children must be protected against accidents, but older children, especially those attending school, must be instructed in safe behavior. More needs to be known about children's conception of, and attitudes toward accidents at each stage of their development to plan realistic safety instruction for different age groups.

EFFECTS ON ACCIDENT OCCURRENCE

Organic disease, impaired functions, and aging processes increase the accident potential of individuals, but their effect on accident occurrence is largely speculative. The extent people "compensate" for deficiencies is not known, and differences in exposure make comparisons difficult. When we find greater than expected prevalence of specific conditions among accidents, we must then compare the accident experience of a group of persons with the condition and a control group without the condition, matched on age, exposure, and other variables.

Because of the difficulty of selecting appropriate groups with particular conditions or defects, and following their accident experience, it may be more appropriate to give physical examinations to entire groups of persons, and then do follow-ups for accident experience. In this way many hypotheses could be tested in the same group of persons. Another approach would be through records of an organization which provides routine medical care and physical examinations. Here both the physical condition of participants and also all accidental injury experience needing medical attention would be known.

The prior or future incidence of accidental injuries in persons with particular defects or conditions can be compared with a control group. If the organization enrolls families, additional studies can be done on family accidental injury experience.

In considering the relationship of physical conditions to accidents, children's growth and development and their effect on their activities offer a very fertile field for developing realistic safety education for children of different ages.

SECONDARY PREVENTION

The term "secondary prevention" in the health field designates measures to minimize disability and death after the illness or infection occurs. To a large extent the first aid and medical care given to injured persons are important to determine whether the injury results in recovery, permanent disability, or death. Accident victims who are not killed immediately can best recover if they receive early and adequate first aid. Proper training in first aid is important but little is known about teaching methods or effectiveness. Present methods of teaching and administering first aid must be studied to be sure that first aid manuals include latest medical information. Medical treatment of injuries also must be continuously appraised and evaluated.

Accidents are a function of the hazards to which people are exposed and a function of peoples' way of living. Socio-economic and cultural patterns help determine the type of accidents people have. Children who accidentally ingest aspirin come from families where aspirin is accepted, probably in childhood medical care Poisoning from kerosene

ingestion obviously occurs in a different cultural pattern from poisoning from tranquilizers and barbiturates. There needs to be definite research into various cultural patterns and ways to motivate people to safer conduct.

MUST STUDY ENVIRONMENT

Epidemiologic research in the field of home accident injuries can not be limited to identifying susceptible individuals nor can they be removed from the environment after identification except by making them less susceptible. The role of the environment in its relation to the host must be studied for general and specific accidents. The contribution of various environmental factors to accidents may offer more immediate control measures than identification of "accident prone" personal characteristics.

For both the environment and the agent, research which identifies causes of specific accidents will produce "pay dirt" most quickly. For example, changing door locks on refrigerators, or removing doors from abandoned refrigerators, may be more immediately profitable than attempting to modify childhood behavior to keep children from entering refrigerators.

This does not mean that a wholesale program of research, such as one directed at housing design for maximum safety would not be a profitable undertaking. On the contrary the elimination and control of hazards by efficient planning design and construction of homes and installation of household appliances and equipment, is of highest priority. It is rather futile to tell householders about even treads or standard risers when they buy or rent houses already built. Research into the design of homes for maximum safety is a vital need, particularly in homes for the elderly.

The differences between the epidemiologic research we propose for home accidents and that ordinarily [illegible] is that the former case deals with a whole spectrum of events and causes. Each innovation brings new ways of injuring, maiming, and killing. The introduction of the tranquilizing drugs immediately presented new opportunities for childhood poisoning and other accidents; the rotary mower brought new opportunities for cutting off toes and putting out eyes.

We must carry out a two-edged research program—general and specific. The general approach is new in public health. To my knowledge, an epidemiologic investigation into "illness" as such has not been conducted although yellow fever, malaria, tuberculosis and syphilis have been studied, and the causative agents isolated. Cuts are not caused by a single agent, but rather by an ever-changing gamut of events, from slipped nailfiles to crashes of huge airliners. Anyone who has looked at the results of a home injury survey, or reviewed the certificates of deaths from accidents could see the almost infinite variety of accidents. Therefore, we must identify the common causes as well as the specific causes of accidents.

RESEARCH INCLUDES CAUSE, EFFECT

Our epidemiologic research will become more specific as sufficient numbers of accidents with common causes are identified. When we learn that power mowers are cutting off toes, we must proceed to try to do something about it. If children are being burned by falling in fires, we must introduce a program of fire-screens.

But all the time we must work toward the goal of identifying common causes—the effect of weather, climate, topography, training, education, personal factors, fatigue, drugs and alcohol and housing design. Otherwise we will just be plugging holes, while other holes appear as fast as the economy and technology advance. The *Daily Tribune* of Gallipolis, Ohio, wrote an editorial which illustrates my main point: "The number of serious accidents is appalling. Fractured skulls, broken limbs, mutilated faces, scalps and ears torn off, and spines crippled, are the daily record. And almost without exception every accident is the result of fast and reckless....." The year was 1897. The agent was the bicycle!

REMARKS OF FLOYD A. VAN ATTA

Industrial Hygienist, United Automobile Workers, Detroit, Mich.

One of the primary needs in accident prevention research is to know what we are really talking about. And I do not find it easy—or even possible to distinguish home accident prevention research from any other type of accident prevention research in this respect.

This necessity for knowing what you are talking about is simple and primary, but the human mind is so constituted that we make it complicated—almost all of us make every new question hopelessly complicated before we even start to look for an answer. One of our favorite ways of complicating matters beyond any hope of recognition is by means of our own sloppy speech and slovenly thinking. This is a very fundamental part of our problem.

One example which annoys me more than most, mainly because the habit of speech becomes or signals the habit of thought, is the almost universal trait of talking about accident rates when what are really under discussion are injury rates. There may be some a priori reason to assume that accident rates will follow a course parallel to that of injury rates. I do not know, nor do I know of any objective attempt to find out.

FIND INJURY CAUSES

Certainly there is no good reason for not finding out the causes of injuries and means for preventing them if possible. And in recent years we have made some progress in this direction. But let us do it in the knowledge that we are preventing injuries and not preventing accidents. We are accustomed to filling out an Accident Report on every disabling injury in industry and to collecting many of our home accident statistics from hospital records.

I am quite sure also that one of the things which has made the investigation of home accidents peculiarly uninviting to any research people who would not have been repelled by the general tone of accident prevention propaganda has been this same peculiarity of the basic data. It has generally been collected for clinical, for insurance, or for other purposes not necessarily related to accident prevention or even to injury prevention.

I once had a desire to find out something about the causes of window washing accidents. I set myself an easy task by looking for the ones which resulted in compensated injuries because there had to be a complete report on each of them in the custody of the compensation authorities. The Industrial Commissions of three of our larger industrial states were quite cooperative and in each of them I read the original "accident" reports on every reported injury of this type for three years.

NO CAUSAL INFORMATION

At the end of this rather tedious chore I had, in addition to sore eyes, a great deal of information on the nature, location and extent of the injuries; the clinical course of the patients; and the amounts of compensation and medical payments. The only thing which I lacked was any clue as to where to start to look for the causes of any of these accidents.

This is a specific example of a general condition. To look a little closer to home I might suggest a look at the rather famous "heart kitchen." I do not wish to suggest that the idea of the "heart kitchen" is not good or even that its practical effect has not been desirable, but I do wish to suggest that the whole thing was set up in the presence of a woefully inadequate amount of evidence.

The general idea is to save effort, and presumably strain on the heart, by saving steps and by saving stooping. It would seem logical before going into this project to determine in an objective manner what types of activity would demand the maximum metabolic price and, presumably, put the maximum strain on the ailing heart. A preliminary determination of the metabolic cost of a number of movements of this sort has since been made for quite another purpose and it turns out that the values are surprising, at least to me.

RESEARCH—CRITICAL STUDY

This brings me to a second general point, that research in general is not only a close

or intensive study of a phenomenon or substance. It is also a critical study. I have seen a Master's Degree thesis on the use of articles by Shakespeare. It certainly represented a close study of some parts of Shakespeare's writing but it was, in my estimation, about as much a research project as it would have been for the young man to have spent the same amount of time in counting his toes.

It established with an unspecified precision a series of numbers which were already known with an unspecified, although presumably lower, precision. I do not classify it as useless research; for all I know it may have some very practical application, and I think that it is generally both risky and unprofitable to comment on the practicality of any project.

I criticize only the fact that it is completely uncritical and, as a direct consequence, adds nothing to the sum of human knowledge. This is the fundamental difficulty with a great deal of what has frequently passed as research in home accident prevention. It has been more closely related to propaganda or education than to research.

RESEARCH—UNGLAMOROUS

It is an unfortunate fact that research is seldom glamorous and seldom spectacular—that is something which the press agents have thought up for the purpose of capturing the public's money for medical research to the probable detriment of the research.

Research is normally a process of isolating a part of a phenomenon small enough that you can begin to understand, or at least observe, the conditions which control that part. Having picked out the controlling conditions it is necessary only to arbitrarily vary each of them in turn while holding the others constant to arrive at an understanding of that particular system.

Sometimes we are lucky enough to be concerned with a relatively simple system—a rigid ball on a rigid plane perhaps—in which we can observe the significant conditions directly and unequivocally. In this instance any single ball from a universe of balls and any single plane from a universe of planes will tell us all that we require to set up a mathematical formulation of the system.

Sometimes the situation is more complex and we cannot observe the boundary conditions directly—perhaps we are concerned with the molecules of a gas. In this instance, if we are really lucky, the unobservable [illegible] may follow the simple laws of [illegible] and by observing a sufficient number of instances their effects will cancel themselves out, permitting us to observe the effects of the conditions which we can control or which we can observe. We then have become in some sense statisticians.

HUMAN EXPERIMENTS DIFFICULT

If the *universe in which we wish to make* our examinations happens to be a human population there is generally an unwillingness on the part of the experimenter to apply experimental conditions with rigid controls and an even greater reluctance on the part of organized society to permit him to do so even if he has the desire. Normally this makes it extremely difficult to carry on meaningful investigations of any sort with human populations.

If we can locate two closely similar populations in one of which chance has provided *us with a condition*—perhaps a *smallpox* organism—which is not operating in the other we have a controlled experiment provided by chance and in observing it we become not only statisticians but epidemiologists.

Obviously it is not necessary for the experimental variable to be an organism. Any defined variations between two recognizable and otherwise homogeneous populations will yield results by the methods of the epidemiologist.

It is, however, necessary in any such investigation to be able to define the populations involved, to demonstrate that there is a single defined cause or a finite number of defined causes at work, and to demonstrate that except for these causes the populations are homogeneous.

DEFINING ACCIDENT CAUSES

In accident prevention investigations the difficulty which the epidemiologists have lies in the fact that there has been, up to now, no demonstration that there are two or more *definable populations at any point in time* or space one of which is contracting accidents as the result of one or more definable causes while the other is not contracting accidents because of the absence of these causes. It would be more hopeful if you could demonstrate two otherwise homogeneous populations one of which was contracting accidents.

R.S.F. Schilling has expr[illegible]situation well for industrial health investigations when he says:

"It seems we must await the development of better techniques for assessing mental illness and determining its cause, and we must define health in measurable terms. Until this is done the research worker will be inclined to leave health and mental illness aside and study disease which can be measured. As he grows older and becomes more aware of the immense difficulties of methodology in occupational health research he will derive more satisfaction from planning and completing neat and conclusive investigations than from making heroic attempts to achieve unattainable ideals."

MUST PIN-POINT CONDITIONS

Change the industrial health phraseology to accidents and it applies perfectly and completely. When we come down out of the clouds, stop being do-gooders, strip our problems down to a size where we can actually see the important conditions, define precisely what it is that we wish to know, and consider critically how to find it out, we may begin to make some substantial progress in accident prevention research.

This is not nearly as glamorous a prospect as looking at the "big picture" and writing erudite papers on the "accident prone" or on the "wish for self destruction" or on "*guilt feelings in* accident causation" but it will eventually bring some definable results. When it has proceeded far enough that it is possible to set up a reasonable research project with definable and possibly achievable goals it might even become easier to get some money to carry on the work.

As a start on the language side, which I think is an essential ground-work, I would recommend to you the definitions in the September 1957 issue of Home Safety Review.▲

THE ROLE OF NATIONAL SURGICAL ORGANIZATIONS IN PUBLIC SAFETY

by DR. JAMES K. STACK

secretary, American Association for the Surgery of Trauma, Chicago

The American Association for the Surgery of Trauma was founded in 1938, and Article II of its Constitution states:—"The object of this Association shall be the cultivation and improvement of the science and art of the surgery of trauma . . . and the consideration of such other matters as may properly come within its sphere." We feel that public safety comes within our sphere.

The Association has 250 active members, approximately 80 senior members and 25 honorary members. The founding members felt that the surgery of trauma would be of *increasing importance and set out to stimulate* the medical profession of this country and Canada to a correspondingly greater interest in this field.

The fellowship is made up of surgeons who are active in the practice and/or teaching of surgery, or one of its branches, and are in a position to bring about this influence in the communities in which they work.

The Association has no administrative staff. Its activities are directed by its officers and Council and participated in by all of its members. They are in a position to influence medical school curricula, hospital teaching programs, and the trends of postgraduate education on the local, state and national level.

COLLEGE OF SURGEONS

The American College of Surgeons was founded by the surgeons of the United States and Canada in 1913 and its fellowship numbers about 16,000. It is divided into state chapters, and, in the larger cities, metropolitan chapters. Of particular interest

to you, is its Committee on Trauma—a group of 42.

This Committee was originally established in 1922 as the Committee on Fractures, and its appointment was stimulated by the generally poor results that were being obtained country-wise in that era. Later, it became the Committee on Industrial Medicine and Traumatic Surgery, and its present title—Committee on Trauma—was authorized by the Board of Regents in 1950.

There is a similarity between you and us, and a difference between another part of you and us. Let me illustrate. Most of you are dealing in your everyday work with individual problems arising, usually one at a time, with the accident victim, with the colleague who is responsible, with the morale of a single worker who can set the mood for a group.

We, too, are dealing, for the most part, with a succession of individual problems of people, and for that reason we both are concerned with the question of individual variability. Let us say that none of your "accident-prone" workers, and none of our patients will react in the same way in point of time regardless of other similarities they may have.

DATA NOT APPLICABLE

When you deal with a single person for whose safety you are responsible, you are practicing an art, and you cannot validly apply data you have on him to conclusions reached by data drawn from a group. There are others, especially those within the organization of the National Safety Council itself, who are practicing a science, namely, that of statistical measurement.

They are safe in applying statistics to a given problem and passing them along for your consideration, but, no matter how accurate their tools of collection and assimulation become, you will err if you attempt to apply it exclusively to a single problem.

In our work, the temptation to do so is great. To statisticians, the five people killed when their car failed on the curve are five rectangular holes in one of St Peter's IBM cards. To you, they are five different problems causing you to review your off-the-job safety program, and to us they are five deaths on which to ponder cause, from the medical standpoint, and prevention, perhaps through closer contact with you.

I am sure that we are closer together than we may think. "Whatever the values of a manager or supervisor, whatever wonderful potentialities he may have, he is limited on the job by the skill with which he is able to guide, lead, teach, direct, control and motivate others." Isn't that also a characterization of a dedicated doctor? Newer trends in medical education are leading the student away from the statistical trap and emphasizing more, both in the pre-professional and professional years the art of understanding and handling people.

FRUSTRATING PROFESSION

Medicine is unique in that its professed purpose and highest end is its own oblivion. It is on our road to this oblivion that we meet with many frustrations, and these keep us from getting there as quickly and directly as we would like.

There are many road blocks and detours over which we have no control, and we find ourselves stopping too frequently to classify repair or dispose of human debris. The road block of poliomyelitis, for instance, still has some debris around it, but the wall is lower now because a large crew under a man named Salk is at work on it with much modern machinery provided by both private and government funds.

There is a long and ancient detour lined by many dead and many more pulmonary and skeletal cripples, and these have for years slowed our journey. It seems that they are mostly people who have been underprivileged and social and economic conditions made it difficult for them to combat tuberculosis. This detour is, however, a little smoother than it used to be because streptomycin and other drugs and surgical advances have been so helpful.

But just when we think we are making good headway to this oblivion, and the road seems clearer, other obstructions keep appearing, and there is one with a frightening potential that seems to be developing fast. It is labeled "highway accidents" and it is unusual in that it is at a place which is quite wide and smooth and generally attractive, and also in that the human debris around it seems to include all ages and types and all socio-economic groups, too.

YEARLY DEATHS

It is striking, though, how many are young and would have been in the prime of life. This block is said to be increasing in size, and, of the 93,000 deaths at all ages from accidents in 1955, almost 40,000 are piled up here. Home accidents are not far behind—28,000 of the same 93,000 in the same period. This increase is taking place in spite of the many groups of people who seem busy in this area.

These workers do not seem to be always as well coordinated as they might be. Some are working in a plodding manner, observing, measuring, noting, while others are working feverishly, almost vengefully, as one might spit into the hurricane that has just destroyed his home.

These are homely examples of the many frustrations and disappointments in the daily life of a doctor. There are so many instances in which safety directors and workers can correct potentially-dangerous machines and locations; you can erect guards, change design and install fire-doors to make sure that such an accident will not happen in just that way again.

But we cannot change the design, for instance, to restore calcium in aging bones so that the left hip won't give 'way a year after recovery from the fracture and pinning of the right. You can solve the problem of the hazardous, incompetent alcoholic who has been wrecking your safety record by letting him go, but we are unable to reach the underlying cause that will enable him to keep from injuring himself or others in the area of everyday living when constant conduct supervision is impossible.

SUGGEST HABIT CHANGES

You can grant a pension to the old employee who has developed a Parkinsonian tremor and whose unsteady gait makes him liable to fall, but we cannot protect him because we do not know the basic cause of the degenerative changes occurring in a certain part of his brain.

The surgeon's contribution to accident prevention consists most likely of suggesting little changes in the mechanics of living. You had better take up those throw rugs in the parlor so grandma won't trip and fall. You had better move that window seat or radiator so father won't hurt his back when he leans over with his knees straight to open the window.

It would be best to put a guard on that open gas heater or Sally will be burned again (but the question of flammable clothing is not such an easy one). Why don't you send that rotary lawn mower back to the factory so that shrapnel-like flying broken blade won't cut the tendons of your other foot the next time.

MUST BEGIN PREVENTION

Surgeons, through their organizations, especially the two groups I have described, have done somewhat more, particularly along the lines of education of the medical profession toward better results in the treatment of accident victims, but here again we are dealing with the wreckage after the fire and not helping to hold the hose that is pouring water on the base of the flame.

We surgeons, because of our first-hand knowledge of the immediate and final results of accidents, in our emergency rooms and wards, and in practice in general, are, we think, in a position to contribute more to accident prevention.

We certainly are in a position to have impressions, and, even if we do not always have statistical evidence, these impressions are passed along to our colleagues through the medium of meetings, publications and the like, so that those of us in one community may know the nature of the problems in another, and be ready should they strike.

We may know by having things told to us through privileged communication that would not appear in an accident report, and these could be acted upon in an indirect way that would be helpful and still not be a breach of professional confidence. The accident victim may not admit to an investigator that he has had trouble recently adjusting his insulin dosage, that he had some strange feelings and slight seizures that made him wonder if he was going to be like his uncle who "used to have fits."

PEOPLE CONCEAL FACTS

He might not reach into his bedside table and show the insurance adjuster the little tablets he takes when he gets attacks of shortness of breath and dizziness. His wife would not repeat to the safety man from

the company that John drinks heavily over the week end and that she hates to see him leave home on Monday morning so shaky and depressed; besides, she wanted him to give up the job of structural steel worker a long time ago. Thus, we see the effects, but could we, by, a posteriori reasoning perhaps throw more light on the cause.

How many people suffer really serious injury or death in their first accident? Is this the first time they have had an impressive injury (one that requires special treatment other than household care)? What is the percentage of repeaters and is this high enough to be a factor in the patient-surgeon relationship the first time?

In other words, if all surgeons caring for accident victims the first time were more prevention-conscious, could they, during the time of this care, make such an impression on the patient by word, deed or opportunity to observe other casualities, that the chances of this person ever getting into another accident would be lessened?

To put it another way, would the primary accident victim be less likely to have another, perhaps worse accident, if he was in some way impressed with the people around him in the ward, in the physical therapy department, who were so much worse off than he? What is the role of such comparison? What is the role of remorse?

VICTIM RECEIVES NOTICE

I am sure many of you are aware that the accident victim becomes the center of attraction as his family and friends surround his hospital bed. Later, he may wear his cast, crutch, brace or sling as a badge of merit, or, certainly, as a comment-inviting device. We know that children just gloat on a bandage or cast, as witnessed by the present-day vogue of signatures on it. The more signatures, the greater the triumph. "Your cast just went up to your knee; that's nothing—mine went all the way to the hip."

We must not forget that in the care of the injured we are dealing, for the most part, with the average person, and I need not remind you of the intelligence or educational level of the average. Does it make any difference whether the patient was truly an innocent victim or not? Whether he was hurt because of his own ignorance or foolishness or not?

Should we, as surgeons, use a different personal approach (naturally, the quality of the medical care will be the same for all)? In other words, should some accident patients be treated as if the cast on the arm should be a dunce cap on the head? For awhile in Chicago, a traffic judge sent certain serious violators to visit the larger fracture wards of the Cook County Hospital so that they might see the actual results of their violations. Is such a course effective?

What do the parents do when the son riding his bicycle illegally on the sidewalk, carelessly 'rounds the corner and injures the aged pedestrian and, of course, falls off his bike? Does the abraded knee get the same loving care; are the tears kissed away in the same way as if he had injured the knee on the catcher's cleat while sliding home with a winning run in a Little League game?

MAKE PATIENT AWARE

Can we utilize the time (and it may be considerable) and relationship (and it may be close) to impress the patient so that it will really make him be more careful and observant? Can we help in this way? Last year 30 some inmates of a Georgia prison farm fractured their legs simultaneously by sitting down, putting their foot up on a rock and hitting themselves on the shin bone with sledge hammers.

The management of these patients, i.e. the medical management, will be discussed at the coming meeting of the American Association for the Surgery of Trauma, and perhaps we will learn of an effective method to keep them from becoming repeaters.

We, as doctors, are at the grass-roots level of any safety campaign because we participate from the beginning. As far as highway accidents are concerned, local or state police are also there from the beginning, and, at least in Illinois, a medical report is sent by the treating doctor to the Secretary of State which completes the statistical picture.

REPORTING PROBLEMS

The reporting would be somewhat similar in railway, aviation, industrial and marine accidents, but, supposing the victim is taken to his home and no hospital report is available; then only the doctor knows of it. Is the reporting of these accidents vital in prevention? You will immediately answer "only if something is done about it."

If I, as an individual doctor, see a patient with, let us say, serious fractures and lacerations because of a defective electrical tool or lawn mower, or the like, to whom do I report? He is admitted to the hospital as a private patient and the police, therefore, are not notified.

Do I report it to the retailer who sold him the gadget, the wholesaler, the manufacturer, the local Better Business Bureau, the Consumer's Research, the Underwriters' Laboratory, the National Safety Council? The first three may have a financial stake in the patient's predicament and be on the defensive. The next four might say that it is out of their field and they might or might not be able to help.

They might not think that a single mishap such as this was important, or they may even consider it a case of personal negligence. If, on the other hand, one of these surgical organizations had a means of collecting a number of such mishaps countrywide and then presenting these data to the National Safety Council, to the manufacturers, to the Consumer's Research, would this add to the safety of the product, and, thus, promote the public safety, at least in this instance?

PROMOTING PUBLIC SAFETY

Or would it be like getting the slum landlord to repair the third floor back porch railing, or the city to fix the sidewalk after the third broken ankle? You may think these are very foolish questions, but I am sure that in asking them I represent the average doctor's wonderment about his position in regard to public safety. He may know his duty as a citizen, but does he know his duty in this area as a doctor? Or does he have a duty?

