8.4 Hiding measure of t however, de influenced b practical tes thickness is visually as c affected by paint. Test precise and a standard. Pa the effects o measured, a

7.4 Drying Properties—The drying time of a floor paint is important in determining when a freshly painted floor or stair may be subjected to traffic. Slow drying of the film may result in dust pickup, poor appearance and, if used on an exterior surface, rain or dew may cause a nonuniform appearance. Generally, water-thinned paints are dry-to-touch in 1 or 2 h when the water has evaporated from the film. Determine drying time in accordance with Test Methods D 1640.

7.5 Leveling Properties—Leveling is an important factor when uniform surfaces are to be produced, as it affects hiding and appearance. The referenced method covers the laboratory determination of the relative leveling characteristics of liquid coatings. Determine leveling characteristics in accordance with Test Method D 4062.

7.6 Producing Films of Uniform Thickness—Test Methods D 823 covers the preparation of various films of uniform thickness essential in conducting tests.

8. Appearance of the Dry Film

8.1 Color Difference of Opaque Materials by Visual Evaluation—Visual comparison of color is fast and often acceptable although numerical values are not obtained. The referenced method covers the spectral, photometric, and geometric characteristics of the light source, illuminating and viewing conditions, size of specimens, and general procedures to be used in the visual evaluation of color differences of opaque materials. Determine color difference in accordance with Practice D 1729.

8.2 Color Differences of Opaque Materials by Instrumental Evaluation—Color difference between a product and the standard can be measured by instrument. Generally the tolerance is agreed upon between the purchaser and the seller. The referenced method covers the calculation of instrumental determinations of small color differences, observable in daylight illumination, between nonfluorescent, nonmetameric, opaque surfaces such as coated specimens. If metamerism is suspected, visual evaluation (8.1) should be used to verify instrumental results. Calculate the color difference measured instrumentally in accordance with Method D 2244.

8.3 Gloss—Water-thinned floor paints generally have a semi-gloss finish which resists penetration of dirt and improves washability. A range from 20 to 40 may be considered typical. Determine the specular gloss in accordance with Test Methods D 523.

8.4 Hiding Power (Dry Opacity)—Hiding power is the measure of the ability of a paint to hide the substrate. It is, however, dependent upon uniform film thickness which is influenced by flow and leveling. Test Method D 344 is a practical test in which paint is applied with a brush, film thickness is approximately measured, opacity is evaluated visually as compared to a standard paint, and results are affected by flow and leveling application properties of the paint. Test Method D 2805 is considered to be a more precise and accurate test that does not need a material paint standard. Paint is applied with an applicator bar to minimize the effects of flow and leveling, film thickness is rigorously measured, and opacity is instrumentally evaluated. Determine

hiding power in accordance with Test Methods D 344 or D 2805.

9. Properties of the Dry Film

9.1 Abrasion Resistance—Abrasion resistance is a measure of the ability of a dried film to withstand wear from foot traffic and marring from objects rolled or pulled across the surface. Determine abrasion resistance in accordance with Test Methods D 658 or D 968.

9.2 Elongation—Elongation is a measure of the flexibility of a paint film. Determine elongation in accordance with Test Methods D 1737 or D 522.

9.3 Adhesion—Adhesion is the property of the film that resists removal from the substrate when scuffed or scraped. It is an important property in a floor paint. Determine adhesion in accordance with Test Method D 2197.

9.4 Resistance to Chemicals—An important property of a floor paint is its ability to resist spotting, softening, or removal when subjected to household chemicals or strong cleaners. Determine resistance to chemicals in accordance with Test Method D 1308.

9.5 Exterior Exposure—If the paint is intended for use on porches, decks, or outside stairways and railings, tests for resistance to exterior exposure may be required and may include the following:

9.5.1 Conducting Exterior Exposures—In conducting exterior exposures, refer to Practice D 1006 and Classification D 1848.

9.5.2 Wood Panel Description—In establishing exposure performance, use the panels as described in Specification D 358.

9.5.3 Chalking Resistance—Determine the chalk-resistance rating by reference to Test Method D 659.

9.5.4 Checking Resistance—Determine the checking resistance rating by reference to Test Method D 660.

9.5.5 Cracking Resistance—Determine the cracking resistance rating by reference to Test Method D 661.

9.5.6 Erosion Resistance—Determine the erosion resistance rating by reference to Test Method D 662.

9.5.7 Flaking Resistance—Determine the flaking resistance rating by reference to Test Method D 772.

10. Analysis of Paint

10.1 Chemical Analysis—If a specification requires certain raw materials or certain components in a given amount then chemical analysis is required to determine whether the specified components are present and in what amounts. Analysis does not necessarily establish paint quality which can also be greatly affected by manufacturing techniques. Most ASTM analytical methods apply to solvent-reducible coatings. However, some of these can be adapted for analysis of water-borne paints.

10.2 Volatile Content—The percent of volatile matter indicates the thinner loss from the film as it dries. This quantity subtracted from 100 % gives the nonvolatile content. Determine the volatile content in accordance with Test Method D 2369.

10.3 Pigment Analysis—The analysis of pigment may be required if the product is covered by a specification or if it is

agreed between the purchaser and the seller. Analyze the pigment in accordance with selected test procedures from Methods D 215.

11. Index Terms

11.1 This guide is indexed under the following terms: floor paints/coatings.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Methods for Measuring Adhesion by Tape Test¹

This standard is issued under the fixed designation D 3359; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

These methods have been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

1. Scope

1.1 These test methods cover procedures for assessing the adhesion of coating films to metallic substrates by applying and removing pressure-sensitive tape over cuts made in the film.

1.2 Test Method A is primarily intended for use at job sites while Test Method B is more suitable for use in the laboratory. Also, Test Method B is not considered suitable for films thicker than 5 mils (125 μm).

NOTE 1—Subject to agreement between the purchaser and the seller, Test Method B can be used for thicker films if wider spaced cuts are employed.

1.3 These test methods are used to establish whether the adhesion of a coating to a substrate is at a generally adequate level. They do not distinguish between higher levels of adhesion for which more sophisticated methods of measurement are required.

NOTE 2—It should be recognized that differences in adherability of the coating surface can affect the results obtained with coatings having the same inherent adhesion.

1.4 In multicoat systems adhesion failure may occur between coats so that the adhesion of the coating system to the substrate is not determined.

1.5 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

D 2370 Test Method for Tensile Properties of Organic Coatings²

D 3330 Test Method for Peel Adhesion of Pressure-Sensitive Tape of 180° Angle⁴

D 4060 Test Method for Abrasion Resistance of Organic Coatings by the Taber Abraser²

3. Summary of Test Methods

3.1 *Test Method A*—An X-cut is made in the film to the substrate, pressure-sensitive tape is applied over the cut and then removed, and adhesion is assessed qualitatively on the 0 to 5 scale.

3.2 *Test Method B*—A lattice pattern with either six or eleven cuts in each direction is made in the film to the substrate, pressure-sensitive tape is applied over the lattice and then removed, and adhesion is evaluated by comparison with descriptions and illustrations.

4. Significance and Use

4.1 If a coating is to fulfill its function of protecting or decorating a substrate, it must adhere to it for the expected service life. Because surface preparation (or lack of it) has a drastic effect on adhesion of coatings, a test method for evaluating adhesion to different surface treatments or of different coatings to the same treatment is of considerable use in the industry.

4.2 The limitations of all adhesion methods and the specific limitation of this test method to lower levels of adhesion (see 1.3) should be recognized before using it. The intra- and inter-laboratory precision of this test method is similar to other widely-accepted tests for coated substrates (for example, Test Method D 2370 and Test Method D 4060), but this is partly the result of it being insensitive to all but large differences in adhesion. The limited scale of 0 to 5 was selected deliberately to avoid a false impression of being sensitive.

TEST METHOD A—X-CUT TAPE TEST

5. Apparatus and Materials

5.1 *Cutting Tool*—Sharp razor blade, scalpel, knife or other cutting devices. It is of particular importance that the

⁴ Annual Book of ASTM Standards, Vol 15.09.

⁵ Permacel 99 manufactured by Permacel, New Brunswick, NJ 08903, and available from various Permacel tape distributors, is reported to be suitable for this purpose. The manufacturer of this tape and the manufacturer of the tape used in the interlaboratory study⁵ have advised this subcommittee that the properties of these tapes were changed. Users of it should, therefore, check whether current material gives comparable results to previous supplied material.

cutting edges be in good condition.

5.2 *Cutting Guide*—Steel or other hard metal straightedge to ensure straight cuts.

5.3 *Tape*—One-inch (25-mm) wide semitransparent pressure-sensitive tape with an adhesion strength agreed upon by the supplier and the user is needed. Because of the variability in adhesion strength from batch-to-batch and with time, it is essential that tape from the same batch be used when tests are to be run in different laboratories. If this is not possible the test method should be used only for ranking a series of test coatings.

5.4 *Rubber Eraser*, on the end of a pencil.

5.5 *Illumination*—A light source is helpful in determining whether the cuts have been made through the film to the substrate.

6. Test Specimens

6.1 When this test method is used in the field, the specimen is the coated structure or article on which the adhesion is to be evaluated.

6.2 For laboratory use apply the materials to be tested to panels of the composition and surface conditions on which it is desired to determine the adhesion.

NOTE 3—Applicable test panel description and surface preparation methods are given in Methods D 609 and Practices D 1730 and D 2092.

NOTE 4—Coatings should be applied in accordance with Test Methods D 823, or as agreed upon between the purchaser and the seller.

NOTE 5—If desired or specified, the coated test panels may be subjected to a preliminary exposure such as water immersion, salt spray, or high humidity before conducting the tape test. The conditions and time of exposure will be governed by ultimate coating use or shall be agreed upon between the purchaser and seller.

7. Procedure

7.1 Select an area free of blemishes and minor surface imperfections. For tests in the field, ensure that the surface is clean and dry. Extremes in temperature or relative humidity may affect the adhesion of the tape or the coating.

7.2 Make two cuts in the film each about 1.5 in. (40 mm) long that intersect near their middle with a smaller angle of between 30 and 45°. When making the incisions, use the straightedge and cut through the coating to the substrate in one steady motion.

7.3 Inspect the incisions for reflection of light from the metal substrate to establish that the coating film has been penetrated. If the substrate has not been reached make another X in a different location. Do not attempt to deepen a previous cut as this may affect adhesion along the incision.

7.4 Remove two complete laps of the pressure-sensitive tape from the roll and discard. Remove an additional length at a steady (that is, not jerked) rate and cut a piece about 3 in. (75 mm) long.

7.5 Place the center of the tape at the intersection of the cuts with the tape running in the same direction as the smaller angles. Smooth the tape into place by finger in the area of the incisions and then rub firmly with the eraser on the end of a pencil. The color under the transparent tape is a useful indication of when good contact has been made.

7.6 Within 90 ± 30 s of application, remove the tape by seizing the free end and pulling it off rapidly (not jerked) back upon itself at as close to an angle of 180° as possible.

7.7 Inspect the X-cut area for removal of coating from the

substrate or previous coating and rate the adhesion in accordance with the following scale:

- 5A No peeling or removal,
- 4A Trace peeling or removal along incisions or at their intersection,
- 3A Jagged removal along incisions up to $\frac{1}{16}$ in. (1.6 mm) on either side,
- 2A Jagged removal along most of incisions up to $\frac{1}{8}$ in. (3.2 mm) on either side,
- 1A Removal from most of the area of the X under the tape, and
- 0A Removal beyond the area of the X.

7.8 Repeat the test in two other locations on each test panel. For large structures make sufficient tests to ensure that the adhesion evaluation is representative of the whole surface.

7.9 After making several cuts examine the cutting edge and, if necessary, remove any flat spots or wire-edge by abrading lightly on a fine oil stone before using again. Discard cutting tools that develop nicks or other defects that tear the film.

8. Report

8.1 Report the number of tests, their mean and range, and for coating systems, where the failure occurred that is, between first coat and substrate, between first and second coat, etc.

8.2 For field tests report the structure or article tested, the location and the environmental conditions at the time of testing.

8.3 For test panels report the substrate employed, the type of coating, the method of cure, and the environmental conditions at the time of testing.

8.4 If the adhesion strength of the tape has been determined in accordance with Test Method D 3330, report the results with the adhesion rating(s).

9. Precision and Bias⁶

9.1 In an interlaboratory study of this test method in which operators in six laboratories made one adhesion measurement on three panels each of three coatings covering a wide range of adhesion, the within-laboratories standard deviation was found to be 0.33 and the between-laboratories 0.44. Based on these standard deviations, the following criteria should be used for judging the acceptability of results, at the 95 % confidence level:

9.1.1 *Repeatability*—Provided adhesion is uniform over a large surface, results obtained by the same operator should be considered suspect if they differ by more than 1 rating unit for two measurements.

9.1.2 *Reproducibility*—Two results, each the mean of triplicates, obtained by different operators should be considered suspect if they differ by more than 1.5 rating units.

9.2 Bias cannot be established for these test methods.

TEST METHOD B—CROSS-CUT TAPE TEST

10. Apparatus and Materials

10.1 *Cutting Tool*—Sharp razor blade, scalpel, knife or other cutting device having a cutting edge or edges angled.

⁶ Supporting data are available from ASTM Headquarters. Request RR D01-1008.

between 15 and 30° that will make either a single cut or several cuts at once. It is of particular importance that the cutting edge be in good condition.

10.2 *Cutting Guide*—If cuts are made manually (as opposed to a mechanical apparatus) a steel or other hard metal straightedge or template to ensure straight cuts.

10.3 *Rule*—Tempered steel rule graduated in 0.5 mm for measuring individual cuts.

10.4 *Tape*, as described in 5.3.

10.5 *Rubber Eraser*, on the end of a pencil.

10.6 *Illumination*, as described in 5.5.

10.7 *Magnifying Glass*—An illuminated magnifier to be used while making individual cuts and examining the test area.

11. Test Specimens

11.1 Test specimens shall be as described in Section 6.

12. Procedure

12.1 Where required or when agreed upon, subject the specimens to a preliminary test before conducting the tape test (see Note 3). After drying or testing, select an area free of blemishes and minor surface imperfections.

12.2 Place the panel on a firm base and under the illuminated magnifier make parallel cuts as follows:

12.2.1 For coatings having a dry film thickness up to and including 2.0 mils (50 µm) space the cuts 1 mm apart and make eleven cuts unless otherwise agreed upon.

12.2.2 For coatings having a dry film thickness between 2.0 mils (50 µm) and 5 mils (125 µm), space the cuts 2 mm apart and make six cuts. For films thicker than 5 mils use Test Method A.

12.2.3 Make all cuts about ¾ in. (20 mm) long. Cut through the film to the substrate in one steady motion using just sufficient pressure on the cutting tool to have the cutting edge reach the substrate. When making successive single cuts with the aid of a guide, place the guide on the uncut area.

12.3 After making the required cuts brush the film lightly with a soft brush or tissue to remove any detached flakes or ribbons of coatings.

12.4 Examine the cutting edge and, if necessary, remove any flat spots or wire-edge by abrading lightly on a fine oil stone. Make the additional number of cuts at 90° to and centered on the original cuts.

12.5 Brush the area as before and inspect the incisions for reflection of light from the substrate. If the metal has not been reached make another grid in a different location.

12.6 Remove two complete laps of tape and discard. Remove an additional length at a steady (that is, not jerked) rate and cut a piece about 3 in. (75 mm) long.

12.7 Place the center of the tape over the grid and in the area of the grid smooth into place by a finger. To ensure good contact with the film rub the tape firmly with the eraser on the end of a pencil. The color under the tape is a useful indication of when good contact has been made.

12.8 Within 90 ± 30 s of application, remove the tape by seizing the free end and rapidly (not jerked) pulling it off at as close to an angle of 180° as possible.

12.9 Inspect the grid area for removal of coating from the substrate or from a previous coating using the illuminated magnifier. Rate the adhesion in accordance with the fol-

lowing scale illustrated in Fig. 1:

- 5B The edges of the cuts are completely smooth; none of the squares of the lattice is detached.
- 4B Small flakes of the coating are detached at intersections; less than 5 % of the area is affected.
- 3B Small flakes of the coating are detached along edges and at intersections of cuts. The area affected is 5 to 15 % of the lattice.
- 2B The coating has flaked along the edges and on parts of the squares. The area affected is 15 to 35 % of the lattice.
- 1B The coating has flaked along the edges of cuts in large ribbons and whole squares have detached. The area affected is 35 to 65 % of the lattice.
- 0B Flaking and detachment worse than Grade 1.

12.10 Repeat the test in two other locations on each test panel.

13. Report

13.1 Report the number of tests, their mean and range, and for coating systems, where the failure occurred, that is, between first coat and substrate, between first and second coat, etc.

13.2 Report the substrate employed, the type of coating and the method of cure.

13.3 If the adhesion strength of the tape has been determined in accordance with Test Method D 3330, report the

Classification of Adhesion Test Results

Classification	Surface of cross-cut area from which flaking has occurred. (Example for six parallel cuts)
5B	None
4B	
3B	
2B	
1B	
0B	Greater than 65%

FIG. 1 Classification of Adhesion Test Results

results with the adhesion rating(s).

14. Precision and Bias⁶

14.1 On the basis of two interlaboratory tests of this test method in one of which operators in six laboratories made one adhesion measurement on three panels each of three coatings covering a wide range of adhesion and in the other operators in six laboratories made three measurements on two panels each of four different coatings applied over two other coatings, the pooled standard deviations for within- and between-laboratories were found to be 0.37 and 0.7.

Based on these standard deviations, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

14.1.1 *Repeatability*—Provided adhesion is uniform over a large surface, results obtained by the same operator should be considered suspect if they differ by more than one rating unit for two measurements.

14.1.2 *Reproducibility*—Two results, each the mean of duplicates or triplicates, obtained by different operators should be considered suspect if they differ by more than two rating units.

14.2 Bias cannot be established for these test methods.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Operating Light- and Water-Exposure Apparatus (Unfiltered Open-Flame Carbon-Arc Type) for Testing Paint, Varnish, Lacquer, and Related Products Using the Dew Cycle¹

This standard is issued under the fixed designation D 3361; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers the specific variations in test conditions that are applicable when Method 2 in Recommended Practice G 23 is employed for the exposure of paint and related coatings and materials using the dew cycle with unfiltered open-flame carbon arc.

NOTE 1—Another procedure for exposing these products is covered by Practice D 822 in which specimens are subjected to radiation from the enclosed carbon arc or the filtered open-flame carbon arc. The filters in Practice D 822 remove some of the shorter wavelength ultraviolet radiation not normally received at the earth's surface.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Significance and Use

3.1 Organic coatings on exterior exposure are subjected to attack by degrading elements of the weather, particularly ultraviolet light, oxygen, and water. This practice may be used for evaluating the behavior of films exposed in apparatus that produces ultraviolet radiation, high temperatures, and water condensation on the films. This apparatus is used

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.27 on Accelerated Testing.

Current edition approved Nov. 27, 1987. Published January 1988. Originally published as D 3361 - 74. Last previous edition D 3361 - 81.

⁵ Annual Book of ASTM Standards, Vols 06.01 and 14.02.

⁶ Annual Book of ASTM Standards, Vols 06.01, 06.03, and 14.02.

to make an early materials comparison of the exterior exposure quality of paints. However, light sources, such as the carbon arc, that emit a significant amount of radiation at wavelengths shorter than those in natural sunlight, may cause results that lead to unrealistic evaluations of weathering properties.

3.2 This test method produces failure of films at a very rapid rate because the test is run without filters. The unfiltered carbon arc produces light that does not exist at the earth's surface. Failure caused by this light may bear no relationship to failures in natural sunlight. It is essential to have a control material of known performance of a similar vehicle type in every test. Substrates that have good thermal insulating properties should not be used because sufficient condensation cannot be obtained.

3.3 As no single light exposure apparatus, with or without water, can be specified as a direct simulation of natural exposure, this practice does not imply expressly, or otherwise, a specific correlation with outdoor exposure. It has, however, been useful in many instances.

3.4 Since climatic conditions vary with respect to time, geography, and topography, it may be expected that the effects of natural exposure will vary accordingly. All materials are not affected equally by the same environment. Results obtained by use of this practice should not be represented as equivalent to those of any outdoor weathering test unless the degree of quantitative correlation has been established for the material in question.

3.5 Variations in results may be expected when operating conditions among similar type instruments vary within accepted limits of this standard procedure.

4. Hazards

4.1 **Warning**—Never look directly at the carbon arc because ultraviolet radiation can damage the eye. Most carbon arc apparatus machines are equipped with door safety switches, but users of old equipment must be certain to turn the operate switch off before opening the test chamber door.

4.2 This light source generates ozone and nitrous oxides. Exhaust from the cabinet should be vented to the atmosphere.

5. Test Specimens

5.1 Unless otherwise agreed upon, choose panels that meet the applicable base panel requirements specified in Test Methods D 609 and Practices D 1730, D 1731, D 1732, or D 2092. Select panel sizes suitable for exhibiting the failure mode to be observed.

5.2 Apply the coatings to flat panels with the base panel material, method of application, coating system, film thickness, and method of drying consistent with the anticipated end use, or as mutually agreed upon between the producer and the user.

5.3 Unless otherwise agreed upon, coat test panels in accordance with Test Methods D 823 and measure the film thickness in accordance with an appropriate procedure selected from Test Methods D 1005, D 1186, D 1212, or D 1400. Nondestructive methods are preferred because panels so measured do not need to be repaired.

5.4 Unless otherwise specified, before exposing coated

panels in the apparatus, condition them at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity for one of the following periods in accordance with the type of coating:

Baked coatings	24 h
Radiation-cured coatings	24 h
All other coatings	7 days min

6. Apparatus

6.1 *Type EH Apparatus* (open-flame carbon arc), of Practice G 23, without filters.⁷

7. Procedure

7.1 Mount the test specimens vertically both above and below the horizontal center line of the source of radiation. Rotate the specimens from upper to lower rack to provide uniform exposure conditions over their surface. Specimens should be exposed approximately as many hours in the top rack as in the bottom rack, but need not be inverted.

7.2 Base temperature measurement and control on the black panel thermometer unit. Support the panel with the thermometer attached in the top row of the specimen drum or rack in the same manner as the test specimens so that it will be subjected to the same influences. If necessary, read black panel temperatures through the window in the test chamber without opening the door. The black panel temperature shall reach a maximum of $145 \pm 9^\circ\text{F}$ ($63 \pm 5^\circ\text{C}$) during the light-on-without-water-spray period of the test cycle and the equilibrium relative humidity of the air in the test chamber shall be $50 \pm 5\%$. The chamber temperature shall be $90 \pm 5^\circ\text{F}$ ($32 \pm 3^\circ\text{C}$) during the light-off-with-water-spray period of the test and the relative humidity of the air shall be $95 \pm 5\%$.

7.3 The water from the rack spray shall strike the back of the test specimens so that the only water on the face of the panels is from the dew formation caused by the chilled water on the back of the panels. The temperature of the water shall be $45 \pm 4^\circ\text{F}$ ($7.2 \pm 2^\circ\text{C}$). The water should have less than 20 ppm of solids.

7.4 Operate the apparatus on a cycle of 60 min dark with water-back spray and 60 min light without water spray.

8. Periods of Exposure

8.1 Use one of the following methods to determine the duration of the exposure under this practice:

8.1.1 A mutually agreed upon specified number of total hours (light and dark hours),

8.1.2 Number of total hours of exposure required to produce a mutually agreed upon amount of change in either the test specimen or an agreed upon standard sample.

9. Evaluation of Results

9.1 Evaluate conditions of exposed test specimens by means of one or more of the following standards: Test Methods D 523, D 610, D 659, D 660, D 661, D 662, D 714, D 772, D 2244, D 2616, D 4214, and E 97 and Practice D 1729. Select methods in accordance with product use requirements.

9.2 Because of possible variations in results as described in

⁷ Apparatus and carbon arcs from the Atlas Electric Devices Co., 4114 Ravenswood Ave., Chicago, IL 60613, have been found suitable for this purpose.

3.5, no reference tests corroborate accompanying reference procedure.

10. Report

10.1 Report
10.1.1 Test results

3.5, no reference should be made to results obtained from the tests conducted in the apparatus using this practice unless accompanied by Section 10 or unless otherwise specified in a reference procedure.

10. Report

10.1 Report the following information:

10.1.1 Type and model of apparatus used and type of

carbon arc,

10.1.2 Total hours of test (dark plus light hours),

10.1.3 Operating black-panel temperatures,

10.1.4 Operating relative humidities,

10.1.5 Test specimen preparation,

10.1.6 Results of evaluation tests, and

10.1.7 Identification of standards used for comparative evaluation.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Film Hardness by Pencil Test¹

This standard is issued under the fixed designation D 3363; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Sections 2 and 3 were editorially renumbered in March 1989.

1. Scope

1.1 This test method covers a procedure for rapid, inexpensive determination of the film hardness of an organic coating on a substrate in terms of drawing leads or pencil leads of known hardness.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Summary of Test Method

2.1 A coated panel is placed on a firm horizontal surface. The pencil is held firmly against the film at a 45° angle (point away from the operator) and pushed away from the operator in a 1/4-in. (6.5-mm) stroke. The process is started with the hardest pencil and continued down the scale of hardness to either of two end points: one, the pencil that will not cut into or gouge the film (pencil hardness), or two, the pencil that will not scratch the film (scratch hardness).

3. Significance and Use

3.1 This test method is especially useful in developmental work and in production control testing in a single laboratory. It should be recognized that the results obtained may vary between different operators and laboratories. Every effort should be made to standardize the hardness of the lead used and the technique followed. If used as a basis for purchase agreement, this test method will achieve maximum precision if a given set of referee pencils be agreed upon between the purchaser and the seller.

4. Apparatus

4.1 A set of calibrated drawing leads (preferred) or equivalent calibrated wood pencils meeting the following scale of hardness:²

6B-5B-4B-3B-2B-B-HB-F-H-2H-3H-4H-5H-6H	
Softer	Harder

The difference between two adjacent leads shall be considered one unit of hardness.

4.2 *Mechanical Lead Holder*, for drawing leads if used.³

4.3 *Mechanical Sharpener*, draftsman-type, is helpful for trimming wood pencils if used.⁴

4.4 *Abrasive Paper*, grit No. 400.

5. Test Specimens and Conditions

5.1 Apply the surface coating by appropriate means to a smooth rigid substrate and cure properly, or use representative panels cut from coated stock. The panels used, the curing conditions, and the age of the coating prior to the test shall be within the limits agreed upon between the purchaser and the seller.

5.2 The film thickness of the coating shall be as specified or as agreed upon between the purchaser and the seller.

5.3 Conduct the test at $77 \pm 3.5^\circ\text{F}$ ($25 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity.

6. Procedure

6.1 For wood pencils, remove approximately 3/16 to 1/4 in. (5 to 6 mm) of wood from the point of each pencil using a draftsman-type mechanical sharpener, being careful to leave an undisturbed, unmarked, smooth cylinder of lead. Holding the pencil or lead holder (when using drawing leads) at an angle of 90° to the abrasive paper, rub the lead against the paper maintaining an exact angle of 90° to the abrasive paper until a flat, smooth and circular cross section is obtained, free of chips or nicks in the edge of the cross section. The desired edge may be attained by cementing the abrasive paper to a flat motor-driven disk. By supporting the pencil at 90° to the rotating disk a uniform flat lead end may be obtained more reproducibly.⁵

6.2 Place the coated panel on a level, firm, horizontal surface. Starting with the hardest lead, hold the pencil or lead holder firmly with the lead against the film at a 45° angle (point away from the operator) and push away from the operator. Exert sufficient uniform pressure downward and forward either to cut or scratch the film or to crumble the

¹ This method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.23 on Physical Properties of Applied Paint Films.

Current edition approved Oct. 25, 1974. Published November 1974.

² Pencils from many manufacturers have been and may be used in pencil hardness testing but it was apparent to the test group (D01.53.02) that the leads supplied by two manufacturers were more uniform, and reproducible results could be obtained from batch to batch of leads. These are Microtomic, manufactured by Faber Castell, 551 Spring Place Rd., Lewisburg, TN 37091, and Turquoise-T2375, manufactured by Mohawk, Route #30, Perth Road, Amsterdam, NY 12010.

³ Turquoise No. 10 is the preferred holder, however, any holder adequately constructed to eliminate lead slippage may be used.

⁴ Dexter Super 10 Draftsman Type A10D Cutter Assembly, manufactured by Apco Products, Inc., or equivalent, has been found suitable.

⁵ A suitable device for this purpose is available from Gardner Laboratories, Inc., P. O. Box 5728, Bethesda, Md.

edge of the lead. It is suggested that the length of the stroke be $\frac{1}{4}$ in. (6.5 mm).

6.3 Repeat the process down the hardness scale until a pencil is found that will not cut through the film to the substrate (either metal or a previous coat) for a distance of at least $\frac{1}{8}$ in. (3 mm) (see 7.1.1).

NOTE 1—The operator must watch closely for cutting into or scratching the film. Some finishes contain compounds that may tend to lubricate the film. Checks should be made by close visual inspection and by fingernail feel.

NOTE 2—In conducting the test, if the sharp edge of the lead is slightly chipped or crumbled, the lead must be resharpened.

6.4 Continue the process until a pencil is found that will neither cut through nor scratch the surface of the film. Any defacement of the film other than a cut (gouge) is considered a scratch. Record each end point (if applicable) for gouge and scratch hardness (see 7.1).

NOTE 3—With some films, the two end points will be identical.

6.5 Make a minimum of two determinations for gouge hardness (6.3) and scratch hardness (6.4) for each pencil or lead.

7. Report

7.1 Report the following information:

7.1.1 The two end points as follows:

7.1.1.1 *Gouge Hardness*—The hardest pencil that will

leave the film uncut for a stroke length of at least $\frac{1}{8}$ in. (3 mm).

7.1.1.2 *Scratch Hardness*—The hardest pencil that will not rupture or scratch the film.

7.1.2 The make and grade of lead or pencil used, and

7.1.3 Any deviation from standard conditions, including roughness in the finish.

8. Precision

8.1 In an interlaboratory test of this test method with three different films on panels, ten laboratories and operators, and repeated by switching leads and panels between laboratories, the within-laboratory standard deviation was found to be 0.52 and the between-laboratory standard deviation was found to be 0.61. Based on these standard deviations, the following criteria should be used for judging the acceptability of results at a 95 % confidence level:

8.1.1 *Repeatability*—Two results obtained by two operators within a laboratory using the same pencils and panels should be considered suspect if they differ by more than one pencil unit on the scale described in 4.1.

8.1.2 *Operator Reproducibility*—Two results, each the mean of at least two determinations, obtained by operators in different laboratories using the same pencils and panels or different pencils with the same panels should be considered suspect if they differ by more than one pencil unit on the scale described in 4.1.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Guide for Testing Solvent-Reducible Floor Paints¹

This standard is issued under the fixed designation D 3383; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

[†] NOTE—Sections 3 and 4 were renumbered and the title was changed in October 1988.

1. Scope

1.1 This guide covers the selection and use of procedures for testing solvent-reducible floor paints and enamels. The test methods included are listed in Tables 1 and 2.

1.2 This guide covers the testing of ready-mixed finish coats applied by brush or roller on surfaces subjected to traffic, such as floors, decks, platforms, stairs, and adjacent surfaces such as stair risers and railings.

1.3 Floor paints may be intended for interior use only or may also be suitable for use on exterior surfaces exposed to the weather such as decks, porches, porch steps, and carport floors. Paints intended for both exterior and interior use will require certain test procedures not applicable to paints intended for interior use only. Selection of test methods must be governed by the requirements in each individual case, together with agreement between the purchaser and the seller.

Wood panel description	9.5.2	D 358	2031

tion, skinning, or other undesirable effects in the coating. Determine the condition of the coating in accordance with 6.1 and 6.2.

5.2 Sample in accordance with 4.2.1 of Method 1021 of U.S. Federal Test Method Standard No. 141. Determine the weight per gallon in accordance with Test Method D 1475. Repeat this procedure until successive readings agree within 0.1 lb (45 g) or as agreed upon between the purchaser and the seller. Samples for testing may then be taken.

5.3 Specify the amount of sample, the package sizes, and identification codes to assure a representative sample. A 1-gal (4-L) sample is usually sufficient for the recommended tests, but for guidance in selecting a sampling plan consult Recommended Practice E 105.

6. Liquid Paint Properties

6.1 *Skimming*—Coatings containing a binder that dries by oxidation may be subject to skin formation in a partially filled can. Since skins are insoluble in the material, they must be removed before use. The referenced test method indicates the tendency of a paint to skin. Examine the original sample for skins, both on the surface and in its mass. On a well-mixed, skin-free portion of the sample, perform a skinning test in accordance with Guide D 154.

6.2 *Condition in Container*—Thickening, settling, and separation are undesirable and objectionable if a paint cannot be reconditioned and made suitable for application

with a reasonable amount of stirring. The referenced method covers procedures for determining changes in properties of paints after storage. Determine the condition in the container in accordance with Method 3011.1 of Federal Test Method Standard No. 141.

6.3 *Coarse Particles and Foreign Matter*—Paints must be free of coarse particles to form uniform films of good appearance, typical maximum being 1 weight % of total paint. The specified test with a No. 325 (45- μ m) screen gives the percent of these particles in a paint. Determine coarse particles and foreign matter in accordance with Test Methods D 185.

6.4 *Density or Weight per Gallon*—The density as measured by weight per gallon or kilogram per litre is used to assure product uniformity from batch to batch. In the referenced test method, the density is expressed as the weight in pounds avoirdupois of 1 U. S. gal (kilogram/litre) of the paint at a specified temperature. A calibrated weight-per-gallon cup is used. Determine density in accordance with Test Method D 1475.

6.5 *Fineness of Dispersion*—The more finely a pigment is dispersed, the more efficiently it is being used. One method for measuring the degree of dispersion (commonly referred to as "fineness of grind") is to draw the material down a calibrated, tapered groove in a hardened steel block with the groove varying in depth from 4 to 0 mils (100 to 0 μ m). erates, or both, protrude through the surface of the liquid is taken as the fineness reading. Lower readings in mils or micrometres or higher readings in Hegman units indicate better fineness of dispersion. Determine fineness of dispersion in accordance with Test Method D 1210.

6.6 Consistency—Consistency is important, relating to application and flow, and should fall within a range agreed upon. In the referenced test method, consistency is defined as the load in grams required to produce a specified rate of shear. Determine consistency in accordance with Test Method D 562.

6.7 Absorption—The referenced method provides a rapid determination of the relative penetration of the binder into a porous surface. It provides a rough measure of the wetting and penetrating properties of liquid materials. Loss of binder and the resultant change in pigment volume concentration, as the film dries, are indicated by the test. Determine absorption in accordance with Method 4421 of Federal Test Method Standard No. 141.

6.8 Flash Point—When the flash point of a material is required for shipping information, use Test Methods D 93, Part B, or D 3278.

7. Paint Application and Film Formation

7.1 Application of Brushed Films—Brushed films should be smooth and free from seeds, color streaking, and brush marks. Test application of a brushed film in accordance with Method 2141.1 of Federal Test Method Standard No. 141.

7.2 Brushing Properties—The specified method covers a means for determining the brushing properties of coatings. The test is quite subjective; however, someone experienced in the art can produce quite consistent results, particularly in the determination of "drag" qualities. Floor paints are generally applied to horizontal surfaces but evaluation on vertical surfaces may be necessary to determine performance on stair risers, railings, posts, etc. Determine the brushing properties in accordance with Method 4321.1 of Federal Test Method Standard No. 141.

7.3 Roller Coating Properties—Floor enamels are frequently applied by roller. The referenced method outlines a procedure for making an evaluation of a material's characteristics when applied by a roller. Determine roller coating properties in accordance with Method 4335 of Federal Test Method Standard No. 141.

7.4 Drying Properties—The drying time of a floor paint is important in determining when a freshly painted floor or stair may be subjected to traffic. Slow drying of the film may result in dust pickup, poor appearance, and, if used on an exterior surface, rain or dew may cause a nonuniform appearance. The test can also be used to determine whether or not the drying properties of the paint have changed during storage in the container. Determine drying time in accordance with Test Method D 1640.

7.5 Leveling Properties—Leveling is an important factor when uniform surfaces are to be produced, as it affects hiding and appearance. The referenced test method covers the laboratory determination of the relative leveling characteristics of liquid coatings. Determine leveling characteristics in accordance with Test Method D 2801.

7.6 Producing Films of Uniform Thickness—The following test method covers the preparation of various films of

uniform thickness essential in conducting tests. Prepare films in accordance with Test Methods D 823.

8. Appearance of The Dry Film

8.1 Color Differences of Opaque Materials by Visual Evaluation—Visual comparison of color is fast and often acceptable although numerical values are not obtained. The referenced method covers the spectral, photometric, and geometric characteristics of light source, illuminating and viewing conditions, size of specimens, and general procedures to be used in the visual evaluation of color differences of opaque materials. Determine color difference in accordance with Practice D 1729.

8.2 Color Differences of Opaque Materials by Instrumental Evaluation—Color difference between a product and the standard can be measured by instrument. Generally the tolerance is agreed upon between the purchaser and the seller. The referenced method covers the instrumental determination of small color differences, observable in daylight illumination, between nonfluorescent, nonmetameric, opaque surfaces such as paint specimens. If metamerism is suspected, visual evaluation (8.1) should be used to verify instrumental results. Conduct instrumental evaluation of color difference in accordance with Method D 2244.

8.3 Gloss—Floor enamels generally have a high initial 60-deg gloss reading when first applied. Determine the specular gloss in accordance with Test Methods D 523 or D 1471.

8.4 Hiding Power (Dry Opacity)—Hiding power is the measure of the ability of a paint to hide the substrate. It is, however, dependent upon uniform film thickness which is influenced by flow and leveling. Test Method D 344 is a practical test in which paint is applied with a brush, film thickness is approximately measured, opacity is evaluated visually as compared to a standard paint, and results are affected by flow and leveling application properties of the paint. Test Method D 2805 is considered to be a more precise and accurate test which does not need a material paint standard. Paint is applied with an applicator bar to minimize the effects of flow and leveling, film thickness is rigorously measured, and opacity is instrumentally evaluated. Determine hiding power in accordance with Test Methods D 344 or D 2805.

9. Properties of the Dry Film

9.1 Abrasion Resistance—Abrasion resistance is a measure of the ability of a dried film to withstand wear from foot traffic and marring from objects rolled or pulled across the surface. Determine abrasion resistance in accordance with Test Methods D 658 or D 968.

9.2 Elongation—Elongation is a measure of the flexibility of paint films. Determining elongation in accordance with Test Methods D 1737 or D 522.

9.3 Adhesion—Adhesion is the property of the film which resists removal from the substrate when scuffed or scraped. It is an important property in a floor paint. Determine adhesion in accordance with Test Methods D 2197.

9.4 Resistance to Chemicals—An important property of a floor paint is its ability to resist spotting, softening, or removal when subjected to household chemicals or strong

cleaners. Determine resistance to chemicals in accordance with Test Method D 1308.

9.5 *Exterior Exposure*—If the paint is intended for use on porches, decks, or outside stairways and railings, tests for resistance to exterior exposure may be required.

9.5.1 *Conducting Exterior Exposures*—In conducting exterior exposures, refer to Practice D 1006 or Test Method D 1014.

9.5.2 *Wood Panel Description*—In establishing exposure performance, use the panels as described in Specification D 358.

9.5.3 *Chalk Resistance*—Determine the chalk-resistance rating by reference to Method D 659.

9.5.4 *Checking Resistance*—Determine the checking resistance rating by reference to Test Method D 660.

9.5.5 *Cracking Resistance*—Determine the cracking resistance rating by reference to Test Method D 661.

9.5.6 *Erosion Resistance*—Determine the erosion resistance rating by reference to Test Method D 662.

9.5.7 *Flaking Resistance*—Determine the flaking resistance rating by reference to Test Method D 772.

10. Analysis of Paint

10.1 *Chemical Analysis*—If a specification requires certain raw materials or certain components in a given amount then chemical analysis is required. Chemical analysis determines whether the specified components are present and if they are, in what amounts. It does not necessarily establish

paint quality which can also be greatly affected by manufacturing techniques. No single schematic analysis is comprehensive enough to cover the wide variety of floor enamel composition.

10.2 *Volatile Content*—The percent of volatile matter indicates the thinner loss from the film as it dries. This quantity subtracted from 100 % gives the nonvolatile content. Determine the volatile content in accordance with Test Method D 2369.

10.3 *Pigment Content*—Pigment gives the hiding and color and influences many other properties of a coating. Determine the percent pigment in accordance with Test Method D 2371.

10.4 *Pigment Analysis*—The analysis of pigment may be required if the product is covered by a specification, or if it is agreed between the purchaser and the seller. Analyze the pigment in accordance with selected test procedures from Method D 215 and other appropriate ASTM Test methods.

10.5 *Identification of Vehicle Solids*—The type of nonvolatile vehicle used in a coating has a great influence on its properties. The referenced test method gives a procedure for identifying the main components of the binder. Determine the identity of the vehicle solids in accordance with Method D 2621.

10.6 *Identification of Oils*—The composition of the nonvolatile vehicle can, if desired, be further broken down into the types of oils present. Determine the identity of oils in accordance with Method D 2245.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Method of Evaluating the Lightfastness of Printed Matter¹

This standard is issued under the fixed designation D 3424; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This method covers evaluation of the lightfastness of printed matter. Two methods of exposure, direct to artificial light and under glass to natural light, and three methods of rating the fastness are provided.

2. Referenced Documents

2.1 ASTM Standards:

D 1729 Practice for Visual Evaluation of Color Differences of Opaque Materials²

D 2244 Test Method for Calculation of Color Differences from Instrumentally Measured Color Coordinates³

D 2616 Test Method for Evaluation of Visual Color Difference With a Gray Scale²

G 24 Practice for Conducting Natural Light Exposures Under Glass²

G 25 Practice for Operating Enclosed Carbon-Arc Type Apparatus for Light Exposure of Nonmetallic Materials⁴

G 27 Practice for Operating Xenon-Arc Type Apparatus for Light Exposure of Nonmetallic Materials⁴

3. Significance

3.1 Lightfastness of printed matter is of particular importance in uses such as posters, billboard prints, advertising matter, and display materials generally.

4. Apparatus

4.1 *Method A, Exposure to Artificial Light*—The apparatus to be used is described in Section 3 of Practice G 27. An alternative light source is described in Section 3 of Practice G 25. The spectrum of the xenon arc is closer to the spectrum of daylight.

4.2 *Method B, Exposure to Natural Light Under Glass*—The apparatus to be used is described in Section 3 of Practice G 24.

5. Test Specimens

5.1 The type and number of test specimens to be used shall be defined in specifications covering the product being tested or shall be mutually agreed upon by the purchaser and the seller.

6. Procedure

6.1 Mask approximately one quarter of each print with a material opaque to light. Expose the prints for a period mutually agreed upon by the purchaser and the seller to the required conditions.

6.2 After exposure, compare the unexposed portion to the exposed part using one of the following three procedures as agreed upon by the purchaser and the seller:

6.2.1 Visual rating against a control exposed at the same time.

6.2.2 Visual rating using gray scale color chips in accordance with Method D 2616.

6.2.3 Instrumental measurement in accordance with Method D 2244.

7. Report

7.1 When a report is required, the designation of the specimen and the description or identification of the method used to prepare the specimen should be included.

7.2 The report will depend upon the procedure used for evaluating the results and should be agreed upon by the purchaser and the seller.

7.2.1 For Procedure 6.2.1, visual rating against a control exposed at the same time, viewing condition should be included as described in Practice D 1729. Report the specimen as being equal to or having more or less light fastness than the control.

7.2.2 For Procedure 6.2.2, visual rating using gray scale color chips, report information as in Method D 2616.

7.2.3 For Procedure 6.2.3, instrument measurement, report information as in Method D 2244.

8. Precision

8.1 For precision of the rating method, see Method D 2244 or Method D 2616, where applicable.

¹ This method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials, and is the direct responsibility of Subcommittee D 01.56 on Printing Inks.

Standard Guide for Testing Solvent-Reducible Interior Semigloss Wall and Trim Enamels¹

This standard is issued under the fixed designation D 3425; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Editorial changes were made throughout, including the title, in October 1988.

1. Scope

1.1 This guide covers the selection and use of procedures for testing solvent-reducible interior wall and trim semigloss enamels. The test methods included are listed in Tables 1 and 2. All of these tests may not be required for each enamel. Selection of the test methods to be followed must be governed by experience and the requirements in each individual case, together with agreement between the purchaser and the seller.

TABLE 1 List of Test Methods by Properties

Test Method	Section	ASTM Test Method	Federal Test Method Standard No. 141
Liquid enamel properties:			
Skimming	6.1	D 154	3021
Condition in container	6.2	...	3011.1
Coarse particles and foreign matter	6.3	D 185	4091
Weight per gallon or density	6.4	D 1475	4184.1
Fineness of dispersion	6.5	D 1210	4411.1
Odor	6.6	...	4401
Consistency (viscosity)	6.7	D 562	4281
Rheological properties of non-newtonian liquids	6.8	D 2196	...
Dilution stability	6.9	...	4203.1
Absorption	6.10	...	4421
Flash point	6.11	D 93, D 3278	4293
Color compatibility	6.12	...	...
Enamel application and film formation:			
Application of brushed films	7.1	...	2141.1, 4321.1
Application by roller	7.2	...	2112
Application of sprayed films	7.3	...	2131
Drying properties	7.4	D 1640	4061.1
Leveling properties	7.5	D 2801	...
Working properties	7.6	...	4541
Sag resistance	7.7	...	4494
Wet film thickness	7.8	D 1212	...
Producing films of uniform thickness	7.9	D 823	2121, 2162
Appearance of dry enamel film:			
Color difference of opaque materials, visual evaluation	8.1	D 2244	4249.1
Color difference of opaque materials, instrument evaluation	8.2	D 1729	6123
Directional reflectance	8.3	E 97	6121
Gloss (60 deg specular)	8.4	D 523	6101
Hiding power	8.5	D 344, D 2805	...
Color change of white architectural enamels	8.6	D 1543	...
Properties of dry enamel film:			
Elongation (flexibility)	9.1	D 1737, D 522	6221
Washability	9.2	...	6141
Analysis of enamel:			
Chemical analysis	10.1	...	...
Volatile content	10.2	D 2369	4041.1
Pigment content	10.3	D 2371	4021, 4022
Analysis of pigment			
Nonvolatile content (volume percent)	10.4	...	...
	10.5	D 2697	4311

Nonvolatile content (volume percent)	10.5	D 2697	4311
Odor	6.6	...	4401
Pigment content	10.3	D 2371, D 2698	4021, 4022
Producing films of uniform thickness	7.9	D 823	2121, 2162
Rheological properties of non-Newtonian liquids	6.8	D 2196	...
Sag resistance	7.7	...	4494
Sampling	5	E 105	...
Skimming	6.1	D 154	3021
Volatile content	10.2	D 2369	4041.1
Washability	9.2	...	6141
Weight per gallon or density	6.4	D 1475	4184.1
Wet film thickness	7.8	D 1212	...
Working properties	7.6	...	4541

4.1.1 Substrate, such as type and quality of drywall, plaster, wood, or hardboard.

4.1.2 Condition of substrates—presence of grease, dirt, and mold; also porosity, adhesion, and general condition of previous coating.

4.1.3 Preparation of previously painted substrates including detergent cleaning, solvent etching, and sanding.

4.1.4 Type and quality of primer or undercoat and time of drying before topcoating.

4.1.5 Environmental conditions, both general and specific, at the time of enamel application and immediately after application.

5. Sampling

5.1 The condition of the container prior to sampling, should be established since damage to it may cause evaporation, skinning, or other undesirable effects. Determine the condition of the enamel in accordance with 6.1 and 6.2.

5.2 Sample in accordance with Section 4.2.1 of Method 1021 of Federal Test Method Standard No. 141. Determine

the weight per gallon in accordance with Test Method D 1475. Repeat this procedure until successive readings agree within 0.1 lb (45 g) or as agreed between the purchaser and the seller. Then take samples for testing.

5.3 Specify the amount of sample, the package sizes, and identification codes to assure a representative sample. A 1-gal (4-L) sample is usually sufficient for the recommended tests but for guidance in selecting a sample plan consult Recommended Practice E 105.

6. Liquid Enamel Properties

6.1 *Skimming*—Enamels containing a binder, that dries by oxidation may be subject to skin formation in a partially filled can or by diffusion of air into a filled can. Since skins are insoluble in the enamel, they must be removed before use. This test in a partially filled container indicates the tendency of an enamel to skin. A typical minimum time for skinning in accordance with the referenced test method is 48 h. Examine the original sample for skins, both on the surface and in its mass. On a well-mixed, skin-free portion of the sample, perform a skinning test in accordance with Guide D 154.

6.2 *Condition in Container*—Thickening, settling, and separation are undesirable and objectionable if an enamel, after storage, cannot be readily reconditioned and made suitable for application with a reasonable amount of stirring. The referenced method covers procedures for determining changes in properties after storage. Determine the condition in the container in accordance with Method 3011.1 of Federal Test Method Standard No. 141.

6.3 *Coarse Particles and Foreign Matter*—Enamels must be free of oversize particles and foreign matter to form a uniform film of good appearance, a typical maximum being 0.5 weight % of total enamel. The specified test with a No. 325 (45- μ m) screen gives the percent of these particles in an enamel. Determine coarse particles and foreign matter in accordance with Test Method D 185.

6.4 *Weight per Gallon*—The density of an enamel as measured by weight per gallon (or kilograms per litre) is used to assure product uniformity from batch to batch and provides a check against the theoretical weight calculated from the formula. The referenced test method gives a procedure for measurement of the density of an enamel. The density is expressed as weight in pounds of 1 U.S. gal (kilograms per litre) of the enamel at a specified temperature. A calibrated weight-per-gallon cup is used. Determine weight per gallon in accordance with Test Method D 1475.

6.5 *Fineness of Dispersion*—One method for measuring the degree of dispersion is to draw the enamel down in a tapered groove in a hardened steel block with the groove varying in depth from 4 to 0 mils (100 to 0 μ m). The point at which continuous groupings of particles or agglomerates, or both, protrude through the surface of the wet film is taken as the fineness reading. Lower readings in mils or micrometres or higher readings in Hegman units indicate better dispersion. A typical fineness of dispersion requirement is a reading of 1.0 mil (25 μ m) or 6 Hegman for interior semigloss wall and trim enamels. Determine fineness of dispersion in accordance with Test Method D 1210.

6.6 *Odor*—Some solvent combinations produce obnoxious odors, particularly when painting indoors with inadequate

ventilation and under adverse temperature-humidity conditions. Test for odor in accordance with Method 4401 of Federal Test Method Standard No. 141.

6.7 *Consistency*—Enamels of a given type should fall within a consistency range agreed upon. In the referenced test method, consistency is defined as the load in grams required to produce a specified rate of shear. Enamels for professional painters are usually formulated at a higher consistency range than consumer enamels. A typical range is 75 to 90-Krebs unit (KU) for consumer enamels and 90 to 100 KU for professional painter enamels. Determine the consistency of the product in accordance with Test Method D 562.

6.8 *Rheological Properties of Non-Newtonian Liquids*—Rheological properties are related to the application and flow properties of the liquid coating. The referenced test method covers the determination of the rheological properties of an enamel and is particularly suited for use with enamels that display thixotropic characteristics. In fact, viscosity under varying conditions of time and rotational speed of the spindle is measured. Determine the rheological properties in accordance with Test Method D 2196.

6.9 *Dilution Stability*—The diluent suggested for reduction should be readily incorporated into the enamel without excessive stirring or shaking. This test is a measure of the stability of an enamel that has been reduced to a desired viscosity, for example, for spray application. Determine dilution stability in accordance with Method 4203 of Federal Test Method Standard No. 141.

6.10 *Absorption*—The referenced method provides a rapid means for measuring the relative penetration of the binder into a porous surface. It provides a rough measure of the wetting and penetrating quality of liquid materials. Loss of binder and the resultant change in pigment volume concentration, as the film dries, are indicated by this test. Determine the absorption in accordance with Method 4421 of Federal Test Method Standard No. 141.

6.11 *Flash Point*—Organic solvents used in enamels have characteristic temperatures at which they will support combustion. This temperature is known as the flash point. It is often used for danger classification in shipment by common carriers. It is also used to determine conditions of storage to meet fire regulations and also the safety requirements of the Occupational Safety and Health Act (OSHA). Determine the flash point in accordance with Test Methods D 93 or D 3278.

6.12 *Color Compatibility*—If tinting colors are not adequately compatible with enamel tint base, lighter, darker, or nonuniform shades of color will develop. Tintability of white bases with colorants of standardized tinting strength is a trade requirement. The test method shall be agreed upon between the purchaser and the seller. An ASTM test method is now being developed.

7. Enamel Application and Film Formation

7.1 *Application by Brush*—Brushed films should be smooth and free of seeds and on vertical surfaces should show no sagging, color streaking, or excessive brush marks. Test application of brushed films in accordance with Method 2141.1 of Federal Test Method Standard No. 141.

7.2 *Application by Roller*—Walls are frequently painted

with rollers that produce slight stipple effects. Test roller coating properties in accordance with Method 2112 of Federal Test Method Standard No. 141.

7.3 Application by Spray—Interior paints and enamels are sometimes applied by spray. Both air and airless spray are used in commercial work. Test in accordance with Method 2131 of Federal Test Method Standard No. 141.

7.4 Drying Properties—The drying time of an enamel is determined by the composition of the enamel and by atmospheric conditions during drying. Insufficient drying may result in dirt pickup causing a poor appearance. Typical drying times are $\frac{1}{3}$ to 2-h set-to-touch and 18-h dry-hard. The test can also be used to determine whether the enamel has lost its drying properties during storage or whether drier was included in the product at the time of manufacture. Determine the drying time in accordance with Test Methods D 1640.

7.5 Leveling Properties—Leveling is a factor in hiding and appearance of wall and trim enamels. The referenced test method covers the laboratory determination of the relative leveling characteristics of liquid coatings. Determine leveling property in accordance with Test Method D 2801.

7.6 Working Properties—Working properties of an enamel are generally compared to a standard or described by requirement in the product specification. Test working properties in accordance with Method 4541 of Federal Test Method Standard No. 141.

7.7 Sag Resistance—Some enamels sag and form curtains before the film sets. Test for sag resistance in accordance with Method 4494 of Federal Test Method Standard No. 141.

7.8 Wet Film Thickness—Measurement of wet film thickness is useful in calculating spreading capacity or adjusting application to an agreed square feet per gallon (or square metres per litre). Determine wet film thickness in accordance with Method D 1212.

7.9 Producing Films of Uniform Thickness—The following test method covers the preparation of enamel films of uniform thickness essential in conducting various tests. Prepare films in accordance with Test Method D 823.

8. Appearance of Dry Enamel Film

8.1 Color Difference of Opaque Materials by Visual Evaluation—Visual comparison of color is fast and often acceptable although numerical values are not obtained. The referenced practice covers the illuminating and viewing condition to be used in the visual evaluation of color differences. Determine color difference in accordance with Practice D 1729.

8.2 Color Difference of Opaque Materials by Instrument Evaluation—Color difference between a product and the standard can be measured by instrument. Generally the tolerance is agreed upon between the purchaser and the seller, and may also be required if a production specification is involved. Determine the color difference in accordance with Method D 2244.

8.3 Directional Reflectance—This property is a measure of light reflected from the surface of the enamel. It usually is assigned a value in specifications for white and pastel shades. A typical minimum reflectance value is 86 for white.

Determine daylight directional reflectance in accordance with Test Method E 97.

8.4 Gloss (60-deg Specular)—Semigloss enamels are particularly sensitive to enamel hold-out of primers and undercoats. Low or uneven gloss readings are indicative of the defect. Interior semigloss enamels after drying 48 h are typically in the range from 40 to 70 when applied to glass. Gloss measurements taken after 7 days are more indicative of the final gloss of the dried film. Determine the specular gloss in accordance with Test Method D 523.

8.5 Hiding Power (Dry Opacity)—Hiding power is the measure of the ability of a paint to hide the substrate. It is, however, dependent upon uniform film thickness which is influenced by flow and leveling. Test Method D 344 is a practical test in which paint is applied with a brush, film thickness is approximately measured, opacity is evaluated visually as compared to a standard paint, and results are affected by flow and leveling application properties of the paint. Test Method D 2805 is considered to be a more precise and accurate test which does not need a material paint standard. Paint is applied with an applicator bar to minimize the effects of flow and leveling, film thickness is rigorously measured, and opacity is instrumentally evaluated. Determine hiding power in accordance with Test Methods D 344 or D 2805.

8.6 Color Change of White Architectural Enamels—Color permanence is an important requirement in interior white semigloss enamels. Lack of permanence is usually caused by after-yellowing. Determine color change in accordance with Test Method D 1543.

9. Properties of Dry Enamel Film

9.1 Elongation (Flexibility)—Elongation is a measure of flexibility of an enamel film. Determine elongation in accordance with Test Method D 1737 or D 522.

9.2 Washability—Washability is an important property of semigloss enamels in service. It is determined from gloss and reflectance measurements before and after removal of stains. Determine washability in accordance with Method 6141 of Federal Test Method Standard No. 141.

10. Analysis of Enamel

10.1 Chemical Analysis—If a specification requires certain raw materials or certain components in given amount then analysis is required. Chemical analysis is primarily a measure of uniformity. It does not necessarily establish paint quality which can also be greatly affected by manufacturing techniques. No single schematic analysis is comprehensive enough to cover the wide variety of semigloss wall and trim enamels.

10.2 Volatile Content—The percent of volatile matter indicates the thinner loss from the film as it dries. Determine volatile content of the paint in accordance with Test Method D 2369.

10.3 Pigment Content—Pigment gives the hiding and color and influences many other properties of the enamel. Determine percent pigment in accordance with Test Method D 2371.

10.4 Analysis of Pigment—The analysis of pigment may be required if the enamel is covered by a specification or if it is agreed between the purchaser and the seller. Determine

analysis of pigment in accordance with selected ASTM test methods.

10.5 *Nonvolatile Content (Volume Percent)*—Nonvolatile content volume percent is a useful figure in calculating

coverage or spreading capacity per gallon (or litre) at a specified dry film thickness. Determine nonvolatile content volume percent of the paint in accordance with Test Method D 2697.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Washability Properties of Interior Architectural Coatings¹

This standard is issued under the fixed designation D 3450; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the relative ease of removing soilent discolorations from the dried film of an interior coating by washing with either an abrasive or nonabrasive cleaner.

1.2 This test method is limited to coatings having a CIE-Y reflectance of 60 % or more, as measured in accordance with Test Method E 97.

1.3 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 562 Test Method for Consistency of Paints Using the Stormer Viscometer²

D 1193 Specification for Reagent Water³

D 1210 Test Method for Fineness of Dispersion of Pigment-Vehicle Systems²

E 70 Test Method for pH of Aqueous Solutions with the Glass Electrode⁴

E 97 Test Method for Directional Reflectance Factor, 45-deg 0-deg, of Opaque Specimens by Broad-Band Filter Reflectometry⁵

3. Terminology

3.1 Description of Term Specific to This Standard:

3.1.1 *soilent*—a discoloring substance that clings to the surface of a coating, whose dispersed color component is not in solution and therefore does not penetrate into the film.

3.1.1.1 *Discussion*—Soilent differs from stain in that the colorant of a stain is in solution, and therefore, can penetrate into the film.

4. Summary of Test Method

4.1 The test material is applied to a black plastic panel and allowed to dry for 7 days. The reflectance of the film is measured (R_1) and then a soilent consisting of carbon black dispersed in mineral oil is applied on the film. The panel is

placed on a glass plate in a washability machine and the film is washed with either an abrasive or nonabrasive scrub medium for 100 cycles. The panel is rinsed and dried and the reflectance in the stained area is read (R_2). The ratio of the reflectance, R_2/R_1 , is a measure of the degree to which the soilent has been removed.

5. Significance and Use

5.1 Interior architectural paints are often discolored by dirt and other soilent materials. This test method covers the relative ease and completeness of removal of a specific soilent from such a surface by scrubbing. The greater the ease of soil removal with a minimum of film erosion, the greater the useful service life is expected to be.

5.2 Results obtained by this test method do not necessarily correlate with all types of soilent.

5.3 Semigloss finishes generally require only the nonabrasive type cleaner for good soilent removal, whereas flat paints may require the abrasive type.

6. Apparatus

6.1 *Washability Tester*,⁶ also referred to as washability machine.

6.1.1 Accessory Apparatus:

6.1.1.1 *Glass Plate*, measured to fit, 17 $\frac{7}{8}$ by 6 $\frac{1}{2}$ by $\frac{1}{4}$ in. (454 by 165 by 6.3 mm).

6.1.1.2 *Stainless Steel Pan*.

6.1.1.3 *"C" Clamps*.

6.1.1.4 *Scale*, standard.

6.1.1.5 *White Blotter*.

6.2 *U-Shaped Film Caster*,⁷ having both a 7-mil (0.18-mm) clearance by 132 mm width and a 10-mil (0.25-mm) clearance by 138 mm width.

6.3 *Film Applicator*, 3 in. (76 mm) width with 3-mil (76- μ m) clearance.

6.4 *Suction Plate* for drawdowns (large size).⁸

6.5 45°, 0° *Reflectometer*, with green filter, as specified in Test Method E 97.

6.6 *Balance*, with 0.1-g scale graduation.

6.7 *Fineness of Dispersion Gage*, as specified in Test Method D 1210.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.42 on Architectural Finishes.

1. Reagents and Materials

7.1 Purity of Reagents—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁹ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

7.2 Purity of Water—Unless otherwise indicated, reference to water shall be understood to mean reagent water conforming to Type IV of Specification D 1193.

7.3 Black Plastic Panels.¹⁰

7.4 Sponge and Holder.¹¹

7.5 Masking Tape.

7.6 Soilant Medium,¹² consisting of the following:

	grams
Mineral oil, USP heavy	60
Odorless mineral spirits	32
Carbon black ¹³	8
	100

7.6.1 Mix components and disperse to a Hegman fineness of 7 (0.5 mils or 13 μ m) or when measured in accordance with Test Method D 1210.

7.7 Scrub Media (Note 1).

7.7.1 Nonabrasive Medium¹² consisting of the following:

	grams
Water	89.6 ⁴
Hydroxyethyl cellulose ¹⁴	2.0
Detergent ¹⁵	4.0
Trisodium phosphate, anhydrous	4.0
Acetic acid glacial	0.3 ^B
Preservative ¹⁶	0.1
	100.0

7.7.2 Abrasive Medium¹², consisting of the following:

	grams
Water	49.4 ^C
Hydroxyethyl cellulose ¹⁴	0.8
Ammonium hydroxide 28 %	—
Detergent ¹⁵	2.0
Trisodium phosphate, anhydrous	2.0
Silica ¹⁷	45.0
Acetic acid, glacial	0.7 ^D
Preservative ¹⁶	0.1
	100.0

⁴ Vary to achieve a final consistency of 165 to 220 g (75 to 85 Krebs Units) with a Stormer Viscometer in accordance with Test Method D 562.

⁹ "Reagent Chemicals, American Chemical Society Specifications," Am. Chemical Soc., Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY, and the "United States Pharmacopeia."

¹⁰ Leneta, P-121-10N dull black plastic panels 6½ by 17 in. by 10 mils (432 by 165 by 0.25 mm) in size, obtainable from the Leneta Co., P.O. Box 86, Ho-Ho-Kus, NJ are suitable for this purpose. An equivalent may be used.

¹¹ Sponge is a cellulosic type, coarse pore grade, ¾ by 3 by 1½ in. (95 by 76 by 38 mm) meeting Federal Spec. L-S-626, Type II; available also from O'Cel-O Div., General Mills, Inc., 305 Sawyer Ave., Tonawanda, NY 14150. Brass holder measuring ¾ by 3 by 1 in. (95 by 76 by 25.4 mm).

¹² Laboratory standardized stain and scrub media have been found suitable and are available from the Leneta Co., P.O. Box 86, Ho-Ho-Kus, NJ. An equivalent may be used.

¹³ Printex U Beads, obtainable from DeGussa Corp., 65 Challenger Road, Ridgefield Park, NJ 07660, has been found suitable for this purpose. An equivalent may be used.

^B Vary to achieve a final pH from 9.5 to 10.0 in accordance with Test Method E 70.

^C Vary to achieve a final consistency of 475 to 600 g (110 to 120 Krebs Units) with the Stormer Viscometer in accordance with Test Method D 562.

^D Vary to achieve a final pH of 9.5 to 10.0 in accordance with Test Method E 70.

7.8 Slowly add the hydroxyethyl cellulose to the water while stirring mechanically. Stir until uniform and then slowly add 2 to 3 drops of 28 % ammonium hydroxide solution while mixing and continue mixing until the solution turns clear. In the order shown, add the other ingredients separately, stirring continuously. Be sure each item is uniformly dispersed before adding the next one. Add the silica slowly to ensure uniform dispersion. Finally, add the preservative and adjust the pH with glacial acetic acid.

NOTE 1—When a referee test is made, prepare fresh medium or use standardized scrub medium¹¹ from a previously unopened container that is no more than 1 year old.

8. Preparation of Apparatus

8.1 Washability Machine—The washability machine should be leveled before use and operated at 37 ± 1 cpm; each cycle consisting of a complete forward and reverse stroke. Adjust tautness of the cables with a spring scale to approximately 5 lb.

8.2 Sponge and Holder—Add sufficient weight to the holder in the form of lead sheets or other flat weights to give a combined weight of 1500 g, including the dry sponge.

NOTE 2—Check the compression of the damp sponge under the 1500-g weight to ensure that the holder does not drag along the panel and tear the film.

9. Procedure

9.1 Clean the top of the glass plate (or preferably the suction plate) and both sides of the black plastic panel to be sure they are free of specks. Place the black panel on the plate and tape one end to the plate. Smooth the panel along the plate to ensure a close fit.

9.2 Stir the test material thoroughly and strain to remove all skins and particles. Draw down the material on the panel, starting from the taped end of the panel. For latex paints, the 10-mil (0.25-mm) side of the applicator will generally be satisfactory, whereas the 7-mil (0.18-mm) side can be used for solvent-based coatings. However, the film thickness of paint to be applied may be varied as mutually agreed upon between the purchaser and the seller. The rate of application should be fairly slow, 3 to 4 s from end to end, to prevent

¹⁴ Hydroxyethyl cellulose having a molar substitution (MS) value from 1.8 to 2.5 and a viscosity of a 2 % solution in the range from 4400 to 6500 cps. Cellosize QP-4400 is available from Union Carbide Corp., P.O. Box 8720, South Charleston, WV 25303 and Natrosol 250M, available from Aqualon Co., 2711 Centerville Rd., Wilmington, DE 19850 have been found suitable for this purpose.

¹⁵ Octyl phenoxy polyethoxyethanol, as represented by Triton X-100, obtainable from Rohm & Haas Co., 2 Executive Campus, Suite 320, Cherry Hill, NJ 08002, has been found satisfactory for this purpose. An equivalent may be used.

¹⁶ 1,3,5-triethyl hexahydro-sym-triazine (Vancide TH), obtainable from R. T. Vanderbilt Co., 30 Winfield St., Norwalk, CT 06855, has been found satisfactory. An equivalent may be used.

¹⁷ Silica No. 22, obtainable from Whittaker, Clark and Daniels, Inc., 100 Church St., New York, NY 10007, has been found satisfactory for this purpose. This silica is an amorphous grade of 99+ % silicon dioxide. Average particle size is 2.95 μ m with 92 % being less than 40 μ m. Surface area is 7600 cm²/g, and will give a pH from 6.8 to 7.2 in reagent water. An equivalent may be used.

pinholes or holidays in the film. Air dry in a horizontal position for 7 days in a room preferably maintained at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity, or under conditions mutually agreeable to the purchaser and the seller.

9.3 On the last day of drying, measure the directional reflectance (green filter) of a portion of the panel in accordance with Test Method E 97. Record this value as R_1 .

9.4 After reading the reflectance, use the applicator with the 3-mil (76- μm) clearance to draw down a film of soilant medium perpendicular to the coating film and in the area where the reflectance was measured. Permit the stained panel to dry for 16 to 24 h under the same drying conditions specified in 9.2.

9.5 Clean the glass surface on which the test panel is to be mounted and also the back of the test panel. Attach the test panel to the glass plate and place the mounted test panel, coated side up, in the pan. Clamp the assembly securely to the pan with the "C" clamps, centering the pan so that the sponge boat can move lengthwise on the panel.

9.6 Remove the sponge from the holder and soak it in reagent water at room temperature. Remove the sponge and squeeze repeatedly with one hand until no more water drips from the sponge. Replace the sponge in the holder and pour $15 \pm 1\text{ mL}$ of water on the exposed face of the sponge. Stir the scrub medium and spread uniformly across the face of the sponge $10.0 \pm 0.1\text{ g}$ of nonabrasive scrub medium. (Use a spatula if necessary, when applying the abrasive scrub medium, to apply uniformly over the sponge.)

9.7 Attach the sponge holder, with the sponge and cleaner face down, to the cables of the washability machine. Add 5 mL of water on each side of the holder in the path of the sponge. Start the motor and allow the sponge to travel 25 cycles at the rate of $37 \pm 1\text{ cpm}$. Ensure that the sponge and holder are level during the run, otherwise uneven wear will occur on the test panel. At the end of 25 cycles, stop the machine, remove the sponge, clean in running water, squeeze dry, and resoak in water. Wipe off excess stain outside the test area. Repeat the procedure starting in 9.6 with "remove the sponge and squeeze it repeatedly. . . ." for an additional 25 cycles. Repeat the 25-cycle procedure for a total of 100 cycles, each time trying to start and stop the sponge outside the stained area of the panel.

9.8 Remove the test panel from the pan, rinse with running tap water, gently moving the palm of the hand over the path of the sponge to remove clinging particles of scrub medium. Blot the panel and then allow to dry at room temperature. After the panel has dried thoroughly, wipe off excess stain outside the test area and measure reflectance in the soiled and washed area of the panel. Record as R_2 .

9.9 Repeat the test on a second panel and, for each, calculate the reflectance recovery in percent as $(R_2/R_1) \times 100$.

9.10 If the mean reflectance recovery for the two panels is less than 96 %, repeat the test on another set of panels using the abrasive scrub medium specified in 7.7.2 and report the results with both mediums.

10. Report

10.1 Report the mean of the two determinations and the type of scrub medium used.

10.2 Report any deviations from the standard procedure.

10.3 Note if erosion occurred in the soiled area.

11. Precision and Bias

11.1 On the basis of an interlaboratory study in which operators in six laboratories tested six coatings, including solvent and water-based systems, and covering a range of pigment volume concentrations (PVC's), the following criteria should be used for judging the acceptability of the results at the 95 % confidence level:

11.1.1 *Repeatability*—Two results obtained by the same operator should be considered suspect if they differ by more than 1.5 % in reflectance recovery with the abrasive cleaner and 9 % in reflectance recovery with the nonabrasive cleaner.

11.1.2 *Reproducibility*—Two results, each the mean of two measurements, obtained by operators in different laboratories should be considered suspect if they differ by more than 6 % in reflectance recovery with the abrasive cleaner and 25 % with the nonabrasive cleaner.

