TO:

SUBJECT: X-RAY

1-31-84 CHEST (PA): The heart size is within normal limits. There is no evidence of lobar consolidation or pleural fluid. There is very slight blunting of the right lateral costophrenic angle. There are believed to be bilateral pleural plaques. A small nodular density blends with the medial right hemi-diaphragm and there appears to be a large plaque viewed on *face* in the left mid lung field near the lateral chest wall. Very little interval change is noted comparing films dating back to 1980. I do not clearly define any pleural calcifications. These findings are suggestive of asbestosis, however and correlation with clinical history would be helpful.

Conclusion: Multiple pleural changes with little interval change noted over the past four years.