Each year many new products come into the market to beautify the home, to decrease the burden of those who live in it, to expand their recreational activities, both at home and on vacation; just like each year many new medications come on the market. Then later it is found that these new medications are not as effective as first announced, and that some have produced under certain conditions dangerous complications or unpleasant side effects.

These announcements are not necessarily made by the manufacturers of the product, but are published by those doctors whose patients have been involved. The article may not condemn; it may simply show that under certain circumstances this is what happened. We, in the medical profession, are helped in this way. Is this an equally effective way to protect the public against the new nonmedical products that may be equally hazardous and equally disappointing to their originators?

KNOW THE HAZARDS

Does the salesman, selling the home tool, know about the potential hazard as much as the doctor writing the prescription, and, in the event it does not live up to its expectations, does he, the salesman, have the benefit of this knowledge presented in a factual and timely way?

Would a trade journal accept an article published under the aegis of a committee of a national surgical organization, outlining the surgical experiences that prompted it to be labelled a public hazard? Or would such an item be more properly presented to the public through the National Safety Council, or some other medium? In other words, could we as an organization, promote the public safety in such a way, and would the end result justify the time, effort and expense involved?

The medical profession is pretty well tied down, so to speak, to the job of practicing, teaching, learning and disseminating information at the postgraduate level, so that most of us do not have the opportunity to acquire the answers to the questions above. We can't be sure of our own knowledge of the motivation of those who manufacture and distribute products that are related to public safety.

ARE YOU SURE?

Can you, who are not in the insurance business, be sure that the advertisement that you read, cautioning you to do this or that, or advising you to have an examination at this or that time, is prompted by the company's true interest in a long and healthy life for you, or by the fact that more people healthy means less waiver of premiums and more people older means more annual premiums?

In the efforts of one of our sub-committees to promote the installation and advertising of safety devices, they were told that one doesn't sell automobiles by calling the cus-

tomer's attention to the fact that he will be less likely to be killed in it if certain equipment is included. Judging by the automobile advertisements, the pitch is beauty in the sweeping line, plus power and comfort. The safety part of it is the customer's option; he can take it or leave it.

At a meeting of the American College of Surgeons in April of this year, Dr. George M. Wheatley, vice president for Homes of the National Safety Council, said, "It is gratifying to have surgeons begin to turn their attention to the study of the cause and prevention of trauma . . . the public has learned to look to the medical profession for this kind of leadership."

DOCTORS PREVENT ACCIDENTS

I should remind you that, in spite of the numerous questions I have asked, indicating perhaps a frightening ignorance of many phases of public safety, many doctors are already actively engaged in accident prevention.

For instance, the team physician who supervises or applies preventative bandages or appliances to vulnerable parts of athletes; the boxing commission physician who decides that the fight will stop to prevent lasting injury to a participant; the industrial specialist who confers with the safety director and industrial hygienist about certain potentially-hazardous working conditions; the flight surgeon, or specialist in aviation medicine, or his counter-part in the submarine and diving activities; those doctors engaged in protecting against radiation injuries in the ever-increasing expansion of nuclear energy programs.

Other medical organizations are also awakening to their responsibility in prevention. The American Association of Plastic Surgeons in 1954 began to participate in prevention efforts because, as one of them said, "In spite of all surgery and medical care can offer in the way of repair, there is bound to be residual scars of body function and mind."

In 1950 the American Academy of Pediatrics established its national committee on accident prevention, and the surgical section of this Academy is playing its part. For example, they established shortly afterward the Chicago Poison Control Center. This aroused great national interest and similar centers are now established in some 44 other cities. Dr. S. D. Woodward, Chairman of the Committee on Automobile Crash Injuries and Deaths of the American Medical Association did much to persuade manufacturers that designing safer cars was part of their business.

NSC POLICY

I started this talk with a quotation taken from the published policy of the National Safety Council, and now let me conclude it with a further excerpt from this same statement of policy:—

"The Council is also properly engaged in . . . helping formulate model safety legislation when the force of law is required, in participation in planning and executing educational programs, in disseminating accurate information to the public and in encouraging the establishment of community and state safety organizations."

Surely in such a varied attack on the factors that kill and cripple so many Americans each year there is a place for the particular outlook and ability of surgical organizations. Let us not continue to go our parallel but separate ways like the ships in the Tales of a Wayside Inn—"That pass in the night and speak each other in passing. Only a look and a voice; then darkness again and a silence."

THE ACCIDENT PREVENTION PROGRAM OF THE PUBLIC HEALTH SERVICE

by DR. JAMES L. GODDARD

chief, Accident Prevention Program, U. S. Public Health Service, Washington, D. C.

In no field is the work of the voluntary organization more valid and appropriate than in the area of accident prevention. In many of the major problem areas of public health the conscientious private citizen finds that his chief contribution at the present time is limited to the support of medical research.

But everyone can take direct action to help prevent accidents. Only when everyone is persuaded to take action—personally and consistently—shall we see a significant reduction in the toll of death and disability caused by accidents in this country.

RECENTLY ORGANIZED

The National Safety Congress has for 45 years demonstrated the value of organized effort in the accident prevention field. Compared to this history, the record of my own agency, the Public Health Service, is a brief one: although we have carried on activities in the home accident prevention field for many years, (for example, the Division of Sanitary Engineering Services established a home accident prevention unit in 1949), it was only recently (1956) that an official entity, designated as the "Accident Prevention Program," was established in the Division of Special Health Services of the Bureau of State Services.

The State Health Departments—cooperation with which is one of the leading functions of the Federal Public Health Service—are also considerably junior to the National Safety Council in the accident prevention profession.

The public agencies have, indeed, received support as well as inspiration from private sources interested in home accident prevention. I refer to the generous contribution of the W. K. Kellogg Foundation, which has awarded grants making possible demonstration projects in home accident prevention. Three local health departments were thus enabled to undertake such projects in 1951, and eight State health departments received Kellogg grants in 1953 for statewide demonstration projects (California, Georgia, Kansas, Kentucky, Maryland, Massachusetts, North Carolina, and Oregon).

AGENCIES CONTRIBUTE

At a recent meeting in Washington of representatives of these state and local demonstration projects the Public Health Service received the benefit of some half-dozen years of experience by typical official health agencies engaged in home accident prevention work, and we participated in a detailed evaluation of that experience. In all the reports and discussions of the group, great emphasis was placed on the value of cooperation with local branches of the National Safety Council.

It was the hope of the Kellogg Foundation, in sponsoring these projects, that the states involved would perpetuate the activities in the form of permanent programs, and it is equally the hope of the Public Health Service that this development will be a major result of the demonstrations.

It is still too early to tell how many of the seeds thus planted will grow into vigorous plants, but we have faith in this method of program development, and, indeed, are committed to it as a principal modus operandi of the Public Health Service in carrying out its function of providing leadership to state and local health departments.

The public health movement in this country recognizes accident prevention as one of its prime responsibilities for the same reasons that carry weight with your own organization.

Accidents are now the leading cause of death at every age from one to 35. Accidents are now what tuberculosis was a half-century ago—the leading health menace to young Americans.

NEED INTENSIVE EFFORTS

These two grave and disturbing facts are in themselves, and standing alone, sufficient justification for intensive public health pre-

ventive effort at every level—federal, state, and local.

The last 50 years have witnessed many public health victories over communicable diseases. The last decade, in particular, has seen an amazing advance in preventive as well as curative medicine. The techniques of prevention, perfected during the long fight against infectious disease, are now being employed in the chronic disease area to minimize disability through early detection and to maximize rehabilitation. Accidents would seem to qualify as chronic diseases in this country, and we are all dedicated to the proposition that accidents are preventable diseases.

Accidents don't just happen. They are caused. And home accidents are quite as definitely caused by human behavior as are motor vehicle accidents. In both cases, alteration of human behavior patterns is the ultimate solution to the accident problem.

RESEARCH, CONSULTATION

The Accident Prevention Program follows a traditional Public Health Service procedure by emphasizing two basic functions, namely research and consultation. On the one hand, we have, during the few short months of our "Programs" existence, drawn up plans for research studies designed to probe more deeply into the behavior problems that underlie accident causation.

On the other hand, we attempt to supply consultation service and technical assistance to state and local health departments concerned with accident prevention. We hope to make a contribution to the accident prevention education field, to the extent that this is appropriate at the federal level.

The three operating sections of our Program are designated as Operational Research, Program Services, and the National Clearinghouse for Poison Control Centers.

OPERATIONAL RESEARCH

Operational Research is concerned with identifying the basic causes of accidental injuries, in developing and testing hypotheses for accidental injury reduction, and in developing and operating a program of accidental injury reporting, which is basic to evaluation. Areas of research in which we shall concern ourselves in the future include:

1. *Studies of the behavioral and "attitudinal" aspects of accident prevention.*

Much more information is needed along the following lines: possible relationships between individual characteristics and the tendency to have accidents; the effect of individual attitudes on accident experience; possible methods of altering individual attitudes to achieve accident prevention; and evaluation of the effectiveness of attempts to produce safety-mindedness.

The ultimate goal, that of changing unsafe behavior to safe behavior, requires, we believe, extensive research in the directions enumerated.

2. *Epidemiologic studies into accident causation.*

In 1948 Dr. John Gordon, at the seventy-sixth meeting of the American Public Health Association delivered his now famous address on the epidemiology of accidents. In that speech he stated that the home accident problem should be approached in the same manner as any other public health problem, namely 1) epidemiologic analysis, 2) establishment of causes, 3) development of preventive measures and 4) evaluation.

EPIDEMIOLOGICAL MEANS

We in the Accident Prevention Program sincerely believe that the epidemiologic approach will produce many tentative hypotheses which can be tested in accident prevention programs. Much of our effort in the years to come will be placed on epidemiologic investigations into accidents.

We propose to use the team approach in some of these studies, utilizing the skill of many professions, including engineering, social science, psychology and statistics as well as medicine. During this fiscal year we have planned an epidemiologic study of accidents in old people and one in children. We have planned an epidemiologic study of injuries due to kerosene explosions in a southern state, and a large scale study of poisoning.

3. *Effect of physical conditions on accident causation.*

While we generally agree that physical conditions seem to affect accident occurrence, we are not sure to what extent they do so. While we feel sure that persons with diminished reflexes and failing sight are "more likely" to have an accident, we do not know

to what extent people compensate for these defects. We propose to find out more about the relationship of physical conditions to accidental injury experience in a group of old persons who have a complete physical examination and a continuous medical history.

ACCIDENT HISTORY

A complete history of their accidental injury experience will be maintained. Also in a large organization where physical examinations are given every two years, and a complete history of accidental injury experience has been maintained, we propose to compare the physical status of those with frequent accidents to that of the accident free.

For our major research project in this area we propose to study a large prepaid medical-care plan, where complete medical care is furnished, including treatment of injuries, and where periodic physical examinations are performed. We propose to abstract the records of approximately twenty thousand members, and relate the accidental injury experience to the various physical abnormalities.

4. *Effect of socio-economic and cultural factors in accident causation.*

It would seem obvious that accidents are, in large part, a function of the hazards to which people are exposed, which in turn are functions of ways of living. For example, injuries caused by accidental ingestion of poisonous substances occur mainly in younger children, while injuries from falls are frequent both among young children and old persons. Deaths from automobile accidents are highest in the late teens and early twenties, and are much more frequent in males than females.

These are obvious differences in the types of accidents that occur to persons of different ages. Some states have non-automobile accidental death rates twice as high as other states, and automobile death rates five times as high as other states. Evidently geography affects the occurrence of accidents. The effect of income, education, family size, weather, etc., are less clearly defined.

STUDY POISONINGS

During fiscal year 1958 we intend to engage to a limited extent in studies of accidental poisonings, from data collected in connection with the National Poison Information Center. We also intend to extend studies into accidental mortality in an attempt to identify some of the socio-economic factors associated with excess mortality.

5. *Study of methods of secondary prevention.*

During the year we expect to engage in a study to obtain information regarding the types of persons administering first-aid or emergency medical care, and the kinds of emergency care given for different types of injuries resulting from various kinds of accidents. We hope, through this research, to improve the quality of first-aid, and thereby prevent much disability and death through more effective teaching methods.

Currently we are participating in a study of the effectiveness of various types of treatment for kerosene poisoning, and we expect to expand this type of therapy evaluation to treatment for other types of poisoning.

I should like now to mention briefly, some of the Program Services operations of the Accident Prevention Program, which supplement and complement our research work.

STATE AIDS

Services to states have included assignment of a medical officer to the New York State Department of Health. This officer helped to design a project for a Driver Research and Testing Center, a cooperative undertaking of the Bureau of Motor Vehicles and the State Department of Health. A public health representatives was also assigned to assist the California State Department of Public Health in activities connected with the Cornell Crash Injury Studies.

These studies have been conducted since 1952 in the Department of Public Health and Preventive Medicine, Cornell University Medical College, New York City with support of outside grants from the Commission on Accidental Trauma of the Armed Forces Epidemiological Board and the National Institutes of Health of the Public Health Service.

Assistance was provided to several states in developing portions of institutes on principles of epidemiology, which presented the epidemiological aspects of accident control.

Consultative work done in various states had some specific results. In Wayne County, Michigan, for instance, experimental nursing records were revised to include recording and coding of specific work in accident prevention. In Pennsylvania long-range plans were developed for improving nursing services in home accident prevention.

In Rochester, N. Y., analysis of data concerning accidental injuries collected over a three-year period by the staff of the Visiting Nurses Association resulted in revision of the record form to provide clearer information. In Arkansas a plan was developed to begin evaluation of nursing services in accident prevention and to provide a basis for staff education conferences to be conducted during 1957.

AID UNIVERSITIES

Assistance was also extended to educational institutions, such as the University of North Carolina and the University of Puerto Rico, in preparing and presenting courses on accident prevention to nursing, sanitary engineering, and medical students.

There has been increasing acceptance of accident prevention responsibilitiles by state and territorial health departments during the year. Thirty-eight reported specific accident prevention services as part of their total public health programs. Eleven additional departments, in their official state program plans, expressed an awareness of the problem and a desire to undertake accident services.

Following broadening of the scope of the Public Health Service Accident Prevention Program, there was an extensive movement among the state health departments to expand activities formerly directed toward prevention of home accidents. These enlarged activities are in such fields as traffic, school, recreational, and farm safety.

PUBLIC HEALTH TRAINING

The training function is always an important operation in public health. This principle applies with more than usual force to the field of accident prevention. We plan to conduct training in accident prevention methods and techniques through assignments to schools of public health (and other specialized schools,) organization of seminars in various parts of the country, assignment of personnel to training situations in state and local health departments active in accident prevention work, and through financial aid to schools to develop course materials and curriculum content in accident prevention.

The third operational unit of the Accident Prevention Program is the National Clearinghouse for Poison Control Centers.

POISON CONTROL CENTER

Staffed by a pediatrician, a pharmacist, an education specialist, a records analyst, and statistical and clerical personnel, the Program's Clearinghouse for Poison Control Centers has been set up to service the rapidly expanding network of local poison control centers which are now operating in more than 101 communities in 38 states and the District of Columbia.

The first local poison control center was opened in Chicago four years ago as a cooperative undertaking under the chairmanship of Dr. Edward Press, jointly sponsored by the heads of the pediatric services in major local hospitals, by the Chicago Health Department, the Illinois State Toxicological Laboratory, and other state and local agencies.

From this beginning the poison control center movement has spread throughout the country, preserving the initial purpose of supplying essential information on an immediate and round-the-clock basis to physicians who are treating cases of poisoning. Research, follow-up, reporting, and similar functions are closely related to this primary operation.

PURPOSES OF CENTER

The National Clearinghouse for Poison Control Centers, which was established following requests for such a national service from the American Academy of Pediatrics and the American Public Health Association, has the following purposes:

1. Interchange of information with local poison control centers throughout the country.
2. Stimulation of development of new or improved methods of prevention and treatment of poison cases, and encouragement of research, both basic and clinical.
3. Assistance to states and local communities in establishing poison control centers by providing technical assistance and consultation.
4. Study of national and area trends in poisoning and successful methods of prevention and treatment; preparation of news releases for professional and lay health education.
5. Serving as a repository of information voluntarily provided by manufacturers.

In connection with this last item, the almost endless list of household products containing harmful ingredients has created perhaps the greatest potential accidental poisoning hazard. The American Medical Association estimates that a quarter of a million brand-name chemical products are now on the market.

Here are a few categories of such products, suggestive of the extent to which these goods have become a common feature of the average American home: laundry and dry cleaning chemicals; cleaning, polishing, and deodorizing products; auto care and repair supplies; art and hobby materials; and the garden-group, composed of fertilizers, weed-killers and pesticides.

CENTER AIDS COMMUNITY

The Public Health Service believes that, whatever the organizational pattern of the local poison control center may be, the local health department belongs in the center of such a community activity. In New York City and in Florida, for example, it has been demonstrated that operation of a poison control center has strengthened the cooperative relationships between the health department and the local hospital and medical groups.

It is inevitable that the long experience of health departments in liaison and advisory operations can be of great value in pooling efforts and facilities that must be achieved if a successful poison control center is to be created in the community. Furthermore, the traditional public health techniques, such as epidemiology, casefinding, and follow-up, lend themselves naturally to poison control work.

The processing of information received from all over the country will be a major activity of the National Clearinghouse.

The analysis and tabulation of this material, and the preparation of summary reports, will be supplemented, from time to time, by the issuance of special reports devoted to new treatments, changes in formula of trade name products, new toxic materials or toxic materials encountered under new conditions, and the like.

MORE RESEARCH NEEDED

Opportunities for further research will be brought to the attention of individuals and groups having competence in the areas involved. We need to know more, for instance, about the action of certain poisons, and experience has shown that some current forms of treatment are unsatisfactory.

Our plans for the future of the Accident Prevention Program of the Public Health Service have been formulated in cooperation with the leaders of many groups, both public and private, having long experience in the field.

It was on the basis of recommendations by such groups that a categorical program in accident prevention was established at the federal level, and we look forward to many years of fruitful collaboration with organizations such as the National Safety Council in mutual efforts to reduce the alarming hazard of accidental death and injury in this country.▲

THE 1956 HOME SAFETY INVENTORY

by A. F. SCHAPLOWSKY

director, health education services, Kansas State Board of Health, Topeka, Kan.

No businessman today would consider staying in business without periodically taking an inventory of various aspects of his operations. His success or failure depends to a large extent upon how well he analyzes what he has done in the past and how well he plans for the future. It is just as logical to conduct periodic inventories and appraisals of health and safety programs. In this way they will continue to be improved and developed.

Prior to 1954 individuals interested in the prevention of home accidents frequently asked themselves, "I wonder what is really going on around the country in this field," and "How do the things we are doing in our community compare to what others are doing?"

At the 1954 annual meeting of the home safety conference of the National Safety Council, this very matter was discussed. Who in this country is doing what in home safety? How could such information be obtained? Would an inventory of program activities be a helpful addition to the Home Safety movement? At this meeting the home conference instructed the home division staff to implement the organization of such an inventory, guided by a special inventory committee appointed by the conference. Financial assistance was afforded by a grant from the W. K. Kellogg Foundation.

600 ANSWER TRIAL TEST

A trial of the inventory was conducted in 1955. Questionnaires were distributed to state and local organizations asking them to report their program activities. Six hundred reports were received in this initial effort.

The inventory committee and the home safety conference recognized the potentials in these reports and endorsed the expansion of the program for 1956. Two staff members were added to the home division to devote their time and efforts largely to this activity. Inventory centers were established in each of the 48 states, the District of Columbia, Hawaii, the Virgin Islands, three of the Canadian provinces, and in more than 100 local communities throughout the nation.

The two primary objectives of the 1956 inventory were, to find out who is doing what in home safety, and to stimulate future home safety program activities.

A program summary form was prepared, tested, refined and finally printed and distributed. Some 85,000 copies of this form were sent to clubs, organizations, industries, governmental agencies, fire departments and similar organizations and groups throughout the states, territories and provinces which had set up inventory centers. These forms were distributed and the completed reports were collected later through the local and state inventory centers.

41 HUNDRED GROUPS RESPOND

By January, 1957, the replies began to return to the inventory centers. The forms collected by local centers were sent to state centers, and in turn, sent to the National Safety Council. The reports were then coded and the data was put on punch cards. A total of 4,126 organizations submitted summaries of their 1956 home safety activities. It is obvious that these program summaries do not begin to include all the home safety activities conducted throughout the country in 1956. These summaries, however, do provide more information than ever before available about what is being done. Thus, no claim is made that this inventory is a statistically accurate sampling of existing program activities. However, it does offer practices and suggestions which may be of assistance to future program planning.

A breakdown of the sources of the summaries received indicated that 145 were submitted by organizations whose programs are national in scope, 348 were from statewide organizations, 1,600 from groups which function at the county level, and 1,993 from clubs and organizations active mainly on the community level.

Program summaries were obtained from 55 separate types of clubs, groups and organizations. More summaries were received from business and industries than from any other type of organization.

MANY TEACH HOME SAFETY

An overwhelming percentage of those replying to the inventory questionnaire indicated that their home safety activities involved educational methods. This is as one would expect, as the very nature of the problem dictates that this approach must be the main method of reaching people in their homes.

A wide variety of specific activities were listed and described in the narratives which accompanied many of the program forms. The findings revealed the tendency for organizations to pick their subject matter because it "was a good idea" or because it "was part of a regular annual pattern." Only a limited number of organizations took a survey of their local accident situation to discover whether the aspects of home safety emphasized were those which needed attention. This is a defect of many programs, as our changing environment creates new hazards each year and programs must be developed to meet them.

Inventory centers prepared reports for their states or local areas. These reports were distributed to groups who participated in the inventory. They were an important step in the process of community-wide planning, and served as a stimulus to new and improved programs. Thus every group which contributed learned what all other groups were doing. This is a brief description of the mechanics and findings of the 1956 home safety inventory. The objectives were met, in that the inventory revealed for the first time, on a national basis, who is doing what in home safety. It is now a guide for future plans and projects, and is stimulating the development of increased activitiy in this field, especially at the local level.

WHAT ABOUT THE $64,000 QUESTION

In planning development and improvement of the home safety inventory field, the inventory committee during this last year asked itself questions like these: "Sure, in the 1956 inventory, we found out that a lot of different types of organizations are engaging in a great variety of activities throughout the country, but what about the $64,000 question? Do any of these activities actually prevent any accidents, and if so, are certain types of activities more productive in this regard than others, or are a lot of people merely engaging in a lot of activties with little or no effect? Can future inventories be designed and improved so that the data obtained will bring us nearer to the answers to these questions?"

To be sure if such information could be obtained, accident prevention workers could develop programs using tools which would compare in effectiveness with the Salk vaccine in its prevention of paralytic polio. Unfortunately the answers to these questions are elusive and may never be completely sound. However, when more and more dedicated workers throughout the country add bits of knowledge here and there in the years to come, the answers will begin to emerge. Inventories can play an important part in this process by periodically gathering, analyzing and disseminating details about the thousands of programs and ideas that will continue to develop.

When I become impatient with our progress, I remind myself that in the field of public health those problems with known single biologic causes have been solved and controlled. Those diseases with multiple and varied causes such as heart disease, cancer and mental health are still defying man's attempts at prevention and control. Activities undertaken in communities in attempts to control these diseases are almost as great and varied as are those employed in home accident prevention programs, and yet the time and money expended on these programs is tremendous when compared to that expended on home accident prevention.

SHOULD PROGRAMS CONTINUE?

Indeed, the causes of accidents are equally as multiple and complex as any of these diseases if not more so. Independent research and inventories with improved procedures, techniques and instruments in the years to come can provide us with data which will enable us to improve our programs and effectiveness in reducing the number of accidents.

Another question which I have occasionally been asked in regard to the inventory is, "Should we continue to stimulate more

groups and agencies to engage in activities which we aren't sure will really help solve the problem? Shouldn't we wait until we have more definite information?"