11.2 *Bias*—The concept of bias is not applicable to this test method.

12. Keywords

12.1 soilant resistance; washability

Standard Practices for Testing Polymeric Powders and Powder Coatings¹

This standard is issued under the fixed designation D 3451; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last revision or approval. A superscript (c) indicates an editorial change since the last revision or approval.

¹ NOTE—Footnote numbers 8 through 18 inclusive were renumbered editorially in December 1987.

1. Scope

1.1 These practices cover the selection and use of procedures for testing polymeric powders and powder coatings. The test methods included are listed in Table 1. Where more than one test method is listed for the same characteristic, no attempt is made to indicate superiority of one method over another. Selection of the methods to be followed must be governed by experience and the requirements in each individual case, together with agreement between the purchaser and the seller.

1.2 These practices describe the testing of polymeric powders as applied by electrostatic spray, fluidized bed, or any other applicable method.

1.3 These practices apply to proper and safe packaging, shipping and receiving, and storage and handling during use and application of polymeric powders.

1.4 This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

¹² Annual Book of ASTM Standards, Vol 10.02.

remain finely divided during storage under suitable conditions.

4.3 *film formation from a coating powder*—the forming of a continuous film by melting powder particles and coalescing them by the application of energy. For thermosetting materials, a chemical reaction, either condensation or addition, also takes place. This fused film has the uniformity, color, toughness, and other properties associated with protective and decorative coatings.

4.4 *fluidity*—the ability of a powder to move freely, uniformly, and continuously (somewhat like a liquid) when subjected to certain conditions of pressure, temperature, and velocity of a carrier gas.

4.5 *gel time*—interval required at a given temperature for a powder to be transformed from a dry solid to a gel-like state.

4.6 *particle size*—average diameter of an object having irregular boundaries that can be described in an artificial way as having a diameter.

4.7 *particle-size distribution*—arrangement of particle size measurements on a powder in groups of specified diameters.

4.8 *pourability*—the ability of a powder to flow uniformly or to be continuously poured from a container at a steady rate.

4.9 *powder coatings*—coatings which are protective or decorative, or both, formed by the application of a coating powder (4.2) to a substrate and fused into a continuous film by the application of heat or radiant energy.

4.10 *storage stability*—the ability of a powder to maintain uniform physical and chemical properties after being subjected to specified storage conditions.

4.11 *volatile content*—the quantity expressed as weight percent of the powder which is lost under specified conditions of temperatures and time.

4.12 *cloud chamber technique*—method of moving a charged or uncharged object through a charged or uncharged cloud of powder in an enclosed chamber.

4.13 *electrostatic deposition*—technique of moving and charging powder so that it is deposited onto an oppositely charged substrate by one of the following methods.

4.13.1 *fluidized bed technique*—method of moving a grounded object over or through an oppositely charged fluidized powder.

4.13.2 *spray technique*—method of spraying and charging powder so that it is deposited onto an oppositely charged substrate.

4.14 *nonelectrostatic deposition*—technique of moving powder onto a substrate which may be heated above the fusion point of the powdered material.

4.14.1 *spray technique*—method of spraying powder onto a substrate which may be heated above the fusion point of the powdered material.

4.14.2 *fluidized bed technique*—method of dipping a hot object into a container holding the powder suspended in a gas stream so that it resembles a fluid and allowing the powder to melt onto the object being coated.

4.14.3 *flame spread technique*—method of applying powder using a compressed gas and melting the powder in a

flame before the powder impinges on the surface.

5. Sampling

5.1 Sample the powder in accordance with Practice D 1898.

5.2 Prepare specimens as required for the specific tests on the coating.

6. Equipment

6.1 Use the equipment as specified in each method of test.

7. Conditions Affecting Polymeric Powder or Powder Coatings, or Both

7.1 Practical requirements and performance of powder and powder coating may vary with:

7.1.1 *Substrate Type*—Ferrous, nonferrous types, plastic, or elastomeric.

7.1.2 *Substrate Weathering*—Weathering of the substrate will probably adversely affect the performance.

7.1.3 The type, quality, and suitability of the metal treatment or primer used under the powder coating and the time before coating application.

7.1.4 Application conditions.

7.1.5 Contaminants on the surface of the substrate.

7.1.6 Damage to container, size of container, storage time, excessive temperature, and temperature fluctuations which may cause settling, caking, or chemical change.

POLYMERIC POWDER PROPERTIES

8. Particle Size and Distribution

8.1 *Multiple Sieve Analysis*:

8.1.1 This method employs multiple sieves to determine particle sizes and their distribution. Standard 200-mm (8-in.) diameter sieves and a mechanical shaker are used. A representative quantity of the sample is sifted through a series of sieves and the amount retained on each sieve is weighed and calculated as percent of the total specimen.

8.1.2 *Apparatus*:

8.1.2.1 *Sieves*—Half-height sieves, 200 mm (8 in.) in diameter, conforming to the requirements of Specification E 11. A selection of sieves encompassing the expected range of particle sizes together with a cover and a bottom pan are required.

8.1.2.2 *Mechanical Sieve Shaker with Automatic Time Switch*¹³—The mechanical sieve-shaking device shall be capable of imparting uniform rotary motion and a tapping action at the rate of 150 ± 10 taps/min.

8.1.2.3 *Balance*—A laboratory balance with a minimum capacity of 500 g sensitive to 0.1 g, for weighing the specimen and the residues retained on the sieves.

8.1.3 *Procedure*:

8.1.3.1 If the residues are not to be transferred for weighing, weigh each of the selected sieves and the bottom pan to 0.1 g. Nest the desired sieves in order of diminishing openings with the coarsest sieve on top and the pan on the bottom.

¹³ Ro-Tap Sieve Shaker has been found suitable for this purpose and is available from W. S. Tyler Co., Cleveland, Ohio 44114. An equivalent may be used.

8.1.3.2 Weigh out a 100 ± 0.1 -g specimen and transfer it to the top sieve of the stack.

NOTE 1—If necessary this test may be made on a specimen of any size from 50 to 200 g. The weight of specimen used shall be stated in the report.

8.1.3.3 Place the cover on the top sieve, and place the stack in the mechanical sieve shaker. Operate the shaker for $10 \text{ min} \pm 15 \text{ s}$.

8.1.3.4 After shaking, carefully separate the stack of sieves, beginning at the top, and weigh the quantity of material retained on each sieve and that contained in the pan to 0.1 g. This may be accomplished either by transferring the fractions to the balance or by weighing the sieve or pan and its contents, and subtracting the tare weight from the total. If the material is transferred to the balance, carefully brush the sieve on both sides to ensure that adhering particles are transferred.

8.1.3.5 Calculate the percent in each fraction as follows:

$$\% = (R/S) \times 100$$

where:

R = residue weight, g, and

S = specimen weight, g.

NOTE 2—Ordinarily there is a small loss of dust as indicated by the cumulative total weight being less than 100 %. If this loss is not over 2 %, the amount reported through the finest sieve shall be increased until the total of all portions of the sample equals 100 %. If the cumulative total is less than 98 %, repeat the test.

8.1.4 Report—The report shall include the following:

8.1.4.1 Complete identification of the sample,

8.1.4.2 Specimen weight,

8.1.4.3 Percent of material retained on each sieve,

8.1.4.4 If required, the total cumulative percent of material retained on each sieve and in the pan,

8.1.4.5 Temperature, and

8.1.4.6 Relative humidity.

8.2 Vacuum Sieve Analysis:

8.2.1 Summary of Method:

8.2.1.1 In this method sieving is accomplished by aerodynamics so that there is no reduction in particle size and absolutely no wear on the sieves.

8.2.1.2 The housing holds a standard 200-mm (8-in.) sieve and a transparent sieve cover. A slit nozzle rotates slowly below the sieve. An air current, produced by a standard vacuum cleaner-type device, is blown upwards through a hollow shaft and the slit nozzle to the sieve, where it clears the screen. The particles thus suspended in air between the sieve and the sieve cover are separated as the air current circulates. The fine materials are blown through the sieve and into a filter bag, while the coarse materials remain on top of the sieve. A manometer indicates the vacuum inside the housing.

8.2.2 Apparatus:

8.2.2.1 Sieves—As described in 8.1.2.1 and transparent sieve cover.

8.2.2.2 Vacuum Sieve Apparatus—A vacuum sieving device¹⁴ capable of maintaining inside the housing a vacuum

of 5 ± 0.5 in. (127 ± 12.7 mm) of water as measured by a manometer. The slit nozzle which rotates below the sieve shall revolve at a speed of 25 ± 2 rpm.

8.2.2.3 Balance—See 8.1.2.3.

8.2.3 Procedure:

8.2.3.1 If the residues are not to be transferred for weighing, weigh each of the selected sieves to 0.1 g.

8.2.3.2 Weigh out a 100 ± 0.1 g specimen and transfer it to one of the sieves.

NOTE 3—If necessary, this test may be made on a specimen of any size from 10 to 50 g. The weight of specimen used shall be stated in the report. For small sieve openings, 1 to 10 g is recommended.

8.2.3.3 Place the transparent cover on the sieve and place the sieve in position on the vacuum sieving apparatus. Operate the sieving apparatus for $5 \text{ min} \pm 15 \text{ s}$ at a vacuum of 5 ± 0.5 in. (127 ± 12.7 mm) of water.

8.2.3.4 Remove the sieve and cover from the apparatus and weigh the quantity of material retained on the sieve and adhering to the cover to the nearest 0.1 g. This may be accomplished either by transferring the retained material to the balance or by weighing the sieve, cover, and contents, and subtracting the tare weight from the total. If the material is transferred to the balance carefully brush the sieve on both sides, and removed all powder from the cover to ensure that all adhering particles are transferred.

8.2.3.5 Repeat the procedure for each sieve used.

8.2.4 Calculate the percent retained on each sieve as follows:

$$\% = (R/S) \times 100$$

where:

R = residue weight, g, and

S = specimen weight, g.

8.2.5 Report—The report shall include the following:

8.2.5.1 Complete identification of the sample,

8.2.5.2 Specimen weight,

8.2.5.3 Percent of material retained on each sieve,

8.2.5.4 Temperature, and

8.2.5.5 Relative humidity.

8.3 Sonic Sifter Analysis:

8.3.1 Summary of Method:

8.3.1.1 In the sonic sifter, the sieves are stationary and agitation is imparted to the particles by an oscillating column of air. Sieve wear and particle attrition are minimal.

8.3.1.2 The sonic sifter consists of a sieving chamber, a diaphragm at the top vibrating at 60 Hz, and a motor with the necessary controls. The amplitude of vibration is adjustable to the nature of the specimen.

8.3.2 Apparatus:

8.3.2.1 Sieves—See 8.1.2.1.

8.3.2.2 Sonic Sifter—A sonic sieving device¹⁵ utilizing a diaphragm vibrating at 60 Hz with controls to adjust the sift amplitude and the pulse amplitude.

8.3.2.3 Balance—An analytical balance with a minimum capacity of 150 g sensitive to 1 mg for weighing the specimen and the residues retained on the sieves.

8.3.3 Procedure:

¹⁴ Alpine Air Jet Sieve, Model 200, has been found suitable for this purpose and is available from Alpine American Corp., Michigan Drive, Natick, Mass. 01760. An equivalent may be used.

¹⁵ Model L3P Sonic Sifter has been found suitable for this purpose and is available from ATM Corp., P.O. Box 2405, Milwaukee, Wisc. 53214. An equivalent may be used.

8.3.3.1 Weigh and record the weight of each sieve, and of the collar, cover, and fines collector.

8.3.3.2 Weigh out a 2.5 ± 0.001 -g specimen.

8.3.3.3 Stack the sieves in descending order, coarsest on top, finest on the bottom, and transfer the specimen to the top sieve.

8.3.3.4 Insert the sieve stack assembly in the sieve chamber and lock. Set the sift amplitude at 3 and the pulse amplitude at 10. Operate the sifter for $3 \text{ min} \pm 15 \text{ s}$.

8.3.3.5 Weigh each sieve, the fines collector, cover, and the collar, subtract the tare weight for each, and calculate the percent retained on each sieve.

NOTE 4—Include any material adhering to the cover and the collar in the weights for the top sieve.

8.3.4 Report—The report shall include the following:

8.3.4.1 Complete identification of the sample;

8.3.4.2 Specimen weight,

8.3.4.3 Percent of material retained on each sieve,

8.3.4.4 Temperature, and

8.3.4.5 Relative humidity.

8.4 Electronic Counting Analysis:

8.4.1 Summary of Method:

8.4.1.1 This method, one of several found valuable for the measurement of particle size, covers the determination of the particle size distribution of powder coatings (0.6 to $80.0 \mu\text{m}$) using the electronic particle counter.¹⁶ This instrument uses an electric current path of small dimensions which is modulated by individual particle passage through an aperture, and produces individual pulses of amplitude proportional to the particle volume.

8.4.1.2 The powder is carefully dispersed ultrasonically or by some other appropriate method and a portion is added to a filtered electrolyte. Particle counts are obtained at several selected particle size levels and converted to relative weight fractions assuming constant particle density.

8.4.1.3 The instrument response is essentially to particle volume (liquid displacement); therefore equivalent spherical diameter is commonly used to express the particle size.

8.4.2 Apparatus:

8.4.2.1 Electronic Particle Counter,¹⁶ detecting particles using electric current through a liquid resistor.

8.4.2.2 Aperture Tube, $200\text{-}\mu\text{m}$ diameter. The diameter required is dependent upon the particle size distribution of the sample. Generally any given tube will cover a particle size range from 2 to 40 % of its aperture diameter.

8.4.2.3 Beaker, 250 to 500-ml, capable of maintaining all particles uniformly in suspension (for example, baffled or round bottom).

8.4.2.4 Ultrasonic Agitator.

8.4.2.5 Membrane Filtering Device, $0.45\text{-}\mu\text{m}$ filters.¹⁷

8.4.3 Reagents:

8.4.3.1 Purity of Reagents—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications

of the committee on Analytical Reagents of the American Chemical Society, where such specifications are available.¹⁸ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

8.4.3.2 Purity of Water—Unless otherwise indicated, references to water shall be understood to mean reagent water conforming to Type II of Specification D 1193.

8.4.3.3 Dispersing Medium—5 % solution of octyl phenoxy polyethoxyethanol¹⁹ in reagent water.

8.4.3.4 Electrolyte—Dissolve 10.0 g of reagent grade sodium chloride (NaCl) in 1000 ml of reagent water, add some bactericide such as 70 mg of sodium trichlorophenate then filter twice through the membrane (8.4.2.5).

8.4.3.5 Wash Water—Reagent water filtered twice.

8.4.4 Procedure:

8.4.4.1 Precalibrate the aperture and electrolyte combination following the manufacturer's instruction manual.

NOTE 5—Calibration should be carried out using a lycopodium of microspheres suspension of $18.04\text{-}\mu\text{m}$ diameter with the half-count procedure as given in the instruction manual. It is necessary to have mutual agreement on monosized system diameters for interlaboratory comparisons.

8.4.4.2 Cone and quarter the sample until a specimen of convenient size is obtained.

8.4.4.3 Disperse the specimen by adding dispersing medium from the eye-dropper. Use gentle spatulation until a pasty consistency is obtained. Pick up a small portion of this mixture (about 0.1 ml more or less depending on the particle size of the powder) on a small spatula and rinse with wash water into a 25-ml beaker containing 5 ml of dispersing medium. Place the beaker in the ultrasonic agitator for 30 s and then rinse into 200 ml of electrolyte in the 250 to 500-ml beaker. Fill the beaker to capacity and place in the counting position of the counter stand.

8.4.4.4 Fill the aperture tube with electrolyte. Check the aperture for blockage and clear with a brush if necessary. Set the instrument controls for the smallest particle appropriate for the aperture in use. Typical instrument settings are shown in Figs. 1, 2, or 3.

8.4.4.5 Take three cumulative counts with 500- μl volume manometer and calculate the mean, which should be between 2700 and 5000. If it is not, adjust the particle concentration until it is. If more powder is added, it must be treated the same as the original specimen, except it may be rinsed directly into the beaker after ultrasonic agitation. If the suspension needs dilution, drain some of the suspension through a clean glass tube while agitating and then refill the beaker with electrolyte.

8.4.4.6 Set the instrument controls for normal accumulation of differential data. Typical instrument settings are shown in Figs. 1, 2, and 3. Take three counts at each size level for averaging.

¹⁸ "Reagent Chemicals, American Chemical Society Specifications," Am. Chemical Soc., Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY, and the "United States Pharmacopeia."

¹⁹ Triton X-100 has been found suitable for this purpose and is available from Rohm and Haas Co., Independence Square, Philadelphia, PA. An equivalent may be used.

¹⁶ Models ZB with M2 accessory, Model B with Model M accessory, Model T, Model TA, and Model TALL have been suitable for this purpose and are available from Coulter Electronics, Inc., 590 W. 20 St., Hialeah, FL 33010. An equivalent may be used.

¹⁷ The membrane filters may be Millipore, Gelman, General Electric, Nuclepore, Selas Flotronics metal type, or their equivalent.

FIG. 2 Model "T" Typical Worksheet

9.1.2.3 At 24-h intervals perform the following tests until failure or as agreed upon between the purchaser and the seller.

(a) Particle size and particle size distribution (see Section 8).

(b) Gel time (see Section 14).

(c) Spray a panel of the powder coating and bake as specified. Compare with a panel prepared with unheated powder.

(d) If there is noticeable caking, test for pourability by Method D 1895.

9.1.3 Report:

9.1.3.1 Duration of test,

9.1.3.2 Particle size distribution before and after testing,

9.1.3.3 Gel time before and after testing,

9.1.3.4 General appearance of panels coated with aged and unaged powders, and

9.1.3.5 Degree of caking.

Cumulative Value Plot - - - - Differential Value Plot
FIG. 4 Size Distribution Curve on Semilog Paper

12.1.2 *Aluminum Dishes*, 60 mm in diameter and 17 mm deep.

12.2 Procedure:

12.2.1 Weigh two aluminum dishes to 0.1 mg and weigh by difference two specimens of 1.9 to 2.1 g or as otherwise specified of coating powder into them.

12.2.2 By gentle tilting spread the powder uniformly over the bottom of the dishes.

12.2.3 Heat the dishes and contents in an oven for 2 h at $60 \pm 2^\circ\text{C}$ or at $100 \pm 2^\circ\text{C}$ or at the temperature specified between the purchaser and the seller. Cool in a desiccator and weigh.

12.3 *Calculation*—Calculate the nonvolatile content as follows:

$$\text{Nonvolatile content, weight \%} = (C - A) 100/S$$

where:

A = weight of dish, g,

S = weight of specimen, g, and

C = weight of dish and contents after heating, g.

13. Volatile Content at Baking or Fusion Temperature

13.1 Use the apparatus and procedure given in Section 12 but heat the specimen at the normal baking temperature and

time unless otherwise specified.

13.2 Calculate the percent volatile matter by subtracting the nonvolatile content from 100.

14. Gel Time or Stroke Curve (for Thermosetting Powders Only)

14.1 Apparatus:

14.1.1 *Hot Plate*, suitable for use at 200°C .

14.1.2 *Stop Watch or Electric Timer*, 0.1 s interval.

14.1.3 *Wooden Tongue Depressor*, 6 by 1 in. (150 by 25 mm) or *Wooden Splints*, 6 by 1/4 in. (150 by 6 mm).

14.1.4 *Aluminum Foil*.

14.1.5 *Analytic Balance*.

14.1.6 *Pyrometer*, suitable for use at 200°C .

14.2 Procedure:

14.2.1 Measure 0.5 ± 0.1 g of powder.

14.2.2 Cover the hot plate with aluminum foil or use a non-silicon mold release lubricant. Set the heat to $190 \pm 1^\circ\text{C}$ or as agreed between the purchaser and seller, and check with the pyrometer.

NOTE 6—A shroud may be required to prevent air circulation from cooling the hot plate.

14.2.3 Drop the powder specimen on the foil and start the

FIG. 5 Powder Flowmeter

timer. Rub the powder with the edge of the tongue depressor in 1 in. (25 mm) diameter circular strokes. Continue this motion with slight pressure until a solid gel is produced as found by lifting the depressor at least 2 in. (50 mm) from the hot plate. If the material produces a continuous filament from the plate to the depressor it has not gelled.

14.2.4 Stop the timer when the strand breaks readily. Repeat the test with a fresh specimen. Calculate and report the mean gel time.

15. Melting Point Determination

15.1 Apparatus:

15.1.1 *Kofler Hot Bench*,²⁰ hot bench agreed upon between the purchaser and the seller.

15.1.2 Calibrating Test Substances:

	Melting Point, °C
Azobenzene	68 ± 1
Naphthalene	80 ± 0.5
Benzoic acid	122 ± 1

15.1.3 *Paint Brush*, stiff bristle, 1/2-in. (12.7-mm).

15.2 Procedure:

15.2.1 Calibrate the apparatus as follows. Allow 60 min for the warm up of the heating bar. Sprinkle a calibrating substance having the closest melting point to that of the powder on the heating bar. Observe the sharp division between solid and liquid. Place the pointer between these two divisions. Slide the reading device to the melting point of the calibrating substance.

15.2.2 Sprinkle the specimen over the heating bar in a uniform manner. Observe the specimen after 1 to 2 min. Brush the material towards the lower temperature and note the location where particles of powder adhere to the bar when brushed lightly. Place the pointer at this point. Read the temperature and report in degrees Celsius.

NOTE 7—Powder will fuse and "set" on the hot bar. Remove the powder quickly and thoroughly before the setting occurs. Do not use abrasives to clean the bar.

16. Viscosity Measurement for Molten Powder Coatings by Weissenberg Rheogoniometer

16.1 *Summary of Method*—This method covers the determination of the viscosity of powder coatings at baking temperatures and consists simply of preheating the cone and plate of a Weissenberg rheogoniometer, pouring an adequate sample of powder onto the plate, closing the apparatus and recording revolutions per minute and the corresponding

²⁰ Kofler hot bench has been found suitable and is available from Reichert Co., Vienna, Austria. An equivalent may be used.

Technical

steady torque transducer deflection.

16.2 *Apparatus*—Weissenberg rheogoniometer²¹ with at least capability for constant-speed rotational shear, high-temperature electric oven, and cone and plate shearing surfaces.

16.3 Procedure:

16.3.1 By consulting the rheogoniometer instruction manual, select the cone, plate, and torsion wire adequate to measure the largest anticipated viscosity in no more than 10 s. After alignment of the cone and plate, use the electric oven to bring them to the baking temperature of the coating (as agreed upon between the purchaser and the seller), or to a few degrees above that temperature.

16.3.2 As quickly as possible, with the air bearing functioning, open the oven, raise the cone a few inches, pour sufficient powder to fill the volume between the cone and the plate onto the center of the plate, and lower the cone sufficiently to close the oven. Continue to lower the cone until the proper gap between the cone and plate, as specified by the manufacturer of the rheogoniometer, has been reached.

16.3.3 Start the plate rotating at 1 to 5 rpm, with the torque transducer at the largest possible full-scale setting. **Caution**—Stop the plate rotation should the full-scale torque be exceeded since this may damage the instrument. Start again at a lower rpm. Record torque reading at this rpm. At several lower rotational speeds, record rpm, steady torque reading and the ratio of torque to rpm until the ratio of these two becomes essentially constant, indicating a low shear rate Newtonian (constant viscosity) behavior.

16.3.4 If lack of sensitivity prevents measurements at low shear rates, repeat the above procedure with a more sensitive torsion wire. If there is no low shear rate Newtonian region evident, the powder may be crosslinking or increasing in viscosity because of loss of volatiles. Repeated measurements on the same specimen at a given shear rate should indicate this. Several measurements made quickly at very low shear rates on fresh specimens may allow calculation of viscosities before crosslinking or volatile loss causes a significant change.

16.4 *Report*—The viscosity and shear rate values obtained, the value of the low shear rate Newtonian viscosity and the temperature at which the test was conducted.

16.5 *Precision*—Repeatability and reproducibility of viscosity readings at any given shear rate should be within 10 % relative. However, sample age and storage history may well affect the results obtained.

17. Inclined Plate Flow Test

17.1 Apparatus:

17.1.1 *Constant-Temperature Convection Electric Oven*, thermostatically controlled to maintain temperature of $150 \pm 2^\circ\text{C}$ or as agreed upon between the purchaser and the seller.

17.1.2 *Metal Plate Rack Assembly*, 8 by 11 in. (203 by 280 mm) that fits into inner oven chamber and is capable of being maintained in either a horizontal position or at a

65-deg angle by means of an exterior lever.

17.1.3 *Tin Plate Panel*, 8 by 11 in. (203 by 280 mm).

17.1.4 *Analytical Balance*, sensitive to 1.0 mg.

17.1.5 *Steel Pellet Mold Press*²² and knockout rod to make pellets 0.25 in. (6 mm) thick by 0.50-in. (12.7-mm) diameter.

17.1.6 *Stop Watch*.

17.1.7 *Steel Rule*.

17.2 Procedure:

17.2.1 Weigh out 0.50 g of coating powder and transfer to the steel pellet mold. Press to 0.25-in. (6-mm) thickness and push the pellet out of the mold with the knockout.

17.2.2 Place the pellet on a tin plate panel in a 1/2-in. circle scribed or marked on the panel.

17.2.3 Place the panel holding the pellet(s) on the metal rack assembly in the oven in a horizontal position. Close the oven door quickly. Allow the assembly to remain in the horizontal position for 3 min.

17.2.4 Tilt the rack assembly holding the panel to 65 deg from the horizontal without opening the oven door and allowing the oven to cool. Allow the rack and panel to remain in this position for 30 min.

17.2.5 After 30 min remove the panel from the oven and allow to cool to room temperature. Measure the amount of flow from the original diameter and line scribed on the panel.

17.3 *Report*—Maximum flow in millimetres from the original diameter.

NOTE 8—A control pellet if possible of known reactivity and flow should be run in each test. Sample material should be stored in sealed polyethylene bags prior to use and likewise pressed pellets should be stored in a desiccator or sealed bags to prevent moisture absorption.

NOTE 9—The 0.5-g charge should be sufficient for most powders with a cured specific gravity of 1.1 to 1.4. For heavier resins, it may be necessary to increase the pellet weight. If so, this should be recorded as a variance in specimen size.

18. Density and Specific Gravity

18.1 *Apparent Density*—Determine in accordance with Method A of Test Method D 1895.

18.2 *Bulk Factor*—Determine in accordance with Test Method D 1895.

18.3 *Specific Gravity*—Determine in accordance with Test Method D 153 or as follows.

18.3.1 In place of the pycnometer, a weight-per-gallon cup may be substituted. Because of its wide opening, the cup allows ready transfer of powder without loss. In addition the powder can be more readily wet with kerosine (or other suitable carrier agreed upon between the purchaser and the seller) by thorough use of a glass stirrer to remove the entrapped air. Care must be exercised to return any powder particles adhering to the glass rod to the weight per gallon cup to ensure accuracy of the method.

²² Parr Calorimeter Pellet Press, Cam and Cover type, stainless steel die with standard cavity for making 1/2-in. diameter pellets up to 1/2 in. thickness obtainable from Fisher Scientific Co., Pittsburgh, PA, has been found suitable. An equivalent may be used.

²¹ Weissenberg Rheogoniometer is available from Diano Corp., Midwest Technical Center, 1866 Production Dr, Louisville, KY 40299.

APPLICATION PROPERTIES

19. Determining the Relative Deposition Efficiency of Organic Polymeric Powders on Moving Targets

19.1 *Summary of Method*—The method essentially consists of spraying powder at a known flow rate on a number of similarly shaped targets moving at a known rate past a powder spraying device mounted in a spray booth.

19.2 Apparatus:

19.2.1 *Set of Targets*, consisting of 15 flat steel panels 6 by 36 by 0.063 in. (152 by 915 by 1.6 mm) wrapped in aluminum foil. (Use other targets as agreed upon between the purchaser and the seller.) The panels should have holes drilled at one end for hanging from a conveyor. The aluminum foil should be of the lowest possible temper and should be 13½ by 37 by 0.0015 in. (340 by 940 by 0.04 mm) (these characteristics have been found to be the best for easy wrapping of the panels). Other tempers, thicknesses, and dimensions may be used, however (for example, regular commercial aluminum foil is satisfactory).

19.2.2 *Fifteen Target Hangers* constructed so that the targets will hang from the conveyor in one plane within ±½ in. (±13 mm) with the flat surfaces perpendicular to the source of the powder spray. The target hangers should be long enough so the source of the powder spray can be pointed at the center of the targets.

19.2.3 *Powder Flowmeter*, consisting of a vacuum cleaner attached to a small vacuum chamber (powder receiver) constructed as shown in Fig. 5.

19.2.4 *Balance*, sensitive to 100 mg.

19.2.5 *Balance*, sensitive to 1 mg.

19.2.6 *Stop Watch*, accurate and readable to ⅓ s.

19.2.7 *Powder Spray System*.

19.3 Procedure:

19.3.1 Cut the number of aluminum-foil wrappings necessary for the desired number of tests and number (with a felt tip pen, grease pencil, etc.) on one corner. If the available balance can weigh the entire target, weigh the panels with the aluminum-foil wrappings. If the balance cannot weigh the entire target, weigh the aluminum-foil wrappings alone. Record the numbers and corresponding weights.

19.3.2 Wrap the targets with the foil. The best method of doing this is simply to lay the foil on a flat surface with the numbered side down. Place the target on the foil so that it is centered on the foil and ½ to 1 in. (13 to 25 mm) from the long edge of the foil. For convenience, the top of the target (where the hanger holes are) should be at the numbered end of the foil wrap. Fold the ½ to 1-in. (13 to 25-mm) piece of foil over the edge of the target, creasing it firmly. Then turn the panel over so that it wraps the foil around itself, and crease the new edge firmly. Then turn the panel over again (this will fold the remaining foil over) and crease it firmly.

19.3.3 Determine the conveyor speed by measuring the distance between two points on the conveyor track at least 10 ft (3.05 m) apart and by measuring, with the stop watch, the time it takes a location on the conveyor chain to travel the distance between the two points. If possible, adjust the conveyor speed to as close to 10 ft/min as possible (±2 %).

19.3.4 If possible, hang the 15 targets on the conveyor on 12 in. (305 mm) centers far enough ahead of the spray booth to allow the conveyor to come up to speed (at least 1 min

travel) or for this test, 10 ft (3.05 m).

19.3.5 Break up any powder agglomerates in the powder by mixing or sieving before adding to the powder hopper. Determine the powder flow by first weighing the vacuum cleaner bag with the balance and then installing it in the bag chamber. The vacuum cleaner bag alignment holes should go on the alignment pins on the bag chamber. Install the cover on the bag chamber (simply place on bag chamber). Start the vacuum cleaner and adjust the damper so that very little air is felt moving through the hole in the cover (vacuum in the vacuum bag should be 0.3 to 0.7 in. (8 to 17 mm) of water, vacuum in the flowmeter should be 1.5 to 2.5 in. (38 to 64 mm) of water).

19.3.6 Insert the powder spray device into the opening in the top of the powder flowmeter and turn on the dust collector. Turn on the powder spraying device for 30 or 60 s. (Caution—Be sure high voltage is turned off or, if that is not possible, at the lowest possible adjustment), measuring the time with the stop watch. Disassemble the powder flowmeter and reweigh the vacuum cleaner bag on the balance. The increase in weight divided by the time the powder was flowing is the rate of powder flow. The powder in the vacuum cleaner bag can be recovered simply by tearing the bag in half and dumping the powder in the booth or hopper.

19.3.7 Adjust the powder flow, if possible, to 300 g/min ± 5 % by successive process changes. Also adjust or record, or both, all the process variables possible including the following:

19.3.7.1 The powder and its state of use,

19.3.7.2 The particle size distribution if available,

19.3.7.3 The high-voltage power supply output potential and output current,

19.3.7.4 The resistor in the gun,

19.3.7.5 The potential of the powder gun's charging tip,

19.3.7.6 The distance between the target and the charging tip,

19.3.7.7 The pattern adjustment mechanism (measure such things as the relative locations of the parts),

19.3.7.8 The conveyor speed,

19.3.7.9 The powder flow,

19.3.7.10 The powder collector system air flow or some pressure which changes as a function of air flow only,

19.3.7.11 The powder transfer air flow and air pressure,

19.3.7.12 The powder quantity control pressure or whatever variable controls this,

19.3.7.13 For fluidized beds; air flow, air pressure, the amount of powder, and bed depth,

19.3.7.14 Other variables such as vortex air, dosing air, powder density air, pattern air, etc., and

19.3.7.15 The atmospheric variables: temperature, barometric pressure, and humidity.

19.3.8 Mount and level the powder spray device in the spray booth so that it is aimed at the centers of the targets as they pass. Position it so that its charging tip is 8 ± ½ in. (203 ± 13 mm) from the plane in which the targets will pass.

19.3.9 Turn on the powder flow, adjust the high voltage to 60 ± 1 kV (use other voltages as agreed upon between the purchaser and the seller), turn on the powder collection system, etc. Start the conveyor and spray the targets after all other systems seem to be operating normally and powder is spraying into the spray booth.

19.3.10 After remove the targets from the powder off of the targets in the booth. This is also an excellent method for the removal of powder retained after preweighed 5-Place this in the

19.3.11 After and pull the targets as soon as possible. This facilitates because the targets become handle. If necessary, after the foil wrapping.

19.3.12 Weighings from the each end of because they relative to the powder added powder and powder was wiped off to

19.3.13 Calculate the following equation: % E

where:
% E = percent
 $\bar{W}_p$ = mean
 V_c = coefficient
 D_T = distance
 Q_p = powder
% R = percent (1)

19.3.14 coating, calculate following equation:

where:
 V = volume
 $\bar{W}_p$ = weight
 n = number
 $\bar{W}_p$ = mean

19.3.14.1 indicates that This is due to the fact that, sometimes powder collection results agree

19.3.10 After spraying the targets, stop the conveyor and remove the targets, taking care not to knock or jar the powder off of them. If it is desired to cure the powder, place the targets in an oven for the time and temperature recommended for the specific powder being used. If necessary, this is also an excellent time to determine the weight percent retained after curing the powder. Weigh 1 g of powder in a preweighed 5-in. (127-mm) diameter aluminum foil "pan." Place this in the oven along with the targets.

19.3.11 After curing, remove the targets from the oven and pull the aluminum foil down 1 to 2 ft (305 to 610 mm) as soon as possible using asbestos or thick workman's gloves. This facilitates the final removal of the aluminum foil because the coated foil tends to contract slightly with cooling and become very difficult to remove when cool enough to handle. If necessary, also remove the pan of powder from the oven. After they are reasonably cool, remove the aluminum-foil wrappings, if they are to be weighed alone.

19.3.12 Weigh the center 11 targets or aluminum wrappings from the center 11 targets excluding the two targets on each end of the target set. (The end targets are excluded because they tend to collect excessive amounts of powder relative to the other targets.) Determine the amount of powder added to each target. If necessary, weigh the pan of powder and determine the weight percent retained. If the powder was not cured, the targets may be blown off and then wiped off to prepare them for the next test.

19.3.13 Calculate the mean weight of powder deposited. Calculate the percent deposition efficiency using the following equation:

$$\% E = (\bar{W}_p \times V_c \times 10\,000) / (D_T \times Q_p \times \% R)$$

where:

$\% E$ = percent deposition efficiency,

$\bar{W}_p$ = mean powder deposition, g,

V_c = conveyor speed cm/min,

D_T = distance between target centers, cm,

Q_p = powder flow, g/min, and

$\% R$ = percent by weight powder retained after curing (100 % if not cured).

19.3.14 To determine the variation in application of the coating, calculate the coefficient of variation using the following equation:

$$V = \frac{(\sum W_p^2 - n \bar{W}_p^2)^{1/2}}{\bar{W}_p}$$

where:

V = coefficient of variation %,

$\bar{W}_p$ = weight of powder on a foil wrapping, g,

n = number of targets used (11), and

$\bar{W}_p$ = mean powder deposition, g.

19.3.14.1 If the coefficient of variation exceeds 10 % it indicates that the powder cloud is fluctuating excessively. This is due usually to poor (slugging) powder pump operation, sometimes to unstable booth air flow profiles, and sometimes to unstable air flow patterns created by spray gun powder cloud control system.

19.3.15 Repeat the above procedure until two consecutive results agree within ± 10 %. Use the set of conditions under

which these results were obtained as a standard to which to relate future work. It is wise to run the test within the standard conditions at the beginning and end of each day. If results do not agree within ± 10 % the day's work should be suspect. Results will vary from day to day and even during the day due to variables beyond the user's control. Long-term variations can even be as large as 50 %. Tests run with different powders or under different conditions should have the results reported in terms of the standard test results. For example, if the efficiency results under the standard conditions were 50 % with one powder and 75 % with another powder, the second powder would be 50 % more efficient than the first powder.

19.4 Report:

19.4.1 Report the variables and their values as recorded for 19.3.7. Report the percent deposition efficiency and its coefficient of variation, the percent efficiency compared to the average percent efficiency obtained using the standard conditions on the day of the test.

19.5 *Precision*—Deposition efficiency results should be repeatable within ± 10 % during a day.

PHYSICAL PROPERTIES OF POWDER COATING

20. Panel Preparation

20.1 *Treatment of the Substrate*—Clean and prepare test panels in accordance with one of the following standard test methods or recommended practices or as agreed upon between the purchaser and the seller:

20.1.1 Method D 609.

20.1.2 Practices D 1730.

20.1.3 Practices D 1731.

20.1.4 Practices D 1732.

20.1.5 Method D 1733.

20.1.6 Practices D 2092.

20.1.7 Test Method D 2201.

20.2 *Priming and Sealing*—In many instances, the use of a primer, primer surfacer or sealer is required. The type, application, and treatment of any undercoat system should be agreed upon between the purchaser and the seller.

20.3 *Application of Powder Coatings*—The coatings may be applied by fluidized bed, electrostatic spray, or other methods.

20.4 Curing of Powder Coatings:

20.4.1 Fuse or bake the powder coating to a uniform film according to the established schedule and temperature and age as agreed upon between the purchaser and the seller before running tests.

20.4.2 The powder coating should be overbaked to determine the time/temperature effect on the physical and chemical properties in accordance with Recommended Practice D 2454.

20.5 *Measurement of Film Thickness*—Since the properties of a powder coating can vary considerably with its thickness, it is important to know the film thickness. Measure the film thickness in accordance with Test Method D 1005, D 1186, or D 1400.

21. Abrasion Resistance

21.1 Determine the abrasion resistance in accordance with Test Method D 658, D 968, or D 1044.

22. Adhesion

22.1 The powder coatings of a specified thickness and over a specified substrate as agreed upon between the purchaser and the seller is subjected to an adhesion test to determine the degree of attachment the coating has to the substrate.

22.2 Determine the adhesion of the powder coating to the specified substrate in accordance with Test Methods D 2197 or D 3359.

23. Chemical Resistance

23.1 Coating systems frequently come into contact with various chemicals which may have an effect on the properties of the system. Failure, when it occurs, is usually in the form of discoloration, change in gloss, blistering, softening, swelling, or loss of adhesion.

23.2 *Household Chemical Resistance*—Determine the effect of chemicals in accordance with Test Method D 1308.

23.3 *Detergent Resistance*—Determine the resistance to failure when immersed in a detergent solution in accordance with Practice D 2248.

24. Chip Resistance

24.1 In many end uses, the ability of a powder coating to withstand sudden impact from stones, gravel, etc., without being loosened from the substrate is important.

24.2 Determine chip resistance in accordance with Test Method D 3170.

25. Color—Pigmented Coatings

25.1 The colors of opaque objects such as coated surfaces may be specified by visual or instrumental requirements.

25.2 For visual evaluation, determine the color of a coated surface in accordance with Method D 1535.

25.3 Determine the color of a coated surface instrumentally in accordance with Method E 308.

26. Color Difference—Pigmented Coatings

26.1 The color difference between two homogeneously colored opaque films may be determined by visual evaluation or by instrumental means.

26.2 Determine color differences visually in accordance with Practice D 1729 or instrumentally by Method D 2244.

27. Cracking Resistance

27.1 The cracking resistance test is designed to give an indication of the resistance of a coating system to cracking and checking caused by temperature and humidity changes. Some factors which may affect results are type of substrate, substrate thickness, undercoat, topcoat, and film thickness.

27.2 Determine cracking resistance in accordance with Test Method D 2246.

28. Elongation

28.1 An elongation test may give an indication of the flexibility of a powder coating. It can also show whether there is any change in flexibility due to the aging of the film.

28.2 Determine elongation in accordance with Test Method D 522 or D 1737.

29. Filiform Corrosion Resistance

29.1 Filiform corrosion is a type of corrosion that occurs under coatings on metal substrates and is characterized by a definite thread-like structure and directional growth.

29.2 Determine the susceptibility of a powder coating on a metal substrate to this type of corrosion by Test Method D 2803.

30. Gloss

30.1 Determine the gloss of a powder coating in accordance with Test Method D 523.

31. Hardness

31.1 Determine the hardness of powder coating in accordance with Test Method D 1474 using either Method A (Knoop Indentation Hardness) or Method B (Pfund Indentation Hardness).

31.2 Other methods of determining hardness are widely used in some industries and may be used as agreed upon between the purchaser and the seller.

32. Impact Resistance

32.1 Films formed from powder coatings may be subject to sudden impact in certain end uses. Determine impact resistance in accordance with Test Method D 2794.

33. Outdoor Exposures

33.1 While the accelerated tests given elsewhere in this recommended practice are intended to enable prediction of probable performance, actual outdoor exposures should be made on coatings intended for exterior use. Usage of paint systems is so varied that no one set of conditions (length or place of exposure) can be given in this practice to cover all situations. These conditions as well as the type of substrate, substrate preparation, etc., should be agreed upon between the purchaser and the seller. However, it is suggested that unless otherwise agreed upon, panels for outdoor exposure should be prepared in accordance with Section 19 of this practice.

33.2 Many properties of powder coating films should be evaluated periodically throughout the outdoor exposure period. These properties may be evaluated as follows:

33.2.1 *Blistering*—Test Method D 714.

33.2.2 *Chalking*—Test Method D 659.

33.2.3 *Checking*—Method D 660.

33.2.4 *Cracking*—Test Method D 661.

33.2.5 *Rusting*—Method D 610.

33.2.6 *Erosion*—Test Method D 662.

33.2.7 *Flaking*—Test Method D 772.

34. Print Resistance

34.1 A print test may be used to determine the degree of thermoplasticity or solvent retention of a film and hence whether the product can be safely stacked or packaged and, in the case of a thermoplastic film, at what temperature the film prints or mars. The print test can also determine the degree of marring due to pressure.

34.2 Determine the imprinting and thermoplasticity of a powder coating film in accordance with Test Method D 2091.

35. Salt Spray

35.1 Salt spray determining the conditions of the accelerated atmosphere, pH, composition, physical parameters of the substrate, the coating is scribed within the cabinets and panels and the upon between.

35.2 Test in Method B 117

36. Water Resistance

36.1 Test in determining the high humidity usually evident adhesion which of the ab

36.2 Determine of high humidity

36.3 Determine of water immersion test is best soaked in water

37. Safety and Health

37.1 This aging, shipping and application decorative volumes of paint

37.2 When chemical aspects: Administrative

37.3.2 Labeled as to manufacturer

37.4 Shipping 37.4.1 Packing

manner to be

37.4.2 Bundled in a manner Precautions of the powder

37.5 Storage

35. Salt Spray Resistance

35.1 Salt spray testing of coatings may be helpful in determining their resistance to failure in service under conditions of high humidity and salt concentrations. Under the accelerated conditions of the laboratory test the temperature, pH, concentration of the salt solution and other physical parameters can be controlled. The selection of the substrate, the coating system, the manner in which the coating is scribed, the location or position of the panels within the cabinet, the length of the test, the inspection of panels and the method of reporting results must be agreed upon between the purchaser and the seller.

35.2 Test for salt spray resistance in accordance with Method B 117.

36. Water Resistance

36.1 Testing of coating systems with water is helpful in determining their resistance to failure under conditions of high humidity or water immersion. Failure in water tests is usually evidenced by blistering, dulling, softening, or loss of adhesion which does not disappear or recover upon evaporation of the absorbed water.

36.2 Determine the resistance to failure under conditions of high humidity in accordance with Practice D 1735.

36.3 Determine the resistance to failure under conditions of water immersion in accordance with Practice D 870. This test is best suited for coating systems that will actually be soaked in water during service.

37. Safety and Handling Precautions

37.1 This recommended practice covers the safe packaging, shipping, receiving, storage, and handling during use and application of organic powders used for protective and decorative coatings. Procedures for handling large and small volumes of powder are included.

37.2 Where required, attention shall be directed to ecological aspects and pertinent Occupational Safety and Health Administration (OSHA) regulations.

37.3 Packaging:

37.3.1 *Container*—For small and medium operations, containers designed to give moisture protection, such as plastic-lined boxes or drums, should be used.

37.3.2 *Labeling*—All containers should be clearly identified as to type material, color, batch number, and date of manufacture.

37.4 Shipping and Receiving:

37.4.1 *Palletizing*—Containers should be palletized in a manner to avoid crushing or packing.

37.4.2 *Bulk Shipment*—Large shipments should be handled in a manner agreeable to the purchaser and the seller. Precautions should be taken to avoid hard packing or caking of the powder.

37.5 Storage:

37.5.1 All containers must be sealed when not in use.

37.5.2 Temperature and relative humidity during storage should not exceed 80°F (27°C) and 50 %, respectively, or as specified on the label.

37.6 Precautions in Handling and Application:

37.6.1 All metal equipment must be properly grounded.

37.6.2 The fluid bed must be cleaned periodically to ensure proper operation.

37.6.3 Under certain conditions organic powders may be subject to dust explosions. Trade association bulletins such as the National Fire Protection Association Bulletins No. 33, Spray Finishing and No. 654, Dust Explosion Prevention—Plastics Industry, may be helpful in identifying conditions and minimizing their occurrences.

37.6.4 Spraying:

37.6.4.1 Spray booths, dust collectors, and ducts should be built with smooth surfaces to facilitate cleaning. If possible, surfaces should be of a material to which the powder will not stick.

37.6.4.2 During nonoperating periods all equipment should be flushed with air or the manufacturer's recommended procedure should be followed.

37.6.5 *Blending*—If reclaimed or recycled powder is to be blended with virgin material, a suitable device for sifting, drying, and blending should be used.

37.6.6 *Dust Collection and Ventilation*—All handling and application equipment should be fitted with a suitable dust collector and filter system.

37.6.7 Suitable electrical grounding is required. Precautions are necessary to ensure ratio of powder to air are held below or above the explosive mixture.

37.7 Ecology:

37.7.1 Exhaust stacks should be equipped with dust collectors or absorbers or both to avoid air pollution.

37.7.2 *Waste Disposal*—Powder must be disposed of in the manner governed by local laws and regulations.

37.8 OSHA Requirements:

37.8.1 *Operator Safety*—All personnel should be equipped with suitable air masks, gloves, and any other specified devices for personal protection.

38. Data Report

38.1 The report shall include the following:

38.1.1 Complete identification of the powder coating material tested,

38.1.2 Description of specimens, including numbers, preparation method, and thickness of coating,

38.1.3 Temperature of test if other than specified by test method,

38.1.4 Type and manufacture of test equipment,

38.1.5 All specific information called for on the individual test method report,

38.1.6 Test results as calculated or observed values on the basis of data, median or mean value, and

38.1.7 Date of test.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Determining by Exterior Exposure Tests the Susceptibility of Paint Films to Microbiological Attack¹

This standard is issued under the fixed designation D 3456; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{ε1} NOTE—Keywords were added editorially in July 1991.

1. Scope

1.1 This practice provides guidelines for determining the susceptibility of paint films to microbiological attack on exterior exposure. While it is recognized that various organisms may occur on an exposed coating, the specific types of organisms are mainly of academic interest. The degree to which microbiological discoloration occurs is the primary concern.

1.2 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

- D 1006 Practice for Conducting Exterior Exposure Tests of Paints on Wood²
- D 1849 Test Method for Package Stability of Paint²
- D 3274 Test Method of Evaluating Degree of Surface Disfigurement of Paint Films by Microbial (Fungal or Algal) Growth or Soil and Dirt Accumulation²

3. Summary of Practice

3.1 Simple observation of a coated object subjected to exterior exposure is considered a practical and reliable method for determining the degree that microorganisms discolor the coating. However, this applies to a specific coated object exposed under a given set of conditions. It should be recognized that there are critical factors that influence the amount of fungal growth that may occur on the same coated object when exposed to other conditions. These factors include the geographic location, local atmospheric conditions such as the dust and pollen content of the air, angle of exposure, degree to which the coating is subjected to weathering, effects of moisture and sunlight, the substrates on which the coating is applied, and the coatings in the paint system under test. The latter factor includes the stability of the coating while packaged in the container, as well as the composition of the coatings included in the total system and

the thickness of each coating applied. Thus, while microorganisms occur on the surface of the last film applied, the degree of microbiological growth that will occur is also influenced by the composition of the undercoats. All the above factors should be considered in the selection of a coating resistant to discoloration by microorganisms.

4. Significance and Use

4.1 The growth of fungi and algae in and on the surface of paint films represents a major cause of discoloration or disfigurement of painted surfaces. This practice covers the preparation of coatings for testing, their application on substrates, and the arrangement of the coated panels on exterior test fences to determine the degree of microbiological attack that may occur on the surface of the coatings over a period of time. This practice is intended to provide guidelines for, and a discussion of, the various factors critical in selection of exterior coatings resistant to discoloration or disfigurement by algae and fungi.

5. Preparation and Application of Coatings

5.1 *Conditioning of Coatings Prior to Application*—Individual coatings to be used in the paint system should be properly aged under suitable conditions prior to testing. Hydrolysis, amalgamation, absorption, and other physical and chemical changes that may have a profound influence on the resistance of a coating to microorganisms usually increase with increasing temperature. It is recognized that actual storage periods of paints prior to use may vary from one to several years, and the peak temperature encountered may be as warm as 160°F (70°C). However, a recommended conditioning period consists of 1 year at room temperatures or 1 month at 125°F (50°C) as in Test Method D 1849. The conditioning of coatings prior to testing shall be agreeable to the producer and the user in the case of a referee test.

5.2 *Preparation of Coatings for Application*—Prior to application of the various coatings to be included in the total paint system, thoroughly reconstitute each coating by appropriate mixing or shaking. At the time of application, there must be no settling, incompatibility, or other stability problem observable in the coating in the container.

5.3 *Application of Paint System*—Apply each coating in the total paint system in an appropriate manner to provide a specified and reasonably uniform film thickness. The presence and thickness of different coatings in the complete system can have a pronounced effect on the degree of microbiological discoloration that will occur. Thus, each

² Annual Book of ASTM Standards, Vol 06.01.

paint in the system must be applied as recommended by the manufacturer. It is important that the procedure and the user agree on the type of coatings and the spreading rate of each coating in the final test film. The drying time between coats and the curing time of the total system prior to exposure should also be specified. Recommended practice for house paint is 2 days between coats and no less than 7 days and not longer than 1 month prior to the exterior exposure. Industrial and industrial maintenance coatings may require a different practice that should be acceptable to the producer and the user.

5.4. On each substrate use a test area not less than 48 in.² (310 cm²) in size. When only one type of substrate is being used, expose at least duplicate panels. When more than one substrate is employed for each exposure condition, duplicate panels of each substrate are not usually required. In case of a referee test, it is recommended that replication and size of test area be agreed on between the producer and the user. Common practice in the industry is to use 6 in. (nominal) by 36-in. (152 by 915-mm) panels for house paint exposures and to use 12-in. (305-mm) metal panels of various widths for exposures of industrial and industrial maintenance coatings.

6. Substrates for Testing

6.1 *General Considerations*—The substrate on which a paint system is exposed can have a significant effect on the degree of microbiological discoloration that may occur. Coated wood surfaces generally support more mold and algae than do coatings on metals or masonry surfaces. This is perhaps due to some nutrients and greater porosity for retention of available moisture in wood surfaces. The type of metal substrate can have either an adverse or beneficial influence on the growth of fungi and algae. Some metals can inactivate certain microbiocides, thereby allowing greater microbiological discoloration. It should also be recognized that metals may also reduce the growth of microorganisms because of toxic compounds resulting from weathering of the metal. Masonry surfaces generally inhibit microbiological growth because of their alkaline nature. However, this same characteristic can contribute to microbiological discoloration by hydrolyzing alkali-sensitive microbiocides that may have been used in the coating. The recommended substrates for testing coatings for resistance to discoloration by microorganisms vary according to the intended use of the coatings. In referee cases, the substrate for testing shall be mutually agreeable to the producer and the user. Industrial coatings should be evaluated on the surface for which they are designed. Trade sales and industrial maintenance coatings are general-purpose coatings and should perform on a variety of substrates. For such coatings, test exposures on the following substrates are recommended for the indicated reasons.

6.2 *Wood Substrates*—Sapwood of pine and fir generally is considered conducive to growth of microorganisms. This may be due to nutrients in the wood and to the low dimensional stability, resulting in microcracking of coatings applied on the wood with subsequent mold growth in these cracks. Plywood, hardboard, and other wood-derived products support varying degrees of fungal growth depending on the nutrient value, degree of moisture absorption, and

dimensional stability of the base material. Redwood tends to have better dimensional stability and otherwise has insignificant effect on the microbiological growth on coatings applied over it. Cedar lumber generally contains compounds that aid in resisting microbiological growth. Both cedar and redwood contain colored extractives that can bleed through coatings to discolor the surface. Some of these extractives can also be nutrients that contribute to microbiological growth, resulting in added discoloration.

6.3 *Metal Substrates*—Iron, galvanized steel, and aluminum are common substrates for paints. Iron and zinc compounds generally inhibit microbiological growth. On the other hand, these metals may react with certain microbiocides to reduce the microbiological inhibition. Certain microbiocides can also cause discolored corrosion products or loss of adhesion by the coating on these surfaces. Aluminum is rather chemically inert and does not itself promote microbiological growth. It may, however, cause loss of microbiological resistance of coatings containing certain mercury compounds because of the amalgamation reaction by aluminum and mercury. This can result in loss of adhesion.

6.4 *Masonry Substrates*—The extremes of masonry surfaces generally consist of two conditions: fresh surfaces, which are relatively alkaline and free of fungi and algae, and weathered surfaces that are less alkaline and may be discolored because of microbiological growth. Weathered masonry surfaces represent useful test surfaces since microbiological contamination can grow through inadequately preserved coatings from the underside. Weathered masonry surfaces also offer a relatively uniform surface from panel to panel. Such uniformity is useful in statistically determining the relative effectiveness of various coatings or of various wash solutions for cleaning or "sterilizing" a surface before repainting. Exposures of coatings on both clean masonry panels and weathered panels can provide useful results and both are recommended as test substrates.

6.5 *Moldy "Mildewed" Repaint Surfaces*—Weathered paint films that are discolored by microbiological growth are also useful in determining the efficacy of wash solutions to clean or "sterilize" an old paint film prior to repainting. Such moldy repaint surfaces also are useful in determining the resistance of a coating system to discoloration due to microorganisms growing through the paint system from the underside.

7. Arrangement of Coated Panels on Exterior Test Fences

7.1 Paint systems should offer long-term resistance to microbiological growth both in completely exposed areas and in shady, protected areas. Where sunlight and moisture are in abundance, chalking will occur. However, chalking is slow to occur in shady areas. Thus, an effective microbiocide for a coating must have long-term light stability, heat resistance, and be sufficiently soluble and toxic to cause microbiological inhibition, and it must have limited solubility or leachability from the coating system such that it remains in the system for sufficiently long periods of time. Ideally, it should not induce chalking for cleaning of the surface, since such chalking will cause fading or tinted paints.

7.2 The most realistic conditions of exposure can best be realized on the exterior of houses. Unfortunately, buildings

with the various substrates and located in desirable localities and geographic locations are seldom available. However, comparisons of various coating systems can be made by exposing coated panels on exterior test fences. Positions of exposure should vary to include completely exposed weathering conditions and also protection from weathering. The exposed conditions are useful in determining the influence of temperature, sunlight, moisture, various substrates, and subsequent chalking on a coating. The protected, shady exposures are useful in determining the relative microbiological inhibition of coatings in the absence of chalking.

7.3 Construction of test fences for *protected or shady conditions* can be similar to that given in Practice D 1006 but modified to provide for a larger test area in the protection of an eave. A protected area under an eave facing north best represents the desired conditions. This eave should have a minimum of 18 in. (455 mm) overhang. The panels should be exposed in a lapped position as would be encountered with wood siding on a house. The test area for each system should begin immediately under the eave and continue down the test fence to a point at least 2 ft (610 mm) below an imaginary horizontal line, which is derived by projecting at a 45° angle from the outer edge of the eave, downward and inward to the test panels. Thus, an 18-in. eave would require a minimum of 3.5 ft (1.06 m) of test panels, beginning immediately under the eave down to the bottom edge of the exposure area. The inverted horizontal surface of the soffit under the northerly eave is an ideal test environment as well. Also, this area does not usually collect excessive dirt. Thus, any microbiological discoloration is readily apparent.

7.4 Construction of test fences for *exposed conditions* can be similar to that in Practice D 1006 but modified to provide for offset panels held at an angle of 5° (±5°) off vertical facing south. Construction should allow exposures such that moisture falling on the test area of one panel will not drip on the next panels below.

8. Geographic Location of Test Fences

8.1 The climatic and environmental conditions of the test fences should be similar to those of the areas in which the

paint system is intended for use. For coatings to be used nationally, it is desirable to expose in warm and humid environments. Exposures should be made in both shady conditions and in direct sunlight. It should be recognized that the microflora occurring in different parts of a country will vary so that mold and algae encountered in one test location may not necessarily be those of another.

9. Periods of Exposure

9.1 The time of the year when the initial exposure is first made can be critical. Because of differences in weather from year to year, results of exposures from one year to another may also vary. In order to compare the tendency for two or more paint systems to become discolored through microbiological growth, it is advisable that the paint systems be exposed at the same time. It is frequently desirable to include both a positive and a negative control. The negative (fail) control is a paint system known to discolor quite severely under standard exposure conditions and may be used on each panel. A positive (pass) control is a paint system that will perform reasonably well in the same known exposure conditions.

10. Ratings for Microbiological Discoloration

10.1 Ratings should be made in accordance with Test Method D 3274.

10.2 It is desirable to obtain mold ratings prior to initiation of chalking and erosion, since it is prior to this occurrence that a paint film is most prone to discoloration by spore-cluster type (dirt-like) mold growth. Chalking can occur within several months, or it may never occur, depending on the paint formulation and its exposure to weathering conditions. Therefore, mold ratings are suggested after 3, 6, 9, 12, 18, and 24 months and yearly thereafter. Make yearly inspections immediately following seasonal growing conditions. Most extensive microbiological growth usually develops during periods of warm and humid weather. Thus, make any ratings of microbiological discoloration immediately following the warm, humid period of the year.

Standard Test Method for Humid-Dry Cycling for Coatings on Wood and Wood Products¹

This standard is issued under the fixed designation D 3459; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the evaluation of coatings designed for use on interior wood and wood products substrates by exposure alternately to low and high humidity at an elevated temperature.

1.2 This test method is applicable to any coated material or product that is affected either entirely or partly by changes in atmospheric relative humidity.

1.3 This test method applies only to those coatings applied in sufficient quantity to form a continuous film.

1.4 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

- E 145 Specification for Gravity-Convection and Forced-Ventilation Ovens³

3. Significance and Use

3.1 Wood substrates and the coatings applied to them expand and contract to different degrees as the humidity changes, causing stresses that may produce checks, cracks, splits, blisters, swelling, loss of adhesion, and various changes in surface appearance. This test method is intended for use where the coating is applied in sufficient quantity to form a continuous film on the wood or wood product substrate. It is not possible to make any direct correlation between the

results obtained from humid/dry cycling and the results expected in a specific period of time in service because of variations resulting from geographic locations, location within the building, care of the panel (such as waxing), and variations within materials involved.

4. Test Panels and Panel Preparation

4.1 Test panels shall be regular production finished panels if available.

4.2 If regular production finished panels are not available the purchaser and the seller shall agree upon the following variables: type of wood or wood substrate, sanding method(s) and paper(s), sealer(s) or toner(s), filler(s), stain, primer or basecoat, print(s), and topcoat(s), methods of application, and the number of surfaces to be coated. If rotary-cut veneered panels are used, it should also be agreed whether the veneer is to be open or close faced.

5. Apparatus

5.1 *Oven*—a gravity-convection or forced-ventilation electrically heated oven meeting the requirements of Specification E 145 and providing a continuous temperature of $122 \pm 3.5^\circ\text{F}$ ($50 \pm 2^\circ\text{C}$).

5.2 *Constant Elevated-Temperature and Constant-Humidity Chamber*, maintained at a relative humidity of $97 \pm 2\%$ and a temperature of $122 \pm 3.5^\circ\text{F}$ ($50 \pm 2^\circ\text{C}$).

5.3 *Constant-Temperature and Constant-Humidity Chamber*, maintained at a relative humidity of $50 \pm 5\%$ and a temperature of $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$).

6. Test Specimens

6.1 Test specimens shall be large enough to be representative of the material or product and to permit easy observation of possible defects. This usually means a minimum area of approximately 12 by 12 in. (300 by 300 mm).

6.2 Unexposed control specimens of each coating or coating system or product tested shall be held in reserve in a constant-temperature and constant-humidity area (5.3) to prevent any changes.

6.3 Whenever possible, comparative control specimens of a similar material or product with known service characteristics should also be exposed.

6.4 Three specimens are usually adequate unless a lack of uniformity is suspected in the substrate, coating, or coating system.

7. Conditioning

7.1 Place the specimens in a conditioned room or chamber (5.3) so that air is free to circulate on all sides of

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D 01.55 on Factory-Applied Coatings on Preformed Products.

Current edition approved May 29, 1987. Published July 1987. Originally published as D 3459 - 75. Last previous edition D 3459 - 75 (1981)⁴.

² Annual Book of ASTM Standards, Vol 06.01.

³ Annual Book of ASTM Standards, Vol 14.02.

each specimen so as to avoid localized overheating. Allow them to remain there 14 days.

8. Procedure

8.1 Measure the dry film thickness of the coating system on the control panel to the nearest 0.1 mil (2.5 μm) by an appropriate method such as Test Methods D 1005, Methods D 2691, or an Optical Surfer Analyzer.⁴ The results of humid dry cycling are directly affected by the dry film thickness as well as by the coating system itself.

8.2 After conditioning measure thickness of each specimen to the nearest mil (25 μm) at a marked location about 1 in. (25 mm) from one edge and midway along one side at the beginning and after each change of conditions.

8.3 Place the specimens in the oven maintained at $120 \pm 3.5^\circ\text{F}$ ($50 \pm 2^\circ\text{C}$) (5.1) so that air is free to circulate on all sides of each specimen to prevent localized overheating. After 48 h remove the specimens from the oven and place them in the high-humidity elevated-temperature chamber (5.2) so that air is free to circulate on all sides of each specimen. Leave the specimens in the humidity cabinet 48 h. The period of 48 h of dry heat followed by 48 h of humid heat constitutes one cycle. Expose the specimens to the number of cycles as agreed upon between the purchaser and the seller.

8.4 At each change of conditions during cycling, visually inspect each specimen under a strong light and at various

angles to the light for possible damage or change. Note any change in or damage to each specimen. Damage may be found in the base material (plywood, hardboard, flakeboard, solid wood, etc.) or in the coating, in a finish or overlay on the substrate material. Some defects that may occur as a result of humid/dry cycling are as follows: checks, cracks, splits, blisters, (see Test Method D 714) raised grain, localized lumps or swelling, photographing of substrate through the coating, loss of particle adhesion, loss of adhesion in glue lines, change in the dimensions of the overlay, changes in surface color, gloss, or hardness, cohesion loss in the coating. If open-faced rotary-cut veneer has been used, checking may result from this fact.

9. Report

9.1 Report the following information:

9.1.1 Complete description of the test material and the comparative control material,

9.1.2 Size and number of the specimens,

9.1.3 Dry film thickness of the material under test and the control (comparison material).

9.1.4 Number of cycles agreed upon between the purchaser and the seller,

9.1.5 Any deviations from the standard procedure, and

9.1.6 Defects or changes as described under 8.4.

10. Precision

10.1 Since the observed changes can take several forms no numerical values have been developed, and meaningful estimates of precision cannot be given. Round-robin tests showed that cooperators can obtain satisfactory agreement in ranking of results.

Standard Test Methods for Evaporation Rates of Volatile Liquids by Shell Thin-Film Evaporometer¹

This standard is issued under the fixed designation D 3539; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

These test methods have been approved for use by agencies of the Department of Defense and for listing in the DoD Index of Specifications and Standards.

1. Scope

1.1 These test methods cover the determination of the rate of evaporation of volatile liquids of low viscosity using the Shell Thin-Film Evaporometer. The test methods have been applied to a wide range of volatile liquids, including paint, varnish, and lacquer solvents and thinners to various hydrocarbons and to insecticide spray-base oils.

1.2 The test methods for the determination of evaporation rate using the thin-film evaporometer are:

	Sections
Method A ^{2,3} —Manual Recording	5 to 11
Method B—Automatic Recording	12 to 17

1.3 The test methods are limited only by the viscosity of the volatile liquid which must be sufficiently low to permit the dispensing of an accurately measured specimen from a syringe.

1.4 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. Specific hazard statements are given in Notes 1 and 2.*

2. Referenced Documents

- 2.1 *ASTM Standards:*

E 1 Specification for ASTM Thermometers⁵

3. Summary of Method

3.1 A known volume of liquid is spread on a known area of filter paper that is suspended from a sensitive balance in a

cabinet. Dried air or nitrogen at 25°C is passed through the cabinet at a known rate. The loss of weight of the filter paper/liquid is determined and plotted against time.

4. Significance and Use

4.1 The rate of evaporation of volatile liquids from a solution or dispersion is important because it affects the rate of deposition of a film and flow during deposition, and thereby controls the structure and appearance of the film. In the formulation of paints and related products, solvents are chosen based on the evaporation characteristics appropriate to the application technique and the curing temperature.

METHOD A—EVAPORATION RATE USING THE MANUAL THIN-FILM EVAPOROMETER

5. Apparatus

5.1 *Evaporometer*, thin-film evaporometer⁶ as shown in Fig. 1.

5.2 *Constant-Temperature Cabinet* for evaporometer.

NOTE 1—*Precaution:* In instances with the solvents and other volatile materials normally tested using this apparatus and under the conditions specified in this method, the concentration of solvent or other flammable material being exhausted into the laboratory atmosphere will be significantly below any concentration that could be hazardous, that is, a lower flammable limit. However, it may be desirable to locate the instrument and cabinet in a laboratory exhaust hood if the routine handling of certain materials may present a hazard due to toxicity, extreme volatility, or flammability.

5.3 *Interval Timer: Stop Watch or Electric Timer*—A timer that gives an audible signal at 10 or 20-s intervals and that gives a warning signal approximately 3 s before the end of the interval is preferred.

5.4 *Filter Paper Disk*—Fast, open-texture filter paper, 90 mm in diameter, with a circle approximately 60 mm in diameter (and concentric with the edge) lightly drawn on the paper with a pencil.

5.5 *Syringe*—A 1.00-mL hypodermic syringe equipped with a 9-in. (225-mm) needle of 0.050-in. (1.3-mm) outside diameter stainless steel tubing.⁷ Due to manufacturing variations, the syringe should be calibrated before use.

5.6 *Dehumidification Equipment*—A suggested setup is given in a schematic diagram, Fig. 2.

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.24 on Physical Properties of Liquid Paints and Paint Materials.

Current edition approved May 29, 1987. Published July 1987. Originally published as D 3539 - 76. Last previous edition D 3539 - 76.

² These test methods are essentially the same as the one developed by the New York Society for Paint Technology. The Precision section was added by ASTM Subcommittee D01.24 and is based upon the data of the New York Society for Paint Technology.

³ See "Comparative Evaporation Rates of Solvents: II," New York Club, Technical Subcommittee No. 66, *Official Digest*, 28, No. 382, 1956, p. 1060.

⁴ *Annual Book of ASTM Standards*, Vol 15.05.

⁵ *Annual Book of ASTM Standards*, Vols 05.03 and 14.03.

⁶ The manual Shell thin-film evaporometer is no longer available.

⁷ Syringe: Becton, Dickinson and Co., No. 1YT available from Fisher Scientific Co. Needle: Special Syringe Needle Type LNR, 18 gage, 9 in. long blunt round end, no bevel—available on special order from Becton, Dickinson and Co. through Fisher Scientific Co., 711 Forbes Ave., Pittsburgh, PA 15239.

FIG. 1 Details of the Thin-Film Evaporometer

NOTE 2—Precaution: Use of this dehumidification apparatus requires the safety practices relative to the handling, use, and disposal of hazardous acids and caustics be observed. When handling these materials, protective eye or face, or both, shields and protective clothing are recommended.

NOTE 3—In those instances where dry nitrogen is available it may be used directly instead of air and thus eliminate the dehumidification equipment. The use of nitrogen does not alter the evaporation rate.

5.7 *Hygrometer (or other humidity-sensing device)*, capable of indicating low humidities.

5.8 *Thermometers*, of suitable accuracy such as ASTM Bomb Calorimeter thermometer 56C having a range from 19 to 35°C, subdivisions 0.02°C or Thermometer 56F (66 to 95°F with 0.05°F subdivisions), and conforming to the requirements of Specification E 1.

6. Preparation of Evaporometer

6.1 Place the filter paper disk on the wire support, threading the hook through a small hole in the center of the paper. Attach the hook to the steel spring below the sighting disk and allow the paper and the paper support to hang therefrom.

6.2 Close the evaporometer and cabinet doors and allow the temperature in both chambers and the humidity to

equilibrate at the following test conditions:

Cabinet and evaporation temperature: $77 \pm 0.5^\circ\text{F}$ ($25 \pm 0.25^\circ\text{C}$)
Evaporometer humidity: 0 to 5 % relative humidity

Approximately 2 h are required for the humidity to drop to less than 5 %.

6.3 Adjust the air flow to 21 L/min (center of ball float opposite correct mark on the rotometer scale).

7. Conditioning

7.1 Bring the sample or a portion of it to an equilibrium temperature of $77 \pm 1.0^\circ\text{F}$ ($25 \pm 0.5^\circ\text{C}$) in a constant-temperature bath. Determine the specific gravity of the sample at this temperature in accordance with Test Methods D 891.

8. Procedure

8.1 Record the position of the filter paper as indicated by alignment of the sighting disk with its mirror image. This is the no-load position.

8.2 Raise the wire mesh bracket until the bottom of the disk support rests lightly on it.

8.3 Withdraw into the syringe 0.70 mL of the solvent which is at $77 \pm 1.0^\circ\text{F}$ ($25 \pm 0.5^\circ\text{C}$). Make certain that all air bubbles are expelled from the syringe and the needle before application of the specimen to the filter paper.

8.4 Insert the hypodermic needle into the small opening on the right-hand side of the instrument and position the needle tip so that it almost touches the disk and is just over the line that was drawn.

8.5 Start applying the solvent to the disk. As the first drop hits the disk, start the timer. The solvent should be applied at a uniform rate in ± 2 s and as evenly as possible along the drawn line. To ensure consistent specimen size, touch the tip of the hypodermic needle to the filter paper to dispense the last drop of solvent.

