Aroclor 1254 report: wgt gain data for UC females do not agree with data for same animals in other reports (# 8 = 5.4) mean = 3.7

It is difficult not to conclude that there may be an effect on body wgt. for T-III males and FII + T-III females with 1254 and T-III males and females with 1260. I question whether one has the right to discount animals that show low gains, particularly T-II or T-III animals. These lower gains occurred even though food consumption was unaltered (even higher for T-III 1260 animals).

? Nothing is said anywhere about recovery periods until there are notes on the tables starting with Table XI. Was the purpose of this to permit clearance of tissues for analysis? No clinical studies were done after 24 mo. (e.g. SAP's for 1260) and it is stated on p. 7 that all dogs were sacrificed at the conclusion of the investigation & without suggesting that there was a staggered conclusion.