I have answered these questions in this manner. Research in other fields is not based on an "all or nothing" program. Man simply will not sit back and wait for the day when someone announces a complete cure or preventative. He does what his best information and judgment indicates will help in the situation at the present time. From his attempts, experimentations and activities will come some new thoughts and some answers. Indeed if more individuals and groups concern themselves with the problem of home accident prevention, successful techniques and activities soon become clearer and better defined. Today we might say we are using a shot gun in our home accident prevention programs; tomorrow we will be using a rifle.

The Inventory has been an important step in the home safety field. It can continue to crystalize home accident prevention activities and techniques throughout the country. The present inventory committee of the National Safety Council has recommended that a national inventory not be taken in 1958 but that one be taken in 1959 of activities which were conducted in the year 1958. Changes have been suggested for the form to be used and the methods to be employed in conducting it.

State and local inventory centers will again be requested to conduct the inventory in their respective areas. The format of the inventory forms will resemble those now being used for the traffic inventory in that one compiled report will be developed by each center and sent in to the National Safety Council. A kit of state and a list of local forms will be developed. To assist the inventory representative in gathering information from local organizations supplemental forms will be developed.

No long range plan for continuation of the inventory beyond the one to be conducted in 1959 has been developed.

Members of present and future inventory committees of this Home Safety Conference and staff members of the home division will welcome any suggestions individuals may have to improve the procedures and instruments used in future inventories.

HOME FIRE INSPECTIONS BY FIRE DEPARTMENTS

by CHIEF REYNOLD C. MALMQUIST

first vice president, International Association of Fire Chiefs, Chief of Minneapolis Fire Department, Minneapolis, Minn.

In attempting to prevent the loss of life and the start of fires in this country, the more we join hands with other organizations, the greater the possibility of reducing the loss of life and losses from fires. No one fire department or no one organization is large enough or capable of doing the job alone.

It is fitting that the tragic loss from fire be considered one of our major fields of activity. Each year America faces a tragic human and economic loss from fire.

When we consider that we are approaching, or probably already have arrived at the one millionth fire per year and that our fire loss will probably exceed the one billion dollar mark, we realize the challenge which confronts us, at least economically.

Serious as these figures are, the most tragic results from these fires are the loss of more than 10,000 citizens with probably 4,000 of the victims young people who have not had an opportunity to live.

FIRE CHIEF'S DUTIES

The International Association of Fire Chiefs is truly an international organization concerned with the problem which confronts the chief fire officer. As an administrator, the fire chief's duties today are not solely concerned with the extinguishment of fire. He must be equally concerned with the frequency with which fires occur. The best trained men and the most modern equipment are available to help him in his fight to extinguish the fire. Manpower and sound planning are needed to help him to prevent fire from occurring.

With this thought in mind, the International Association of Fire Chiefs two years ago entered into a program of promoting the inspection of the home. When this program was undertaken, there were many who felt that because of the sanctity of the home, the right to enter it by firemen would be seriously questioned.

The home inspection program to date is successful. At the end of the year the ten millionth home in the United States and Canada will have been visited by members of the fire service.

Generally speaking, the program is planned on a year-round basis, and while it is a part of fire prevention, the activities are not limited to fire prevention week.

OFFICERS MUST EDUCATE

While it is true that any experienced fire officer can, from his desk, describe the conditions which make fire a receptive visitor in the home, the challenge to him is to bring this information to the home owner and his family in such a way that common, every-day carelessness will not sadden his residence.

We have found that where the home inspection program enjoys the support of the chief executive of the state, it is much easier to consolidate our work and effort. Some 22 states are now actively engaged in the home inspection program. In the other states many departments have developed new ways to "back the attack on fire."

While statistics are dry, cold figures, sometimes they can be used to point up areas requiring additional consideration. We found that 94 per cent of our citizens invited firemen to their homes. The remaining 6 per cent feel that this is an intrusion of the home. Wherever a program has been successfully conducted for a 12-month period, we found that there is an approximate 30 per cent reduction in calls to the fire department for fire emergencies in the home.

WASTE OF MANPOWER

America today is an industrial and chemical nation. It is right that it should be for our standard of living is the highest of any country in the world. Yet, we can also brag that the loss from fire is equally high. No other country in the civilized world could support this tragic waste of manpower and natural resources year in and year out.

Hand in hand with this improved standard of living come the many new inventions and processes which make the home a better place to live. Home owners are not necessarily engineers or firemen and, while they enjoy modern scientific developments and improved household equipment, they fail to recognize that, while safe, they may contribute to a problem which is dangerous and hazardous to them.

The trained fireman can bring these points of danger to the attention of the home owner. In turn, he will develop a friendly public relations program which places the fireman as the partner in this group of public officials who are working for the safety of their citizens.

MUST PLAN DETAILS

Those of you engaged in the development of safety programs know full well that the success of any program depends upon the details of the planning. There is no spot where this is truer than in the area that undertakes the home inspection program. It is necessary that the chief completely sell his governing body on the intent and purpose of fire prevention in the home.

It is necessary that he sell the skeptics the soundness of bringing home inspections to the citizens of the community. Many will say that this is evidence of the rapidly developing theory of a police state. If steps taken by the department are so judged, and if subsequent investigations by other municipal agencies indicate that the information derived from home inspections is used for other purposes, the program will fail.

The people of the press, TV and radio can do much to bring the problem to the home owner. They can open the doors when they fairly present the soundness of the program and the reasons why it has been undertaken.

Generally, we find that fire department personnel, once they understand the need for home inspection, undertake it as a part

of the fire prevention program. They should be thoroughly versed in the reasons for the program. They should be trained on their approach to the public because usually it has not been within the scope and duty of the firemen to make good-will calls.

They must develop a spirit of cooperation and helpfulness. They must never institute inspections in the spirit of an investigation. They must assume that the conditions they find are human failures and are not developed as the result of intention or design.

In many communities the home inspection visit has been followed up by a personal telephone call by a chief officer. This gives evidence to the home owner that the program is supported by the entire department. It also acquaints the home owner with the recognized fact that he has been pledged, with his neighbor, to maintain a fire safe home.

The National Safety Council has become a partner with the fire chief in this program. Their annual home safety inventory now questions the fire activity in the communities surveyed. This, in turn, acquaints the fire chief with the fact that his work is being recognized by committees which normally undertake safety programs locally. Many times it places him on the advisory boards of such committees. To a greater degree it places before him a challenge to make his area a safer place in which to live.

Many of you, I am sure, are wondering how long an active program of this type can be kept going. As we envision it, there is no limit to the preventive side of fire fighting.

Our association is seriously considering the promotion of fire administration training on the college level. Should this be developed, we hope to include more and more fire prevention training in our teaching to firemen each year.

The day has long since passed when we considered the fire service as only an extinguishing agent, remaining exclusively within the fire station until some area of trouble develops. While it is true that there is considerable activity, which can only be undertaken in the fire house, it is equally true if we are to reduce the number of fires and the loss of lives, which are increasing each year, we must take our problems to the people who are, in fact, our customers.

HOME SAFETY NEARING INDUSTRIAL

Safety in the home has now reached the level of importance that safety in industry arrived at some time ago. This is correct because today more people are spending a greater number of hours in their homes than ever before.

There are many programs, which are being undertaken to bring to children—and through the children to their parents—the need for fire safety. We in the fire service feel that we must back up these programs by emphasizing to the parents the need for the greatest care and consideration possible in order that their homes may be kept intact and that their children have the privilege and the right to grow up and enjoy the benefits which are ahead for those living in America.

COMMUNITY FIRE PREVENTION PLANNING

by E. W. FOWLER

director, Codes & Standards, National Board of Fire Underwriters, New York city

The National Board of Fire Underwriters directs many of its activities to the community approach to fire prevention.

Three National Board of Fire Underwriters' activities most worthy of discussion are fire protection surveys of cities, building codes, and fire prevention codes.

FIRE PROTECTION SURVEYS OF CITIES

These surveys specifically deal with community fire prevention and coping with serious fires and conflagrations. In most of the conflagrations in primarily residential areas, wood shingle roofs on closely built dwellings of combustible construction were an important factor in fire spread. Other conflagrations, such as from hazardous occupancies or large buildings with combustible interior construction, usually developed because of inadequate public fire protection —that is, inadequate fire departments, water supply and other features for effective fire fighting.

Three large forest or brush fires known as the Malibu fires occurred nearly simultaneously in December 1956 in Southern California near Los Angeles county. In these fires 90 homes were destroyed and an estimated 1,350 homes burned. Effective work of local county fire departments kept the loss of homes down to about six per cent. Fighting conflagrations is definitely a community function.

Fire loss is also a community fire prevention problem. The community approach to this problem matches closely the approach of fire protection engineering surveys of cities made by the National Board of Fire Underwriters in larger cities, and local fire insurance inspection bureaus in smaller communities.

These surveys and reports include a detailed study, with recommendations, of public fire protection. These studies cover the adequacy and reliability of the water supply system, the effectiveness of the fire department, such as manpower, equipment and methods of operation, and the adequacy and reliability of the community fire alarm system.

They also analyze the size, type, congestion and fire hazard of buildings and the effectiveness of building and fire prevention codes in controlling fire hazards. These are studied for possibilities of conflagrations.

A local building code is important in the community approach to home fire prevention. It can prevent conflagrations and fires from one building to adjoining ones and can also prevent the fire from spreading in the house itself.

BUILDING CODES HELP FIRE PREVENTION

Many features of a building code relate to control of fire spread in business, commercial, industrial buildings and apartment houses. Other features deal with fire prevention in dwelling houses. Some features that relate to fire spread in buildings generally are:

1. Fire limits or zones prohibiting wood frame construction and unprotected metal construction should be established. This can reduce the likelihood of spreading fires in congested business districts.

2. Heights of buildings must be limited according to the type of construction. Any building too high for the fire department to fight a fire effectively must have floors and other structures that will resist as ordinary fire without collapsing.

3. Areas of buildings must be restricted to type of construction and occupancy. Consideration should be given to sprinkler protection and height and separation from other buildings. The larger the building the greater the difficulty fighting a fire, and the greater the likelihood to involve other buildings.

4. Exterior wall openings near other buildings must have suitable protection such as wired glass in metal frames. Such protection helps the fire department stop fires from spreading from building to building.

5. Stair, elevator and other openings to floors of buildings are important elements in fire spread if not properly protected. This is particularly important for the safety of occupants.

6. Fire walls dividing buildings must have sufficient structural stability and fire resistance to control the spread of fire from building to building. Openings in fire walls must have standard fire door protection or the walls are ineffective.

The important features of a building code related to fire prevention in the individual dwelling house are roof coverings, firestopping, chimneys and heating appliances and systems, and proper installation of electric wiring and equipment.

ROOF COVERINGS AND FIRESTOPPING

The combustibility of roof coverings should be regulated to control fires spread by flying brands landing on roofs. In a large midwestern city a fire in a four-story building set 70 other buildings on fire from flying brands which carried about a mile away. A good building code limits roof coverings to those Class C or better under Underwriters' Laboratories' classification of roof coverings. This class is effective against light fire exposure and has no flying brand hazard.

Wood floors and walls and furred masonry walls can be hazardous, if proper firestopping is not installed. A fire starting in any concealed space will spread throughout the building before being detected. In such cases there is little possibility of extinguishing the fire before extensive damage is done.

A house had an oil burner fire in the basement a few years ago. By the time the local fire department arrived the fire spread through the unfirestopped stud spaces in the exterior walls and smoke came out around the eaves. The fire department had difficulty locating and extinguishing the fire in concealed stud spaces and the building was a complete loss. Suitable firestopping would have kept the fire in the basement until the fire department extinguished it.

CHIMNEYS AND HEATING APPLIANCES

Among the most important causes of dwelling house fires are chimneys, flues and vents, and heating appliances and systems. A properly enforced building code on such items can control this hazard.

Masonry chimneys should be solid masonry units, with wood beams, headers, joists and studs properly spaced from the chimney. Factory-built chimneys and special types of gas vents should be installed according to manufacturers' instructions and within the limits of their approval. Heating appliances and systems must have proper safety controls and be installed with proper clearances to combustible material.

Communities usually control installation of electric wiring through enforcement of the National Electrical Code, either by a separate electrical inspection department or by an electrical inspector working in the building department. Electric wiring should be installed in a standard manner and sufficient outlets installed to avoid overloading the circuits. In older dwellings proper extensions should be added to the house wiring system.

There are several widely used model building codes. The National Board of Fire Underwriters has published a recommended building code since 1905, the latest being the 1955 Golden Anniversary edition. An abbreviated form is available for communities which can use a shorter code.

The National Building Code recommended by the National Board of Fire Underwriters is the product of many years experience in building code writing and enforcement—experience with hundreds of adoptions, experience of specialists in all branches of fire protection and building construction.

On items which vary with local conditions, the code's provisions are flexible enough to use in any area of the country. Localities with heavy snowfall, exceptionally high winds, earthquakes or other conditions increase the requirements according to their needs.

Approximately 1,000 cities and towns use our code or have a similar building code.

In recent years several building officials' organizations produced and fostered adoption of model building codes. The three model codes of building officials' organizations are much superior in regulating building construction to control fire hazards than the average old locally prepared code.

FIRE PREVENTION CODES

A local fire prevention code may seem less related to preventing fire loss in a dwelling than the building code. But fire prevention codes do have an important relationship. A fire prevention code which specifies safeguards for oil burning equipments has a direct relationship to dwellings where fuel oil is used.

Other code provisions, such as storage and handling of gasoline, all highly flammable liquids, explosives and hazardous chemicals, are important because fires or explosions from these products could effect many dwelling houses. These fire and explosion hazards occur where these products are regularly handled and also when transported through the community.

The National Board of Fire Underwriters has been a pioneer of model codes to aid communities in their fire prevention responsibilities. In 1895 the National Board published the first nationally recommended electrical code, in 1905 the first model building code, and in 1930 the first model fire prevention code.

Zoning regulations are not often considered home fire preventions, but they are significant. Zoning regulations often separate dwellings from lot lines and limit heights of buildings. Separations are helpful to a fire department in controlling a dwelling fire.

An effective community fire prevention program cannot be accomplished without the support of people in the community. The services of the National Board of Fire Underwriters are available to all communities. Communities must do their part for an effective community fire prevention program. By working for fire prevention you protect your own home as well as your neighbor's. ▲

LET'S STOP THESE FIRE DEATHS!

by PERCY BUGBEE

general manager, National Fire Protection assn., Boston

Present estimates are that we have 5,000 fires every day of which about 1,600 occur in buildings. The great majority of all of these fires are due to simple, readily understood causes. One has only to look at the daily record of fires in any large city to realize that this is so.

As an example, I took a look at the fire record prepared by the Insurance Patrol in Chicago for one recent day. There were 80 fires recorded on this particular day. Of these, 27 were from careless disposal of cigarettes or matches, 14 from accumulations of rubbish near heaters or other open flames, 11 from defective furnaces or chimneys, nine from the careless handling of gasoline or kerosene, eight from portable oil stoves, six from defective electrical wiring, four from gas burners, and only one from a special hazard.

When it comes to deaths and injuries due to fire, the same general situation applies. Every day our Fire Record department receives reports of local tragic incidents such as these.

Perhaps one reason why the general public does not become aroused over such needless waste and suffering is that good, reliable statistics nationally on deaths and injuries in fire have not been available and these isolated cases arouse interest only in the local area where they occur.

For many years we have been struggling with this subject of reliable fire casualty statistics and the NFPA Committee on Fire Casualty Statistics has come up with a standard form for reporting fire casualties. This is being tried out at the present time in a number of states and we hope eventually to persuade all of the states to use it so that in course of time reliable fire casualty statistics may be forthcoming. Your help in getting recognition of this form and its use in your own states and communities would be very much appreciated.

EDUCATE CHILDREN ON FIRES

How can we attack this problem which is so important? How can we effect a mass education of all of the people so that as part of their daily routine they will not commit acts of carelessness that result in death and destruction? What are the forces that are or ought to be available to us in a mass attack upon this problem? Rather obviously, a basic consideration is the education of the children in the schools in the simple principles of fire prevention. The National Education Association has been tackling that problem in recent years with conspicuous success.

Teachers are overburdened and resist any attempts to introduce new material and new subjects into their courses of study. But the NEA proceeds on the principle that teachers will much more readily accept suggestions and material prepared by teachers for teachers. It produced a series of excellent manuals on how to teach fire prevention in existing courses of study from the elementary grades up to the high school grades.

The teachers that have experimented with this material and have taught fire prevention in their classes in science, English, art or civics have found that the subject is a great attraction to children and the response is excellent. In view of this development, all that remains to be done in this field is to gain the teacher's acceptance of the material so that we can insure that subsequent generations will not handle fire so tragically carelessly as does the present generation.

HOUSING INSPECTIONS

Another new and growing and very important force in the overall attack upon fire deaths is the campaign initiated by the International Association of Fire Chiefs through the Fire Prevention committee of that association headed by Jay Stevens of San Francisco. Stevens has recognized that one simple, effective and inexpensive method of attacking this problem is through the simple inspection of all dwellings in a community by the fire department.

This approach is not new. It has been tried in several hundred cities, in some as much as 20 to 25 years ago. Wherever it has been tried it has shown a marked reduction in dwelling fires with subsequent reduction in loss of life because after all, the great majority of fire deaths are in homes and among the children and the aged. Stevens says that already on the West Coast more than 2,000,000 homes have had such inspections by the firemen and that the campaign has been successful in such cities as Los Angeles and Berkeley, Calif., Seattle, Wash., and Portland, Ore.

A third approach to this problem and also one that has been tried with great success in numerous individual communities in various parts of the country is the inspection of homes for simple fire hazards through home inspection blanks distributed to the children in the schools. Here again we have a device that is simple, inexpensive and effective, and wherever it has been done on a consistent basis it has worked.

USED INSPECTION BLANKS SUCCESSFULLY

Kansas City, Mo. was perhaps the most notable example of this type of approach when during a period of several years of consistent home inspections by the school children a bad record of deaths, injuries and destruction in dwelling fires was materially reduced.

A fourth attack upon this problem of fire deaths is the year-round educational campaign directed at home fire prevention conducted by the National Fire Protection Association through all of the existing publicity media such as the newspapers, the television and radio stations, magazines, house organs, and the like.

Sparky, the firehouse Dalmatian dog, is the symbol of this campaign and has become a familiar and well-liked figure to the American public. Hundreds of communities have organized Sparky Fire Departments for the children of the community under the sponsorship of the fire department.

We have now available, therefore, these movements and these tools that we know will do this job and we must find ways and means of utilizing them effectively. The great American Red Cross has realized through its disaster relief program that a substantial majority of all the disasters are fire disasters.

UTILIZE COMMUNITY GROUPS

Certainly we should take advantage of the widespread community organization of Red Cross chapters everywhere to work through this now interested group to gain acceptance of the educational program, the fire chiefs' program, the home inspection program through school children, and the Sparky home fire prevention program everywhere.

The Boy Scouts of America have discovered that one of the potent sources of sponsorship for Boy Scout troops are the volunteer fire departments of the country. Here is another great nationwide organization that can be of tremendous help in a broad attack upon the problem of reduction of fire deaths.

There are other great national groups that we have yet to reach effectively but that I think can be reached. I am thinking of the General Federation of Women's Clubs, the life insurance companies and the labor unions as examples. I can see no reason why these and other groups cannot be interested in supporting in every community throughout the country the principles of fire prevention once they understand that such support is not costly or difficult or unreasonable.

Such forces working in each community with the help of the local Chamber of Commerce, safety council, insurance board, Rotary and Kiwanis Clubs, and similar local civic groups, can effectively stop these fire deaths.

I have tried to outline the simple measures that need to be taken and in broad terms the sort of support that is needed to put across such measures. Is this job too big, too comprehensive and too scattered so that we must admit defeat, or is this problem so simple and so common place that it is not challenging enough to fire protection people? I am not suggesting for a moment that we should not proceed in every way that we can to improve our standards of fire protection engineering, to improve our fire training programs, our fire department operations and our fire prevention activities in more complicated fields.

But if we are to perform the greatest public service then we must constantly hammer away at the simple, every day things that cause the greatest toll of death and destruction by fires.

OFF-THE-JOB ACCIDENTS HURT INDUSTRY TOO

by J. L. RIDINGER

director, safety and plant protection, Inland Steel co., East Chicago, Indiana

During the year 1956, 80,700 people died because of off-the-job accidents. If these accidental deaths continue at the current rate for 1957, the undertakers, the grave diggers, the tombstone people, the florists and the cemetery associations can say they have had another successful year.

Have we become so calloused to accidents that we are no longer impressed with the seriousness of this humane and economic problem? Are the medias of communications such as the press, radio and television, "missing the boat" to the extent that the general public has accepted unnecessary off-the-job accidents as a part of modern day living?

I have taken issue with the press and radio on several occasions, for their gory accident stories. I have been told the public is more interested in spectacular bad news than in constructive good news. How many times have you been disappointed in finding safety articles relating to industrial or civic safety accomplishments, relegated to the back pages of Section #2 of your local newspaper?

If the public is more interested in reading about bad news than good news then our job is to change public opinion. How can this be done? First there must be a common understanding of the need for safe practices and conditions on streets and highways, in

the home and in other public endeavors. Second, the public must demonstrate their desire for traffic safety, home and public safety by complying with regulations and by cooperating with the various law-enforcement agencies.

PEOPLE ARE LAZY

My experience with various public endeavors, political, civic and social, is that the average person feels he is too busy to take an active part in these affairs because he is more concerned with utilizing more and more of his time for personal enjoyment. Also I believe most people are naturally lazy, both mentally and physically, when it comes to joining a worthwhile crusade that may interfere with personal plans.

I also believe to be successful in our campaign against off-the-job accidents we must form the type of crusade that will shake the average person from his complacency. At present this crusade is in the formation stage. Its nucleus consists of the mourners of the dead, the National Safety Council, the press, the radio, the TV, manufacturers, business people, civic and political groups.

Our main objective is to get this safety crusade on the road. To do this job effectively we must have more than casual support from sponsoring groups and the public.

The National Safety News article, "The Challenging Decade," stated, "Population in the age groups 45 years and over will increase during the next 10 years because of the small families during the early 30's. In the age group 25 to 44 years it will decrease."

"If our economy continues to expand at recent rates, the gross national product must increase more than 40 per cent with the per capita share of this product to increase some 25 per cent."

"These figures all boil down to the fact that our productive population will be decreasing while our non-productive population and overall demand for goods and services are increasing."

"To keep pace with this situation we must conserve our manpower, upgrade its skill and increase individual productivity."

To illustrate the effect of off-the-job accidents upon industrial productivity, here are a few case examples.

A steel mill roller with 40 years of experience had the bumper of his car and another become locked. Trying to free his car he sustained a severe back injury and lost two months work. As a roller, his knowledge, training and experience is invaluable, and his company had to upgrade different crew members and break-in a new man to fill the crew.

In spite of close supervision there was a daily loss of production. This accident was costly to the injured and his family in terms of lost wages, to the crew in terms of a reduction in tonnage bonus, to the employer in the loss of production. Customers were dissatisfied because of delayed shipments.

CASE NO. 2

Elmer was a farmer when he was not running an open hearth hot-metal crane. Last year he helped his neighbor harvest corn. Elmer started around the corn elevator, but at a point inches from the coupling of the unguarded drive shaft, he slipped and his leg skidded against the rotating shaft. Quickly his trouser wound itself around the shaft, and his trapped leg became a pulpy mass of flesh.

This accident has changed Elmer's way of life—off and on he spent over two months in the hospital. Approximately five months later Elmer was ready to return to modified work. He lost $2,500 in wages, aside from an estimated $2,000 cost of living expense.

Elmer's accident also caused a chain reaction at the plant. Although Elmer's replacement had been well trained in the proper operation of hot metal cranes, additional time and experience was still required before he became as proficient as he should be on a single crane. Accident exposure is certain to be greater during such periods.