8.6 Immediately lower the wire mesh bracket away from the disk support. Obtain the first reading of the position of the sighting disk at 40 s and then every 20 s. Record the time and the scale reading on the report form. A sample report form is shown in Annex A2.

NOTE 4—With very slow evaporating solvents, it is not necessary to take readings as often as every 20 s. The operator can determine a

NOTE—One-litre flasks should be used throughout.

FIG. 2 Diagram of Dehumidification Apparatus

suitable time interval after the first 200 s.

8.7 Stop the timer when the sighting disk has returned to the original unloaded position.

NOTE 5—The filter paper may be reused provided the solvent leaves no appreciable residue in evaporating.

9. Calculation

9.1 Calculate the evaporation rate as follows:

$$ER = \frac{C}{S} \times 100(B - Z)$$

where:

$S = V \times D$ and $Z = N - (S/C)$

ER = evaporation rate, wt %,

C = spring constant, g/cm elongation,

S = specimen weight,

$V = 0.70$ mL aliquot volatile liquid at $77 \pm 1.0^\circ\text{F}$ ($25 \pm 0.5^\circ\text{C}$),

D = density of volatile liquid at $77 \pm 1.0^\circ\text{F}$ ($25 \pm 0.5^\circ\text{C}$) (Taken as equivalent to specific gravity but with units of g/mL)

B = scale reading taken during evaporation of aliquot,

Z = zero percent evaporated, scale reading = $N - (S/C)$ and

N = no-load scale reading (100 % evaporated reading).

9.2 Plot the percent evaporated against elapsed time in seconds and draw a smooth curve through the points. From the curve, determine at 10 weight % increments to 90 % and for 95 and 100 % evaporation the time in seconds to the nearest value as follows:

Approximate Elapsed Time to 100 % Evaporated Point, s	Report to Nearest Indicated Value, s
Less than 300	1
300 to 600	5
600 to 1800	10
1800 to 3600	30
3600 to 7200	60
More than 7200	nearest 2 % of indicated value

NOTE 6—The curve drawn through the various points should pass through zero or the origin. If it passes to the right of the origin, the delivery time was in excess of 12 s or an aliquot larger than that specified was delivered. If it passes to the left of the origin, then the aliquot was smaller than specified.

10. Report

10.1 Report the elapsed time in seconds at 10 weight % intervals through 90 % and for 95 and 100 % evaporation, and the relative evaporation rate (*n*-butyl acetate = 1.0). Relative evaporation rate is calculated from the 90 weight % evaporated times for the test solvent and for *n*-butyl acetate (99 % ester).

11. Precision⁸

11.1 On the basis of an interlaboratory study of the test method in which operators in six laboratories determined the 90 % evaporation point of six solvents covering a broad range in evaporation rate, the between-laboratories coefficient of variation was found to be 6.3 % relative at 24 degrees

of freedom after discarding two divergent values. On the basis of the results obtained by three laboratories on three of the solvents having 90 % evaporated times of 200 to 600 s, the within-laboratory coefficient of variation was found to be 0.83 % relative at 18 degrees of freedom. Based on these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

11.1.1 *Repeatability*—For solvents with 90 % evaporation times of 200 to 600 s, two results, each the mean of two determinations, obtained by the same operator on different days should be considered suspect if they differ by more than 2.5 %.

11.1.2 *Reproducibility*—Two results, each the mean of two determinations, obtained by operators in different laboratories should be considered suspect if they differ by more than 18.2 %.

METHOD B—EVAPORATION RATE USING THIN-FILM EVAPOROMETER, AUTOMATIC RECORDING

12. Apparatus

12.1 *Evaporometer*, Automatic Thin-Film Evaporometer,⁹ as shown in Fig. 3.

12.2 *Filter Paper Disk*—See 5.4.

12.3 *Syringe*—See 5.5.

12.4 *Dehumidification Equipment*—See 5.6.

12.5 *Strip Chart Recorder*—Any strip chart recorder capable of recording the output signal (0 to 15 mA) from the electronic optical weight-sensing device. The recorder should provide a range of chart speeds including ¼ to 2 in. (6.3 to 50 mm)/min. It is also desirable for the recorder to accommodate 2 or more mA ranges in order to regulate the sensitivity of measurement.

13. Preparation of Evaporometer

13.1 Place the filter paper disk on the wire frame threading the hook through a small hole in the center of the paper. Attach the wire frame to the support hook in the evaporometer.

13.2 Close the evaporometer and cabinet doors and equilibrate both chambers as in 6.2.

13.3 Adjust the air flow to 21 L/min.

14. Conditioning of Sample

14.1 See 7.1.

15. Procedure

15.1 When all components (including the filter paper in place) are at equilibrium, adjust the recording pen to a prominent "zero" position near the edge of the chart on the recorder; then turn the switch for the chart motor to the OFF position. This constitutes the "zero" load and time position for the test.

⁹ The automatic Shell thin-film evaporometer, Apparatus Catalog No. F1522 is available from the FLC Instruments, Inc., 2055 Comprehensive Drive, Aurora, IL 60505. Another evaporometer, the Arizona Instrument EV-1, is available (Arizona Instrument Corp., 2078 East University Drive, Tempe, AZ 85281-4098). Precision data is not yet available, but the instrument operates in the same manner as that described in this test method and is reported to give similar results.

⁸ Supporting data are available from ASTM Headquarters. Request RR:D01-1003.

FIG. 3 Automatic Thin-Film Evaporometer

NOTE 7—The milliamperage range and chart speed should be selected, if possible, so that the dimensions of the weight and time axes of the plotted curve are approximately the same length.

15.2 Measure 0.70 mL of test sample into the hypodermic syringe (see 8.3).

15.3 Open the small side door on the right hand side of the insulating cabinet and insert the hypodermic needle through the rubber porthole until the needle tip almost touches the disk and is just over the penciled line.

NOTE 8—Care must be exercised to avoid depressing the plunger of the syringe during this operation. Otherwise the solvent will be accidentally and prematurely dispensed onto the paper before the strip chart recorder is started.

15.4 When all is ready turn the strip chart motor switch to the ON position and simultaneously start distribution of the specimen onto the filter paper. The complete specimen should be dispensed uniformly in 10 ± 2 s along the line. The recorder pen will "advance" immediately to an "apex" position equivalent to the total weight of the specimen, less that portion that evaporated during the application period. The pen will gradually return to its original position as the solvent evaporates and the chart advances. The evaporation is complete when the recording pen has returned to its original "no-load" position.

NOTE 9—It is common for the final portion of the curve to exhibit a "tailing-off." This is due to artifacts of the method such as (1) hydrogen bonding of the last traces of solvent with the cellulose fibers of the filter paper and (2) a gradual diminution of the area of the filter paper wet by solvent (that is, in the final stage of evaporation, drying of the paper progresses from the outer edge toward the center of the disk). Thus, it is common practice for the evaporation cycle to be considered "complete"

when the recording pen returns to 99.5 % of the original displacement.

16. Calculations and Reporting

16.1 Determine the evaporation time in seconds at 10 % weight % increments to 90 %, and for 95 to 100 % from the evaporation curve as follows:

16.1.1 Divide the theoretical recording pen displacement for the total specimen into ten equal units along the weight axis of the evaporation curve; then project the established 10 % divisions to corresponding intersecting points on the evaporation curve. The 0 % evaporated or full-load point at zero time can be obtained either by extrapolation of the evaporation curve back to zero evaporation time or calculation using the weight of the sample and the calibration data for the instrument (See Annex A3). The routine calculation of the 0 % evaporated, full-load point is recommended as a check for correct specimen size.

16.1.2 Multiply the distance along the time axis from the zero starting time by the chart speed factor in seconds giving the total elapsed time for each defined point along the curve. For example, at a chart speed of 1 in./min and a 20 % evaporation point at 3.30 in. the evaporation time is 198 s ($60 \times 3.30 = 198$). Use the procedure given in 9.2 to round results.

16.2 An alternative method of reporting evaporation results is to express an Area Evaporation Rate in terms of grams evaporated per second per square centimetre of evaporating surface. This method is not exact because the evaporation rate is not linear throughout the complete evaporation period, but it is a useful approximation to represent the general volatility of a solvent. The calculation of evaporation rate is as follows:

Area Evapora

poration rate,
factor = 0.004?
0 mL = sp
0 = in

8 cm² = t
=

en C =

specific gravity
0 % evaporat
0 % evaporat
multiplicand,
al fractions.

recision^s

with a small
again surp
position of
analytical
in record t
stant, C, i
vided by th

$$\text{Area Evaporation Rate, } R = \frac{C \times B}{A - B} \times 10^8$$

where:

R = evaporation rate, $\text{g/cm}^2 \cdot \text{s} \times 10^8$,

C = a factor = 0.00438 mL/cm^2 obtained from:

0.70 mL = specimen size,

0.80 = increment between the 10 % and 90 % evaporation points (the first and last 10 % increment are disregarded),

128 cm^2 = total evaporating surface of 90-mm diameter filter paper,

then $C = \frac{0.70 \times 0.80}{128} = 0.00438 \text{ mL/cm}^2$

C = specific gravity of the solvent at 77°F (25°C),

A = 90 % evaporation time, s, and

B = 10 % evaporation time, s.

The multiplicand, 10^8 , is inserted in the equation to avoid decimal fractions.

17. Precision⁸

17.1 On the basis of an interlaboratory study of the test

method in which operators in four laboratories determined the 90 % evaporation point of seven solvents covering a broad range in evaporation rate, the within-laboratory coefficient of variation was found to be 1.78 % relative at 35 degrees of freedom and the between-laboratories coefficient of variation was found to be 3.88 % relative at 28 degrees of freedom. Based on these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

17.1.1 *Repeatability*—Two results, each the mean of two determinations, obtained by the same operator on different days should be considered suspect if they differ by more than 5.1 %.

17.1.2 *Reproducibility*—Two results, each the mean of two determinations, obtained by operators in different laboratories should be considered suspect if they differ by more than 11.25 %.

18. Index Terms

18.1 These test methods are indexed under the following terms: evaporation rate, Shell thin film evaporometer, and evaporation rates of solvents.

ANNEXES

(Mandatory Information)

A1. CALIBRATION OF THE THIN-FILM EVAPOROMETER, MANUAL RECORDING

A1.1 Remove the filter from its wire support and replace it with a small piece of aluminum foil, about 50 by 50 mm; then again suspend the support from the coil spring. Record the position of the sighting disk. Load the spring by placing a 1-g analytical balance weight onto the aluminum foil and again record the elongation of the spring. Thus, the spring constant, C , in grams per centimetre, is equal to 1.000 g divided by the elongation in centimetres.

A1.2 *Standardization of the Evaporometer*—Since there may be slight variations in manufacture, the evaporometer should be standardized prior to routine usage. The standard solvent, *n*-butyl acetate, (99 % ester), should have a 90 % evaporation time of $470 \pm 10 \text{ s}$ under the prescribed test conditions. If the evaporation time is outside these limits, a slight increase or decrease of the air flow should be sufficient to bring about the desired results.

A2. SAMPLE EVAPORATION RATE REPORT FORM

A2.1 A sample evaporation rate report form is shown in Table A2.1.

A3. CALIBRATION OF THE THIN-FILM EVAPOROMETER, AUTOMATIC RECORDING

A3.1 The total deflection of the recording pen in chart units divided by the weight added corresponds to the sensitivity of the apparatus. For example, if the total pen deflection is 60 chart divisions for a 0.500-g weight, the sensitivity factor is 120 chart divisions per gram. This value can then be used to establish the 100 % specimen load at "zero" evaporation time and to calculate the percent evaporated at various time intervals. For instance, pure *n*-butyl acetate (99 mol %) has a density of 0.878 at 25°C, so a 0.70-mL specimen at the cited calibration would deflect the pen 73.75 chart units (that is, $0.878 \times 0.70 \times 120 = 73.75$).

Each 10 % increment that evaporates corresponds to 73.75 chart divisions.

A3.2 Standardization of the Evaporometer—Since there may be slight unavoidable variations in manufacture, the evaporometer should be standardized prior to routine usage. Normal butyl acetate (99% ester) should have a 90% evaporation time of 470 ± 10 s under the prescribed test conditions. If the evaporation time is outside these limits, a small adjustment should be made to the position of the inlet air (or nitrogen) ports within the inner chamber of the evaporometer. **Caution:** The air should *not* be directed above or onto the filter paper.

A4. EVAPORATION RATES OF VOLATILE MATERIALS

A4.1 The evaporation values presented in Table A4.1 are typical of commercial materials. Deviations from the values shown can be expected due to normal variations in test

conditions and purity, composition, source, etc. of test samples.

TABLE A4.1 Evaporation Rates of Volatile Materials

	Automatic Evaporometer		Manual Evaporometer	
	Seconds to 90 % Evaporation	Relative Rate <i>n</i> -Butyl Acetate = 1.0	Seconds to 90 % Evaporation	Relative Rate ^a <i>n</i> -Butyl Acetate = 1.0

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Detection of Lead in Paint and Dried Paint Films¹

This standard is issued under the fixed designation D 3618; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^e) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Keywords were added editorially in July 1991.

1. Scope

1.1 This test method is intended as a screening test to determine if the solids in a paint contain more than 0.5 % lead. The test described barely detects the presence of 0.4 % but gives a definite positive result at the 0.5 % level.

NOTE 1—This test method may be used to detect the presence of lead at concentrations higher or lower than 0.5 % by making appropriate changes in the specimen size and reagent quantities specified.

1.2 Paints giving an unexpected positive or questionable result should be analyzed quantitatively for lead, using Test Method D 3335.

1.3 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. Specific hazard statements are given in Section 7.*

2. Referenced Documents

- 2.1 *ASTM Standards:*
D 1193 Specification for Reagent Water²
D 2832 Guide for Determining Volatile and Nonvolatile Content of Paint and Related Coatings³
D 3335 Test Method for Low Concentrations of Lead, Cadmium, and Cobalt in Paint by Atomic Absorption Spectroscopy³

3. Summary of Test Method

3.1 The sample of liquid paint or dried film is prepared by dry ashing a weighed specimen at 475 to 500°C. The ash is extracted with hot sodium hydroxide solution and a drop of the extract is transferred to filter paper. Lead present is oxidized to lead peroxide with bromine water, then treated with "tetrabase" to produce a blue quinoidal salt. Known amounts of lead are added to standard paints that are concurrently tested to provide a base for comparison.

4. Significance and Use

4.1 The permissible level of heavy metals in certain

coatings is specified by governmental regulatory agencies. This test method provides a fully documented procedure for determining low concentrations of lead present in both water and solvent-reducible coatings to determine compliance.

5. Apparatus

- 5.1 *Burner*, Meker-type.
5.2 *Crucibles*, porcelain, high-form, 15-mL, with covers.
5.3 *Filter Paper*, ashless, medium texture.
5.4 *Hot Plate*, with variable surface temperature control over the range from 70 to 200°C.
5.5 *Muffle Furnace*, maintained at $475 \pm 25^\circ\text{C}$.
5.6 *Syringe*, glass, 2-mL.
5.7 *Volumetric Flasks*, 50, 100, 1000-mL.
5.8 *Paint Shaker*.
5.9 *Paint Draw-Down Bar*.

6. Reagents

6.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests unless otherwise specified. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁴ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

6.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent grade water conforming to Type II of Specification D 1193.

6.3 *Acetic Acid*, glacial.

6.4 *Ammonium Hydroxide* (1+1)—Mix 1 volume of concentrated ammonium hydroxide (NH_4OH , sp gr 0.90) with 1 volume of water.

6.5 *Bromine Water*, saturated.

6.6 *Nitric Acid* (sp gr 1.42)—Concentrated nitric acid (HNO_3).

6.7 *Lead Standard Stock Solution, Aqueous* (1 mg/mL)—Dissolve 1.600 g of lead nitrate ($\text{Pb}(\text{NO}_3)_2$) in 100 mL of water, add 2 mL of nitric acid (sp gr 1.42), and dilute to 1 L.

6.8 *Lead Standard Working Solution, Aqueous* (0.2 mg/mL)—Pipet 10 mL of the aqueous lead standard stock

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Materials.

Current edition approved May 31 and Sept. 27, 1985. Published November 1985. Originally published as D 3618 - 77. Last previous edition D 3618 - 77 (1984).

Van Nostrand Co., Inc., New York, NY, and the "United States Pharmacopeia."

solution into a 50-mL volumetric flask and dilute to volume with water.

6.9 *Toluene*, technical grade.

6.10 *Lead Standard Stock Solution, Solvent-Based* (1 mg/mL)—Dissolve 4.2 g of lead naphthenate (containing 24 % lead) in 100 mL of toluene and dilute to 1 L.

NOTE 2—Other toluene-soluble lead driers such as lead tallate, lead linoleate, and lead octoate may also be used provided that the lead content is accurately known and the appropriate weight is diluted to 100 mL to provide a toluene solution containing 1 mg/mL of lead.

6.11 *Lead Standard Working Solution, Solvent-Based* (0.2 mg/mL)—Pipet 10 mL of the solvent-based standard stock solution into a 50-mL volumetric flask and dilute to volume with toluene.

6.12 *Sodium Hydroxide Solution* (12 % w/v)—Carefully dissolve 12 g of sodium hydroxide in 100 mL of water.

6.13 *Paint, Standard Solvent-Reducible*, any solvent-reducible paint known to contain less than 100 ppm of lead.

6.14 *Paint, Standard Water-Reducible*, any water-reducible paint known to contain less than 100 ppm of lead.

6.15 *Tetabase Reagent* (4,4'-Methylenebis (N,N-dimethylaniline)), 1 % in 10 % *Acetic Acid*—Dissolve 1 g of tetabase³ in 50 mL of water to which 10 mL of glacial acetic acid has been added. Dilute to 100 mL with water.

7. Hazards

7.1 Glacial acetic and concentrated nitric acids will cause burns of the skin and eyes. Sodium hydroxide is corrosive. Use care in handling these materials. Avoid contact with skin. Refer to suppliers' Material Safety Data Sheets. Bromine water should be prepared and used in a laboratory hood.⁶

7.2 Use only a rubber bulb aspirator for pipetting liquids.

8. Procedure

8.1 If the sample is a liquid coating, mix it until homogeneous, preferably on a mechanical shaker. Determine the nonvolatile content in accordance with Guide D 2832.

NOTE 3—Recover dried paint films from previously coated substrates (being careful not to remove any underlying material from the substrate) or prepare in the laboratory from liquid samples. For the laboratory preparation, flow some of the well-mixed sample onto a clean glass plate. The use of a paint draw-down bar is recommended to obtain a uniform film thickness not exceeding 2 mils (50 μ m). Allow to dry in an oven at 105°C for a minimum of 1 h. Scrape the dried film off the glass plate, preferably with a single edge razor blade.

8.2 Weigh to 0.1 mg, 50 mg of paint solids into a porcelain crucible or 50-mL glass beaker. For a liquid coating, determine the specimen weight to be taken by the following equation:

$$S = \frac{5}{C}$$

where:

S = specimen weight, g, and
 C = nonvolatile content, %

³ Eastman-244 (Eastman Organic Chemicals, Rochester, NY 14650) has been found to be satisfactory; equivalent grades may be used.

⁶ Saturated bromine water may be purchased from chemical supply houses.

NOTE 4—Crucibles or beakers used in this test method should be new or in very good condition. Otherwise, it is possible that some lead may be lost and a false negative obtained.

8.3 Weigh 50 mg of solids from the appropriate standard paint (solvent-reducible or water-reducible) into each of two additional porcelain crucibles or 50-mL glass beakers. Using a 2-mL glass syringe, add 1.0 mL of the appropriate 200-ppm standard working solution (solvent-reducible or water-reducible) to one of the crucibles or beakers, and 1.8 mL to the other.

NOTE 5—The standard paint to which has been added 1.0 mL of standard working solution contains approximately 0.4 % lead based on the paint solids, and the one to which has been added 1.8 mL of standard working solution will contain approximately 0.72 % lead based on the paint solids.

8.4 Place all three crucibles or beakers on a cold hot plate and slowly increase the temperature until the material is dried. With some types of coatings, an initial oven-drying at 105°C may be necessary to remove solvents without incurring losses due to spattering.

8.5 When the specimens appear to be dry, or when starting with a dried film, gradually increase the temperature of the hot plate until the material chars.

8.6 After charring is complete, place the crucibles or beakers in a preheated muffle furnace and ash at 475 to 500°C.

8.7 When the ashing appears to be complete, (approximately 1 to 2 h) remove the crucibles or beakers from the muffle furnace and allow them to cool to room temperature. Add 5 mL of 3 N sodium hydroxide solution to each crucible or beaker and mix thoroughly with a stirring rod. Scrape any adhering residue from the sides or bottom of the container and break up any particles, using a separate stirring rod for each specimen.

8.8 Place covers on the crucibles or watch glasses on the beakers, and boil gently for approximately 5 min. Remove from the hot plate and allow the contents to settle. Do not filter.

8.9 With the tip of the stirring rod, transfer 1 to 2 drops of each extract to the center of a piece of filter paper. Using separate droppers, successively apply directly on each specimen spot a drop of bromine water and a drop of NH_4OH solution. Remove excess ammonia by holding each filter paper over a hot plate until no odor is detectable, but do not take to complete dryness. Place 2 drops of tetabase reagent on each spot and compare the color developed on the specimen spot with those on the standard paint spots. To ensure that maximum color development has been achieved, add 1 or 2 more drops of tetabase reagent on the center of each spot after the first addition has almost-dried (if still wet, the color may diffuse).

NOTE 6—Although the color is stable, it is barely visible in the range from 0.4 to 0.5 %. Comparing results with those obtained on the two standard paints helps to orient the observer to the color intensity to be expected.

NOTE 7—Certain iron-based pigments have high natural manganese levels. The ash extract of products containing high manganese may produce a diffuse blue ring on the filter paper. With experience, this is easily distinguished from the small blue spot produced by lead.

9. Report

9.1 Report a positive test (lead content equal to or in excess of 0.5 % of paint solids) when a blue color forms and persists for several seconds.

10. Precision and Bias⁷

10.1 An interlaboratory test was conducted in which

Standard Method for Testing Antifouling Panels in Shallow Submergence¹

This standard is issued under the fixed designation D 3623; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This method covers a procedure for testing antifouling compositions in shallow marine environments and a standard antifouling panel of known performance to serve as a control in antifouling studies.

NOTE—Subcommittee D01.45 has a revised rating procedure now being evaluated by round robin.

2. Referenced Documents

2.1 ASTM Standards:

A 569/A 569M Specification for Steel, Sheet and Strip, Carbon (0.15 Maximum Percent), Hot-Rolled, Commercial Quality²

D 2200 Pictorial Surface Preparation Standards for Painting Steel Surfaces³

2.2 U.S. Military Specifications:

MIL-P-15328D Primer Pretreatment (Formula 117 for Metals)⁴

MIL-P-15929C Primer Coating, Shipboard, Vinyl-Red Lead (Formula 119—For Hot Spray)⁴

MIL-P-15931B Paint, Antifouling, Vinyl, Red (Formula 121/63)⁴

MIL-S-22698A Steel Plate, Carbon, Structural⁴

3. Significance and Use

3.1 This method is designed as a screening test in evaluating antifouling coating systems. Results of the standard system in a specific marine environment are included to assist in interpreting results.

3.2 Antifouling systems providing positive comparisons with the standard system should be considered acceptable for use in protecting underwater marine structures.

3.3 The degree and type of fouling will vary depending on the environment. Hence, differences in geographic location of test sites, in time of year when panels are exposed, and in weather conditions from 1 year to the next can affect results. Therefore, a fouling census on a nontoxic surface is taken. For the exposure to be valid the nontoxic surface should show heavy fouling, and the standard system should show significantly less fouling than the nontoxic surface.

¹ This method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.45 on Marine Coatings.

4. Terminology

4.1 Definition:

4.1.1 *shallow submergence*—an immersion to depths between 1 and 10 ft (0.3 and 3.0 m).

4.2 Abbreviations:

4.2.1 The following abbreviations are used in reporting test results:

Al	algae
Barn	barnacles
E.B.	encrusting bryozoans
Hyd	hydroids
Sl	slime
Tun	tunicates
C.F.	completely fouled
F.R.	fouling resistance rating
A.F.	antifouling rating
A.C.	anticorrosive rating
O.P.	overall performance rating
CO	coelenterates
F.B.	filamentous bryozoans
Mol	molluscs
PC	polychaetes

4.2.2 Algal Mups may be delineated by classification notation by phylum as follows:

Al-b	Phaeophyta (brown)
Al-bg	Cyanophyta (blue-green)
Al-g	Chlorophyta (green)
Al-r	Rhodophyta (red)

5. Apparatus

5.1 *Blast Cleaning Apparatus* capable of preparing panels in compliance with 8.1.

5.2 *Application Equipment* consisting of brush, roller, conventional spray, or airless spray. Usually the equipment is dictated by the physical properties of the coating and the film thickness desired.

5.3 *Exposure Rack* to provide firm positioning of the specimen panels such that they are held vertically in place in spite of the current and are electrically insulated from metallic contact with the rack or other panels. The rack should be positioned such that the prevailing tidal currents will move parallel to the panel face, and the panels will be immersed to a depth of a minimum of 1 ft (0.3 m) and a maximum of 10 ft (3 m). In a rack where the panels are stacked front to back, they should be spaced at least 2 1/2 in. (60 mm) apart, with the two end positions filled with blank panels. In a rack where the panels are mounted side by side, the distance between adjacent panels should be a minimum 1/2 in. (1.5 mm).

6. Materials

6.1 *Test Panel*—The substrate for the standard antifouling coating system shall be medium low-carbon steel

plate per Sp
to 12 in. (31

plate per Specification A 569,⁵ 1/8 in. thick by 6 to 10 by 10 to 12 in. (3 mm thick by 150 to 250 mm by 250 to 300 mm) with a minimum area per side of 72 in.² (465 cm²). A 1/4-in. (6-mm) diameter hole, 1/2 to 1 in. from the top and centered shall be drilled for holding the panel while handling and painting. The test coating system shall be applied to that substrate for which it is designed provided there is a minimum area per side of 72 in.² (466 cm²).

6.2 *Standard Coating System*—The standard antifouling coating system shall consist of:

6.2.1 Green pretreatment coating conforming to U.S. Military Specification MIL-P-15328B (Formula 117), B revision only.

6.2.2 Vinyl red lead primer conforming to U.S. Military Specification MIL-P-15929C (Formula 119), C revision only.

6.2.3 Vinyl antifouling coating conforming to U.S. Military Specification MIL-P-15931B (Formula 121/63), B revision only.

6.3 *Test Coating System*—The test antifouling coating may be applied to the standard primer system, or to any other suitable anticorrosive primer system.

7. Safety Precautions

7.1 *Caution*—Antifouling paints contain toxic materials that could cause skin and eye irritation on contact and adverse physiological effects if ingested or inhaled. In the preparation of panels and the application of various types of antifouling paints the use of appropriate protective clothing and equipment is required consistent with local, state, and federal government regulations, and recognized industrial and technical standards. Spills, overspray, and unused material should not be flushed down the drain, but should be disposed of as hazardous waste.

8. Procedure

8.1 Abrasive blast the required number of panels to near-white metal (Sa 2 1/2 of Method D 2200) to obtain a profile of 1 to 1.5 mils (25 to 38 μm).

NOTE 1—A profile of 1 to 1.5 mils (25 to 38 μm) can be obtained with the following parameters: (1) Type and size of grit, No. 46 (sand); (2) Pressure, 90 psi (620 kPa); (3) Angle, 90 deg; (4) Distance from surface, 3 to 5 in. (75 to 125 mm); (5) Nozzle size, 3/8 in. (9 mm).

8.2 On the clean, dry, uncontaminated, blasted surface apply to each standard panel one coat of pretreatment coating MIL-P-15328D to give a nominal dry film thickness of 1/2 mil (13 μm).

NOTE 2—All coating drying times are for a minimum temperature of 21°C and a maximum relative humidity of 70 %.

8.3 Within 24 h of application of the pretreatment coating apply the first coat of red lead vinyl primer MIL-P-15929C. Apply a total of four coats of red lead vinyl primer to give a nominal dry film thickness of 6 mils (150 μm). Allow a minimum of 2 h and a maximum of 24 h drying between coats of red lead vinyl primer.

8.4 Allowing a minimum of 2 h and a maximum of 24 h drying after the last coat of red lead vinyl primer, apply the first coat of vinyl antifouling coating MIL-P-15931B to the

standard panels, and the test coating to the test panels. A 3/4-in. (19-mm) numbered vinyl tape can be applied before the second coat of antifouling coating for identification. Allowing a minimum of 2 h and a maximum of 24 h drying after the first coat, apply a second coat of the respective antifouling coating to give a nominal dry film thickness for both antifouling coats of 4 mils (100 μm).

8.5 Before immersion permit the second coat of antifouling coating to dry a minimum of 4 h and a maximum of 2 weeks, the latter time allowing for shipping the panels to the immersion site.

8.6 Expose for a minimum period of 1 year at an immersion site with a high incidence of fouling as indicated by attachments on a dark nontoxic surface such as slate. A monthly fouling census as well as a yearly accumulation when appropriate is required.

8.7 Evaluate the antifouling panels for surface fouling and physical condition of the film system at least monthly as follows using the report form in Table 1.

8.7.1 *Fouling on Surfaces*—Rate fouling present on that portion of the antifouling test surface which is intact at the time of inspection (see 9.1). Rate both sides of the panel if appropriate. Ignore fouling present on the substrate or on anticorrosive undercoats. Barnacles, polychaetes, coelenterates, etc., that are immature or loosely attached should be so reported in the appropriate space. Report fouling by initial algal germination, low-form algae and diatoms as "algal slime." Report absorbed organic and inorganic chemicals, trapped silt and detritus, and other unidentified slimes as "silt."

8.7.2 *Physical Condition*—Rate the condition of coating films in accordance with 9.2. Record qualitative descriptions of film deterioration and discoloration in this column, and unless otherwise specified, refer only to the antifouling test surface. Indicate deterioration of undercoats, when evident, by the notation "A.C.". For example, "Peeling, A.F. from A.C." or "Chipping, A.C. from steel".

9. Calculations:

9.1 *Fouling Resistance (F.R.)*—Award each test surface free of fouling except for the presence of algal spores and other biological slimes a rating of 100. Reduce the rating to 95 if only incipient fouling is present. If mature forms of fouling are present, obtain the rating by subtracting from 95 the sum of the number of individuals present and percent surface covered by colonial forms. For example, if the "fouling on surface" is:

Barn	6, 3 to 10 mm
E.B.	None
Others	Mol 1,20 mm
	Al-g (green) 10 %

then the F.R. percent rating would be $95 - (6 + 1 + 10) = 78$.

9.2 *Physical Condition:*

9.2.1 *Antifouling Film (A.F.)*—Award an antifouling test surface having no physical defects a rating of 100. Subtract the percent surface affected by film defects from 100 to obtain the rating for imperfect films.

9.2.2 *Anticorrosive Film (A.C.)*—Obtain the rating by the same procedure as 9.2.1.

	Barn: E.B.: Others:					
	Barn: E.B.: Others:					
	Barn: E.B.: Others:					
	Barn: E.B.: Others:					
	Barn: E.B.: Others:					
	Barn: E.B.: Others:					

^A Fouling reported as found on the more heavily fouled surface. Solitary forms reported numerically; colonial forms by percent surface covered, Al: algae; Barn: barnacles; E.B.: encrusting bryozoans; Hyd: hydroids; Tun: tunicates; C.F.: completely fouled; CO: coelenterates; F.B.: filamentous bryozoans; Mol: molluscs; Pol: polychaetes.

9.3 Overall Performance (O.P.)—For overall performance, award the panel the lowest percent rating of the three preceding values.

9.4 Normalization—The rating system described above is based on a minimum test on one side area of 72 in.² (465 cm²). Correct the percent ratings for test surfaces of non-standard dimensions for the difference between the minimum standard panel area of 72 in.² (465 cm²) and the area on one side of the test specimen.

10. Report

10.1 Report the results of the immersion test in terms of fouling resistance and overall performance for both the material under test and the standard system.

10.2 Other Data—Report the place, depth, and date of immersion, whether mounted from a dock or a floating raft, date the panels were removed and inspected, panel size, and panel identification number. A census of fouling on a nontoxic surface taken each month for the period of expo-

sure must be included in the report.

11. Precision

11.1 The precision statements are based on an inter-laboratory study in which seven laboratories prepared pairs of panels coated with the standard antifouling system, submerged them, and after 1 year rated the fouling. The within-laboratory standard deviation was found to be 2.08. The between-laboratory standard deviation was found to be 4.67. Based on these standard deviations, the following criteria should be used to judge the acceptability of results at the 95 % confidence level:

11.1.1 Repeatability—Two results each the mean of duplicates obtained by the same operator should be considered suspect if they differ by more than seven units.

11.1.2 Reproducibility—Two results each the mean of duplicates obtained by operators in different laboratories should be considered suspect if they differ by more than 16 units.

ANNEXES

A1. STANDARD COATING SYSTEM FORMULAS

TABLE A1.1 Green Pretreatment Coating, MIL-P-15328D (Formula 117)

	Pounds per 100 gal of Mixed Material	Gallons per 100 gal of Mixed Material
Ingredients of resin component (80 gal):		
Polyvinyl-butylal resin ^A	56	6.10
Zinc chromate (insoluble type) ^B	54	1.78
Magnesium-silicate (Type A or B of Specification MIL-M-15173)	8	0.34
Lampblack (Specification TT-L-70)	0.6	0.04
Butyl alcohol, normal (Spec. TT-B-846)	125	18.48
Isopropyl alcohol, 99 % ^C	353	53.80
Water	15	1.80
Ingredients of acid component (20 gal):		
Phosphoric acid (Class A of Spec. O-P-313)	28	2.0
Water	25	3.0
Isopropyl alcohol, 99 % ^C	99	15.0

^A The resin shall be a polyvinyl partial butylal resin containing only poly(vinyl butylal), poly(vinyl alcohol), and poly(vinyl acetate) in the molecule. The resin shall contain 18.0 to 20.0 % vinyl alcohol, and not more than 1.0 % of vinyl acetate. A 6 % solution of the resin in methanol shall have a viscosity of 12 to 18 cP at 20°C. The specific gravity of the resin shall be 1.05 to 1.15.

^B The zinc chromate shall be of an insoluble type, showing an analysis of 16 to 19 % CrO₃, and 67 to 72 % ZnO, and not more than 1 % water-soluble salts.

^C Isopropyl alcohol, 99 % shall have a specific gravity of 0.785 to 0.790 at 20/20°C and a distillation range not greater than 1.5°C and this range shall include 82.3°C.

TABLE A1.2 Vinyl Red Lead Primer, MIL-P-15929C (Formula 119)

Ingredients	Specifications	Pounds per 100 gal	
		Composition G	Composition L
Red lead, 98 % Pb ₃ O ₄		247.0	247.0
Organic suspension agent 24 % NV		8.2	8.2
Vinyl resin ^A		162.8	162.8
Tricresyl phosphate	TT-T-656	16.8	16.8
Methyl isobutyl ketone	TT-M-268	284.7	
Methyl n-butyl ketone ^B	TT-M-261		273.2
Methyl ethyl ketone	TT-M-261	47.0	105.5
Toluene	TT-T-548	217.7	75.1
Aliphatic naphtha ^C	TT-N-95(I)		81.1

^A Hydroxyl containing vinyl chloride-acetate copolymer (89.5 to 91.5 % vinyl chloride, 5.3 to 7.0 % vinyl alcohol and 2 to 4.0 % vinyl acetate); white powder, specific gravity not under 1.35, not less than 98 % through sieve 20.

^B To contain not over 5 volume % of branched chain ketones.

^C To contain not over 11 volume % of aromatic hydrocarbons.

TABLE A1.3 Vinyl Antifouling Coating, MIL-P-15931B (Formula 121/63)

Ingredients	Specifications	Pounds ^A
Cuprous oxide	MIL-P-15169	1440
Rosin	LLL-R-626, Class A, Grade WW	215
Vinyl resin ^B		55
Tricresyl phosphate	TT-T-656	50
Methyl isobutyl ketone	TT-M-286	165
Xylene	TT-X-916	115
Antisettling agent ^C		5 to 9

^A The formula given is slightly in excess of 100 gal to allow for normal manufacturing loss, may be proportioned to the size batch desired.

^B The resin shall be a vinyl chloride-vinyl acetate copolymer. It shall contain 85 to 88 % vinyl chloride and 12 to 15 % vinyl acetate. The resin shall have a specific gravity of 1.35 to 1.37. Material shall be furnished as a powdered white solid, not less than 98 % of which shall pass through a No. 20 sieve, conforming to RR-S-366.

^C The antisettling agent shall be sufficient to prevent hard pigment settling and otherwise meet requirements of Military Specification MIL-P-15328D, Section 3.4.6.

A2. RESULTS OF EXPOSURE OF STANDARD ANTIFOULING PANELS 1 YEAR AT MIAMI BEACH, FLA., AT A MINIMUM DEPTH OF 1 FT (0.3 m) UNDER A FLOATING RAFT

NOTE—Physical condition or its extent indeterminate, or both, due to intensive, extensive algae spore growth. Ratings for A.F. and A.C. are as recorded before surface became obscured by spore foulings.

A4. SUMMARY OF BARNACLE SETTLEMENT FOR EXPOSURE PERIOD OF ANNEX A2.

ANNUAL SUMMARY OF BARNACLE SETTLEMENT

FIG. A4.1 Summary of Barnacle Settlement.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Low Concentrations of Mercury in Paint by Atomic Absorption Spectroscopy¹

This standard is issued under the fixed designation D 3624; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{ε1} NOTE—Keywords were added editorially in July 1991.

1. Scope

1.1 This test method covers the determination of the content of mercury in the range between 10 and 1000 ppm (mg/kg) present in liquid coatings, coatings vehicles, or in dried films obtained from previously coated substrates. There is no reason to believe that higher levels could not be determined by this test method, provided that appropriate dilutions and adjustments in specimen size and reagent quantities are made.

1.2 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. Specific hazard statements are given in Section 7 and 9.1.1.*

2. Referenced Document

- 2.1 *ASTM Standard:*
D 1193 Specification for Reagent Water²

3. Summary of Test Method

3.1 The sample of liquid coating or dried film is weighed into a polytetrafluoroethylene (PTFE)-lined acid decomposition vessel and digested at an elevated temperature using sulfuric and nitric acids. Use of a sealed acid decomposition vessel prevents loss of mercury during the digestion. The digested sample is diluted to a known volume with water and the concentration of mercury is determined using a cold-vapor, atomic absorption technique.

4. Significance and Use

4.1 The permissible level of heavy metals in certain coatings is specified by governmental regulatory agencies. This test method provides a fully documented procedure for determining low concentrations of mercury present in both water and solvent-reducible coatings to determine compliance.

5. Apparatus

- 5.1 *Atomic Absorption Spectrophotometer*—Any commer-

cial instrument having an open sample presentation area in which to mount the absorption cell or an instrument designed specifically for the measurement of mercury using the cold vapor technique.

- 5.2 *Recorder*, 0 to 10 mV.

- 5.3 *Mercury Source Lamp*.

5.4 *Absorption Cell*—Standard spectrophotometer cells 100 mm long, having quartz end windows may be used. Prior to use, the cell must be positioned in the optical path of the spectrophotometer and held in place by suitable clamps or straps. The cell should be carefully aligned both vertically and horizontally to give the maximum transmittance.

5.5 *Reduction Vessel*—Cylindrical gas washing bottle, 250-mL, equipped with a coarse (40 to 60- μ m) fritted glass inlet tube and a standard-taper glass stopper. Polyethylene or poly(vinyl chloride) tubing may be used for connecting the reduction vessel to the absorption cell.

5.6 *Flowmeter*, capable of measuring a gas flow of 1 L/min.

5.7 *Drying Tube*—Approximately 6 by 3/4-in. (150 by 20-mm) glass tube filled with magnesium perchlorate. The tube should be filled each day that it is in use, and the $Mg(ClO_4)_2$ should be replaced whenever it becomes saturated (carefully observe after each analysis).

NOTE 1—Use of an indicator desiccant at the exit end of the tube will make this observation easier.

5.8 *Water Vapor Trap*—A second 250-mL gas washing bottle (the same as used for the reduction vessel). If preferred, a 250-mL Erlenmeyer vacuum flask fitted with a one-hole stopper and 200 mm of 5-mm outside diameter glass tubing, may be substituted.

5.9 *Mercury Trap*—A 250-mL Erlenmeyer vacuum flask containing 75 mL of 10 % sulfuric acid and 75 mL of 0.1 N potassium permanganate solution to absorb the mercury vapor after analysis.

- 5.10 *Circulating Oven*, maintained at $140 \pm 5^\circ\text{C}$.

5.11 *Acid Decomposition Vessel*, with 25-mL PTFE digestion cup.³

- 5.12 *Volumetric Flasks*, 100, 250, and 1000-mL.

- 5.13 *Paint Shaker*.

- 5.14 *Paint Draw-Down Bar*.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Materials.

Current edition approved July 17 and Nov. 29, 1985. Published January 1986. Originally published as D 3624 - 77. Last previous edition D 3624 - 84.

² *Annual Book of ASTM Standards*, Vols 06.03 and 11.01.

³ Acid decomposition vessel manufactured by the Parr Instrument Co., 211 Fifty-third St., Moline, IL 61265 (Catalog No. 4745) has been found satisfactory for this purpose.

FIG. 1 Apparatus

6. Reagents

6.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁴ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

6.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water conforming to Type II of Specification D 1193.

6.3 *Hydroxylamine Hydrochloride Solution* (100 g/L)—Dissolve 10 g of NH₂OH·HCl in 100 mL of water. Transfer a portion of this solution to a small dropping bottle.

6.4 *Mercury Solution, Stock* (1 mg/mL)—Dissolve 0.1354 g of HgCl₂ in 50 mL of water. Carefully add 5 mL of concentrated H₂SO₄ and 3 mL of concentrated HNO₃ and dilute to 100 mL. This solution contains 1000 µg/mL of mercury.

6.5 *Mercury Standard, Working* (0.1 µg/mL)—Make successive dilutions of the stock mercury solution to obtain a working standard containing 0.1 mg/L (0.1 µg/mL), maintaining a concentration of 5 % H₂SO₄ and 3 % HNO₃ by volume, in the diluted solutions. The working mercury standard and the dilutions of the stock mercury solution should be prepared fresh each day that it is used.

6.6 *Nitric Acid* (sp gr 1.42)—Concentrated nitric acid (HNO₃).

6.7 *Nitrogen*.

6.8 *Potassium Permanganate Solution* (0.1 N)—Dissolve 15.8 g of KMnO₄ in water and dilute to 1 L.

6.9 *Stannous Chloride Solution* (100 g/L)—Dissolve 25 g of tin (II) chloride (SnCl₂) by adding it to 60 mL of concentrated HCl (sp gr 1.19) and warming on a hotplate. When all of the SnCl₂ has dissolved, transfer to a 250-mL volumetric flask and dilute to volume with water. Mix well.

⁴ "Reagent Chemicals, American Chemical Society Specifications," Am. Chem. Soc., Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY, and the "United States Pharmacopeia."

This solution should be prepared fresh each week that it is used.

6.10 *Sulfuric Acid* (sp gr 1.84)—Concentrated sulfuric acid (H₂SO₄).

6.11 *Sulfuric Acid* (1+9)—Carefully mix 1 volume of H₂SO₄ (sp gr 1.84) into 9 volumes of water.

7. Hazards

7.1 Concentrated nitric and sulfuric acids are corrosive and may cause severe burns of the skin or eyes. The vapor from concentrated nitric acid is irritating to mucous membranes. Use care in handling these acidic substances. Refer to suppliers' Material Safety Data Sheet.

7.2 Mercury and its compounds are harmful and accumulate in the aquatic environment. Mixtures containing mercury compounds should not be flushed down a drain, but disposed of as hazardous waste.

7.3 Use only a rubber bulb aspirator for pipetting liquids.

8. Calibration and Standardization

8.1 Assemble the various components, as illustrated in Fig. 1 if an atomic absorption spectrophotometer is used, or prepare the instrument for operation if a commercial mercury analyzer is being used.

NOTE 2—Be sure that all glassware has been thoroughly cleaned and rinsed with reagent water prior to use.

8.2 Operational instructions for atomic absorption spectrophotometers and commercial mercury analyzers vary with different models. Consult the manufacturer's literature for establishing optimum conditions for the specific instrument used.

8.3 With the apparatus empty, stabilize the recorder base line while maintaining a flowrate of 250 mL of nitrogen per minute.

8.4 Transfer 0, 5, 10, 15, and 20-mL aliquots of the working mercury standard (containing 0 to 2 µg of mercury) to a series of 250-mL gas washing bottles. Add enough water to each bottle to make a total volume of 100 mL. Add 5 mL of H₂SO₄ and 3 mL of HNO₃ to each bottle and mix thoroughly. Make dropwise additions of 0.1 N KMnO₄ solution to each bottle in turn until a pink color persists for at least 30 s (1 mL is usually sufficient). Add exactly 1 mL of NH₂OH·HCl solution dropwise to each bottle and swirl

until the pink color is discharged.

8.5 Add 10 mL of SnCl_2 solution to the bottle containing no added working mercury standard. Immediately insert the fritted glass inlet tube, making sure that the stopper provides a good seal. Adjust the nitrogen flow rate to a previously determined optimum setting (see Note 3) and take a reading. A blank value greater than 5 % of full scale indicates either reagent or apparatus contamination. When the recorder, meter, or other readout device reaches a maximum value, it should be immediately zeroed. Repeat this blank determination until a steady, repeatable zero value is obtained at the maximum response.

NOTE 3—Optimum nitrogen flow rate may be determined by analyzing 1- μg quantities of mercury (10 mL of working mercury standard diluted to 100 mL) by this procedure, varying the flow rate to determine the optimum mercury signal and time required for analysis. Then use this optimum flow rate for all analyses, unless a change is made in the volume or geometry of the apparatus.

8.6 Similarly treat each standard solution made up in 8.4, recording the maximum peak height for each. When the recorder pen begins dropping, remove the fritted glass inlet tube from the gas washing bottle and insert it into another bottle containing only water. Continue nitrogen flow until the absorbance reaches zero, when the apparatus is ready for the next solution.

NOTE 4—Because mercury vapor is very toxic, take precautions to avoid its inhalation. Bubble the exhaust from the absorption cell through an absorbing solution consisting of equal volumes of 0.1 N KMnO_4 solution and 10 % H_2SO_4 (see Fig. 1). Do not discharge the absorbing solution into a sewer system.

8.7 Construct a standard curve by plotting peak heights versus micrograms of mercury. Peak heights used should be the mean of duplicate determinations on each solution.

9. Procedure

9.1 If the sample is a liquid coating, mix it until homogeneous, preferably on a mechanical paint shaker. Prepare at least two replicate specimens by weighing to 0.1 mg by difference from a dropping bottle or syringe, 100 to 200 mg of the mixed paint into the PTFE insert of the acid decomposition vessel. Place the insert in an oven set at 60°C (140°F) for 1 h to remove all volatiles.

9.1.1 **Caution**—If the solvent present in a sample is not removed prior to the digestion step as recommended, potentially dangerous pressures may result when the vessel is heated at 140°C.

9.2 If the sample consists of dried film, coarsely grind it and weigh 50 to 100 mg by difference from a weighing bottle into the digestion vessel.

NOTE 5—Recover dried paint films from previously coated substrates (being careful not to remove any underlying material from the substrate) or prepare in the laboratory from liquid samples. For the laboratory preparation, flow some of the well-mixed sample onto a clean glass plate. The use of a paint draw-down bar is recommended to obtain a uniform wet film thickness not exceeding 2 mils (50 μm). Allow the film to dry in an oven at 60°C for a minimum of 1 h. Scrape the dried film off the glass plate, preferably with a single-edge razor blade.

9.3 Pipet 5 mL of concentrated H_2SO_4 and 3 mL of concentrated HNO_3 into the decomposition vessel insert, using a fume hood for the operation. Seal the vessel tightly and place in the circulating oven at 140°C for 1½ h. Remove

the vessel from the oven and allow it to cool slowly to room temperature.

NOTE 6—Do not assist cooling by putting the vessel in a refrigerator or freezer, or by submerging it in a cooling liquid; otherwise mercury losses may occur due to leakage of pressurized gases resulting from uneven contraction of the bomb parts and PTFE seal.

NOTE 7—Analysis of the digested specimen (9.4 to 9.7) should be completed within 1 h after the digestion step.

9.4 When completely cooled, carefully unseal the vessel in a fume hood, add approximately 5 mL of cold water and swirl gently. Quantitatively transfer the contents to a 100-mL beaker, using several small quantities of water. Dilute to a volume of 30 to 40 mL and filter through filter paper directly into a 100-mL volumetric flask. Wash the residue on the filter paper several times with small volumes of water. Dilute to volume with water and mix thoroughly.

9.5 Transfer an aliquot of each digested specimen containing not over 2 μg of mercury to a 250-mL gas washing bottle. Add enough water to make a total volume of 100 mL. To each bottle, add 5 mL of concentrated H_2SO_4 and 3 mL of concentrated HNO_3 and mix thoroughly.

NOTE 8—If large aliquots are taken for analysis, reduce the amount of added H_2SO_4 and HNO_3 proportionately to compensate for the amounts present in the digested solutions.

9.6 Proceed with the addition of KMnO_4 , $\text{NH}_2\text{OH} \cdot \text{HCl}$, and SnCl_2 solutions as described in 8.4 and 8.5. Record the maximum peak height for each solution.

9.7 If the response obtained is above or below the response obtained for the standards (8.7), repeat 9.5 and 9.6 using an appropriate aliquot size. Determine the concentration of mercury present in microgram per millilitre from the calibration curve.

10. Calculation

10.1 Calculate the mean concentration of mercury in the sample as follows:

$$\text{mercury in sample, ppm (mg/kg)} = (100 \times C) / (F \times S)$$

where:

C = concentration of mercury in aliquot used, $\mu\text{g/mL}$,

F = dilution factor from 9.5 (aliquot volume used), and

S = grams of sample.

11. Report

11.1 Report the mercury content in the material being tested and whether the analysis was conducted on a liquid coating or a dried film.

12. Precision and Bias⁵

12.1 **Precision**—The precision estimates are based on an interlaboratory study in which seven different laboratories analyzed in duplicate, on two different days, four samples of water-reducible paints and four samples of solvent-reducible paints containing from 1 to 1000 ppm mercury. The within laboratory coefficient of variation was found to be 6.4 % relative at 42 degrees of freedom, and the between-laboratory coefficient of variation 10 % relative at 36 degrees of freedom. Based on these coefficients, the following criteria

⁵ Supporting data are available from ASTM Headquarters. Request RR: D01-1006.

laboratories, should be considered suspect if they differ by more than 30 % relative.

12.2 Bias—The true value for the amount of mercury present in a coating should be between 79 and 121 % of the experimental value.

12.1.2 *Reproducibility*—Two results, each the mean of duplicate determinations, obtained by operators in different

Standard Guide for Determining Constituents Classified as Hazardous Contained in Protective Coatings¹

This standard is issued under the fixed designation D 3630; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide applies to liquid protective coatings, related products, and their dried films. It is a guide for the selection of analytical procedures for the determination of the presence and quantity of selected materials that may present potential physiological hazards.

1.2 Various levels of government have established laws and regulations that limit the quantity or prohibit the presence of certain materials classified as hazardous in protective coatings. Materials subject to such regulations are within the scope of this guide.

1.3 A hazardous material within the scope of this guide is one that exhibits harmful physiological effects through ingestion, inhalation, absorption, or skin or eye contact. Hazards associated with combustion are not within its scope.

1.4 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Summary of Guide

3.1 This guide covers each material separately, discussing the methods available, the advantages and drawbacks of each, including the range, the equipment needed, and when information is available, the precision. Methods discussed are:

- 3.1.1 ASTM methods adopted by Committee D-1,
- 3.1.2 Other ASTM methods believed to be applicable to paint and related products,
- 3.1.3 Methods adopted as standard by other scientific and technical or governmental organizations, and
- 3.1.4 Widely used methods reported in the literature.

4. Significance and Use

4.1 Protective coatings and related products containing materials classified as hazardous may be regulated or controlled in various ways as follows:

4.1.1 Precautionary Labeling Required:

4.1.1.1 Under the U.S. Federal Hazardous Substances Act and corresponding state laws, "consumer" paint products must carry precautionary labeling as specified in the laws, or implementing regulations, or both.

NOTE 1—Under the Federal Hazardous Substances Act lead, ethylene and diethylene glycol, petroleum distillates, and turpentine are classed as hazardous through ingestion. Methyl alcohol, benzene, xylene, and toluene are classed as hazardous through ingestion and inhalation. Ethylene diamine, diethylene triamine, and diglycidyl ethers are classed as strong sensitizers.

4.1.1.2 In certain states, coatings and related materials packaged and sold for industrial application are subject to precautionary labeling laws and regulations.

4.1.2 Use Prohibited in Certain Areas:

4.1.2.1 Under the U.S. Federal Hazardous Substances Act and the Lead Paint Poisoning Prevention Act, and the laws of certain states and municipalities, coatings and related products containing more than a specified quantity of lead are banned for use in and around a household or other areas where children might be exposed.

4.1.2.2 Under certain local ordinances, coatings and related products containing more than a specified quantity of "other toxic heavy metals" are also subject to control.

NOTE 2—The amount of lead, antimony, arsenic, cadmium, mercury, selenium, and soluble barium that may be present in coatings for use on children's furniture and toys and areas that might be chewed by children is restricted under ANSI Standard Z66.1 and under various U.S. municipal ordinances.

4.1.3 Subject to Approval for Certain Uses:

4.1.3.1 The U.S. Food and Drug Administration permits only approved ingredients to be used in coatings for food and beverage containers or processing equipment that comes into contact with the product.

4.1.3.2 The U.S. Department of Agriculture authorizes for use on structural surfaces in federally inspected meat and poultry processing plants only coatings accepted as nonhazardous.

4.1.3.3 The U.S. Environmental Protection Agency regulations control the distribution of paints that claim special fungicidal or pesticidal characteristics, and the use in ship-bottom paints of materials that have the potential for harming the aquatic environment.

NOTE 3—Cuprous oxide, bis(tributyltin oxide), arsenic, and mercury are classed as hazardous materials by the U.S. Environmental Protection Agency when used in antifouling paints.

4.1.4 Environmental Controls During Use and Corrective Measures in the Event of Accidents or Misuse Required:

4.1.4.1 Under U.S. Occupational Safety and Health Act regulations, airborne concentrations of certain vapors, fumes, and dusts are limited in the work-place atmosphere. Coatings, when applied, may emit solvent vapors that are subject to these limits.

4.1.4.2 Under Occupational Safety and Health Act regulations, skin or eye contact with liquid paint containing specified potentially hazardous materials must be avoided and protective apparel may be required. In the event of hazardous skin or eye contact, corrective action to ameliorate physiological injury is prescribed.

NOTE 4—Over 400 materials have been classified by the Occupational Safety and Health Administration as being potentially hazardous.

Of this number approximately 80 may be found in varying amounts as components of coatings and related products.¹⁰

4.1.4.3 To achieve air quality standards under the Clean Air Act, regulations of various states and regions control emissions of volatile organic compounds resulting from the application of surface coatings.

5. Pigment, Vehicle Separations (Centrifugal)

5.1 The methods listed in this section cover centrifugal separation of pigment from vehicle. The pigment may then be analyzed as described in subsequent sections. More recent methods utilizing analysis of the whole paint by atomic absorption spectroscopy may be preferred due to greater speed and accuracy.

5.2 Separation of the vehicle from the pigment is generally the first step in coatings analysis. There are three ASTM methods covering the use of centrifuges:

5.2.1 Test Method D 2371 describes the use of the normal laboratory centrifuge that develops 2000 g. It should be used where a quantitative determination of the amount of pigment in the coating is required.

5.2.2 Method D 2372 covers use of a high-speed centrifuge that develops 10 000 g and is used when analysis of the vehicle is of main interest.

5.2.3 Method D 2698 covers use of a centrifuge that develops at least 32 000 g. Determination of the pigment content is the main objective of the method although the separated pigment may be solvent-extracted to remove residual vehicle.

NOTE 5—Centrifuge methods do not generally give good separations of pigments that bleed (partially dissolve) or have low densities and fine particle sizes (such as carbon black).

5.3 U.S. Federal Test Method Standard 141 contains two centrifuge methods. Federal Method 4021.1 is similar to Test Method D 2371 except that additional extraction mixtures are listed for difficult pigments and for cellulosic and vinyl lacquers. Federal Method 4032 is similar to Method D 2698 but has the same extraction solvents as in Federal Method 4021.1.

6. Solvent Separation

6.1 Practice D 3272 covers a vacuum distillation procedure that separates the solvents from the nonvolatile portion of paints so they may be analyzed.

6.2 Practice D 3271 covers analysis of the solvents by injection of the liquid coating into a gas chromatograph. Prior separation is not required.

ANALYTICAL METHODS

7. Heavy Metals Analysis, ASTM Methods

7.1 Methods for the analysis of pigments apply to dry pigment or to pigment separated from the vehicle in accordance with Section 5.

7.2 Lead:

7.2.1 *Pigment Analysis*—In all the following methods except for Methods D 2742, the concentration range for which the method is applicable is not given.

7.2.1.1 Methods D 49 cover procedures for the chemical analysis of dry red lead having the approximate formula Pb_3O_4 (probably $PbO_2 \cdot 2PbO$). Total lead is determined gravimetrically as lead sulfate.

7.2.1.2 Test Methods D 126—Total lead is determined gravimetrically as lead sulfate. The comparable Fed. Test Methods Std. 141 methods are 7271 and 7281.

7.2.1.3 Methods D 215—Two methods are described for the gravimetric determination of total lead, one as the sulfate and the other as the chromate. The choice of method may be dictated by potential interferences discussed in the text.

7.2.1.4 Test Methods D 1301 cover procedures for the chemical analysis of basic carbonate white lead and basic sulfate white lead. Total lead is determined gravimetrically as lead chromate. The comparable Fed. Test Method Std. 141 method is 7041.

7.2.1.5 Test Methods D 1844—Total lead is determined gravimetrically as lead chromate.

7.2.1.6 Methods D 2742—Silicon is removed by filtration and total lead determined gravimetrically as lead sulfate. The methods are designed for the analysis of essentially pure pigment.

7.2.1.7 Methods D 3280 cover procedures for the analysis of white zinc pigments, including leaded zinc oxide. Total lead is determined gravimetrically as lead sulfate.

7.2.2 *Analysis of Liquid Material or Dried Film:*

7.2.2.1 Test Methods D 564 cover the determination of percent lead in liquid driers (see Section 9). Total lead is determined gravimetrically as lead sulfate. The comparable Fed. Test Method Std. No. 141 method is 7231.

7.2.2.2 Test Method D 2374 covers a titrimetric determination of lead in paint driers that can be dissolved in a suitable solvent and utilizes excess EDTA (ethylene diamine tetraacetic acid) to react with lead and cupric sulfate to back titrate. The drier is dissolved in glacial acetic acid, diluted with isopropyl alcohol and water, and treated with an excess of standard EDTA solution. The excess is titrated with standard cupric sulfate solution using an indicator. The method includes a precision statement but the applicable concentration range is not given.

7.2.2.3 Test Method D 3335 covers the determination of lead contents between 0.01 and 5 % present in the solids of liquid coatings or in dried films. A specimen of liquid paint or dried film is prepared for analysis by dry ashing. The lead content of an acid extract of the ash is determined by atomic absorption spectroscopy. The precision statement is based on a relative scale.

7.2.2.4 Test Method D 3618 is intended as a screening test to determine if a sample of paint solids contains more than 0.5 % lead. The test will barely detect the presence of 0.4 % and will give a definite test at the 0.5 % level. The specimen is dry ashed and extracted. Lead present is oxidized to lead peroxide and spotted with "tetrabase" to develop a blue coloration. Higher or lower concentrations may be detected by this test method by making appropriate changes in the specimen size and reagent quantities.

7.3 Chromium:

7.3.1 *Pigment Analysis:*

7.3.1.1 *Test Methods D 126*—In these test methods the chromium content of pigments is only calculated as Cr_2O_3 for chromium oxide green. For chrome oranges, yellows, and

¹⁰ Occupational Safety and Health Reporter, Section 1910.1000 Table Z.1.

greens the chromium is calculated as lead chromate.

7.3.1.2 *Test Methods D 444* cover procedures for the chemical analysis of the pigment known commercially as "zinc yellow" or "zinc chromate yellow." Total chromium in the pigment is determined by titration using either the dichromate method or the thiosulfate method and calculated as CrO_3 .

7.3.1.3 *Test Methods D 1844*—Total chromium in the pigment is determined as chromium trioxide by titration using the thiosulfate method.

7.3.1.4 *Test Methods D 1845*—Total chromium in the pigment is determined as chromium trioxide by titration using the thiosulfate method.

7.3.2 *Analysis of Liquid Paint or Dried Film:*

7.3.2.1 *Test Method D 3718* covers the determination of chromium or chromium compounds (including chromium oxide) when present in the solids of liquid coatings or in dried films in the concentration range from 0.005 to 1.0 % (50 to 10 000 ppm) expressed as chromium. A specimen of liquid paint or dried film is prepared for analysis by dry ashing. A weighed quantity of the ash is digested with potassium permanganate and sulfuric acid. Chromium is determined on the filtered digestion mixture by atomic absorption spectroscopy.

7.4 *Barium:*

7.4.1 *Pigment Analysis:*

7.4.1.1 *Methods D 215*—Soluble barium is determined gravimetrically as the sulfate.

7.4.1.2 *Test Methods D 715*—Applicability to mixed pigments when barium is a minor component is not indicated.

7.4.1.3 *Methods D 3280* cover procedures for the analysis of white zinc pigments. Determination of total barium sulfate content is described in Section 20 of *Methods D 3280*.

7.4.2 *Analysis of Liquid Paint or Dried Film*—Current legislation restricts the quantity of "soluble" barium in coatings used in areas accessible to children, but the conditions of solubility are not usually defined. There is no ASTM method for soluble barium; see Section 10.

7.5 *Mercury:*

7.5.1 *Analysis of Liquid Paint or Dried Film*—*Test Method D 3624* covers the determination of mercury contents between 10 and 1000 ppm in liquid coatings and dried films. The specimen of whole paint, paint vehicle, or dried film is digested using sulfuric and nitric acids, and the concentration of mercury determined using cold-vapor atomic absorption.

7.6 *Arsenic:*

7.6.1 *Analysis of Liquid Paint or Dried Film*—*Test Method D 2348* covers the determination of less than 0.5 % arsenic in liquid coatings or dried films. Whole paint or dried film is digested in nitric and sulfuric acid. Sodium chloride is added and the arsenic trichloride distilled. Total arsenic is determined by titration with potassium bromate.

7.7 *Antimony:*

7.7.1 *Pigment Analysis: Test Method D 2350*—Total antimony is calculated from the antimony oxide content determined by titration with potassium permanganate. The concentration range for which the method is applicable is not given. The comparable Federal Method is 7106.

7.7.2 *Analysis of Liquid Paint or Dried Film*—*Test*

Method D 3717 covers the determination of antimony contents between 50 and 200 ppm present in the solids of liquid coatings in dried films. The specimen of liquid paint or dried film is prepared for analysis by dry ashing at 500°C followed by refluxing with hydrochloric acid and stannous chloride. The antimony content of the acid extract is determined by atomic absorption spectroscopy.

7.8 *Cadmium:*

7.8.1 *Analysis of Whole Paint or Dried Film*—*Test Method D 3335* covers the determination of cadmium contents between 50 and 150 ppm present in the solids of liquid coatings or in dried films. The sample of liquid paint or dried film is prepared for analysis by dry ashing. The content of cadmium is determined by atomic absorption spectroscopy.

8. Other Regulated Metallic Components

8.1 *Copper:*

8.1.1 *Pigment Analysis*—Methods for the analysis of the pigment portion of the coating after separation.

8.1.2 *Methods D 283* cover analysis for total copper in copper-based pigments.

9. U.S. Federal Test Method Standard No. 141

9.1 *Lead:*

9.1.1 *Method 7041* is comparable to *Test Methods D 1301*.

9.1.2 *Method 7051* is comparable to *Test Methods D 1301*.

9.1.3 *Method 7071.1* is for the quantitative measure of red lead in paint pigments.

9.1.4 *Method 7111* is comparable to *Test Methods D 126*.

9.1.5 *Method 7131* is comparable to *Test Methods D 126*.

10. Other Analytical Methods for Materials Classified as Hazardous Within the Scope of This Practice

10.1 National Standard of Canada CAN2-1.500 describes test methods for determining toxic elements in low concentrations in protective coatings, employing wet chemical and atomic absorption and visible-ultraviolet spectrophotometric techniques. Determination of leachable elements are made on a dilute hydrochloric acid extract of the dried film that has first been ground to a specific fineness.

10.1.1 1-GP-500.1 is used for determining total lead in liquid and applied coatings by atomic absorption spectroscopy.

10.1.2 1-GP-500.2 is used for determining soluble cadmium in applied coatings by atomic absorption spectroscopy.

10.1.3 1-GP-500.3 is used for determining soluble barium in applied coatings by atomic absorption spectroscopy.

10.1.4 1-GP-500.4 is used for determining soluble antimony in applied coatings by visible-ultraviolet spectroscopy.

10.1.5 1-GP-500.5 is used for determining soluble selenium in applied coatings by visible-ultraviolet spectroscopy.

10.1.6 1-GP-500.6 is used for the detection of, and the quantitative determination of, soluble mercury in applied coatings by visible-ultraviolet spectroscopy.

11. Nonvolatile Vehicle Components, ASTM Methods

11.1 Test Method D 2621 covers the qualitative characterization or identification of separated paint vehicle solids by infrared spectroscopy within the limitations of this procedure.

12. Volatile Components

12.1 The volatile components of protective coatings must be identified to determine compliance with regulations covering labeling, work place concentrations, and air quality standards.

12.2 Gas chromatography is widely used for this purpose. However, owing to the empirical nature of the technique, chemical or instrumental confirmatory tests may be necessary as supplementary procedures.

12.3 Identification of the components of an unknown solvent blend would in many cases be expedited by means of a combination of gas chromatography and infrared spectroscopy or mass spectrometry.

12.4 Interconnected chromatographic, infrared analyzers are available that separate multicomponent mixtures into their pure components for infrared analysis.

12.5 Analysis of the volatile component of whole paint has been covered in Section 6.

12.6 The following ASTM methods cover the analysis of some of the volatile components of protective coatings currently subject to regulation as potentially hazardous materials:

12.6.1 Method D 2349 covers the determination of the nature of thinner in solvent-reducible house paints containing only hydrocarbon solvents.

12.6.2 Test Method D 3432 covers low molecular weight urethane products containing (a) 0.1 to 1.0 % and (b) 1.0 to 10 % of free toluene diisocyanate (TDI) content.

12.6.3 Test Methods D 3257 cover the determination of ethylbenzene and total eight-carbon (C_8) and heavier aromatics in the concentration range from 0.1 to 30 % in mineral spirits having a distillation range from 300 to 410°F (150 to 210°C). Oxygenated compounds, if present, may interfere and cause erroneous results.

12.6.4 Method D 3329 covers the determination of the purity of methyl isobutyl ketone by gas chromatography.

12.6.5 Test Methods E 202—See Sections 26 to 35 (Gas Chromatographic Techniques).

12.6.6 Practice E 260.

13.1 antimony; aromatics; barium; cadmium; Canadian methods; chromium; copper; government regulations; hazardous substances; heavy metals; lead; mercury; pigments; selenium; solvents; zinc

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Low Concentrations of Antimony in Paint by Atomic Absorption Spectroscopy¹

This standard is issued under the fixed designation D 3717; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{ε1} NOTE—Keywords were added editorially in July 1991.

1. Scope

1.1 This test method covers the determination of the content of antimony in the range between 50 and 200 ppm (mg/kg) present in the solids of liquid coatings or in dried films obtained from previously coated substrates. There is no reason to believe that higher levels could not be determined by this test method, provided that appropriate dilutions and adjustments in specimen size and reagent quantities are made.

1.2 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. Specific hazard statements are given in Section 7.*

2. Referenced Documents

2.1 ASTM Standards:

D 1193 Specification for Reagent Water²

D 2832 Guide for Determining Volatile and Nonvolatile Content of Paint and Related Coatings³

3. Summary of Test Method

3.1 The sample of liquid coating or dried film is prepared for analysis by dry ashing at 500°C, followed by refluxing with hydrochloric acid and stannous chloride. The antimony content of the acid extract is determined by atomic absorption spectroscopy.

4. Significance and Use

4.1 The permissible level of heavy metals in certain coatings is specified by governmental regulatory agencies. This test method provides a fully documented procedure for determining low concentrations of antimony present in both water- and solvent-reducible coatings to determine compliance.

5. Apparatus

5.1 *Atomic Absorption Spectrophotometer*, consisting of

an atomizer and either a single- or three-slot burner; gas pressure regulating and metering devices for air and acetylene; an antimony source lamp with a regulated constant current supply; a monochromator and associated optics; a photosensitive detector connected to an electronic amplifier, and a readout device.

5.2 *Muffle Furnace*, maintained at $500 \pm 10^\circ\text{C}$.

5.3 *Oven*, maintained at $105 \pm 2^\circ\text{C}$.

5.4 *Hot-Plate*, with variable surface temperature control over the range from 70 to 200°C.

5.5 *Reflux Condenser*, water-cooled, and fitted with a standard-taper joint.

5.6 *Erlenmeyer Flask*, 125-mL, with standard-taper joint to fit condenser.

5.7 *Volumetric Flasks*, 100 and 1000-mL.

5.8 *Dropping Bottles*, $\frac{1}{4}$ or $\frac{1}{2}$ -oz (8 or 15-mL) capacity.

5.9 *Glass or Disposable Syringes*, 10-mL capacity.

5.10 *Pipets*, 1, 5, 10, and 15-mL capacity.

5.11 *Filter Paper*, ashless, medium or slow filtering.

5.12 *Paint Shaker*.

5.13 *Paint Draw-Down Bar*.

6. Reagents

6.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁴ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

6.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent grade water conforming to Type II of Specification D 1193.

6.3 *Antimony Standard Stock Solution* (0.1 mg/mL)—Dissolve 0.1000 g of antimony metal in 40 mL of sulfuric acid (H_2SO_4 , sp gr 1.84) by heating. Cool, carefully transfer quantitatively to a 1-L volumetric flask already approximately half full with water, allow to cool to room temperature, and dilute to 1 L.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Materials.

Current edition approved May 31 and Nov. 29, 1985. Published January 1986. Originally published as D 3717 - 78. Last previous edition D 3717 - 84.

³ *Annual Book of ASTM Standards*, Vol 06.01.

⁴ "Reagent Chemicals, American Chemical Society Specifications," Am. Chemical Soc., Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY, and the "United States Pharmacopeia."

6.4 *Hydrochloric Acid* (sp gr 1.19)—Concentrated hydrochloric acid (HCl).

6.5 *Stannous Chloride Solution* (400 g/L in HCl)—Dissolve 40 g of tin (II) chloride (SnCl_2) in 50 mL of HCl (sp gr 1.19). Transfer to a 100-mL volumetric flask and fill to the mark with concentrated HCl.