The relief craneman, in turn, had to be replaced by a crane operator learner. The problem faced by this man is a magnification of what the relief craneman had to undergo. Then another employee had to be placed as a crane operator learner. This chain reaction of operational changes created problems for everyone from the lowest hooker to top departmental supervision.

CASE NO. 3

Robert, a sheet piler was driving home, missed a curve and crashed into a ditch. He fractured his left tibia and fibula and was hospitalized nine months.

One month before Robert's accident, his department had installed a new production line. A three week training period was held on the new unit. The department was desperate for trained personnel so Robert's loss to the department was even more frustrating.

His replacement created additional work difficulty and presented greater accident exposure which had to be offset by additional supervision and personal awareness of the new man. During the new man's training period as piler, lifts had to be repiled, sheets rejected, and everyone on the line had to cope with the added consideration of working with a new man.

Because Robert had to be retrained for the piler job, the entire training period in wages alone was a complete loss—about $200. Wages paid Robert during his training periods when he returned to work were beneficial since they were an investment for future job needs, but this was a needless cost, amounting to $900 or $1,000. Other cost figures not available, were wages for repiling badly piled lifts, and other incidental costs in connection with handling of same. Finally, additional services were required from the staff and departmental personnel to integrate Robert into the work force.

These are but a few of our off-the-job case records. Others involve supervisors, clerical workers and a variety of skilled craftsmen.

PUBLIC RESPONSIBILITY

Most men and women involved in off-the-job accidents are parents of children, or have parents or relatives dependent on them for support. Although more than 90 per cent of our employees are covered by off-the-job insurance we cannot expect insurance to replace the worker's wages for an indefinite period of time. When insurance payments run out, various types of tax-supported welfare aid begins, which means tax bills and industry pay the greatest share of the country's tax.

The public should be interested in accident prevention work to prevent pain and suffering from accidents, and at the same time eliminate the need for public charity.

Whether your business employs one or a thousand workers, accidents hurt industry too. Workers are part of the assets of any business. Whenever a worker is fatally or seriously injured on or off-the-job, both the worker and business suffer an economic loss.

Although much credit must be given the National Safety Council, local safety councils, civic groups and law-enforcement agencies for reducing off-the-job accidents, our crusade against accidents will not be successful until all business and industrial groups take an active part in off-the-job accident prevention work.

During the past three years the Inland Steel company has spent considerable time and money to make our workers more safety conscious about off-the-job accidents. We have used the following programs with a favorable degree of success:

TRAFFIC SAFETY CAMPAIGN

- Inland Safe Drivers club—Membership in the club is voluntary. Workers are solicted by their foremen at safety meetings. Those that sign a safe drivers pledge are given a reflectorized bumper sticker for their cars. This is a continuous campaign.
- Safety seat belts—In addition to equipping all company cars and trucks with seat belts, our employees can purchase seat belts and have them properly installed at a reduced rate. Seat belts should be considered standard equipment on all cars and highway trucks.

During the past year you have had the opportunity to read many articles on the pros and cons of seat belts. Seat belts should not be considered as a panacea for all automobile accidents. Like safety glass, tires and highway rail guards, their use can only help to minimize injuries.

- Safety car checks—During the past two years we have cooperated with the local police by checking all company cars and trucks. In addition we have set up check lanes to check all cars driving in the plant.
- Education program—(a) Traffic safety films are shown at group safety meetings. (b) We publicize and post pictures of local highway accidents, furnished by the Indiana state police. (c) Our employees are kept

abreast of traffic safety activities in the state by information we receive from the Indiana Traffic Safety foundation. (d) Facts and figures published in the National Safety Council *Traffic Safety* magazine are used extensively.

HOME AND PUBLIC SAFETY

——Home inspections—At intervals our safety engineers inspect the homes of employees for unsafe acts and unsafe conditions. Pictures are taken and safety stories are published in the plant newspaper. These inspections are made at the request of our employees.

——Cartoon Contests—Safety cartoons showing unsafe conditions and unsafe acts, in the home and on city streets, are published in the plant newspaper. Wives of employees submit a list of unsafe acts and unsafe conditions found in the cartoons and are eligible to compete in a turkey drawing contest.

——First Aid Training—Each year more than 10 per cent of our employees are trained in first aid. Some employees have saved lives because of their knowledge of first aid. This year we expect more than 40 plant teams will compete in our annual first aid meet.

——Safety eye glass program—Employees who must wear prescription glasses are encouraged to purchase safety glasses. The company pays for part of the cost. With safety glasses the worker is safer in his car, at home, on the golf course and while participating in other sports and activities.

INJURY STATISTICS

For the past two years we have publicized throughout the plant on-the-job and off-the-job injury statistics once a month. Figures for the first eight months of 1957 are as follows:

Plant disabling injuries	54
Fatalities	0
Off-the-job injuries	144
Fatalities	13

Employees spend more time away from work than on the job, but this is no justification for people to have more injuries at home, on the streets and highways, or while on vacation and week end pleasure trips.

There are several reasons why workers should be safer on-the-job than off-the-job, even though exposure to injury is greater on-the-job than off-the-job:

1. Industry, whenever possible, selects the proper type of person for the job.

2. Workers are trained to develop and use safe work habits.

3. The employer's machines and equipment are equipped with approved safeguards.

4. Workers who willfully disregard safety regulations are subject to disciplinary action.

5. Last, but most important, employers know that accident prevention programs can not be successful without a continuous campaign to improve the worker's attitude toward his own safety and that of his coworkers.

Over the years industry has made tremendous progress in the scientific field. This has resulted in fewer accidents, increased productivity, push button control operations and better working conditions.

Many of the new technological devices such as automatic switches, safety interlocks, electric eyes, television and radar controls prevent accidents and injuries to workers.

. . . BECAUSE OF HUMAN FAILURE

We still have not reached the push button stage insofar as using it as a positive control for human behavior. Human failure is still responsible for 85 per cent of the industrial injuries. However, the total number of industrial injuries has been considerably reduced because of our accident awareness program. We believe that because of this continuous program to prevent injuries anywhere, we have helped to make our workers' homes and communities a safer place in which to live.

Many of the safety control measures used in industry can be used to control off-the-job accidents if properly applied.

EDUCATION is most important. There must be a common understanding of what is right and what is wrong, by all agencies such as schools, churches, civic, social and political groups.

LEADERSHIP—There must be leadership and cooperation. Every person must assume his share of responsibility for his safety and that of his family.

The National Safety Council and the American Society of Safety Engineers are well qualified to provide leadership on a nation wide basis. But each community can be best served by its own local safety council in cooperation with the National Safety Council.

Our big job is to stimulate an awareness within people to want safe homes and safe highways and other public places. Until people develop this awareness they will continue to destroy themselves and others, at home and on the highways and in other public places.

FLEXIBILITY AND FEEDBACK PROGRAMMING FOR A MULTI-LOCATION OPERATION

by M. FRANCES DEVINE

personnel supervisor, Northwestern Bell Telephone company, Des Moines, Iowa

We are keenly aware of what safety means to people and what people mean to industry—people alive, healthy and whole. There is nothing more important in the whole world. People mean life. Abraham Lincoln said, "next to creating life, the greatest thing a man can do is save a life." We are interested in this since we are vitally concerned with the number of bodies being needlessly dismembered, disabled, and lives lost from not realizing the dividends of safe living.

How can industry get more and more people imbued with the knowledge of living safely no matter where they are or what they are doing? Industry has accomplished a great deal in promoting safety on-the-job. Of recent years many have expanded these activities to safety off-the-job, many with special emphasis on home safety. The Northwestern Bell Telephone company, like all Bell System companies, has had active on-the-job safety education for many years and with splendid results. Results earned the National Safety Council Award of Honor five out of the last six years.

Telephone work is safe and is becoming more safe as time goes by. But how much of this is being carried away from work? Our company examined off-duty lost time injuries three years ago. Our off-duty injuries far surpassed those on duty. The need to expand our program for preventing off-duty injuries was urgent. This problem is far reaching, involving not only employees but their families. How does industry approach such a problem? A challenge indeed —off-duty safety promotion requires a different approach than on-the-job. To be of assistance when needed is a basic characteristic of human nature. We knew if our people were informed of the problem and enlisted to prevent painful injuries, we would get some effective action.

Our problem was to reach the 7,000 employees in the Iowa area. We have offices of varying sizes in many locations. On-the-job safety education is to a great extent departmentalized, but off-the-job safety lends itself better to an interdepartmental set up.

COMMUNICATIONS IMPROVED BETWEEN DEPARTMENTS

Number one in importance: effective communications from one location to another. This required a multi-location operation by expanding existing safety committees and organizing additional ones, such as:

1. Area interdepartmental safety committee, Iowa area headquarters, expanded activities to off-the-job promotion.
2. District interdepartmental committees organized in each of the eight districts and
3. Local interdepartmental committees in most of the 64 exchanges in Iowa.

The program had to be adaptable to all locations. Because every person is different in background, motivation, previous experience and viewpoint, the information had to

be able to reach not only each force group but each individual.

People should not have to experience injuries to learn to live safely. Our objective was to generate interest and participation from our people to think of their responsibility in the prevention of injuries and then to act. This requires a program flexible in all phases with many different approaches and ideas. What will interest and appeal to one will have no effect on another. Our objective could be accomplished if enough interest was sparked to get each location actively engaged in formulating ideas of their own.

Initially the material was referred from the area to the district committee and then to local committees. After the interest was stimulated and various committees produced ideas and material of their own, a feedback of what is being done and how, is necessary. It is valuable information for passing on for use elsewhere and also for appraising results. This requires sustained interest and effective communication at all points in our multi-location set up, from our top executive down. The better the communication the better the feedback.

MULTI-LOCATION OPERATION

A letter signed by department heads containing comparative figures of on- and off-the-job injuries was forwarded to 32 district heads in our eight districts. The letter emphasized knowing what the situation was to stimulate their thinking and lead to corrective measures. To assist them and safety committees, printed matter and visual aid material was sent to the district interdepartmental committees for all employees. The area interdepartmental committee assisted in organizing district interdepartmental committees and supported them. The area group also encouraged reports of the program from each district.

District interdepartmental committees were organized and the names of the chairmen and members sent to the area committee. The committee chairmanship is rotated in some locations. Many existing departmental committees in the local exchanges were expanded to interdepartmental membership. The committee membership in the local exchanges is on a rotating basis to reach and interest each individual and stimulate ideas and suggestions from the group. Their meetings are held monthly during working hours. Here is some of the material forwarded (and some on a continuing basis) by the area committee to the district committees for a review and distribution to local exchanges to stimulate interest and participation:

1. *Living Safely Off-the-Job* prepared quarterly.
2. Summary of off-the-job employee lost-time injuries.
3. *What's the Answer*—booklet about child accidents, also samples of universal antidotes for poisons.
4. Copies of Home Safety News Service (N.S.C.) and subscriptions for this service for each district head.
5. *Industrial Supervisor*, another N.S.C. publication.
6. District chairmen placed on mailing list for *Targets for Home* and *Traffic Safety*. National Safety Council. Also mailing list of Iowa State Department of Public Safety.
7. Promotional material for national campaigns for traffic safety and campaign to prevent falls.
8. Minutes of area interdepartmental safety committee meetings. Supervisors informed of problems and expansion of activity to prevent off-the-job injuries.
9. Bell System booklet—*Safety In the Bell System*—pertaining to both on- and off-the-job injuries.
10. Safety buttons for safety committee members.
11. Safety films suggested.

FEEDBACK MATERIAL

It wasn't too long before we started getting "a take" so to speak. The district and local committees began originating ideas of their own and securing material from other sources. Following is some of the feedback we received from them:

—Employee made posters—poster contests.
—Join the crusade—Against home accident prevention.
—"Could This Be You or Yours"—for posting.
—Newspaper clippings submitted by employees.

—Rickard's method of artificial respiration for children under two years of age — reproduced from Home Safety News Service and mailed to all employees' homes.
—Danger of using carbon tetrachloride—reproduced from Home Safety News Service—also mailed to employees' homes.
—"Let's Make April Fall Free"
—Bulletin on safely cleaning yards
—Open Season Booklet—Outdoor Activities
—Safety Slogan Contest
—First Aid Training
—Home Safety Displays
—First Aid Charts
—Safety Jingles—Act put on from wheelchair demonstrating various kinds of injuries.
—Article on Power Lawn Mowers
—The Road Ahead—As You See It
—Various pamphlets from National Safety Council—*Vacation Safety—10,000 Mile Living Room, Take It Home With You, Dennis the Menace, On Safety* and many others.

We knew there was a great deal going on in various locations, but it wasn't until all this information was compiled for the National Safety Council *1956 Home Safety Inventory* that we saw it all together.

How has this effected results?

OFF THE JOB LOST TIME INJURIES

1956

No. of Cases		*Days Lost*
83		1138
1 Fatal Auto Accident		
Two Major Cases and Most Serious		
Falls — 36	—	623 Days
Auto — 17	—	319 Days

1957

No. of Cases		*Days Lost*
73		699
0 Fatal Auto Accidents		
Two Major Cases and Most Serious		
Falls — 33	—	317 Days
Auto — 21	—	282 Days

Approximately 50 per cent of the accidents occurred in the home.

As can be noted from the results, the first six months of 1957 had 10 less cases and 437 less days and no fatalities. Safety activities are more far reaching than we know—there are others, such as familiy members, friends and neighbors who no doubt have also been saved from injuries. For instance, in one case an employee used the Rickard method of artificial respiration on his six day old baby and feels this saved the child's life.

These results are immensely encouraging and satisfying to all who have helped promote safe living. It makes us realize even more the big job to be done. Programming for a multi-location safety operation is not simple or easy. It can present some real difficulties, such as, some of our barriers to a successful safety operation:

1. Sustaining interest at the area, district and local levels.
2. Breakdown in communications.
3. Failure to plan ahead.
4. Failure to follow through.
5. Recognition—insufficient or none.
6. Effective distribution of material.

Constant attention to these barriers is essential to a continuous safety program. Promoting safety, especially off-the-job requires time, patience and persistence because we are dealing with people and the habits of people and some people are more adaptable to changing habits than others. Industry can approach the problem of educating people to be safe at all times by:

1. Employee participation — people who work on safety, become safety conscious.
2. Effective communications — two-way—through all lines of organization.
3. Recognition—for participation—results and interest.
4. Flexibility — throughout to reach all people.
5. A feedback of what is being done, will in turn strengthen and reinforce the entire program.

When this program is actively under way, an ever increasing circle of employees, their families, friends and neighbors will work and live more safely, and spread the message of safety. Every action we take in support of such a program has its compensating effect somewhere—on someone. It can truly become, a crusade for safe living!

CONSUMER EDUCATION AND PROTECTION

by JACK H. CORNELIUS

manager, Community Relations, The Peoples Gas, Light & Coke co., Chicago

In a story on safety in a magazine that crossed my desk recently there appeared this quote. "Unguarded machines cause less than five per cent of total accidents; unguarded minds cause 95 per cent."

At Peoples Gas we are not quite sure of the accuracy of these percentages, but to be on the safe side we have developed a full program in both areas.

The appliances on our lines must be soundly engineered and properly constructed to utilize our fuel safely. The gas industry as a whole, long has recognized this basic fact and as a result has for many years conducted a program of laboratory testing of gas fired appliances. This laboratory testing program, conducted by the American Gas Association, has led to the development of a set of performance requirements to be met before the appliance can be granted a seal of approval.

The gas appliance manufacturers fully approve, in fact, financially support this program and work closely with industry testing people in developing new features to be incorporated into modern gas appliances. The industry has been responsible for the attachment (by manufacturers) of clear, simple operating and lighting instructions to all automatically controlled gas appliances.

TESTS APPLIANCES

Peoples Gas also has a laboratory in which it tests appliances distributed in the Chicago area. This may seem like gross duplication since we test appliances previously approved by the American Gas Association industry-wide laboratories, but I hasten to point out that the AGA tests hand-tooled prototype models while we test production models. Often there is a considerable difference. Then, too, Chicago has some problems peculiar to this area, such as the large number of small stove heated dwelling units, that make it desirable for us to have more rigid safety requirements.

Our testing people also help find practical solutions to service problems which may arise as a result of a serviceman or engineer visiting a customers premises. Testing also closely observes the performance in the field of newly developed equipment. At present they are conducting tests of gas air conditioning installations.

Another way in which we attempt to upgrade the quality of appliances attached to our distribution system is through a dealer education program in which we urge the dealer to sell a better equipped gas appliance. Our sales division has a dealer contact section to administer this program.

INSTALLATION INSURES SAFETY

In order to get top efficiency from a well designed appliance it must be properly installed and adjusted. Peoples Gas makes few installations of appliances. Recognizing the need for improving the knowledge and ability of outside service personnel who install and adjust appliances the company has established a training program at one of our public schools, the Washburne Trade School, where plumbers and steamfitters are taught proper installation practices.

In addition, our sales engineers cooperate with heating contractors in advising them on proper space heating equipment installation methods. We inspect all completed water heater and space heating installations to make certain they meet safety standards and that they are operating efficiently.

So you see, we do recognize the importance of the machine and men in any safety program and we have developed this comprehensive plan to insure a minimum amount of trouble due to appliance failure.

Our late president, Mr. George F. Mitchell, often said, "Wherever you have concentrated energy, you handle it with respect." The gas industry has long recognized the truth of this statement and has developed programs to implement Mr. Mitchell's philosophy. This problem is not peculiar to the gas industry alone. The electric industry faces the same situation. Each industry has of necessity recognized its responsibilities, and has developed educational programs to teach customers to handle these forms of concentrated energy with respect.

ADDED ODOR FOR PROTECTION

Natural gas in its original state has no taste, no smell, nor can you see it. In order that uncontrolled gas can easily be detected we have added a very unpleasant odor in the form of a specially developed chemical —and we have made it just as "stinky" as we possibly could and still have it smell like the manufactured gas we remember so well.

Then too our customers receive, from several sources, instructions on how to use their gas burning appliances. It starts when the salesman is making a sale. Part of his pitch is what the appliance will do and how it does it. This necessarily entails an explanation of proper operation of the gas appliance.

If after the customer has received delivery of the appliance he or she does not understand fully its operation, one of our home service representatives will, upon request, visit the customer's premises and give on-the-spot instructions.

SERVICEMAN AIDS CUSTOMERS

Another source of customer education is the serviceman's call. Thousands of such visits to customers' premises are made each working day of the year. And in many instances the serviceman is called on to explain to the customer what has gone wrong and what should be done in the future to insure efficient operation of the appliance.

For example, if the serviceman finds excessive grease on the range burner or in the broiler he will point out this is a potential fire hazard; then he will instruct the customer in the best way to clean the burner and how to keep it clean easily.

Our public contact employees, those who talk with customers coming into our offices and those who answer telephone calls to the company, have all been instructed in safety measures to be observed in appliance operation. As a matter of fact, each of these persons has undergone a course of training in our Fitters School, originally established to train our servicemen. Each newly appointed customer-contact employee is given a course in appliance operation and in safety precautions to be observed, and each year all customer-contact employees are sent back to school for a refresher course.

During the war, when we had a shortage of servicemen, our customer-contact employees advised customers how they could correct many of the minor difficulties affecting the operation of an appliance.

PAMPHLETS, EXHIBITS EDUCATE

Pamphlets have been developed which instruct the customer in the safe, economical operation of the gas burning appliances. Here are some examples of booklets available at Gas Company offices:

Helpful Information on Gas Heating.

You Can Have More Hot Water Faster For Less Money.

The Gas Water Heater Installation Guide.

Practical Chimney Construction.

We also maintain at our main office location a customer display floor where we exhibit examples of proper installation of gas appliances and heating systems; where we have diagrammed and constructed models showing proper insulation of buildings; the proper construction and lining of chimneys; the correct venting of gas appliances and all the other safety features that lead to respectful handling of this concentrated energy. There are on duty at all times sales engineers to answer the questions about gas appliance installation from customers, contractors, and builders.

When a customer plans remodeling or adding a new gas appliance, he or the plumber can call the Gas Company and ask for an experienced inspector to advise on how the piping job should be done. One of our supervisory people will visit the premises in question and outline in detail what steps to follow and the pipe sizes to use to insure safe, efficient operation.

COOKING SCHOOL TEACHING

In furthering our program of consumer education we periodically furnish to the daily and neighborhood newspapers feature articles describing best practices to be followed when using gas appliances and instructions for proper maintenance to keep the appliances operating at peak efficiency.

Another phase of our consumer education program, which also is part of our sales promotion effort, is that of conducting cooking schools for our customers and the placing of gas ranges in Chicago schools to

teach high school girls how to use these appliances properly. This teaching includes operation and care of the equipment, safety precautions to be observed, and helpful hints in the efficient use of the appliance.

This then is the program we have developed to teach the public that properly controlled gas is a wonderful servant.

To complete our safety picture we follow-up these two programs with one of inspection—to insure our teachings are being heeded.

First let me point out that we cooperate fully with the municipal authorities—not only in the development of housing and building code regulation of gas appliance installations, but also, because of our frequent contacts with our customers, in helping secure compliance with the codes.

Some of these regulations have to do with proper venting of appliances, restrictions on location of various appliances, room sizes and materials to be used for piping. Because we make literally hundreds of thousands of visits to customers premises each year, our people can discover and report installations which are not in compliance with safety requirements.

We notify the customer he is in violation of a given ordinance, tell him what must be done to correct the violation and after a reasonable period of time has elapsed, inspect the premises to insure compliance with the statutes. The offending appliance is disconnected and left disconnected until the violation is corrected. All our people who visit customer premises (these include servicemen, meter readers and inspectors) are trained to recognize these violations.

CHANGING METERS

Just consider one phase of our customer premises operations—that of changing meters. We do a volume of 100,000 each year because we adhere to the requirements of the Illinois Commerce Commission in changing a meter each 10 years to insure its accurate registration.

By the way, we find, of the few meters not accurate within the allowed range, most of them register slightly in favor of the customer. In addition, meter readers read our more than one million meters six times a year, and our servicemen average about 2,000 calls a day on customer premises.

We are careful to set meters in locations where they can easily be reached and read, and we insist on the customer maintaining easy access to the meter location so our service people will not have difficulties.

In addition we have a program of renewing service pipes in areas where needed. And in the areas of substandard housing, where most of the breaking up of large apartments into small takes place, we make a house-to-house inspection looking for house piping installations which do not meet safety requirements.

How effective has this program been? It is difficult to measure accurately the results of such a program, but we know we are on the right track when reading the following report of the National Board of Fire Underwriters for the decade 1946 through 1955. Of the 19 categories of causes of fires, gas ranks 14th.

Fires in U. S. Resulting from Known Causes
(As reported to National Board of Fire Underwriters)
For the decade Jan. 1, 1946-Dec. 31, 1955

CAUSES	PER CENT CLAIMS
1. Matches, Smoking	26.26
2. Misuse of Electricity	14.00
3. Lightning	9.86
4. Petroleum and its products	6.90
5. Stoves, Furnaces, Boilers and Their Pipes	6.76
6. Exposure (fire originating off Premises)	6.43
7. Ignition of Hot Grease, etc.	4.36
8. Overheated or Defective Chimneys, Flues, etc.	4.28
9. Miscellaneous: Cause Known but not Classified	2.69
10. Hot Ashes and Coals: Open Fires	2.42
11. Open Lights	2.26
12. Rubbish and Litter	2.19
13. Spontaneous Combustion	1.74
14. Gas: Natural and Artificial	1.72
15. Sparks on Roof	1.62
16. Friction, Sparks from Running Machinery	0.94
17. Sparks Arising from Combustion	0.80
18. Explosions	0.36
19. Fireworks, Balloons, etc.	0.15
	100.00

These figures indicate our program has resulted in some measure of success, but we will not relax our vigilance or curtail our program. Safety is a full time, unrelenting job. We shall continue to work in the fields of appliance design and installation, to educate our users in safe practices, and to continue our inspection program to insure that all our customers can handle this concentrated energy called gas—and handle it with respect.

WOMEN'S SAFETY COUNCILS— THE BEST WAY TO THE MEN

by J. H. WILLIAMS
superintendent of safety, Texas & Pacific Railway co., Dallas, Tex.

We, of the Texas and Pacific Railway company, have found through study that an accident occurring to a member of a worker's family often is the direct result of the worker himself being injured, or by his mind being elsewhere, causing others to be hurt or causing damage to company property. This was my first real concern with home safety prior to the time that I became the safety officer of our company seven years ago while I was a division operating officer.

There have been occasions where it was necessary to relieve an experienced man of long service from duty immediately when an accident at his home involved his wife, mother or children, due to mental anxiety brought on by grief and worry. It was for this reason that as soon as I took over the responsibility of safety among our employees, I, together with our superintendents, gave serious consideration to doing something that might bring about desired results —"safety among our workers' families at home."

We knew that the women of our employees had to be reached and in such a way that they too, would become vitally interested in this subject and would assist us. The job was one that would require many people among our personnel if the plan was to succeed. With the help of our division superintendents we set out to encourage the organizations of T&P Ladies' Safety Councils at our terminal points where a sufficient number of our forces made their residence. These councils were to be made up of wives and mothers of our employees.

WHY WOMEN HELP

We felt that the women had three good, solid reasons for wanting to do what they could to help in the program by keeping things at home safe and pleasant so as not to ever send the menfolks off to work with a heavy heart and troubled mind. The wives, we knew, would cooperate because:

First . . . the man involved is the one that she loves and the one for whom she is most concerned.

Second . . . he is the father of her children, for whose safety she is also constantly concerned, and

Third . . her future happiness and well-being, and that of her children depend entirely upon his safety.

We were successful in getting these organizations started. At the beginning a few ladies, probably four or five, whom we thought would be interested, were asked to meet with us at a luncheon where we discussed the proposed setup, it being thoroughly explained that we did not expect nor desire that these groups take any part in our safety program among employees on the job . . . but to confine their efforts strictly to the job of eliminating accidents in their own homes and to do what they could toward encouraging the wives of other employees to do likewise . . . we pointed out why.

LADIES ORGANIZED GROUP

The small group immediately caught on and by circular letters addressed to all Texas and Pacific ladies in that particular town, signed by the four or five ladies who attended the luncheon, a meeting was called of any ladies interested, explaining fully in the circular what the conference would be about. To our utter surprise and delight they came in large numbers and were enrolled.

At this meeting, without any suggestions from the division superintendent or me, they nominated and elected their own officers and were furnished a membership card and a book of by-laws, and the regular monthly meeting place, date and time were decided upon.

As the councils at various points were organized, our company magazine carried the stories, and it was not long before groups in other towns were requesting such

an organization. We now have 11 councils at terminal points between El Paso, Texas and New Orleans, Louisiana, some with memberships running into several hundred, and most of them have been in existence for five or six years.

SOCIALIZING PROMOTED

We rarely hear of an injury in any of these homes because they meet monthly and discuss accident prevention and any accidents that might have occurred in the home must be reported for discussion. Another great thing that has resulted is that the men have fewer accidents at work. These organizations have been a fine thing in other ways, also.

The families occasionally get together for an outing such as a picnic or a party and they have formed great friendships where prior to the creation of such organizations they hardly knew each other at all. The really surprising thing that we did not expect is the part that these councils have played in safety throughout their entire respective communities. They have come to be recognized as an important organization and helpful public-wise.

I could go on and on telling you about their city-wide safety programs in the schools, their organization of baby-sitter clubs, their work with the state, county and local police departments, their city-wise bicycle safety contests, and work with the state and local safety organizations, and the many, many honors that they have received from persons in high station from the Governor down.

WOMEN BRING HONORS

For the past four years our company has been honored by receiving the coveted Public Safety Activities Award from the National Safety Council, which honor—for the most part—was directly the result of the work carried on by our Texas & Pacific Ladies' Safety Councils. Their activities have been most helpful from an employee and public relations standpoint.

They have used to a great advantage "Targets for Home Safety" which is distributed by the National Safety Council and which is reproduced in large quantities for their ready use. Much of the other material offered by the National Safety Council has been found helpful also. They receive a lot of help in the way of safety material from insurance companies, state and local safety organizations, and others.

They have written scripts and acted out the parts in colored, sound moving pictures on home safety that have not only been shown to our employees, but to the public as well. By the use of our Ladies' Safety Councils for these films and employing magnetic sound, the cost of such films have been kept to less than $100.00.

AID TO WOMEN'S WORK

These councils receive an unlimited amount of help in their work from ministers of all faiths, school officials, service clubs, newspapers, police departments, Chambers of Commerce, and from the state, county and city. Also leading doctors—particularly pediatricians—have helped them immensely. Any group of wives can do what they did, but they must receive proper encouragement and assistance.

Personally, I think it is a great thing, and so does our top management. In addition to helping in a small way financially, letters of encouragement are occasionally written by our Executive Officers to the heads of the councils, and to point this up I will quote a letter written to one of the councils by W. G. Vollmer, the President of our railroad, which reads:

> "I was given an opportunity to read the item in the Bunkie Record of Friday, October 7, about your big bicycle safety contest held on Thursday evening, September 29th, on the Bunkie Elementary School campus.
>
> "It gives me a lot of pleasure to extend congratulations to you, and to Mrs. Nelson and Mrs. Crouch, your co-chairman for this wonderful work. God bless you for your interest in it and in all mankind.
>
> Sincerely,"

Many letters of this type have been written to these ladies, complimenting their work, by our top management—and I must say that if any organization of this kind is contemplated by industry, it must have continued, enthusiastic support from the management of whatever company is concerned.

SAFE AT HOME

by WILLIAM V. KAHLER

president, Illinois Bell Telephone co., Chicago

(Presented before the Home Safety Conference Committee of National Organizations)

The telephone business started with a home accident.

Alexander Graham Bell—working in his rooming house laboratory—was trying out a new dilute sulphuric acid transmitter when he accidentally spilled some of the acid on his clothing. And as he called for help to his assistant in another room, "Mr. Watson, come here, I want you!" the transmitter in his hands carried his words as its first intelligible speech.

So far as I know, that is the only accident in any business that has been celebrated as a happy and momentous occasion. Ever since the telephone was invented—and made safe for all to use—safety has been the working creed of everyone in the telephone business.

For some 80 years folks in this country have been turning to their telephones when accidents occur in their lives. We're mighty proud of the reputation our operators, linemen—in fact all of our employees—have earned, over the years, for helping others in time of emergency.

TAKE SAFETY SERIOUSLY

In our handling of emergencies we take our safety seriously and that's why we take an active part in National Safety Council work. We hope that by so doing we will become increasingly conscious of—and better educated in—accident prevention and safety.

My interest in home safety is based on a practical consideration—which I'm sure motivates many other businesses, too. It is simply that in this country about half of all accidental injuries—and about a third of all accidental deaths—take place in the home.

Can we afford to be apathetic when we know that someone in this country is accidentally injured at home every seven seconds—that there is one fatal accident in the home every 17½ minutes? In one hour about 500 home accidents occur and 3 or more of the injured die because someone failed to form reasonably safe habits around the home.

ECONOMIC FACTORS

Aside from humanitarian reasons—which in themselves are sufficient to motivate us—the economic impact of home accidents is many times that of on-the-job accidents. Business men would be foolish indeed if they didn't do all they could to promote safety both at home and on-the-job—since in fact—these are times when fringe benefits are a considerable part of business payroll costs—and any improvement in the accident rate actually helps control the price of a product or service.

Perhaps some of you have seen this statement by James Cantlen, Vice President of Pacific Telephone:

> "For some reason, whenever people leave the job at 5 o'clock a big majority leave behind most of their training in safety. They rush down the stairs for the bus. They jaywalk. They do hundreds of foolhardy things to endanger their life and limbs. And they do it without thinking. In the average of the last 10 years, 173 Bell System employees have died in accidents off-the-job to 15 on-the-job, a ratio of about 11 to one. The dangers of just living seem to be greater than the hazards of working . . ." (at least in the telephone company).

And that 11 to one ratio of fatal accidents in the home to those on-the-job is more than matched by the less serious ones. In our company the ratio of all lost-time accidents is 13 off-the-job to one on-the-job.

JOBS SAFER THAN HOMES

These statistics—and I imagine they are representative of what happens in many other employee groups—all boil down to one simple fact: Our jobs are safer than our homes!

And that shouldn't be!

We have to admit to certain difficulties, however, as we look at the home safety problem. This emergency room record at Stamford (Conn.) hospital for one recent day suggests what some of them are:

A 4-year-old girl *injured in the ear* by a toothpick-wielding playmate.

An 11-year-old *struck in the eye* by an umbrella thrown by a playmate.

A 10-year-old boy *hit on the head* by a tin can.

An 11-year-old boy *broke an arm* playing basketball in his own back yard.

A 4-year-old girl and an 8-year-old boy *bitten by a dog.*

A 3-year-old girl *poisoned by a toadstool.*

A 3-year-old boy and an 8-year-old girl *sprained their wrists* falling from a tree.

A 9-year-old boy *stung by a bee.*

We can train an adult employee, but can we train a 9-year-old boy—or a bee?

MAKE MOTHER SAFETY LEADER

Busy as she is, can Mother add one more job to her manifold duties and responsibilities—that of Safety Supervisor? She's already the family chef, chauffeur, maid, and nurse—and goodness knows what else!

But in spite of these difficulties, the goal of this home safety conference is, I'm sure, no less than making our home life as safe as our business life.

As you work together for home safety, three areas of activity might be kept in mind:

INVESTIGATION
CONCENTRATION
INFORMATION

All of them must be keynoted by *coordination.*

Let's now look at three fields of opportunity where coordination can be applied.

INVESTIGATION

In a period of 30 years industrial management has cut accidents in half by eliminating accident causes. This excellent record of safety-on-the-job didn't just happen. It has come about because much investigation, research and analysis has been applied to individual accident occurrences. A similar opportunity exists in the field of home accidents.

Whenever a serious accident occurs in our business, we make a complete on-the-site investigation to determine all the contributing factors. This gives us the knowledge to educate and supervise our employees—to redesign tools—to change our work practices—as the case may be—so that a similar occurrence may not happen in the future.

A few months ago, an accident occurred inside our Cicero Exchange Building. A young apprentice cable splicer was identifying cable pairs at the top of a tall frame. He was standing on a rolling type track ladder, with both of his feet on the same step about eight feet from the floor.

NINE CAUSES OF ACCIDENT

Another employee was sweeping the floor around the ladder. In so doing, he moved the ladder sufficiently to cause the man on it to lose his balance and jump. He landed with all his weight on his heels. The result, the heel bones in both feet were fractured. He was off the job for several weeks.

Now this seems like a simple enough set of circumstances—and yet it was investigated and analyzed from every conceivable angle—to get at the contributing causes.

Nine factors were unearthed which combined to cause the accident—and nine recommendations were made to prevent a recurrence.

These recommendations—and all but two of them have been put into practice—involved everything from retraining our men in the use of rolling ladders—better use of ladder blocks—to best body position and other ways to provide greater body stability at the top of ladders.

Now I recognize that gathering facts from a family involved in a home accident takes some dedicated doing. But surely there is already pertinent information available in insurance company accident claim files—medical cases histories—and coroners' reports—so that a wealth of analytical material could be gathered. It seems we ought to get the material in these files in proper form for all to use. Coordination should make possible full utilization of this information, and our specific targets for attack are bound to emerge.

CONCENTRATION

In this phase we begin to use the products of investigation and analysis. If we are to be most productive in reducing home accidents, we should concentrate on those causes which contribute to our most frequent accidents—and also concentrate our efforts by proper timing.

Let's assume for the moment that *falls* perennially lead in home accident statistics. We would determine the period of greatest incidence of falls in the home and their predominant causes. We would then concentrate our efforts on a program specifically designed to prevent falls. We would review safety codes—standards—design deficiencies —explore manufacturing cooperation—and develop effective ways to strengthen our attack on this type of accident.

We would then have an opportunity to bring to the family group (1) a continuing consciousness of these particular hazards in the home and (2) specific seasonal messages to help in avoiding falls.

NEED GROUP EFFORT

Some years ago Illinois Bell mailed to the homes of our 2,000,000 customers an insert with the telephone bill, a home chart on first aid. I am certain that we went off on our own, either without thought as to the efforts of others, or proper timing, or proper emphasis on most frequent accidents, or any of the other factors of concentration. By hind sight, we would now most certainly want to merge our individual efforts (and I'm sure everyone else would) with consolidated group effort.

As an incidental thought about falls, I'm sure manufacturers would—if asked—cooperate by putting large safety reminder decals on ladders and appropriate signs on other appliances. Also, directions for using appliances and tools are so often ignored that decals could be put on the appliance, warning the user to "play safe—read the directions."

A concentrated attack on home accidents, supported by adequate investigative procedures would be of little value—it seems to me—without an imaginative public information program.

INFORMATION

The National Safety Council has among its membership such widely read publications as the *American Home Magazine* and *Practical Builders Magazine.* Suppose it enlisted the aid of other members of the press and folks in allied fields—organizations like the American Newspaper Publishers' Association—and the National Association of Radio and Television Broadcasters. Don't overlook the Advertising Council, and the Public Relations Society of America. I am convinced that—given the facts—they would all be glad to help in bringing vital home safety messages to the public.

And how about the artists—writers—and composers? Homes have always been a favorite theme of composers. Maybe we should write some new songs—and re-write some old ones—with safety as the theme.

SING OF SAFETY

"Home Sweet Home" might become "Home Safe Home" and "Home on the Range":

Give me a home that's not accident prone
Where the hazards are all stashed away
Where always is heard the right warning word
And the stairs are not cluttered all day.

Millions of impressions in trade papers—home magazines—on radio and television—all directed in unison at avoiding the same type of home accident—would have an indelible impact on many households—and I'll wager eventually would make a big dent in home accidents.

I'm convinced that industry would help, too, with your information program. I have already referred to possible use of Illinois Bell bill enclosures which go to some two million addresses. We also have an employee magazine which is mailed to the homes of our 44,000 employees 10 times a year.

Our company is one that stands ready to put these facilities to work in behalf of home safety, and I'm sure that many other businesses would help in this way, too, if they were asked.

We've found at Illinois Bell that employees and their families welcome Home Safety information and guidance.

SAFETY GLASSES AT HOME

As one phase of our on-the-job safety training we suggest that employees who are "do-it-yourself" fans borrow their com-

pany's safety glasses when doing any work around home involving a potential threat to their eyes. This program has already paid off. There have been at least two cases this year where employees followed our suggestion and avoided serious damage to their eyes. Pictures in our files showing cracked safety glasses are dramatic evidence of the effectiveness of this kind of safety training and practice.

Recently we gave certain groups of our employees refresher courses in automobile driving and suggested that they take printed pieces home to be read by other members of the household. One employee had this interesting reaction:

> "My wife believes this type of program is better than the group insurance. For some reason she would rather have me than the money."

Whatever methods and media are used, I'm convinced that any message on home safety must have imagination and punch.

HOME SAFETY WEEK

You could launch a National Home Safety Week. If we already have too many weeks, maybe we could hitch on to one that's already well established and call it National Fire Prevention and Home Safety Week.

I've looked into a specific or two—and I wonder if there may not be opportunities to look at home safety from a longer-range information and education viewpoint.

Again realizing we're dealing with an already overworked person—can we persuade the housewife-of-the-future to be more safety conscious than her mother or grandmother? It is encouraging to find—for example—that *in our Chicago high schools*, girls in home economics learn safety practices as an integral part of sewing—cooking—and home decorating classes.

Girls learn not only to concoct a tasty stew—but also how to do it without scalding themselves. Perhaps there are other schools in the country that are less mindful of the future housewife's role in home safety. And if there are, there is work to do!

FIRST AID TRAINING

Here's an idea which is certainly not new—but I'm impressed by the fact that experience has shown persons who have completed a *first aid course* are more *likely* to have better safety attitudes and fewer accidents than those who haven't. Is it possible to make first aid training even more widespread than it is?

Perhaps I am talking directly to Red Cross people when I make the suggestion that block or neighborhood first aid classes for parents could be organized on a wide scale. Enlist the interest of a key family in the neighborhood to invite their neighbors into their home to learn first aid. Such a neighborhood party, which can rotate month by month, *might be the* motivating urge.

This idea assumes a sufficient supply of first aid instructors from the Red Cross or other sources—firemen—scout instructors—industry trained people, etc.

I learned that in one of our outstanding engineering *schools, there are actually* sequences on safety; however in some schools of engineering the teaching of safety and design for home safety depends largely upon the individual instructor. Can more be done in this field? After all, who should be more mindful of safety than our engineers of *tomorrow*—*who will* design our structures and appliances.

As we look at the many ramifications, we can all agree that improvement in home safety will not come easily. It will require imagination and hard work.

COMMITTEE ORGANIZED

Investigation—concentration—and information—and all other aspects—require workable coordinating machinery to be effective.

Wisely, a "Committee of National Organizations" has been set up to explore the means of strengthening home safety activities through the coordinated efforts of interested national organizations. Such a committee can be the seed that will grow into an effective national effort—if everyone will provide the necessary nutrients.

You are the *policy makers*—the steering committee—and the rich source of ideas and facts. But I have found in my business that matters as complicated as home safety require a point of centralized staff responsibility.

Fortunately, you have that, too, in the National Safety Council Home Safety Division.

You in the Home Safety Conference have the respect and support of all persons interested in Home Safety. Collectively you represent millions of people whose joint efforts —if directed and focused—can save many human lives—most of them children.

And what greater work could any of us do?▲

OFF-THE-JOB ACCIDENTS

Statistics are such boresome things
And figures rather dull.
It's hundreds, millions, billions, trillions,
Over which we mull.

But facts are facts where ere we go
Regardless of amounts.
So here's some facts on accidents,
And that's what really counts.

It isn't always big machines
With blades of sharpened steel
That rob a man of arm or leg
And make his senses reel.

Nor is it always "on the job"
Most accidents take place,
But just the opposite is true
And figures prove our case.

It's carelessness in little things
At home and on the street
Neglect in moving objects small
Away from running feet.

A makeshift ladder, sliding rugs,
Electric cords that spark
A disregard for cellar stairs
And stumbling in the dark.

Crossing where no crossings are
While looking at the sky,
Driving on a slippery road
With milestones whizzing by.

These are the things that take a toll
We all should frown upon
So watch for them when off the job,
As well as when you're on.

—Humble Pipe Line Company, Houston, Texas

The three day series of lectures entitled Accident Prevention Fundamentals, sponsored by the American Society of Safety Engineers, has been published in a special volume, *Basic Steps in Accident Prevention—volume 3 of the 1957 Current Safety Topics.*

LEARNING TO LIVE . . .

Learning to live—safely—was the drawing card which brought more than 13,000 men and women from the United States and 27 other countries to Chicago for the 45th National Safety Congress. These people gathered to exchange the latest ideas in safe attitudes, safe methods and safe equipment. Through speeches, panel discussions and symposiums, they acquired new ideas for helping others—and themselves—to live, work, and play safely.

This was the reason the National Safety Council was organized less than half a century ago, a time when man's thoughts barely kept pace with the industrial revolution. Since then, man has introduced an atomic age which is bringing the continents closer and has made the earth a smaller world. And now man anticipates inter-space travel!

Through science and technology, man is progressing to increasing speeds in travel and production, and increasing dangers—new dangers never before encountered. These, in addition to the everyday hazards of life, occupied the thoughts of the safety people at the Congress.

To encourage more widespread knowledge of the various fields of safety, the National Safety Council publishes the Current Safety Topics—30 volumes of condensations of Congress speeches and exchanges of ideas. Each volume is a handy reference to different phases of accident prevention. The complete set of volumes are listed on the back page of each volume.

Since the proceedings have been edited and condensed for reference purposes, the complete original manuscripts with any charts or illustrations used, are available in the National Safety Council files. Views expressed at the Congress or in any volume of Current Safety Topics are those of the Congress participants, and not necessarily those of the National Safety Council.

ASSE SUBJECT SESSIONS

This volume is a record of the subject sessions sponsored by the American Society of Safety Engineers at the 1957 National Safety Congress. The conduct of these Congress sessions each year is only one of the many cooperative activities which the ASSE carries on in behalf of its members, and for the benefit of accident prevention work in industry generally.

ARE TRAFFIC ACCIDENTS CRIPPLING YOUR INDUSTRIAL SAFETY PROGRAM?

OUR AUTO FLEET DRIVES FOR SAFETY

by E. J. EMOND
director, Automotive Safety, Armour & co., Chicago

We make sure our auto fleet drives for safety. We select our drivers carefully, educate them in traffic safety and guard their physical condition. We maintain a safe driving incentive program, develop safety standards, work methods, equipment and create safety facilities incorporating all the latest innovations. We constantly create and maintain interest in automotive safety to insure understanding and conformance to safety standards.

We know how much an accident involving our driver and vehicle costs—our carefully compiled statistics graphically illustrate the costs, hidden and direct. Our fleet drives for safety because we know how much it costs in dollars and cents. What it costs in tears and suffering, we can only guess. We watch our company drivers and our accident frequency closely to stifle quickly any increase in accidents and costs.

We will not tolerate traffic accidents in our business, but we certainly do tolerate it on our highways. And this inefficiency off the job reflects itself in our profit-loss column whether we are aware of it or not.

For example, four of our cattle splitters get together for a gay evening. On the way home, they have a traffic accident and can not come to work the next day. You cannot put the cleavers they use in the hands of an inexperienced man. If four of our key men are absent—work in the beef kill is crippled to a standstill, and this setback is reflected throughout the entire plant. This is an obvious leakage in our profits—but what about the other leaks?

Time is lost as other employees stand around excitedly discussing the accident. Production time is lost not only from manpower, but because of idle equipment. Time is spent by the personnel department, payroll departments and insurance departments, filling in forms and checking records.

Time is lost in training fill-in help or new help to replace the injured employees and finally, even when the injured employees return to work. Because they are not paid their full salary while away, they often return before completely recovered, and their productivity is much slower than normal.

ACCIDENTS ARE EXPENSIVE

Based on a conservative estimate of $2.00 an hour, and without including the hidden costs, the industries in Chicago lost seven million dollars in 1956 from off-the-job accidents. For every $100 an employee loses in wages because of an off-the-job accident, industry loses $1,000 in production costs.

Traffic accidents are a big factor in absenteeism. They cost more lost time, are more severe, more frequent and result in more fatalities than any other type of off-the-job accident.

Last year, the highways killed seven times as many children as did polio. We have the Salk vaccine now for polio, but how can we be vaccinated against traffic accidents? An eternal traffic accident prevention program of unremitting education, strong appeal and stimulation, administered with the zeal of an evangelist and planned analytically like a military battle, is our vaccine against automotive accidents.

Traffic safety must be taught, instilled and developed by organized effort. Who is more organized and better equipped to institute and administrate a strong traffic safety program than industry? It is the obligation of industry to incorporate a traffic accident prevention program with industrial accident prevention, because management speaks with authority.

An employee is a captive audience. He comes to his job rested, refreshed, ready to go to work. It is the best time and place to inoculate him in safety on the job and off the job. Safety should be built into the mind and habits of drivers and pedestrians through education. A traffic accident prevention program conducted on the job will be carried into the home where safety habits will be instilled.

THE ALL-TIMES PROJECT

When a child begins to walk, we should begin his safety education. A respect for traffic should be ground into his subconscious. When he is old enough to get his two-wheeler, he is old enough to learn the traffic laws. Before he is allowed to sit behind the wheel of that lethal weapon, the automobile, he should have been so steeped in safety from infancy that the safe way will be the only way he will react.

You may say to yourself, "Why, our firm warns its employees about traffic safety. Every holiday, we put up the appropriate posters." But traffic safety education is not just for holidays, vacations, or Christmas; it is an ALWAYS, ALL TIMES project. Every item in an industrial safety program can be applied to a traffic safety program. It is our moral duty to use them, not only in our plants, but also included in the traffic accident prevention program.