7. Hazards

7.1 Use care in handling concentrated HCl because it is corrosive and may cause burns to the skin and eyes and its vapor is irritating to mucous membranes. Refer to suppliers' Material Safety Data Sheet.

7.2 Use only a rubber bulb aspirator for pipetting liquids.

8. Calibration and Standardization

8.1 Prepare 100-mL quantities of at least four standard solutions bracketing the expected antimony concentration in the sample to be tested. To suitable aliquots of the 0.1 mg/mL standard antimony solution, add 40 mL of concentrated HCl and 8 drops of SnCl_2 solution. Dilute to 100 mL with water. Prepare a blank solution by diluting 40 mL of concentrated HCl and 8 drops of SnCl_2 solution to 100 mL with water.

8.2 Operational instructions for atomic absorption spectrophotometers vary with different models. Consult the manufacturer's literature for establishing optimum conditions for the specific instrument used.

8.3 Turn the instrument on and set the wavelength to the 217.6-nm antimony line. Apply the recommended current to the antimony source lamp. Allow the instrument to warm up for about 15 min and set the slit width. Adjust the air and acetylene pressures and ignite the burner in accordance with instructions.

8.4 Aspirate water to rinse the atomizer chamber. Aspirate a standard solution and make any necessary readjustment in instrument parameters to obtain maximum absorption.

8.5 Aspirate the blank solution. When the recorder, meter, or other readout device reaches a constant value, it should be immediately zeroed. Repeat this blank determination until a steady, repeatable zero value is obtained at the maximum response.

8.6 Aspirate each of the appropriate standard solutions in ascending antimony concentrations and record the corresponding instrument readings. Aspirate water between each standard.

NOTE 1—A deuterium background corrector, if available, should be used to correct for background absorption. If not available, it is necessary to reaspirate each standard solution and measure the background at a nearby nonabsorbing region of the spectrum.

NOTE 2—Because of the high concentration and corrosive nature of the acids used for the analysis, it is essential that the burner assembly be disassembled and thoroughly cleaned out immediately after the analyses are completed. Consult the instrument manual for cleaning instructions.

8.7 Construct a calibration curve on linear graph paper by plotting the absorbance (corrected for background) versus concentration (micrograms per millilitre) for each standard solution.

9. Procedure

9.1 If the sample is a liquid coating, mix it until homogeneous, preferably on a mechanical paint shaker. Determine the nonvolatile content in accordance with Guide D 2832.

9.2 Prepare at least two replicate samples by weighing by difference from a dropping bottle or syringe, 5 to 10 g of the mixed liquid coating, or by directly weighing approximately 2 to 6 g of dried film, into 125-mL Erlenmeyer flasks. Weigh to the nearest 0.1 mg.

NOTE 3—The specimen size called for will have a concentration of approximately 4 to 12 $\mu\text{g/mL}$ antimony in the final diluted solution for paints containing approximately 200 ppm (mg/kg) antimony based on the nonvolatile content, and 1 to 3 $\mu\text{g/mL}$ for paints containing approximately 50 ppm antimony, based on the nonvolatile content.

NOTE 4—Recover dried paint films from previously coated substrates (being careful not to remove any underlying material from the substrate) or prepare in the laboratory from liquid samples. For the laboratory preparation, flow some of the well-mixed sample onto a clean glass plate. The use of a paint draw-down bar is recommended to obtain a uniform film thickness not exceeding 2 mils (50 μm). Allow the film to dry in an oven at 105°C for a minimum of 1 h. Scrape the dried film off the glass plate, preferably with a single-edge razor blade.

9.3 Place the flasks containing the liquid coating on the hot plate and slowly increase the temperature until the material is dried.

9.4 When the sample appears to be dry, or when starting with a dried film, gradually increase the temperature of the hot plate until the material chars.

9.5 After charring appears complete, place the flasks in the muffle furnace and ash at 500°C. When the ashing appears to be complete (approximately 1 to 2 h), remove the flasks from the muffle furnace and allow to cool to room temperature.

9.6 Carefully add 40 mL of concentrated HCl and 8 drops of SnCl_2 solution to each flask. Connect the flasks to water-cooled condensers and reflux for 1 h.

9.7 Filter each digested specimen through medium-porosity filter paper into a 100-mL volumetric flask. If the filtrate is not clear, refilter through fine-porosity filter paper. Rinse each flask several times with water, adding the rinsings to the filter paper. Wash the filter paper several times with water. Adjust the volume to 100 mL with water and mix.

9.8 Aspirate each test solution and determine the absorbance in the same manner in which the instrument was calibrated (see Notes 1 and 2). Determine the concentration of antimony in micrograms per millilitre from the calibration curve. If the absorbance is above the range covered by the calibration curve, dilute an aliquot of the test solution to a suitable volume with water containing 40 mL of HCl and 8 drops of SnCl_2 solution per 100 mL. If the absorbance is below the range covered by the calibration curve, repeat the analysis using a larger specimen size.

NOTE 5—Increased sensitivity may be obtained with instruments possessing scale expansion and concentration readout capability.

NOTE 6—The method of standard additions may be used to improve the accuracy of the analysis. This method is particularly recommended for use with unknown samples where matrix effects may be potentially significant. For a detailed description of the procedure and calculations used in the method of standard additions, consult a standard text on atomic absorption spectroscopy or the instruction manual provided by the instrument manufacturer.

10. Calculation

10.1 Calculate the mean concentration of antimony in the nonvolatile portion of the sample as follows:

$$\text{Antimony, ppm (mg/kg) in nonvolatile} = (C \times F \times 10^4) / (NV \times S)$$

where:

- C = concentration of antimony in the aspirated test solution, $\mu\text{g/mL}$,
 F = dilution factor from 9.8 (volume diluted to/volume of aliquot),
 NV = percent nonvolatile of paint sample (use 100 if sample was dried film), and
 S = grams of sample.

11. Report

11.1 Report the antimony content of the nonvolatile content of the sample and whether the analysis was conducted on a liquid coating or a dried film.

⁵ Supporting data are available from ASTM Headquarters. Request RR: D01-1011.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

12. Precision and Bias⁵

12.1 The precision estimates are based on an inter-laboratory study in which eight different laboratories analyzed in duplicate, on two different days, three samples of water-reducible paints and three samples of solvent-reducible paints containing from 50 to 200 ppm (mg/kg) antimony. The within-laboratory coefficient of variation was found to be 4.8 % relative at 31 degrees of freedom and the between-laboratory coefficient of variation was 8.8 % relative at 25 degrees of freedom. Based on these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

12.1.1 *Repeatability*—Two results, each the mean of duplicate determinations, obtained by the same operator on different days, should be considered suspect if they differ by more than 14 % relative.

12.1.2 *Reproducibility*—Two results, each the mean of duplicate determinations, obtained by operators in different laboratories, should be considered suspect if they differ by more than 26 % relative.

12.2 *Bias*—The mean of duplicate determinations within any laboratory should be within 18 % relative of true value.

Standard Test Method for Low Concentrations of Chromium in Paint by Atomic Absorption Spectroscopy¹

This standard is issued under the fixed designation D 3718; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{ε1} NOTE—Keywords were added editorially in July 1991.

1. Scope

1.1 This test method covers the determination of the content of chromium (including chromium oxide) in the range between 0.005 and 1.0 % present in the solids of liquid coatings or in dried films obtained from previously coated substrates. There is no reason to believe that higher levels could not be determined by this test method, provided that appropriate dilutions and adjustments in specimen size and reagent quantities are made.

1.2 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. Specific hazard statements are given in Section 7.*

2. Referenced Documents

- 2.1 *ASTM Standards:*
D 1193 Specification for Reagent Water²
D 2832 Guide for Determining Volatile and Nonvolatile Content of Paint and Related Coatings³

3. Summary of Test Method

3.1 The sample of liquid coating or dried film is prepared for analysis by dry ashing at 500°C followed by digestion with potassium permanganate and sulfuric acid in a polytetrafluoroethylene (PTFE)-lined acid decomposition vessel at an elevated temperature. The chromium in the filtered digestion mixture is determined by atomic absorption spectroscopy.

4. Significance and Use

4.1 The permissible level of heavy metals in certain coatings is specified by governmental regulatory agencies. This test method provides a fully documented procedure for determining low concentrations of chromium present in both water- and solvent-reducible coatings to determine compliance.

5. Apparatus

5.1 *Atomic Absorption Spectrophotometer*, consisting of an atomizer and either a single- or three-slot burner; gas pressure-regulating and metering devices for nitrous oxide (N_2O) and acetylene; a chromium hollow cathode lamp with a regulated constant current supply; a monochromator and associated optics; a photosensitive detector connected to an electronic amplifier; and a readout device.

5.2 *Muffle Furnace*, maintained at $500 \pm 10^\circ C$.

5.3 *Force-Draft Oven*, maintained at $105 \pm 2^\circ C$.

5.4 *Acid Decomposition Vessel*, with PTFE digestion cup.⁴

5.5 *Hot Plate*, with variable surface temperature control over the range from 70 to 200°C.

5.6 *Volumetric Flasks*, 50, 100 and 1000-mL.

5.7 *Pipets*, 5, 10, 15, and 20-mL capacity.

5.8 *Filter Paper*, ashless, medium filtering 15-cm.

5.9 *Paint Shaker*.

5.10 *Crucibles*, wide form, porcelain, approximately 30-mL capacity.⁵

5.11 *Mortar and Pestle*.

5.12 *Paint Draw-Down Bar*.

6. Reagents

6.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁶ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

6.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water conforming to Type II of Specification D 1193.

6.3 *Chromium Standard Stock Solution* (1 mg/mL)—

⁴ Acid decomposition cup manufactured by the Parr Instrument Co., 211 Fifty-third St., Moline, IL 61265 (Catalog Number 4745) has been found satisfactory for this purpose.

⁵ Coors No. 25007 crucibles, or equivalent, have been found satisfactory for this purpose.

³ *Annual Book of ASTM Standards*, Vol 06.01.

Dissolve 3.735 g of potassium chromate (K_2CrO_4) in 100 mL of water and dilute to 1 L.

6.4 *Chromium Standard Working Solution* (0.1 mg/mL)—Pipet 10 mL of the chromium standard stock solution into a 100-mL volumetric flask and dilute to volume with water.

6.5 *Oxidizing Solution*—Dissolve 0.2 g of potassium permanganate ($KMnO_4$) in 100 mL of H_2SO_4 (1+1). Stir until completely dissolved. The color of this solution is dark brown.

6.6 *Reducing Solution*—Dissolve 1 g of hydroxylamine hydrochloride ($NH_2OH \cdot HCl$) in 100 mL of water.

6.7 *Reagent Blank*—Pipet 5 mL of oxidizing solution into 25 mL of water contained in a 50-mL volumetric flask. Add reducing solution dropwise until the permanganate color has been discharged; then dilute to 50 mL with water.

6.8 *Sulfuric Acid* (1+1)—Carefully add 1 volume of concentrated H_2SO_4 (sp gr 1.84) to 1 volume of water.

6.9 *Sulfuric Acid* (5 % volume per volume)—Carefully add 50 mL of concentrated H_2SO_4 (sp gr 1.84) to 500 mL of water and dilute to 1 L.

7. Hazards

7.1 Use care in handling concentrated H_2SO_4 because it is corrosive and may cause severe burns of the skin or eyes. Refer to suppliers' Material Safety Data Sheet.

7.2 The National Institute for Occupational Safety and Health has stated that hexavalent chromium compounds are hazardous to health. Care should be exercised in preparation of a sample for test. The wearing of a respirator and rubber or synthetic gloves is recommended. In case of contact, wash thoroughly with soap and water. Mixtures containing hexavalent chromium compounds should not be flushed down a drain but disposed of as hazardous waste.

7.3 Use only a rubber bulb aspirator for pipetting liquids.

8. Calibration and Standardization

8.1 Prepare 50-mL quantities of at least four standard solutions bracketing the expected chromium concentration in the sample to be tested. To suitable aliquots of the 100-ppm chromium standard working solution, add 10 mL of the oxidizing solution with a pipet, followed by the dropwise addition of reducing solution until the permanganate color has been discharged; then dilute to 50 mL with water.

8.2 Operational instructions for atomic absorption spectrophotometers vary with different models. Consult the manufacturer's literature for establishing optimum conditions for the specific instrument used.

8.3 Turn the instrument on and set the wavelength to the 357.9-nm chromium line. Apply the recommended current to the chromium hollow-cathode lamp. Allow the instrument to warm up for about 15 min and set the slit width. Adjust the nitrous oxide and acetylene pressures and ignite the burner according to instructions.

8.4 Aspirate water to rinse the atomizer chamber. Aspirate a standard solution and make any necessary readjustment in instrument parameters to obtain maximum absorption. Zero the instrument while aspirating reagent blank solution (6.7). Aspirate each of the appropriate standard solutions and record the corresponding instrument readings.

Aspirate water between each standard.

8.5 Transfer a 25-mL aliquot from each of the standard solutions prepared in 8.1 to 50-mL volumetric flasks and dilute to volume with water. Repeat the steps outlined in 8.4 for the diluted aliquot solutions.

8.6 Construct a calibration curve on linear graph paper by plotting the absorbance versus concentration (micrograms per millilitre) for each set of standard solutions.

NOTE 1—To obtain maximum accuracy one should complete calibration and standardization just prior to sample analysis.

9. Procedure

9.1 If the sample is a liquid coating, mix it until homogeneous, preferably on a mechanical paint shaker. Determine the nonvolatile content in accordance with Guide D 2832.

9.2 Determine the ash content of the material under test in duplicate.

9.2.1 Weigh to the nearest 0.1 mg approximately 5 g of liquid coating or 3 g of dried film into each of two tared porcelain crucibles.

NOTE 2—Recover dried paint films from previously coated substrates (being careful not to remove any underlying material from the substrate) or prepare in the laboratory from liquid samples. For the laboratory preparation, flow some of the well-mixed sample onto a clean glass plate. The use of a paint draw-down bar is recommended to obtain a uniform film thickness not exceeding 2 mils (50 μm). Allow the film to dry in an oven at 105°C for a minimum of 1 h. Scrape the dried film off the glass plate, preferably with a single-edge razor blade.

9.2.2 Place the crucibles containing the liquid coating on the hot plate and slowly increase the temperature until the material is dried. With some types of coatings, an initial oven-drying at 105°C may be necessary to remove solvents without incurring losses due to spattering.

9.2.3 When the specimen appears to be dry, or when starting with a dried film, gradually increase the temperature of the hot plate until the material chars.

9.2.4 After charring is complete, place the crucibles in the muffle furnace and ash at 500°C.

9.2.5 When the ashing appears to be complete (approximately 1 to 2 h), remove the crucibles from the muffle furnace and allow to cool to room temperature in a desiccator. Weigh and calculate the mean value for the percent ash.

9.3 Transfer each ash to a clean, dry mortar and grind to a fine, uniform powder. Weigh to the nearest 0.1 mg, 0.02 to 0.2 g of each ash directly into separate decomposition vessel inserts.

NOTE 3—For a material containing 50 ppm (mg/kg) of chromium based on the solids and having 50 % ash and 70 % nonvolatile material, 0.2 g of ash extracted and diluted to 50 mL will contain 0.28 μg of chromium per millilitre, and for one containing 10 000 ppm, 0.02 g of ash extracted and diluted to 100 mL will contain 2.8 μg of chromium per millilitre. To ensure complete recovery of chromium, do not use more than 0.05 g of ash for materials that are known or suspected to contain over 1000 ppm of chromium based on the solids.

9.4 Pipet exactly 10 mL of oxidizing solution into the cup. Swirl gently to facilitate mixing. Place the vessel in a circulating oven at 105°C for 1½ h.

9.5 Remove the vessel from the oven and allow to cool slowly to ambient temperature. Do not cool by placing the vessel in a refrigerator or freezer, or by submerging it in a

cooling liquid. When cooled, carefully unseal the vessel in a fume hood.

NOTE 4—When the vessel is disassembled, if the solution does not show the presence of excess permanganate, repeat the digestion using a smaller weight of ash.

9.6 Quantitatively filter the contents through filter paper directly into a 50 or 100-mL volumetric flask. Rinse the digestion cup several times with water, transferring any insoluble material to the filter paper. Wash the filter paper several times with small volumes of water. Add hydroxylamine hydrochloride solution dropwise to the filtrate until the permanganate color has been discharged, then dilute to volume with water.

9.7 Aspirate each test solution and determine the absorbance in the same manner in which the instrument was calibrated. Determine the concentration of chromium in micrograms per millilitre from the appropriate calibration curve. If the absorbance is above the range covered by the calibration curve, dilute an aliquot of the test solutions to a suitable volume with H_2SO_4 (5 % volume per volume) and repeat the determinations.

NOTE 5—The method of standard additions may be used to improve the accuracy of the analysis. This test method is particularly recommended for use with unknown samples where matrix effects may be potentially significant. For a detailed description of the procedure and calculations used in the method of standard additions, consult a standard text on atomic absorption spectroscopy or the instruction manual provided by the instrument manufacturer.

10. Calculation

10.1 Calculate the mean concentration of chromium in the nonvolatile portion of the sample as follows:

$$\text{Chromium, ppm (mg/kg) in nonvolatile} = (C \times F \times A \times V) / (S \times NV)$$

where:

- C = concentration of chromium in the aspirated test solution, $\mu\text{g/mL}$,
 F = dilution factor from 9.7 (volume diluted to volume of aliquot),

- A = mean percent ash as determined in 9.2.5,
 V = volume diluted to in 9.6 (50 or 100 mL),
 S = weight of ash, and
 NV = percent nonvolatile of paint sample (use 100 if sample was a dried film).

11. Report

11.1 Report the chromium content of the nonvolatile portion of the sample tested and whether the analysis was conducted on a liquid coating or a dried film.

12. Precision and Bias⁷

12.1 The precision estimates are based on an inter-laboratory study in which six different laboratories analyzed in duplicate, on two different days, four samples of water-reducible paints and four samples of solvent-reducible paints containing from 50 to 10 000 ppm (mg/kg) chromium. The within-laboratory coefficient of variation was found to be 4.9 % relative at 39 degrees of freedom and the between-laboratory coefficient of variation was 8.5 % relative at 31 degrees of freedom. Based on these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

12.1.1 *Repeatability*—Two results, each the mean of duplicate determinations, obtained by the same operator on different days should be considered suspect if they differ by more than 14 % relative.

12.1.2 *Reproducibility*—Two results, each the mean of duplicate determinations, obtained by operators in different laboratories should be considered suspect if they differ by more than 24 % relative.

12.2 *Bias*—The mean of duplicate determinations within any laboratory should be within 17 % relative of true value.

13. Keywords

13.1 AAS, chromium; low concentration of antimony in paints

⁷ Supporting data are available from ASTM Headquarters. Request RR: D01-1012.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. Standard Test Method for Quantifying Dirt Collection on Coated Exterior Panels¹

This standard is issued under the fixed designation D 3719; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

1. Scope

1.1 This test method covers an instrumental procedure for quantifying the degree of dirt collection on exposed exterior coated panels.

1.2 This test method is limited to those coated exterior panels with lightness values before exposure greater than that of dirt, that is, above a value of 52.

1.3 The instrumental readings do not distinguish between dirt collection and mildew growth.

1.4 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels²

D 2244 Test Method for Calculation of Color Differences from Instrumentally Measured Color Coordinates²

D 3274 Test Method for Evaluating Degree of Surface Disfigurement of Paint Films by Microbial (Fungal or Algal) Growth or Soil and Dirt Accumulation²

3. Definition

3.1 *dirt collection*—the deposit of foreign matter consisting of dirt, soot, or stain present on the surface of exposed exterior coated panels.

3.1.1 This test method measures total dirt collection. Loose dirt may be washed and removed from specimens if only imbedded dirt collection is to be measured.

4. Summary of Test Method

4.1 Lightness readings using a color difference meter are made before and after exposure, and the difference is considered to be due to dirt collection.

5. Significance and Use

5.1 Change in color or appearance of coated exterior surfaces due to such factors as dirt collection or retention is undesirable. If Test Method D 3274 or other test methods

are used to establish that dirt collection is the primary cause of such a change, this test method can be used to quantify the degree of dirt collection or, more properly, the degree of change in visual appearance of the coated surface due to dirt collection.

5.2 When used in this manner and with color change, exposure duration and environment specified, this test method can provide a performance specification with respect to dirt collection.

6. Apparatus and Materials

6.1 *Color Difference Meter*, complying with Method D 2244.

6.2 *Test Panels*, of any convenient size and of substrate suitable for exterior use.

7. Preparation of Test Panels

7.1 Apply the material under test to the test panels in accordance with Test Method D 823, or as agreed upon between the purchaser and the seller. Allow the final coat of air drying systems to cure for 7 days before exposure.

8. Procedure

8.1 Operate the color difference meter in accordance with the manufacturer's instructions. Standardize with either a primary or working standard as defined in Test Method D 2244. Restandardize at sufficient intervals, in accordance with the manufacturer's instructions, to minimize the effects of instrumental drift.

8.2 Determine the metric lightness, L^* , in the CIE 1976 $L^*a^*b^*$ Uniform Color Space (CIE LAB), for each unexposed panel at three marked, random locations. Calculate the arithmetic mean, L^*A .

8.3. Expose the panels at a 45° angle to the horizontal facing the equator at an exterior location for 61 days.

8.3.1 The calendar time, location, angle of exposure, orientation, exposure time, and method of exposure may be modified by mutual agreement.

8.4 Remove the panels and determine, using the procedure outlined above, the percent light reflectance value, L^* , for the exposed panels. Calculate the arithmetic mean of the marked locations, L^*B .

9. Calculations

9.1 Compute the dirt collection index, D_c , as follows:

where:
 L^*A = ar
 L^*B = ar

10. Report

10.1 Re

10.1.1 value, and as well as exposed p value.

10.1.2 other than

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.52 on Factory-Coated Wood Products.

Current edition approved Oct. 30, 1987. Published December 1987. Originally published as D 3719 - 78. Last previous edition D 3719 - 80.

² Annual Book of ASTM Standards, Vol 06.01.

$$D_c = \frac{L^*B}{L^*A} \times 100$$

where:

L^*A = arithmetic mean of unexposed panel values, and
 L^*B = arithmetic mean of exposed panel values.

10. Report

10.1 Report the following information:

10.1.1 Arithmetic mean and range of each panel's L_x value, and whether fungal growth is included in the reading, as well as the calculated dirt collection index. Report if the exposed panel was washed before taking the light reflectance value.

10.1.2 Any noticeable color change which, for reasons other than dirt accumulation, may have occurred. The dirt

collection index is not valid if these color changes or fungal growth are significant.

10.1.3 Description of the method of panel preparation, including substrate identity, coating types, number of coatings used, methods of application, coverage, and drying conditions.

10.1.4 Description of the exposure conditions including location and calendar time of exposure period.

10.1.5 Identification of the color difference meter by manufacturer's name and code number.

10.1.6 Which Adams color scale was used.

11. Precision and Bias

11.1 *Precision*—Precision of the dirt collection index has not been determined but the precision of the lightness values used in its calculation has been defined.

11.2 *Bias*—Bias cannot be determined.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. Standard Test Method for Pigment Content of Water-Emulsion Paints by Low- Temperature Ashing¹

This standard is issued under the fixed designation D 3723; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Section 9 was added editorially in May 1990.

1. Scope

1.1 This test method covers a procedure for the pigment content determination of water-based paints. It is applicable only to pigments that do not decompose or lose weight at temperatures below 500°C. Such pigments include most metal oxides, silicates, and a majority of anhydrous inorganic salts.

1.2 Many water-based paints contain pigments and organic colorants that lose water of hydration or decompose at this temperature. The residual ash should be carefully inspected for changes in color or texture that could indicate a pigment alteration and hence lead to erroneous results. Caution should therefore be exercised when applying this test method to samples containing unknown pigment compositions.

1.3 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

- 2.1 *ASTM Standard:*
D1193 Specification for Reagent Water²

3. Significance and Use

3.1 This test method is used by paint producers and consumers for product process control and for product acceptance.

4. Apparatus

- 4.1 *Oven*, forced draft, maintained at $105 \pm 2^\circ\text{C}$.
4.2 *Furnace*, muffle, maintained at $450 \pm 25^\circ\text{C}$.
4.3 *Syringe*, 5-mL.
4.4 *Aluminum Foil Dish*, 58 mm in diameter by 18 mm high with a flat bottom. The bottom of the dish should be as nearly flat as possible so that a uniform film is produced.

5. Reagents

- 5.1 *Purity of Reagents*—Reagent grade chemicals shall be

used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.³ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water conforming to Type III of Specification D 1193.

5.3 *Ammonium Hydroxide*⁴—Add 1 volume of concentrated NH_4OH (sp gr 0.90) to 3 volumes of water.

6. Procedure

6.1 Mix samples until homogeneous, preferably on a mechanical shaker. If air bubbles become entrapped in a sample, stir it by hand.

6.2 Draw approximately 1.5 g of the test paint into a 5-mL syringe and weigh to 1 mg. Add the paint dropwise (about 30 drops) into a tared-aluminum foil dish that contains 2 mL of water (5.2). Swirl the dish during the addition and continue the swirling until the specimen is completely dispersed. Reweigh the syringe to 1 mg. Transfer between 0.4 and 0.6 g of sample to the dish. If not, adjust the transferred volume and prepare a new specimen. If the specimen agglomerates or forms a lump that cannot be dispersed, a drop or two of ammonia (5.3) may facilitate the dispersement. If the lumping persists, discard the specimen and prepare a new one. Prepare a duplicate specimen in the same manner.

6.3 Dry the specimen and dishes in the $105 \pm 2^\circ\text{C}$ oven for a minimum of 1 h after making certain that the dishes are level. If the coating does not uniformly cover the bottom of a dish, prepare a new specimen and repeat.

NOTE—The percent nonvolatile content, N , at 105°C may be determined by drying dishes to constant weight and calculating as follows:

$$N = \frac{A - B}{S} \times 100 \quad (1)$$

where:

A = weight of dish and specimen after heating,

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Materials.

Current edition approved Oct. 26, 1984. Published January 1985. Originally published as D 3723 - 78. Last previous edition D 3723 - 78.

² *Annual Book of ASTM Standards*, Vols 06.03 and 11.01.

³ "Reagent Chemicals, American Chemical Society Specifications," Am. Chem. Soc., Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY, and the "United States Pharmacopeia."

⁴ For guidance in the safe handling of ammonium hydroxide consult the Manufacturing Chemists Association's Chemical Safety Data Sheet.

B = weight of dish alone, and
 S = specimen weight.

6.4 Transfer the dishes to a muffle furnace and heat at $450 \pm 25^\circ\text{C}$ for 1 h. Remove from the furnace, cool in a desiccator and weigh.

7. Calculation

7.1 Calculate the percent pigment content, P , as follows:

$$P = \frac{C - B}{S} \times 100 \quad (2)$$

where:

C = weight of the dish and specimen after ignition in the furnace,

B = weight of the dish alone, and

S = specimen weight.

8. Precision and Bias⁵

8.1 *Precision: Pigment Content*—On the basis of an interlaboratory test of this test method in which eighteen operators in nine laboratories analyzed three materials containing three pigment levels between 24 and 28 %, the within-laboratory standard deviation was found to be 0.24 % absolute and the between-laboratories 0.38 % absolute. Based on these standard deviations, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

8.1.1 *Repeatability*—Two results obtained by the same operator should be considered suspect if they differ by more than 0.66 % absolute.

8.1.2 *Reproducibility*—Two results, each the mean of duplicate determinations, obtained by operators in different laboratories should be considered suspect if they differ by more than 1.05 % absolute.

8.2 *Bias: Pigment Content*—On the basis of the same study, the mean of two determinations should be within 5 % relative of the formula pigment content of a waterborne paint containing only inorganic pigments.

8.3 *Precision: Nonvolatile Content*—On the basis of an interlaboratory test of this test method in which fourteen operators in seven laboratories analyzed three materials containing three nonvolatile levels between 43 and 48 %, the within-laboratory standard deviation was found to be 0.18 % absolute and the between-laboratories standard deviation was found to be 0.445 % absolute. Based on these standard deviations the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

8.3.1 *Repeatability*—Two results obtained by the same operator should be considered suspect if they differ by more than 0.49 % absolute.

8.3.2 *Reproducibility*—Two results, each the mean of duplicate determinations, obtained by operators in different laboratories should be considered suspect if they differ by more than 1.23 % absolute.

9. Keywords

9.1 low-temperature ashing; pigment content; water emulsion paints

⁵ Supporting data are available from ASTM Headquarters. Request RR:D01.1014.

Standard Guide for Testing High-Performance Interior Architectural Wall Coatings¹

This standard is issued under the fixed designation D 3730; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{ε1} NOTE—Editorial changes were made throughout, including the title, in October 1988.

1. Scope

1.1 This guide covers the selection and use of test methods for high-performance interior architectural wall coatings (HIPAC) that differ from more conventional coatings in that they are tougher, more stain-resistant, more abrasion-resistant and, ordinarily, designed to be applied to wall surfaces of steel, masonry (poured concrete, concrete block, or cinder block), and plaster or gypsum wallboard. The tests that are listed in Tables 1 and 2 are designed to measure performance properties. These tests may not all be required for each HIPAC system. Selection of the test methods to be followed must be governed by experience and the requirements in each individual case, together with agreement between the purchaser and the seller.

1.2 High-performance architectural coatings are tough, extra-durable organic coating systems that are applied as a continuous (seamless) film and that cure to a hard finish. The finish can be high gloss, semigloss, or low gloss as desired. These coatings are resistant to persistent heat, humidity, abrasion, staining, chemicals, and fungus growth. They are used in areas where humidity, wear, or unusual chemical resistance requirements, particularly to soiling, are required and where strong detergents are used to maintain sanitary conditions. Halls and stairways in public buildings, lavatories, stall showers, locker areas, animal pens, and biological laboratories are typical applications. In addition, food processing plants, dairies, restaurants, schools, and transport terminals frequently use HIPAC systems. These are effective in many areas of building interiors compared with tile and are of low materials and maintenance costs. HIPAC systems should be used as a complete system only as recommended by the manufacturer since the individual coats in a system are formulated to be compatible with each other. HIPAC systems should be applied only to properly prepared surfaces such as steel and masonry that includes cinder blocks and cement blocks. They can be applied over plaster and gypsum wallboard. Ordinarily, a prime or fill coat, if required, is part of the system.

1.3 While they are excellent for walls, HIPAC are not usually intended for ceilings and floors. They would not ordinarily be used in homes, although parents with small children might want to use HIPAC coatings on some walls.

1.4 The types or resin ordinarily used are the following: epoxy-polyamide, two-package; polyester-epoxy type, two-package; polyurethane, one-package or two-package. However, other resin types are not excluded provided they can meet the requirements (performance specifications) laid down by the purchaser.

1.5 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* For a specific hazard statement, see the Note in 7.5.

MIL-C-83286, Determination of Free Aliphatic Diisocyanate Monomer by Infrared Spectroscopy

3. Definitions

3.1 For definitions of terms used in these practices, refer to Definitions D 16.

4. Conditions Affecting Performance of HIPAC Coating Systems

4.1 Practical requirements for high performance coatings may vary with:

4.1.1 Substrate type such as concrete, poured or precast block, lime-gypsum plaster, etc.

4.1.2 Climatic conditions, both generally and specifically, at the time of coating application. ASTM standard conditions for laboratory testing are 73.5 ± 3.5°F (23 ± 2°C) and 50 ± 5 % relative humidity.

5. Sampling

5.1 Prior to sampling, establish the condition of the container since damage to it may cause evaporation, skinning, or other undesirable effects. Excessive storage time and temperature fluctuations may cause settling or changes in viscosity.

5.2 Sample the coating in accordance with the Practice E 300. Determine the weight per gallon or kilogram per litre in accordance with Test Method D 1475 and repeat until two successive readings agree within 0.2 lb (90 g) or as agreed upon between the purchaser and the seller. Samples for testing may then be taken.

5.3 Specify the amount of the sample, the package sizes, and identification codes to assure a representative sample. A 1-gal (3.8-L) sample is usually sufficient for the recommended tests but the practice gives sample size in relation to quantity and size of container.

6. Laboratory Tests

6.1 Preparation of Test Panels:

6.1.1 Unless otherwise specified, test panels shall be 1½ by 7½ by 15½-in. (38 by 190 by 395-mm) masonry units made from either standard lightweight concrete block, having an apparent specific gravity of 1.60 to 1.62 or smooth asbestos cement board complying with Specification C 220.

6.1.2 One face only of the test panel shall be coated with the complete system, in a vertical position. For concrete, the filler shall either comply with U.S. Federal Specification TT-F-1098 or be the material specified and supplied by the manufacturer. The filler coat shall be applied in conformance with the manufacturer's printed directions for surface preparation, mixing, application, coverage, and curing time under standard conditions of temperature and humidity.

7. Liquid Coating Properties

7.1 Condition in Container—Thickening, settling, and separation are undesirable and objectionable if a coating, after storage, cannot be readily reconditioned and made suitable for application with a reasonable amount of stirring. The referenced method covers procedures for determining changes in properties after storage. Determine the condition in the container in accordance with Method 3011 of Federal

TABLE 1 List of Test Methods by Properties

Test Method	Section	ASTM Test Method	Federal Test Method Standard No. 141
Liquid coating properties:			
Condition in container	7.1	...	3011
Coarse particles and foreign matter	7.2	D 185, Section C	
Density or weight per gallon	7.3	D 1475	
Fineness of dispersion	7.4	D 1210	
Odor	7.5	D 1296	
Consistency	7.6	D 562

^A Modified.

Test Method Standard No. 141.

7.2 Coarse Particles and Foreign Matter—Coatings must be free of oversize particles and foreign matter to form a uniform film of good appearance, a typical maximum being 0.5 weight % of total coating. The specified test with a No. 325 (45- μ m) screen gives the percent of these particles in a material. Determine coarse particles and foreign matter in accordance with Test Methods D 185, Section C.

7.3 Density or Weight Per Gallon—The density of a coating as measured by weight per gallon is used to assure product uniformity from batch to batch and provides a check against the theoretical weight calculated from the formula. The referenced test method gives a procedure for measurement of the density of a liquid coating. The density is expressed as weight in pounds per 1 U.S. gal or in kilograms per litre of the coating at a specified temperature. A calibrated weight-per-gallon cup is used. Determine weight per gallon in accordance with Test Method D 1475.

7.4 Fineness of Dispersion—One method for measuring the degree of dispersion is to draw a liquid coating down in a tapered groove in a hardened steel block with a groove varying in depth from 4 to 0 mils (100 to 0 μ m). The point at which continuous groupings of particles or agglomerates, or both, protrude through the surface of the wet film is taken as

the fineness reading. Lower readings in mils or micrometers or higher readings in Hegman units indicate better dispersion. A typical fineness of dispersion requirement is a reading of 1.5 mil (38 μ m) or 5 Hegman for HIPAC. Determine fineness of dispersion in accordance with Test Method D 1210.

7.5 Odor—Adequate ventilation is required as some solvent combinations produce obnoxious odors. Test for odor in accordance with Test Method D 1296.

NOTE: Warning—Even though the odor may be pleasant, the fumes may be dangerously toxic.

7.6 Consistency—Coatings of a given type should fall within a consistency range agreed upon. In the referenced test method, consistency is defined as the load in grams required to produce a specified rate of shear. A typical range is 85 to 135 Krebs' unit (KU) for base coats and 70 to 95 KU for glaze coats. Determine the consistency of the product in accordance with Test Method D 562.

7.7 Dilution Stability—The diluent suggested for reduction should be readily incorporated into the coating without excessive stirring or shaking. This test is a measure of the stability of a coating that has been reduced to a desired viscosity, for example, for spray application. Determine

^A Modified.

dilution stability in accordance with Method 4203 of Federal Test Method Standard No. 141.

7.8 Flash Point—Organic solvents used in coatings have characteristic temperatures at which they will support combustion. This temperature is known as the flash point. It is often used for danger classification in shipment by common carriers. It is also used to determine conditions of storage to meet fire regulations and also the safety requirements of the Occupational Safety and Health Act (OSHA). This temperature is not directly translatable as the danger level when applied as films to surfaces. Determine the flash point in accordance with Test Methods D 93, when in closed or open cups.

7.9 Free Diisocyanate Content—It is generally recognized that diisocyanate vapors from polyurethane-type HIPAC coatings are potential health hazards. Therefore, the free diisocyanate content of urethane coating systems must be controlled at an acceptable maximum level, the present accepted maximum being 0.5 % based on total coating weight, which is applicable only to toluene diisocyanate (TDI) and hexamethylene diisocyanate (HMDI). It has not been shown that this level is applicable to all diisocyanates. Determine free toluene diisocyanate content in accordance with Test Method D 2615. There is no ASTM test method applicable for the other diisocyanates, but test methods are now being developed by ASTM. The presence of free HMDI can be determined by the method described in Appendix I of U.S. Military Specification MIL-C-83286.

7.10 Volatile Content (Weight Percent)—The percent of volatile matter indicates the thinner loss from the film as it dries. Calculate the volatile content of the coating by difference after determining the nonvolatile content in accordance with Test Methods D 1644.

8. HIPAC Application and Film Formulation

8.1 Application by Brush—Brushed films should be smooth and free of seeds and on vertical surfaces should show no sagging, color streaking, or excessive brush marks. Test application or brushed films in accordance with Method 2141 of Federal Test Method Standard No. 141.

8.2 Application by Roller—Walls are frequently painted with rollers that produce slight stipple effects. Test roller coating properties in accordance with Method 2112 of Federal Test Method Standard No. 141.

8.3 Application by Spray—Interior coatings are sometimes applied by spray. Both air and airless spray are used in commercial work. Test in accordance with Method 2131 of Federal Test Method Standard No. 141.

8.4 Leveling Properties—Leveling is a factor in hiding and appearance of coatings. The referenced test method covers the laboratory determination of the relative leveling characteristics of liquid coatings. Determine leveling property in accordance with Test Method D 2801.

8.5 Working Properties—Working properties of a coating are generally compared to a standard or described by requirement in the product specification. Test working

properties in accordance with Method 4541 of Federal Test Method Standard No. 141.

8.6 *Sag Resistance*—Some coatings sag and form curtains before the film sets. Test for sag resistance in accordance with Method 4494 of Federal Test Method Standard No. 141.

8.7 *Wet Film Thickness*—Measurement of wet film thickness is useful in calculating spreading capacity or adjusting application to an agreed upon square feet per gallon or square metres per litre. Determine wet film thickness in accordance with Test Methods D 1212.

8.8 *Producing Films of Uniform Thickness*—The following test method covers the preparation of enamel films of uniform thickness essential in conducting various tests. Prepare films in accordance with Test Methods D 823.

8.9 *Curing Time*—The cure of a HIPAC system is governed by the composition of the coating and by atmospheric conditions during cure. Insufficient cure may result in poor stain and abrasion performance. Typical cure times are between 3 and 21 days depending upon the system. There are no applicable ASTM or Federal test methods to measure cure of HIPAC systems, but one method used is as follows:

8.9.1 After the final cure for the duration specified by the manufacturer, place 10 drops of acetone on the coated surface and cover with a 25-mm watchglass. After 3 min lift the watchglass and remove the acetone by blotting. Allow a recovery period of 1 h and examine for evidence of softening or wrinkling of the coating.

9. Appearance of Dry Coating

9.1 *Color Difference*—Visual comparison of color is fast and often acceptable, although numerical values are not obtained. However, the appearance of a color is greatly influenced by several factors.

9.1.1 A color next to a yellow wall will look different than the same color next to a blue wall. The same color illuminated by incandescent light, fluorescent light, and natural northern light, will appear to be different because the spectral makeup of the incident lights vary.

9.1.2 Gloss also affects color appearance. The same color with a low gloss and high gloss will usually appear to differ, although instrumentally the colors may be identical. The reason is that the color seen is different when the incident light is unevenly scattered by the rougher surface of the low-gloss finish. Often times, the paint manufacturer is expected to produce color matches for all sorts of incident conditions. Hence, the method given in Method 4250 of Federal Test Method Standard No. 141 provides a reasonably accurate method of visual comparison using natural northern light as the incident source. Where a more accurate method of visual comparison is desired, Practice D 1729 should be employed since it specifies the composition of the incident light.

9.1.3 Determination of color difference by instrument in accordance with Method D 2244 is the more reproducible, but visual perception is the more nearly related to the needs in actual use, where the conditions are unpredictable but may be expected to include many types of lighting.

9.2 *Directional Reflectance*—This is an important property of a white coating as it is a measure of the brightness of the surface. Frequently the reflectance of a white coating

may be reduced to increase hiding power. To maintain brightness, a typical minimum reflectance value of 84 may be specified for white. Determine directional reflectance in accordance with Test Method E 97.

9.3 *Gloss (60-deg Specular)*—Semigloss HIPAC coatings are particularly sensitive to loss of gloss due to differential absorption on some surfaces. This is often controlled by testing the gloss of a system applied over a nonabsorbent substrate such as glass and an absorbent surface like gypsum board. Determine the specular gloss on appropriate substrates in accordance with Test Method D 523.

9.4 Hiding Power:

9.4.1 Hiding power is a measure of the ability of a coating to hide the substrate. However hiding power of a white coating is inversely related to its reflectance so that it decreases with increasing directional reflectance. Hiding power is expressed as area covered per unit volume of coating to produce a reflectance over a black surface that is 98 % of the reflectance over a white surface (contrast ratio of 0.98).

9.4.2 Hiding power by contrast ratio can be determined by application of a coating to black and to white glass panels or to black and white charts. The former is more accurate and is the preferred procedure in Test Method D 2805, which also employs automatic film application to eliminate rheological effects. Method 4122 of Federal Test Method Standard 141 is a less detailed procedure using drawdown application on black and on white glass. Contrast ratio on black and white charts can also be determined in accordance with Procedure B of Method 4121.

9.4.3. Hiding power is determined in Test Method D 344 by comparison of brush application of the material under test and a standard coating.

9.4.4 Determine hiding power by one of the above methods consistent with the degree of importance attached to this parameter.

10. Properties of Dry Coatings

10.1 *Abrasion Resistance*—Wear resistance of HIPAC coatings is one of the outstanding qualities which distinguishes them from ordinary interior wall and trim enamels. Determine abrasion resistance in accordance with Method 6192 of Federal Test Method Standard No. 141.

10.2 *Adhesion*—Adhesion is the property of the film that resists removal from the substrate when scuffed or scraped and is an important property in a HIPAC system. There are no applicable ASTM or Federal test methods to measure adhesion of HIPAC systems, but one method used is as follows:

10.2.1 Attach heavy screw eyes to one end of each of twelve 1-in. (25-mm) diameter wood or metal dowels approximately 1½ in. (38 mm) long. Glue the dowels to the cured coating on a test panel at 3-in. (75-mm) centers, using a cold-curing epoxy adhesive applied to both the coating and the dowel. Make sure that the button of adhesive does not extend beyond the diameter of the dowel or the area will be larger than intended. After conditioning for 3 days at 73.5 ± 3.5°F (23 ± 2°C), slowly apply an axial pull of 150 lbf (680 N) to each of three dowels. The force may be applied by any method having an accuracy of 5 %, such as by a system of weights and pulleys or through a spring scale (spring bal-

ance). To provide a surface having through removal of between the occurs between

To prevent injury should the dowel come loose, provide a suitable guard by placing over the dowel a length of pipe having a cap at one end and a drilled hole in the cap through which to apply the force. Failure is defined as removal of at least one of the three dowels due to separation between the test panel and the top or glaze coat(s). If failure occurs between the adhesive and the coating, test an additional dowel.

10.2.2 If the above portion of test is passed, place the test panel coated side up in a pan containing water maintained at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$). Keep about 0.5 in. (13 mm) of water in contact with the uncoated portion of the panel. At the end of 7 days, pull three more dowels, using a force of 20 lbf (90 N). Dry the coating for 24 h and pull three more dowels, using a force of 30 lbf (135 N).

10.3 *Chemical Resistance*—An important property of a HIPAC system is its ability to resist spotting, softening, or removal when subjected to household chemicals or strong cleaners. There is no applicable ASTM or Federal test method specifically designated for measuring resistance of HIPAC systems to chemical and cleaning agents, but Test Method D 1308 has been modified as follows: Prepare 5 weight % solutions of sodium hydroxide, sodium hypochlorite, detergent, hydrochloric acid, sodium phosphate, and sulfuric acid. For each solution saturate a small piece of absorbent cotton, place them on the cured surface, and cover with a 25-mm watchglass. After 4 h, remove, blot dry, allow to recover for 24 h, and examine the exposed surface of the coating for evidence of softening or wrinkling.

10.4 *Coating Thickness*—Measure total dry film thickness from the top of the substrate to the top of the applied coating system. When applied to steel, use Test Methods D 1186. When applied to nonmagnetic surfaces, use Test Methods D 1005 if the surface is plain and rigid.

10.5 *Flame Spread Test*—For some uses HIPAC coatings should not increase fire hazard. Where required, determine the flame spread and smoke development rating in accordance with Test Method E 84.

10.6 *Fungus Resistance*—Since HIPAC coatings may be used in food processing plants and locations of high humidity, they should be resistant to mold growth on the surface. For this test, an environmental chamber is needed. Determine the resistance to mold growth in accordance with Test Method D 3273.

10.7 *Heat and Cold Resistance*—Buildings can undergo cycling of temperatures that could, through differential thermal expansion between the coating and the masonry substrate, cause failure. There is no applicable ASTM or Federal test methods specifically designated for measuring resistance of HIPAC systems to cold and heat cycles but Test Method D 1211 has been modified as follows:

10.7.1 Place coated panels of the substrate of interest in a cold chamber maintained at 5°F (-21°C) for 1 h. Remove and immediately place in an oven maintained at 120°F (49°C) for 1 h. Repeat this cycle 10 times and examine the coating for cracks, checks, or other defects.

10.8 *Heat and Humidity Resistance*—HIPAC coatings can be subjected to environmental conditions where high heat and humidity are present. There is no applicable ASTM or Federal test method specifically designated for measuring resistance of HIPAC systems to heat and humidity but

Practice D 2247 has been modified as follows:

10.8.1 Coat panels with the complete system and expose to an environment of 95 % relative humidity minimum, and 140°F (60°C) for 7 days in an enclosed cabinet. Determine the 60-deg gloss before and after by Test Method D 523 and color change by Method D 2244.

10.9 *Impact Resistance*—An important property of HIPAC coatings is their ability to withstand impact when objects are accidentally knocked against them. Determine impact resistance in accordance with Test Method D 2794, except use zinc phosphate-treated steel panels. Some materials, such as urethanes, require a wash primer or an epoxy primer to give the adhesion needed for this test. Apply top or glaze coat(s) at a minimum dry-film thickness of 3 mils (75 mm) and examine the surface of the impacted coated area under $7\times$ magnification for cracking and crazing of the coating immediately after testing and 72 h after the test.

10.10 *Perspiration Resistance*—HIPAC coatings can sometimes come in contact with perspiration that could stain the coating. There are no ASTM or Federal test methods to measure perspiration resistance of HIPAC systems but where considered important the following method can be used:

10.10.1 Prepare synthetic perspiration fluid having the following composition by weight:

Urea	1.30
K_2CO_3	0.11
$\text{Na}_2\text{SO}_4 \cdot 10 \text{H}_2\text{O}$	0.65
NaCl	2.71
Acetic acid (5 % solution)	1.08
H_2O	10.85
Anhydrous lanolin	83.30

10.10.1.1 Dissolve the urea and inorganic salts in the acetic acid solution and water. Heat the lanolin to 45°C and add the solution to form an emulsion. Combine with a dye and wetting agent in the following proportions:

Scarlet red	0.1
Methanol	3.7
Wetting agent	3.8
Synthetic perspirant	92.4

10.10.1.2 Dissolve the dye in the methanol, then mix with the wetting agent and synthetic perspirant. Apply an excess of the mixture to a small area of a test panel, using a 1 in. (25 mm) wide artist's brush. Cover with a 25-mm watchglass and place the panel in an oven at $120 \pm 3.5^\circ\text{F}$ ($49 \pm 2^\circ\text{C}$), for 4 h. Remove the panel and allow to cool at room temperature for 1 h. Wipe off the excess with a soft dry cloth. If the stain is not completely removed, subject the panel to not more than 25 cycles of the washing procedure described in Method 6141 of Federal Test Method Standard No. 141. Examine the film under $7\times$ magnification for stain retention.

10.11 *Scrubability*—The ability of an interior finish to resist scrubbing is an important property. The referenced method provides a measure of the wet abrasion resistance of a film. However, wet abrasion resistance is not necessarily a measure of how well soils or stains can be removed since some porous materials have good scrubability but poor stain cleansability. Test the coating for at least 4000 cycles in accordance with Method 6142 of Federal Test Method Standard No. 141 except use smooth cement asbestos board complying with Specification C 220 as substrate. Apply the coating system to be tested in conformance with the manufacturer's printed directions for surface preparation, mixing,

application, coverage, and curing time (usually 21 days) at standard conditions of temperature and humidity.

10.12 *Cleansability*—The ability to remove marks satisfactorily without damaging the film is an important property of interior finishes. A test method to determine how well stain and soils can be removed from a cured film is now in preparation and will be included in the guides when it is approved by ASTM. Test methods used by the paint industry consist of applying various household soils or stains to the cured film and attempting to remove them by a washing or scrubbing operation. A suggested test for washability, based on Method 6141 of Federal Test Method Standard No. 141 is given below:

10.12.1 *Coating Application*—Coat a test panel approximately 12 by 4 in. (305 by 102 mm) with the complete system of the product under test, applying the glaze or top coating to at least 3-mils (75-mm) dry-film thickness is not more than two coats. Allow to cure under standard condi-

tions for the time specified by the manufacturer but not more than 21 days.

10.12.2 *Stain Application*—Typical household stain media are coffee, grape juice, ink, soil, crayon, and lipstick. (See Practice D 3023 for specific materials.) Apply the stain media about 1 in. (25 mm) apart in the center of the panel. Apply crayon and lipstick by normal hand pressure; smear coffee, grape juice, and ink with an artist's brush; apply soil under load by placing a 1-lb (500-g) weight on top of an applicator in such a manner that the soil is uniform in thickness.

10.12.3 *Removal of Stain*—After allowing the stains to set for 24 h under standard conditions, wash the stains for 100 cycles in accordance with Method 6141 of Federal Test Method Standard No. 141. Observe the panel for stain removal during and at the end of 100 cycles. If a stain is removed in 100 cycles or less, report the number of cycles required. If not removed in 100 cycles, report the test as a failure.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

1. Scope

1.1 This test method covers the determination of the resistance of a coating to energy.

3. Terminology

3.1 Descriptions of Terms Specific to This Standard:

- 3.1.1 *cure*—the condition of a coating after conversion to the final state of cure as measured by tests generally related to end-use performance and mutually agreeable to supplier and purchaser.
- 3.1.2 *ultraviolet curing*—conversion of a coating from its application state to its final use state by means of a mechanism initiated by ultraviolet radiation generated by equipment designed for that purpose.

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.55 on Factory-Applied Coatings on Preformed Products.
Current edition approved Oct. 29, 1982. Published January 1983. Originally published as D 3732 - 78. Last previous edition D 3732 - 78.

² Annual Book of ASTM Standards, Vol 06.01.

4. Significance and Use

- 4.1 This practice provides a guide whereby all pertinent variables relating to the ultraviolet cure of a coating are described.

5. Procedure

- 5.1 Apply the coating to be cured to the desired substrate at a film thickness typical to that normally used. After approximately the time delay encountered in production pass the coated substrate through the curing equipment and subsequently test for cure, as defined in 3.1.1, using the appropriate methods listed in 5.1.1 through 5.1.11. The most commonly used test methods are listed in 5.1.1 through 5.1.4.

5.1.1 Impact Resistance—Test Method D 2794.

5.1.2 Film Hardness—Test Method D 3363.

- 5.1.3 *Solvent Rub Test*—Hold a pad of cheesecloth or other cloth saturated with an agreed-upon solvent, usually methyl ethyl ketone, over two adjacent fingers using a protective covering. Rub the wet pad back and forth across a 100-mm portion of the cured film using vigorous pressure, one forward and one backward movement constituting one double rub. Take the end point as the number of double rubs required to soften or penetrate the film. Fully cured films are normally required to resist a specified number of rubs and the result of the test is given as exceeding the limit or failing the test.

- 5.1.4 *Sandability*—Ultraviolet cured fillers are usually judged by their sandability with an agreed-upon grit of paper. This test is often made immediately after the material leaves the ultraviolet processor.

5.1.5 Specifying Properties—Practice D 2336.

5.1.6 Abrasion Resistance—Test Methods D 658 and D 968.

5.1.7 Indentation Hardness—Test Methods D 1474.

5.1.8 Adhesion—Test Methods D 2197 and D 3359.

5.1.9 Block Resistance—Test Method D 2793.

5.1.10 Formability—Test Method D 3281.

5.1.11 Stain and Reagent Resistance—Practice D 3023.

- 5.2 Repeat the application, curing, and testing with fresh material on fresh substrates until the shortest time that yields a cured film is obtained.

6. Report

- 6.1 Ultraviolet curing equipment is available with several design variables. Therefore, include the following information with results where applicable:

6.1.1 Number of bulbs,

- 6.1.2 Bulb type (intensity, spectral distribution, composition),
- 6.1.3 Bulb age,
- 6.1.4 Bulb location (height from work and orientation to workpiece),
- 6.1.5 Reflector design,
- 6.1.6 Conveyor speed or exposure time to achieve cure,
- 6.1.7 Substrate,
- 6.1.8 Coating identification and age of sample if known,

- 6.1.9 Wet film thickness,
- 6.1.10 Temperature conditions in the curing unit,
- 6.1.11 Curing environment (air, nitrogen, or other atmosphere),
- 6.1.12 Cure tests used (refer to Section 5), and
- 6.1.13 Age of cured film when tests were run.

7. Keywords

- 7.1 cure time; ultraviolet-cured coatings

Standard Test Method for Water Content of Water-Reducible Paints by Direct Injection Into a Gas Chromatograph¹

This standard is issued under the fixed designation D 3792; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method is for the determination of the total water content of water-reducible paints. It has been evaluated for latex systems (styrene-butadiene, poly(vinylacetate)-acrylic, acrylic). It has not yet been evaluated for other water-reducible paints but is believed to be applicable. The established working range of this method is from 40 to 55 % water. There is no reason to believe that it will not work outside of this range.

1.2 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 1193 Specification for Reagent Water²

D 1364 Test Method for Water in Volatile Solvents (Fischer Reagent Titration Method)³

E 180 Practice for Determining Precision Data of ASTM Methods for Analysis and Testing of Industrial Chemicals⁴

3. Summary of Test Method

3.1 A suitable aliquot of whole paint is internally standardized with anhydrous 2-propanol, diluted with dimethylformamide, and then injected into a gas chromatographic column containing a porous polymer packing that separates water from other volatile components. The water content is determined from area calculations of the materials producing peaks on the chromatogram.

4. Significance and Use

4.1 With the need to calculate volatile organic content (VOC) of water-reducible paints, it is necessary to know the water content. This gas chromatographic test method provides a relatively simple and direct way to determine water content.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Materials.

Current edition approved May 15, 1991. Published July 1991. Originally published as D 3792 - 79. Last previous edition D 3792 - 86.

³ *Annual Book of ASTM Standards*, Vol 06.03.

⁴ *Annual Book of ASTM Standards*, Vol 15.05.

TABLE 1 Instrument Conditions

Detector	thermal conductivity
Temperatures, °C:	
Sample inlet	200
Detector	240
Column ^a	
Initial	80
Final	170
Program rate	30/min
Carrier Gas	helium or nitrogen
Flow rate, mL/min	50
Detector current	150 mA
Specimen size	1 μ L

^a For isothermal operation set the column temperature at 140°C. After the 2-propanol has cleared the column adjust the temperature to 170°C until DMF clears the column. Reset the temperature to 140°C for subsequent runs.

5. Apparatus

5.1 *Gas Chromatograph*—Any gas-liquid chromatographic instrument having a thermoconductivity detector may be used. Temperature programming capability is preferable, but isothermal operations may be adequate. See Table 1.

5.2 *Column*—The column should be 4 ft (1.22 m) of 1/8-in. (3.2-mm) outside diameter tubing of stainless steel, or other suitable material, packed with 60/80 mesh (180 to 250 μ m) porous polymer packing material.⁵ A replaceable glass sleeve, glass wool plug, or other suitable material may be placed on the entrance end of the column to retain any nonvolatile materials. This will minimize sludge buildup in the column.

5.3 *Recorder*—A recording potentiometer with a full-scale deflection of 1 to 10 mV, full-scale response time of 2 s or less and sufficient sensitivity and stability to meet the requirements of 5.1.

5.4 *Liquid Charging Devices*—Micro syringes of 10 or 25- μ L capacity.

6. Column Conditioning

6.1 *Procedure*—The packed column is installed in the gas chromatographic unit leaving the exit end disconnected from the detector. This will prevent any contamination of the detector with the column bleed. Set the helium or nitrogen flow rate at 20 to 30 mL/min if a 1/8-in. (3.2-mm) outside diameter column is used. Purge the column 5 or 10 min before heating. Heat the column from room temperature to 200°C at 5°C/min and hold this temperature for at least 12 h (overnight). At the end of this time, heat the column at

⁵ Parapak Q[®], a trademark of Waters Assoc., Inc., Milford, MA, has been found satisfactory. Any other porous polymer packing or other column giving equivalents or superior performance may be used. These products are available from most gas chromatograph suppliers and distributors.

5°C/min to 250°C (the maximum temperature for this packing) and hold for several hours. Cool the column to room temperature and connect the column detector. Reheat the column to 250°C at 5°C/min to observe if there is column bleed. Optimum conditioning of this column may take several cycles of the heating program before a good recorder baseline is achieved.

6.2 Before each calibration and series of determinations (or daily) condition the column at 200°C for 1 h with carrier gas flow.

7. Reagents and Materials

7.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁶ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

7.2 *Purity of Water*—Unless otherwise indicated, reference to water shall be understood to mean reagent water conforming to Type II of Specification D 1193.

7.3 *Carrier Gas*—Helium of 99.995 % or higher purity. High-purity nitrogen may also be used.

NOTE 1—Care should be taken that any moisture that may be present in the carrier gas is eliminated through the use of a suitable carrier gas purifier. Trace levels of water will accumulate on the column at low oven temperatures and may affect the reproducibility as well as the accuracy of the determination.

7.4 *Dimethylformamide (DMF) (Anhydrous)* gas chromatography, spectrophotometric quality (Note 2).

7.5 *2-Propanol (Anhydrous) (Isopropanol)*—See Note 2.

7.6 *Septum Sample Vials*, 10-mL capacity with fluorocarbon-faced septa are preferred.

NOTE 2—Determine the water content of the DMF and 2-propanol by Karl Fischer titration in accordance with Test Method D 1364. Dry the 2-propanol if water is found in it or replace with anhydrous grade.

8. Hazards

8.1 *Dimethylformamide* is hazardous. Check the supplier's Material Safety Data Sheet (MSDS) before use.

9. Preparation of Apparatus

9.1 Install the column in the chromatograph and establish the operating conditions required to give the desired separation (see Table 1). Allow sufficient time for the instrument to reach equilibrium as indicated by a stable base line. Control the detector temperature so that it is constant to within 1°C without thermostat cycling which causes an uneven baseline. Adjust the carrier-gas flow to a constant value.

10. Calibration

10.1 Using the information in Table 1 (as a guide), select the conditions of temperature and carrier gas flow that give

the necessary resolution of the components.

10.2 *Determination of Relative Response Factors*—Anhydrous 2-propanol is used as an internal standard. The response factor to water relative to the standard is determined by means of the following procedure. See Fig. 1 for a typical chromatogram. It is good practice to determine the relative retention time daily or with each series of determinations.

10.2.1 Weigh about 0.2 g of water and 0.2 g of 2-propanol to 0.1 mg into a septum sample vial. If it has been determined that a correction for the water content is necessary, weigh 2 mL of dimethylformamide (DMF) into the vial. If the DMF is anhydrous, simply add 2 mL of it as weighing is not necessary.

10.2.2 Inject a 1-μL aliquot of the above solution into the column and record the chromatogram. The retention order and approximate retention times after the air peak are (1) water, about 0.7 min; (2) 2-propanol, about 2.8 min; and (3) DMF, about 7 min.

10.2.3 The preferred procedure to obtain the water content of the DMF is the Karl Fischer titration (Note 1). If this has been determined, calculate the response factor for water by means of the following equation:

$$R = \frac{W_i A_{H_2O}}{(W_{H_2O} + P W_s) A_i}$$

where:

R = response factor,
 W_i = weight of 2-propanol,
 W_{H_2O} = weight of water added,
 W_s = weight of dimethylformamide,
 A_{H_2O} = area of water peak,
 A_i = area of 2-propanol peak, and
 P = weight % water in DMF

100

10.2.4 If Karl Fischer titration is not available, the following procedure may be used to obtain a reasonable

FIG. 1 Typical Chromatogram

⁶ "Reagent Chemicals, American Chemical Society Specifications," Am. Chemical Soc., Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY and the "United States Pharmacopeia."

estimate of the response factor:

10.2.4.1 Inject the same size aliquot of DMF and 2-propanol mixture, but without added water, as a blank. Note the area of the water peak in the blank.

10.2.4.2 The response factor for water is calculated by means of the following equation:

$$R = \frac{W_i(A_{H_2O} - B)}{W_{H_2O}A_i}$$

where:

- R = response factor,
- W_i = weight of 2-propanol,
- W_{H_2O} = weight of the water,
- A_i = area of 2-propanol peak,
- A_{H_2O} = area of the water peak, and
- B = area of the water peak in the blank.

11. Procedure

11.1 Weigh to 0.1 mg, 0.6 g of water-reducible paint (see Note 3) and 0.2 g of 2-propanol into a septum vial. Add 2-mL of DMF into the vial. Seal the vial. Prepare a blank containing the 2-propanol and DMF but no paint.

NOTE 3—Check each paint system to be analyzed for interfering peaks. Coalescing agents do not interfere with this determination.

11.2 Shake the vials on a wrist action shaker or other suitable device for 15 min. To facilitate settling of solids allow the vials to stand for 5 min just prior to injection into the chromatograph. Low-speed centrifugation may also be used.

11.3 Inject a 1-μL sample of the supernatant from the prepared solutions into the chromatographic column. Record the chromatograms using the conditions described in Table 1.

12. Calculations

12.1 Measure the area of the water peak and the 2-propanol internal standard peak and multiply each area by the appropriate attenuation factor to express the peak areas on a common basis. Use of an electronic integrator is recommended to obtain the best accuracy and precision. However, triangulation, planimeter, paper cut out, or ball and disk integrator may be used.

12.2 Calculate the water concentration in the paint by means of the following equation:

$$H_2O, \% = \frac{A_{H_2O} \times W_i \times 100}{A_i \times W_p \times R}$$

where:

- A_{H_2O} = area of water peak,
- A_i = area of 2-propanol peak,
- W_i = weight of 2-propanol added,
- W_p = weight of paint, and

R = response factor determined in 10.2.

12.3 Correction for Water Content of Solvent:

12.3.1 If the blank indicates the presence of a detectable peak for water in the dimethylformamide used as solvent, make a correction in the calculation.

12.3.2 The water content of the dimethylformamide determined by either chromatography (10.2.4) or, preferably, Karl Fischer titration (10.2.3) is used to make the correction. Calculate the water content due to the solvent by using the following equation:

$$H_2O(S), \% = \frac{(W_s)(P)100}{W_p}$$

where:

- W_s = weight of dimethylformamide,
- W_p = weight of paint, and
- P = weight % water in DMF

100

12.3.3 The water content of the paint in this case is the difference between the total percent determined in 12.2 and the correction for the solvent water content as determined in 12.3.2.

13. Precision and Bias⁷

13.1 The precision estimates are based on an inter-laboratory study in which nine different laboratories analyzed in duplicate on two days four samples of water-reducible paints containing from 40 to 55 % H_2O (theoretical). The results obtained were analyzed statistically in accordance with Practice E 180. The within-laboratory coefficient of variation was found to be 1.0 % relative at 34 df and the between-laboratories coefficient of variation 2.6 % relative at 30 df. Based on these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level.

13.1.1 *Repeatability*—Two results, each the mean of duplicate determinations, obtained by the same operator on different days should be considered suspect if they differ by more than 2.9 % relative.

13.1.2 *Reproducibility*—Two results, each the mean of duplicate determinations, obtained by operators in different laboratories should be considered suspect if they differ by more than 7.5 % relative.

13.2 *Bias*—Bias has not been determined.

14. Keywords

14.1 gas chromatograph; water content of paints by gas chromatograph

⁷ Supporting data are available from ASTM Headquarters. Request RR: D01 - 1022.

Standard Test Method for Low-Temperature Coalescence of Latex Paint Films¹

This standard is issued under the fixed designation D 3793; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the comparative coalescence of a series of latex paints by determining the porosity of films dried at standard and at low temperature. Porosity is evaluated with a penetrating medium as in Test Method D 3258.

1.2 The texture of the film, which can affect cleanup, will influence the results of the test. Stain applied to a high-hiding paint will not lower the reflectance as much as the same stain applied to a low-hiding paint of equal porosity. These points must be considered in comparing the different paints.

1.3 This method should be used only for comparative testing within one laboratory, as the numerical results obtained by different laboratories do not usually agree.

1.4 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 3258 Test Method for Porosity of Paint Films²

E 97 Test Method for Directional Reflectance Factor, 45-deg 0-deg, of Opaque Specimens by Broad-Band Filter Reflectometry³

3. Summary of Test Method

3.1 The test paints are applied to porous cardboard panels, dried at standard temperature and at 40°F (4.5°C) with 50 % relative humidity in both cases, and their reflectances measured. A special colored penetrating medium is applied to each, the excess removed in a specified manner, and reflectances measured again. The difference between the readings on the stained and unstained films indicates the porosity of that film; the difference between the readings for the two temperatures indicates the coalescence of that film compared to others in the series.

4. Significance and Use

4.1 This test method provides no absolute information, rather ranking only of the selected series of paints.

4.2 This test method can provide a pass-fail situation if known acceptable and unacceptable paints are included in the test.

5. Apparatus and Materials

5.1 *Plate Glass Panel* (base for cardboard panel).

5.2 *Strippable Adhesive*.⁴

5.3 *Test Panel*—Smooth porous cardboard panel such as the back of a white drawdown chart.⁵

5.4 *Film Applicator*, 6 in. (150 mm) wide with a clearance of 6 mils (150 μ m).⁶

5.5 *Film Applicator*, 5½ in. (140 mm) wide with a clearance of 10 mils (255 μ m).⁷

5.6 *Reflectometer*, meeting the requirements of Test Method E 97.

NOTE—Although Test Method E 97 specifies a 45/0 reflectometer, other types of instruments that measure the Y tristimulus value can be used.

5.7 *Cold Cabinet*, maintaining 40 $\pm$ 2°F (4.5 $\pm$ 1°C) and 50 $\pm$ 5 % relative humidity.

5.8 *Camel's Hair Brush*, approximately ½ in. (13 mm) wide.

5.9 *Plastic Wash Bottle*, about 16 oz or 500 mL containing mineral spirits of the odorless type.

5.10 *Penetrating Medium*⁸—A proprietary composition of pigments or dye, or both, dispersed in a liquid vehicle.

5.11 *Filter Paper*.

6. Procedure

6.1 Adhere a porous cardboard test panel to each of as many plate glass panels as needed, using the strippable adhesive and ensuring that the cardboard panels are smooth with no wrinkles.

6.2 For each paint, coat one panel using the 6-mil (150- μ m) clearance drawdown blade. Air dry 48 h under

⁴ Any strippable adhesive such as represented by the following formulas: Vinyl acrylic emulsion such as Flexbond 325, available from Air Products and Chemicals, P.O. Box 538, Allentown, PA 18105 (800 parts by weight) or polyethylene glycol, molecular weight 1500, such as Carbowax 1500, available from Union Carbide Corp., 1300 Lakeside Ave., Cleveland, Ohio 44114 (16 parts by weight).

⁵ Form WA or equivalent white cardboard drawdown chart available from the Leneta Co., P.O. Box 576, Ho-Ho-Kus, NJ 07423, has been found satisfactory for this purpose.

⁶ Bird film applicators or their equivalent available from Byk-Gardner, Inc., Gardner Laboratory, 1110 East West Highway, Silver Spring, MD 20910, have been found satisfactory for this purpose. It should be noted that some applicators are marked with the nominal wet film thickness which is one half of the clearance.

⁷ The Dow latex film caster available from Byk-Gardner, Inc. has been found satisfactory for this purpose.

⁸ K & N S-68 Special Compound available from: K & N Laboratories, Inc. 5331 Dansher Rd., Countryside, IL 60525, has been found suitable for this purpose.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.42 on Architectural Finishes.

Current edition approved March 31, 1989. Published May 1989. Originally published as D 3793 - 79. Last previous edition D 3793 - 84.

standard conditions of $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity.

6.3 Determine the percent reflectance (Y tristimulus value) of the dry films. Use the green filter when using a reflectometer. When making these readings, back up each panel with a flat rigid opaque object and mark the area on which the reading was made.

6.4 Using the 10-mil (255- μm) blade, apply the penetrating medium to each test paint, covering the area marked as above and drawing the applicator blade in the same direction as before.

6.5 After $5 \text{ min} \pm 15 \text{ s}$, wash off excess penetrating medium. To do this hold the panel vertically and remove the medium using the camel's hair brush wet with odorless mineral spirits. Repeat the process until most of the excess is removed then apply the mineral spirits directly from the wash bottle to the area above the stain and allow to flow down across the stained area. Pause to observe the bead that forms at the bottom of the panel. If the bead is not clear, continue washing with odorless mineral spirits until the bead is essentially clear. Test with filter paper to be sure no dye remains in the bead.

6.6 Hang the panel in a vertical position and air dry for 3 h. As before, read the percent reflectance over the same area on the panels with the same flat rigid opaque object behind them.

6.7 Place one panel for each paint, the 6-mil (150- μm) clearance drawdown blade, and the can of each paint into the cold cabinet maintained at $40 \pm 2^\circ\text{F}$ ($4.5 \pm 1^\circ\text{C}$) and $50 \pm 5\%$ relative humidity.

6.8 At the end of 24 h remove one can of paint and stir thoroughly. Then remove the drawdown blade along with one panel and make the drawdown immediately. Repeat the process for each paint under test. All items should be kept

out of the cold cabinet only long enough to make drawdowns.

6.9 Place all the panels back into the cold cabinet and dry for 48 h.

6.10 Repeat the reflectance readings before and after application of the penetrating medium to these panels in accordance with 6.3, 6.4, 6.5, and 6.6.

7. Calculation

7.1 For each paint calculate the difference between the percent reflectance of the unstained and stained films at both standard and low temperatures. These two differences indicate the porosity of the film formed at the two temperatures. Calculate the low-temperature coalescence of each paint as the ratio of the porosity at low temperature to the porosity at standard temperature which is indicative of relative coalescence.