There are many other ways for industry to cut the accidents on our highways. Industry and business should be represented by management in the safety organizations of their community. It is a wise investment since traffic accidents and violations have such a large influence on our job attendance.

When community traffic safety programs are supported year-round by industry, lives are saved, injuries reduced and industry has benefited. It can help itself and its community by financial contribution, by loaning its top safety men to local organizations, by offering its engineers to build safety into streets and highways, by working on committees and in other ways supporting the crusade for safety.

Industry should also support official activities if only for self-preservation. It should, for instance, back a courageous judge in his battle against a traffic violator who might be an employee. It should come out for stricter licensing, traffic legislation, better law enforcement and engineering improvements to protect itself against the unsafe acts of other vehicle operators and pedestrians. When we show consideration for the safety of others, we are also protecting ourselves.

We must do our utmost to remove from highways the individual who has been making our employees into statistics of traffic accidents and fatalities. These can no longer be titled "accidents." As stated at President Eisenhower's Highway Safety Conference, they are murder! A vehicle improperly controlled is an instrument of destruction!

INDUSTRY CAN BE A LEADER

Industry is morally responsible to be the economic and social leaders in the community, the state and the nation for backing the campaign for off-the-job safety. They should bring prestige to the program by lending their names to it. We are very proud of our individual products and their quality. We have quality control departments to maintain the top quality of our "brand." We should apply these reputations to the traffic safety program, so that our company behind the traffic safety program will bring the same assurance and dependability to the program as it does behind our product.

As in any enterprise, teamwork is the secret of success. What greater team is there than American Industry? We proved it when we teamed together to win the war, now we must team together to fight a larger, seemingly endless war—the war on traffic accidents—death—murder on our highways.

COMMERCIAL VEHICLE SAFETY CAN BE IMPROVED

by KARL SCHULZE
senior safety engineer, Western Div., Standard Oil co., San Francisco

Through contacts with the industrial safety engineers in the American Society of Safety Engineers, and observation of the injury statistics that are available, one can't help but conclude that engineers aren't doing the job they are capable of doing.

"Accident Facts," published by the National Safety Council tells us that motor vehicle accidents cause about one-fifth of all industrial deaths. No other source of deaths is as large. In California, which has more vehicles than any other state and probably uses vehicles more in industry than most states, the figure is considerably higher. Approximately 40 per cent of all industrial deaths in California result from motor vehicle accidents. No other agency even reaches 10 per cent by comparison.

In the petroleum industry, motor vehicle accidents are the leading cause of deaths, causing about one out of every four.

The statistics prove that the industrial safety engineer has a problem with motor vehicles he may not recognize and doesn't appear to be solving.

Can he solve it? I think so. That brings up the question, "What tools should all of us be using to solve this problem?" I would say, "You should use the same tools to solve your motor vehicle problem as you used to solve the rest of your injury problem."

TOOLS FOR PREVENTION

A couple of years ago a survey of education activities being carried on by a representative group of companies in the oil industry showed the following:

● Only 64 per cent of the companies occasionally distributed special literature on safe driving to their employees. Yet, everyone knows that a well-balanced safety program uses these education materials all the time. Literature on safe driving is available almost everywhere, much of it free. The insurance companies, the safety councils and the state departments of motor vehicles all are sources of this material. Set up a schedule in your organization and do some of this educational work.

● Only 61 per cent hold periodic safety meetings on safe driving. Here is another well-known medium that only a little more than half the companies are using. Certainly, again, the material for meetings is not hard to secure. Film strips and movies are available from many sources. Speakers are also available from the safety councils, highway patrols, safety societies—the sources of material are endless.

● Only 50 per cent use their house organ to carry the message of safe driving by means of articles, pictures, statistics, or other features. Now I know not every company has a house organ, but only half of those that do are using it for this purpose. Some editors may tell you that safety isn't newsworthy, yet surveys by responsible organizations have shown great reader interest in safety articles that have been prepared by smart editors.

HALF TEST DRIVERS

● Only 50 per cent give their drivers vision or other psychophysical tests. This may sound expensive or difficult, but it is not. A very useful, impressive set of equipment, including such tests as an eye screener, side vision test, color test, and coordination and reaction time test, can be had for $800. Some outfits are available for even less.

● Only 50 per cent give their drivers road tests. Now here is a funny thing. A big rig, such as a diesel tank truck and trailer or a full truck and trailer, may cost thirty or thirty-five thousand dollars, yet companies send employees out with these investments, and they haven't even checked to see if they know the clutch from the steering wheel.

● Only 46 per cent have some sort of rule book, safe practice handbook, or other published standards for the guidance of their drivers. What a wonderful out for the driver involved in an accident—"Nobody ever told me." Even if it's only a few pages of mimeographed material, we should give our drivers something to guide by, and it's wonderful material for discussion in safety meetings.

● Only 43 per cent use the National Safety Council or other posters on safe driving. Posters have long been recognized as one of the staples in a safety program. While we may sometimes wonder about them, many surveys have shown them to be an effective medium of very low cost.

● Only 36 per cent have Safe Driving Award Programs. Awards are controversial, yet I know of companies with fine rates, and almost their entire program is based on the National Safety Council Safe Driver Awards—a very inexpensive way to carry on an effective program.

FEW PUBLISH STATISTICS

● Only 11 per cent publicize their accident statistics to create interest. I don't know how you can get anyone to try to do better when they have no measure of where they stand or any progress they might make. In my own company, we spend quite a bit of money to put out our statistics in a nice printed pamphlet, and you will notice that the motor vehicle experience gets the same space and importance as the injury experience.

● Only 7 per cent use dash board cards or stickers. Cards or stickers are a very cheap, effective means of getting over a safety message. You can buy them from the National Safety Council, trade associations, or make them yourself. It's hard to understand the neglect of this effective medium.

There you have it, a survey of companies with good rates that are making progress, yet the highest percentage on any one item was only 64 per cent.

I would suspect that the same figures would hold not just for the educational part of the safety program, but to all the features of a complete Motor Vehicle Accident Prevention Program.

GOOD PROGRAM ESSENTIALS

A complete Motor Vehicle Accident Prevention Program would have all these features:

1. Proper testing, selection, and hiring of candidates.
2. A Driver Training Program for new hires.
3. A Driver Training Program for in-service drivers.
4. A procedure for thoroughly investigating the accidents that do occur.
5. A Repeater Program for those who become involved in accidents, with retraining, counseling, and the setting of goals of achievement.
6. A record system for keeping track of the accidents and developing proper statistics on frequency, types, basic causes, mechanical condition, and all the other factors which may influence types and frequency of accidents.
7. A record system for keeping track of the individual drivers and their performance.
8. A complete general educational program as already discussed, for maintaining driver interest, based on the statistical information developed regarding basic causes and types.
9. An award system.
10. A Supervisory Training Program so that the entire program can be effectively carried on.
11. A Vehicle Selection and Maintenance Program that provides adequate, safe vehicles in good mechanical condition.

To sum it up, the well-known tools will get the job done. Were we to adopt and use these features to the fullest, we would then have effective programs. We might then, in fact, have truly safe transportation. We would be "Backing the Attack on Accidents."▲

WHAT IS THE INDUSTRIAL SAFETY ENGINEER'S RESPONSIBILITY FOR MOTOR VEHICLE SAFETY EQUIPMENT?

by W. F. BROWN

safety director, Consolidated Edison co. of New York Inc., New York city

A recent sampling of the Motor Transportation Industry shows a frequency rate of disabling injuries of 24.02. Assuming that this sampling was large enough to be statistically significant, this places the industry in 40th position and Marine Transportation in 41st, or last place.

The automobile is one of the greatest killers of all time when it is unsafe or in unsafe hands. In each of the 40 major industries, a large percentage of accidents arises out of the operation of motor vehicles and auxiliary equipment. The problem is worthy of the best efforts of safety people everywhere.

THE SAFETY ENGINEER'S PLACE

The 1957 edition of "Accident Facts" shows that 3,000 (21 per cent) of the 14,300 occupational deaths were in the motor vehicle classification. If we added all the fatalities which occur as a result of faulty auxiliary equipment of motor trucks the percentage would be considerably higher. A sampling of 23 states shows 8 per cent of all vehicles in accidents had unsafe conditions such as unsafe brakes, improper lights, unsafe tires and unsafe steering mechanism.

"What is the industrial safety engineer's responsibility for motor vehicle safety equipment?" The answer is that the industrial safety engineer is responsibile for motor vehicle safety equipment to the same degree that he is responsible for any other safety equipment. As a staff man he is not responsible for the procurement and functioning of any equipment. This is the direct responsibility of the operating manager or supervisor of the activity. In other words, the safety engineer is not responsibile for accidents, but is responsible for the promotion of accident prevention. It is the safety engineer's function to inform and advise the transportation executive in all matters pertaining to safety, including motor safety equipment.

The equipment included in motor vehicle safety equipment — hand and foot brakes, headlights, directional signal lights, stoplights — are some of the most important safety devices and are usually regulated by state or federal laws. In some states they are inspected periodically and required to meet a predetermined standard under penalty of law. Every industrial safety engineer should have a working knowledge of the motor vehicle safety laws. These laws differ among the 48 states and there is a great difference in the degree of compliance and enforcement.

The horn, when used for warning purposes and not to express irritation, is an important safety device required by law. Its use, in many cities, is restricted to dangerous situations.

The fire extinguisher, if one is required, must be ready for immediate use. There is nothing quite as useless as an empty extinguisher when the vehicle is in flames.

Safe tires, with sound sidewalls and adequate treads, are important factors in any safety program. Where snow and ice is a problem, skid chains provide a margin of safety within their natural limitations of reduced speeds.

MOTOR VEHICLE SEAT BELTS

The big question today is whether or not to install safety belts in passenger cars and trucks. The automobile seat belt is intended to offer protection to the person in the vehicle at the time of a collision, either broadside or head-on or of an upset or roll-over.

Wearing safety belts does not insure freedom from injury in motor vehicle collisions, or plane crashes. But they minimize the injuries by preventing the wearer from being thrown out of an opened doorway and by

reducing the impact of his body against the dashboard or windshield. Of course, in a head-on collision or striking a tree at excessively high speed, no belt will prevent serious injury or death.

The following is an excerpt from our safety bulletin on auto seat belts:

"The belt, one for each individual, is securely anchored to the vehicle floor or chassis at its two ends, the straps passing between the seat and the back rest at about a 45 degree angle to the horizontal. The two straps are joined in front of the person's body with a special friction-type buckle with a quick release such as on aircraft seat belts.

"The belt is brought up both sides of the rider and buckle snapped, then the take-up is adjusted until the belt is comfortably tight. (The tighter, the better at the time of a crash.)

"The belt should hold the body by the lower abdomen and the hips, not by the softer parts of the body at the waist line. At the instant of impact, a person without a belt will be thrown forward and strike the dash or windshield with his head, the entire weight of his torso being thrust against his neck. When wearing a belt, if his head does strike, it will be only with the force of the head alone.

"The belt, the buckle and the anchorage all are of sufficient strength to withstand the force of 3,000 lbs. Also, if the vehicle is overturned, the buckle should be released by a finger pull on the latch of only 45 pounds even though a 250 pound person is suspended by the belt.

"The rider is warned when alighting from the vehicle to make certain that the strap does not hang out of the car where it may be damaged by being squeezed between the door and the sill. Self-retracing belts are now available.

"Although seat belts serve a very definite purpose, especially where vehicles are operated at relatively high speeds such as on parkways, no blanket installation of these belts is contemplated. The safety bureau will, however, approve their installation if requested by the department using the vehicle."

There are several other types of equipment or devices which have an important safety factor. These include devices to improve the driver's ability to see, such as proper windshields, free from stickers, and properly functioning windshield wipers, adequate rear view mirrors, properly installed, and easy to adjust headlight-dimming equipment and back-up lights.

DRIVER'S ABILITY TO SEE

Devices to permit others to see the vehicle also have an important bearing on safety. A light color paint provides greater visibility than dark paint, so we changed our vehicles from a dark gray to a bright orange. Larger and more powerful warning lights and reflectors, and reflecting material on rear and sides of vehicles also provide a greater factor of safety.

Serious hazards on the highway are weak directional signals which cannot be seen by drivers until too late to avoid a rear end collision. This is especially bad when the signal lens is dirty and is competing with brilliant sunshine. To make it worse, the driver signaling for a stop or turn believes he is doing everything required and therefore develops a false sense of security.

Devices intended for emergency use include safe jack, flags, emergency lights, tow rope and chains, first-aid kits. These are certainly of great concern to the safety engineer.

One of the basic fundamentals of a motor fleet safety program is the proper selection and adequate maintenance of vehicles to insure maximum safety and efficiency of both vehicle and driver. The safety engineer has the opportunity and the responsibility to advise and assist management in this matter.

Accident investigation, when properly conducted, usually suggests a remedy to prevent recurrence. The safety engineer has access to channels of information—insurance companies, safety councils, police authorities and others, which can be of great value to the fleet supervisor.

RELIABILITY OF BRAKES

A recent accident was caused by a rupture of the flexible hydraulic hose to the brake cylinder. This hose is subject to rapid deterioration and failure from higher pressures and higher temperatures. The best grade of hose is, therefore, the cheapest in the long run.

In a recent issue of *Society of Automotive Engineers Journal* there is a statement which is tremendously important to safety engineers and safety-minded fleet operators everywhere. It says "Brake fluids with low boiling temperatures are potential highway killers." That is why S.A.E. is recommending for safe motoring use only heavy duty 70R-1 brake fluids.

The statement continues—"Moderate duty brake fluids are no longer considered safe for modern, high-speed vehicles, so the S.A.E. has dropped the 70R-2 brake fluid specification from the Handbook. It is hoped that this action will guide state legislatures in passing laws prohibiting the sale of brake fluids which do not meet the S.A.E. specification of 300° F. minimum boiling point. Seven states, Minnesota, Georgia, California, New Jersey, North Carolina, South Carolina and Tennessee prohibit the sale of any brake fluid not meeting S.A.E. 70R-1 heavy duty specification.

"Main reason for the action is that today's vehicles are placing heavier demands on braking systems. Increased horsepower, automatic transmissions, smaller wheels, and smaller brakes all contribute to increasing the heat generated in brakes when stopping a car. For example, a 4,000-pound car, when repeatedly stopped from high speeds, may generate fluid temperatures of 250 F. or more from friction between brake linings and brake drums. This heat is transmitted to the wheel cylinders containing brake fluid. If this fluid has a low boiling point, the 250° F. heat may vaporize some of the fluid and cause brake failure.

HEAVIER VEHICLES AND SMALLER WHEELS

"Changing from open wheels to solid disc type, reducing wheel size, increasing width of rims and tires, placing brakes completely inside the wheel, lowering and streamlining the car bodies, adding fender skirts, improving heat resistance to brake linings, adopting automatic transmissions, and increasing the weight of the cars have increased the temperatures to which brake fluids are subjected.

"When fluid reaches its boiling point it starts to vaporize. Gas pockets or bubbles are formed in the top of the wheel cylinders or in the brake fluid lines. The vapor is compressible, so when you step on the brake pedal the pressure is absorbed instead of transmitted through the fluid to the brake shoe. Thus, the vehicle may not be stopped in time."

Recently one of our top executives had a serious accident in Florida resulting from brake failure caused by either fluid vaporizing or "phantom failure" due to heavy traffic brake applications. He is now using heavy duty brake fluids. There is still plenty of light duty fluid on the shelves of service stations all over the country.

75 POUNDS OF AIR IN A TRUCK TIRE CAN KILL!

"Death sometimes sets weird booby-traps for even the best mechanic.

"It was the evening of December 9th, 1954. One of our huge manhole cleaning trucks was in the garage with a curb-cut in its right rear outside tire. A simple routine job for two men with many years of service in the transportation department.

"They jacked up the truck and let the air out of the damaged tire. They removed the six nuts and two of the lugs that held the dual tire wheel assembly together. As the third lug was about to be removed something exploded. The tire shot forward hurling the mechanic backward. He lay unconscious on the garage floor. An ambulance rushed him to the hospital and three days later he was dead. His skull had been fractured.

DUAL ASSEMBLY

"The dual tire assembly is a mechanically logical and sound device. But like many other mechanical devices, it can and did go wrong. This time with fatal consequences.

"The defective lock-ring on the inner tire opened but the tightness of the assembly held it in place. When the pressure was released, the ring sprung and the inner tube could not contain pressure and it blew out.

"There are ways of preventing such accidents. We are checking all such tires in use or in storage. From now on all lock rings and rims must be unquestionably flawless. Until such time as a better method is developed to guard against this sort of accident, mechanics have been instructed to thoroughly deflate both tires of a dual assembly before starting to remove a tire."

Recently a heavy truck was involved in a serious rear end collision. The investigation revealed that the brake assembly made contact with the accelerator assembly at the exact moment the driver attempted to stop at a traffic light. Obviously, this is a matter of great interest and concern to the industrial safety engineer.

THE DRIVER TRAINING COURSE

This Training Course method has been a most effective means of obtaining the cooperation of drivers and mechanics to keep the vehicle safe. It is important that every driver have a general knowledge of how the power of the motor vehicle is developed and how it is transmitted to the wheels. Even though the driver is not expected to be a mechanic, he will, if he has some knowledge of the construction and functioning of the various parts, be more likely to keep his vehicle in the best possible operating condition, be less likely to strain or otherwise abuse his vehicle, and be better equipped to detect and report vehicle faults in their earliest stages.

It is the obligation of every company driver to perform the "7 Point Vehicle Check" before taking a vehicle on the road. So that this check will mean something to him and so he may recognize other types of erratic vehicle operation, a treatment of the basic mechanics of the vehicle will be given. This explanation will include a working knowledge of:

1—Brakes—how they operate.

2—Clutch—proper use of—how it is sometimes abused.

3—The Steering—its importance to safe operation.

4—Ignition—the electrical system of the vehicle.

5—Cooling system—its importance in relation to operation.

6—Lubrication—its importance.

7—The engine—how it operates.

8—The instrument panel—what does it tell?

9—The accessories—lights, horn, windshield wipers.

10—Exhaust system.

The alert safety engineer will take all necessary steps to insure the safety of auxiliary equipment which is a functional part of the vehicle and not a part of locomotion. Safe tow bars with secondary chains, properly designed safety props for dump trucks, wheel chocks and hydraulic stabilizers to keep the vehicle stationary, and many more items from the general safety environment of good vehicle operation.

AMERICAN STANDARD INSPECTION REQUIREMENTS

One of the most effective steps taken in motor vehicle safety is the development of the American Standard Inspection Requirements for Motor Vehicles D7-1-1956, approved and newly published by the American Standards Association.

This code is intended for use by inspection stations in states where regular inspection is required by law. It is also recommended to fleet owners, school and city buses, taxicabs and even owners of private cars.

Every industrial safety engineer should obtain a copy of this new standard and take the necessary steps to put it to use in his own firm.

The safety engineer is charged with the responsibility for organizing, stimulating and guiding the accident prevention program. If he is smart he will not overlook the problems of automotive safety equipment, or safe automotive equipment. This will have a beneficial effect on both the industrial accident record and the vehicular accident experience of his firm.

MOTOR VEHICLE AND SAFETY MEASURES AND DEVICES—

What Can the Safety Engineer Support and Recommend?

by J. H. MATHEWSON
professor of engineering and research engineer,
Institute of Transportation and Traffic Engineering, University of California

and D. M. SEVERY
associate research engineer, Institute of Transportation and Traffic Engineering,
University of California

Broadly stated our way of life is characterized, in one respect at least, by our attitude of not remaining satisfied with any of the devices we use on a daily or even less frequent basis. This situation is mirrored by our continuing attempts to improve almost everything we use. Superficial examination would lead us to the conclusion that we have contrived to bring about a nice balance.

A more conscientious examination forces us to conclude that all is not well, however, in that we have not yet found out how to bring some of our larger problems into proper focus or, therefore, to subject them to rational evaluation. If we agree that these problems should be evaluated and ordered, then we must further agree that the longer we go on without doing so, the longer we are postponing the solutions. Within this general concept, motor vehicle traffic safety constitutes one of our most perplexing problems.

FAILURE IN STUDY OF MAN

During the past 40 years or so we have devoted discernible effort to research but in large measure it has been concerned with the physical sciences. Neglect, on the other hand, is more nearly descriptive of the effort in the life sciences or more properly, perhaps, in those areas of mobility where interactions between man and his environment are of prime importance.

Notwithstanding the upsurge in effort engendered by the needs and threats constantly confronting us throughout World War II we failed with the return of peace (however uneasy that peace might be), to recognize the need for employing adequate resources on the study of man. Consequently, we know all too little about his motivations, needs, capabilities and limitations in different roles in various dynamic environments.

In the matter of design for optimum safety performance there is substantial evidence to indicate that man is in the most compatible environment when he is in the workplace. This evidence, in part, consists of the record of improvement in conditions relating to health and safety during the past 50 years, and also by the year-in and year-out better safety record of the workplace compared with the records of other principal environments.

There is, however, at least one notable exception. When the workplace is behind the wheel of a motor vehicle on a public thoroughfare, the over-all safety record deteriorates; it does so because the operator is much more of a free agent than he is in almost any other work environment.

Even though less accident prevention control can be exercised over commercial vehicle drivers than is exercised in most other work situations, the control is nevertheless much greater than is presently feasible over the private passenger car driver. In the commercial category the selection, testing and training processes are quite well developed. Beyond this a variety of operational checks are utilized.

For example, many of the heavier vehicles are equipped with recording devices that furnish a profile of the vehicle's movement and speed ranges—starts and stops and the duration of the stops—and, therefore, of

the driver's performance. In the case of the vast majority of private passenger car drivers, the selection factor is non-existent, the testing is on a minimum basis, and training is predominantly in the form of self instruction on a trial and error basis after licensing. Parenthetically, we should point out a notable exception in the training area; this consists of the ever-expanding training function in driver education and training programs in our secondary school system.

RECORD VEHICLE MOVEMENTS

The continuous control exercised over drivers by recording instruments of appropriately equipped heavy vehicles is completely missing in the case of passenger vehicles and in most of the lighter commercial vehicles. But there are still other forms of broad control over the operation of light commercial vehicles including company owned passenger-type cars. One is the rate of fuel consumption, i.e., miles per gallon; another is the maintenance check coupled with the record of maintenance costs.

Before taking up specific safety devices we should like to discuss some further impressions and observations. Among traffic accident researchers a not inconsiderable number believe that continuous and adequate control of the present-day vehicle is beyond the capacity of the average driver. Of course this belief must be viewed in proper context, i.e., in the everyday driving environment in which occur incidents over which the driver has little or no influence as long as he elects to be in a driving situation.

WHAT CAN BE DONE?

If there is even a modicum of truth in the belief that the control demand of the automobile is beyond the consistent control capabilities of the driver, we might well ask what should be done about it? It seems crystal clear that there is no one panacea and equally clear that as a practical matter in this day and age it would be a waste of time to search for one. But there are many things we can do, as can be illustrated with an example. This example portrays both a deficiency and a belated corrective action, although credit rather than discredit accrues to the authorities who took the corrective action.

Some years ago a new type of highway facility was made available to the motoring public. Such a facility is variously called a freeway, an expressway or a throughway, depending upon the section of the country in which it is located. To guard against misunderstanding we should perhaps make it clear that we are referring to high-speed roadways having fully controlled access and no intersections at grade. Just how were motorists introduced to these new type facilities?

In general it was through publicity informing them that average speeds would be much higher than before, that congestion would be eliminated or greatly alleviated, that safety would be greatly increased, and that new low levels of economy in car operation would be attained. Few of these goals have been attained to the extent originally visualized and some not at all. There is increasing evidence that the congestion was merely transferred from one kind of a facility to another.