8. Report

8.1 Report the order of low-temperature coalescence of the test paints in the series.

9. Precision and Bias

9.1 In an interlaboratory study of this test method in which one operator in each of six laboratories tested paint films of three normally different levels of coalescence, all six laboratories ranked the three paints in the same order of coalescence. However, there were considerable differences between the values obtained by the laboratories for any one paint.

10. Keywords

10.1 coalescence; latex paint; porosity

Standard Practice for Testing Coil Coatings¹

This standard is issued under the fixed designation D 3794; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{ε1} NOTE—Table 1 was editorially corrected in April 1987.

1. Scope

1.1 This practice covers procedures for testing coil coatings. The test methods included are listed in Table 1. Where more than one test method is listed for the same characteristic, *no attempt is made to indicate superiority of one method over another*. Selection of methods to be followed must be governed by the requirements in each individual case, together with agreement between the producer and user.

1.2 This practice also refers to methods developed specifically for the Coil Industry by the National Coil Coaters Association.²

TABLE 1 List of Test Methods and Recommended Practices

	Section	ASTM Method	NCCA Method
Liquid Paint Properties:	6		
Viscosity:	6.1		
Rotational viscometer	6.1.2	D 2196†	
Ford cup	6.1.2	D 1200	
Zahn cup	6.1.3		
Weight solids	6.2	D 1353	
Volume solids	6.3	D 2697	
Fineness of dispersion	6.4	D 1210	
pH	6.5	E 70	
Metal Treatment:	7		
Treatment for zinc-coated steel	7.2	D 2092	
Phosphate weight on steel	7.3.1		NCCA II-1
Phosphate weight on hot-dipped galvanized	7.3.1		NCCA II-3
Chromate weight on aluminum	7.3.2		NCCA II-2
Panel Preparation:	8		
Drawdowns	8.5		
Wet film thickness	8.6	D 1212	
Bake schedule	8.7		
Physical Properties of Cured Coating:	9.0		
Dry film thickness:	9.1		
Nonmagnetic base	9.1	D 1400	
Magnetic base	9.1.1	D 1186	
Micrometre (destructive)	9.1	D 1005	
Color difference	9.2	D 2244 & D 1729	
Gloss	9.3	D 523	
Hardness:	9.4		
Pencil hardness	9.4.1	D 3363	
Indentation hardness	9.4.2	D 1474	
Flexibility:	9.5		
Impact	9.5.2	D 2794	
Wedge bend	9.5.3	D 3281	
Conical mandrel	9.5.4	D 522	
T bends	9.5.5		
Adhesion (tape)	9.6	D 3359	
Pressure marking and blocking	9.7	D 3003	
Overbake	9.8	D 2454	
Detergent resistance	9.9	D 2248	
Stain resistance	9.10	D 1308	
Exterior and Accelerated Durability Tests:	10		
Outdoor exposure	10.1	D 1014	
Accelerated durability:	10.2		
Salt spray	10.2.1	B 117	
Acidified salt spray	10.2.2	B 287	
Humidity	10.2.3	D 2247	
Water immersion	10.2.4	D 870	
Accelerated weathering	10.2.5	D 822	
Accelerated weathering	10.2.5	D 3361	
Filiform corrosion	10.2.6	D 2803

D 3361 Practice for Operating Light- and Water-Exposure Apparatus (Unfiltered Open Flame Carbon-Arc Type) for Testing Paint, Varnish, Lacquer, and Related Products Using the Dew Cycle⁴

D 3363 Test Method for Film Hardness by Pencil Test⁴
E 70 Test Method for pH of Aqueous Solutions with the Glass Electrode⁷

2.2 *National Coil Coaters Standards:*⁸

No. II-1, Specification for Determination of Phosphate Coating Weights on Steel

No. II-2, Specification for Coating Weight Determination for Chromate Conversion Coatings on Aged or Baked Aluminum Alloy Panels

No. II-3, Specification for Determination of Phosphate Coating Weight on Hot Dip Galvanized and Electro-galvanized Steel

3. General Requirements

3.1 All tests shall be made in diffused light (not direct sunlight) and at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity, immediately after baking unless otherwise specified.

4. Definitions

4.1 *coil coating*—application of coatings or films to continuous metal coil stock.

4.2 *metal pretreatment*—chemical treatment normally applied to the metal substrate prior to prime or finish coating. The treatment is designed to react with and modify the metal substrate to produce a surface suitable for coating or adhesive bonding.

⁷ Annual Book of ASTM Standards, Vol 15.05.

⁸ Copies of National Coil Coaters Assn. methods are available through NCCA Headquarters, 1900 Arch St., Philadelphia, PA 19103.

4.3 *reverse roller coat*—coating with the applicator or coating roll revolving in a direction opposite to that of the strip.

4.4 *direct roller coat*—coating with the applicator or coating roll revolving in the same direction as the strip.

5. Sampling

5.1 The number of samples per unit of production shall be agreed upon between producer and user.

6. Liquid Coatings Properties

6.1 Viscosity:

6.1.1 Coatings in the coil industry cover a wide range of generic qualities with many of them having non-Newtonian characteristics. It is therefore important to consider the behavior of these coatings under different shear conditions as well as measuring efflux viscosity by the Ford cup.

6.1.2 Determine viscosity in accordance with Test Methods D 2196 and D 1200.

6.1.3 Viscosity by Zahn cup.⁹

6.1.3.1 *Apparatus*—Standard Zahn cup with specified orifice, a No. 4 or 2 orifice is most commonly used. Stop watch.

6.1.3.2 *Procedure*—Clean the Zahn cup thoroughly. The sample must have a volume of at least 1 pt and the Zahn cup and sample must be $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$). Thoroughly mix the sample. Dip the Zahn cup in a vertical position into the sample being tested, making certain the cup is completely immersed in the liquid but do not allow the cup to touch the bottom of the container. Rapidly lift the cup out of the sample and as the top edge of the Zahn cup breaks the surface start the stop watch. Stop the watch when the first break in the flowing stream of liquid is noted at the orifice exit. Record the seconds elapsed, temperature and number of the Zahn cup used.

6.2 *Weight Solids (NVM)*—Determine nonvolatile matter in accordance with Test Method D 1353.

6.3 *Volume Solids*—Determine volume solids in accordance with Test Method D 2697.

6.4 *Fineness of Dispersion*—Determine fineness of grind in accordance with Test Method D 1210.

6.5 pH:

6.5.1 Control of pH in the pretreatment section of the coil line as well as of waterborne coatings is important in production.

6.5.2 Determine pH in accordance with Method E 70.

7. Metal Pretreatment (Conversion Coating)

7.1 The successful performance of any coil-coated material is dependent not only on the organic coating used but also on the metal preparation. Metal preparation in the coil coating industry usually consists of one of the following:

A		B	
(a)	Clean	(a)	Clean
(b)	Rinse	(b)	Rinse
(c)	Formation of conversion coating	(c)	Formation of conversion coating
(d)	Rinse	(d)	Drying

⁹ Zahn Cups are available from Paul N. Gardner Co. Inc., 316 N.E. First St., Pompano Beach, FL 33061.

A		B	
(e)	Posttreatment of conversion coating		
(f)	Drying		

7.1.1 The metal pretreatment promotes maximum formability and improves adhesion and environmental exposure resistance of the coil coating material. Cleaners, conversion coating treatments and posttreatments used vary with the performance desired, the paint and the metal. Because there is an interdependency between the cleaning, conversion coating, and posttreatment steps, in order to obtain relevant test data, it is necessary that the chemicals, times, concentrations, temperatures, and application methods be as close as possible to those encountered under production conditions.

7.2 In the case of zinc coated steel surfaces, Practices D 2092 Methods A, B, C, and D illustrate the variety of pretreatments available.

7.3 *Coating Weight of Metal Pretreatment*—In many cases, one quality control measurement is the coating weight of the metal pretreatment formed. The following methods are recommended:

7.3.1 *Zinc or Iron Phosphate Conversion Coatings on Steel*—Determine the weight of the iron phosphate conversion coating on steel in accordance with NCCA II-1 and the weight of the phosphate conversion coating on hot dip galvanized steel in accordance with NCCA II-3.

7.3.2 *Chromate-Conversion Coatings on Aluminum*—Determine the weight of the chromate conversion coating on aluminum in accordance with NCCA II-2.

8. Panel Preparation

8.1 *Summary of Method*—This method includes substrate and pretreatment selection for application of coatings by wire wound draw-down bars¹⁰ on laboratory panels.

8.2 *Choice of Substrate*—The substrate to be coated, substrate size, gage, temper, alloy, pretreatment to be used shall be agreed upon between the producer and user. Avoid using treated substrates that have been contaminated by handling or cleaned with solvents or cleaners.

8.3 *Degassing of Substrate*—Some galvanized substrates tend to absorb gasses on aging. To avoid blistering when the substrate is coated and baked it may be necessary to degas the substrate by heating and cooling to room temperature prior to application of the coating. The time and temperature of the degassing cycle shall be agreed upon between the producer and user.

8.4 Drawdowns:

8.4.1 *Apparatus*—Wire-wound draw-down bars, stainless steel bars preferably $\frac{1}{2}$ in. (12.7 mm) in diameter to prevent bowing during application. The choice of the specific draw-down bar is dependent on the dry film thickness required and the volume solids of the coating being tested.

8.4.2 *Procedure*—Secure the substrate to be coated on a hard uniform, even surface. Place an excess amount of the coating to be used near the top of the substrate. Place the draw-down bar in the puddle of the coating to be applied. Rotate or turn the draw-down bar slightly in the coating puddle to ensure complete distribution of the coating in the

¹⁰ Wire-Wound Draw Down Bars available from R. D. Specialties, P.O. Box 206, Webster, N Y 14580, or equivalent may be used.

FIG. 1 OT, 1T Bend

ends of the bar. Without rotating the bar, draw it down the length of the substrate at a uniform speed, so that a uniform film is produced. Draw-down speed is dependent on the technology and quality of the coating being tested.

9.5 Wet Film Thickness—Determine the wet thickness of applied coating in accordance with Method D 1212.

9.6 Bake Schedule—Bake the panel at a time and temperature to meet a metal temperature range agreed upon between the producer and user.

Physical Properties of Cured Coating

9.1 Dry Film Thickness—There are several methods currently being used for determining dry film thickness. Depending on the substrates being checked, the following methods should be considered: Test Methods D 1400, D 1186, and D 1005.

9.2 Color:

9.2.1 The color difference between two homogeneously colored opaque films may be determined by visual evaluation or by instrumental means. The color standard used shall be agreed upon between the producer and user.

9.2.2 Color Differences of Opaque Materials by Visual Evaluation—Visual comparison of color is fast and often acceptable although numerical values are not obtained. The referenced method covers the spectral, photometric and colorimetric characteristics of light source, illuminating and viewing conditions, size of specimens and general procedures to be used in the visual evaluation of color differences of opaque materials. Determine color difference in accordance with Practice D 1729.

9.2.3 Color Difference of Opaque Material by Instrumental Evaluation—Color difference between a product and standard can be measured by instrument. The tolerance agreed upon between the producer and user. The referenced method covers the instrumental determination of color differences observable in daylight illumination between nonfluorescent, nonmetameric, opaque surfaces such as coated specimens. If metamerism is suspected, visual evaluation (9.2.2) should be used to verify the results. Make instrumental measurement of color difference in accordance with Test Method D 2244.

9.3 Gloss:

9.3.1 Gloss in the coil industry is generally determined by readings at angles of 20, 60, or 85 deg and in some applications by 60/85-deg or 60/20-deg relationships.

9.3.2 Determine gloss of a coil-coated material in accordance with Test Method D 523.

9.4 Hardness:

9.4.1 Pencil Hardness—Determine the hardness of a coil-coated material by the pencil hardness method in accordance with Test Method D 3363.

9.4.2 Indentation Hardness—Determine the hardness of a coil-coated material in accordance with Test Methods D 1474, using either Method A (Knoop indentation hardness) or Method B (Pfund indentation hardness).

9.5 Flexibility:

9.5.1 There are several flexibility tests used in the coil industry, all giving indications of what the fabrication properties of the coatings are going to be. The most common tests used are impact, wedge bend, T bends, and conical mandrel flexibility.

9.5.2 Impact—Determine the impact resistance of a coil-coated material in accordance with Test Method D 2794.

9.5.3 Wedge Bend—Determine the wedge bend flexibility in accordance with Test Method D 3281.

9.5.4 Conical Mandrel—Determine the conical mandrel flexibility in accordance with Test Methods D 522.

9.5.5 T Bends:

9.5.5.1 Summary of Method—T bend flexibility is a means of evaluating film flexibility and correlating T bends to fabrication properties, by examining the individual T bends for fracturing and tape adhesion of the coating on each bend. The bends are classified OT, 1T, 2T, 3T, etc., with a OT bend being defined as a 180 deg bend, (paint on the outside of the bend) pressed flat so there is no space between the metal and the bend (Note 1). The 1T bend is made by wrapping or bending the metal around the first bent (OT) so that one thickness of metal is between the new wrap, this bend is pressed flat so there is no space between the metal and the bend. This process is repeated to produce the number of T bends required. (See Fig. 1.) The type of metal substrate to be used, whether or not the bends are to be made with or against the grain of the metal, the designation for identifying T bends and the temperature at which the bends will be made should be agreed upon between the producer and user.

NOTE 1—This is the preferred identification of T bends, however, another method is used based on the inside radius of the bend and is $\frac{1}{2}$ of the preferred designation.

9.5.5.2 Apparatus—Brake form machine.¹¹

9.5.5.3 Procedure—Place the panel to be tested into the bed of the brake face, coated side down. Bend panel 180 deg at a uniform rate and press panels flat so there is no space between the metal and the bend, this is the OT bend. Repeat this process to achieve the desired number of T bends. Examine the T bends under 10-power magnification and report the degree of fracturing on each bend based on a rating system agreed upon between the producer and user. Tape each bend with a tape¹² agreed upon between the producer and user.

9.5.5.4 Report—Report the degree of pick off on each bend in a manner agreed upon between the producer and user.

9.6 Adhesion—Determine the tape adhesion of coil materials in accordance with Test Method D 3359.

9.7 Pressure Marking and Blocking—Determine pressure marking and blocking resistance of coil-coated materials in accordance with Test Method D 3003.

9.8 Overbake—Determine the effect of overbaking a coil-coating material in accordance with Practice D 2454.

¹¹ Di Arco Brake form available from Di Arco Manufacturing, Lake City, MN.

¹² Scotch Brand Acetate Fiber Tape No. 710 manufactured by Minnesota Mining and Manufacturing Co., St. Paul, MN., has been found suitable for this purpose.

9.9 *Detergent Resistance*—Determine the detergent resistance of an organic coating for the appliance industry in accordance with Practice D 2248.

9.10 *Stain Resistance*—Determine the stain resistance and effect of household chemicals on a coil-coated finish in accordance with Method D 1308.

10. Exterior Durability and Accelerated Tests

10.1 *Outdoor Exposure*:

10.1.1 While the accelerated tests given elsewhere in this practice are intended to enable prediction of probable performance, actual outdoor exposures should be made on coatings intended for exterior use. The usage of paint systems in the coil area and the liability connected with these systems is so varied that no one set of conditions (length, location, and manner of exposure) can be given in this practice to cover all situations. These conditions, as well as the type of substrate, pretreatment, bake schedule, etc., should be agreed upon between the producer and the user.

10.1.2 Throughout the outdoor weathering tests, several properties should be evaluated periodically or at time intervals agreed upon between the producer and user in accordance with the following methods:

10.1.2.1 *Blistering*—Test Method D 714.

10.1.2.2 *Chalking*—Test Method D 659.

10.1.2.3 *Checking*—Test Method D 660.

10.1.2.4 *Cracking*—Method D 661.

10.1.2.5 *Rusting*—Method D 610.

10.1.2.6 *Corrosion*—Method D 1654.

10.2 *Accelerated Durability*:

10.2.1 *Salt Spray Resistance*—Salt spray testing of coatings may be helpful in determining their resistance to failure in service under conditions of high humidity and salt concentrations. Under the accelerated conditions of the laboratory test, the temperature, pH, concentration of the salt solution and other physical parameters can be controlled. The selection of substrate, pretreatment, the coating system, the manner in which the coating is scribed, the location or position of the panels within the cabinet, the length of the test, the inspection of panels and method of reporting results must be agreed upon between the producer

and user. Test for salt spray resistance in accordance with Method B 117.

10.2.2 *Acidified Salt Spray*—The acidified salt spray is used in the coil industry as a more accelerated test (compared to regular salt spray) for evaluating corrosion resistance of coatings over aluminum. Determine the acidified salt spray resistance of a coating in accordance with Method B 287.

10.2.3 *Humidity*—Determine the humidity resistance of coil-coated material in accordance with Practice D 2247.

10.2.4 *Water Immersion*—Determine the resistance of a coil-coated material to water immersion in accordance with Practice D 870.

10.2.5 *Accelerated Weathering*—The intention of the accelerated weathering test is to cause the degradation of coating films to occur much faster than in natural weathering in various field conditions. The apparatus produces more rapid, but not necessarily the same type of failure of films as does natural sunlight because of its higher level and larger peaks of UV irradiation. Materials which absorb at wavelengths where the peaks in UV occur will degrade more rapidly than those that are transparent to those wavelengths. Most, but not all, organic binders are especially sensitive to radiation below 300 nm, and in some cases, no realistic evaluation of weathering properties can be expected. For these reasons, correlation between natural and accelerated weathering is not always obtained. Whenever possible comparisons should be made with materials having similar vehicles and known durability. Conduct accelerated weathering testing on coil-coated finishes in accordance with Practices D 822 or D 3361 (Note 2), or method agreed upon between producer and user.

NOTE 2—Practice D 3361 does not use filters and the specimens are exposed to UV below 300 nm.

10.2.6 *Filiform Corrosion Resistance*—Filiform corrosion is a type of corrosion that occurs under single-coat systems on a metal substrate and is characterized by definite thread-like structure and directional growth. When filiform corrosion occurs on residential siding the esthetic value of the siding is reduced since the corrosion cannot be washed off. Determine the susceptibility of a coil coated material to this type of corrosion by Test Method D 2803.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method of Small-Scale Evaluation of Fire-Retardant Paints (2-Foot Tunnel Method)¹

This standard is issued under the fixed designation D 3806; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

This test method determines the protection a coating affords its substrate and the comparative burning characteristics of coatings by evaluating the flame spread over the surface when ignited under controlled conditions in a small tunnel. This establishes a basis for comparing surface-burning characteristics of different coatings without specific consideration of all the end-use parameters that might affect surface-burning characteristics under actual fire conditions.

In addition to the experimental flamespread rate, the weight of panel consumed, time of afterflaming and afterglow, char dimensions and index, and height of intumescent may be measured in this test. However, a relationship should not be presumed among these measurements.

This standard should be used to measure and describe the properties of materials, products, or assemblies in response to heat and flame under controlled laboratory conditions and should not be used to describe or appraise the fire hazard or fire risk of materials, products, or assemblies under actual fire conditions. However, results of this test may be used as elements of a fire risk assessment which takes into account all of the factors which are pertinent to an assessment of the fire hazard of a particular end use.

This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

Fed. Spec. TT-V-119 Varnish, Spar, Phenolic Resin⁵

3. Significance and Use

3.1 A number of laboratory procedures are used to evaluate the effectiveness of fire-retardant and fire-resistant treatments and coatings. In general, these methods measure the three stages of fire development: (1) ignition; (2) flame spread (rate of growth of the fire); and (3) conflagration extent. While all three are of extreme importance, flame spread has been recognized as the main factor associated with testing fire-retardant coatings.

3.2 Flame spread ratings based upon Test Method E 84 have acquired common acceptance by regulatory agencies, but such large-scale tests are seldom practical during the development or modification of a fire-retardant coating.

3.3 This test method provides the relative flame spread of experimental coatings using small test specimens. By calibrating the 2-foot tunnel with Test Method E 84-rated fire-retardant paint, results obtained by this test method should be indicative of those obtained with a large specimen in the Test Method E 84 tunnel.

4. Apparatus

4.1 *Flame Tunnel*⁶ (see Fig. 1A)—two-foot (610-mm) flame tunnel consisting of asbestos-cement board mounted on an iron framework and supplied with natural gas fuel of uniform quality.

4.1.1 The framework is constructed of 1/4 by 1 by 1-in. (3 by 25 by 25-mm) angle iron, the top of which provides a 24 by 4-in. (610 by 100-mm) specimen holder inclined at 28° to the horizontal. The framework is mounted on a 10 by 24 by 1/2-in. (250 by 610 by 13-mm) steel base. The specimen holder is elevated 7 3/8 in. (185 mm) above the base at the lower (fire) end and 18 3/8 in. (480 mm) at the upper (flue) end.

4.1.2 The fire end and sides of the tunnel are covered to the extent shown in Fig. 1, with 1/4-in. (6-mm) asbestos-cement board⁷ or 1/4-in. (6-mm) inorganic reinforced-cement

⁵ Standardization Documents Order Desk, Bldg. 4 Section D, 700 Robbins Ave., Philadelphia, PA 19111-5094, Attn: NPODS.

⁶ Flame tunnels manufactured to similar specifications are available from Custom Scientific Instruments, 13 Wing Drive, Cedar Knolls, NJ 07927 and Monsanto Co., Functional Products, Special Chemicals Div., 800 N. Lindbergh Blvd., St. Louis, MO 63167.

⁷ Transite, manufactured by Manville Corp., Denver CO 80217 has been found satisfactory for this purpose.

Materials of Construction and Equipment List

Item No	Item	Description	Item No	Item	Description
A	Base Plate	1/2 x 10 x 24 Steel plate	F	Glare Shield	1/16 x 2 1/4 x 22 Metal sheeting
B	Framework	1/2 x 1 x Angle iron throughout	G	Ignition Transformer	115 V, 60 Hz, 5000 V, 20 A secondary
C	Side and Front Panels	1/4 Transite or Chem-Fil 100S or 100 H ⁸ cut to specifications	H	Spark Switch	Push button type

FIG. 1 Flame Tunnel

board⁸ attached to the inside of the angle iron framework. The open flue end and the cut-out sides allow a natural draft through the tunnel. Additional air access is provided by a 1-in. (25-mm) hole drilled in the cover at the fire end, centered and 4 1/2 in. (115 mm) above the base.

4.1.3 An observation window made of a 2-in. (50-mm) wide strip of 1/8-in. (3-mm) polished heat-resistant sheet glass⁹ is located just below the specimen holder, extending the full length of the tunnel, 24 in. (610 mm). This glass is

marked by any appropriate method at 1-in. intervals from 4 to 22 in. A 22 by 2 1/4 by 1/16-in. (560 by 55 by 2-mm) sheet metal shield is attached above the window, slanting downwards at an angle of 60° to shield the observation window. The angle iron panel holder is notched along the bottom or supporting lip of the angle at 1-in. (25-mm) intervals to assist in the measurements of the flame advance.

NOTE 1—A rule may also be mounted outside the observation window to help measure the flame advancement.

4.1.4 A 3/32-in. (2.5-mm) hole is drilled in the side of the specimen holder immediately above the center of the burner to allow insertion of a thermocouple.

4.1.5 The tunnel should be placed in an area as free from

⁸ Chem-Fil 100S and 100H, nominal 100 to 110 lb/ft² (1600 to 1760 kg/m³), Chem-Fil Corp., 100 Spence Lane, Nashville, TN 37210 have been found suitable for this purpose.

⁹ Quartz or high-silica glass has been found satisfactory for this purpose.

TABLE 1 Densities and Panel Weights of Various Woods (Conditioned at Relative Humidity $50 \pm 5\%$ and $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) for 14 days)

Type of Wood	Density (9 to 10 % Moisture), lb/ft ³ (kg/m ³)	Weight of 3 $\frac{7}{8}$ by 23 $\frac{7}{8}$ by $\frac{1}{4}$ in. Panel, g
Red cedar	21.4 to 22.4 (345 to 360)	130 to 140
Douglas fir	29 to 35 (465 to 560)	180 to 215
White pine-Ponderosa pine	22.4 to 26.4 (360 to 420)	140 to 160
Southern yellow pine	31 to 37 (495 to 590)	190 to 225
Redwood	27.2 to 28.2 (435 to 450)	165 to 175

as possible with facilities for removal or escape of combustion products. (Standard laboratory hood with forced draft off during test.)

4.2 *Burner*,¹⁰ 8.5 in. (215 mm) high with 40-mm diameter, 10-mm thick grid for use with natural gas. The burner is placed $2\frac{1}{4}$ in. (57 mm) in from the fire end of the panel and 1 in. (25 mm) below the bottom side of the sample holder, that is, $1\frac{1}{2}$ in. (30 mm) from the bottom of the specimen. See Fig. 1.

NOTE 2—Artificial gas or liquid petroleum (LP) gas may be used, but subjects designed for these types of gases must be used.

4.3 *Ignition Transformer*, or other suitable ignition source, to generate a spark through a $\frac{1}{16}$ -in. (2-mm) nichrome wire to the burner barrel. The transformer is activated by a push-button type spark switch.

4.4 *Gas Supply*, of uniform quality controlled by a positive-flow pressure regulatory valve (0 to 6 in. (0 to 152 mm) water) and a gas flowmeter (0.6 to 5.0 SCFH).

4.5 *Insulating and Fire Resistant Backing for Test Panels* consisting of 3 $\frac{7}{8}$ by 23 $\frac{7}{8}$ -in. (100 by 605-mm) pieces of $\frac{1}{2}$ -in. (13-mm) asbestos-cement board or inorganic reinforced cement board and $\frac{1}{2}$ -in. steel plate applied one above the other with asbestos cement or the inorganic reinforced cement board placed directly on top of the test panel.

4.6 *Thermocouple*¹¹ totally shielded (see Note 3) installed through the hole in the side of the specimen holder so that its tip rests on the back, cool side, of the test panel.

NOTE 3—Some commercial tunnels⁶ are supplied with more than one thermocouple.

4.7 *Recording Potentiometer*, 0 to 300°C range.

4.8 *Audible Timer*, set to sound at 15-s intervals to indicate the time for flame-front measurements.

4.9 *Constant Temperature and Humidity Room or Cabinet*, maintained at $50 \pm 5\%$ relative humidity and $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$).

5. Test Panels

5.1 *Test Panels*—See Table 1 for a list of various woods and their densities. Wood, $\frac{1}{4}$ by 3 $\frac{7}{8}$ by 23 $\frac{7}{8}$ -in. (6 by 100 by 605-mm) close grained, as nearly edge grain as possible and free from knots and imperfections. The panels should be solid wood with surfaces planed and sanded (see Note 4). Kill-dry test panels to contain not more than 10 weight % of moisture on an oven dry basis.

¹⁰ Fisher Burner Catalog No. 3-902 from Fisher Scientific Co. has been found satisfactory for artificial gas. Fisher Burners No. 3-900 and 3-902 may be used for natural gas and LP gas, respectively.

¹¹ Megopak Type J thermocouple has been found satisfactory for this purpose.

NOTE 4—Douglas fir, $\frac{1}{4}$ -in. (6.3-mm) 3-ply, marine-grade plywood may be used upon agreement between manufacturer and user. Asbestos-cement board, steel, or concrete may be used upon agreement between manufacturer and user.

5.1.1 Prior to coating, condition test panels for 14 days in the controlled atmosphere of $50 \pm 5\%$ relative humidity and $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) to a 9 to 10 % moisture content. Refer to Table 1 for the density and weight per panel of each listed wood.

5.1.2 Seal the ends of the panels with two coats of varnish conforming to Fed. Spec. TT-V-119 after conditioning. Allow each coat of varnish to air-dry 18 to 24 h.

6. Calibration Standards

6.1 *Zero-Flame Spread*—Asbestos-cement board, Type F conforming to Specification C 220, $\frac{1}{2}$ by 3 $\frac{7}{8}$ by 23 $\frac{7}{8}$ in. (13 by 100 by 605 mm), conditioned as in 5.1.1.

NOTE 5—Inorganic reinforced cement board, $\frac{1}{4}$ -in. (6.3-mm) thick may be substituted for asbestos cement.

6.2 *Fire-Rated Standard*—A test panel, similar to that used with test coatings, coated with Test Method E 84 rated paint at the manufacturer's recommended spreading rate and conditioned as in Section 7.

NOTE 6—Do not use paint beyond manufacturer's stated shelf life.

7. Preparation of Test Panels

7.1 Thoroughly mix the coating under test by a suitable means until it is uniform in composition and consistency. Test Method D 2196 describes a suitable preparation procedure.

7.2 Determine the density of the coating in accordance with Test Method D 1475 in pounds per gallon (or grams per millilitre) for calculating the weight of the coating to be applied to the panel to comply with the specified spreading rate.

7.3 Brush apply the coating to conditioned test panels in as uniform a manner as possible to obtain the specified spreading rate. A suitable procedure appears in Test Method D 344. Application may be by other conventional means and in as many coats as required to obtain the necessary weight of coating or desired wet- or dry-film thickness.

7.4 Calculate the weight of coating to be applied using the following equation:

$$W = \frac{(3\frac{7}{8} \times 23\frac{7}{8})D}{144 S_R} \times 454$$

where:

W = weight of applied wet coating, g,

D = coating density, lb/gal, and

S_R = spreading rate, ft²/gal.

7.4.1 Use the following equation when metric units are employed:

$$W = \frac{60.5 D}{S_R}$$

where:

W = weight of applied wet coating, g,
 D = coating density, g/mL, and
 S_R = spreading rate in m²/L.

7.5 Dry the coated panels under standard conditions (4.9) until equilibrium weight is obtained, allowing sufficient time for the complete evaporation of solvents, any curing that might be required by the material, and for the attainment of equilibrium moisture content. Forty-eight hours are normally sufficient except for certain coatings that may require longer periods because they trap solvent or contain solvents that evaporate very slowly.

7.6 Apply and cure non-air-drying coatings as recommended by the supplier and condition as specified in 7.5.

8. Calibration of the Tunnel

8.1 Calibrate the tunnel prior to each day's operation with the calibration standards described in Section 6.

8.1.1 Place the zero flame-spread standard in the holder, smooth side down, and back it with the backing plate (4.5).

8.1.2 Open the gas valve and adjust to a pressure of 3 oz/in.² (1.3 kPa) and a constant flow of 4.8 ft³/h (38 mL/s), and actuate the interval timer.

NOTE 7—These conditions are specified for a natural gas supply providing 1055 BTU/ft³ (40 MJ/m³). For any other gas supply, adjust flow to provide 5085 BTU/h (1490 J/s).

8.1.2.1 When the timer sounds, ignite the burner using the ignition transformer. Observe the flame front, measure in inches and record at 15-s intervals the flame position by aligning the notches in the bottom of the specimen holder with the markings on the observation window.

8.1.3 Record the extreme tip of the flame advance (flame front) on the panel surface, disregarding flame extending up the tunnel but completely on the angle iron support. After a total test period of 4 min, extinguish the burner.

8.1.4 Calculate the mean of the three highest consecutive readings of the flame advance of the zero-flame spread standard L_a .

8.2 Repeat the calibration procedure using a fire-rated standard (6.2). Designate the mean of the three highest consecutive readings of the flame advanced as L_R . The difference between the mean readings for the zero flame-spread standard and the fire-rated standard ($L_R - L_a$) is directly related to the Test Method E 84 flame-spread rating of the rated standard (F_{SR}).

9. Procedure for Determination of Flame-Spread Rating

9.1 Remove a test panel (Section 7) from the controlled atmosphere, weigh immediately, and then mount in the specimen holder, coated-side down. Insert the thermocouple through the hole in the holder (4.6) so that its tip is directly above the center of the burner and resting on the back, or uncoated side, of the test panel. Back the panel with the asbestos-cement board and steel backing.

9.2 Apply the flame and determine the advance of the

flame front in the same manner as the calibration procedure (Section 8), except allow the burner to operate for an additional 60 s after making the last of the 15-s readings before extinguishing the burner. Designate the mean of the three highest consecutive readings of the flame advance of the specimen during the 4-min test period as L_s .

9.3 Repeat the determination with at least five panels.

10. Calculation

10.1 Calculate the experimental flame-spread rating using the following equation:

$$F_{SE} = \frac{(L_s - L_a)}{L_R - L_a} \times F_{SR}$$

where:

F_{SE} = flame spread of specimen,
 L_s = mean of three flame advance readings of specimen, in. (mm),
 L_a = mean of three flame advance readings of zero flame-spread standard, in. (mm),
 L_R = mean of three flame advance readings of rated standard, in. (mm), and
 F_{SR} = flame-spread rating of rated standard.

10.2 Calculate the mean of the replicate panels, rounding off to the nearest five units.

11. Optional Measurements

11.1 *Afterflaming Time*—Observe and record the time in seconds that flaming continues on the face of the test specimen after the burner has been extinguished. Report as afterflaming time.

11.2 *Afterglow Time*—Observe in subdued light and record the additional time in seconds that the surface of the test specimen continues to emit light (glows) after the flame has gone out. Report as afterglow time.

11.3 *Panel Consumption*—After the completion of the flame-spread test (Section 9), replace the specimen in the constant atmosphere (see 5.1.1) for not less than 72 h. Reweigh the panel and determine the weight loss in grams. Report loss as panel consumption.

11.4 *Degree of Intumescence*—Measure the height of intumescence (foam formation) in millimetres at the point on the specimen that was directly above the burner. Report the height as intumescence.

11.5 *Insulation Value*—Measure the initial panel temperature in degrees Celsius or Fahrenheit and subtract it from the maximum temperature observed during the flame-spread test (Section 9). Report the difference as ΔT .

11.6 *Char Dimensions and Index*—Cut the panel into four rectangular pieces using a fine-toothed saw so that the cuts intersect at the point of flame impingement (directly over the burner). Measure in centimetres the maximum width of charring of the wood found below the paint film on the lateral cut. Likewise, measure the maximum length of charring found on the longitudinal cut. Measure the maximum depth to which charring has penetrated as evidenced on either cut. Determine the char index by multiplying the maximum char width, length, and depth.

- 2.1.1 The calibration values of L_R and L_a (Section 8),
- 2.1.2 Type of substrate used,
- 2.1.3 Number of test panels,
- 2.1.4 Mean spreading rate,
- 2.1.5 Pressure, flow rate, and type of gas fuel,
- 2.1.6 Mean L_a value for each panel (Section 9), and
- 2.1.7 Mean flame-spread value (F_{SE}) for each material under test (Section 9).
- 2.2 *Optional Measurements*—Report may contain the following information:
 - 2.2.1 *Panel Consumption*—Mean initial and final weight of coated specimens and mean weight loss in grams (11.3),
 - 2.2.2 Afterflaming time in seconds (11.1),
 - 2.2.3 Afterglow time in seconds (11.2),
 - 2.2.4 Height of intumescence in millimetres (11.4),
 - 2.2.5 *Insulation Value*—Initial and maximum temperatures, and temperature difference (ΔT) (11.5), and
 - 2.2.6 *Char Depth and Volume*—Maximum width, length, and depth of charring of wood in centimetres and the char index in cubic centimetres (11.6).

3. Precision and Bias

3.1 Precision:

- 3.1.1 Nonuniformity of test panels (both in the wood and in the coating), variations in fuel supply and rate, and

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

TABLE 2 Repeatability^a

Flame-Spread Ratings	Standard Deviation	Coefficient of Variation
0 to 25	1.2	9.6
25 to 75	3.1	6.2
75 to 135	3.65	3.5
0 to 135	2.85	4.6

^a This information was derived from *Journal of Paint Technology*, Vol. 39, No. 511, 1967, p. 495.

operator error are the chief sources of error in operation of the 2-foot (610-mm) tunnel.

13.1.2 The degree of repeatability is dependent on the level of flame-spread ratings. Table 2 shows that while the standard deviation of duplicate results increases with an increase in ratings, the coefficient of variation decreases by a factor of more than 2.0.

13.1.3 The standard deviation in Table 2 relates to the maximum difference that would be expected between duplicate panels; that is, a second result in the flame-spread range from 0 to 25 should fall within 4.8 units ($\pm 2.8 \times 1.2$) at the 95 % confidence level.

13.2 *Bias*—The procedure in this test method for measuring flame spread has no bias because the value of flame spread can be defined only in terms of a test method.

Standard Guide for Selection of Test Methods for Coatings for Use in Light-Water Nuclear Power Plants¹

This standard is issued under the fixed designation D 3842; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide is intended to provide a common basis in the selection of test methods that may be required to evaluate and qualify protective coatings (paints) for use in a light-water nuclear power plant, and all the listed items are for Coating Service Level I application. It lists and describes tests to be conducted on all coatings specified for this service.

1.2 This guide also lists the specifications and their scopes that describe evaluation tests for these coating systems.

1.3 Coating Service Level I pertains to those coating systems whose failure could impair the operation of the engineered safety features that are essential for preventing the possible consequences of postulated accidents that could cause undue risk to the health and safety of the general public. Coating Service Level I applies principally to the interior surface of the primary containment for both Pressurized Water Reactors (PWR) and Boiling Water Reactors (BWR) and to the structures and equipment contained therein. Coated surfaces include, but are not limited to, carbon steel, stainless steel, galvanized steel, aluminum, and masonry.

1.4 Requirements for coatings applied to other areas shall be assigned at the option of the owner or his designated representative. It is intended that this standard be incorporated in specifications, by reference, on the basis of owner requirements.

1.5 *This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

¹ This guide is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generation Facilities and is the direct responsibility of Subcommittee D33.02 on Service and Material Parameters.

Current edition approved Sept. 29, 1986. Published November 1986. Originally published as D 3842 - 80. Last previous edition D 3842 - 80.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

2.1 ASTM Standards:

D 3911 Test Method for Evaluating Coatings Used in Light-Water Nuclear Power Plants at Simulated Design Basis Accident (DBA) Conditions²

D 3912 Test Method for Chemical Resistance of Coatings Used in Light-Water Nuclear Power Plants²

D 4082 Test Method for Effects of Radiation on Coatings Used in Light-Water Nuclear Power Plants²

D 4256 Test Method for Determination of the Decontaminability of Coatings Used in Light-Water Nuclear Power Plants²

3. Significance and Use

3.1 This guide covers methods of testing coatings for use in light-water nuclear power plants.

4. Test Methods

4.1 *Test Method D 3911*—This test method establishes procedures for evaluating protective coating systems test specimens under simulated Design Basis Accident (DBA) Conditions. Included is a description of conditions and apparatus for temperature-pressure testing, condition for radiation testing, and procedures for preparing, examining, and evaluating the samples after testing.

4.2 *Test Method D 3912*—This test method establishes procedures for the evaluation of the chemical resistance of coatings used in light-water nuclear power plants.

4.3 *Test Method D 4082*—This test method establishes a standard procedure for evaluating the lifetime radiation tolerance of coatings to be used in nuclear power plants.

4.4 *Test Method D 4256*—This test method establishes procedures for determining and ranking the ease of the decontaminability of coatings used in nuclear power plants.

Standard Practice for Quality Assurance for Protective Coatings Applied to Nuclear Facilities¹

This standard is issued under the fixed designation D 3843; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice provides a common basis for, and specifically comprises quality assurance requirements applicable to, safety-related protective coating work in Coating Service Level I areas of nuclear facilities.

1.2 Applicable portions of this practice may be used as the basis for limited quality assurance for protective coating work in Coating Service Level II areas of nuclear facilities.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 Description of Terms Specific to This Standard:

3.1.1 *certification*—the written documentation of the qualification of personnel or material.

3.1.2 *coating applicator*—an organization or individual responsible for applying a protective or decorative coating system.

3.1.3 *coating (paint)*—a liquid, liquifiable, or mastic composition that is converted to a solid protective or functional adherent film after application as a thin layer.

3.1.4 *coating manufacturer*—an organization responsible for manufacturing coating materials.

3.1.5 *coating system*—a polymeric protective film consisting of one or more coats, applied in a predetermined order by prescribed methods.

3.1.6 *coating work*—an all-inclusive term to define all operations required to accomplish a complete coating job. The term shall be construed to include materials, equipment, labor, preparation of surfaces, control of ambient conditions, application and repair of coating systems, and inspection.

3.1.7 *Code of Federal Regulations (CFR)*—the rules and regulations of the United States Federal Government. The code is subdivided into titles, with Title 10 (10 CFR) applying to energy.

3.1.8 *deviation*—a departure of a characteristic from established procedures or specified requirements.

3.1.9 *documentation*—any written or pictorial information describing, defining, specifying, reporting, or certifying activities, requirements, procedures, or results.

3.1.10 *inspection*—a phase of quality control which by means of examination, observation, or measurement determines the conformance of materials, supplies, components, parts, appurtenances, systems, processes, or structures to predetermined quality requirements.

3.1.11 *inspection agency*—a person or persons authorized by the owner or owner's designee to verify conformance of the coating work.

3.1.12 *nonconformance*—a deficiency in characteristic, documentation, or procedure that renders the quality of an item unacceptable or indeterminate. Examples of nonconformances include: physical defects, test failures, incorrect or inadequate documentation, or deviation from prescribed processing, inspection, or test procedures.

3.1.13 *owner*—the person, group, company, or corporation who has or will have the license for the facility or installation.

3.1.14 *owner's designee*—a person or persons authorized by the owner to act in his behalf.

3.1.15 *vendor*—any individual or organization who furnishes items or service to a procurement document.

4. Significance and Use

4.1 Quality assurance, as covered by this practice, comprises all those planned and systematic actions necessary to provide adequate confidence that safety-related coating work in nuclear facilities will perform satisfactorily in service.

4.2 Coating Service Level I applies to areas where coatings failure could adversely affect the operation of post-accident fluid systems. With some exceptions, Coating Service Level I applies to coatings inside primary containment.

4.3 Coating Service Level II applies to areas where coatings failure could impair, but not prevent, normal operating performance. The primary function of Service Level II coatings is to provide corrosion protection and decontaminability in those areas outside primary containment subject to radiation exposure and radionuclide contamination.

4.4 It is not practical to impose all the requirements of this practice on certain specific items that require only a small quantity of coating material. The owner, consistent with his formal Quality Assurance Program, may accept affidavits of compliance or certification attesting to the quality of a shop or field coating for such items. If required by licensing commitments, uncontrolled (unqualified, non-conforming, or unidentified) coatings shall be identified, quantified, and documented.

4.5 This practice may be incorporated in a project specification by direct reference or may be used to provide guidelines for the quality assurance program for coatings, on the basis of the owner's requirements. Effective use of this practice may also require the incorporation of applicable sections in project specifications for coatings on concrete, steel, equipment, and other related items.

5. General Quality Assurance Requirements

5.1 This section defines the general quality assurance requirements necessary for compliance with this practice. These requirements shall apply to all other sections of this practice.

5.2 The owner or the owner's designee shall be responsible for determining whether source inspection or a certificate of compliance attesting to the quality of coating work activity is required.

5.3 The general quality assurance requirements necessary to meet the purpose of this practice provide an acceptable basis for establishing a protective coating quality assurance program. All deviations from or exceptions to these requirements shall be reviewed by and shall be subject to approval by the owner or his designee before implementation. If unapproved deviations are discovered during any phase of the coating work activity, a nonconformance report shall be completed either by the owner, vendor, or owner's designee. The owner or the owner's designee shall approve the disposition of the nonconformance report.

NOTE—Notification of the Nuclear Regulatory Commission (NRC) is required by 10 CFR 21 for certain types of defects and noncompliances.

5.4 There are five major activities that shall be controlled and documented as a minimum for Service Level I protective coatings applied to nuclear facilities as follows:

- 5.4.1 Qualification and selection of coating materials,
- 5.4.2 Coating manufacturing,
- 5.4.3 Surface preparation of substrates,
- 5.4.4 Control of coating application, and
- 5.4.5 Coating inspection.

5.5 The five major activities specified in 5.4 are designed to meet the applicable quality assurance requirements of Appendix B to 10 CFR 50, and of ANSI N45.2. All five of these controlled activities shall have appropriate documentation including approved procedures and records to meet the Appendix B and N45.2 requirements.

5.6 The qualification and selection of coating materials shall be evaluated by the owner on the basis of criteria defined in Section 6 of this practice.

5.7 The coating manufacturer shall furnish a quality assurance program describing his methods for quality control of the specified coatings on the basis of criteria defined in Section 7, which is approved by the owner.

5.8 Should the owner designate an outside coating applicator to apply the specified coatings, the coating applicator shall provide a quality assurance program based on the criteria defined in Sections 8 and 9, which is approved by the owner.

5.9 Should the owner designate an inspection agency to inspect the application of the specified coatings, the inspection agency shall provide a quality assurance program based on the criteria defined in Section 10, which is approved by the owner.

5.10 If application or inspection, or both, are performed under the owner's quality assurance program, procedures shall be established to control these activities.

6. Control of Selection and Qualification of Coating Materials

6.1 All qualifications of coating materials shall meet the applicable standards referenced in Guide D 3842 to the extent defined by the owner or the owner's designee in design criteria, safety analysis reports, quality assurance program, or other controlling documents.

6.2 The coating manufacturer shall furnish recommended surface preparation and application procedures for each coating system on each substrate as covered by the project specification including previously coated surfaces as applicable. The coating manufacturer shall also furnish recommended storage conditions for each coating material specified.

7. Control of Coating Manufacturing

7.1 The coating manufacturer shall maintain a Quality Assurance Program and shall provide adequate documentation to show that the quality of a given coating system as supplied is the same composition (within owner approved manufacturing tolerances) the coating system previously tested for qualification. The coating system shall be requalified if there are significant changes in formulation or end-product properties. The manufacturer shall provide the owner or the owner's designee documentation based on the criteria stated in 7.1.1 through 7.1.5.

7.1.1 The coating manufacturer shall provide the purchaser with a product identity certification record for each batch of coating material shipped. As a minimum, the

als, product identity certification record shall contain the following information:

- 1.1 Established acceptance criteria ranges and batch characteristics for weight per gallon and viscosity,
- 1.2 Batch number,
- 1.3 Date manufactured,
- 1.4 Shelf life expiration date,
- 1.5 Certification (signed by a responsible technical manager) that the product shipped is the same composition (within owner-approved manufacturing tolerances) as the product tested for qualification.

1.2 Separate acceptance criteria may be established for evaluation at time of manufacture and for evaluation during the shelf life period, but these shall be separately identified.

1.3 Data which is generic to the product and not batch specific (for example, nonvolatile, cure time, pot life, etc.) shall be furnished to the owner as requested, but need not be duplicated on each product identity certification record.

1.4 Material which has exceeded shelf life may be evaluated by testing and the shelf life extended in writing by the manufacturer's technical department. Testing for extension of shelf life shall be performed on an unopened container removed from the job site storage area, and not from a retained laboratory sample.

1.5 The owner may elect to perform verification testing on products received to ensure compliance with this practice.

2 Each container shall be labeled with the product designation. The label or container shall bear a batch number or other factory marking, permanently affixed, showing the individual lot or batch designation. The date of manufacture, and the shelf life expiration date shall appear separately on the label or container.

3 Retained batch samples from products furnished for the project shall be kept by the manufacturer for the stated shelf life.

Control of Surface Preparation of Substrates

3.1 This section defines the quality assurance requirements for the surface preparation of bare substrates or of previously coated surfaces.

3.2 The surface preparation of substrates or of previously coated surfaces shall conform to the requirements of the project specification. Treatment of nonqualified or incompatible concrete primers/sealers and concrete form-release agents shall be addressed.

3.3 The project specification shall include inspection methods to ensure the requirements of the specification are met.

3.4 The coating applicator shall submit written surface preparation procedures addressing each substrate to be coated including previously coated surfaces.

3.5 The responsible organization shall report daily on

surface preparation during each shift for each area of work.

9. Control of Application of Coating Systems

9.1 This section defines the quality-assurance requirements necessary to comply with this practice to ensure that the applied coating system is basically the same as that which was tested for qualification.

9.2 The coating applicator shall follow written owner accepted application procedures for applying each coating system on each substrate and on each previously coated surface. The coating manufacturer's latest written application instructions shall be incorporated as part of the procedures.

9.3 All application personnel shall be qualified and their qualification documented in accordance with the applicable quality assurance program and Practices D 4227 or D 4228.

9.4 Receiving, storing, and dispensing of coating materials shall be appropriately documented as per established requirements.

9.5 The responsible organization shall report daily on the application work for each shift for each area of work.

10. Control of Coating Inspection

10.1 It is the responsibility of the owner as identified in 5.3 to specify and verify control measures to assure that the inspection of the coating work is adequate to achieve the required quality. Inspection hold points shall be established to ensure in-process inspection results are adequate. The owner or the owner's designee shall be responsible for the inspection activity. In all cases the inspection function shall be properly documented as required by Appendix B of 10 CFR 50 and ANSI N45.2 for record purposes.

10.2 All inspection personnel shall be qualified and certified in accordance with Guide D 4537.

10.3 Inspection shall conform to all the applicable requirements of the project specification and all other applicable requirements of this document.

10.4 A written daily coating inspection record shall be maintained by the owner.

10.5 In the case of any significant deviation or defective work, the corrective action shall be documented.

10.6 Final acceptance of completed work shall be documented.

11. Documentation

11.1 Sufficient quality-assurance records and documents shall be maintained to furnish objective evidence of compliance with the specifications and the specified quality assurance procedures.

11.2 Documentation shall be maintained by the owner or the owner's designee as defined in the owner's quality assurance program.

11.3 Distribution of documentation shall be as defined in the quality assurance procedures.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Preparation of Glass Panels for Testing Paint, Varnish, Lacquer, and Related Products¹

This standard is issued under the fixed designation D 3891; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

1. Scope

1.1 This practice covers the preparation of glass panels for subsequent testing of paint, varnish, lacquer, and related products.²

1.2 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

- D 364 Specification for Industrial Grade Xylene³
- D 1152 Specification for Methanol (Methyl Alcohol)⁴
- D 1193 Specification for Reagent Water⁵

3. Significance and Use

3.1 The procedures described in this practice are designed to provide uniform glass panels for testing of paint, varnish, lacquer, conversion coatings and related products.

4. Reagents and Materials

4.1 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water conforming to Type IV of Specification D 1193.

4.2 *Solvents*—V M & P naphtha, xylene, 2-methoxypropanol, and methanol complying with the appropriate specifications (see Specifications D 364 and D 1152).

4.3 Glass of the following types may be specified in the applicable test methods:

4.3.1 *Window Glass*, (float glass) the surface of which is plain and free of irregularities.

4.3.2 *Clear Plate Glass*, not less than 5 mm thick.

4.3.3 *Plate Glass* that has been ground uniformly on one side with 1F carborundum.

4.3.4 *Black Structural Glass*,⁶ one side of which has been polished to a smooth, high-gloss surface.

4.3.5 *White Structural Glass*, one side of which has been polished to a smooth, high gloss.

5. Method of Preparation

5.1 *New Panels*—Using a clean lintless cloth, wipe the panel with a solvent mixture consisting of equal volumes of V M & P naphtha and xylene or of 3 volumes of V M & P naphtha and 1 volume of 2-methoxypropanol or with water. When all soluble and loosely adhering soil has been washed off, flush with clean solvent. Allow panels to dry at room temperature or force dry at a temperature no higher than 300°F (150°C). After cooling to room temperature, rub with a clean lintless cloth if necessary.

5.1.1 The surface after cleaning shall be water-break free. This is determined by momentarily immersing in reagent water one panel of each twenty prepared. If a continuous water film is not retained (that is, the water film breaks), immerse the panel in methyl alcohol to obtain a water-break-free surface. After removal, dry at a temperature of 125 to 200°F (52 to 93°C) and allow to cool before coating or storing.

5.1.2 Other combinations or organic reagents that will produce a surface equal in cleanliness to the solvent mixtures mentioned in 5.1 may be used if agreed upon between the purchaser and the supplier.

5.2 *Used Panels*—Remove the old paint, using a paint and varnish remover of the organic solvent type or a suitable solvent mixture. Do not use a spatula, sandpaper, or other instrument of treatment that might scratch or etch the surface. After washing off the residues clean the panels as described in 5.1.

5.3 *Protection After Preparation*—Use panels immediately after preparation or store wrapped in clean, hard surfaced paper to minimize lint on the glass surface. To avoid contamination by fingerprints, do not touch the surface of the panels after preparation. Handle only by the edges.

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.27 on Accelerated Tests for Protective Coatings.

Current edition approved Aug. 30, 1990. Published November 1990. Originally published as D 3891 - 80. Last previous edition D 3891 - 80.

² This practice is intended to be equivalent to Method 2021 of U.S. Federal Test Method Standard 141.

³ Discontinued, see 1982 *Annual Book of ASTM Standards*, Vol 06.03.

⁴ *Annual Book of ASTM Standards*, Vol 06.03.

⁵ *Annual Book of ASTM Standards*, Vols 06.03 and 11.01.

⁶ Black Vitrolite (Libby-Owens-Ford Glass Co.) and Carrara (PPG Industries) glass have been found satisfactory for this purpose and are obtainable from some local glaziers.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Evaluating Coatings Used in Light-Water Nuclear Power Plants at Simulated Design Basis Accident (DBA) Conditions¹

This standard is issued under the fixed designation D 3911; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

INTRODUCTION

During a design basis accident (DBA) in nuclear power plants, conditions in the reactor containment will be characterized by elevated temperature and pressure, as well as the presence of a radiation environment. Water sprays, with or without chemical additives, may be used in the primary containment to suppress the consequences of the incident, to scavenge radioactive products, and to return the containment to near-ambient conditions.

1. Scope

1.1 This test method establishes procedures for evaluating protective coating systems test specimens under simulated DBA conditions. Included are a description of conditions and apparatus for temperature-pressure testing, conditions for radiation testing, and procedures for preparing, examining, and evaluating the samples.

1.2 This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Referenced Documents

2.1 ASTM Standards:

- D 714 Test Method of Evaluating Degree of Blistering of Paints²
- D 1193 Specification for Reagent Water³
- D 4082 Test Method for Effects of Radiation on Coatings Used in Light-Water Nuclear Power Plants²

2.2 ANSI Standard:⁴

- N512-1974 Protective Coatings (Paints) for the Nuclear Industry.

3. Terminology

3.1 Definitions:

3.1.1 *blistering*—the formation of bubbles in a coating (paint) film.

3.1.2 *boiling water reactor (BWR)*—a reactor in which the water moderator-coolant is boiled directly within the reactor

core. The pressure in the reactor vessel is only slightly greater than the steam turbine pressure.

3.1.3 *chemical spray*—a solution of chemicals, such as those contained in Table 1, which could be used during a loss of coolant accident (LOCA) to suppress the incident, to scavenge fission products, and to return the facility to near-ambient conditions.

3.1.4 *coating (paint) system*—a polymeric protective film consisting of one or more coats applied in a predetermined order by prescribed methods to a defined substrate.

3.1.5 *cracking*—a break or a split in the coating (paint) system extending through the film or to the substrate.

3.1.6 *curing*—the transformation of a coating or other material into a solid phase or film.

3.1.7 *DBA*—a generic term for any one of a family of accident conditions which can result from postulated events. These conditions are generally associated with the rupture of high energy piping. The more commonly recognized accident conditions used to evaluate coating systems for primary containment are the LOCA or main steam pipe break.

3.1.8 *deionized water*—water prepared by an ion exchange process meeting the requirements of Specification D 1193, Types II and III.

3.1.9 *delamination*—separation of one coat or layer from another coat or layer, or from the substrate.

3.1.10 *engineered safety system*—a system designed to mitigate the effects of a design basis accident.

3.1.11 *irradiation*—exposure to ionizing radiation.

3.1.12 *light-water nuclear reactor*—an apparatus, using light water as a moderator, in which fissionable material is arrayed so that controlled nuclear fission may be sustained in a self-supporting chain reaction.

3.1.13 *LOCA*—the specific conditions anticipated fol-

TABLE 1 Typical Spray Solutions

Composition	Chemical Compound	Concentration (in Deionized Water)
A	Sodium borate	2000 to 4000 ppm boron
	Sodium hydroxide	adjust solution to pH 9.0 to 10.0
B	Boric acid	2000 to 4000 ppm boron
	Hydrazine	50 ppm unreacted excess
	Sodium phosphate, dibasic	adjust solution pH to 6.8 to 10.0

¹ This method is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generation Facilities and is the direct responsibility of Subcommittee D33.02 on Service and Material Parameters. Current edition approved Feb. 24, 1989. Published April 1989. Originally published as D 3911 - 80. Last previous edition D 3911 - 80¹.

² Annual Book of ASTM Standards, Vol 06.01.

Following a loss of coolant accident that would expose the heated surface of the containments of a light-water nuclear power facility to the temperature-pressure environmental parameters described.

3.1.14 *peeling*—separation of one or more coats or layers of a coating from the substrate.

3.1.15 *pressurized-water reactor (PWR)*—a nuclear power reactor design utilizing liquid water under high pressure as moderator-coolant.

3.1.16 *quality assurance*—the verification of the conformance of materials and methods of application to the governing specifications, in order to achieve the desired result.

3.1.17 *reactor containment (containment)*—the enclosure provided to protect the environment from the consequences of a nuclear incident.

Significance and Use

4.1 This test method is designed to provide a uniform test to determine the suitability of coatings used inside primary containment of light-water nuclear facilities under simulated DBA conditions. Variations in actual surface preparation and in application and curing of the coating materials may require additional testing as deemed necessary by the specifying or qualifying agency, or both, if it is anticipated that the variations may adversely affect the performance of the coating system during a DBA. This test method is intended only to demonstrate that under DBA conditions, the coatings will remain intact and not become debris which could compromise engineered safety systems.

Apparatus

5.1 *Environmental Test Chamber*, constructed of materials that are corrosion-resistant to the test solutions.

5.2 The equipment shall be capable of reproducing and continuously recording the temperature and pressure profiles of the DBA conditions.

5.3 A sufficient number of thermocouples shall be located in the test chamber to assure conformity to the test curve,

and so that both the temperature of the vapor phase and of the liquid phase (if present) can be recorded.

6. Preparation of Test Specimens

6.1 Determine the appearance of the test panels prior to testing by photo documentation or equivalent methods in order to provide a basis for post-test comparison. The testing requirements should indicate if this assessment will be done prior to shipping to the test facility.

6.2 Unless otherwise specified, a minimum of four samples shall be required to establish conformance of a given coating system on a given substrate, with two of the four samples being irradiated prior to testing in accordance with Test Method D 4082. Typical laboratory test panels are 2 by 4 by 1/8 in. for steel panels and 2 by 2 by 4 in. for concrete panels.

6.2.1 *Steel Panels*—Prepare in accordance with ANSI N512 or as necessary to duplicate actual conditions.

6.2.2 *Concrete Blocks*—Prepare in accordance with ANSI N512 or as necessary to duplicate actual conditions.

7. Procedure

7.1 Test Parameters:

7.1.1 Test coatings using the applicable curves from the latest Safety Analysis Report (SAR) identified by the owner for the specific containment. Illustrations of time-temperature-pressure test curves that simulate primary containment atmospheres during a DBA are shown in Figs. 1 and 2.

7.1.2 The curves depicted in Figs. 1 or 2 may be used if they represent conditions equal to or more severe than those DBA conditions anticipated.

7.1.3 The parameters of the curves may be simulated during testing as continuous functions or as an enveloping stepwise function.

7.1.4 Steam is used initially to achieve the desired thermal shock and to raise the test chamber and its environment to the prescribed test conditions. After equilibrium is achieved, the temperature of the test chamber is maintained by means

FIG. 1 Typical Design Basis Accident (DBA) Testing Parameters (Temperature-Time-Pressure)—BWR Drywell

FIG. 2 Typical Design Basis (DBA) Testing Parameters (Temperature-Time-Pressure)—PWR Containment

of internal or external resistance, or both, heating elements, or other suitable means. The duration of steam injection should be minimized, as much as feasible, and the duration shall be recorded. Where inlet steam temperatures exceed 370°F, initial steam injection shall be no longer than 15 min.

7.2 Spray Solution:

7.2.1 Unless otherwise specified, use deionized water when testing under simulated DBA conditions.

7.2.2 Record the chemical composition of the spray solution before each test.

8. Examination and Report

8.1 Examination:

8.1.1 Examine and evaluate test specimens within 4 h and again after 14 days following removal from the test chamber for the following coating defects:

8.1.1.1 Delamination and peeling.

8.1.1.2 Cracking.

8.1.1.3 Blistering in accordance with Test Method D 714.

8.1.2 Unless otherwise instructed, disregard the condition of the edges and plane areas within 1/4 in. (6.4 mm) from the edges of the steel or concrete test surfaces, and the top and bottom ends of the concrete surfaces.

8.2 Report—Report the following information:

8.2.1 The results of the evaluation of each test specimen. Report for all sides of concrete blocks and front and back of steel panels.

8.2.2 The extent of each defect from 8.1. Report "none" if no defects are present.

8.2.3 Any observations of unusual appearances.

9. Acceptance Criteria

9.1 Peeling shall not be permitted.

9.2 Delamination shall not be permitted.

9.3 Cracking is not considered a failure unless accompanied by delamination or loss of adhesion.

9.4 Blisters shall be limited to intact blisters which are

completely surrounded by sound coating bonded to the surface.

9.5 An owner may establish acceptance criteria more stringent than above. The above criteria are meant to establish minimum standards only.

10. Documentation

10.1 Testing Procedures—Document each of the following:

10.1.1 A description of the test apparatus, temperature and pressure profiles, spray solution composition including pH, duration, frequency, and rate of spray solutions, and any other pertinent test conditions.

10.2 Test Agency:

10.2.1 The testing agency shall be responsible for the documenting, reporting, and certifying of all tests.

10.2.2 The testing agency shall be responsible for meeting applicable quality assurance requirements.

10.2.3 The testing agency shall be responsible for providing color photographic documentation of the test surfaces as required.

10.2.3.1 Photographs shall reflect the actual size as close as possible of the test specimens.

11. Repairability

11.1 Test repair coatings applied to significant areas within Service Level I in accordance with the requirements for radiation and DBA conditions.

11.2 The test shall include evaluation of the repair coating applied in accordance with the repair procedure over the intended surface preparation or the original qualified coating system, or both.

11.3 Significant areas shall be determined by the specifying or qualifying agency. Nonsignificant areas have been determined as being less than 2 ft² in an approximate 2000 ft² area; larger areas require a decision regarding significance.

Precision

2.1 Test equipment must be demonstrated to have the capability to reproduce the design time/temperature parameters within ± 10 s and $\pm 5^\circ$ F and the design pressure within

± 3 psig. In any test where the test equipment imposes variances in the pressure/temperature parameters that are outside this range, an analysis of the validity of these test results should accompany the test data.

Standard Test Method for Chemical Resistance of Coatings Used in Light-Water Nuclear Power Plants¹

This standard is issued under the fixed designation D 3912; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method establishes procedures for the evaluation of the chemical resistance of coatings used in light-water nuclear power plants.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*

D 714 Test Method for Evaluating Degree of Blistering of Paints²

D 1193 Specification for Reagent Water³

2.2 *NACE Standard:*

NACE TM-01-74 Laboratory Methods for the Evaluation of Protective Coatings Used as Lining Materials in Immersion Service⁴

2.3 *ANSI Standard:*

N512-1974 Protective Coatings (Paints) for the Nuclear Industry, Section 7⁵

3. Significance and Use

3.1 The specific chemical resistance tests to be performed are dependent upon the relative severity of the service conditions. Figure 1 should be used as a guide to chemical solutions commonly used in various types of facilities. These listed solutions should not be construed as all-inclusive. Specialized conditions may require chemicals or concentrations not listed. In such cases, applicable solutions may be used.

3.2 The lining test may be used to evaluate the resistance characteristics of coating systems for lining surfaces of tanks, vessels and similar facilities used in a light-water nuclear power plant.

4. Preparation of Test Specimens

4.1 Steel Panels:

4.1.1 Prepare steel panels in accordance with ANSI N512.⁶

4.1.2 Use carbon steel panels in lining tests at least 7 by 7 by 1/4 in. (178 by 178 by 6.4 mm) thick for Procedure A only.

4.2 *Concrete Blocks*—Prepare blocks in accordance with ANSI N512 with the exception that the top and bottom ends of the block shall be coated.

5. Sampling

5.1 Prepare individual specimens for testing in each of the pertinent solutions.

5.2 Prepare one additional specimen as a control. Multiple tests may be performed.

6. Procedure

6.1 Test in accordance with NACE TM-01-74, Procedure B, Immersion Testing, except use Procedure A, One-Side Testing (cold wall) when a significant temperature differential is anticipated across the coating film as for tank linings.

6.2 Lining Test:

6.2.1 Immerse lining test specimens in the appropriate test solutions listed in Fig. 1 or as otherwise specified for a minimum of 180 days.

6.2.2 Maintain a temperature of $72 \pm 5^\circ\text{F}$ ($22 \pm 3^\circ\text{C}$) unless otherwise specified by the purchaser.

6.2.3 Use deionized water with an initial resistivity of not less than $1 \text{ M}\Omega/\text{cm}$ at 77°F and with a total solids of more than 0.5 ppm, more than 0.15 ppm of chloride or more than 0.15 ppm of fluoride. Maintain the pH range from 6.0 to 8.0.

6.2.4 Change the deionized water daily during the first week and weekly thereafter. Measure any constituents leached out before the water is changed.

6.3 Chemical Exposure Tests:

6.3.1 Test the chemical resistance properties of the coatings by immersion in the appropriate test solutions listed in Fig. 1 or as otherwise specified for a time interval that shall vary as follows.

6.3.1.1 For simulated exposure to occasional splash and spillage on areas where the solution may evaporate in place, immerse the specimens for a period of 5 days in the listed reagent solutions.

6.3.1.2 For simulated exposure to decontamination solutions, immerse the specimens for a period of 24 h in the listed solutions.

6.3.1.3 For simulated exposures to corrosive fumes of the listed reagents, immerse the specimens for a period of 8 h.

¹ This test method is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generation Facilities and is the direct responsibility of Subcommittee D33.02 on Service and Material Parameters. Current edition approved May 30, 1980. Published July 1980.

FIG. 1 Sample Form

6.3.2 Maintain a temperature of $72 \pm 5^\circ\text{F}$ (22 to 3°C) unless the service conditions require a higher temperature.

6.3.3 Use reagent grade chemicals and distilled water conforming to Specification D 1193, Type III, for all solutions.

Examination and Evaluation

7.1 Lining Test:

- 7.1.1 Examine the test specimens weekly for the first month and then monthly thereafter.
- 7.1.2 Inspect specimens immediately upon completion of the test period. Make a final inspection not later than 24 h after removal from the test solution.
- 7.1.3 Evaluate the test specimens at each inspection for peeling, delamination, blistering (Test Method D 714), discoloration, and softening.

7.2 Chemical Exposure Tests:

- 7.2.1 Examine the test specimens at the end of the test period or every 24 h, whichever is the shorter time.
- 7.2.2 Evaluate the condition of the specimens within 1 h after removal from the test solutions.
- 7.2.3 Evaluate the test specimens at each inspection as in 7.1.3.

8. Documentation and Report

- 8.1 Report all procedures and conditions relating to the test specimen preparation.
- 8.2 Document the testing procedure and test results. A suggested format is illustrated by Fig. 1.

9. Precision and Bias

- 9.1 These tests are qualitative in nature. Precision and bias are not definable.

Standard Specification for Standard Environment for Conditioning and Testing Paint, Varnish, Lacquer, and Related Materials¹

This standard is issued under the fixed designation D 3924; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

¹ NOTE—Keywords were added editorially in January 1991.

1. Scope

1.1 This specification defines the standard atmospheres for normal conditioning and testing of paint, varnish, lacquer, and related materials, at approximately ambient conditions.

NOTE 1—See Definitions E 41, Specification E 171 and Method E 337.

2. Referenced Documents

2.1 ASTM Standards:

E 41 Definitions of Terms Relating to Conditioning²

E 171 Specification for Standard Atmospheres for Conditioning and Testing Materials³

E 337 Test Method for Measuring Humidity with a Psychrometer (The Measurement of Wet- and Dry-Bulb Temperatures)⁴

3. Standard Atmosphere

3.1 Unless otherwise specified, conditioning and testing of coating materials known to be sensitive to variations in temperature or relative humidity shall be carried out in an atmosphere having a temperature of $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and a relative humidity of $50 \pm 5\%$. If closer tolerances are

required, $\pm 2^\circ\text{F}$ ($\pm 1^\circ\text{C}$) or even narrower limits, and $\pm 2\%$ relative humidity may be specified.

3.2 The standard room or cabinet shall be well-ventilated but free of drafts, dust, products of combustion, and laboratory fumes. Lighting conditions, unless otherwise specified, shall be that normally maintained in a room used for paint test purposes.

4. Standard Temperature

4.1 Unless otherwise specified, the standard test temperature shall be as specified in Section 3.

5. Room Temperature

5.1 A temperature in the range from 65 to 85°F (18 to 29.5°C) shall be called room temperature.

6. Conditioning and Testing

6.1 Unless otherwise specified in the test method, condition the organic coating materials or dried test films thereof and the test equipment for not less than 3 h in the appropriate atmosphere and verify the temperature of the material before conducting the test in the same atmosphere.

6.2 For routine testing where close temperature control is not critical, conduct all physical tests on organic coating materials or dried test films thereof at the room temperature of 65 to 85°F (18 to 29.5°C).

6.3 For referee testing, unless otherwise specified in the test method, conduct all physical tests on organic coating materials or dried test films thereof in the standard atmosphere as specified in Section 3.

7. Keyword

7.1 conditioning environment

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Sampling Liquid Paints and Related Pigmented Coatings¹

This standard is issued under the fixed designation D 3925; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice describes methods of taking representative samples of fluid paint or pigmented coating products from containers of any type.

1.2 The sampling of dry powder paints, clear coatings, mixed solvents, and nonpigmented materials of any type is not covered in this procedure.

1.3 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 *ASTM Standard:*

D 1475 Test Method for Density of Paint, Varnish, Lacquer, and Related Products²

3. Terminology

3.1 *Description of Term Specific to This Standard:*

3.1.1 *batch*—the quantity of liquid paint or coating produced in the final mixing operation after all production processes are complete. For example, when a number of pigment dispersions are reduced with additional vehicle together in a large tank, the resulting final mixture is one batch.

4. Significance and Use

4.1 Samples are taken from batches, lots, and shipments of paint in order to determine their uniformity and compliance with specification requirements. It is very important that these samples be of convenient and economical size and that they be representative of the batch of paint at the time it was filled into shipping or storage containers.

4.2 The time and effort necessary to ensure that the sample is representative of the original material will be repaid in reduction of laboratory work and elimination of possible rejections of acceptable material.

5. Sampling Considerations

5.1 The use of common sense and good judgment is important even in the apparently simple task of taking samples.

5.2 Use care to assure that all containers, agitating equipment, and sampling apparatus are *clean* and that they can in no way contaminate the sample being taken. Slight contamination of the paint sample may lead to false test results.

5.3 The sample container should be dry and not cooler than the temperature of the area in which the sample is to be taken.

5.4 Because pigmented coatings are dispersions and not solutions, finely divided pigment particles dispersed in the coating vehicle may settle upon standing. Consequently, thorough and careful agitation before sampling is necessary to restore the paint to its original, uniform condition. The method of agitating or stirring is therefore of prime importance.