FREEWAYS REQUIRE NEW SKILLS

There is widespread agreement that the driving task on one of these high-speed facilities is quite different from that on any lower class of facility. This is to say that we need new skills in the form of keener exercise of judgment, sharpening of anticipation and higher levels of attention to the task. These are characteristics that can be improved through education and training. But during the years these new type facilities were being planned and built, no attempt was made to utilize such education and training to prepare the public on how best to use them.

Earlier we indicated that some authorities (actually two in this instance) had taken remedial action for which they are certainly to be commended. However, neither authority is a designer of the system treated and it is the thesis of the authors that the designer of any enginering product must bear responsibility for prescribing the rules governing its use.

It would seem to be quite clear that the people best qualified to promulgate the "rules of the road" are those who design and operate the road systems. This would be a combination of state highway departments (and their counterparts in county and city jurisdictions) and state departments of motor vehicles. Thus far, for the most part,

such agencies have not been able to interpret their legislatively granted authority to include responsibility for adequate dissemination of user rules. The lack of such logical activity has resulted in the assumption of responsibility for the task by a large heterogeneous group of official, quasi-official and private organizations some of which are in direct economic competition with each other.

In no sense are these remarks to be construed to mean, however, that the public school system does not have an educational function in the matter. On the contrary, it has prime responsibility for including all proper aspects of the task in the formal educational process. It is gratifying that this is being done on an increasing scale.

NEW SAFETY DEVICES

Education and training are not, of course, the only means at our disposal, but they are present, or should be, in some degree in all other accident prevention or injury mitigating measures. Another means lies in the use of safety devices. Here, however, we enter into an area that has long been characterized by controversy. It will now be our purpose to appraise a number of safety innovations that have been introduced by automobile manufacturers during the past few years.

Although we do not propose to discuss all of them in great detail, these innovations include safety door latches, padded dashboards or instrument panels, safety rear-view mirrors, dished steering wheels, torsion stabilizers, seat belts and others. Somewhat earlier the automatic transmission was introduced and although it would be difficult to evaluate its contribution to safety it certainly increased the efficiency of the large number of drivers who had recurring difficulty with the manual gearshift.

Safety Door Latches

A strong case has been made for safety door latches. Clearly they should be standard equipment on all motor vehicles, from the lightest to the heaviest. The lighter the vehicle the greater the need and the greater the potential benefit. In accordance with the philosophy of the industry we may confidently expect that door locks will periodically be further improved.

Padded Dashboards

Padding of dashboards or instrument panels is a step in the right direction and there would now seem to be a good understanding of the desirable characteristics of the materials used for padding. Earlier, sponge rubber and a variety of other next-to-useless materials were proposed and in some cases actually used. Basically, the material used should be energy dissipating, not just energy absorbing, and uniformly yield but stay in continuous contact with any part of the human anatomy impacting it. Clearly, too, the resistance offered by the material must not result in a "G" loading above the tolerance level of that part of the anatomy contacted. Complete restitution is also desirable but this must not be obtained through any compromise with the first stated requirements.

Dished Steering Wheel

Although the dished steering wheel has been evaluated as an improvement, designers have a long way to go in reducing the injury potential of the steering wheel and column. There is an immediate need to eliminate from the steering wheel all knife-like edges, decorative plastic cups (such as on those on the tops of some columns) and all pot metal components whatever their purpose. Eventually, the steering wheel and column, as we know them today, will have to be eliminated or, possibly, the column will be designed to yield under some predetermined loading without rendering it ineffective for its prime function.

Torsion Stabilizers

Torsion stablizers not only add to the comfort of car occupants but, more significantly, prevent certain distractive motions of the car. Thus, the driver is less likely to have his attention momentarily diverted from the driving task and, therefore, less likely instinctively to attempt some incorrect or dangerous maneuver.

Seat Belts

Beyond much doubt seat belts or, if you prefer, safety belts are the most controversial of all safety devices applied to automobiles in recent years. Inasmuch as we, the authors, have devoted a good deal of research effort to the design and evaluation of seat belts and other restraining configurations, we shall discuss certain aspects of such restraints in some detail.

During 1955, veritable rash of articles on seat belts appeared in periodicals ranging from top level professional journals like the American Medical Journal and Bulletin of the American College of Surgeons, to the popular mass media variety. These were augmented by a relatively larger number of articles in daily and weekly newspapers, another segment of the mass media. Throughout 1956 and up to recently in 1957, the argument has continued more or less unabated. During this same period a number of pertinent research papers or reports have been published, as well as factually based information bulletins.

RESEARCH OF SEAT BELTS

In the case of our own organization, the Institute of Transportation and Traffic Engineering of the University of California, we published during 1955 and 1956 a number of research papers on seat belts and other force moderating devices or principles. These augmented previous publications or presentations covering Automobile Collision Injury Research we commenced in 1949.

A discussion of seat belts generally includes some reference to anchorage requirements. It should, but often does not, also include consideration of seat configurations and anchorages. In all but the low-speed collisions (under 15 mph, into fixed barriers, and car-to-car closing speeds below 30 mph) in our experiments the seat anchorages of manufacturers proved to be inadequate.

Our objectives included the discovery of basic information covering the nature and extent of the force systems impressed on car occupants, and the collapse characteristics of the cars in collision events. Having determined the loadings under which seat failures occur, it no longer served our purposes to continue to permit such failures in our experiments. Accordingly, in subsequent experiments we reinforced seat anchorages to withstand the G loadings we anticipated. Such loadings were arrived at on the basis of our findings from previously conducted experiments.

Some years ago we suggested the anchorages of front seats of automobiles should be designed to withstand 10G or, preferably, 20G loadings. This same suggestion applies also to rear seats the backs of most of which are loosely held in place. As yet there is little evidence to indicate that designers have heeded this suggestion. In the meantime a greater variety of adjustments have been introduced in the seats of late model cars. This action compounds the difficulty of designing adequate anchorages but by no means places it beyond the capabilities of designers.

ANCHORAGE METHODS

Although there is general agreement that seat belts should never be anchored to seats, there is some difference of opinion as to the merits of frame versus floor-pan anchorages. Floor-pan anchorages can readily be made adequate by using plates or large washers to distribute the load. This is the method specified in the legal requirements of the California Highway Patrol.

With the notion that slight yielding of the floor-pan, under load, was wholly detrimental, some persons and agencies have advocated that anchorages be only to the car frame. In actuality, slight yielding of the floor-pan anchorage is beneficial in that it results in a reduction of both the rate of onset of loading and the peak deceleration. This valuable force moderating quality is essentially missing in the frame-type anchorage because of its greater rigidity.

FINDINGS OF STUDY

Without question there is a need for more information on the performance of seat belts in collisions. Also, since the deficiency of the lap belt in protecting the head and upper torso of drivers and front seat passengers is well known, there is a need for some sort of improved restraining device but it should not be concluded that this means further restriction of movement of car occupants. But even so there is substantial evidence to show that the lap-type seat belt can furnish highly significant protection to occupants of cars involved in collisions.

The validity of this statement is well supported by findings in a recently published report from Cornell University. These findings stemmed from "two preliminary controlled 'experiments' using the 'paired-

comparison' technique." In the first experiment analyses were made on 46 matched pairs of persons as to the relative injury risk of those who wore belts and remained inside a collision vehicle versus those who were not wearing belts and were ejected from a vehicle. The findings were that:

1. Users of seat belts experienced less risk of becoming injured (to any degree, including minor) than the ejected non-users.
2. Users of seat belts had less risk of sustaining moderate through fatal grades of injury (injuries requiring expert medical treatment) than the ejected non-users. The frequency of their injuries of this type was almost 80 per cent lower.
3. Users of seat belts had less risk of sustaining dangerous or fatal grades of injury than the ejected non-users. The frequency of their injuries of this type was over 85 per cent lower.

In the second experiment analyses were made on 81 matched pairs of cars as to whether the risks were different for those wearing seat belts and those who were not, with no ejections from either group. Here, it should be noted, the occupants without seat belts numbered 139 as against 97 occupants with belts. The findings were that:

1. Users of seat belts had less risk of sustaining injury than non-users. The frequency with which they were injured was about 60 per cent lower.
2. Users of seat belts had less risk of sustaining moderate through fatal grades of injury than did non-users. The frequency of their injuries of these types was about 60 per cent lower.
3. Users of seat belts had less risk of sustaining dangerous or fatal grades of injury than did non-users. The frequency of their injuries of these types was lower, but the amount of improvement cannot be stated statistically due to the present level of case volume. In another section of the same report it is stated, again on the basis of statistical analysis of actual accident data, that "Ejected occupants have a five-fold greater risk of fatality over non-ejectees."

In the light of the foregoing based-on-fact evidence one might well ask, What, then, are the grounds for the controversy referred to earlier?

The answer is not difficult to find. To begin with one must see truth in the premise that in all human activities there is no such thing as absolute safety. This is to say that in the safest possible situation contrived by man there is always some degree of risk. When the exceptional or against-fantastic-odds accident occurs it is a matter of widespread human interest and receives publicity out of all proportion to its true worth. On the basis of such a single case many people will make an unqualified decision, with respect to their own conduct, that can clearly be proven incorrect.

REASONS FOR CONTROVERSY

People in this category must subsequently be influenced to change their decision and, in general, this can only be done by furnishing them with adequate and completely understandable information based on fact. Additionally, of course, we know that humans view new procedures and devices with skepticism and will adopt them but reluctantly, if at all, if the change requires or seems to require added effort or an upsetting of habit.

These, then, are handicaps to more widespread acceptance of seat belts in automobiles but they do not constitute a revelation. Nor is the solution, namely education and training, or retraining, anything that we have not known for a long time.

LEGISLATION SUGGESTED

As is well known, it has been proposed that the installation of seat belts in automobiles be made mandatory. Assuming the enactment of appropriate legislation, the fact remains that it would by no means ensure the actual use of belts. Moreover, it seems fairly obvious that enforcement of the use of such belts would inevitably require the use of police power or what many people would view as serious invasion of private human rights.

Some authorities take a more comprehensive view, presumably in recognition of the belief that no great headway has been made in coping with the highway traffic accident problem. Avoiding single issues such as the pros and cons of seat belts these authorities suggest or advocate the establishment of some sort of a national automotive safety agency. If we agree with the idea of a national agency, the paramount issue is whether it should be implemented through a government agency with sweeping legal authority or through a non-profit private agency whose function would be limited to testing and approving safety devices.

"OPERATIONS PLAN"

We believe we would be remiss if we did not avail ourselves of this opportunity to cover some additional aspects of the Automobile Collision Injury Research performed at the University of California. In all of our experiments our objectives have been primarily to discover facts or basic information that would be useful in engineering design.

The nature of the task required, of course, that we include human considerations since our initial over-all objective was to mitigate casualties on our streets and highways. In an "Operations Plan" covering a series of experiments performed during the spring of last year our objectives were set forth as follows:

1. To determine the deceleration rates of the principal sections of the automobile during collision. Special attention will be given to the deceleration rates of the passenger compartment (unitized and frame type structures). The mechanism of collapse of the structure will be studied to determine possible means of improving its collision performance.
2. Evaluation of the forward interior surfaces of the passenger compartment with respect to their potential injury producing features.
3. Determination of seat belt loading and passenger deceleration rates for comparison of relative passenger protection for the unitized and frame type structures.
4. Determination of the comparative costs to repair the unitized and frame type cars following identical collisions.
5. Comparative analysis of permanent deformation for both type structures.
6. Determination of vertical accelerations for the two type structures.
7. To provide motion picture films of the dynamical features of collision deceleration for both the car and occupants for study and review by engineers.

In the light of our experience in experiments conducted five years earlier we had long since resorted to the use of anthropometric dummies as drivers and passengers to take the place of human subjects. These dummies are constructed to U.S. Air Force specifications and have been extensively used by John P. Stapp and others in experiments relating to both aviation and automotive transportation. In our pertinent technical reports, moreover, we should like to emphasize that analyses or diagnoses of injuries to dummies, including interpretation of what the effect would have been on humans similarly exposed, were performed by competent medical authorities.

PROMOTE SEAT BELTS

Where it was proper to do so we have, in our technical reports and other presentations, clearly set forth the benefits to be gained through the use of properly designed and installed seat belts. Although fatal injuries were inferred for all occupants of one car in one of our more recent high-speed experiments this finding certainly does not provide adequate grounds for condemning seat belts. It is widely believed that the vast majority of collision-type accidents occur at moderate speeds of 40 mph or less and it is in this range, therefore, that significant benefits can be gained on both an individual and national basis.

Despite the large resources being employed to cope with the highway accident problem, the gains are small, not always positive, and out of all reasonable proportion to the time and money being expended. In short, the situation is essentially out of control. Can we look forward to comprehensive and effective control and in what direction or directions? Without minimizing the importance of laws and punitive measures, we see little promise in adding greatly to the existing conglomeration of laws and regulations which, in large measure, are unenforceable on anything approaching a universal basis.

Rather we believe that control must be contrived through a more intelligent and subtle approach. This would be, for example, through expansion and intensification of education and training of highway users, application of the techniques of operations research to bring about improved design of the vehicle, the roadway, and the signal, signing and lighting systems used to guide and regulate traffic on the roadway, better licensing of drivers, improved accident reporting systems leading to effective use of the design criteria statistical analysis can provide, and, finally, the allocation or reallocation of greater sums of money for the necessary research.

AUTOMATIC OPERATING CARS

Laboratory experiments, utilizing small-scale models, have already been carried out on the automatic operation of an automobile. Thus, we might look forward to universal application of a device that would automatically cut off the power and apply the brakes under certain predetermined (dangerous) conditions. Short of complete automatic control, something we neither visualize nor advocate in the foreseeable future, such a device would be highly beneficial in that while it would not prevent all collision-type accidents it would bring about a very substantial decrease.

Likewise, we might well consider the development of a device that would record the speed of an automobile at the instant it impacted any moving or stationary object; here also, of course, above that determined dangerous. Such a device would naturally be as tamper-proof as possible and admittedly would have to be under the complete jurisdiction of legally constituted authority. Subsequent to a collision-type accident, the device would be removed, in its sealed condition, for determination of the impact speed and presentation in Court, if need be, as evidence.

It takes little imagination to visualize a number of highly significant benefits that would stem from the universal use of such a device. We might also give consideration to non-extensible or fixed periscope-type rear-view mirrors on all passenger vehicles.

In the commercial vehicle field, proposed remedies for several hazardous conditions might be mentioned. In the driver stand-up-type light delivery vehicle the use of any kind of a restraining device by the driver cannot logically be expected. In good weather the doors on such vehicles are generally kept open and in the event of a mishap that brings about a sudden change of course of the vehicle, the driver can readily be centrifuged out of it. To prevent this, air-actuated net-type doors constructed out of two to three inch webbing, such as that used in baggage compartments on some types of transport aircraft, could well be used.

It is common practice for light delivery-type vehicles to enter private driveways in residential districts. Backing up of the vehicles then becomes necessary and this operation annually results in the death of many small children who have not yet learned how to protect themselves from the hazard of the automobile.

In the long run, entry of delivery vehicles into private driveways should be made unnecessary and impossible but an interim preventive measure that is well within the realm of feasibility would be to equip all such vehicle with an electronic proximity device that would warn the driver of any object moving into the danger zone behind his vehicle in the course of a backing-up maneuver. Although the cost would be considerably greater, the device, through a servo-mechanism, could be made to control the movement of the vehicle.

VARIED WEIGHTS—HAZARD

Another type of hazard, or really two types, stems from the use of our highways by all weights of vehicles from the lightest passenger car to the heaviest truck-trailer combinations. The front bumper on truck tractors and the like are substantially higher than the bumpers on passenger cars.

When a passenger car is struck, in the rear for example, by a tractor or heavy truck travelling at any substantial speed the bumpers serve no useful purpose. Consideration might well be given, therefore, to redesign bumper configurations on trucks so that the trucks will not climb over and grind between them and the pavement passenger cars caught in accidents of the type just cited.

As can readily be verified by observation, truck trailers, as well as most of the heavier

type trucks, are not equipped with rear bumpers. Considering speed differences between trucks and passenger cars on grades, night driving with its inherent reduced visibility compared with that of the daytime, poor dynamic distance judgment of drivers, etc., it is not surprising to find that rear-end collisions between passenger cars and trucks (a passenger car running into the rear end of a slow-moving or broken-down stationary truck) are not uncommon.

In few of these accidents do the passenger car occupants stand much chance of survival, and in some such accidents—spectacular to be sure—the occupants of the front seats of the passenger cars actually have been beheaded. The solution is clear but, as is well known to most people concerned with highway operations, truck owners have great reluctance to add anything in the form of dead-weight to their vehicles.

SPEED PROBLEM

In the area of highway design and operation two conditions should suffice to illustrate the approach advocated herein. Speed currently is, and for a long time has been, the whipping boy of private and quasi-official safety organizations as a prime cause of accidents. These organizations seem to be not at all discouraged by their lack of accomplishment in bringing about any substantial change.

There is a growing awareness, however, that differences in speed, especially on high-speed facilities, are much more important to safety than speed per se. We are confronted here with a large-scale educational and training need that should, in our opinion, be met through the secondary schools and those official agencies that design and operate the highways.

The practice of constructing high-speed highways without adequate physical separation of the opposing ways of travel should be discontinued. By physical separation we mean physical barriers that will prevent crossovers and the often ensuing catastrophic head-on collisions. Although this is not a high-frequency type of accident its characteristics, the certainty of death or serious injury, wholesale destruction and lengthy periods of disruption in the operation of the traffic facility, should prompt us to adopt the preventive measure indicated above.

These are but a few of the possible steps we might be well advised to take. Their implementation, of course, costs large sums of money and some critics will no doubt ridicule them from the viewpoint of economic feasibility. A principal obstacle to resolution of the economic question is our failure to agree on a set of values. The much bandied statement that a dollar value cannot be placed on human life appears to be an opiate for national conscience, and one that prevents us from making a more realistic approach to a problem that is by all odds national in scope.

Perhaps it is not out of order to point out that in one area of our economic structure monetary values have been set on human life. This may be readily verified by reference to the workmen's compensation laws enacted by the Congress and every one of the legislatures of the 48 states.▲

TOTAL CAUSES OF ACCIDENTS ON FREEWAYS IN LOS ANGELES, SAN FRANCISCO AND SAN DIEGO

INDUSTRIAL FIRE PROTECTION

THE SAFETY ENGINEER'S RESPONSIBILITY IN FIRE PROTECTION

by ALLEN L. COBB

safety director, Eastman Kodak co., Rochester, N. Y.

Before beginning any discussion on the safety engineer's responsibility in fire protection, we must appreciate that there are just about as many concepts of the safety engineer's job and his responsibilities as there are industrial plants with variations in organization and in policy. In addition, there is often no established written policy regarding overall management responsibilities.

There is of course a general knowledge that fire and safety matters should be carried out. But without a clear policy the safety engineer's responsibility in the fire protection field is difficult to define.

However, there are two general types of organization in which the responsibilities are fairly well outlined.

The first type of organization creates a sharp separation of fire and safety responsibility. This is common and is most often encountered in smaller plants and industries where the fire problem is relatively simple, such as textile plants and the automotive and machine shop industry. In such plants it is common for management to delegate its fire protection responsibility to an insurance organization.

FOLLOWS INSURANCE COMPANY'S ADVICE

Since the majority of insurance recommendations concern matters of fire protection equipment such as automatic sprinklers and the typical safeguards against fire involved in equipment selection and plant design, the plant engineer or master mechanic carries out the insurance company recommendations which are often considered direct orders.

The plant provides a mechanic to take care of sprinkler valves, to refill the extinguishers and follow the mechanical details of the fire protection system. He may be called fire chief or fire marshal and may have the responsibility of organizing a plant fire brigade if recommended by the fire insurance inspector.

In larger plants with a similar organization the setup may be more complex. Someone in the engineering divisions may be charged with fire protection engineering layout and design and the fire chief may have more responsibility in routine inspections and supervision of open flame permits.

Basically however, there is a complete separation of fire and safety responsibility and the principal accent of fire protection work is mechanical in nature. Considerable reliance is placed on the fire insurance inspector and management may feel it has fulfilled its responsibilities by following laws and ordinances and by being insured.

SAFETY MAN SUPERVISES WORKERS

Under these conditions the safety engineer's responsibility may be very limited. The safety engineer is responsible for staff assistance to management in matters affecting the plant's personnel safety. Death or injury by fire is an industrial accident as is death or injury from machinery or from unsafe acts of individuals.

Therefore the safety engineer — even though job descriptions and organization charts show little fire safety responsibility under his general direction — does supervise safe means of egress, safety clothing, safety showers for clothing fires and fire safety matters in employee indoctrination programs.

Although there is no organization, the safety director and the fire chief or marshal are in close communication and the safety engineer is frequently called for suggestions in fire safety.

The second type of organization is the exact opposite and most often found in the chemical industry where fire and explosion are serious hazards to individual employees, and to the continued existence of the industry itself. Under such conditions management takes an active interest in fire protection and fully appreciates its responsibilities and prerogatives. It uses the technical assistance of the insurance organizations but carefully evaluates these recommendations in the light of in-plant knowledge of the processes.

Typical of such organizations are Carbide and Carbon Chemicals corporation, the du Pont company, the American Cyanamid company and Eastman Kodak company. A pamphlet entitled, "A Guide for the Organization of Fire Safety and Modern Industrial Establishments" is a publication of the National Fire Protection Association. Prepared by the Industrial Committee of the Association, the principal author was Stanley Spence, director of safety and fire protection, American Cyanamid company.

This is the best available guide to plant organization on fires and discusses types of organization and responsibilities in simple centralized plants and plants operating in centralized, partly centralized or completely decentralized organizations.

FIRE PREVENTION AND SAFETY

A fire or explosion in a chemical plant is just as serious a hazard to the individual employee as an acid splash. In many instances the same equipment used for fires would also be used in a chemical spill. Fire and safety matters are completely interwoven, and can not be separated.

When fire and safety are combined into a single organization operations with a relatively low fire hazard often have separate fire and safety inspectors but in serious situations, one man handles the entire job. For example, in the apparatus and optical division of the Kodak Company, the safety organization has separate safety inspectors and fire inspectors. But in plants having chemical operations such as Kodak Park and the Tennessee Eastman Division, each safety engineer or inspector covers fire matters as well.

In the plant with the complex problems the safety personnel require a greater degree of competence and take all phases of the work in stride. Any man technically competent in all aspects of fire protection engineering will also be able to undertake all engineering aspects of safety work.

The best background for a safety engineer is a thorough training in fire protection engineering. Some men responsible for this combined job in the chemical plant have had eight to 10 years experience in the engineering divisions in the industrial insurance organizations such as the Factory Mutual Engineering Division or the Factory Insurance Association.

SAFETY TRAINING EASY FOR ENGINEERS

A man with an engineering degree from a recognized college and with this amount of experience in fire protection engineering can master the engineering requirements of safety work in a relatively short time. The human relations aspect of the safety engineer's work is something else.

However, a man trained in engineering can usually acquire the human relations and human engineering subjects more readily than a man who starts out initially in the human relations field. This is not to say that the man who started in safety or in industrial relations cannot master the fire protection field. There are many outstanding safety engineers in industry who have followed this route, but the course is usually more difficult.

The safety policy of our company is typical of other companies so situated. Our policy states:

"In general, the company's policy is to do all that is reasonable to prevent injury to persons and damage to property and to protect the interest of the employees, the company, the customer and the public from the results of accident and fire. In interpreting this policy the company goes to great lengths to provide adequate safeguards against the fire and accident hazards with proper equipment, materials, methods and trained and instructed employees."

RESPONSIBILITIES OF ENGINEERS

Several items in this statement present a challenge. For example, the protection of the customer indicates the company products should be safe for the prospective users. Many items will have to be considered. The company may bring out a new gadget with mechanical hazards such as pinch points, toxic chemicals or a possible

fire hazard. The trained safety engineer can evaluate the hazards and make necessary recommendations.