5.5 As soon as samples of paint are taken from the shipping or storage container, place them in clean, nonreactive, dry, air-tight containers to prevent evaporation. Do not store samples in plastic bottles because volatile solvents may diffuse through the walls. Loss of volatile solvents may introduce errors in such tests as viscosity, weight per gallon, and nonvolatile content as well as other properties. If cap liners are used, they should also be nonreactive with the material. If the sample is self reactive or highly volatile, appropriate sample container precautions should be taken to prevent over-pressurization of the container.

5.6 When representative samples have been obtained and packaged in clean, closed containers, deliver them promptly to the testing laboratory. During the period between sampling and delivery to the testing laboratory it is important that samples be kept at temperatures from 40 to 100°F (5 to 40°C) because extremes of temperature may change properties of some paint products.

6. Procedure

6.1 Because of differences in physical properties, somewhat different procedures are required for agitating and sampling those paints containing water as the volatile component in comparison to those containing organic solvents. For coatings with no volatile ingredients, use the method applicable to materials containing organic solvents.

6.2 *Pigmented Coatings Containing Organic Solvents*—Materials in this group are of many different types but all contain organic solvents, not water, as their volatile portion and they are fluids, not dry powders.

6.2.1 *Small Containers:*

6.2.1.1 When the batch to be sampled is filled in small containers and batch numbers are marked on the container, put all containers from the same batch together. From *each batch* select at random 1 % of, but not more than five containers, using the next larger whole number if a fraction

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.20 on Quality Assurance and Statistics.

Current edition approved Sept. 15, 1991. Published November 1991. Originally published as D 3925 - 80. Last previous edition D 3925 - 81 (1985) ϵ 1.

² *Annual Book of ASTM Standards*, Vol 06.01.

results. For example, if there are 275 containers in a batch, select three for test.

6.2.1.2 After selection of the filled, unopened containers, thoroughly agitate or stir the contents by the best means available. Acceptable methods of mixing are mechanical shaking or stirring or hand stirring with a paddle, followed by "boxing," that is pouring back and forth between the original and a clean empty container. Mechanical shakers are desirable for most materials since there is thorough agitation in a closed container. To prevent evaporation, agitate in a closed container lacquers and other coatings containing a highly volatile solvent.

6.2.1.3 Before mechanical shaking, open the container and check to be sure that the pigment has not caked on the bottom of the container. If this condition exists, stir manually to break up the hard settling and then put the containers on the mechanical shaker. Agitate paints having a weight per gallon of 11 lb (1.3 g/mL) or less on the shaker for 10 min and those with a weight per gallon of more than 11 lb for 20 min.

6.2.1.4 Once the contents have been thoroughly agitated, pour half of the material into an empty container and take a 1 qt (1 L) (or smaller if taken from a container of 1 qt or less) sample from each half. Determine the weight per gallon on each sample in accordance with Test Method D 1475. The two determinations should not differ more than 0.5 %. If the results differ by more than this the paint is not thoroughly mixed. Return the material to the original container, stir again, and repeat the test.

6.2.2 Containers Larger than 5 Gal:

6.2.2.1 30 and 55-Gal Drums—From each batch select at random 5 % of but not more than three containers. Drums may be stirred satisfactorily by several means. With open-head types, mechanical or manual stirring may be used. Some drums contain their own agitators; drum shakers or rollers may also be used. After thorough agitation, take samples from the top and bottom of the drum and compare weights per gallon as described in 6.2.1.4.

6.2.2.2 250 to 500-Gal Containers (Tote Tanks)—Select

at random 25 % of all containers for test. Take samples from top and bottom of the container and compare weight per gallon determinations as described in 6.2.1.4.

6.2.2.3 Tank Wagons and Tank Cars—Sample each compartment of the wagon or car. Pigmented paints and coatings packaged in large containers are generally formulated to be essentially nonsettling. Therefore, take samples from the top, middle, and bottom of the container and make weight-per-gallon determinations before any vigorous stirring is done. If the resulting tests fall within the limits described earlier, no further agitation is necessary. Samples may be obtained with a Bacon-bomb sampler or a "thief" apparatus.

6.3 Pigmented Coatings Containing Water:

6.3.1 Handle pigmented coatings containing water (latex paints, etc.) in a slightly different manner from solvent-thinned coatings. Water-thinned paints, if stirred too vigorously, have a tendency to incorporate air bubbles, which sometimes result in changing the physical properties of the paint.

6.3.2 With the above consideration, take the samples in accordance with the same general procedure outlined in 6.2 for paints containing organic solvents. If it has been necessary to shake, stir, or agitate a water-thinned paint vigorously, deaerate the samples before the weight-per-gallon tests are run.

6.4 Sampling from Tanks at the Factory—Mix the material in the tank thoroughly before completely filling two 1-qt (1-L) containers. If the containers are to be filled from a valve on the bottom or side of the tank, mix the material, draw off at least 5 gal (20 L) through the valve and return to the tank before taking the sample.

6.5 Sampling During Filling of Containers at the Factory—After the material is thoroughly mixed in the tank and filling of containers has commenced, take a 1-qt (1-L) sample when about 25 gal (100 L) have been filled and another when about 25 gal remain to be filled.

7.1 sampling

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Guide for State and Institutional Purchasing of Paint¹

This standard is issued under the fixed designation D 3927; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

The committee responsible for this standard has voted its withdrawal. In the absence of substantial reasons that it should be continued, the Society will approve withdrawal from publication in February 1993.

Scope

1.1 This guide aids state and local governments to make logical decisions in purchasing architectural paints on the basis of both quality and cost.

1.2 This guide concerns itself primarily with architectural grade sales paints as listed in Annex A2.2 especially whites and tints. Emphasis on this group of products is justified by their preeminence in usage and the difficulty in describing in simple terms requirements applicable to them.

NOTE 1—With experience much of the logic and many of the techniques described herein can be found applicable to a broad range of architectural coatings.

1.3 Many different methods can be used to select coatings. Three methods are presented in this guide and the user may choose the method or combination of methods best suited to his needs. The three methods are:

	Sections
Vehicle Ingredients/Cost Ratio Method	4
Performance/Cost Ratio Method	5
Application Method	6

3. Products

3.1 It is recommended that standard commercial products offered to the general public for a period of 2 years or produced and sold in accordance with applicable government specifications be considered for purchase by the methods described in Sections 4, 5, or 6.

4. Active Ingredients/Cost Ratio Method

4.1 This method utilizes, as an indication of quality, the coating composition provided by the manufacturer and is limited to interior and exterior wall paints listed in Annex A2.2.

4.2 Only those ingredients considered to contribute directly to quality are considered. The major active ingredients in most paints are vehicle solids or binder and primary hiding pigments.

4.2.1 The weight percent of vehicle solids may help to predict the scrubability or cleanability of a paint, but the quantity of pigment must also be considered. In general, the greater the ratio of vehicle solids to pigment, the better the scrubability and cleanability will be. The ratio of vehicle solids volume to pigment volume is a more useful parameter

³ Discontinued; see 1988 Annual Book of ASTM Standards, Vol 06.01.

but is not readily available. Moreover, each type of vehicle solids, such as alkyd in solvent-borne paints and vinyl or acrylic latex in waterborne paints, has its own properties and there are many other additives not shown that can affect scrubability, cleanability, and other properties.

4.2.2 The amount of primary hiding pigment, for example, titanium dioxide in a white or pastel gloss finish, is an indication of hiding power. Paints of equal depth of color (light reflectance) should be compared, since lightness affects visual hiding.

4.3 An advantage of the method is that no special equipment or experience is required. Even if extensive testing is possible, the active ingredients/cost ratio method is valuable for initial screening. The active ingredients/cost ratio for several types of paint can be combined into a single figure for each supplier with each paint's "Use Factor." (see Section 7 and Annex A5).

4.4 The active ingredients/cost ratio method is not as conclusive for flat paints that often have a high "Use Factor." The hiding (opacity) of flat paints, particularly latex paints, cannot be predicted from the amount of hiding pigments since these paints often obtain much of their hiding from air in a porous paint film (conventional dry hiding) or air incorporated in the components of the film (micro-void techniques). Consequently, performance tests should be made on latex flat paints whenever possible. The cost per gallon of those latex flat paints with acceptable performance can be used in conjunction with the active ingredients/cost ratio for this type of paint.

4.5 *Calculation of Ingredients/Cost Ratio*—Use the procedure in Annex A1 to calculate the ratio of active ingredients to unit cost of the paint. The greater the ratio, the more active ingredients a paint has per unit cost. In general, this will help determine if a paint is a good buy for the money, but may not determine the quality of a paint.

NOTE 2—A lower quality paint at a lower cost may be a good buy, but may not be of the desired quality.

5. Performance/Cost Ratio Method

5.1 Paint can be tested using standard test methods such as those suggested in Annex A2. Although there are many other test methods used in paint formulating and manufacture, the methods listed have been found to be most useful to the consumer in determining the quality of a product.

5.2 Since different products have different properties, specific test methods have been suggested for each type of product shown in Annex A2. The purchaser may eliminate some of these tests, if the property that the test measures is not important to him, or may add other tests.

5.3 Paint testing by the purchaser requires purchase of test equipment and some skill in performing and interpreting test results. However, a few basic tests such as hiding (opacity), porosity, or scrubability can be run with relatively inexpensive equipment and will help considerably in determining the quality of a paint.

5.4 The quality of a paint can be determined by analysis of test results. Some results are descriptive, such as "good" or "poor" while others are numerical but with large numbers from some test methods, such as 450 for scrubability, or small numbers from others, such as 0.990 in measuring hiding. Also with some tests the higher the numerical values,

the better the quality, but with others lower values indicate better quality. For these reasons the original results from the different tests cannot be directly combined into an equation to provide a numerical ranking.

5.5 If the purchaser wants a numerical value for overall quality to use in ranking various products, it is suggested that a scale from 0 to 10 be used for all test methods. Descriptive words can be converted to a numerical rating scale such as:

10	Excellent
8	Very good
6	Good
4	Fair
2	Poor
1	Very poor

Many ASTM test methods already use the 0 to 10 scale, but numerical results can be converted to this scale as shown in Annex A3.

NOTE 3—ASTM does not intend to define quality for the purchaser. The scales shown in Annex A3 are given as examples that can be modified by the purchaser, if desired.

5.6 Many of the important properties of a paint that can be tested and evaluated by a professional painter are listed in Annex A2. The purchaser can request that the painter note unusual behavior during the application of the coating; such judgemental rating of properties not normally tested can be used as an aid in the paint selection process.

5.7 Calculation of Performance/Cost Ratio

5.7.1 Use the procedure in Annex A4 to calculate the performance/cost ratio from the results obtained from laboratory tests or those supplied by painters, or both.

5.7.2 The calculated ratio will indicate if a paint has high performance relative to cost. It is possible to have a high relative ratio even though the overall quality may be low if the paint is low in cost. The overall quality of products should, therefore, enter into cost comparisons to ensure that they provide the quality desired by the purchaser. It is also possible to have a high overall quality rating for a paint and still have some property that is not acceptable to the purchaser. It is therefore suggested that minimum standards be established by the purchaser for those properties he considers important.

5.8 *Information Provided by the Supplier*—If the purchaser is not equipped to perform tests, he can request the manufacturer to supply test results that can be used for performance/cost evaluations. If the purchaser is equipped to run some simple tests or if a professional painter is available for evaluation, he need ask the manufacturer to supply data only for those properties requiring considerable skill or expensive equipment to measure.

6. Specification Method

6.1 Specifications can provide a useful, mutually satisfactory mechanism for listing essential quality requirements of a product. A specification is a document that attempts to describe precisely the requirements that a product must meet to be considered suitable for a particular use. Requirements may be based on composition of the product or its performance. Composition requirements are easier to monitor while performance requirements, which are preferred, are more difficult to establish and evaluate. Consequently, most coating specifications are a combination of both types.

6.2 Specifications establish the minimum level for a product, but if requirements are set too low it becomes difficult to purchase superior coatings that may be a better value. Specifications may encourage manufacturers to formulate special products that meet the specification but are different from those sold to the general public.

6.3 State and local government purchasers may write a specification for each product, but considerable knowledge of paint properties and how they are related to practical application and performance of the product is required. Government purchasers may use Federal specifications already prepared for many products.

7. Use Factor

7.1 A use factor can be determined by dividing the total

annual cost or quantity of each type of paint by the total cost or quantity of all paints used by the purchaser. These factors permit each type of paint to influence the evaluation of bids in direct proportion to the quantity used.

7.2 If a purchaser wishes to consider the purchase of a complete line of paint from one supplier, then all of the ingredient/cost or performance/cost ratios for each of the supplier's products can be averaged to give an overall value for each supplier's line of products. Since different products in a line may vary in quality, more emphasis should be given to those that the purchaser intends to use the most. This can be done by multiplying the ratio for each paint by the use factor as shown in Annex A5 to determine the weighted average.

ANNEXES

A1. CALCULATION OF INGREDIENT/COST RATIO

A1.1 Obtain from the supplier the weight per gallon of the paint or take the weight per gallon in accordance with Test Method D 1475.

A1.2 Obtain the weight percent of active ingredients from the supplier.

A1.3 The relative hiding efficiency of the most common white hiding pigments are as follows:

	Efficiency Factor
Rutile titanium dioxide	1.00
Anatase titanium dioxide	0.75

	Efficiency Factor
Lithopone	0.18
Zinc oxide	0.14

Consider all grades of high content rutile titanium dioxide as 100 % active pigment even though the actual percent of titanium dioxide in the pigment is less than 100 %, since the total pigment contributes to hiding efficiency.

A1.4 Example of Calculations:

Three latex paints A, B, and C are being considered for purchase

Ingredients ⁴	Composition Weight, %			×	Weight/gal			=	Active Ingredient, lb/gal		
	A	B	C		A	B	C		A	B	C
Titanium dioxide (83 % TiO ₂)	17		13		11.54	11.50	11.00		1.96		1.43
Titanium dioxide (90 % TiO ₂)		16				(for all ingredients)					
Lithopone		5								1.84	
Silicates	13	10	20							0.58	
Silica	9		9								
Calcium carbonate		8									
Vinyl-acrylic resin solids	13	13	9						1.50	1.50	0.99
Additives	2	2	2								
Water	46	46	47								

Paint	Hiding Pigment	Efficiency Factor	Active Hiding Pigments	Vehicle Solids	Total Active Ingredients/Gal	Cost/gal	Ingredients/Cost Ratio
A	1.96	×	1.00	1.50	3.46	5.00	0.69
B	1.84	×	1.00	1.50	3.44	7.00	0.49
C	0.58	×	0.18		0.10		
	1.43	×	1.00	0.99	2.42	3.40	0.71

Paints A and B both have about the same amount of active ingredients, but the cost of B is higher. Paint B may have acceptable quality but it could be eliminated because of cost.

Paints A and C both appear to be good buys, but C with its lower amount of active ingredients may have a lower quality than A and some performance tests would be recommended.

⁴ Chemical tests may be run to confirm the accuracy of composition presented by the manufacturer.

A2. RECOMMENDED TEST METHODS

Property	Test Method	Recommended for Paint Type	D 2805
Adhesion of organic coatings	D 2197	BCD	10
Adhesion by tape test	D 3359	DE	9
Brush application characteristics	painter	all	8
Blister resistance—accelerated testing of moisture blister resistance of exterior house paints on wood	D 2366	DE	7
Chalking of exterior paints	D 659	DE	6
Checking of exterior paints	D 660	DE	5
Color compatibility	in preparation	alt	4
Color difference of opaque materials	D 2244	all	3
Condition in container	painter	all	2
Consistency of paints using the stormer viscometer	D 562	all	1
Cracking of exterior paints	D 661	DE	0
Dirt pick-up	D 3719	DE	
Drying, curing, or film formation of organic coatings at room temperature	D 1640	CE	
Erosion of exterior paints	D 662	DE	
Flaking (scaling) of exterior paints	D 772	DE	10
Flow properties	painter	all	
Freeze-thaw resistance of latex and emulsion paints	D 2243	ABD	
Gloss—specular gloss	D 523	DE	
Hiding power of paints	D 2805	all	
Hiding power, practical	painter	all	A4.1
Hiding power—relative dry hiding power of paints	D 344	all	inside
Leveling characteristics of paint by draw-down method	D 4062	BC	Test
Porosity of paint films	D 3258	A	Test
Scrub resistance of interior latex flat wall paints	D 2486	A	Test
Sag resistance of paints using a multinoth applicator	D 4400	all	Test
Stain removal	in preparation	A	Test
Uniformity of gloss or sheen	D 3928	all	Test

A2.1 These tests may be performed at the discretion of the purchaser to ensure satisfactory performance.

A2.2 Types of Paint:

- A Interior latex flat
- B Interior latex gloss and semigloss
- C Interior solvent gloss and semigloss
- D Exterior latex gloss and flat
- E Exterior solvent-borne gloss and flat

A3. SUGGESTED 0 TO 10 SCALES FOR METHODS NOT ALREADY USING THIS SCALE⁴

D 2805 Hiding Power (Contrast Ratio)	D 3258 Porosity (Percent Reflectance Drop)	Flat ^a	Gloss or Semigloss (Wall Paints)
10 1.000	10 0 to 4	9 360 to 399	1350 to 1499
9 0.995 to 0.999	9 5 to 9	8 320 to 359	1200 to 1349
8 0.990 to 0.994	8 10 to 14	7 280 to 319	1050 to 1199
7 0.985 to 0.994	7 15 to 19	6 240 to 279	900 to 1049
6 0.980 to 0.984	6 20 to 24	5 200 to 239	750 to 899
5 0.975 to 0.979	5 25 to 29	4 160 to 199	600 to 749
4 0.970 to 0.974	4 30 to 34	3 120 to 159	450 to 599
3 0.965 to 0.969	3 35 to 39	2 80 to 119	300 to 449
2 0.960 to 0.964	2 40 to 44	1 79 to 40	150 to 299
1 0.955 to 0.959	1 45 to 49	0 0 to 39	0 to 149
0 0.950 to 0.954	0 50 to over		
D 2486 Scrubbability			
Flat ^a	Gloss or Semigloss (Wall Paints)		
10 400 or over	1500 or over		

⁴ The purchaser may wish to include a control material when paints are evaluated or a series of paints could be ranked to allow for variations in test methods or subjective evaluations.

^a See Footnote 5.

A4. PERFORMANCE/COST RATIO

A4.1 Three latex flat wall paints A, B and C being considered for purchase are tested for the four listed properties with the following results:
 Test 19—Hiding, Test Method D 2805
 Test 3—Brush Application, Painter
 Test 23—Porosity, Test Method D 3258
 Test 24—Scrubbability, Test Method D 2486

Method (from Annex A2)	19	3	23	24
Paint A	7	5	8	4
Rating (0 to 10)				
Overall rating (mean)				6.0
Cost per gallon				\$8.50
Performance/cost ratio				0.71
Paint B	8	4	7	5

Overall rating (mean)	6.0
Cost per gallon	\$7.50
Performance/cost ratio	0.80
Paint C	
Rating	9 6 2 5
Overall rating (mean)	5.5
Cost per gallon	\$6.85
Performance/cost ratio	0.80

A4.2 Paints A and B have the same overall performance rating, but paint A could be rejected because of its higher cost. Paints B and C have the same performance/cost ratio so they are both equal buys for the money. The purchaser, however, could decide that the value of 2 for the porosity of paint C is below his acceptable requirements for this property and reject this paint.

A5. USE FACTOR

A5.1 Paints from two different suppliers being considered for purchase are evaluated according to the active ingredients/cost ratio method with the following results:

Supplier 1					
Paint Type	Ingredients/Cost Ratio		Use Factor		Weighted Ratio
A	0.71	x	42.7 %	=	0.30
B	0.69	x	24.0 %	=	0.17
C	0.70	x	15.0 %	=	0.10
D	0.65	x	10.0 %	=	0.07
E	0.49	x	8.3 %	=	0.04
mean	0.648			Total	0.68

Supplier 2					
Paint Type	Ingredients/Cost Ratio		Use Factor		Weighted Ratio
A	0.65	x	42.7 %	=	0.28
B	0.49	x	24.0 %	=	0.12
C	0.69	x	15.0 %	=	0.10
D	0.70	x	10.0 %	=	0.07
E	0.71	x	8.3 %	=	0.06
mean	0.648			Total	0.63

^A Calculated from Annex A1.

A5.2 The ingredients/cost ratios of each supplier's line of paints averaged the same (0.648), but when these ratios are weighted according to a use factor, then supplier No. 1 is the better choice since paints with the better ingredient/cost ratios are the ones most used by the purchaser. However,

testing is the key to assurance of obtaining an acceptable product.

A5.3 A use factor can also be used to weigh paint lines evaluated by the performance/cost method.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Evaluation of Gloss or Sheen Uniformity¹

This standard is issued under the fixed designation D 3928; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the uniformity of gloss or sheen of a paint applied by brush to a test panel simulating an interior wall section. Variations in gloss or sheen that may be caused by short wet edge time, poor leveling, and pigment orientation or flotation during and after application are evaluated visually.

1.2 Because both the application and the panel evaluation are very subjective, this test method should be used only for comparative testing within one laboratory as the ratings assigned by different laboratories do not usually agree (see Note 1).

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Summary of Test Method

2.1 Paint is brush applied to a test panel using procedures and conditions that are most likely to cause nonuniformity of gloss or sheen. The dry film is then viewed under conditions that accentuate variations in gloss or sheen and the overall appearance is evaluated.

3. Significance and Use

3.1 When coatings are applied to large flat surfaces such as walls, the film thickness may vary or there may be small areas missed entirely (holidays) when the color of the fresh material and the previous film are very similar. It is much less costly if these areas can be touched up instead of having to repaint the entire surface.

3.2 Thickness is also affected in the locations where an area coated a short time before is joined with the area currently being coated (laps). An application technique that may affect the final appearance of the film is brushing or rolling the material in different directions in adjacent areas.

3.3 Both buyers and sellers are interested in determining whether a coating can be applied without exhibiting areas that differ in appearance because of laps and brush or roller marks, and whether it can be readily touched up to provide a uniform appearance in regard to gloss or sheen and all other aspects.

4. Apparatus

4.1 *Paint Brush*,² 2 in. (50 mm) wide with polyester bristles 2 3/4 in. (70 mm) long, chisel tip 7/16 in. (10 mm) thick. Previously used brushes are preferred.

4.2 *Paint Brush*,³ 1 in. (25 mm) wide with polyester bristles 2 1/4 in. (57 mm) long, chisel tip 9/16 in. (15 mm) thick. Previously used brushes are preferred.

5. Reagents and Materials

5.1 *Laminated Fiber Board*,⁴ 24 by 12 in. (610 by 300 mm) with at least one smooth side.

5.2 *Latex-Base Primer*.⁵

5.3 *Control Paint* (optional)—Since there are no standard panels, photographs, or paints for this test method, an agreed-upon paint of known uniformity of appearance should be included with the test paints as a control, unless the paints are only ranked.

6. Procedure

6.1 Apply the latex primer by spray to the entire face of a smooth side of the test panel so as to coat it uniformly at a spreading rate of about 450 ft²/gal (11 m²/L).

6.2 Air dry at least 18 h under standard conditions of 73.5 $\pm$ 3.5°F (23 $\pm$ 2°C) and 50 $\pm$ 5 % relative humidity and examine the panel for uniformity of primer application. If this appears satisfactory, divide the coated area into sections A and B as shown in Fig. 1.

6.3 Mount the panel vertically and position it as shown in Fig. 1 with section A to the right and section B to the left of the operator. Before painting, wet the brush with water if latex paints are to be tested or VM & P naphtha if the test paints are solvent reducible and shake out as much liquid as possible before using. Apply the paint under test to section A with the 2-in. (50-mm) brush (Note) at a spreading rate of 450 $\pm$ 25 ft²/gal (11 $\pm$ 0.5 m²/L). About 13 g are required to cover this area but the exact amount can be determined from the following equation:

$$g = [(A \times W)/S] \times 3.15$$

where:

A = area, in.²,

W = weight per gallon, lb/gal, and

S = spreading rate, ft²/gal.

² A polyester brush No. B-20CS from The Leneta Co., Ho-Ho-Kus, NJ, has been found suitable for this purpose.

³ A polyester brush No. B-10 from The Leneta Co. has been found suitable for this purpose.

⁴ Upson board, available from General Distributing Co., Lockport, NY, or The Leneta Co., has been found suitable for this purpose.

⁵ Similar to U.S. Federal Specification TT-P-650c Primer Coating Latex Base, White (for Gypsum Wallboard).

¹ This method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.42 on Architectural Finishes.

Current edition approved April 14, 1989. Published June 1989. Originally published as D 3928 - 80. Last previous edition D 3928 - 80 (1987).

FIG. 1 Test Panel

or the following metric equation:

$$g = [(A_m \times D)/S_m] \times 1000$$

where:

A_m = area, m^2 ,

D = density, g/mL or kg/L , and

S_m = spreading rate, m^2/L .

Make the initial brush strokes in the direction of the length of the panel and finishing strokes across the width of the panel with the wet edge feathered. Complete the painting of this section in about 45 s.

NOTE—This test method can be modified for roller application by using a small 3-in. (75-mm) roller instead of the 2-in. (50-mm) brush to rank the uniformity of a series of paints when applied by roller. The 1-in. (25-mm) brush should still be used for touch up.

6.4 One minute after completing the painting of section A, apply paint to section B with the same brush still wet with the test paint. Use the same amount of paint and time to coat section B as for section A but make initial brush strokes across the width of the panel and finishing strokes along the length of the panel. Brush the finishing strokes into section A overlapping this section by about 2 in. (50 mm) (see Fig. 1, area C).

6.5 Thirty seconds after completing the painting of section B, use the still-wet brush but without additional test material to cross brush a figure X on this section as shown in Fig. 1, area D. Air dry for at least 18 h under standard conditions.

6.6 Using the 1-in. (25-mm) brush and the spreading rate as in 6.2, apply the test paint to an area of about 3 by 5 in. (75 by 125 mm) of section A (Fig. 1, area E). This is to simulate a wall section that has been touched up after the previous coat has dried. Allow the completed test panel to dry a minimum of 18 h under standard conditions.

6.7 View low gloss finishes at a 5° angle to the plane of the panel (85° to the normal) looking toward a strong light source. View gloss or semigloss coatings at 30° to the panel (60° to the normal). Rotate the panel 360° in the same plane while viewing in order to determine the overall appearance of the panel as viewed from different sides. Rate the test panel for gloss or sheen uniformity between sections using the following scale:

Rating	Score
Excellent	5
Very good	4
Good	3
Fair	2
Poor	1
Very poor	0

A rating of excellent means that there is no discernible variation in gloss or sheen between different areas of the panel. A rating of very poor means that there is a great variation in gloss or sheen between different areas.

6.7.1 Variations in gloss or sheen may be caused by various paint and substrate properties and application techniques so that lapped, cross-brushed, and touched up areas will not necessarily have the same degree of sheen or gloss uniformity and it may be advantageous to rate each of these areas separately.

7. Interpretation of Results

7.1 The uniformity in appearance of a wall can be estimated by evaluating the variation in gloss or sheen between areas A and C of the test panel.

7.2 The uniformity in appearance of a paint that has been applied by brush in different directions can be estimated by evaluating the variation in gloss or sheen between areas B and D.

7.3 The uniformity in appearance of touched-up areas can

estimated by evaluating the variation in gloss or sheen between areas A and E.

Precision

8.1 In an interlaboratory study of this test method in which one operator in each of six laboratories tested three paints of different levels of uniformity of appearance, all six

laboratories ranked the three paints in the same order of appearance but there were considerable differences between the actual ratings assigned by the laboratories to any one paint. The test method should, therefore, be used only for the comparative evaluation of a test paint against a mutually agreed upon control paint or for ranking a series of test paints.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Determining Volatile Organic Compound (VOC) Content of Paints and Related Coatings¹

This standard is issued under the fixed designation D 3960; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice provides measures of the volatile organic compound (VOC) content of solventborne and waterborne paints and related coatings as determined from the quantity of material released from a sample under specified bake conditions.

NOTE 1—Other terms used as synonyms for volatile organic compound are photochemically reactive organic compound (PROC) and volatile organic substance (VOS).

1.2 This practice provides a guide to the selection of appropriate ASTM test methods for the determination of VOC content.

1.3 Certain organic compounds that may be released under the specified bake conditions are not classified as VOC as they do not participate in atmospheric photochemical reactions. Such nonphotochemically reactive compounds are referred to as exempt solvents in this practice.

1.4 VOC content is calculated as a function of (1) the volume of coating less water and exempt solvents, and (2) the volume of coating solids.

3. Terminology

3.1 Definitions:

3.1.1 *exempt solvent*—organic compounds that do not participate in atmospheric photochemical reactions.

3.1.2 *nonvolatile material*—the solid material remaining after volatiles have been removed from a coating under specified test conditions.

3.1.3 *volatile organic compound (VOC)*—any organic compound that participates in atmospheric photochemical reactions.

3.1.3.1 *Discussion*—The definition of VOC adopted by the U.S. EPA and a list of exempt compounds are included in Appendix X3.

3.1.4 *volatile organic compound content (VOC content)*—the mass of VOC released from a coating under specified test conditions.

3.1.4.1 *Discussion*—VOC content is expressed in this practice as a function of: (1) the coating volume less water and exempt solvents, and (2) the volume of coating solids.

4. Summary of Practice

4.1 The volatile content, density, water content, volume solids and exempt solvent content of the coating are determined in accordance with designated methods and instructions. For multicomponent coatings, the components are first mixed in the appropriate ratios and the applicable values determined on the mixture. These values are combined using

³ Annual Book of ASTM Standards, Vol. 15.05.

⁴ Available from the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402.

⁵ Published in the *Federal Register*, January 16, 1989, Vol. 54, No. 11, p. 1966. Available from the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402.

specified equations to calculate the VOC content of the coating.

NOTE 2—In Reference Method 24, the U.S. EPA defines a waterborne coating as any coating with more than 5 % water by weight in its volatile fraction, and requires/allows water determination for waterborne coatings only.

Significance and Use

5.1 This practice discusses applicable ASTM test methods used in the determination of the VOC content of paints and related coatings and provides equations for calculating the VOC content expressed as the mass of VOC in: (1) per unit volume of coating less water and exempt solvents, and (2) per unit volume of coating solids.

5.2 Volatile organic compound content is used to compare the amount of VOC released from different coatings used for the same application; that is, to coat the same area in the same dry film thickness (assuming the same application efficiency).

5.3 VOC content data are required by various regulatory agencies.

5.4 Only the expression of VOC content as a function of the volume of coating solids gives a linear measure of the difference in VOC released from different coatings used for the same application.

NOTE 3—Thus assuming the same transfer efficiency, a coating with VOC content of 3 lb of VOC/gal of solids would release 1/2 the VOC that a coating with 6 lb of VOC/gal of solids.

5.5 When VOC content is expressed as a function of the volume of coating less water and exempt solvents, the values obtained do not account for differences in the volume solids content of the coatings being compared; this expression, therefore, does not provide a linear measure of the difference in VOC emitted from different coatings used for the same application.

NOTE 4—Thus, a coating with VOC content of 3 lb of VOC/gal less water and exempt solvents would release about 85 % less VOC than a coating with 6 lb of VOC/gal of solids.

6. Nonvolatile and Volatile Content

6.1 Guide D 2832 includes suggested time/temperature drying schedules for the determination of the nonvolatile and volatile content of various types of coatings.

NOTE 5—For regulatory compliance testing, follow the method and conditions specified in the applicable regulation. Federal Reference Method 24 specifies the use of Test Method D 2369.

6.2 Test Method D 2369 includes a specific drying schedule and sample weight, and heating 1 h at $110 \pm 5^\circ\text{C}$ for the determination of the weight percent volatile content of solventborne and waterborne coatings.

6.2.1 For multicomponent coatings, Test Method D 2369 specifies the components should be mixed first, then the volatile content should be determined on the mixture. Test specimens are held in the aluminum dish for at least 1 h before baking.

NOTE 6—U.S. EPA will allow the test specimens to stand at room temperature for up to 24 h prior to baking at $110 \pm 5^\circ\text{C}$ for 1 h.

7. Water Content

7.1 To determine the water content of waterborne coatings two test methods are available:

7.1.1 In Test Method D 3792, a paint specimen is diluted with dimethyl formamide, an internal standard (2-propanol) is added, and an aliquot of the mixture is injected directly into a gas chromatograph.

7.1.2 In Test Method D 4017, a paint specimen is diluted with pyridine and a catalyst (1-ethylpiperidine) is added to obtain a rapid and definitive titration end point.

7.1.3 With waterborne multicomponent coatings, the components are first mixed in the appropriate ratios, then water content is determined using Test Methods D 3792 or D 4017.

8. Density

8.1 The density of the paint or coating at 25°C is determined in accordance with Test Method D 1475. Although both the pycnometer and weight-per-gallon cup are covered by the test method, and the former is more accurate and precise, the weight-per-gallon cup is recommended because of its speed and ease of use.

8.2 With multicomponent coatings, first mix the components in appropriate ratios in sufficient quantity to determine the weight-per-gallon using Test Method D 1475.

9. Exempt Solvents

9.1 In Test Method D 4457 an internal standard (1-propanol) is added to the test specimen, and then the specimen is injected directly into a gas chromatograph.

9.1.2 With multicomponent coatings, the exempt solvent content is determined on the mixture of the components.

10. Calculation of VOC Content

10.1 In this practice VOC content is expressed in two ways: (1) as the mass of VOC per unit volume of the coating less water and exempt solvents, and (2) as the mass of VOC per unit volume of coating solids. The following equations should be used to calculate VOC content and may be used for coatings both "as supplied" and "as applied" (see Note 7).

NOTE 7—For compliance with VOC regulations, the VOC content should be calculated after any thinning or dilution ("as applied"). Instructions for VOC calculations of such diluted coatings are available in EPA 450/3-84-019.

10.2 *VOC Content Expressed as the Mass of VOC per Unit Volume of Coating Less Water and Exempt Solvent:*

10.2.1 *General Expression:*

$$\text{VOC} = \frac{(\text{weight percent of total volatiles less water less exempt solvents})(\text{density of coating})}{100 \% - (\text{volume percent of water}) - (\text{volume percent of exempt solvents})}$$

$$\text{VOC} = \frac{(W_o)(D_o)}{100 - V_w - V_{ex}} = \frac{(W_o - W_w - W_{ex})(D_o)}{100 - (W_w)(D_o/D_w) - (W_{ex})(D_o/D_{ex})} \quad (1)$$

where:

VOC = VOC content in g/L of coating less water and exempt solvent (see Note 8),

W_o = weight percent of organic volatiles, ($W_o - W_w - W_{ex}$),

W_v = weight percent of total volatiles, (100 % - weight % nonvolatiles, see Test Method D 2369),

W_w = weight percent of water, (see Test Methods D 3792 or D 4017),

W_{ex} = weight percent of exempt solvent, (see 3.1.3.1, Note 9, and Test Method D 4457),

V_w = volume percent of water, ($(W_w)(D_o/D_w)$),

V_{ex} = volume percent of exempt solvent, (see 3.1.3.1, Note 9), ($(W_{ex})(D_o/D_{ex})$),

D_o = density of coating, g/L, at 25°C, (see Test Method D 1475),

D_w = density of water, g/L, at 25°C, (0.997×10^3), and

D_{ex} = density of exempt solvent g/L, at 25°C, (see Test Method D 1475).

NOTE 8—To convert from g/L to lb/gal, multiply the result (VOC content) by 8.345×10^{-3} (lb/gal/g/L). To convert g/L to kg/L, divide the result by 10³.

NOTE 9—See Appendix X2.1 and X2.2 for comments on coatings containing one or more exempt solvents.

10.2.2 *Solventborne Coatings*—Calculate the VOC content in grams of VOC per litre of coating less water and exempt solvents using the appropriate equation:

10.2.2.1 For solventborne coatings that do not contain water or exempt solvents:

$$\text{VOC} = \frac{(W_o)(D_o)}{100} \quad (2)$$

10.2.2.2 For solventborne coatings that contain an exempt solvent but do not contain water (see 3.1.2.1 and Note 2):

$$\text{VOC} = \frac{(W_v - W_{ex})(D_o)}{100 - (W_{ex})(D_o/D_{ex})} \quad (3)$$

10.2.2.3 For solventborne coatings that contain water but do not contain exempt solvents (see 3.1.3.1 and Note 2):

$$\text{VOC} = \frac{(W_v - W_w)(D_o)}{100 - (W_w)(D_o/D_w)} \quad (4)$$

10.2.2.4 For solventborne coatings that contain both an exempt solvent and water, use Eq 1 in 10.2.1 (see 3.1.3.1 and Note 2).

10.2.3 *Waterborne Coatings*—Calculate the VOC content in grams of VOC per litre of coating less water and exempt solvent using the appropriate equation.

10.2.3.1 For waterborne coatings that contain no exempt solvents, use Eq 4 in 10.2.2.3 (see 3.1.3.1 and Note 2).

10.2.3.2 For waterborne coatings that contain exempt solvents, use Eq 1 in 10.2.1 (see 3.1.3.1 and Note 2).

10.3 *VOC Content Expressed in Terms of the Mass of VOC per Unit Volume of Coating Solids (Nonvolatiles)*:

10.3.1 Calculate the VOC content in grams of VOC per litre of coating solids according to the following equation:

$$\text{VOC}_m = \frac{(W_o)(D_o)}{V_n} \quad (5)$$

where:

VOC_m = VOC content in g/L of coating solids,

W_o = $W_v - W_w - W_{ex}$ (terms defined as in 10.2.1), and

V_n = volume percent of nonvolatile content of the liquid coating, (see Test Method D 2697, and Notes 10 and 11).

NOTE 10—The EPA Reference Method 24 does not include an analytical method for determining V_n , but states that the value be calculated from the coating manufacturer's formulation.

NOTE 11—An expression for calculating formula V_n from the coating formulation is included in Appendix X2.3, Eq X2.1.

11. Keywords

11.1 VOC; VOC calculations; VOC content; VOC content of paint; VOC content, test precision

APPENDIX

(Nonmandatory Information)

X1. AUTOMOTIVE COATINGS SUPPLIERS ROUND ROBIN

X1.1 A round robin was conducted at the laboratories of automotive coatings suppliers for determination of VOC using Practice D 3960. The analysts involved were persons experienced in running all the test methods involved in VOC determination. The data was analyzed statistically in accordance with Practice E 180. As was suspected from previous round robins conducted to evaluate Practice D 3960 (which involved some laboratories not familiar with these test methods), when well experienced analysts conduct the tests, the precision data is much improved.

X1.2 The interlaboratory study involved four laboratories and six samples; four solvent-reducible automotive topcoats and two water-reducible automotive topcoats. One operator in each of the four laboratories analyzed the sample in duplicate on 2 different days. The following duplicates, repeatability, and reproducibility coefficients of variation were obtained.

Automotive Topcoats	Duplicates, %	Repeatability, % (Within Laboratory)	Reproducibility, % (Between Laboratory)
Solvent-reducible	0.86	1.62	2.86
Water-reducible	3.94	5.29	9.75

X2. CALCULATION OF VOC CONTENT (SECTION 10)

X2.1 Measurement of Exempt Solvent Content—The value of the weight percent or volume percent of exempt solvent in the VOC expression (Eqs 1, 3, and 5) can be obtained using Test Methods D 4457 and D 1475 if the solvent is methylene chloride or 1,1,1-trichloroethane.

X2.2 Two or More Exempt Solvents—For solvent or water-reducible coatings containing more than one exempt solvent, the values for Ex and $(Ex)(D_o/D_w)$ to be used in Eq 3 (10.2.1, 10.2.2.2, 10.2.2.4 or 10.2.3.2) are the summations of the values of Ex and $(Ex)(D_o/D_w)$ for each individual solvent. Also, the value for Ex to be used in 10.3.1 to determine V_o in Eq 5 is the summation of the individual values.

X2.3 Volume Nonvolatile Content—The volume percent nonvolatile content, V_n , in Eq 5 (10.3.1) can be calculated from the summation of the individual contributions of each component in the coating formulation ("p" components) using the following equation (Notes X2.1 and X2.2):

$$V_n, \% = \sum_{j=1}^p [(V_n)](V_j/100) \quad (X2.1)$$

where:

V_n = volume percent of nonvolatile component "j," [(100 %) × (volume of nonvolatiles of "j" per unit volume of "j")], and

V_j = volume percent of component "j" in the coating [(100 %) × (volume of "j" used)/(total volume of coating)].

NOTE X2.1—Instructions for calculating the value for the formula weight of volatile solids (or formula volume percent nonvolatile) content of the coating are provided in Practice D 5201.

NOTE X2.2—Eq X2.1 is meant to clarify the equation (11-4) currently in the EPA certification manual EPA-450/3-84-019 for the expression of calculated volume percent nonvolatile content, V_n .

X2.4 Amount of VOC in a Coating Expressed in Terms of Mass of VOC per Unit Volume of Coating Including Water and Exempt Solvents—The amount of volatile organic compounds in both solvent- and waterborne coatings can be expressed in terms of the mass of volatile organic compounds per unit volume of coating including water and exempt solvents according to the following equation (Note X2.3)

$$VOA = \frac{(W_o)(D_o)}{100} \quad (X2.2)$$

where:

VOA = Amount of volatile organic compounds in g/L of coating including water and exempt solvents.

NOTE X2.3—Calculation of the amount of volatile organic compound based on the total volume of coating (including water and exempt solvents), as illustrated in Eq X2.2, does not provide a measure of the amount of VOC that would be released from two coatings used for the same application (that is, to coat the same area to the same dry film thickness assuming the same application efficiency for each coating) when one or both of the coatings contain water or exempt solvents. These units do not identify which of the coatings will release the greater amount of VOC as they treat water and exempt solvents as coating solids. These units, therefore, have not been used, recommended or accepted by U.S. EPA for demonstration of compliance with VOC content regulations as such calculations yield misleading results for coatings that contain water or exempt solvents.

NOTE X2.4—The expression in X2.2 is useful for the calculation of the mass of VOC released per unit of time (for example, the mass of VOC per unit of volume including water and exempt solvents times the volume of total coating used per unit of time). This expression may also be useful for certain labeling purposes where the amount of VOC per unit container is desired.

APPENDIX 3

X3. REGULATORY DEFINITION OF VOC

X3.1 The regulatory definition of volatile organic compounds (VOC) has evolved into the following statement by the EPA.^{4,5,6}

X3.1.1 Volatile Organic Compounds (VOC)—Any organic compound that participates in atmospheric photochemical reactions; that is, any organic compound other than those which the administrator designates as having negligible photochemical reactivity. VOC may be measured by a reference method, an equivalent method, an alternative method, or by procedures specified under any subpart. A reference method, an equivalent method, or an alternative method, however, may also measure nonreactive organic

compounds. In such cases, an owner or operator may exclude the nonreactive organic compounds when determining compliance with a standard. The administrator has designated the following organic compounds as negligibly reactive: methane, ethane, 1,1,1-trichloroethane (methyl chloroform), methylene chloride (dichloromethane), dichlorotrifluoroethane (HCFC-123), tetrafluoroethane (HCFC-134a), dichlorodifluoroethane (HCFC-141b) and chlorodifluoroethane (HCFC-142b), trichlorofluoromethane (CFC-11), dichlorodifluoromethane (CFC-12), chlorodifluoromethane (CFC-22), trifluoromethane (CFC-23), trichlorotrifluoroethane (CFC-113), dichlorotetrafluoroethane (CFC-114), and chloropentafluoroethane (CFC-15).

NOTE X3.1—The regulatory definition, under the control of the U.S. EPA, can and will change. A proposal to add compounds to this list is under consideration. To ensure currency, contact the local air pollution control agency.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Selection of Coating Specimens for Appearance Measurements¹

This standard is issued under the fixed designation D 3964; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

INTRODUCTION

In making appearance measurements, it is important that the specimens selected be representative of the material of interest. Once selected, the specimens must be carefully examined to determine if they are suitable for measurement, and if not, they must be cleaned or otherwise prepared. Careful attention to these factors is necessary if the measurements are to be valid.

Scope

1.1 This practice provides a guide to selection of specimens for appearance measurement as well as a discussion of factors to be considered in their preparation for measurement. Standardized selection and presentation procedures will assist in achieving agreement between evaluations carried out in different laboratories as well as helping to achieve better correlations between visual evaluations and instrumental measurements.

NOTE 1—This standard is not a practice for preparation of test panels for coatings; see Test Methods D 823.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

E 284 Definitions of Terms Relating to Appearance of Materials³

Terminology

- 3.1 *Definitions:*
3.1.1 For definitions of terms used in this practice, refer to definitions E 284.

Significance and Use

- 4.1 Many of the specimens that are regularly submitted to measurement depart in some degree from the ideal require-

ments. For this reason instrumental readings are affected importantly by the manner in which specimens are selected and presented for measurement. Reproducible measurements are facilitated by standardization and control of test conditions.

5. General Requirements

5.1 *Specimen Size*—The minimum size is dictated by the size of the specimen port of the instrument to be used for measurement. When an instrument provides a choice of specimen port sizes, use the largest port that can be completely covered by the specimen. A large measured area helps to minimize the effect of any small area nonuniformity and is therefore more likely to provide results that agree with the involuntary averaging that takes place when specimens are observed visually. A large specimen also permits the operator to make measurements on several areas of the specimen when desired thereby providing further specimen averaging.

5.2 *Opacity*—An opaque specimen shall be selected whenever possible for gloss and color evaluation. When the specimen is translucent or transparent, the following points should be considered:

5.2.1 *For Gloss Evaluation*—The specimen shall be sufficiently thick that a secondary reflection from the back or second surface of the specimen cannot enter the receptor optics of the glossmeter. When thin transparent specimens must be measured, adopt one of the following procedures:

5.2.1.1 Back the specimen with a light absorbing material of the same refractive index as the specimen, and in optical contact with it.

5.2.1.2 Use an agreed upon specimen thickness, including coating and substrate and place a black backing behind the specimen.

5.2.2 *For Color Evaluation*—The choice of backing of even slightly translucent specimens will affect their measurement. Use the most applicable of the backing techniques that follow. In each case it is essential that the backing material and color be reproducible, stable, and durable for reliable results.

5.2.2.1 Back the specimen with the same material with which it will be backed in its intended use.

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and is the direct responsibility of Subcommittee D01.26 on Optical Properties.

Current edition approved Oct. 31, 1980. Published December 1980.

² Annual Book of ASTM Standards, Vol 06.01.

³ Annual Book of ASTM Standards, Vol 14.02.

5.2.2.2 Back the specimen with identical or similar material.

5.2.2.3 Back the specimen with a neutral material whose luminous reflectance is essentially the same as that of the specimen being evaluated.

5.2.2.4 Back the specimen with a black surface such as a painted panel or black glass.

5.2.2.5 Back the specimen with a white backing of known reflectance.

6. Physical Properties

6.1 The specimen shall be rigid and have a plane surface. Specimens of thin, flexible material that can bulge or sag when presented to an instrument require special holding equipment. When the specimen is moderately flexible, a plane surface may be achieved by pressing the specimen against the instrument with a flat, rigid object. The pressing technique must be reproducible. A vacuum plate or specially designed clamping device has proven satisfactory in some applications. Note that specimens coated on thin plastic film or paper may trap air between the specimen and the holder (vacuum plate or clamping device) causing the specimen to billow (blisters) resulting in erroneous readings.

6.2 *Surface Texture*—Some coatings have pronounced surface texture, making it desirable to rotate a specimen in its own plane. Those with marked directionality, usually due to the production process, will have different values when measured in different directions. Good practice dictates that measurements be made with the plane of measurement of the instrument both parallel to as well as perpendicular to the process direction.

7. Cleaning of Specimens

7.1 The specimen must be clean. There should be no dirt, dust, oil or foreign material on the surface that will affect the

instrumental evaluation of the specimen. If the specimen appears to require cleaning, the procedure should be agreed upon and it should be carried out with care. Any cleaning of a low-gloss or fragile surface may scratch or polish the surface and thus change the appearance of the specimen and render it useless for measurement. A high-gloss specimen can usually be washed with clear water and blotted with untreated lens tissue or paper towel. If the specimen is durable, a mild nonfluorescent, nonionic detergent that does not leave a film can be used with a soft cloth or bristle brush. If the specimen is durable and has an oily or stubborn contamination that should be removed, reagent grade isopropyl alcohol may be used. Follow all cleaning techniques with a warm water rinse and drying by blotting, using untreated lint-free paper towel.

NOTE 2—Ceramic or porcelain enameled instrument calibration standards require periodic cleaning and the above procedures can generally be used safely.

8. Handling Specimens

8.1 Handle specimens by their edges. Do not allow objects to contact the front surface of the specimen. When placing the specimen on the instrument, avoid sliding it across the specimen port.

9. Report

9.1 When the specimens submitted for appearance measurements depart from the ideal requirements, report the following:

9.1.1 Their condition (Section 6),

9.1.2 Method of cleaning (Section 7),

9.1.3 Method of backing (5.2.1, 5.2.2, and 6.1), and

9.1.4 Indicate direction of specimen submitted for measurement or averaging of data, or both, when required by directionality (6.2).

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. Standard Practice for Interlaboratory Testing of Paint and Related Materials¹

This standard is issued under the fixed designation D 3980; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

1.1 This practice covers the interlaboratory testing of paint and related materials. The information presented is intended to assist task groups in the effective planning of round-robin test programs.

1.2 The various parts appear in the following order:

	Sections
Part A—Definitions	3
Part B—Planning	4 to 11
Part C—Statistical Analysis	12 to 16
Part D—Analysis Presentation	17 to 20

1.3 This practice, in spite of its length, is not intended to cover all aspects of statistical design and analysis. For example, the analysis of variance used in the practice as the basis for estimating the precision is abridged in comparison to that normally used for establishing the significance of experimental factors. The publications listed in the appendix should be consulted for further information or explanations. For convenience, comparable practices developed by other ASTM technical committees are also shown.

- D3793 Test Method for Low-Temperature Coalescence of Latex Paint Films²
- E180 Practice for Determining the Precision of ASTM Methods for Analysis and Testing of Industrial Chemicals³

PART A—TERMINOLOGY

Definitions

3.1 The statistical terms used in this practice are defined, as nearly as possible, in every day language. For convenience, the terms are listed in order of use in this practice.

3.2 *experimental design*—the complete plan for conducting an investigation or an interlaboratory study of materials, processes, or test methods. It is conveniently set forth in the form of a single comprehensive table showing number of laboratories, materials to be tested, test methods, number of operators, testing conditions, time of testing, and

degree of replication and repetition. The experimental design should provide the basis for an efficient statistical analysis of the results (see Part B, Planning).

3.3 *replication*—the execution of multiple chemical or physical determinations on the same specimen or physical measurements on the same panel at the same time, as closely as possible. Two replicates are called duplicates, three are called triplicates, etc. The individual results are not suitable for estimating precision but are used only to ensure by comparison with similar measurements that there is not a gross error among them (see 15.1.3.3).

3.4 *repetition*—The execution of multiple physical measurements on the same panel or chemical determinations at different times, or physical measurements on different panels, areas of large structures, or specimens of a liquid sample within a short time interval, to establish the precision of a method. In most cases the measurements are the mean of replicates as defined in 3.3.

3.5 *population*—the totality of observations on or determinations of a certain property or component obtained by the same procedure; theoretically, an infinite collection of measurements on a given item of interest but, practically, a large number of measurements of the item. Thus, when statistical procedures are used to determine whether or not two (or more) materials or test methods differ significantly with respect to some measurable property, in effect, the determination is whether these materials belong to the same or to different populations.

3.6 *sample*—a randomly selected subset of a population intended to be representative of it so as to enable obtaining an estimate of the property or composition of the entire population. The reliability of such an estimate can be expressed in terms of confidence limits (see 3.19). Through tests of significance (see 3.21), it is possible to state, with a specified degree of confidence, whether two or more samples are drawn from the same or from different populations.

3.7 *average*—a typical numerical value that attempts to summarize or reflect the location of a group of observations by a single number. While it is a measure of central tendency, it does not provide information on the variability of the individual observations. The following are different types of averages: arithmetic mean, weighted mean, algebraic mean, geometric mean, harmonic mean, median, and mode.

3.7.1 *mean (arithmetic)*—the value obtained by dividing the sum of a set of observations or results by their number. This value is an estimate of the mean of the parent population. Although the arithmetic mean is affected by extreme values and therefore may not be typical, it is amenable to statistical treatment and is the most commonly used average.

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.20 on Sampling, Statistics, etc.

Current edition approved May 27, 1988. Published December 1988. Originally published as D 3980 - 81. Last previous edition D 3980 - 87.

² Annual Book of ASTM Standards, Vol 06.01.

³ Annual Book of ASTM Standards, Vol 15.05.

3.7.2 *median*—the central observation in an ordered set that contains an odd number of observations or the mean of the two central observations in an ordered set with an even number of observations. The median is not distorted by extreme values so that where the observations are not symmetrically distributed it is a more representative average than the mean.

3.8 *expected value*—the mean of an infinite series of independent determinations on the same item obtained by the same procedure; also thought of as the true value that would be obtained if all extraneous variations were eliminated. In practice, it can be closely approached by a finite series of tests, the number of tests needed being dependent on the extent of variation (scatter) of the observed values.

3.9 *accepted reference value*—a value that serves as an agreed-upon reference for measured values. It is derived as a theoretical value based on scientific principles or an assigned value based on experimental work by (a) competent national or international organization(s).

NOTE—When the accepted reference value is the theoretical value, it is sometimes referred to as the "true" value.

3.10 *accuracy*—the degree of agreement of individual or mean measurements with the expected or accepted reference value.

3.11 *error*—the deviation of a measured value or group of measured values from the expected value or accepted reference value.

3.11.1 *random error*—the chance variation that occurs in all experimental measurements despite the closest possible control of all factors. It is characterized by the fortuitous occurrence of both positive and negative deviations from the mean or the expected value. The algebraic mean of the deviations is zero in a large series of measurements.

3.11.2 *bias*—a systematic as opposed to a random error that contributes to the difference between the estimated mean of the population and the accepted reference or the true value.

3.12 *dispersion*—the variability (scatter) of the observed values, usually measured about some central value such as the mean.

3.13 *range*—the difference between the lowest and highest values in a set of observations or results. The range is a simple but useful indicator of the variability of test results.

3.14 *outlier*—an extreme value far enough from other results in a series to be suspected of not belonging to the particular population under consideration. Statistical criteria are available for judging whether a given outlier should be included in the analysis of results or discarded (see Section 13). Also called "wild," "rogue," "maverick."

3.15 *variance*—a measure of the dispersion of a series of results around their mean. The variance of the parent population is estimated by summing the squares of the individual deviations from the mean and dividing by one less than the number of results.

DISCUSSION—Since the variance of a set of results and the estimated variance of the parent population are not equal because of different divisors (n for the set, $n - 1$ for the population), the same symbol should not be used for both.

3.16 *standard deviation*—a measure of the dispersion of a series of results around their mean, defined as the positive square root of the variance.

DISCUSSION—The advantages of the standard deviation are that it is in the same units as the original results and is of the same order of magnitude as the deviations from the mean. The standard deviation is the basis for most statements of precision and may be obtained from an analysis of variance of results of an interlaboratory test program.

3.16.1 *pooled value*—the weighted mean obtained by combining in accordance with statistical rules two or more separate values shown to be members of the same (homogeneous) population. Variances, if shown to be homogeneous by appropriate statistical criteria, may be combined by weighting each variance in accordance with its degrees of freedom, summing them and dividing by the sum of the degrees of freedom. Standard deviations must not be arithmetically averaged; they must be squared to convert them to variances, combined, and the square root taken to obtain the pooled value.

3.16.2 *coefficient of variation*—a measure of relative precision calculated as the ratio of the standard deviation to the mean of a series of values, expressed in percent.

3.17 *degrees of freedom*—in a set or subset of observations, the number of values minus the number of constraints. In general, there is only one constraint—the number of values. For example, a set of n observations can be arranged into g groups. The group degrees of freedom is then $g - 1$ because n is already determined. Similarly the total df is $n - 1$ (see Table 8).

3.18 *probability*—the chance of occurrence of an event expressed in terms of a relative frequency, a fraction, or a percent. For example, the probability that a tossed coin will land head up is one in two, or 0.5, or 50 %.

3.19 *confidence limits*—the limits on either side of the mean value of a group of observations that will, in a stated fraction or percent of the cases, include the expected value. Thus the 95 % confidence limits are the values between which the population mean will be situated in 95 out of 100 cases.

3.20 *confidence level*—the probability level (usually with reference to a statistical table) with which the significance of differences between measurements is assessed. Thus, a difference that is significant at the 95 % level (0.05 probability level, sometimes called significance level) would represent a real difference 95 times in 100; however, 5 times in 100 a difference this large might arise by chance even with identical material because of experimental error.

3.21 *significant difference*—a difference between two values, means, or variances that is shown by tests of significance to be a real difference at the stated level of confidence.

3.21.1 *Student's t test*—a statistical test for assessing the significance of a deviation from the mean or of the difference between two means. The t -value is based on the ratio of the observed deviation, or difference, to the standard deviation and is compared with tabulated t -values that indicate the frequency with which a difference of this magnitude should occur by chance in samples having the appropriate degrees of freedom.

3.21.2 *variance ratio (F) test*—a statistical test for assessing the significance of the difference between two or more variances. The F test (named in honor of R. A. Fisher) is based on the ratio of the larger variance to the smaller

material before dividing them into groups to be distributed among the laboratories. Where necessary, the same specimens may be sent in turn to each participating laboratory.

NOTE 2—Test panels are frequently prepared in one laboratory to establish the variability only of measurements obtained in different laboratories. Consequently, if panel preparation has a significant effect on test results, the resulting precision will be better than where panels are independently prepared by each laboratory. If, because of difficulty in obtaining a sufficient quantity, the same test panels are circulated to participants, the test method may, depending upon the variability of panel preparation and the sensitivity of the test method, also appear more precise than if different panels were sent to each participant.

11.4.1 Effect of Aging—If the specimens are such that their properties may change noticeably in a few days or weeks, coordinate the tests among the laboratories so that each laboratory performs the test on specimens of the same age.

11.5 Report Form—Supply each laboratory with report forms like Fig. 2 to ensure that all results and pertinent information are reported in a uniform manner. In addition

to space for measurement results, the form should provide space for such information as: relative humidity, temperature, instrument type, deviations from the specified procedure, unusual observations, and constructive comments, as required.

PART C—STATISTICAL ANALYSIS OF INTERLABORATORY TEST RESULTS

12. Scope

12.1 Appropriate statistical methods are described for computing the correlation, precision, and sensitivity of a test procedure from interlaboratory test results.

12.1.1 Outliers—For each material, ranges are computed between replicates run at each time by all laboratories, between means for each time for each laboratory, and between laboratory means of all repeats (usually two or three). Results from the different materials exhibiting similar variability or having similar mean values can be grouped and the ranges for each material calculated. For each type of range, the results are examined for suspected outliers and the

test described in 13.3 applied, as illustrated in 15.1.3.4 and 15.1.3.5, to determine whether any values can be rejected.

12.1.2 *Correlation*—If a test procedure is being evaluated for its ability to provide results that correlate with the known property values of materials, a correlation coefficient is computed and tested for significance.

12.1.3 *Precision*—The precision of a test procedure is determined by computing intralaboratory and interlaboratory variances from the test results obtained for each material. If the variances for the materials are homogeneous, they are pooled and an overall intralaboratory standard deviation and an overall interlaboratory standard deviation are calculated and used in the precision calculations. If the variances are inhomogeneous, means of providing homogeneity (such as use of the coefficient of variation or other transformations of the results) are given.

12.1.4 *Sensitivity*—A sensitivity criterion (figure of merit) is computed and used as a measure of the ability of a test procedure to distinguish between materials differing in the property being measured.

13. Test for Outliers

13.1 An outlying observation, or outlier, is one that appears to deviate markedly from other members of the set

in which it occurs. This outlier may be a single value, a mean, or a range.

13.2 When the experimenter is clearly aware that a gross deviation from prescribed experimental procedure has taken place, the resultant observation should be discarded, whether it agrees or not with the rest of the results. If a reliable correction procedure is available the observation may be corrected and retained.

13.3 In many cases, evidence for deviation from the prescribed procedure consists of the discordant value itself. In such cases a statistical test is applied to determine if the doubtful value should be discarded. A simple technique for this purpose is the rejection quotient procedure. It consists of (1) ranking the values (single observations, means, or ranges) in order of their magnitude; (2) taking the difference between the extreme value and the nearest value to it, and (3) dividing that difference by the appropriate range of the values. The resulting quotient, Q , is compared with the established rejection quotient (RQ) for the number of items in the series of values. If Q exceeds the RQ , the extreme value is suspect and may be discarded. Table 1 gives the equations for computing Q and the RQ values for three significance levels as a function of the number of items in the test results. It is recommended that outliers be discarded on the basis of the 0.01 significance level for intralaboratory results and the

TABLE 1 Table for Testing Extreme Values

If Q exceeds the rejection quotient, the suspect value may be rejected.

Number n of Values	Ratio	Significance Level ^a		
		0.10	0.05	0.01
3	$Q = \frac{X_2 - X_1}{X_n - X_1}$ or $\frac{X_n - X_{n-1}}{X_n - X_1}$	0.941	0.970	0.994

30		0.373	0.412	0.483

^a Risk or probability of rejecting a valid extreme result.

0.05 significance level for interlaboratory results. When results from several materials with similar property levels are being analyzed, all the results must be included in the calculation of Q . Also, the test should be applied only once to a set of laboratory results. Although two or more values can be rejected at the same time, the remaining results should not again be tested for outliers.

13.4 Following is an example of the use of the rejection quotient procedure for evaluating extreme values:

13.4.1 In the evaluation of the precision of a test method, a sample was tested within a single laboratory twice on each of two days by each of two operators for a total of eight determinations. Differences between replicates for both operators on both days are ranked as follows:

Rank	1	2	3	4	5	6	7	8
Difference	0.7	3.4	3.9	4.6	5.2	6.0	6.7	7.0

One of the differences between replicates (the smallest difference) appears to be suspect.

From Table 1, for eight items:

$$Q = (X_2 - X_1)/(X_{n-1} - X_1) = (X_2 - X_1)/(X_7 - X_1) = (3.4 - 0.7)/(6.7 - 0.7) = 2.7/6.0 = 0.450$$

To reject one of the eight differences, Q must exceed 0.544 at the 0.10 significance level (90 % confidence level), 0.608 at the 0.05 significance level (95 % confidence level), and 0.717 at the 0.01 significance level (99 % confidence level). Since a significance level of 0.01 should be used for intralaboratory test results, it is concluded that the difference of 0.7 is not rejectable and must be included in the calculation of test precision.

14. Correlation

14.1 To be useful, a test method must provide values for materials that either relate directly to the known property or component values for these materials or that relate to the values from another test method that is related to the known values. The degree of association between the values of a test method under study and the values of a standard test method can be determined by computing the correlation coefficient.

14.1.1 The correlation coefficient, r , may be defined by the equation:

$$r = \frac{\sum(X - \bar{X})(Y - \bar{Y})}{[\sum(X - \bar{X})^2 \sum(Y - \bar{Y})^2]^{1/2}} = \frac{\sum XY - (\sum X \sum Y / n)}{[\sum X^2 - (\sum X)^2 / n][\sum Y^2 - (\sum Y)^2 / n]^{1/2}}$$

where:

X = value obtained for a material by standard test method,
 Y = corresponding value obtained for a material by new test method,

$\bar{X}$ = mean value obtained for a material by standard test method,

$\bar{Y}$ = mean value obtained for a material by new test method, and

n = number of values obtained with each test method.

14.1.2 The reliability of the correlation coefficient depends on the number of materials tested as well as the degree of linear relation between the two test methods. It should be pointed out that a calculated r -value represents the relation of the two test methods only over the range of values obtained. Thus, if the materials selected for evaluating a test method differ only slightly in their property or component levels, the calculated r may not correspond to the correlation that would be obtained if materials differing widely in these values had been tested.

14.1.3 The correlation coefficient, r , is dimensionless and its values range from 1.0, perfect direct relation, to -1.0, which indicates perfect inverse relation. An r of 0 shows no relation between the two test methods. Whether a value of r between 0 and 1 is significantly different from 0 can be determined from Table 2 that gives the critical values at several probability levels as a function of the degrees of freedom, $n - 2$, where n is the number of materials tested.

14.1.4 The correlation coefficient squared, r^2 , (called the coefficient of determination) provides additional information about the degree of correlation between the two test methods. It is a useful concept in the sense that r^2 is equal to the fraction of the variation of the dependent variable Y that may be ascribed to the effect of the independent variable X . To claim good correlation exists between two test methods, a value of at least 0.9 for r is required, since $r^2 = 0.81$ indicates only 81 % of the variation in Y can be ascribed to X . If a value of 0.7 or less is obtained for r , the degree of association is considered to be inadequate for assuming that the two procedures are measuring the same property. It should be pointed out that a high value for r does not guarantee that values of Y can be predicted precisely from values of X .

14.1.5 An example of the computation of the correlation coefficient to determine the degree of association between values of two test procedures is shown in Table 3. This single laboratory test consisted of measuring the drying time of 10

TABLE 2 Critical Values for Correlation Coefficient r

^a df = the number of degrees of freedom (number of pairs minus 2).

samples by two test procedures. The drying time values shown represent the mean of two replicate determinations. Since the computed $r = 0.853$ and $r^2 = 0.728$, it is concluded that the degree of association is adequate to assume that both procedures are measuring drying time because r exceeds

TABLE 3 Example of Calculating Correlation Coefficient

Total	79.0	79.5	634.5	631.5	639.75

$$r = \frac{\Sigma XY - (\Sigma X \times \Sigma Y / n)}{\left(\frac{\Sigma X^2 - (\Sigma X)^2 / n}{n} \right)^{1/2} \left(\frac{\Sigma Y^2 - (\Sigma Y)^2 / n}{n} \right)^{1/2}}$$

$$= \frac{634.5 - (79 \times 79.5 / 10)}{\left(\frac{631.5 - 624.1}{10} \right)^{1/2} \left(\frac{639.75 - 632.025}{10} \right)^{1/2}}$$

$$= \frac{634.5 - 628.05}{\left(\frac{7.4}{10} \right)^{1/2} \left(\frac{7.725}{10} \right)^{1/2}} = \frac{6.45}{57.165^{1/2}}$$

$$= \frac{6.45}{7.561} = 0.853$$

$$r^2 = 0.728$$

0.765, the critical value at the 99 % confidence level for 10 samples (8 degrees of freedom) in Table 2.

14.2 There may be instances where no actual instrumental values are available for the materials tested, only their relative ranking being known. In these cases, a rank correlation coefficient, r_s , can be computed to express the degree of relationship between the ranking of the X values of one test method and the Y values of the other test method.

14.2.1 In computing r_s , the results from the two procedures are each arranged in order of performance and each material assigned a rank. In the cases where two or more materials have the same rank, each is assigned the value corresponding to the mean of the ranks that would be assigned to them if the rankings were sequential. By taking the differences, RD , between the two sets of rankings for the materials, r_s is calculated from Spearman's equation as follows:

$$r_s = 1 - [6\Sigma(RD)^2 / n(n^2 - 1)] = 1 - [(6\Sigma(RD)^2 / (n^3 - n))]$$

where:

n = number of materials and

RD = difference between the rankings of a material.

A test to determine if r_s is significantly different from 0 can be made conveniently with Table 4 in which $\Sigma(RD)^2$ values at two probability levels are given as a function of the number of pairs.

14.2.2 An example of the procedure for computing a rank correlation coefficient is shown in Table 5. In this example, the performance of 10 products subjected to two test procedures is represented by a relative ranking of their performance. It is seen from the significance table of $\Sigma(RD)^2$ as a function of number of pairs that the value of 11 obtained in this example is highly significant (99 %) since $\Sigma(RD)^2$ is less than 39 for the probability level of 0.01. It is concluded that the degree of association between the two test procedures is good.

15. Precision

15.1 The precision of a test method is expressed in two terms, repeatability and reproducibility. Paragraphs 15.1.1 and 15.1.2 provide the complete mathematical formulas for calculating precision, but a shortened procedure for analysis of results from a balanced design is given in 15.1.3. Where values have been discarded as a result of application of the test for outliers in 13.1, the mean of all the values for the respective determination can be used to replace them to retain a balanced design. It should be recognized that the analysis used in this practice is abridged because interactions between factors are disregarded. Consequently, some information that could be obtained from a complete analysis is sacrificed, as in Practice E 180.

15.1.1 *Repeatability (Intralaboratory)*—Test repeatability is determined from the estimated intralaboratory variances computed from the repeat determinations made within each laboratory on each material.

15.1.1.1 For this practice, the equation defining the estimated variance, s_w^2 , (Note 3) within a single laboratory is as follows:

$$s_w^2 = \Sigma(X_i - \bar{X})^2 / (n_R - 1)$$

TABLE 4 Critical Values of $\Sigma(RD)^2$ for the Rank Correlation Method

20	740-1 920	583-2 077	38	6 213-12 065	5 366-12 912
21	873-2 207	695-2 385	39	6 758-13 002	5 853-13 907
22	1 022-2 520	820-2 722	40	7 334-13 986	6 367-14 953

Use of Table—If the observed total, $\Sigma(RD)^2$, for the number of ranked pairs, n , is equal to or less than the lower tabular value, or equal to or greater than the higher tabular value, the correlation is significant for the indicated probability. High values correspond to negative correlations, low values to positive correlations.

TABLE 5 Example of Rank Correlation Calculation

Rank	Ranking of Panels Subjected to									
	Natural Exposure					Cyclic Condensation

15.1.1.3 If, by inspection, the intralaboratory variances of all laboratories for a material appear to be homogeneous (approximately the same) they can be pooled to give a single intralaboratory variance for that material.

15.1.1.4 If the intralaboratory variances for a material do not appear to be homogeneous, a statistical test, such as the Cochran⁴ or Bartlett⁵ tests, should be used to determine whether the variances can be pooled.

15.1.1.5 Pool the variances for all the materials (unless they appear to be nonhomogeneous) to give a single intra-

⁴ Cochran, W. G., and Cox, G. M., *Experimental Designs*, John Wiley and Sons, New York, NY, 1957.

⁵ Youden, W. J., *Statistical Methods for Chemists*, John Wiley and Sons, New York, NY, 1951.

laboratory variance for all materials. Obtain the intralaboratory standard deviation, s_w , by taking the square root of the variance and report.

15.1.1.6 Compute the maximum allowable difference (MAD) by multiplying s_w by the q factor (Table 6) for the appropriate number of replicates in each laboratory and the degrees of freedom $(n_m \text{ materials}) \times (n_L \text{ laboratories}) \times (\text{time} - 1)$. In case test results are missing, compute the $n_L(t-1)$ degrees of freedom for each material and total them.

15.1.1.7 Examine the results from each laboratory for each material to establish whether all results are within the MAD for intralaboratory determinations. If this range is exceeded and outliers were not previously rejected in accordance with 13.3, discard the discordant results and recalculate the variance, standard deviation, and MAD. Compare with the original values to establish whether the rejection is justified; for example, a marked reduction in MAD with the elimination of only one set of results is evidence that they differ significantly from the other results and their retention would adversely affect the precision of the test method.