The statement also implies that the safety engineer is directly concerned in matters entirely outside the plant. The chemical industry has a great responsibility to the public. It just does not pay to make yourself unpopular with the public. The safety engineer also has a direct responsibility in plant operation which may discharge fumes or other nuisances.

The key word in this statement is the word "reasonable." Safety engineers bear a heavy responsibility in making that important decision of just what is reasonable in fire and explosion hazards.

Our Standard Safe Practice Bulletin #1.01 lists the responsibility of the Department of Fire Protection and Safety. Here are the most important items:

"1.01A RESPONSIBILITY OF THE FIRE PROTECTION AND SAFETY DEPARTMENT.

The fire protection and safety department is responsible for staff assistance to line and service departments in fire protection, fire prevention, accident prevention, and in the control of emergencies affecting the safety of persons or serious damage to buildings, equipment and product.

Some specific duties of the department are:

1. To keep in touch with new developments in the field of accident and fire prevention and, if necessary, to carry on or cooperate in research on problems in that field.

2. To consult with and advise all departments on all phases of accident prevention, fire prevention and protection.

3. To prepare or review and approve, when satisfactory from a safety standpoint, all safe practice standards applying either to the plant as a whole or to specific departments.

4. To review new or modified methods, materials, supplies, and equipment, including buildings, machines, tools, and devices. This shall include the review and approval of building plans, plans of new machines and equipment that involve fire and safety hazards.

NOTE: As one purpose of this review is to provide adequate protection at minimum cost, new methods, unusual building plans or construction and new machine designs should be reviewed in early design stages, necessary factors to be agreed upon in consultation with engineers and operating department supervision.

5. To review and recommend the fire protection to be provided after consultation with the engineering division.

COORDINATES DEPARTMENTS' WORK

6. To review all inspections made by insurance or state inspectors, and in consultation with them and representatives of ECM&U service and operating departments where concerned, to arrive at a satisfactory disposal of recommendations.

7. To review standard engineering practices for fire protection and safety with the ECM&U.

8. To coordinate the work of departmental safety leaders, and to delegate to them such parts of the work that may be best handled in a local departmental organization; for example, investigations of certain accidents, investigations of suggestions, and approval of enclosure guards.

9. To train safety leaders in the basic factors of fire and accident prevention, and keep them informed of new methods and devices.

10. Initiate studies of new devices, conduct fire tests, either directly or with the assistance of other departments.

11. Make periodic inspections on the effectiveness of, and compliance with, all safety and fire precautions.

12. To develop plans for the handling of emergency situations, both these resulting from normal operations and those which may result from enemy action in time of war.

13. To direct operations at the scene of any major emergency. This shall include:

a. General direction of fire operations through the fire chief.

b. Requests for assistance of ECM&U emergency crews.

c. Direction of rescue operations through the rescue and salvage chief.

d. Shutting off services, control of dangerous materials.

NOTE: Matters relating to admission to Kodak Park, release of information to the press shall be referred to the Security Director.

14. To investigate and report all fires and lost time and serious non-injury accidents.

15. To make statistical studies of accidents for management, and for use in planning accident and fire prevention programs.

16. To work with law-making bodies and regulatory associations (American Standards Association, National Fire Protection Association, National Safety Council, etc.) in the formulation of acceptable safe standards and codes.

CONDUCT TRAINING PROGRAMS

17. To conduct, or assist in conducting, centralized training programs for supervisory and non-supervisory personnel in fire and accident prevention.

18. To develop a centralized program and to assist in departmental programs to develop and maintain interest in accident and fire prevention.

19. To interpret laws, directives, and codes dealing with accident prevention and fire protection.

20. To maintain a central control over known hazards through permits for work in designated areas or under hazardous conditions.

21. To investigate and report on safety suggestions or delegate such investigation to safety leaders.

22. To conduct fire tests either directly or in cooperation with the manufacturing experiments division, ECM&U division or others.

23. To report action taken and progress on all recommendations of insurance inspectors to Kodak Park General Management. To avoid duplication, those coming to the attention of the ECM&U Division should be reported to the Safety Department to be combined in one complete report. Copies of these reports will be submitted to the Insurance Manager at Kodak Office.

GENERAL NOTE:

In general, (with the exception of ordinary routine problems), all matters regarding fire prevention, accident prevention in plans and in normal operations should have the benefit of consultation with the Plant Safety Organization."

The fire department of Kodak Park is a branch of Fire Protection and Safety and actually might better be called an "emergency department" since the fire department is first on the scene at any plant emergency. Its first duty is rescue. The fire department is equipped to render emergency service in case of ammonia or acid breaks, solvent spills and all situations requiring quick response by an emergency crew. Therefore the fire department is as much a safety unit as the safety men themselves and the integration of fire and safety services may be said to be complete.

It is obvious that the safety engineer cannot be responsible for the layout and design of automatic sprinklers or the many other matters of engineering design bearing on fire protection. To do so, would require a large staff of engineers and it is better that these be within the general engineering organization.

It is, however, a responsibility of the safety engineer in this situation to be thoroughly familiar with fire protection engineering so that he may review and comment on designs and make specific recommendations. The safety engineer recommends the type and extent of fire protection needed and works closely with the design engineers, fire insurance inspectors and any other authorities who have some jurisdiction.

The safety engineer has very definite responsibilities in respect to fire and these duties vary appreciably with the general organization of the plant. You as safety engineers should acquire and demonstrate competence in the field of fire protection. This would insure an increasing degree of integration of fire and safety services and lead to a greater degree of freedom from the effects of fire explosion among the plant people. Lastly, this would also place greater responsibility on the safety engineer with a consequent increased stature both within his own plant and within the engineering profession.▲

FIRE CONTROL OF SOME OF THE NEW PYROPHORIC METALS

by HYLTON R. BROWN
senior engineer, U. S. Department of the Interior, Bureau of Mines, Washington, D. C.

Twenty years ago A. H. Nuckolls, then a chemical engineer with Underwriters' Laboratories, presented to the 1937 National Safety Congress a paper on spontaneous ignition and its prevention. His paper revealed several facts concerning spontaneous heating of oil films and finely divided metal particles. His introductory statement made 20 years ago still holds: "Spontaneous ignition is not as simple as was formerly supposed and much remains to be learned about it."

Scientific progress during the past 20 years might appear negligible, the principal advance being the use of the polysyllabical word "pyrophoricity" — the tendency of certain materials to heat or ignite spontaneously. But a review of current literature and the preliminary results of research projects indicate that an answer to the problem of pyrophoricity or spontaneous combustion may be forthcoming.

TYPES OF SPONTANEOUS HEATING

Mr. Nuckolls made four differentiations in his classification of substances subject to spontaneous ignition.

1. *Oxidation in air with evolution of heat* is a reaction prompted by exposing a relatively large surface area to the oxygen in the air. Mr. Nuckolls referred to the impregnation of a fibrous material such as cotton with linseed oil. This type of heating is rather common, and demonstrations can be arranged for use in classrooms or at lectures by placing the oily, fibrous material in a container where air flow to or through the material can be controlled until ignition occurs.

At first though, structural metals with which we are familiar would not appear susceptible to ignition of this type. Zirconium, however, is an example of what happens when certain types of metal are being handled or processed. In structural form zirconium can withstand temperatures over 3,000 degrees F without igniting, but freshly divided fine zirconium powder exposing a much larger surface area than a solid mass may ignite at room temperature without any apparent source of ignition when it is blown into the air as a cloud.

2. *Microbial thermogeneris* is the form of spontaneous heating commonly associated with fires in agricultural products and the destruction of hay storage barns. Opinion differs widely on the basic causes, the continuity or overlapping of different phases of this reaction. Research has established that the initial heat in stored undercured hay or similar products is due to fermentation or bacterial activity, but it is believed that the known micro-organisms are destroyed at about 180 degrees F, a temperature below the ignition point of the material in which they usually are found. Ensuing action beyond the heat generated by bacteria, enzymes, or oxidases has been attributed to chemical oxidation, the presence of pyrophoric carbon or even pyrophoric iron.

Metals would seem immune to ignition in this way, but recently some interesting studies were made in bacteriological metallurgy to determine the effect of bacteria on the oxidation of metals. It is too early to evaluate any findings, but many theories on the problem cannot be passed by without giving some thought to possible effects of prolonged bacterial action on certain metal powders.

3. *Chemical reactions* in mixing or combining different substances, some or all considered noncombustible, can produce enough heat to ignite nearby combustibles or the mixture itself or cause a violent explosion. Nitric acid and sawdust, activated carbon and chorine, and many other combinations are examples of this form of spontaneous heating. Exothermic decomposition, with or without the evolution of hydogen, can be included here.

In the field of metals there are many known, and probably some unknown, hazardous combinations. Only a few years ago a British chemist mixed some aluminum powder and carbon tetrachloride together with disastrous results. The Underwriters' Laboratories had already warned of this hazard in their Research Bulletin No. 34, "Reactions of Aluminum and Magnesium with Certain Chlorinated Hydrocarbons." In tests reported in this bulletin the temperature of an alumimum powder-carbon tetrachloride mixture increased to 305 degrees F in 53 minutes. Other results showed that methyl chloride in contact with aluminum may form spontaneously combustible aluminum methyl.

Sometime ago an explosion occurred during laboratory corrosion tests to determine the effect of red fuming nitric acid on titanium. Samples of titanium immersed in the acid in glass flasks were examined from time to time to observe any corrosive effects. Evidently some pyrophoric material, probably finely divided titanium, in one of the flasks was disturbed while handled, and a violent raction occurred. Much heat was liberated, resulting in oxidation and even fusion of metal. The strength of the acid is an important factor in such instances.

Dutch metal or tombac, an alloy of copper and zinc, has some peculiar properties, particularly in the form of foil. This material, sometimes referred to as gold and considered stable in air, will ignite spontaneously in an atmosphere of chlorine at ordinary temperatures.

UNUSUAL DIE CASTING EXPLOSIONS

Recently, reports were received of ignitions or explosions of zinc die castings under unusual circumstances. The castings, which contained about four per cent aluminum, had fallen off of a conveyor into a chromate dip tank and remained in the solution for several hours or days. After they were removed and dried, ignitions occurred. It is believed that long exposure in the chromate solution dissolves the zinc-rich phase and leaves behind the finely divided aluminum phase, which, in the presence of the oxidizing agent of hexavalent chromium, combines the ingredients for rapid reaction when heated.

Similar occurrences have been observed with magnesium die castings. Preferential etching in solutions containing chromic acid leaves precipitates such as a magnesium-aluminum compound in powder form. When air-dried, this powdery surface becomes very pyrophoric and will spark or explode on the slightest contact.

4. *Reaction with water.*

Water or moisture is apparently an important contributing factor in many cases of spontaneous heating, and a number of substances react violently with water. Mr. Nuckolls called attention to the action of water on calcium oxide (unslaked lime), which produces enough heat to cause fires when ordinary combustibles are present. He pointed out that one pound of lime with water evolves 124,000 calories (493 B.t.u.). The hydride of phosphorus produced by the putrifaction of damp sawdust may cause ignitions.

Combinations of metals and water that heat spontaneously or produce explosive reactions should be considered under two headings: Reactions that start at normal temperatures and those that occur when water comes in contact with hot or molten metal.

REACTIONS AT NORMAL TEMPERATURES

Substances commonly referred to as "the alkali metals" would be included in the first group. Sodium, potassium, lithium, rubidium, and cesium are generally mentioned in textbooks or technical papers as those that may produce violent metal-water reactions. In the potassium-water reaction the evolved hydrogen is usually quickly ignited by the heat of the reaction; similar reactions can be expected with rubidium. With the others, considerable heat is produced, but ignition of the evolved hydrogen may not occur as readily.

A number of recent fires and explosions in producing, processing, and handling magnesium, titanium, zirconium, thorium, and other metals have been attributed to metal-water reactions. In some instances where finely divided metals or metal powders have been immersed or wet with water, pyrophoric heating, ignitions, and explosions have occurred with apparently no initial preheating and no external source of heat being present. The damage from these ex-

plosions differed from what is normally expected in a steam explosion. These facts have led to the initiation of several research projects designed to obtain more information on metal-water reactions.

No conclusive data are available from the research to determine the different factors that may affect such metal-water reactions, but Russian investigators, have reported some water-metal reactions in which the energy released approached that of high explosives. Their paper, published in the April 1946 issue of the USSR Journal of Applied Chemistry, discusses the possible use of aluminum or magnesium powder with water or certain organic solvents as explosives.

The hazards that exist in metal-melting plants are usually associated with molten-metal spills, and the possibility of an explosion if the hot metal comes in contact with water. Such explosions are attributed to the formation of steam in pockets within or underneath the metal.

ALUMINUM EXPLOSION TESTS

In the May 1957 issue of Metal Progress, George Long, of the Physical Chemistry Division of Alcoa Research Laboratories, reports the results of 880 tests made for information on explosions of molten aluminum in water. Various factors that might affect the explosions of molten metal in water were studied. The size of the opening through which the molten aluminum flowed into the water, the total amount of metal, and the distance the metal dropped before reaching the bottom of the water container had some effect on the explosions. A number of tests with molten magnesium under similar conditions showed that the magnesium-water explosions were analogous to the aluminum-water explosions except for persistent fires caused by scattering burning magnesium.

Several recent explosions in titanium plants have been attributed to contact of molten metal with water when an arc in the consumable-electrode melting furnace punctured the wall of the water-jacketed crucible. The evidence from investigating these explosions has indicated, however, the presence of some unusual forces and damage not ordinarily associated with steam explosions. Research on this phase of the problem is under way to obtain information on possible metal-water reactions, particularly during melting of pyrophoric metals.

A review of some of the conditions under which fires may occur in handling or processing pyrophoric metals shows that no single method of fire prevention or fire protection will be effective in all cases. Likewise, separate treatment is impossible of many individual hazards or combinations of hazardous conditions in handling metals that may ignite spontaneously. One fundamental rule seems to be that pyrophoric materials which, by themselves, are subject to spontaneous ignition in air should be stored and handled under some nonreactive liquid or gas.

ALKALI METALS

The alkali metals in the pyrophoric group can, under certain conditions and with special care, be handled in air, but such handling is usually in laboratory processes where relatively small quantities are used and prolonged exposure from normal storage protection is not contemplated. Elsewhere special protection with liquid or gas is generally required.

Sodium, which oxidizes rapidly in air and reacts violently with water, is usually stored under naphtha, kerosene, or some liquid without oxygen. This method of protecting against sodium ignition introduces a flammable-liquid fire hazard, and the additional hazard presents a serious problem because many fire-extinguishing mediums suitable for oil fires are hazardous if used on sodium. No water, foam, soda acid, carbon tetrachloride, or carbon dioxide fire extinguishers should be permitted in areas where they may be inadvertently used on sodium fires. Under such conditions fire protection is limited to graphite, soda ash, or other dry powders for smothering sodium fires and flammable liquid spill fires. Sometimes storage under inert gases such as nitrogen, helium, or argon will be quite satisfactory, and under such storage conditions it is not necessary to provide flammable-liquid extinguishing equipment.

Potassium, which reacts violently with water and may ignite spontaneously in air, can be stored safely under inert-gas protection. Fire control is extremely difficult. Graphite, soda ash, and other dry powders

can be used on small fires. Ordinary types of extinguishers should be excluded from areas where they might be used on potassium fires. Carbon dioxide may form an unstable or explosive compound if used on a potassium fire.

Lithium is usually kept under an oxygen-free liquid such as kerosene and toluene but can be stored safely under inert gases such as helium and argon. Nitrogen, sometimes used to protect sodium or potassium, is not recommended for lithium. Graphite and some other smothering powders can be used to control lithium fires, but soda ash, recommended for sodium and potassium, should not be used.

Other alkali metals known to be pyrophoric are not widely used in industry at present, and fire protection involves mainly safe storage and handling to prevent small spontaneous ignitions from spreading to surrounding combustibles. Molten lithium will attack glass, but most of the other alkali metals can be stored in glass or steel containers.

Contaminated material, mixtures, and certain compounds of the alkali metals present some unusual fire and explosion hazards. Information on these different phases of the subject is extremely limited because often the experience reported has been one of a kind. For specific planned operations special fire-control methods have been devised. Although powders and smothering-type extinguishers are generally used for fire control, a liquid-type extinguisher has recently given encouraging results in small tests. Trimethoxyboroxine has extinguished fires in some of the alkali metals, and work is progressing to develop suitable extinguishers to broaden the usage of this product.

METAL POWDERS

Laboratory tests with more than 50 samples of finely divided metal powders, including some alloys and compounds, have indicated some of the conditions under which spontaneous ignition can occur and how small fires can be controlled. Particle size is a very important factor. This indicates that the major cause of pyrophoricity is the large amount of surface exposed for oxidation. In an article, "Spontaneous Combustion of Metal Powders" in the February 1953 issue of Metal Progress, Bernard Kopelman and Vera B. Compton state that zirconium powder having an average particle size of 3 microns is very pyrophoric, but similar powder of 12-micron size does not ignite at red heat.

In Report of Investigations 4853 Dr. Hartmann, of the Federal Bureau of Mines, reports ignitions of uranium powder and the hydrides of uranium and thorium within a few minutes after exposure to air. Zirconium and uranium powder ignited immediately upon dispersion in air as a cloud at room temperature. Many other metals, when reduced to very fine powder, become pyrophoric and ignite within a short time after exposure in air. Apparently some powders can be ignited in carbon dioxide and in nitrogen. Dr. Kopelman reports ignitions of uranium powder under boiling water with generation of enough heat to melt the glass container.

Evidently some degree of fire control can be obtained by limiting the relative amount of surface exposure, but even comparatively coarse powder (30-mesh) when dispersed in air will ignite and explode if a source of ignition is present. Zirconium and titanium powders that received a light surface coating of copper in the manufacturing process required more energy for ignition than untreated powders both when dispersed as a cloud and when placed as a layer on a heated surface.

Small fires in metal powders can usually be controlled by carefully spreading graphite, dry sand, or certain other materials on and around the fire. Sometimes the fire can be surrounded with a ring of inert material and allowed to burn itself out. Extinguishing a metal-powder fire can be very dangerous because of a possible explosion if the burning powder is disturbed. These fires cannot be extinguished with water, carbon dioxide, foam, or carbon tetrachloride, and such extinguishing agents may stimulate the burning or cause an explosion when the extinguisher contents are discharged under pressure onto the fire.

Extinguishers, other than those recommended for metal fires, should be excluded from areas where persons unfamiliar with the hazard might use them on burning metal powders. More specific recommendations for the control of different types of metal-powder fires are incorporated in the Na-

tional Fire Protection Association Code for the Prevention of Dust Explosions in the Manufacture of Aluminum Bronze Powder and the Code for Explosion and Fire Protection in Plants Producing or Handling Magnesium Powder or Dust.

METAL SPONGE, CASTINGS, SCRAP

Some of the unexplained metal fires reported in recent years have been caused by spontaneous heating or combinations of metals and other materials having certain pyrophoric characteristics. The ignitions in out-of-doors storage bins filled with zirconium scrap and of zinc die castings, as well as the unusual incidents with uranium and thorium, reported by R. B. Smith and others, all indicate that spontaneous-heating hazards exist and that special precautions are necessary, not only to avoid ignition but to control fires.

To avoid ignitions of zinc or magnesium die castings left too long in solutions containing chromic acid, the parts should be washed promptly upon removal from the solution. For zinc die castings a warm dilute solution of trisodium phosphate to leach or dissolve the chromate film is recommended. Magnesium die castings can be washed in cold water as soon as they are removed from the solution and then coated with a mineral oil.

To prevent explosions of molten aluminum or magnesium in water, George Long, who conducted the tests reported in Metal Progress made some unusual suggestions. Apparently the tests he reported indicated that such explosions can be avoided by greasing or painting the bottom of a metal container into which the molten metal is dropped. Coatings found to be effective were rustoleum, black asphaltum, and black mastic paints.

INERT GASES BEST

Use of inert gases, such as helium and argon, is still the most effective way to prevent ignition of zirconium and titanium during production of processing at elevated temperatures. Arc welding can be performed under inert-gas protection.

Some success has been attained in extinguishing fires in titanium chips and turnings with water sprays, but in other instances reports indicate that the water only intensified the fire. Apparently unknown factors cause metal-water reactions under such conditions. A similar lack of uniformity has been noted in results obtained with different types of fire extinguishers.

Manufacturers and others who have been trying to develop both liquid and powder-type extinguishers effective on pyrophoric metal fires have encountered many baffling problems. For example, a manufacturer of dry-powder extinguishers found his product would readily extinguish fires in titanium sponge obtained from one source and oily titanium chips from another source but failed to extinguish fires in titanium chips produced at another plant.

Encouraging results have been obtained with trimethoxyboroxine on small fires in solid combustible metals. If suitable methods of application are developed, it may be possible to use this compound effectively on larger fires.

Satisfactory methods for the control of fires in heat-treating furnaces at magnesium processing plants have been developed. Boron trichloride gas was formerly recommended for this purpose, but recent tests show that boron trifluoride is more effective. The gas concentration required with the latter product is only about one-tenth that required with boron trichloride. This method of fire control is described in National Fire Protection Association Pamphlet No. 48, Standards for the Storage, Handling, and Processing of Magnesium.

Sludge disposal presents a serious problem wherever combustible metals are machined, ground, or polished and the dust produced in such operations is collected in liquid precipitation-type separators. To avoid possible reactions between magnesium dust, the coolant used in machining, and the water or liquid in the collector, the sludge should be removed daily and burned or rendered chemically inactive and noncombustible by treating it with ferrous chloride. This method of disposal is described in the NFPA pamphlet on magnesium mentioned. Specific chemical treatments can probably be developed for other types of metal sludge.

Research work on many of the other problems associated with the production and handling of pyrophoric or combustible metals is under way in many laboratories and

experiment stations. The Bureau of Mines is developing safe operating methods, and a National Fire Protection Association committee is preparing standards for fire and explosion prevention in plants handling combustible metals. The results of the research work are encouraging, but spontaneous combustion is not as simple as formerly supposed and much remains to be learned about it.

INGENIOUS APPROACHES IN DEVELOPING MATERIALS HANDLING SAFETY

OPERATOR SELECTION AND TRAINING

by ROLAND W. PUDER

group supervisor, materials handling & packaging, engineering dept.,
E. I. du Pont de Nemours & co., Inc., Wilmington, Del.

The purpose of this paper is to discuss du Pont's experience in operator selection and training as a means of reducing accidents in materials handling and to point out how benefits in any industry can be achieved through a similar approach.

The analysis of injuries in 100 plants of the du Pont company for a five-year period shows the frequency rate and the total number of injuries on a downward trend. Nevertheless, the number occurring in materials handling activities has been constant over this period. If we hope to continue the downward trend of overall frequency rate, we must give particular attention to reducing materials handling accidents. What is happening in du Pont is also taking place throughout industry. The National Safety Council figures indicate materials handling accidents account for approximately 25 per cent of all industrial accidents.

As equipment becomes more complex, each accident may become more costly, as measured in terms of human suffering and dollars paid in compensation.

People don't argue against safety. They do, however, differ in their methods of achieving safety. We believe that safety is founded on the fundamental concept that any job should be done properly—the first time. To achieve this, people must be made and kept safety conscious.

MENTAL CONDITIONING

Safety consciousness is the mental conditioning of people to respond in anticipation of an unsafe situation. It is not enough to make people aware of hazards; they must be taught ultimately to deal with them effectively themselves.

The broad objectives of any safety program can be summarized as follows:

1. Elimination or reduction of human suffering and personal tragedy
2. Increased productivity as a result of a safe environment and increased knowledge and skill
3. Reduction of direct and indirect costs as measured by lost men and machine time and the costs of care and compensation.

A well planned training program is an integral part of the overall safety program and is a prime means of attaining these objectives.

OPERATOR TRAINING PROGRAM

In our company in every training program, we endeavor to accomplish three things:

First, we try to install safety consciousness in every operator.

Second, safe procedures are developed for all jobs being analyzed in the training program.