15.1.1.8 If the intralaboratory variances for the materials do not appear homogeneous but appear to be dependent on the level of the mean value of the materials, homogeneity may be achieved generally by converting the standard deviations to coefficients of variation:

$$v_w = 100 s_w / \bar{X}$$

15.1.1.9 If the coefficients of variation are homogeneous, pool them in accordance with the equation, as follows:

$$v_p = \left[\frac{(n_1 - 1)v_1^2 + (n_2 - 1)v_2^2 + \dots + (n_m - 1)v_m^2}{(n_1 - 1) + (n_2 - 1) + \dots + (n_m - 1)} \right]^{1/2}$$

where:

v_1 = coefficient of variation for Material 1, and
 n_1 = number of values used to establish v_1 , etc.

When $n_1 = n_2 = n_m$, this condenses to $(\sum v_i^2 / n_m)^{1/2}$

where:

$\sum v_i^2$ = sum of squared coefficients, and
 n_m = total number of materials.

Calculate the maximum allowable difference in percent relative by multiplying the coefficient of variation by q for the number of repeats and degrees of freedom.

15.1.1.10 If the coefficients of variation do not appear to be homogeneous, a transformation of the test results (such as to logarithms, arc sine, or square root) may provide homogeneous variances.

15.1.1.11 If homogeneous variances or coefficients of variation cannot be obtained from the intralaboratory results, calculate the precision for appropriate levels of the material value.

15.1.2 *Reproducibility (Interlaboratory)*—Test reproducibility is determined from the estimated interlaboratory variance which is the variance of the mean values obtained by the laboratories (s_L^2) plus the intralaboratory variance. Thus, interlaboratory variance is as follows:

$$s_b^2 = (s_w^2 / n_R) + s_L^2$$

where n_R = number of repeats in each laboratory.

NOTE 4—The subscript, b, derives from the previously used term "between-laboratories".

15.1.2.1 The equation defining s_L^2 and the procedures for its computation are discussed in 15.1.1.1 and 15.1.1.2.

15.1.2.2 The equation defining the variance of laboratory means, s_L^2 , is as follows:

$$s_L^2 = \Sigma(\bar{X} - \bar{\bar{X}})^2 / (n_L - 1)$$

where:

$\bar{X}$ = mean obtained for a material by a laboratory,
 $\bar{\bar{X}}$ = grand mean of the values obtained for a material by all laboratories,
 n_L = number of laboratories,
 $(\bar{X} - \bar{\bar{X}})^2$ = sum of squares, ss, and
 $n_L - 1$ = degrees of freedom, df.

To facilitate calculations, the equation is converted to

$$s_L^2 = \frac{\Sigma \bar{X}^2 - [(\Sigma \bar{X})^2 / n_L]}{n_L - 1}$$

15.1.2.3 When the results obtained in the interlaboratory test are from a balanced design and there are no missing values, compute the sum of squares and variance for each material by the analysis of variance technique, described in 15.1.3. Calculate the interlaboratory variance using the equation given in 15.1.2.

15.1.2.4 Pool the interlaboratory variances for all materials (unless they appear nonhomogeneous) to give a single interlaboratory variance for the test. Calculate the interlaboratory standard deviation, s_b , and report.

15.1.2.5 Compute the maximum allowable difference by multiplying s_b by the q factor (Table 6) for the appropriate number of laboratories and the degrees of freedom $(n_L - 1)$ times the number of materials.

15.1.2.6 Examine the results from all laboratories to establish that the range of laboratory means does not exceed the MAD. If the range is exceeded and laboratory outliers were not previously rejected, discard the discordant results and recalculate the MAD as in 15.1.1.7.

15.1.2.7 If the interlaboratory variances for the materials do not appear to be homogeneous, but appear to vary with the level of the means of the materials, convert the standard deviations to coefficients of variation, and if homogeneous, pool them as shown in 15.1.1.8 and 15.1.1.9. Calculate the MAD in percent by multiplying the coefficient of variation by q for the number of laboratories and degrees of freedom.

15.1.2.8 If the coefficients of variation do not appear homogeneous, a transformation of the test results (such as to logarithms, arc sine, or square root) may provide homogeneous variances. If neither variances nor coefficients of variation are homogeneous for the interlaboratory results, calculate the reproducibility for each level of test value of the materials as in 15.1.1.11.

15.1.3 *Analysis of Variance of Balanced Results:*

15.1.3.1 Where a design recommended in Part B has been used and balanced results are available (that is, no missing values from a balanced design or missing values replaced by the appropriate mean value), the analysis of variance technique should be used to compute the intralaboratory (within)

DFA = degrees of freedom associated with standard deviation or coefficient of variation.

n^B = number of repeats for repeatability or number of laboratories for reproducibility.

interlaboratory (between) variances.⁶ In the analysis, it must be ascertained that the intralaboratory variances and mean values are consistent among the laboratories. Interlaboratory values are not necessarily consistent, depending upon the precision of the test method(s). Lack of consistency may arise from a variety of causes, such as materials or equipment. As noted in 3.3, the individual replicates are used only for determining gross errors in test results.

15.1.3.2 Following is an example of the application of the analysis of variance to interlaboratory test results. In this example, one robin, one laboratory coated, baked, and distributed the panels to five co-operators. Each co-operator received three panels and was asked to determine the Knoop hardness at three different times within a given period to eliminate fatigue effects. The results submitted are given in Table 7.

15.1.3.3 The first step (whether using the analysis of variance or not) is to examine each replicate value for possible errors. This is most easily done by calculating the range in results for each time and comparing the ranges at similar levels in results. In the example given here, in which the range appears to increase with increasing hardness, the results for each enamel must be compared separately, but in cases where the values for all materials are at about the same level all results must be considered together. The calculated ranges in the example are presented at the bottom of Table 7.

⁶ A Basic software program to analyze test results in accordance with this practice, even if values are missing or have been rejected as outliers, is available from ETM Information Services Inc., 1829 Chaine Court, Gloucester, Ontario, N1C 2W6, Canada. Equivalent programs may be available from other sources.

15.1.3.4 Next, apply the test for outliers, 13.3, or the control chart technique (D3) of Practice E 180, to see if a suspect value can be rejected. When more than two replications are made at a time and only one result is divergent, that result can be discarded and the mean calculated from the remaining values, thus retaining the balanced design of the interlaboratory study. When only duplicate determinations are made it is usually necessary to reject both results. In the example, Replicate b of Laboratory V on Enamel A at Time 3 has caused the range to be larger than acceptable, possibly the result of inverting figures when taking the readings or preparing the report. The mean for Time 3 is therefore calculated from the two remaining values which changes the subtotal for Laboratory V to 3.9, the total and mean of Enamel A to 18.7 and 1.247, and the Laboratory V total to 140.2.

15.1.3.5 The ranges between the mean results at different times and the laboratory means (or totals) are also examined for discordant results to see if any should be discarded before conducting the analysis of variance. In the example none are rejectable; although the mean (and total) for Enamel E obtained by Laboratory IV appears suspect, the calculated quotient does not exceed the R.Q. of 0.710 for a significance level of 0.05 and five values, as shown:

$$\frac{48.9 - 34.4}{48.9 - 26.7} = 0.653$$

15.1.3.6 An analysis of variance is performed on the results obtained for each material by the test procedure, that is, a total of six analyses. It is necessary to compute first the variances for each material because the variances may differ significantly for different types of materials or for different

laboratory variance for all materials. Obtain the intralaboratory standard deviation, s_w , by taking the square root of the variance and report.

15.1.1.6 Compute the maximum allowable difference (MAD) by multiplying s_w by the q factor (Table 6) for the appropriate number of replicates in each laboratory and the degrees of freedom (n_m materials) $\times$ (n_L laboratories) $\times$ (time - 1). In case test results are missing, compute the n_L ($t - 1$) degrees of freedom for each material and total them.

15.1.1.7 Examine the results from each laboratory for each material to establish whether all results are within the MAD for intralaboratory determinations. If this range is exceeded and outliers were not previously rejected in accordance with 13.3, discard the discordant results and recalculate the variance, standard deviation, and MAD. Compare with the original values to establish whether the rejection is justified; for example, a marked reduction in MAD with the elimination of only one set of results is evidence that they differ significantly from the other results and their retention would adversely affect the precision of the test method.

15.1.1.8 If the intralaboratory variances for the materials do not appear homogeneous but appear to be dependent on the level of the mean value of the materials, homogeneity may be achieved generally by converting the standard deviations to coefficients of variation:

$$v_w = 100 s_w / \bar{X}$$

15.1.1.9 If the coefficients of variation are homogeneous, pool them in accordance with the equation, as follows:

$$v_p = \left[\frac{(n_1 - 1)v_1^2 + (n_2 - 1)v_2^2 + \dots + (n_m - 1)v_m^2}{(n_1 - 1) + (n_2 - 1) + \dots + (n_m - 1)} \right]^{1/2}$$

where:

v_1 = coefficient of variation for Material 1, and

n_1 = number of values used to establish v_1 , etc.

When $n_1 = n_2 = n_m$, this condenses to $(\sum v_i^2 / n_m)^{1/2}$

where:

$\sum v_i^2$ = sum of squared coefficients, and

n_m = total number of materials.

Calculate the maximum allowable difference in percent relative by multiplying the coefficient of variation by q for the number of repeats and degrees of freedom.

15.1.1.10 If the coefficients of variation do not appear to be homogeneous, a transformation of the test results (such as to logarithms, arc sine, or square root) may provide homogeneous variances.

15.1.1.11 If homogeneous variances or coefficients of variation cannot be obtained from the intralaboratory results, calculate the precision for appropriate levels of the material value.

15.1.2 *Reproducibility (Interlaboratory)*—Test reproducibility is determined from the estimated interlaboratory variance which is the variance of the mean values obtained by the laboratories (s_L^2) plus the intralaboratory variance. Thus, interlaboratory variance is as follows:

$$s_b^2 = (s_w^2 / n_R) + s_L^2$$

where n_R = number of repeats in each laboratory.

NOTE 4—The subscript, b, derives from the previously used term "between-laboratories".

15.1.2.1 The equation defining s_w^2 and the procedures for its computation are discussed in 15.1.1.1 and 15.1.1.2.

15.1.2.2 The equation defining the variance of laboratory means, s_L^2 , is as follows:

$$s_L^2 = \sum (\bar{X} - \bar{\bar{X}})^2 / (n_L - 1)$$

where:

$\bar{X}$ = mean obtained for a material by a laboratory,

$\bar{\bar{X}}$ = grand mean of the values obtained for a material by all laboratories,

n_L = number of laboratories,

$(\bar{X} - \bar{\bar{X}})^2$ = sum of squares, ss, and

$n_L - 1$ = degrees of freedom, df.

To facilitate calculations, the equation is converted to

$$s_L^2 = \frac{\sum \bar{X}^2 - ((\sum \bar{X})^2 / n_L)}{n_L - 1}$$

15.1.2.3 When the results obtained in the interlaboratory test are from a balanced design and there are no missing values, compute the sum of squares and variance for each material by the analysis of variance technique, described in 15.1.3. Calculate the interlaboratory variance using the equation given in 15.1.2.

15.1.2.4 Pool the interlaboratory variances for all materials (unless they appear nonhomogeneous) to give a single interlaboratory variance for the test. Calculate the interlaboratory standard deviation, s_b , and report.

15.1.2.5 Compute the maximum allowable difference by multiplying s_b by the q factor (Table 6) for the appropriate number of laboratories and the degrees of freedom of ($n_L - 1$) times the number of materials.

15.1.2.6 Examine the results from all laboratories to establish that the range of laboratory means does not exceed the MAD. If the range is exceeded and laboratory outliers were not previously rejected, discard the discordant results and recalculate the MAD as in 15.1.1.7.

15.1.2.7 If the interlaboratory variances for the materials do not appear to be homogeneous, but appear to vary with the level of the means of the materials, convert the standard deviations to coefficients of variation, and if homogeneous, pool them as shown in 15.1.1.8 and 15.1.1.9. Calculate the MAD in percent by multiplying the coefficient of variation by q for the number of laboratories and degrees of freedom.

15.1.2.8 If the coefficients of variation do not appear homogeneous, a transformation of the test results (such as to logarithms, arc sine, or square root) may provide homogeneous variances. If neither variances nor coefficients of variation are homogeneous for the interlaboratory results, calculate the reproducibility for each level of test value of the materials as in 15.1.1.11.

15.1.3 *Analysis of Variance of Balanced Results:*

15.1.3.1 Where a design recommended in Part B has been used and balanced results are available (that is, no missing values from a balanced design or missing values replaced by the appropriate mean value), the analysis of variance technique should be used to compute the intralaboratory (within)

C	...	...	2	3	5	4	1	...	...	...	...
D	...	...	...	1	4	5	4	1	...	...	...
E	...	...	...	...	1	4	6	3	1	...	...
F	...	...	...	...	...	2	6	4	2	1	...

For 15 values $Q = \frac{X_n - X_{n-2}}{X_n - X_9}$. The only divergent range is with Enamel A where $\frac{1 - 0.4}{1 - 0.2} = \frac{0.6}{0.8} = 0.75$. R.Q. at 0.01 significance = 0.647.

levels of the property measured. The analysis of variance of test results is facilitated by the construction of an analysis of variance table as shown in Table 8.

15.1.3.7 After calculating the means for the replicates, rejecting outliers where necessary, prepare a table of the means, which are considered to be the individual results, for each material as shown in Table 9 for Enamel A.

15.1.3.8 Perform the computations outlined in Table 8 to obtain the total sum of squares and the laboratories and the intralaboratory sums of squares. For each material from the sums of squares and the degrees of freedom, compute mean squares and variances for intralaboratory and for laboratory means as outlined in Table 8 and shown by the example in Table 9.

NOTE 5—In this example, triplicate measurements were made so that n_R equals 3 but in cases where duplicates are sufficient (see 11.2.1) the laboratory total sums of squares and the laboratory mean variances are obtained using two as the divisor. The number of replicates does not affect n_R .

15.1.3.9 Calculate the intralaboratory and interlaboratory standard deviations for each material as in Table 10. Determine the maximum allowable differences for each and compare with the ranges in the results as shown in Table 9. If required, discard discordant results and recalculate.

15.1.3.10 If the standard deviations for the different materials are homogeneous, pool the variances and calculate the overall repeatability and reproducibility, as described in 15.1.1.6, 15.1.1.7, 15.1.2.5, and 15.1.2.6.

15.1.3.11 If the results are not homogeneous, convert the standard deviations to coefficients of variation, pool them and calculate the repeatability, as described in 15.1.1.8, 15.1.1.9, and 15.1.2.7 and shown in Annex A1.

15.1.3.12 Prepare a table showing the standard deviations, coefficients of variation (if required) and the precision as given in Table 11.

16. Sensitivity

16.1 If a reasonably linear relationship ($r > 0.7$) has been

TABLE 8 Analysis of Variance Table

Source of Variance	Sum of Squares (ss)	Degrees of Freedom (DF)	Mean Square	Expected Mean Square ^a
	Eq 1 = $\Sigma X^2 - (\Sigma X)^2/n$	$n - 1$	...	...
Laboratories	Eq 2 = $\Sigma L^2/n_L - (\Sigma X)^2/n$	$n_L - 1$	ss/DF	$s_w^2 + n_L s_L^2$
Intralaboratory	Eq 1 - Eq 2	$(n - 1) - (n_L - 1) = n - n_L$	ss/DF	s_w^2

- ^a = total number of determinations,
 = number of laboratories,
 = number of determinations (repeats) by each laboratory,
 = sum of individual results (usually mean of duplicates),
 = sum of squared individual results,
 = sum of individual results, squared,
 = sum of laboratory totals,
 = intralaboratory variance,
 = variance of laboratory means, and
 = $(s_w^2/n_L) + s_L^2$ = interlaboratory variance.

Occasionally, in an exchange where the intralaboratory variability is very high without a corresponding large difference between laboratory means, subtracting s_w^2 from $s_L^2 + n_L s_L^2$ yields a negative result. Since a variance cannot be negative, the usual practice in such cases is to consider s_L^2 to be zero.⁷

TABLE 9 Example of ANOVA for Enamel A—Means of Triplicates^a

Laboratory	I	II	III	IV	V	Time Total

$n = 15$	$\Sigma X = 18.7$		$\bar{X} = 1.2467$		$\Sigma L^2 = 70.75$	
$n_L = 3$	$\Sigma X^2 = 23.63$		$(\Sigma X)^2/n = 23.3127$		$\Sigma L^2/n_L = 23.5833$	
Source of Variation	Total ss	Net ss	df	Mean Square	Variance	
Grand total	23.63	0.31733	14			
Laboratories	23.58333	0.27067	4	0.06767		
Intralaboratory		0.04666	10	0.00467	0.00467 = s_w^2	
Laboratory means				0.06300 + 3 =	0.021 = s_L^2	
Correction factor $(\Sigma X)^2/n$	23.31267					

Conclusion:

Intralaboratory:

$$s_w^2 = 0.00467 \quad s_w = 0.0683$$

From Table 8, q for 10 df is 3.88 for three determinations. Therefore, the maximum acceptable difference (MAD) = $0.0683 \times 3.88 = 0.265 \approx 0.27$ for three determinations (each the mean of triplicates). All laboratories comply since the maximum range is 0.2 for Laboratory V.

Interlaboratory:

$$s_L^2 = s_w^2/n_L + s_L^2 = \frac{0.00467}{3} + 0.021 = 0.00155 + 0.021 = 0.02255$$

$$s_L = (0.02255)^{1/2} = 0.150$$

From Table 8, q for 4 df = 6.31 for five laboratories. Therefore MAD = $0.15 \times 6.31 = 0.95$ for five laboratories. All laboratories comply since the maximum range between laboratory means = $1.467 - 1.067 = 0.4$ for Laboratories II and IV.

Except for Laboratory V, Time 3.

and between instrumental values and known property or component values for the materials tested by a test method, the certainty with which the test method can detect differences in the parameter should be ascertained.

16.2 A useful measure of this certainty is the sensitivity criterion.⁸ This criterion, SC , is defined as

$$\frac{\Delta A/\Delta P}{s_A/s_P}$$

where:

$\Delta A/\Delta P$ = change in instrumental value A for a unit difference in known parameter P ,

s_A = estimated experimental error for a single instrumental measurement, and

s_P = estimated experimental error for a known parameter value.

In many instances s_P is not available so that s_P and ΔP are assumed to be 1.0, which removes them from the equation. Thus

$$SC = \Delta A/s_A$$

16.3 The value used for s_A depends on the manner in which the test is conducted. For example, if materials are tested by the same operator with a single instrument, s_w is used. Where the materials are tested in different laboratories, s_b is used.

16.4 In the case where it is desired to know which of two alternative test methods, A or B, has the greatest sensitivity for measuring P , a sensitivity ratio, SR , is calculated as follows.⁸

2							
etc. to							
M							

$$SR = \frac{SC_{(A)}}{SC_{(B)}} = \frac{\frac{\Delta A/\Delta P}{s_A/s_P}}{\frac{\Delta B/\Delta P}{s_B/s_P}} = \frac{\Delta A/s_A}{\Delta B/s_B}$$

where, if SR is greater than 1.0, Test Method A is superior to B, and if SR is less than 1.0, Test Method B is superior.

16.5 Obviously, a sensitivity ratio should not be used to compare test methods unless it has been established that one of these test methods provides instrumental values that correlate well with known property or component values of materials. For example, if Test Method A has been found to give instrumental values (observed or transformed) that correlate reasonably well ($r > 0.7$) with known property values, then a plot can be made of Test Method B values versus Test Method A values for the materials tested.

16.5.1 If the plot of points shows a curvilinear relationship, then the values for Test Method B should be transformed to provide a linear relationship. When this has been done, the slope of the straight line relating the points is $\Delta A/\Delta B$ and

$$SR = \text{slope}/(s_A/s_B)$$

16.5.2 In some instances, the SR for two test methods will not be constant over the range of materials tested because of

changes in the test errors with a change in parameter level. In such cases, an SR should be calculated for each of the parameter value levels. A plot of SR values versus parameter values is useful in comparing the sensitivities of the two test methods.

PART D—ANALYSIS PRESENTATION

17. Scope

17.1 This part describes the essential requirements for the preparation of a comprehensive report on an ASTM cooperative test program, for the guidance of working groups and committees or for publication, and of the precision statement to be used in test methods.

18. General Report Requirements

18.1 The essential requirements for a report on a cooperative test program are as follows:

18.1.1 The presentation in one document of details pertaining to the program, including a complete description of the experiment with a clear statement of purpose, procedure, instructions, and list of participants.

18.1.2 The presentation of all the original results reported by the participants, together with their comments.

Column means	...			...			...		

18.1.3 An integrated compilation of the results into tables and in the form of graphs or charts that may be studied to obtain a clear view of the experiment as a whole.

18.1.4 The presentation, in the most concise form, of the conclusions drawn from an analysis of the results.

18.1.5 The presentation of a summary, conclusions, or a list of recommendations.

18.2 The report should provide maximum ease of reference to the details of the experiment, of observing results in tabulation, and the essential conclusions. The report should be available to all members of the task group well in advance of meetings so that there is sufficient time for study and development of new ideas for discussion at meetings.

19. Procedures for Preparing Summaries

19.1 For each material or each test method, prepare a table that compiles in an orderly block arrangement the results from all of the laboratories (including operators and time). A format based on the one given in Fig. 1, but modified to include means and ranges, can be used. Using the design shown in Table 12, prepare a table for each test method giving the laboratory mean values and ranges for the different materials. Prepare a table for each test method listing for each material the means, the intra- and interlaboratory standard deviations, the degrees of freedom, and, if applicable, the coefficients of variation. The format can be based on parts of Table 10 or on Table 11. It should be evident from this tabulation whether the standard deviation varies with the magnitude of the property being measured and, consequently, whether the coefficient of variation is required.

19.2 An appropriate block of results may be compiled into a frequency distribution table that can be prepared in several different ways as follows:

19.2.1 Tabulate the values in increasing order of magnitude and express the frequency with which each value occurs as a fraction or percent calculated by dividing the number of times the value occurs by the total number of values in a group. When a large number of values is being treated, they may be divided into classes of equal range (for example, ten classes) and the frequency of each class calculated.

19.2.2 Calculate the deviation of each value from the mean value of its group noting the sign and tabulate these in order of magnitude. Calculate the frequency of each deviation as a fraction or percent of all the values treated. When a large number of values is being treated, the deviations may be divided into classes of equal range.

19.2.3 Frequency distributions may be expressed in a cumulative way by arranging the values in order of magni-

tude and summing at each stage of this arrangement the total occurrence of all values up to and including the selected stage.

19.2.4 Graphical presentations are very useful and concise allowing rapid inspection and judgment of a collection of related results. They may be prepared from all the results from an experiment or an appropriate segment to obtain a view of the nature of the distribution. If it is revealed that an adequate normal distribution exists, relatively simple mathematical treatments may be applied. Frequency distributions may be presented in graphical form, as histograms whereby values or classes covering a range of values are plotted against their frequency, or as cumulative frequency graphs prepared by plotting at each point the cumulative frequency of all the values up to that point against the value at that point. One of the best ways of displaying results is the dot diagram.⁹ Figure 3 shows the relation of dry-to-touch time to the day on which a test was made and to the type of drier used, and also shows the overall distribution of the results. It can readily be seen that there is definitely a difference between days but none between drier types, as compared to the overall distribution.

19.3 The final summary should be a description of results from the cooperative program, expressed in terms of repeatability and reproducibility stated with supporting information, that is, degrees of freedom.

19.4 Prepare a draft report, with the test results and their analysis, for deposit in ASTM Headquarters files.

20. Applicability and Precision Statements for Test Methods

20.1 The major functions of the interlaboratory test of a measurement procedure are the determination of:

20.1.1 The applicability of the procedure for measuring a property of a material or groups of materials, and

20.1.2 The precision with which repeated measurements according to the test method can be expected to be made.

20.2 Applicability implies both the correlation of a measurable property with an unmeasurable property of a material and the sensitivity with which differing levels of that property are discriminated by the test method. Correlation may be evaluated by means of a rank order correlation coefficient. Sensitivity may be evaluated by means of the sensitivity criterion (ratio of the range in property levels of a material to the standard deviation). As applicability, or

⁹ Box, G., Hunter, W., and Hunter, S., *Statistics for Experimenters*, John Wiley and Sons, New York, NY, 1978, p. 221.

FIG. 3 Illustration of Dot Diagram

validity, of a test method depends on the magnitude of the values of correlation and sensitivity, as well as on the number of materials used in the interlaboratory test, inclusion of a statement of applicability is recommended as follows:

Applicability of Test Method—Based on measurements of _____ materials having known qualitative ratings that range from _____ to _____ (good to poor, for example) the rank correlation coefficient for the test method was found to be _____ and the sensitivity criterion was found to be _____.

20.3 Precision is useful only if the applicability function of the test method is found to be favorable. Precision is defined as the degree of agreement among repeated independent measurements of the same property. Statements of precision may be given in terms of the standard deviation, but this form is not very useful. In addition, when values obtained vary directly with the property levels of the materials tested, the coefficient of variation must be used to express the general precision. Statements of precision can also be expressed in terms of the range in values within which the correct value can be expected to lie a specified percent of the time. The most common precision index is the range that should not be exceeded for a stated number of results at a given confidence level, assuming that the frequency distribution is normal and that a random sample was used in the interlaboratory test. Because only a sample of the total population of measurements is obtained in a test, statements of precision should indicate the number of degrees of freedom and the number of observations that were used in the interlaboratory test to obtain the indicated values.

20.3.1 As can be seen from Tables 11 and 12, the measurements made in an interlaboratory test permit a number of parameter variations. Precision indexes can be devised with respect to differences within and among laboratories, materials, operators, and repeat measurements and

with respect to the interactions among combinations of these parameters. It is evident from this discussion that to provide all of these precision indexes would make this section unnecessarily long and impair its usefulness. The decision on how many of the possible indexes are to be included in a test method is left to the discretion of those who formulate and use the test method. In this practice, however, the precision statement is based on the two indexes—repeatability and reproducibility as defined in 3.26:

Precision of Test Method—In an interlaboratory study of this test method in which _____ operators in _____ laboratories tested _____ coatings with a broad range of _____ (property) levels (analyzed _____ materials containing _____), the intralaboratory standard deviation (coefficient of variation) was found to be _____ units (percent) with _____ degrees of freedom (df) and the interlaboratory standard deviation (coefficient of variation) _____ units (percent) with _____ df after rejecting _____ results(s) from _____ laboratory (ies) for one time because the range between replicates (repeats) differed significantly from all other ranges for material _____, or all results from one laboratory for material _____ because the mean differed significantly from all other means. Based on these standard deviations (coefficients) the following criteria should be used for judging, at the 95% confidence level, the acceptability of results:

Repeatability—_____ results, each the mean of _____ replicates (if applicable), obtained by the same operator should be considered suspect if they differ by more than _____ units (% relative).

Reproducibility—Two results, each the mean of _____ replicates obtained by operators in different laboratories should be considered suspect if they differ by more than _____ units (% relative).

NOTE 6—Where the results obtained are in percent instead of some unit add "absolute" after X% in the repeatability and reproducibility statements to distinguish from cases where use of the coefficients of variation results in percent relative precision limits.

NOTE 7—Users of ASTM test methods should be aware that the precision obtained from an interlaboratory study is for measurements made on the same batch of each material. Consequently, normal batch-to-batch variability, which is governed by manufacturing quality control, is not included in the precision values established for a test method.

ANNEX

(Mandatory Information)

A1. Discussion of Table 10

A1.1 Two points are evident: (1) neither the intralaboratory nor interlaboratory variances can be pooled because the standard deviations increase with higher hardness values; (2) the intralaboratory coefficients of variation are homogeneous, but there is one discordant value (Enamel E) in the interlaboratory coefficients.

A1.2 The tests referred to in 15.1.1.4 can be applied to confirm that the interlaboratory coefficients cannot be pooled or, as shown below, the coefficients are pooled to determine if any maximum allowable difference is then needed. Pooling the coefficients of variation in accordance with the formula in 15.1.1.8 yields the following:

$$\text{Pooled } v_w = \left(\frac{153.2873}{6} \right)^{1/2} = (25.5479)^{1/2} = 5.055 \%$$

For three determinations $v_w \cdot q = 5.055 \times 3.40 = 17.19 \%$.

$$\text{Pooled } v_b = \left(\frac{1411.8364}{6} \right)^{1/2} = (235.3061)^{1/2} = 15.34 \%$$

For five laboratories $v_b \cdot q = 15.34 \times 4.17 = 63.97 \%$.

Therefore the acceptable range for Enamel E is $0.172 \times 1.26 = 1.94$ for intralaboratory results and $0.64 \times 11.26 = 7.21$ for interlaboratory results. The actual maxima obtained for Enamel E in the round robin are for the intralaboratory range 1.3 for Laboratory II, and for the interlaboratory range between Laboratories I and IV. Thus, while the results from Laboratory IV for Enamel E could not be rejected in 15.3.5 on the basis of Enamel E alone, they can be on the basis of all six enamels.

A1.3 Instead of rejecting the results from all laboratories on one material, it is preferable to discard only those of the divergent laboratory. When this procedure is followed for Enamel E the revised values are: $\Sigma X = 120.0$, $n = 12$, $\bar{X} = 10.00$, $\Sigma X^2 = 1213.58$, $(\Sigma X)^2/n = 1200$, net total ss = 13.58, $s^2/n_R = 1210.7667$, net laboratory ss = 10.7667, intralaboratory ss = 2.8133, $df = 8$, $s_w^2 = 0.3517$, $s_w = 0.593$, $s_w^2/n_R = 5.93 \%$, interlaboratory $df = 3$, mean square = 3.5889, $s_b^2 = 3.2372$, $s_b = 1.0791$, $s_b^2/n_R = 0.1172$, $s_b = 1.1963$, $s_b = 1.09$, $v_b = 10.94 \%$.

A1.4 The interlaboratory coefficients of variation are now all homogeneous so they can be pooled with total degrees of freedom of 58 for intralaboratory and 23 for interlaboratory coefficients.

$$\begin{aligned} \text{Pooled } v_w &= \left[\frac{5(127.1548) + 4(35.1667)}{(5 \times 5) + (1 \times 4)} \right]^{1/2} = \left(\frac{776.44035}{29} \right)^{1/2} \\ &= (26.7738)^{1/2} = 5.174 \%; v_w \cdot q = 17.65 \% \\ &\text{for three determinations.} \end{aligned}$$

$$\begin{aligned} \text{Pooled } v_b &= \left[\frac{5(714.9841) + 4(119.6289)}{25 + 4} \right]^{1/2} = \\ &\left(\frac{4053.4359}{29} \right)^{1/2} = (139.7737)^{1/2} = 11.82 \% \end{aligned}$$

Rejecting one laboratory's results for one material reduced the pooled interlaboratory coefficient of variation from 15.34 % to 11.82 %, which is certainly justification for discarding those results.

A1.5 From the pooled coefficient of variation the maximum acceptable difference, $v_b \cdot q$ is 34.4 % for two laboratories, 46.4 % for four laboratories, and 49.5 % for five laboratories (Note A1.1). Based on these values, the acceptable range in Knoop hardness results for each enamel is given in Table A1.1 and compared with the maxima found in the study.

NOTE A1.1—The MAD used for determining the acceptability of results in the round robin must be based on the number of participating laboratories while that used in the final precision statement is for two laboratories.

TABLE A1.1 Knoop-Hardness Ranges For Enamels

Enamel	Intralaboratory		Interlaboratory	
	Calculated	Found	Calculated	Found
A	0.22 ^a	0.2	0.62 ^a	0.4
B	0.51	0.4	1.44	0.73
C	0.89	0.6	2.5	1.63
D	1.3	0.8	3.64	2.33
E	1.8	1.3	4.64 ^a	2.57 ^a
F	3.0	1.7	8.3	4.83

^a These values are smaller than in Table 9 because the precision estimate is better from all six enamels than from just one.

^b For four laboratories.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Water in Paints and Paint Materials by Karl Fischer Method¹

This standard is issued under the fixed designation D 4017; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

Scope

1.1 This test method is applicable to all paints and paint materials, including resins, monomers, and solvents, with the exception of aldehydes and certain active metals, metal oxides, and metal hydroxides. While the evaluation was limited to pigmented products containing amounts of water in the 30 to 70 % range, there is reason to believe that higher and lower concentrations can be determined by this test method.

1.2 *This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. Specific hazard statements are given in Section 7.*

Referenced Documents

- 2.1 *ASTM Standards:*
- D 1193 Specification for Reagent Water²
- E 180 Practice for Determining the Precision of ASTM Methods for Analysis and Testing of Industrial Chemicals³
- E 203 Test Method for Water Using Karl Fischer Reagent³

Summary of Test Method

3.1 The material is dissolved in pyridine, or another appropriate solvent, and titrated directly with standardized Karl Fischer reagent, to an electrometric end point. The sluggish reaction with water in pyridine is accelerated with a chemical catalyst, 1-ethylpiperidine.

3.2 Pyridine is used as a solvent to minimize interference problems caused by ketones. It is also used because the more common solvent, methanol, will not dissolve many common resins and because methanol reacts with some resins to produce water.

Significance and Use

4.1 Control of water content is often important in controlling the performance of paint and paint ingredients, and it is critical in controlling volatile organic compound (VOC) content.

4.2 Paint materials are often insoluble in common Karl Fischer solvents such as methanol. Pyridine has been found

to be a nearly universal solvent for these materials; however, the Karl Fischer reaction is too slow in that solvent at room temperature. To speed it up, 1-ethylpiperidine is added at 5 % as a buffer, or "catalyst".

5. Apparatus

5.1 *Karl Fischer Apparatus*, manual or automatic, encompassed by the description in Test Method E 203. Apparatus should be equipped with a 25-mL buret, Class A, or equivalent.

5.2 *Syringe*, 100-μL capacity, with needle.

5.3 *Syringes*, 1-mL and 10-mL capacity, without needle, but equipped with caps.

6. Reagents

6.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁴ Other grades may be used, provided it is ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

6.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent grade water conforming to Type II of Specification D 1193.

6.3 *Karl Fischer Reagent*.⁵

6.4 *Pyridine*.

6.5 *1-Ethylpiperidine*.⁶

6.6 *Hydrochloric Acid (HCl)*, concentrated.

NOTE 1—All reagents must be fresh. Do not use reagents that are more than 9 months old. Karl Fischer reagent deteriorates with age. Check expiration dates on the reagent bottle.

7. Hazards

7.1 Karl Fischer reagent contains four toxic compounds, namely iodine, sulfur dioxide, pyridine, and methanol or glycol ether. The reagent should be prepared and dispensed in a hood. Care must be exercised to avoid inhalation or skin contact. Following accidental contact or spillage, wash with large quantities of water.

7.2 Pyridine and methanol solvents should be treated with

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Materials.

For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY and the "United States Pharmacopeia."

⁵ So-K-3 available from Fischer Scientific Co., or equivalent has been found suitable for this purpose.

⁶ Use 1-ethylpiperidine, manufactured by the Aldrich Chemical Co., Milwaukee, WI 53233, for the best results.

TABLE 1 Specimen Guidelines

Expected water, %	Approximate Specimen Weight, g	Approximate Titrant Volume at 5 mg/mL titre, mL
0.5-1.0	5	5-10
1-3	2-5	10-20
3-10	1-2	10-20
10-30	0.4-1.0	20-25
30-70	0.1-0.4	15-25
>70	0.1	20

the same care as Karl Fischer reagent.

7.3 1-ethylpiperidine is of unknown toxicity and, therefore, should be handled with the same care as the materials listed in 7.1 and 7.2.

8. Procedure

8.1 Standardization of Karl Fischer Reagent:

8.1.1 Add enough fresh pyridine to cover the electrode tip, plus 1 mL of 1-ethylpiperidine catalyst per 20 mL of pyridine. Catalyst performs best at a concentration of about 5 % of the volume present.

8.1.2 Fill the 100- μ L syringe to about half full with distilled water and weigh to the nearest 0.1 mg.

8.1.3 Pretitrate the pyridine to the end point indicated by the equipment manufacturer, by adding just enough Karl Fischer Reagent I (KFR) to cause the end point to hold for at least 30 s.

8.1.3.1 The use of the catalyst greatly increases the reaction rate between water and Karl Fischer reagent. To obtain reliable results, increase the electrode sensitivity and reduce titration rate to a minimum. Most instruments have controls for these functions. Consult the instructional manual for information on these controls.

8.1.4 Empty the contents of the syringe into the titrator vessel. Immediately replace the stopper of the sample port and titrate with KFR to the end point as described in 8.1.3.

8.1.5 Repeat standardization until replicate values of F agree within 1 %. Determine the mean of at least two such determinations. Carry out calculations retaining at least one extra decimal figure beyond that of the acquired data. Round off figures after final calculations.

8.1.6 Calculation:

8.1.6.1 Calculate the KFR titre F as follows:

$$F = J/P \quad (1)$$

where:

J = water added, g, and

P = KFR used, mL.

The value for F should be recorded to the four significant digits and should be the mean of at least two determinations. Typical values are in the range of 0.004000 to 0.006000 g/mL.

8.2 Analysis of Samples With More Than 0.5 % Water:

8.2.1 The titration vessel should already contain pretitrated pyridine and catalyst, as described in 8.1.1 and 8.1.3 in the standardization procedure. Best results are obtained with fresh solvent, that is, containing no previously titrated specimen in the vessel.

8.2.2 With a 1-mL or 10-mL syringe, draw the amount of material indicated in Table 1.

NOTE 2—Paint samples tend to settle in the syringe and give high percent water content. Obtain a freshly stirred or mixed specimen for each test run.

8.2.2.1 Remove the syringe from the specimen, pull the plunger out a little further, wipe the excess material off the syringe, and place a cap on the syringe tip. Weigh the filled syringe to the nearest 0.1 mg.

8.2.3 Remove the cap, and empty the syringe contents into the pretitrated pyridine vessel. Pull the plunger out and replace the cap.

8.2.4 Stir rapidly for 1 to 2 min before starting titration. Some instruments can be set to do this automatically. If the specimen is still not dissolved or dispersed, continue stirring until it is dissolved, or use a different solvent in place of pyridine in 8.2.1.

8.2.5 Titrate the specimen slowly with KFR to the end point described in 8.1.3.

8.2.6 Reweigh the emptied syringe, and calculate the specimen weight by difference.

8.2.7 Calculation:

8.2.7.1 Calculate the percent water L as follows:

$$L = (P \times F \times 100)/S \quad (2)$$

8.3 Analysis of Materials With Less Than 0.5 % Water:

8.3.1 For 0.1 to 0.5 %, follow procedure in 8.2 (1-g specimen), except substitute a 1-mL microburet for the 25-mL buret in the Karl Fischer apparatus.

8.3.2 For less than 0.1 %, use a 1-mL microburet and increase specimen size as much as needed, up to 10 g. It should be possible to measure moisture levels down to 1 ppm (0.0001 %) by this approach.

NOTE 3—Specimens with less than 0.1 % water may require special handling techniques to prevent pickup of atmospheric moisture. The precision of this test method was determined with specimens containing higher water levels.

9. Recommendations for Good Results

9.1 Make sure electrodes are clean.

9.2 Follow manufacturer's instructions to ensure that venting into the titration vessel is only through a dessiccant.

9.3 Samples should be thoroughly mixed before taking a specimen.

9.4 Paints and paint materials are often slow to dissolve or disperse. To ensure that all of the water is extracted into the pyridine or solvent, stir rapidly for 1 or 2 min before starting the titration.

9.5 Run the titration slowly with rapid stirring.

9.6 Throw out the first result in fresh pyridine.

9.7 Use only Aldrich's 1-ethylpiperidine.⁶ It has been found that other brands produce variable results.

10. Maintenance

10.1 *Cleanup*—Clean the titration vessel by rinsing with fresh pyridine. Do not use methanol or other solvents.

10.2 *Dryness*—Check frequently to be sure that all drying tubes are in good condition and tightly connected. Replace dessiccant when indicator color changes through half of the tube.

10.3 *Electrode Performance*—If electrode response is sluggish or otherwise off standard, take the following steps, in turn, to correct the problem. Test the electrode with a

10.3.1 Wipe the electrode tip with a clean paper towel.

10.3.2 Wash the electrode by dipping in concentrated hydrochloric acid for at least 1 min. Rinse first with distilled water, then with methanol.

10.3.3 Follow manufacturer's instructions on resetting and point meter.

10.3.4 Replace power source. See manual for replacement procedure.

10.3.5 Replace the electrode.

Precision and Bias

11.1 The precision estimates are based on an inter-laboratory study in which one operator in each of seven different laboratories analyzed in duplicate on two different days seven samples of water-based paints of various types containing between 25 to 75 % water. The results were

analyzed statistically in accordance with Practice E 180. The within-laboratory coefficient of variation was found to be 1.7 % relative at 98 df, and the between-laboratory coefficient of variation was 5.3 % relative, at 42 df. Based on these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level.

11.1.1 *Repeatability*—Two results, each the mean of duplicate determinations, obtained by the same operator on different days should be considered suspect if they differ by more than 4.7 % relative.

11.1.2 *Reproducibility*—Two results, each the mean of duplicate determinations, obtained by operators in different laboratories should be considered suspect if they differ by more than 15.0 % relative.

11.2 *Bias*—Bias has not been determined for this test method.

12. Keywords

12.1 Karl Fischer reagent method; moisture content; water content.

Standard Test Method for Reflection Haze of High-Gloss Surfaces¹

This standard is issued under the fixed designation D 4039; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method describes a procedure for using two specular gloss measurements to obtain a haze index for high-gloss nonmetallic specimens (1-4).² It is particularly useful for evaluating the haze in clear finishes on nonglossy substrates, and the haze in reflected images produced by the surfaces of opaque glossy pigmented finishes.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2.1 ASTM Standards:

D 523 Test Method for Specular Gloss³

D 823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels³

D 3964 Practice for Selection of Coating Specimens for Appearance Measurements³

3. Terminology

3.1 Definitions:

3.1.1 *specular gloss*—the relative luminous reflectance factor of a specimen at the specular direction.

3.1.2 *reflection haze*—perceived cloudiness in an image reflected by a glossy surface.

3.2 Descriptions of Terms Specific to This Standard:

3.2.1 *60° specular gloss*—specular gloss measured with the 60° geometry specified in Test Method D 523.

3.2.2 *20° specular gloss*—specular gloss measured with the 20° geometry specified in Test Method D 523.

3.2.3 *haze index, H*—a measure of reflection haze, where $H = (G_{60} - G_{20})$; G_{60} is the 60° specular gloss and G_{20} is the 20° specular gloss.

4. Summary of Test Method

4.1 Measurements of 60° and 20° specular gloss are made on a specimen. The haze index is computed as the difference between the two measurements.

4.2 This test method is applicable to nonmetallic specimens having a 60° specular gloss value greater than 60 in accordance with Test Method D 523.

5. Significance and Use

5.1 Haze is produced by irregularities in the reflecting surface that affect the distribution of flux reflected around the specular angle. The procedures specified in Test Method D 523 are not designed to measure reflected-flux scattering characteristics of high-gloss finishes, particularly where specimens having different surface refractive indexes are being compared. A better index of scattering can be obtained by making two specular reflectance measurements, that is, the use of two receptor apertures of different size.

5.1.1 In this test method, values for reflection haze are obtained from two measurements of specular gloss, one made with a large receptor aperture and the other made with a small receptor aperture. The geometric conditions have been chosen to permit the use of glossmeters that provide 60° specular gloss measurements (large receptor aperture) and 20° specular gloss measurements (small receptor aperture) as specified in Test Method D 523.

5.2 Measured gloss values of specimens depend on the angle of illumination, refractive index of the material, and the geometric distribution of the reflected light. The gloss scale of both the 60° and 20° geometries is defined as 100 for polished black glass with a refractive index of 1.567. However, the polished black glass standards used in this test method usually have a lower refractive index (approximately 1.53). Therefore, they will have a gloss value less than 100. These gloss values will be different for 60° and 20° measurements. If the refractive index is 1.53, the black gloss standard will have a 60° gloss value of approximately 94 and a 20° gloss value of approximately 89. Therefore, this haze-free standard will have a haze index value of $94 - 89 = 5$. A haze-free coating (refractive index of approximately 1.53) will have a corresponding haze index of 5 units, the difference between its 60° and 20° gloss values. Because 20° gloss changes much more rapidly with index than 60° gloss, the reflection haze value of a specimen also depends on the index of refraction of the material. To establish a correction for the effect of refractive index would require measurement of the index for each specimen, which is impractical. Comparisons of reflection haze evaluated by this test method are therefore limited to specimens of essentially the same refractive index.

6. Apparatus

6.1 Glossmeter(s) capable of measuring 60° and 20° specular gloss in accordance with the specifications given in Test Method D 523.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.26 on Optical Properties.

Current edition approved June 26, 1987. Published August 1987. Originally published as D 4039 - 81. Last previous edition D 4039 - 81.

² Boldface numbers in parentheses refer to the list of references at the end of this test method.

³ *Annual Book of ASTM Standards*, Vol 06.01.

Preparation and Selection of Test Specimens

7.1 This test method does not cover preparation techniques. When a test requires the preparation of specimens from a liquid coating, specify the techniques of specimen preparation.

7.2 Select test specimens in accordance with Practice D 3964.

7.2.1 To determine the maximum gloss obtainable from a material, such as a paint or a varnish, use methods in Test Methods D 823 to produce a film of uniform thickness on a smooth, planar substrate.

7.2.2 Use surfaces of good planarity, because surface damage, waviness, or curvature may affect test results significantly. The directions of brush marks or similar texture effects should be parallel to the plane of the axis of the two beams.

Calibration and Standardization

8.1 Calibrate the glossmeters with primary and secondary working standards in accordance with the procedures given in Test Method D 523.

Procedure

9.1 Select an area near the center of the test specimen and determine the 60° specular gloss.

9.2 Determine the 20° specular gloss on the same area of the specimen.

Calculation

10.1 Compute the haze index, H , as follows:

$$H = G_{60} - G_{20}$$

where:

G_{60} = value of 60° specular gloss and

G_{20} = value of 20° specular gloss.

NOTE 1—Because of the difference in the assigned values for the black glass standard at 20° and 60°, the haze index for specimens without haze will have value of approximately 5.

11. Report

11.1 Report the following information:

11.1.1 For each specimen, the measured G_{60} and G_{20} values and the computed haze index, H .

11.1.2 Where preparation of the test specimen has been necessary, describe or otherwise identify the method of preparation.

11.1.3 Identify the glossmeter used by make and model.

11.1.4 Identify the gloss standards used.

12. Precision

12.1 On the basis of interlaboratory studies of this procedure in which six laboratories conducted single determinations on eight high-gloss coatings differing in visually perceived reflection haze, the within-laboratory standard deviation for haze index values was found to be 0.9, and the between-laboratories standard deviation was found to be 2.5.

12.2 Based on these standard deviations, the following criteria should be used for judging the acceptability of single determinations at the 95 % confidence level.

12.2.1 *Repeatability*—Two results obtained by a single operator should be considered suspect if they differ by more than 2 units of haze index.

12.2.2 *Reproducibility*—Two results obtained by operators in different laboratories should be considered suspect if they differ by more than 7 units of haze index.

Standard Test Method for Viscosity of Printing Inks and Vehicles by the Falling-Rod Viscometer¹

This standard is issued under the fixed designation D 4040; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

¹ NOTE—Tables A1.1 and A1.2 editorially corrected and the year date changed to Nov. 15, 1991.

1. Scope

1.1 This test method covers the procedure for determining the falling-rod viscosity of printing inks, vehicles, and similar liquids that are essentially nonvolatile and unreactive under ordinary room conditions.

1.2 For printing inks, which are typically non-Newtonian, this test method is applicable in the apparent viscosity range of about 10 to 300 P at a shear rate of 2500 s⁻¹. For Newtonian liquids, the applicable viscosity range is about 10 to 1000 P (1 P = 0.1 Pa·s).

1.3 This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For specific hazard statements, see Section 8.

2.1 ASTM Standard:

D 445 Test Method for Kinematic Viscosity of Transparent and Opaque Liquids (and the Calculation of Dynamic Viscosity)²

3. Terminology

3.1 Definitions:

3.1.1 *viscosity, V* —the ratio of shear stress to shear rate. The viscosity of a liquid is a measure of the internal friction of the liquid in motion. The cgs unit of viscosity is 1 g/cm·s (1 dyne·s/cm²) and is called a poise. The SI unit is 1 N·s/cm² and is equal to 10 P.

3.1.2 *shear stress, S* —shearing force per unit area; the unit is 1 g/cm·s² (1 dyne/cm²). In the falling-rod viscometer, shear stress is proportional to total weight W per unit of shearing area A times the gravitational constant g , in accordance with the equation: $S = Wg/A$.

3.1.3 *shear rate, D* —velocity gradient through the stressed liquid; the unit is 1/s or 1 s⁻¹. In the falling-rod viscometer, shear rate is inversely proportional to fall time F per unit

distance L over which a unit thickness x of the liquid is stressed: $D = L/xF$.

3.1.4 *Newtonian*—refers to a liquid whose viscosity is constant at all shear rates.

3.1.5 *non-Newtonian*—refers to a liquid whose viscosity varies with shear rate. Such liquids may be either shear-thinning (pseudoplastic) or shear-thickening (dilatant). Most printing inks are shear-thinning.

3.1.6 *apparent viscosity, V_D* —the viscosity of a non-Newtonian fluid at a particular shear rate D . A shear rate of 2500 s⁻¹ has been found useful for printing inks and is specified in this test method.

3.1.7 *yield stress, S_o* —the minimum shear stress required to initiate motion in a non-Newtonian liquid.

3.2 Description of Terms Specific to This Standard:

3.2.1 *power law*—a mathematical model that presumes that the viscosity of a liquid varies with shear rate in accordance with a power function as follows:

$$k = \frac{S}{D^N}$$

where:

k = a constant related to the viscosity of the liquid and
 N = a constant describing the rate at which shear stress varies with shear rate.

The value of N is precisely 1.0 for a Newtonian fluid, less than 1.0 for a shear-thinning liquid, and greater than 1.0 for a shear-thickening liquid.

3.2.2 *power law plot*—a logarithmic plot of shear stress versus shear rate based on the expanded form of the power law equation:

$$\ln S = \ln k + N \ln D$$

For liquids conforming to the power law, the logarithmic plot of S versus D is linear over the shear rate range of interest. The slope of the line is the power law constant N .

3.2.3 *shortness*—the property of a non-Newtonian fluid that prevents it from being drawn into a filament.

3.3 Symbols (for Power-Law Calculations):

B = intercept of a straight line.

F = measured fall time, s.

F_c = corrected fall time, s.

F_{2500} = fall time equivalent to a shear rate of 2500 s⁻¹, s.

K_{2500} = apparent viscosity constant at 2500 s⁻¹, cm⁻¹s⁻¹.

N = slope of the power law plot, a measure of non-Newtonianism, cm²/dyne·s.

SF = shortness factor, s⁻¹.

S'_o = pseudo yield value, dyne/cm².

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.56 on Printing Inks.

² Annual Book of ASTM Standards, Vol 05.01.

- = measured specimen temperature, °C.
- = reference temperature, °C.
- = apparent viscosity at 2.5 s^{-1} , P.
- = apparent viscosity at 2500 s^{-1} , P.
- = total weight, g.
- = added weight, g.
- = weight of rod, g.
- = weight required to obtain a shear rate of 2500 s^{-1} , g.

Summary of Test Method

4.1 This test method is based on measurements of the time required for a weighted rod to fall through an aperture containing the test specimen.

4.2 Fall times are corrected to a reference temperature of 25°C (or other mutually agreed-upon temperature). The test method specifies precise measurement of actual specimen temperature in order to detect fluctuations due to cooling by metal, heat of friction during shearing, and body heat of the operator.

4.3 Each specific instrument must be calibrated in order to establish the fall time that is equivalent to a shear rate of 2500 s^{-1} .

4.4 Fall times as a function of weight are extrapolated to 2500 s^{-1} by means of the power law (logarithmic) relationship between shear stress and shear rate. Apparent viscosity at 2500 s^{-1} and the degree of non-Newtonianism are determined by calculation or graphically. The calculation of several low shear parameters is also covered.

Significance and Use

5.1 Apparent viscosity at the relatively high shear rate of 2500 s^{-1} does not completely define the rheological properties of printing inks but is useful in the practical control of ink viscosity during production and the specification acceptance between supplier and purchaser.

5.2 The slope of the power law plot is the preferred measure of non-Newtonianism. The yield value, which is obtained by extrapolation of high-shear measurements to a shear rate approaching zero, does not conform to the definition of the true yield stress (see 3.1.7). The yield value and other low shear parameters are also subject to a high degree of variability (see the precision table in Section 16).

6. Apparatus

6.1 Fall-Time Runs:

6.1.1 *Falling-Rod Viscometer*,³ equipped with a swinging platform and automatic timing device⁴ accurate to at least 0.1 s, preferably 0.01 s. A special lightweight rod is useful for liquids in the 10-P range.

6.1.2 *Set of Tapped or Slotted Weights*—Weights of 50 or 100 to 500 g are usually provided with the instrument. Extra 500-g weights, approximately 4, totaling about 2000 g are required to handle fluids at the upper end of the practical

range. A 25-g weight is useful for liquids in the 10-P range.

6.1.3 *A Thermostatically Controlled Cabinet*, optional (if room conditioning is not available). Alternatively, a special collar⁵ through which water is circulated from a constant-temperature bath.

6.1.4 *Thermistor*,⁶ equipped with a probe having a response time of 3 to 6 s.

6.1.5 *Ring Stand and Clamp*, or other device for holding the thermistor probe in a suitable position.

6.1.6 *Small Plastic Spatula*—Metal spatulas are not suitable.

6.1.7 *Plastic Scraper*, consisting of a piece of flexible plastic, approximately 30 by 70 mm, having a semicircle cut out at one end; semicircle should fit the rod.

6.2 Instrument Calibration:

6.2.1 *Balance*, weighing to 0.1 g.

6.2.2 *Metric Rule or Scale*, at least 100 mm in length.

6.2.3 *Vernier Caliper*, accurate to 0.01 mm, having a capacity of at least 30 mm.

6.3 Graphical Solutions:

6.3.1 *Chart Paper*, logarithmic 2×2 to 2×3 cycles.⁷

6.3.2 *Triangle*, 45°, with a hypotenuse length of at least 100 mm (approximately 8 in.).

6.3.3 *Protractor*.

7. Materials

7.1 *ASTM Standard Viscosity Oils*,⁸ a minimum of two, preferably three, spanning the practical range of the falling-rod viscometer (used for calibration purposes only).

7.2 *Lithographic Varnish* or similar vehicle having a viscosity of about 200 P.

7.3 *Lint- and Metal-Free Rags or Tissues*.

7.4 *Naphtha* or other low-boiling solvent in a wash bottle or closed metal container.

8. Hazards

8.1 *Safety Precautions*—Since solvents may be hazardous to the skin and eyes, in addition to other precautions, wear rubber gloves and safety glasses during cleanup to avoid solvent contact with skin and eyes. In case of contact, wash skin with water; flush eyes for 15 min with water and call a physician. See supplier's Material Safety Data Sheets for further information on each solvent used.

8.2 Instrument Cautions:

8.2.1 Avoid any operation that will scratch the rod. Do not use a metal spatula. Never drop the rod through an empty aperture.

8.2.2 Weight loads in excess of 3000 g may cause bending of the rod.

³ Collars are available as accessories from the respective manufacturers.

⁶ Suitable thermistors include Tele-Thermometer Model 43TA, with Model 423 probe from Yellow Springs Instrument Co., Inc., Box 279-T, Yellow Springs, OH 45387; and Model TSB with Model TP-7P probe from TRI-R Instruments Inc., 48 Merrick Rd., Rockville Centre, NY 11570.

⁷ Suitable chart paper includes Keuffel & Esser Nos. 46-7200 (22), 46-7280 (22.7), 46-7320 (23), all 8½x11 green drawing; also available in green or orange tracing or 11x16½.

⁸ Certified standard viscosity oils are available from Cannon Instrument Company, P.O. Box 16, State College, PA 16801. Table 3 in Test Method D 445 shows satisfactory oils including S-600 (16 P at 25°C), S-2000 (57 P), S-8000 (220 P), and S-30 000 (750 P). Viscosity at various temperatures is indicated on the label of each container.

³ Commercial units include the Laray Viscometer available from Testing Machines, Inc., 400 Bayview Ave., Amityville, NY 11701; Thwing-Albert Model LR from Thwing-Albert Instrument Co., 10960 Dutton Rd., Philadelphia, PA 19154; Churchill from Churchill Instrument Co., Ltd., Greenford, England.

⁴ Platform and timing device are standard on newer viscometer models. For equipping older models, see Bassenir, R., "Evaluation of the Laray Viscometer," *American Ink Maker*, Vol 39, No. 4, April 1961, pp. 24-26 and 60.

8.2.3 To minimize heat buildup from body temperature during a run, avoid contacting the viscometer block with bare hands. When instructions call for holding the block steady, wear a glove or place a small cloth in the palm of the hand.

8.2.4 When making fall-time measurements, work quickly and without interruption so that the entire run is completed within 5 to 10 min.

NOTE 1—Many modern printing inks and vehicles contain some solvent, and volatile loss during a run can seriously bias test results unless rigorous control of exposure time is exercised. Volatile loss can be detected if successive drops of the rod with the same weight result in increasingly longer fall times.

9. Preparation of Apparatus

9.1 Set the viscometer on a sturdy bench located in an area free of direct drafts, direct sunlight, and other sources of heat. Level the viscometer by turning the adjustable feet up and down until the spirit level bubble is centered.

9.2 Pass a hand over the upper and lower photocells to assure that the timer is activated and deactivated.

9.3 Attach the clamp to the ring stand and place next to or behind the viscometer. Drape the thermistor probe over the clamp; reset the clamp so that the probe end falls close to the viscometer block.

9.4 Clean the block and rod thoroughly with tissues wetted with naphtha. Remove residual solvent with clean dry tissue. Roll the clean dry rod over a flat surface to check for straightness. If rod is bent, discard and obtain a new rod/orifice set.

9.5 Examine the markings at the ends of the rod. Select one marking as an indication of the "proper" end to be always inserted into the aperture first.

10. Calibration

10.1 Determine instrument constants in accordance with the procedure given in Annex A1.

10.2 *Optional*—If a graphical method is to be used for direct conversion of test results to viscosity, prepare Master Sliding Scale Calibration Graph as in Annex A2.

10.3 Periodically check calibration as in Section A1.2.

11. Sample Preparation

11.1.1 Transport the sample to the test area and preserve in a closed container. Skin paper should be used for oxidative drying inks.

11.1.2 Ink samples should be uniform dispersions. If pigment settling is suspected, insert a spatula in the container and gently stir. Be careful not to introduce air bubbles.

11.1.3 Prior to the run, a portion of the sample may be transferred to a slab and gently spread out in order to remove bubbles, skin, or other debris.

NOTE 2: *Caution*—Do not work the sample vigorously; this practice causes a significant increase in sample temperature. Be sure to close the container immediately after removing the desired portion.

12. Conditioning

12.1 The temperature of the room (cabinet or collar) should be set at $23 \pm 1^\circ\text{C}$ (or 2°C below the reference temperature).

NOTE 3—In accordance with Note 8, the allowable range for specimen temperature is $\pm 2^\circ\text{C}$ from the reference temperature. However, during the course of testing, heat of shearing and body heat of the operator both contribute to continuous temperature rises in test specimens, notwithstanding room, cabinet, or collar conditions. To allow for inevitable temperature rises, temperature controls are set at the lower end of the allowable range.

12.2 Equilibration of test samples is not necessary. Specimen sizes are small (less than 2 mL); when spread out on a slab and applied to the viscometer, both hot and cold samples quickly reach the temperature of the metal.

12.3 If the viscometer has been idle for more than an hour, it may be necessary to bring it into equilibrium with the conditioning temperature (23°C or other specified in 12.1). Make preparations for an exploratory run (13.2 to 13.5) using a varnish if the test specimen contains volatiles. Read specimen temperature; if too low (a possibility considering that metal serves as a heat sink), add a 1000-g weight to the rod and make a few drops (13.7 to 13.9 but without recording time) until the specimen temperature reaches that of conditioning. Continue the run or, if a varnish was used, clean up.

13. Procedure for Fall-Time Runs

13.1 If required, prepare, level, and condition the instrument as described in 10.12.1 and 12.3.

13.2 With the proper end of the clean rod down, hold the rod vertically over the clean aperture and gently lower until it rests on the swinging platform.

13.3 Transfer a uniform specimen to the tip of a clean plastic spatula. The specimen size should be sufficient to fill the well of the viscometer.

13.4 Hold the rod with the fingertips and carefully raise about 20 mm. Transfer the specimen from the spatula to the rod as close as possible to the bottom of the well. Rotate the rod slowly to distribute the specimen around the well, ensuring that the well is full. Allow the rod to fall to the platform.

13.5 Place the thermistor probe in the well close to but not touching the rod. The probe can remain in the well throughout the run. Turn the thermistor on.

13.6 Using experience or the information in Table 1 as a guide, select a weight load that will produce a fall time as close to 1 or 2 s as is practical.

NOTE 4—For comparison of non-Newtonian liquids, runs must not be made at pre-specified rod weights. Rather, weights should be adjusted to obtain pre-specified fall times, the first of which corresponds as closely to a shear rate of 2500 s^{-1} as is practical.

13.7 Hold the block level and steady with one hand (see 8.2.3). With the other hand, carefully place the selected weights on top of the rod. If weights are slotted, evenly distribute the slots around the circumference of the rod. Make certain that the rod is vertical. (If weights tend to make the viscometer unsteady, retain the hand on the block so that the rod falls smoothly in 13.8.)

13.8 Set the timer. Release the platform and allow the rod to fall naturally. If the fall time is within the desired range (for example, 1 to 2 s for the first weight, etc.), record the added weight W_A , fall time F , and specimen temperature T on worksheet.

13.9 Remove the weights from the rod. Pull the rod up

TABLE 1 Weight/Fall-Time Relationships for Newtonian Liquids^A
Rod weight = 130 g

Viscosity of Fluid, P	Fall Time, s					
	1	2	4	6	10	20
10	200	50	...	...	...	...
50	1 300	700	300	100	50	...
100	3 000	1 400	700	400	150	25
250	7 000 ^B	3 800 ^B	1 800	1 100	700	300
500	15 000 ^B	7 000 ^B	3 200 ^B	2 200	1 400	600
1000	25 000 ^B	16 000 ^B	8 000 ^B	5 500 ^B	3 000	900

^AWeights required may be more or less depending on instrument type and degree of wear. Printing inks will require additional weight depending on degree of Newtonianism.

^BWeights are impractical or not recommended.

13.9 Repeat the drop (13.7 to 13.9) with the same or adjusted weights until two fall times with a specific set of weights agree within 2 % (0.04 s at a 2-s fall time, 0.2 at a 20-s fall time, etc.).

13.10 Repeat the drop (13.7 to 13.9) with the same or adjusted weights until two fall times with a specific set of weights agree within 2 % (0.04 s at a 2-s fall time, 0.2 at a 20-s fall time, etc.).

NOTE 5—Newtonian liquids may be run with only one or two sets of weights. Non-Newtonian liquids require at least four or five.

13.12 If the specimen is depleted during the run, clean the rod and start over from 13.1, preferably using ink fresh from the container. Make certain that the quantity of specimen is sufficient.

13.13 Immediately after completing the run, turn the thermistor off, remove the probe from the well, and clean the probe, the viscometer orifice, and the rod thoroughly.

NOTE 6—Since each test involves replicate fall-time measurements at up to five weights, a single viscosity determination is usually considered adequate.

14. Calculation

NOTE 7—This section covers calculations by computer or programmable calculator. The list of symbols is given in 3.3. The procedure for graphical solution of test results is described in the Annex A2.

14.1 Enter into the computer the values for the instrument constants, W_R , F_{2500} and K_{2500} and the reference temperature T_R .

14.2 Enter data from fall-time runs in sets of W_A , replicate values of F that agree within 2 %, and the corresponding values of T .

14.3 Compute the non-Newtonianism parameter N by simultaneous solution of the following general equation:

$$\log W = B - N \log F_c \quad (1)$$

where:

$$W = W_A + W_R \quad (2)$$

and

$$F_c = F + 0.1 F (T - T_R) \quad (3)$$

NOTE 8—Equation 3 corrects each measured fall time by 10 % per degree differential between the measured temperature and the reference

temperature and is applicable only within 2°C of T_R . As noted in the third column of Table A1.2, specimen temperature increases progressively during a run. For accurate results, it is important that the temperature correction be applied to the fall time corresponding to each added weight. Otherwise, significant error will be introduced into the slope of the power law plot.

14.4 Examine (by computer) the value of N . Any value over 1.0 is improbable for a printing ink or a vehicle and suggests error in the test measurements; check data or repeat runs. Alternatively, treat any value between 1.0 and 1.05 as 1.0.

14.5 Compute the viscosity at 2500 s⁻¹ as follows:

$$V_{2500} = K_{2500} W_{2500} \quad (4)$$

where:

$$W_{2500} = \text{antilog} (B - N \log F_{2500}) \quad (5)$$

14.6 *Optional*—Compute the viscosity at 2.5 s⁻¹ from either Eqs 6 or 7 as follows:

$$V_{2.5} = V_{2500} (1000)^{1-N} \quad (6)$$

or

$$V_{2.5} = 1000 K_{2500} \text{antilog} (B - N \log 1000 F_{2500}) \quad (7)$$

14.7 *Optional*—Compute the pseudo yield value as follows:

$$S'_0 = 2.5 (V_{2.5} - V_{2500}) \quad (8)$$

NOTE 9—Since the logarithmic nature of the power law precludes a zero shear rate, Eq 8 was derived to approximate the Bingham yield value, which is normally determined by extrapolating the linear portion of a shear stress/shear rate plot to zero rate of shear.

14.8 *Optional*—Compute the shortness factor as follows:

$$SF = S'_0 / V_{2500} \quad (9)$$

15. Report

15.1 Report apparent viscosity at 2500 s⁻¹, degree of non-Newtonianism, reference temperature, and identifying code referring to the specific viscometer.

15.2 *Optional*—Report the viscosity at 2.5 s⁻¹, the pseudo yield value, and the shortness factor.

16. Precision

16.1 An interlaboratory study of this test method was conducted in which a single operator in each of nine laboratories made one run consisting of at least four replicated data points on four inks on two different days. The inks ranged in viscosity from 10 to 300 P. The results were calculated on a single programmable calculator. One labora-

TABLE 2 Precision of Falling-Rod Viscosity Determinations

Test Results	Standard Deviation, % relative	Degrees of Freedom	Maximum Allowable Difference, % relative
Repeatability			
<i>N</i>	3.3	4	7.6
<i>V</i> ₂₅₀₀	5.4	4	15.3
<i>V</i> _{2.5}	11.5	4	31.4
<i>S</i> _o	14.6	3	41.2
<i>SF</i>	17.7	3	50.1
Reproducibility			
<i>N</i>	4.6	28	12.9
<i>V</i> ₂₅₀₀	7.9	28	22.3
<i>V</i> _{2.5}	17.5	21	49.5
<i>S</i> _o	22.3	21	63.1
<i>SF</i>	23.6	21	66.9

tory was a consistent outlier and was deleted from the entire analysis, and the 10 P ink was deleted from analysis of the low shear parameters. The estimated standard deviations and

the degrees of freedom are given in Table 2. (Since the standard deviation was proportional to the test value, precision statements are made in terms of percent of the observed value.) Based on these standard deviations, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

16.1.1 *Repeatability*—Two results obtained by the same operator on different days should be considered suspect if they differ by more than the maximum allowable difference indicated in Table 2.

16.1.2 *Reproducibility*—Two results, each the mean of results obtained on different days by operators in different laboratories, should be considered suspect if they differ by more than the maximum allowable difference indicated in Table 2.

ANNEXES

(Mandatory Information)

A1. CALIBRATION OF FALLING-ROD VISCOMETERS

A1.1 Determination of Instrument Constants:

A1.1.1 Measure the distance between photocells of the timing device. Adjust to 100 ± 0.5 mm. Divide by 10 and record as *L* in centimetres in chart patterned after Table A1.1.

A1.1.2 Weigh the clean rod to 1 g. Record as *W_R*.

A1.1.3 Using a caliper, measure the diameter of the rod to 0.01 mm. Record as *d* in centimetres.

A1.1.4 With the caliper, measure the length of the block over which the liquid is sheared (total height of block minus ink well) to 0.01 mm. Record as *h* in centimetres.

A1.1.5 Calculate apparent shearing area from the equation $A = \pi dh$. Record as *A* in square centimetres.

NOTE A1.1—The shearing length of the block contains both a tapered and a parallel section; therefore, it is understood that *A* is not the true shearing area but an apparent shearing area.

A1.1.6 The thickness *x* of the test liquid is set by the clearance between the aperture and the rod. Since the aperture consists of two radii, both of which are difficult to measure, a value for a mean gap clearance $\bar{x}$ can be

TABLE A1.1 Instrument Constants for Falling-Rod Viscometers

 Complete this column only if sample is a calibrating oil or a Newtonian fluid.
 Editorially corrected.

computed from fall-time runs on Newtonian oils in the following manner:

A1.1.6.1 Using the procedure described in Section 13, make fall-time runs on two or three standard oils in random sequence on two different days.

A1.1.6.2 For each added weight, compute the mean of fall times that agree within 2 %. Also compute the mean of the corresponding temperature. Record as $\bar{F}$ and $\bar{T}$ on worksheet (see Table A1.2). Correct each mean fall time according to Eq. 3, (see 14.3). Record as F_c .

A1.1.6.3 Take the sum of each added weight and the rod weight. Record as the total weight, W .

A1.1.6.4 Multiply each total weight by the corresponding corrected fall time and record as WF_c . Examine trends in WF_c within each run. Values that change progressively with weight are indicative of inadequate temperature sensing or non-Newtonianism in the oil. Check the source of error or repeat with new oil if required.

A1.1.6.5 Compute a mean WF_c for each run and divide into the viscosity of the oil at 25°C (or other reference temperature). The resulting values of V/WF_c should be essentially the same for all oils. Compute the mean V/WF_c .

NOTE A1.2—If the label on the oil container does not list viscosity specifically at the reference temperature, the desired viscosity may be obtained from plots of log viscosity versus reciprocal of temperature on semi-logarithmic chart paper.

A1.1.6.6 Compute the mean gap clearance $\bar{x}$ by multiplying V/WF_c by AL/g . Record to three significant figures in centimetres (10^{-4} cm = 1 μ m).

A1.1.7 Calculate the fall time corresponding to a shear rate of 2500 s^{-1} from the equation: $L/2500 \bar{x}$. Record as F_{2500} in seconds to three significant figures.

A1.1.8 Compute $g/2500 A$ and record as the "apparent viscosity constant at 2500 s^{-1} ," K_{2500} , in $cm \cdot s^{-1}$.

A1.2 Recalibration:

A1.2.1 Periodically determine several corrected fall times with one oil used for the original calibration.

A1.2.2 Calculate values for WF_c and compare with those originally obtained for the oil.

A1.2.3 If the new values do not reasonably agree with the original ones, use the new fall time results to calculate a new value for the mean gap clearance $\bar{x}$. If $\bar{x}$ increases by less than 5 % of the original value, the existing calibration may be retained. If the increase is between 5 and 20 %, repeat the entire calibration process. If gap clearance increases by 20 % or more, replace the rod and aperture.

A2. GRAPHICAL SOLUTION OF VISCOSITY

A2.1 Construction of Sliding Scale Calibration Graph:

A2.1.1 On a sheet of 2 by 2 to 2 by 3 cycle logarithmic

chart paper, label the 2-cycle scale "Corrected fall time, s." (See Fig. A2.1.) Add one zero to the second cycle. Mark

FIG. A2.1 Typical Sliding Scale Calibration Graph

position of F_{2500} (from A1.1.7) on time scale. If below 1.0 s, the position can be located using another sheet of log paper as a guide. Draw a horizontal line across the entire sheet of paper and label "2500 s^{-1} " at the far end.

A2.1.2 Along the 3-cycle axis, mark the start of the cycles as 100, 1000, and 10 000. Label the scale "Total weight, g" so as not to interfere with the line previously drawn for "2500 s^{-1} ."

A2.1.3 Using the the results from fall-time runs made with standard oils (A1.1.6.1) and found satisfactory in accordance with A1.1.6.4, plot corrected fall time versus total weight for each oil-day combination. Using the triangle, draw the best 45° line through the points so that each plot line intercepts the line labeled "2500 s^{-1} ."

A2.1.4 From a second sheet of the same type of chart paper, cut a piece along the 3-cycle axis so that the resulting strip contains the scale plus one or two graph divisions. Add zeros to the scale so that the second cycle starts at 10 and the third at 100; if required for high-viscosity fluids, a fourth cycle starting at 1000 may be obtained by pasting two strips together. Label the strip "Viscosity at 25°C, P." Locate the 25°C viscosity of each calibrating oil on the scale and draw vertical lines to the top. If three oils were used, there should be three lines on the strip.

A2.1.5 Position the top of the strip directly beneath the 2500 s^{-1} line drawn on the first sheet of chart paper so that the viscosity lines on the strip match as closely as possible the intercepts at 2500 s^{-1} . Paste securely in place. Cut off portions of the strip that extend beyond the edges of the chart paper. Relabel "Total weight" scale if strip hides pertinent coordinates.

A2.1.6 The chart paper containing the viscosity strip represents the "Master Sliding-Scale Calibration Graph" for

a specific instrument. Prepare an overlay containing the desired identification information and paste in a suitable place (see example in Fig. A2.1). Make sufficient copies of the master for normal use of the instrument. Be sure to preserve the original.

NOTE A2.1—Use a duplication procedure that reproduces copy exactly. Office copiers and "quick" printing methods are prone to provide distorted copy.

NOTE A2.2—The Master Sliding-Scale Calibration Graph is essentially similar to the Inmont-Lehman chart, which is also based on the power law but presumes that a shear rate of 2500 s^{-1} corresponds to a fall time of 1.0 s in all instruments. The charts issued by viscometer manufacturers are Cartesian ($1/F$ versus W) and are based on Bingham

A2.2 Graphical Solution of Viscosity:

A2.2.1 Make the fall-time run on the test sample according to Section 13. Compute the corrected mean fall times and the total weights according to A1.1.6.2 and A1.1.6.3.

A2.2.2 On a copy of the Master Sliding Scale Calibration Graph (Section A2.1), plot corrected fall time versus total weight for the test material.

A2.2.3 Using the 45° triangle as a guide, check whether the best straight line through the plotted points is 45° or greater to the weight axis. A line less than 45° is improbable for a printing ink or a vehicle and suggests error in the test measurements; check calculations or repeat the run.

A2.2.4 Draw the best straight line through the points, making certain that the angle is at least 45° to the weight axis. Extend the line so that it intersects the horizontal axis at 2500 s^{-1} . Read viscosity as the intercept on the sliding scale. Record as V_{2500} , apparent viscosity at 2500 s^{-1} .

A2.2.5 Center the protractor at the intercept and read the angle of the plot line. Subtract the measured angle from 90° and obtain the tangent from mathematical tables or a

table calculator. Record as the non-Newtonianism parameter N .

NOTE A2.3—By turning Fig. A2.1 90° to the left, the graph can be viewed as a logarithmic plot of shear stress versus shear rate, and the

shear thinning nature of the test ink made more evident. The tangent of the angle with respect to the time (shear rate) axis is the power law constant N .

A2.2.6 *Optional*—Calculate $V_{2.5}$, $S'_{0.0}$, and SF according to Eq 6 (see 14.6), Eq 8 (see 14.7) and Eq 9 (see 14.8).

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Abrasion Resistance of Organic Coatings by the Taber Abraser¹

This standard is issued under the fixed designation D 4060; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the resistance of organic coatings to abrasion produced by the Taber Abraser on coatings applied to a plane, rigid surface, such as a metal panel.

1.2 Because of the poor reproducibility of this test method, it should be restricted to testing in only one laboratory when numerical abrasion resistance values are to be used. Interlaboratory agreement is improved significantly when rankings of coatings are used in place of numerical values.

1.3 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 Descriptions of Terms Specific to This Standard:

3.1.1 Abrasion resistance can be expressed as one or more of the following terms:

3.1.1.1 *wear index*—1000 times the loss in weight in milligrams per cycle.

3.1.1.2 *weight loss*—the loss in weight in milligrams,

determined at a specified number of cycles.

3.1.3 *wear cycles per mil*—the number of cycles of abrasion required to wear a film through to the substrate per mil of film thickness.

4. Summary of Test Method

4.1 The organic coating is applied at uniform thickness to a plane, rigid panel and, after curing, the surface is abraded by rotating the panel under weighted abrasive wheels.

4.2 Abrasion resistance is calculated as loss in weight at a specified number of abrasion cycles, as loss in weight per cycle, or as number of cycles required to remove a unit amount of coating thickness.

5. Significance and Use

5.1 Coating on substrates can be damaged by abrasion during manufacturing and service. This test method has been useful in evaluating the abrasion resistance of attached coatings. Ratings produced by this test method have correlated well with ratings produced by the falling abrasive values in Test Method D 968.

6. Apparatus

6.1 Taber Abraser.⁴

6.2 *Abrasive Wheels*—Resilient calibrase wheels No. CS-10 or CS-17, as required, shall be used. Because of the slow hardening of the rubber bonding material in this type of wheel, the wheels should not be used after the date marked on them, or one year after their purchase if the wheels are not dated.

NOTE 1—The hardness of the wheels can be checked by Test Method D 2240. An acceptable hardness for both types of wheels is 81 ± 5 units on Shore Durometer A-2 Scale.

NOTE 2—The CS-17 wheels produce a harsher abrasion than the CS-10 wheels.

6.3 *Resurfacing Medium*, an S-11 abrasive disk, used for resurfacing the abrasion wheels.

6.4 *Vacuum Pick-Up Assembly*, consisting of a vacuum unit, a variable transformer suction regulator, a nozzle with bracket attachment, and a connecting hose with adaptor.

7. Test Specimens

7.1 Apply a uniform coating of the material to be tested to a plane, rigid panel. Specimens shall be a disk 4 in. (100 mm) in diameter or a plate 4-in. (100-mm) square with rounded corners and with a 1/4-in. (6.3-mm) hole centrally located on

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.23 on Physical Properties of Applied Paint Films.

Current edition approved May 25, 1990. Published July 1990. Originally published as D 4060 - 81. Last previous edition D 4060 - 84.

² *Annual Book of ASTM Standards*, Vol 06.01.

³ *Annual Book of ASTM Standards*, Vol 09.01.

⁴ Available from Teledyne Taber, North Tonawanda, NY 14120.

each panel. Prepare a minimum of two coated panels for the material.

NOTE 3—The coatings should be applied in accordance with Test Methods D 823, or as agreed upon between the purchaser and the seller.

NOTE 4—The thickness of the dry coatings should be measured in accordance with Test Methods D 1005, D 1186, or D 1400.

Standardization

8.1 Mount the selected abrasive wheels on their respective change holders, taking care not to handle them by their abrasive surfaces. Adjust the load on the wheels to 1000 g.

8.2 Mount the resurfacing medium (S-11 abrasive disk) on the turntable. Lower the abrading heads carefully until the wheels rest squarely on the abrasive disk. Place the vacuum pick-up nozzle in position and adjust it to a distance of 1/32 in. (1 mm) above the abrasive disk.

8.3 Set the counter to "zero" and set the suction regulator to approximately 50 points on the dial. The setting may be increased to 90 if more effective removal of the abrasings appears necessary.

8.4 Start the vacuum pick-up and then the turntable of the abrader. Resurface the wheels by running them 50 cycles against the resurfacing medium.

NOTE 5—The wheels should be resurfaced in this manner before testing each specimen and after every 500 cycles.

Conditioning

9.1 Cure the coated panel under conditions of humidity and temperature as agreed upon between purchaser and seller.

9.2 Unless otherwise agreed upon between purchaser and seller, condition the coated panel for at least 24 h at $23 \pm 2^\circ\text{C}$ and $50 \pm 5\%$ relative humidity. Conduct the test in the same environment or immediately on removal therefrom.

Procedure

10.1 Weigh the test specimen to the nearest 0.1 mg and record this weight, if either the wear index or the weight loss is to be reported.

10.2 Measure the coating thickness of the test specimen in several locations along the path to be abraded.

10.3 Mount the test specimen on the turntable. Place the abrading heads on the test film and the vacuum pick-up nozzle in position as outlined in 8.2. Set the counter and suction regulator as outlined in 8.3.

10.4 Start the vacuum pick-up and then the turntable of the abrader. Subject the test specimen to abrasion for the specified number of cycles or until wear through of the coating is observed. In determining the point of wear through, stop the instrument at intervals for examination of the test specimen.

10.5 Remove any loose abrasings remaining on the test specimen by light brushing. Reweigh the test specimen.

10.6 Repeat 10.1 to 10.5 on at least one additional test specimen of the material under test.

11. Calculation

11.1 *Wear Index*—Compute the wear index, I , of a test specimen as follows:

$$I = \frac{(A - B) 1000}{C}$$

where:

A = weight of test specimen before abrasion, mg,
 B = weight of test specimen after abrasion, mg, and
 C = number of cycles of abrasion recorded.

NOTE 6—In calculating wear index it may be advisable to discard the last 200 cycles because the results may be affected by abrasion of the exposed substrate.

11.2 *Weight Loss*—Compute weight loss, L , of the test specimen as follows:

$$L = A - B$$

where:

A = weight of test specimen before abrasion, mg, and
 B = weight of test specimen after abrasion, mg.

11.3 *Wear Cycles Per Mil*—Compute the wear cycles per mil, W , of the test specimen as follows:

$$W = D/T$$

where:

D = number of cycles of abrasion required to wear coating through to substrate and
 T = thickness of coating, mils (0.001 in.) (to one decimal place).

NOTE 7—In calculating the wear cycles, it is advisable to discard the first and last readings because the first may be affected by an uneven surface and the last by abrasion of parts of the substrate.

12. Report

12.1 Report the following information for each test material:

12.1.1 Temperature and humidity during conditioning and at the time of testing,

12.1.2 Thickness of coating when wear cycles are specified,

12.1.3 Kind of calibrase abrasive wheels used,

12.1.4 Load applied to the abrasive wheels,

12.1.5 Number of wear cycles recorded for each test specimen,

TABLE 1 Precision of Taber Abrasion Values

	Within Laboratory		Between Laboratories	
	Coefficient of Variation, %	Maximum Allowable Difference, %	Coefficient of Variation, %	Maximum Allowable Difference, %
Weight loss at 500 cycles	12	48	36	105
Weight loss at 1000 cycles	10	46	30	90
Wear index at 500 cycles	13	52	36	106
Wear index at 1000 cycles	10	46	30	92
Cycles per mil	13	44	31	92

12.1.6 Wear index, weight loss, or wear cycles per mil for each test specimen, and

12.1.7 Mean and range of the abrasion resistance values of the replicate coated panels.

13. Precision⁵

13.1 On the basis of an interlaboratory test of this test method in which operators in five laboratories tested four coatings having a broad range of abrasion resistance, the within-laboratory coefficients of variation and between-laboratories coefficients of variation were found to be those in Table 1. Based upon these coefficients, the following

criteria should be used for judging the acceptability of results at the 95 % confidence level:

13.1.1 *Repeatability*—Two results by the same operator should be considered suspect if they differ by more than the maximum allowable difference values shown in Table 1.

13.1.2 *Reproducibility*—Two results obtained by operators in different laboratories should be considered suspect if they differ by more than the maximum allowable difference values shown in Table 1.

NOTE 8—When this test method is used to rank a series of coatings by magnitude of abrasion resistance, the precision is significantly better than shown in Table 1. In the interlaboratory study for evaluating precision, all laboratories ranked the coatings in the same order of abrasion resistance.

⁵ Supporting data are available from ASTM Headquarters. Request RR: D01-1037.

Standard Test Method for Leveling of Paints by Draw-Down Method¹

This standard is issued under the fixed designation D 4062; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

1. This test method² covers the laboratory determination of the relative leveling of water and solvent-reducible architectural paints in white and light tints by comparing the ridges produced in a draw-down film to a series of plastic leveling standards.

2. Unpigmented, texture, and deep-tint coatings cannot be readily evaluated with the shadowing produced by oblique lighting employed in this test method. Such coatings may be evaluated by comparing them with the plastic standards at various angles of reflection. For this purpose ordinary room lighting is satisfactory.

3. Since other factors may influence the tendency of liquid paints to sag, this test method is not intended to measure sagging.

4. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Description of Term Specific to This Standard

1.1 *leveling*—of a paint, a measure of its ability to flow after application so as to obliterate any surface irregularities such as brush marks, orange peel, peaks, or craters that have been produced by the mechanical process of application.

Summary of Test Method

1.2 The material to be tested is presheared and then applied to a sealed chart by means of a special leveling test blade designed to lay down a film with parallel ridges simulating brush marks. After allowing the completed draw-down to dry in a horizontal position, leveling of the test paint is rated by viewing the draw-down under a strong, oblique light source and comparing the contrast of lightness and shadow caused by the paint ridges to that of a series of plastic leveling standards under the same lighting conditions.

Significance and Use

1.3 Instrumental evaluations of leveling by this test

method have been shown to correlate with those made by brush application. Leveling can affect the hiding and appearance of applied architectural coatings, the presence of brushmarks and surface irregularities being more conspicuous with gloss and semi-gloss finishes than with flat finishes.

5. Apparatus

5.1 *Leveling Test Blade*^{3,4}—A grooved draw-down blade designed to lay down a wet film with parallel ridges (see Fig. 1).

5.2 *Draw-Down Plate*,⁵ with two parallel, smooth-faced straightedges to guide the blade during film application and ensure that the ridges are straight.

5.3 *Syringe and Needle*—A 10-mL LuerLok syringe and 1½-in. (38-mm) No. 15 gage needle for placing a fixed amount of the paint in front of the blade while simultaneously preshearing it (as during brushing) prior to drawing-down. Either glass or disposable plastic syringes may be used with water-reducible paints. Glass syringes only may be used with solvent-reducible paints due to swelling of disposable syringes by the solvent.

5.4 *Test Chart*,⁶ plain white (for white or light tints) or predominantly black chart (for deep tints) coated with a suitable varnish or lacquer to render the test surface impervious to the volatile portion of the paint.

5.5 *Light Source*,⁷ oblique, to illuminate the test draw-down and leveling standards (see Fig. 2).

5.6 *Levelness Standards*⁸—Three-dimensional full-scale replicas of draw-downs made with the leveling test blade and nine paints exhibiting very poor to very good leveling, for comparison with the test draw-down.

5.7 *Catch Papers*, disposable, any type for catching excess paint is adequate.

³ The Leneta Leveling Test Blade, available from the Leneta Company, P. O. Box 86, Ho-Ho-Kus, NJ 07423, has been found satisfactory for this purpose.

⁴ The Leneta Leveling Test Blade used in this test method is a modification of the threaded draw-down bar described in an article by Dodge, J. S. "Quantitative Measures of Leveling," *Journal of Paint Technology*, Vol 44, No. 564, January 1972.

⁵ The Leneta Leveling Test Draw-Down Plate has been found satisfactory for this purpose. Available from the Leneta Company. A suitable draw-down plate may be constructed from the description given in 5.2 of this test method.

⁶ Leneta Form WB, a plain white sealed chart, and Leneta Form 7B, a black and white sealed chart, available from the Leneta Company, have been found suitable for light- and deep-tint paints, respectively. Equivalents may be used.

⁷ A standard oblique fluorescent light source (The Level-Luminator), has been found satisfactory for this purpose. Available from the Leneta Company. A suitable light source may be constructed from the description given in 6.5 and Fig. 2 of this test method.

⁸ Leneta Draw-Down Levelness Standards, a series of nine 3 by 5 in. (75 by 125 mm) plastic full-scale replicas of draw-downs of paints having very poor to very good leveling, have been found satisfactory for this purpose. Available from the Leneta Company.

This test method is under the jurisdiction of ASTM Committee D-1 on Paints and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.42 on Architectural Finishes.

Current edition approved May 27, 1988. Published October 1988. Originally published as D 4062 - 81. Last previous edition D 4062 - 81 (1987).

This test method was essentially developed by the Leneta Company as outlined in Leneta Catalog No. 3, pp. 26-7 (1976).

Stock is #303 stainless steel

Dimensions:

	mm	in. (approx.)
A—Length	165	6.5
B—Diameter	22	0.87
C—Supporting edge	25	1.0
D—Minor doctoring edge	1.25	0.05

Dimensions:

	mm	in. (approx.)
E—Major doctoring edge	1.25	0.05
F—Minor clearance	0.10	0.004
G—Clearance step	0.20	0.008
H—Major clearance	0.30	0.012

NOTE—This is actually a cylindrical rod, the term "blade" being employed as a conventional reference to film applicators. Auxiliary plastic side arms not shown. See Figs. 1 (b) and 1 (c).

FIG. 1 (a) Leneta Leveling Test Draw-Down Blade

6. Preparation of Sample

6.1 Adjust the temperature of the paint to $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) or to a temperature agreed upon between buyer and seller.

6.2 Thoroughly mix the paint by hand with a spatula to a smooth, uniform composition and consistency to ensure that the specimen to be taken for testing is representative.

7. Procedure

7.1 Affix the test chart to the draw-down plate. Position the leveling blade at the far end of the chart, between the parallel straightedges, with the longer arm of the blade adjacent to the left edge and pointing toward the operator.

7.2 Place a catch paper just below but in contact with the chart so that it is slightly to the right of the longer arm of the blade.

7.3 With the needle not attached, take up 8 to 10 mL of the material under test into the syringe (Note 1). Wipe off the

syringe orifice and attach the No. 15 gage needle. Eject within 3 to 5 s the entire amount in front of the blade, forming a puddle. Immediately lay the syringe down, grasp the blade arms with both hands, and draw the leveling blade rapidly but smoothly over the test paint at a rate of about 2 ft (0.6 m) per s, keeping the long arm on the left parallel to the surface during the draw-down.

NOTE 1—Filling the syringe and cleaning the orifice are greatly facilitated by temporarily attaching to the orifice a 2-in. (50-mm) length of clear vinyl tubing with inside diameter of $\frac{1}{16}$ in. (3.2 mm) and outside diameter of $\frac{3}{16}$ in. (5 mm), which is removed prior to attaching the needle.

7.4 Allow the completed draw-down to dry overnight in a horizontal position, preferably at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity, or under other conditions

NOTE—Plastic sidearms are for guidance to assure rectilinearity of blade movements.

FIG. 1 (b) Photograph of the Leneta Leveling Test Draw-Down Blade

NOTE—Illustration of use of draw-down plate and catch papers. Note that sidearms are attached to the test blade and parallel straightedge guides on draw-down plate.

FIG. 1 (c) Application With the Leneta Leveling Test Draw-Down Blade

agreed upon between the buyer and the seller.

7.5 Place the dry draw-down, with its ridges perpendicular to the direction of the light, in front of the oblique light as shown in Fig. 2. Place two leveling standards similarly oriented on either side of the test draw-down and view the center portion of the draw-down and the standards from above (that is at a 90° angle to the surface), or as close to 90° as possible if in a lighted room (see Fig. 2). Then successively interchange standards until one is found having the same distinctness of lightness and shadow as the test draw-down. Leveling poorer than Standard No. 1 is designated as 0 or very poor leveling. Leveling better than Standard No. 9 is designated as 10 which represents perfect leveling or no perceptible ridges. Estimate and record the number of the leveling standard that corresponds to the leveling of the test draw-down.

8. Report

8.1 Report the leveling of the test paint on the scale of 0 to 10 as determined by comparison with the numbered leveling standards.

9. Precision

9.1 On the basis of a study in which seven operators, each using a different blade, rated twelve different paints, the between-laboratories standard deviation was found to be 1.5 units on the 0 to 10 scale. Based on this standard deviation, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

9.1.1 *Reproducibility*—Two results, each one by operators in different laboratories, should be considered suspect if they differ by more than 1.5 scale units.

FIG. 2 Oblique Light Source (The Level Luminator) (Side View)

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Effects of Gamma Radiation on Coatings for Use in Light-Water Nuclear Power Plants¹

This standard is issued under the fixed designation D 4082; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

1. Scope

1.1 This test method covers a standard procedure for evaluating the lifetime radiation tolerance of coatings to be used in nuclear power plants. This test method is applicable to Coating Service Levels I and II.

2. Referenced Documents

2.1 ASTM Standards:

D 659 Method of Evaluating Degree of Chalking of Exterior Paints²

D 660 Test Method for Evaluating Degree of Checking of Exterior Paints²

D 661 Test Method for Evaluating Degree of Cracking of Exterior Paints²

D 714 Test Method for Evaluating Degree of Blistering of Paints²

D 772 Test Method for Evaluating Degree of Flaking (Scaling) of Exterior Paints²

2.2 ANSI Standard:³

N512 Protecting Coatings (Paints) for Nuclear Industry

3. Significance and Use

3.1 Variations can occur in surface preparation, application, and curing of coating materials. They may affect the performance of a coating system exposed to radiation when considered in conjunction with applicable engineered safety requirements. This test method is designed to provide a uniform test to assess the suitability of coatings, used in nuclear power facilities, under continuous radiation exposure for the projected 40-year lifetime of the facilities, including radiation during a DBA. Specific plant radiation exposure may exceed or be less than the amount specified in 6.2 of this standard. The gamma dose used may exceed the actual anticipated plant gamma dose in order to account for expected beta exposure as well. Coatings in Level II areas (outside primary containment) are expected to be exposed to lower accumulated radiation doses.

4. Preparation of Test Samples

4.1 *Steel Panels*—Panels shall be prepared in accordance with ANSI N512.

¹ This test method is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generating Facilities and is the direct responsibility of Subcommittee D33.02 on Service and Material Parameters. Current edition approved Feb. 24, 1989. Published April 1989. Originally published as D 4082 - 83. Last previous edition D 4082 - 83.

² *Annual Book of ASTM Standards*, Vol 06.01.

³ Available from American National Standards Institute, 11 W. 42nd St., 13th Floor, New York, NY 10036.

4.2 *Concrete Blocks*—Blocks shall be prepared in accordance with ANSI N512.

5. Sampling

5.1 Prepare and test specimens at least in duplicate, or as otherwise specified by the owner.

6. Procedures

6.1 Irradiation Dose Rate:

6.1.1 Make the gamma energy field at the position of the test specimen 1×10^6 rads/h, or greater. It shall be uniform to within 10 % from one position of the specimen to another.

6.1.2 Make provisions so that all areas receive the same average exposure and dose, if the specimen is irradiated by a nonuniform source.

6.1.3 Determine the dose rate by a procedure acceptable to the coating manufacturer or as otherwise specified by the owner.

6.2 *Irradiation Accumulated Dose*—Make the total accumulated dose 1×10^9 rads, unless otherwise specified by the owner.

6.3 *Radiation Source*—Simulate conditions at a reactor site, closest to the preferred type of gamma source, such as, but not limited to, a fuel assembly.

6.4 Test Environment:

6.4.1 Specimens may be in air or in water during exposure to the gamma source, depending on the intended service as prescribed by the owner.

6.4.2 Do not exceed a temperature of 140°F (60°C) for the specimen during irradiation, or as otherwise acceptable to the coating manufacturer or as specified by the owner.

7. Examination and Reporting

7.1 Examine and evaluate specimens immediately after irradiation for the following coating defects:

7.1.1 *Chalking* (Method D 659)—Report extent.

7.1.2 *Checking* (Test Method D 660)—Report extent.

7.1.3 *Cracking* (Test Method D 661)—Report extent.

7.1.4 *Blistering* (Test Method D 714)—Report number and extent.

7.1.5 *Flaking* (Test Method D 772)—Report extent.

7.1.6 *Delamination*—Report extent.

7.1.7 *Peeling*—Report extent.

7.1.8 Report any observation of unusual appearance or deterioration.

8. Acceptance Criteria

8.1 *Checking, Cracking, Flaking, Delamination, Peeling, and Blistering*—None permitted.

Documentation

9.1 Document the following:

- 9.1.1 The procedures and conditions relating to the test specimen preparation.
- 9.1.2 The type of radiation source and the test procedure and environment.
- 9.1.3 Both the initial dose rate and the total accumulated dose.

10. Testing Laboratory

- 10.1 Testing shall be conducted by an independent laboratory that shall not be affiliated in any manner with the coatings manufacturer unless otherwise specified by the owner.

owner.

10.2 The testing laboratory shall be responsible for the documentation and certification of all test results.

10.3 The testing laboratory shall be responsible for meeting the quality assurance requirements of the owner.

11. Precision and Accuracy

11.1 The precision and accuracy of this test method is reflected in the precision and certified accuracy of the test instruments used.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Photographic Documentation of Coating and Lining Failures and Defects¹

This standard is issued under the fixed designation D 4121; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers the requirements for photographs and photographic equipment to be used to document coating and lining failures or defects. Photographs may also be used to establish acceptance criteria.

1.2 The practice represents only one method to provide consistent, comparable photographs. The important factors to consider when using any type of photographic equipment are also described.

2. Significance and Use

2.1 The proper documentation, through photographic methods, in standard size and color is required for accurate comparison of a wide variety of coating and lining failures or defects. An integral part of the study of defects and failures is the ability to compare by a standardized reproducible method present and past appearances of defect characteristics and failure modes. The equipment should not be complicated or require any special skill to produce good definition and color.

3. Requirements for Photographs

3.1 Requirements are as follows:

3.1.1 Color slides in 2 by 2-in. (50 by 50-mm) cardboard mounts, suitable for projection in all standard 2 by 2-in. slide projectors,

3.1.2 Prints in a minimum 3 by 3-in. (76 by 76-mm) size. Unless a larger scale is needed, the standard 3½ by 3½-in. (89 by 89-mm) size should be used. Prints may be either color or black and white, although color usually provides the greatest information to those viewing the photographs, and

3.1.3 A scale of the area photographed.

4. Requirements for Standardized Photographic Equipment

4.1 The equipment should consist of the following:²

4.1.1 A 3 by 3-in. (76 by 76-mm) copy stand complete with compensating lense. The focal depth should be approximately ¾ in. (10 mm) above the subject plane to approximately ¼ in. (6 mm) below the subject plane.

4.1.2 An 8 by 8-in. (203 by 203-mm) copy stand complete with compensating lense. The focal depth should be approximately 1½ in. (38 mm) above the subject plane to approximately 1 in. (25 mm) below the subject plane.

4.1.3 A camera that will accept 12 or 20 exposures 126 size cartridge and have a lens system compatible with the copy stands in accordance with 4.1.1 and 4.1.2.

4.1.4 A flash cube or an electronic flash unit designed specifically for use with the camera-stand assembly. The electronic flash should have approximately a 40-s recovery time. The electronic flash should be battery-operated and self contained.

4.2 Equipment other than that described above may be used for photographic documentation; but, there may be varying scales and lighting effects.

5. Precautions and Limits

5.1 The following factors are the principal variables affecting photograph clarity over which the user has control:

5.1.1 *Degree of Enlargement*—Enlarging a given negative beyond a certain point yields no additional clarity to the photographs; more clarity must come from either a larger or clearer negative. Enlargement should be great enough so sufficient detail can be seen without the use of a magnifying glass.

5.1.2 *Negative Size*—The larger the negative, the more detail and clarity it can record. It is suggested that a minimum negative size of 26 by 26 mm be used. Negative sizes much larger than this might be needed rarely, if ever.

5.1.3 *Film Speed*—"Faster" films have progressively less resolution. In general, 35-mm ASA 200 film gives poor resolution if enlarged much beyond 4 by 5 in. when printing.

5.1.4 *Lighting*—Insufficient lighting gives poor resolution. Lighting of the wrong color such as incandescent bulbs using daylight film, distorts colors. Bright lights or flash perpendicular to a glossy or shiny surface causes glare. Also, perpendicular lighting may fail to show surface irregularities. Lighting at too oblique an angle may exaggerate the irregularities.

5.1.5 *Camera Stability*—A rigid support such as a copy stand or tripod will minimize camera movement.

5.1.6 *Camera Optics and Quality*—Professional quality cameras and equipment may be impractical due to cost, difficulty to operate, delicacy of equipment, or the need for an immediate print. Acceptable photographs can be obtained with some of the simpler, good-quality cameras.

6. Documentation

6.1 Each photograph shall be identified with the following information:

6.1.1 Date and time of photograph,

6.1.2 Where the photograph was taken and what it is intended to show, and

6.1.3 Name of the photographer.

¹ This practice is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generation Facilities and is the direct responsibility of Subcommittee D33.03 on Quality Systems. Current edition approved March 26, 1982. Published May 1982.

² The Kodak Ektagraphic EF Visualmaker satisfies the requirements of this practice.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Measurement of Dry Film Thickness of Protective Coating Systems by Destructive Means¹

This standard is issued under the fixed designation D 4138; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the measurement of dry film thickness of coating films by microscopical observation of precision-cut angular grooves in the coating film. Field use of this method may require repair of the coating film.

1.2 The substrate may be any rigid material, for example, metal, plastic, concrete, glass, etc. The surface may be plane or moderately curved (pipes as small as 1 in. (25 mm) in diameter may be measured in the axial direction).

1.3 This test method is not recommended for excessively elastomeric or excessively brittle films, although cooling or heating the surface can often modify the coating in the desired direction.

1.4 The range of thickness measurement is 0 to 50 mils (0 to 1.3 mm).

1.5 Measurements may be made on field structures, on manufactured products, or on test panels.

1.6 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels²

D 1005 Test Methods for Measurement of Dry-Film Thickness of Organic Coatings Using Micrometers²

3. Significance and Use

3.1 Measurement of dry film thickness of organic coatings by physically cutting through the film and optically observing and measuring the thickness offers the advantage of direct measurement as compared with nondestructive means.

3.2 The use of this test method is not necessarily limited by the type of substrate material as are nondestructive magnetic-type means.

3.3 Constituent coats of an overall thickness of a coating system can be measured individually by this method.

4. Apparatus

4.1 The measurement shall be performed by first incising a scribe mark of *known configuration* through the coating(s) film to substrate and then viewing the scribe mark with an illuminated microscope with measuring reticle. Scribe cutter and illuminated microscope may be combined as a single instrument (see Fig. 1).³ Instrument calibration shall be performed by taking measurements on applied films of known thickness. (See Test Methods D 1005.)

4.2 The configuration of the tungsten carbide cutting tips shall be designed to provide a very smooth incision in the paint film at a precise angle to the surface (see Fig. 2). Separate tip designs (angles) shall provide cuts of known slopes such as 1 to 1, 1 to 2, and 1 to 10. These tips shall be nominally designated 1 $\times$, 2 $\times$, and 10 $\times$ to indicate the ratio of the lateral measurement (microscope) to film thickness (cut depth in film). Metal guide studs on the gage body shall, together with the cutting tip, form a firm base to assure that the tip aligns vertically with the painted surface for a precisely aligned incision.

4.3 The illuminated, 50-power microscope shall contain a reticle scaled from 0 to 100 divisions (see Fig. 3). The total viewing field of the microscope shall be approximately 125 mils (3.18 mm).

5. Test Specimens

5.1 If multiple coats of paint are to be measured, successive contiguous coats should be of contrasting colors to aid sharp discrimination of interfaces.

5.2 Generally, test specimens shall be prepared (as test panels) or chosen (as sites on a structure) to be representative of localized coating thickness and variability.

5.3 For test panels, if *measurement* repeatability is desired for a particular paint system, painstaking care shall be taken in panel preparation. Steel panels shall be ground plane or rolled to 8.5- μ in. (215-nm) inches flatness. Coating shall be uniformly applied in accordance with Test Methods D 823. Panels shall be placed in a horizontal position during drying. Uniform application thickness shall be verified by another measurement method such as Test Methods D 1005.

6. Procedure

6.1 Select a test panel or choose a site for thickness measurement.

¹ This test method is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generating Facilities.

Current edition approved Feb. 26, 1988. Published April 1988. Originally published as D 4138 - 82. Last previous edition D 4138 - 82.

² Annual Book of ASTM Standards, Vol 06.01.

³ A Tooke Gage, manufactured by Micrometrics, P.O. Box 13804, Atlanta, GA 30324, has been found suitable for this purpose.

FIG. 1 Tooke Inspector Gage—Model Mark II

6.2 Using an appropriate surface marker of contrasting color, mark a line on the surface about 2 in. long.

6.3 Select a cutting tip based on estimated film thickness as follows:

Tip	Thickness Range, mils (mm)	Conversion Factor
1×	20 to 50 (0.51 to 1.3)	1.0
2×	2 to 20 (0.05 to 0.51)	0.5
10×	0 to 3 (0 to 0.76)	0.1

If thickness is unknown, make a trial determination with 2×

6.4 To incise a groove, grasp the gage with the studs and cutting tip firmly forming a tripod on the painted surface. Place the gage at right angles to and about 2 in. (51 mm) perpendicular from a marked line.

6.5 Draw the gage across the paint film toward the body, with guide studs leading the cutting tip, and increase pressure on the cutting tip until it barely cuts into the substrate before it crosses the marked line.

6.6 Take readings at the intersection of the marked line and incision. Read by measuring on the reticle the distance from the substrate/coating demarcation up the longer machined slope of the incision to the upper cut edge of each respective coating or the coating system. Make sure that the machined slope of the incision is measured, not the other, steeper slope. (The machined upper edge usually leaves a less jagged cut than the other side.) If multiple coats are observed, individual thicknesses of each coat may be read. The actual coating thickness is derived by multiplying the reticle reading by the conversion factor for the respective cutting tip.

FIG. 2 Typical Incision Provided by Tungsten Carbide Cutting Tip of Tooke Inspector Gage

7. Report

7.1 Report the following information:

7.1.1 *Results of a Thickness Determination*—If more than one measurement is made and specific results for each location are not needed, report the minimum, the maximum, and the average thickness.

8. Precision

8.1 The replicability of individual observations of a uniform coating on a smooth substrate has been determined to be within $\pm 10\%$. (The percentage error increases as film thickness decreases.)

8.2 Field-applied coatings are characteristically subject to short-range thickness variability resulting from rough substrates and erratic application. The magnitude of this variability will be sensitively reflected by the range or standard deviation of thickness determinations.

FIG. 3 Typical View through Microscope of Tooke Inspector Gage Showing Reticle

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Conducting Accelerated Outdoor Exposure Tests of Coatings¹

This standard is issued under the fixed designation D 4141; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Footnote 3 was editorially changed in November 1987.

Scope

1.1 This practice covers three accelerated outdoor exposure procedures for evaluating the exterior durability of coatings applied to metal substrates.

1.2 The three procedures are as follows:

1.2.1 *Procedure A*—Black Box Exposure.

1.2.2 *Procedure B*—Heated Black Box Exposure.

1.2.3 *Procedure C*—Fresnel Reflector Rack Exposure.

1.3 The durability rankings of coatings provided by these three procedures may not agree when coatings differing widely in composition are compared.

1.4 The acceleration of degradation rates of coatings induced by the three procedures of exposure are discussed.

NOTE 1—Other exposure procedures may provide accelerated results on some types of products.

1.5 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

E 838 Practice for Performing Accelerated Outdoor Weathering Using Concentrated Natural Sunlight³

G 7 Practice for Atmospheric Environmental Exposure Testing of Nonmetallic Materials⁴

3. Summary of Practice

3.1 Several procedures that will provide accelerated rates for the degradation of coatings are described. The procedures appear in the following order:

3.1.1 *Procedure A*—Exposure on a black box panel rack facing the equator at 5° from horizontal.

3.1.2 *Procedure B*—Exposure on a heated black box panel rack facing the equator at 5° from horizontal.

3.1.3 *Procedure C*—Exposure on a Fresnel reflector panel rack that provides a high intensity of sunlight irradiation by following the sun and focusing the sunlight on the test panels by means of mirrors. The panels are wet periodically by deionized water spray.⁵

3.2 Each of these procedures requires that coated test panels be placed on racks of specified design and be exposed under specified conditions of weathering.

3.3 The selection of a procedure for producing accelerated degradation is dependent on the intended end use of the coatings, limitations on the time available for the exposure tests, and the degree of reliability required for predictions of durability performance.

4. Significance and Use

4.1 The procedures described in this practice are designed to provide greater degradation rates of coatings than those provided by fixed angle outdoor exposure racks that optimize the annual incident solar radiation. For many products, fixed-angle exposures accelerate the normal end-use rate.

4.2 Following are comments regarding the relative rates of degradation that can be expected for coatings exposed by the procedures described in this practice.

4.2.1 *Procedure A (Black Box)*—For many coatings, this procedure provides greater rates of degradation than those provided by 5°, equator-facing, open-rack exposures because the black box produces higher panel temperatures during irradiation by the sun and longer time of wetness. The black box panel temperatures are comparable to those encountered

² Annual Book of ASTM Standards, Vols 12.02.

⁴ Annual Book of ASTM Standards, Vol 14.02.

⁵ Fresnel reflector panel racks are located at DSET Laboratories, Inc., Box 1850, Black Canyon Stage 1, Phoenix, AZ 85029 and South Florida Testing Service Inc., Desert Site, 31818 N. 203rd Ave., Whittman, AZ 85361.

on the hoods, roofs, and deck lids of automobiles parked in direct sunlight.

4.2.2 *Procedure B (Heated Black Box)*—This procedure is most useful for exposures conducted in the late fall, winter, and early spring when it produces significantly higher panel temperatures than those produced by the 5°, equator facing, black box. Therefore, this procedure produces greater rates of degradation than those produced by Procedure A, particularly in the case of coatings with rates of degradation that are very temperature dependent.

NOTE 2—The relative rates of gloss loss and color change produced in some automotive and coil coatings by exposures in accordance with Procedures A and B are given in ASTM Special Technical Publication 781.⁶

4.2.3 *Procedure C (Fresnel Reflector Rack)*—This method provides greater rates of degradation of coatings than those provided by Procedure A or Procedure B. This high acceleration is produced by very high sunlight intensity and high panel temperature.

4.2.4 The degradation rates produced by any of the three procedures depend on the seasons of exposure, geographical location, and type of coating. The rates are higher in late spring, summer, and early fall when the intensity of sunlight irradiation is the greatest and when panel temperatures are higher. Also, the rates are highest for exposures in warm, humid environments.

4.2.5 Because outdoor weather conditions vary from season to season and year to year, these procedures are not reliable for establishing absolute performance ratings for coatings. The procedures should be used only for comparing the relative performance of coatings exposed at the same time at the same location.

5. Test Specimens

5.1 Each test specimen and control specimen shall consist of a uniform coating applied to the surface of a rigid panel. Suitable application procedures are given in Test Methods D 823.

5.2 Use surfaces of good planarity because warpage, waviness, or curvature may seriously affect the measurements of gloss and color and may produce a poor air seal on the black box rack.

5.3 Control specimens shall be prepared for inclusion in each exposure series to act as comparison standards and to provide a means for determining the severity of the exposure conditions encountered by the series. For best results, there should be at least two controls differing significantly in their durability performance.

5.4 Using Test Methods D 1186, measure the dry film thickness of the coatings at several different positions on the test and control specimens.

PROCEDURE A—BLACK BOX EXPOSURE

6. Apparatus

6.1 *Black Box Rack* of materials and construction as described in Practice G 7, or its equivalent.

⁶ Symposium on Performance of Organic Coatings, ASTM STP 781, ASTM, 1982.

7. Procedure

7.1 Position the rack so that the surfaces of the test specimens are 5° from the horizontal, facing the equator.

7.2 If change in gloss is to be measured, determine the specular gloss value for each unexposed specimen using a properly calibrated glossmeter in accordance with Test Method D 523.

7.3 If change in color is to be measured, determine the color coordinates for each unexposed specimen using Method D 2244. Unless otherwise agreed upon, use the CIE Lab Instrument Color Scale. The color-measuring instrument shall be stable and properly calibrated.

NOTE 3—As an alternative procedure, reserve unexposed duplicate specimen panels of each coating as reference for color difference measurements to be made on the exposed specimens. To minimize color drift, store these panels in a refrigerator.

7.4 Mount and fasten the specimens on the exposure rack. All empty spaces on the rack should be covered by dark gray or black panels so that the entire surface of the rack is covered.

NOTE 4—The predominant color of the specimen panels on the black box as well as the temperature of a standard panel should be noted. A panel on a black box will attain a lower temperature if all the other panels are white than if all the other samples are black.

7.5 Expose the test and control specimens for a specified period of time on the basis of one of the following:

7.5.1 Exposure for a specified number of days, months, or years with respect to an agreed upon starting date,

7.5.2 Exposure to a specified quantity of irradiation,

7.5.3 Exposure until a specified physical change has occurred in the test specimens, or

7.5.4 Exposure until a specified change has occurred in a control specimen exposed with the test specimens.

7.6 Remove the specimens from the exposure rack and gently wash a portion of the specimen surfaces to remove loose dirt. A suitable procedure consists of gentle rubbing with a sponge wet with water or a 0.05 % solution of a nonionic detergent. Water droplets should be gently removed from the specimen surfaces to prevent water spotting.

7.7 Unless otherwise agreed upon, perform the following on the washed portion of each washed specimen:

7.7.1 Measure the specular gloss by Test Method D 523.

7.7.2 Measure the color coordinates by Method D 2244, using the same color scales as used for measuring the unexposed specimen.

7.7.3 Checking rating by Test Method D 660.

7.7.4 Cracking rating by Test Method D 661.

7.7.5 Blistering rating by Test Method D 714.

7.8 Unless otherwise agreed upon, perform a chalk rating by Method D 659 on an unwashed area of the specimen.

PROCEDURE B—HEATED BLACK BOX EXPOSURE

8. Apparatus

8.1 *Black Box Rack* of materials and construction as described in Practice G 7, or its equivalent. The rack shall be equipped with a device that can heat the air in the interior of the box to the specified temperature.

8.2 *Safety Precautions*—The heated black box rack must be properly grounded to prevent possible electrical shock.

The heating elements in the heated black box must be installed so that, in normal use, a person cannot come in contact with a hot surface.

9. Procedure

9.1 Position the rack so that the surfaces of the test specimens are 5° from the horizontal, facing the equator.

9.2 If change in gloss is to be measured, determine the specular gloss value for each unexposed specimen using a properly calibrated gloss-meter in accordance with Test Method D 523.

9.3 If change in color is to be measured, use the procedure given in 7.3.

9.4 Mount and fasten the specimens on the exposure rack. All empty spaces on the rack shall be covered by dark gray or black panels so that the entire surface of the rack is covered.

9.5 Set the air temperature controller inside the heated black box to maintain an air temperature of approximately 140°F (60°C) or other agreed upon temperature.

9.6 The heater shall be turned on at approximately 9 a.m. each day and turned off at approximately 3 p.m. each day.

9.7 Expose the specimens for a specified period on the basis of one of the procedures outlined in 7.5.1 to 7.5.4.

9.8 Remove the specimens from the exposure rack and gently wash a portion of the specimen surfaces to remove loose dirt. Use the procedure recommended in 7.6.

9.9 Unless otherwise agreed upon, perform the following on the washed portion of each specimen:

9.9.1 Measure specular gloss by Test Method D 523.

9.9.2 Measure the color coordinates by Method D 2244, using the same color scales as used for measurements of the unexposed specimen.

9.9.3 Checking rating by Test Method D 660.

9.9.4 Cracking rating by Test Method D 661.

9.9.5 Blistering rating by Test Method D 714.

9.10 Unless otherwise agreed upon, perform chalk rating by Method D 659 on an unwashed portion of the specimen.

PROCEDURE C—FRESNEL REFLECTOR RACK EXPOSURE

10. Apparatus

10.1 *Fresnel Reflector Exposure Rack* that follows the sun, concentrates sunlight irradiation on the test specimens by means of mirrors, and sprays deionized water on the surfaces of the test specimens at specified intervals. The rack shall have provisions for cooling the test specimens while they are irradiated. Refer to Practice E 838 for detailed descriptions of the apparatus.

11. Procedure

11.1 If change in gloss is to be measured, determine the specular gloss value for each unexposed specimen. The gloss-meter used shall be properly calibrated.

11.2 If change in color is to be measured, use the procedure given in 7.3.

11.3 Mount and fasten the specimens on the exposure rack.

11.4 Set the water spray control to provide a deionized water spray on the specimens during the night at a frequency of 4 per hour, each spray period to be of 3-min duration. Refer to Procedure B of Practice E 838 for detailed operating procedures.

11.5 Expose the specimens for a specified period on the basis of one of the procedures outlined in 7.5.1 to 7.5.4.

11.6 Remove the specimens from the exposure rack and gently wash a portion of the specimen surfaces to remove loose dirt. Use the procedure recommended in 7.6.

11.7 Unless otherwise agreed upon, perform the following on the washed portion of each specimen:

11.7.1 Measure specular gloss by Test Method D 523.

11.7.2 Measure the color coordinates by Method D 2244, using the same color scales as used for measurements of the unexposed specimen.

11.7.3 Checking rating by Test Method D 660.

11.7.4 Cracking rating by Test Method D 661.

11.7.5 Blistering rating by Test Method D 714.

11.8 Unless otherwise agreed upon, perform a chalk rating by Method D 659 on an unwashed portion of the specimen.

12. Evaluation of Results

12.1 Express the change in gloss of each specimen either in terms of units of gloss loss or in percent gloss loss relative to the initial gloss value.

12.2 Express the change in color of each specimen in terms of total color difference, ΔE , using one of the procedures given in Method D 2244.

12.3 Express the amounts of chalking, checking and cracking on a scale of 10 to 0 as outlined in Method D 659, Test Method D 660 and Test Method D 661, respectively.

13. Report

13.1 Report the following information:

13.1.1 The method of exposure used and its geographical location.

13.1.2 The duration of the exposure and the date of the beginning of the test.

13.1.3 The heated black box air temperature used (for Procedure B).

13.1.4 The type of control specimens used and the severity of their degradation.

13.1.5 The evaluation measurements performed on each of the exposed specimens:

13.1.5.1 Units of gloss loss or percent gloss loss.

13.1.5.2 Units of ΔE color change. Denote the color space and color scales used.

13.1.5.3 Ratings for chalking, checking, cracking, and blistering.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. Standard Method for Estimating Package Stability of Coatings for Ultraviolet Curing¹

This standard is issued under the fixed designation D 4144; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

1.1 This method covers procedures for testing the package stability of coatings intended to be cured by ultraviolet radiation. One procedure is given for clear coatings and another for opaque fillers.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Summary of Method

2.1 Specimens are placed in several containers, some of which are subjected to an elevated temperature while others are stored at room temperature. At specified intervals a specimen is checked for evidence of gelling. Clear materials are held in glass containers so they can be examined visually without opening to prevent contact with air which might inhibit polymerization. Opaque materials are checked by opening one can, probing the contents with a spatula to determine the extent of any polymerization, and then recording that specimen.

Significance and Use

3.1 Coatings intended to be cured by ultraviolet radiation, especially those involving free radical chemistry, tend to polymerize during storage. It is of interest to determine how well a formulation resists this effect. Many factors influence the storage stability of a composition. The procedures described here are intended to improve the precision of determining this property. Because the effects of resins, monomers, photoinitiators, synergists, stabilizers, or pigments can alter the relation between elevated and room temperature stabilities, any correlation of performance at different temperatures is possible only with a given formulation and, therefore, is useful only for quality control.

Apparatus

- 4.1 *Oven*, maintained at $60 \pm 2^\circ\text{C}$.
- 4.2 *Glass Jars*, wide-mouth, 4-oz (115-mL), with 38-mm flanges.
- 4.3 *Cans*, lined, 4-oz (115-mL), friction top, with lids.

- 4.4 *Spheres*, glass or porcelain, 7 to 10-mm diameter.

5. Procedure

5.1 Clear Coatings:

5.1.1 Fill three 4-oz (115-mL) wide-mouth jars to $\frac{1}{4}$ in. (6 mm) from the top. Add a small glass or porcelain sphere to each container and put the lids on tightly.

5.1.1.1 The amount of head space in a jar or can is critical because the volume of air in contact with the sample has an effect on the rate of polymerization. The stability is also related to the ratio of the area of liquid-air interface to the volume of liquid.

5.1.2 Put two jars in an oven at $60 \pm 2^\circ\text{C}$. Retain the third at ambient temperature, $25 \pm 2^\circ\text{C}$, and in the dark.

5.1.3 Check an oven jar daily but do not open or invert. Rather, tip slightly, no more than 30° , to determine the extent of polymerization by noting the mobility of the sphere. When gelling is noticed, check the second jar to confirm.

5.1.4 Record the duration of the test in days. Indicate the last day the sphere is mobile followed by the first day it is immobile, and if the days are not consecutive, why the interval occurred.

5.1.5 Check the jar stored at room temperature every week but do not open or invert. Tip slightly, no more than 30° , to determine if the sphere is immobile.

5.1.6 Record the number of weeks not gelled followed by the first week the sphere is immobile.

5.2 Pigmented (Opaque) Coatings:

5.2.1 Fill twelve 4-oz (115-mL) lined cans to $\frac{1}{4}$ in. (6 mm) from the top and put the lids on tightly.

5.2.1.1 See 5.1.1.1.

5.2.2 Put six of the cans in an oven at $60 \pm 2^\circ\text{C}$. Retain six cans at ambient temperature, $25 \pm 2^\circ\text{C}$.

5.2.3 After one day remove one can from the oven, open, and probe to the bottom to determine if gelling is beginning. Discard the can after the test. Check one of the remaining cans on the 2nd, 4th, 8th, 16th, and 32nd days and discard after testing. By starting on a Monday all the testing will fall on normal working days.

5.2.4 Record the condition of the specimen each day tested, indicating the fractional amount of any gelled material present.

5.2.5 After one week check one of the cans held at ambient temperature by opening and probing to the bottom to determine if gelling is beginning. Discard the can after the test. Check one of the remaining cans after 2, 4, 8, 16, and 32 weeks.

¹ This method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D-1.2 on Factory-Coated Wood Products.
Current edition approved June 25, 1982. Published September 1982.

5.2.6 Record the condition of the specimen after each test and indicate the fractional amount of any gelled material present.

6. Report

6.1 Report whether the material was clear or pigmented and the length of time it was stable as indicated by the occurrence of gelation at both ambient and elevated temperatures. Report the age of the material when the test began, if it is known.

7. Precision

7.1 Clear Coatings:

7.1.1 At the elevated temperature, four of five cooperators reported a clear coating without inhibitor gelled on the 8th or 9th day. Four of five cooperators reported a coating with inhibitor gelled on the 32nd day; the fifth reported gelation on the 18th day.

7.1.2 At room temperature four of four cooperators reported no gelling at 32 weeks, with or without inhibitor.

7.2 Pigmented Coatings:

7.2.1 At the elevated temperature six of six cooperators reported a filler gelled at 8 days.

7.2.2 At room temperature four of four cooperators reported various degrees of gelation after 32 weeks.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Coating Flexibility of Prepainted Sheet¹

This standard is issued under the fixed designation D 4145; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Section 2 was deleted and editorial changes were made throughout in May 1990.

1. Scope

1.1 This test method describes a procedure for determining the flexibility and adhesion of organic coatings (paints) on metallic substrates that are deformed by bending when the sheet is fabricated into building panels or other products.

1.2 The metal substrate must be capable of passing this test without fracturing and with no excessive grain development.

1.3 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Terminology

2.1 *Description of Term Specific to This Standard:*

2.1.1 *T-bend*—a description of the severity of a bend in terms of the thickness (T) of the sheet to which the coating has been applied; *as used in this test method*, the T-bend rating is the minimum number of thicknesses of metal around which the coated sheet is bent (Fig. 1), or if bent around a die, the number of thicknesses of metal equivalent to the diameter of the die to achieve no fracture or removal of the coating.

3. Summary of Test Method

3.1 Prepainted panels are bent 180° around progressively more thicknesses of metal or larger diameter dies, the end point being when failures no longer occur. The panels are examined at low magnification (5 to 10 $\times$) after each bend for fracture of the coating (cracking) and, for loss of adhesion (pickoff), by means of a tape pull-off test.

4. Significance and Use

4.1 Organic coatings on precoated sheet are subjected to stresses when fabricated into products by roll forming, brake bending, or other deformation processes. These stresses can exceed the flexibility or adhesive strength of the coating, resulting in fracture of the coating, exposing the substrate, or loss of adhesion to the substrate. This test is a means of evaluating the ability of a coating system to withstand the stresses of fabrication.

4.2 The bend direction, whether the axis of bend is across or along the rolling diameter of the metal, and the temperature of the specimen when it is bent affect the results of this test and should be agreed upon between the supplier and the user.

5. Apparatus

5.1 A means of holding one end of the specimen rigidly while making the bend is needed. A bench vise with smooth jaws or with smooth inserts, preferably of a soft metal to avoid damage to the coating, has been found to be satisfactory.

5.2 If the metal is not bent around itself as in Fig. 1, a series of bending dies with smoothly rounded ends may be used as guides around which the specimen is bent (Fig. 2).

5.3 *Magnifier*, capable of 5 to 10 $\times$ magnification for examining the specimen for coating fracture and pickoff after testing. A stereomicroscope has been found useful for this purpose.

6. Procedure

6.1 Bending the Coated Specimen Around Itself.

6.1.1 The coated specimen shall be at least 2 in. (50 mm) across the bend direction, by a length sufficient to make the required number of bends. A 2 by 6-in. (50 by 150-mm) size is convenient. The specimen shall be at $\pm 2^\circ\text{F}$ of the temperature agreed on.

NOTE—A triangle-shaped specimen (Fig. 3) has been found convenient for making T-bend tests. This shape leaves a portion of each bend exposed for later examination and for a permanent record.

6.1.2 Secure about 0.5 to 0.75 in. (13 to 20 mm) of one end of the specimen in a vise or holding jig as shown in Fig. 1. Bend the free end of the specimen 90° in a smooth and uniform manner so that the coating is on the outside of the specimen after it is bent.

6.1.3 Continue to bend the specimen until the bent end can be inserted in the jaws of the vise. Tighten the vise to complete the 180° bend, which is called an OT bend. Take care to tighten the vise sufficiently so that the apex of the bend is as flat as can be reasonably achieved.

6.1.4 Examine the bend using a hand lens or low-power microscope for cracks in the coating.

6.1.5 Apply pressure-sensitive tape² along the bend. Rub the tape flat; then, holding the specimen firmly, remove the

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.53 on Factory-Precoated Strip Metal.

Current edition approved March 25, 1983. Published July 1983.

² Scotch Brand #610 tape manufactured by 3M Co., St. Paul, MN or equivalent, or as agreed upon between the supplier and the user.

NOTE—The above bends are expanded for clarity. They are actually flat against themselves in the test.

FIG. 1 T-Bend Test in Which the Coated Specimen is Bent Around Itself

tape with a rapid movement at an angle of 180° to the bend surface. Examine the tape for coating removed from the surface of the specimen (that is, pickoff). In the case of a coated steel specimen (for example, galvanized steel), examine the tape to determine whether pickoff is between the organic coating and the metallic surface or between the metallic coating and the base steel.

6.1.6 Secure the bent end of the specimen in the vise and bend the free end 90° . Continue to bend the free end around the first (OT) bend to complete a 180° bend, and tighten in the vise as before. This makes a 1T bend (Fig. 1). Examine under magnification and by tapping for cracking and pickoff, as with the OT bend.

6.1.7 Repeat this procedure, making a 2T, 3T, etc., bends until no cracking or pickoff occurs.

6.2 Bending the Coated Specimen Around a Die:

6.2.1 The coated specimen shall be at least 2 in. (50 mm) across the bend direction.

FIG. 2 T-Bend Test Using a Die Around Which the Specimen is Bent

NOTE—The above bends are expanded for clarity. They are actually flat against themselves in the test.

FIG. 3 Triangular Specimen for T-Bend Test

6.2.2 Secure the specimen and bending die in a vise or holding jig (Fig. 2). Bend the specimen 180° around the die in a smooth and uniform manner.

6.2.3 Examine the bend for cracking as in 6.1.4 and for loss of adhesion as in 6.1.5.

6.2.4 Express the T-bend to no cracking or no pickoff as the number of thickness around which the metal is being bent equal to the thickness of the die.

7. Report

7.1 Report the following information:

7.1.1 Identification of the material, such as coil number and location within the coil if the sample was coated on a coil line.

7.1.2 The coating system, coating thickness, and application and cure conditions.

7.1.3 The temperature at which the specimen is bent.

7.1.4 The bend direction—whether across or along the rolling direction of the sheet.

7.1.5 The minimum T-bend to no paint fracture, and

7.1.6 The minimum T-bend to no pickoff.

8. Precision³

8.1 On the basis of an interlaboratory study of this test method, in which two operators in each of five laboratories tested panels coated with paints of different flexibility and adhesion, the standard deviation was found to be:

	Standard Deviation	
	Aluminum	Galvanized Steel
T-bend to no fracture	0.55	1.33
T-bend to no pickoff	0.76	2.09

8.2 Based on these standard deviations, the following

³ Supporting data are available from ASTM Headquarters. Request RR:D01-1034.

Criteria should be used to judge the acceptability of results at the 95% confidence level:

8.2.1 *Repeatability*—Measurements obtained by two operators in a single laboratory should be considered suspect if they differ by more than:

	Aluminum	Galvanized Steel
T-bend to no fracture	0.4	1.8
T-bend to no pickoff	0.9	3.3

8.2.2 *Reproducibility*—Two measurements obtained in different laboratories, each the mean of measurements made by two operators within a laboratory, should be considered suspect if they differ by more than:

	Aluminum	Galvanized Steel
T-bend to no fracture	2.5	10.1
T-bend to no pickoff	1.8	10.6

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Formability of Zinc-Rich Primer/Chromate Complex Coatings on Steel¹

This standard is issued under the fixed designation D 4146; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

¹ NOTE—Editorial changes were made throughout in March 1989.

1. Scope

1.1 This test method covers the evaluation of the formability and adhesion of factory applied zinc-rich primer/chromate complex coatings on steel with thicknesses of 0.025 to 0.05 in. (0.65 to 1.25 mm) typical of those used in the coil coating industry.

1.2 The degree of oil removal prior to forming, the techniques of taping, and differences in adhesive strength of the tape can affect the adhesion rating.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For a specific hazard statement, see Section 7.*

2. Referenced Documents

2.1 ASTM Standards:

D 3330 Test Method for Peel Adhesion of Pressure-Sensitive Tape at 180-Deg Angle²

2.2 Other Document:

Pictorial Standards of Coating Defects³

3. Terminology

3.1 Description of Terms Specific to This Standard:

3.1.1 *dome height*—the height of the dome formed in the test.

3.1.2 *indenting ball diameter*—the diameter of the spherical-ended penetrator (ball) used to deform the specimen.

3.1.2.1 *Discussion*—The 1½-in. (41-mm) diameter ball was selected because it minimizes the variability in the localized peak strain. This size ball is commercially available and is as large as most testing machines can accommodate.

3.1.3 *percent strain*—the percent elongation of scribed gage lengths after forming. For the draw height of 0.512 in.

(13 mm), using a 1½-in. diameter ball, the localized peak strain is about 19 % (see Fig. 1).

4. Summary of Test Method

4.1 A coated specimen is biaxially stretched a given distance in an appropriate machine, adhesive tape is applied to the deformed area (dome) and then pulled off, and the amount of coating removed is compared with a photographic standard to determine the coating adhesion rating.

5. Significance and Use

5.1 The results of the combined deformation and tape test are related to the ability of the coated metal to withstand stamping in factory applications.

5.2 This test can be used to control the manufacturing process or in development work to improve the product.

5.3 It should be recognized that variability in the results persist due to the test conditions and forming machine variations.

FIG. 1 Survey of Strain Over Biaxially Stretched Dome

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.53 on Coil Coated Metal.

Current edition approved Oct. 28, 1983. Published January 1984.

² Annual Book of ASTM Standards, Vol 15.09.

³ Copies of the pictorial photographic reference standard are contained in the publication *Pictorial Standards of Coating Defects* and may be obtained from the Federation of Societies for Coatings Technology, 492 Norristown Rd., Blue Bell, PA 19422. The silver halide gelatin photographs are intended to be the only primary reference standards for this test method. The reproductions of them in this test method are for the purpose of illustration only.

Apparatus and Materials

6.1 **Forming Machine**, equipped with a spherical-ended penetrator to deform the specimen with appropriate dies, until the required height is obtained, and clamping arrangement to hold the specimen with a minimum pressure of 2000 lbf (8.9 kN).

6.1.1 The speed of forming shall be between 0.2 and 1.0 in./min (4.8 and 25 mm/min). The speed is usually slowed to measure more accurately the final height as shown on the dial indicator, but the final punch speed shall be controlled at 0.24 in. (6 mm)/min maximum.

6.2 **Indenting Ball**, with a diameter of 1½ in. (41 mm), a Rockwell hardness number not less than 61 on the Rockwell C scale (HRC), and a smooth surface finish not exceeding 60 µin. (4 µm). The indenting ball shall not deform during the test. The ball and holder shall move through the centerline of the top and bottom dies. The ball shall be clean and free of oil, grease, oxide buildup, rust, dirt, nicks, or damage.

6.3 **Ball Holder**, to hold the ball in its seat during the test. Most ball holders are removable so that other ball punch information tests can be done in the same machine.

6.4 **Upper and Lower Dies** with a hardness of 56 HRC or higher. The upper die shall have an approach radius of 0.0625 ± 0.002 in. (1.6 ± 0.05 mm). The diameter of the opening in the upper and lower die shall be 1.64 in. (42 mm). In most machines, these dies are removable.

6.5 **Dial Indicator**, riding on the surface of the forming sheet to monitor the movement of the penetrator (ball) and graduated so that the displacement, or ball height, can be measured at least to ± 0.0025 in. (60 µm) but preferably to ± 0.001 in. (25 µm).

6.6 **Adhesive Tape**, 1 in. (25 mm) wide, transparent, high-tack, pressure-sensitive tape⁴ with an adhesive strength of steel of 45 oz/in. (50 g/mm) of width when tested in accordance with Test Method D 3330, and a tensile strength of 28 lb/in. (500 g/mm) of width.

6.7 **Photographic Standard**⁵—Steps in rating from 10 (good, no removal) to 0 (poor, complete removal) to rate the adhesion of the coating after forming and tape removal by comparison with the adhesive-backed tape.

Hazards

7.1 There are possible hazards to personnel when performing tests on any hydraulic equipment. Stand free when machine is operating.

Sampling and Test Specimens

8.1 **Sampling**—The coated steel coil is cut, usually at the head or tail of the coil, into a sheet sample, which can be easily handled.

8.2 **Specimen Size**—The specimens may be square or rectangular but not narrower than 3.5 in. (90 mm) in either

Key	Dimensions	
	Inch-Pound	Metric
1 Test specimen		
2 Spherical-ended penetrator (ball)	1½ in.	41 mm
3 Ball holder		
4 Clamp force (minimum)	2000 lbf	8.9 kN
5 Upper die; bore diameter	1.64 in.	42 mm
6 Lower die; bore diameter	1.64 in.	42 mm
7 Dome height	0.512 in.	13 mm
8 Upper die corner radius	0.0625 in.	1.6 mm

FIG. 2 Tooling for Forming Test

dimension. Strips of full width of the coil can be tested if precautions are taken not to nick or damage the adjacent dome in the machine.

8.3 **Specimen Thickness**—Thicknesses should be 0.025 to 0.05 in. (0.64 to 1.25 mm). With thicknesses less than 0.025 in., fracture of the steel may occur, in which case the dome height can be reduced if agreed upon between the supplier and the user of the sheet product. When thicknesses greater than 0.05 in. are being tested, die modifications may be needed, but such modifications require agreement between the supplier and the user.

8.4 Test specimens shall be free of oil, grease, lubricants, rust, and burrs that may affect the holding pressures or dome height.

8.4.1 Typically a light spindle oil is applied to reduce corrosion on the uncoated side of the coil.

8.4.2 Remove oil, grease, and lubricants by one of two methods, as agreed upon between the supplier and the user. Either heat the specimens to 300°F (150°C) for 30 min or wash them in a cleaning solution⁶, rinse with tap water, and dry. As the solution can become contaminated with oil, do not wash more than 50 panels per gallon of solution.

9. Procedure

9.1 Condition the specimens for at least 24 h at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity before conducting the test, unless otherwise agreed.

⁴ Scotch Brand Transparent Tape No. 610, available from 3M Co., Commercial Tape Division, 3M Center, St. Paul, MN 55101, has been found satisfactory for this purpose. Equivalent material may be used.

⁵ The photographic reference standards that are part of this test method and are provided in the *Pictorial Standards of Coating Defects Handbook*³ are representative of the adhesion ratings. The photograph shown in Fig. 3 is for illustration purposes only and should not be used for evaluation.

⁶ This is one cleaning solution that is used. Add 10 g of Car Wash Concentrate, a product of Borden Inc., Chemical Div., 180T E. Broad St., Columbus, OH 43215 (product formerly called DuPont No. 7 Car Wash), per gallon (2.6 g/L) of water at a temperature of 100°F (40°C).

9.2 Place the specimen in the machine so that the coating to be tested will be on the convex side of the dome away from the punch.

9.3 With the ball touching the uncoated side of the specimen and the dial gage indicating zero penetration at the start of the test, indent the specimen with the ball to a distance of 0.512 in. (13 mm), ensuring that the hold-down pressure does not decrease during forming of the dome and that there is no evidence of slippage of the specimen under the hold-down dies during the test. The speed of forming the domes is done in accordance with 6.1.1.

9.4 Return the ball to the original position, remove the specimen from the machine, and lay it on a flat surface.

9.5 Apply the tape over the peak of the dome, press firmly, and then pull the tape from the dome at a fast, steady rate. The 1-in. (25-mm) wide tape will not fully cover the dome and will wrinkle at the edges.

9.6 Place the tape on a piece of white paper, compare the amount of coating on the tape with the photographic standard, and estimate coating adhesion to the nearest whole number. In Fig. 3, areas of darkness are coating removal so that a tape rating of No. 10 is perfect adhesion and No. 0 is complete removal of the coating. Wrinkles in the tape can be seen in the photographic standards as light areas.

9.7 Typically, a full-width specimen is cut from each coated coil and tested at three areas along the strip. Usually, domes are made at both edges and the center of the coated

full width strip.

10. Report

10.1 Report the following information:

10.1.1 Identification of the material such as coil number and location of the specimen within the coil,

10.1.2 Specimen thickness,

10.1.3 Number of tests or domes evaluated, and

10.1.4 Adhesion rating including mean, range, or standard deviation, if applicable.

11. Precision

11.1 On the basis of an interlaboratory study of this test method, in which one operator in each of three laboratories tested five separate panels cut from the same coated steel, the within-laboratory standard deviation was 0.61 units with 12 df and the between-laboratory standard deviation was 0.35 with 2 df. Based on these standard deviations, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

11.1.1 *Repeatability*—Two results obtained by the same operator should be considered suspect if they differ by more than 2 rating numbers.

11.1.2 *Reproducibility*—Two results, each the mean of two determinations, obtained by operators in different laboratories should be considered suspect if they differ by more than 2.9 rating numbers.

FIG. 3 Photographic Standard Adhesion Rating on Tape After Deformation

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. Standard Practice for Applying Coil Coatings Using The Wire-Wound Drawdown Bar¹

This standard is issued under the fixed designation D 4147; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers a procedure for applying a coating film of uniform thickness on a flat panel using the wire-wound drawdown bar.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Summary of Practice

2.1 A flat panel is secured on a firm horizontal surface. An ample amount of coating is poured across one end of the panel and the drawdown bar placed behind the coating. The bar is then drawn uniformly along the length of the panel toward the operator to apply a uniform film. The dry film thickness obtained is dependent on the combination of the bar used, the volume solids of the coating, and the speed of the drawdown motion.

3. Significance and Use

3.1 This practice is useful in the laboratory to simulate roll-coated films.

4. Apparatus

4.1 *Wire-Wound Drawdown Bars*²—A set of calibrated stainless steel wire-wound drawdown bars at least 1/2 in. (13 mm) in diameter to prevent bowing during application. These bars are calibrated such that the diameter of the wire wound on the bar controls thickness of the wet film applied. The choice of specific drawdown bar is dependent on the dry film thickness required and the volume solids of the coating under test.

4.2 Devices for Securing Panels:

4.2.1 *Magnetic Chuck*³ for securing steel panels to eliminate bowing.

4.2.2 *Vacuum Plate*⁴ for securing very lightweight nonmagnetic panels.

4.2.3 *Tape* for securing the top of thin-gage panels.

5. Safety Precautions

5.1 The flash points of most solvents used in coatings and related products are low enough that adequate ventilation is needed to avoid exceeding 25 % of the lower explosive limits of the solvent when preparing and baking the panels. As these solvents could be toxic, care should be taken to avoid inhalation of the vapors and unnecessary contact of the solvents with the skin.

6. Procedure

6.1 Deburr panels so edges are smooth. Secure a flat panel to be coated on a firm, uniform, level surface. To provide sufficient testing surface pour an ample amount of coating across the end of the panel. Place the drawdown bar behind the coating and pull into the coating. Rotate the drawdown bar 30 to 60° in the coating to ensure complete wetting of the coating in the threads of the bar. Apply moderate pressure equally to both ends of the drawdown bar and hold it firmly without allowing rotation. Using only one pass, draw the bar along the length of and off the panel at a uniform speed so that a continuous film is produced. The drawdown speed is dependent on the rheology and type of the coating being used. Remove the coated panel and bake, force dry, or air dry the coating in accordance with its type so its dry film thickness can be measured. A heavier film thickness is obtained along the edges of the panel and possibly at the top of the panel where the coating was poured. For a two-coat system, the side edges must be trimmed to eliminate the heavier areas on the first coat before applying the second coat.

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.53 on Factory-Precoated Strip Metal.

Current edition approved June 25, 1982. Published September 1982.

² Wire-wound drawdown bars may be obtained from R.D. Specialties, P.O. Box 206, Webster, N.Y. 14580, Paul N. Gardner Co., Inc., 218 Commercial Blvd., Lauderdale-by-the-Sea, Fla. 33308, or the Leneta Co., P.O. Box 86, Ho-Ho-Kus, N.J. 07423, or equivalent may be used.

³ Magnetic chucks may be obtained from Brown & Sharpe Manufacturing Co., Precision Park, North Kingstown, R.I. 02852, or equivalent may be used.

⁴ Vacuum plate may be obtained from Paul N. Gardner Co., Inc., 218 Commercial Blvd., Lauderdale-by-the-Sea, Fla. 33308, or equivalent may be used.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

Standard Test Method for Sustained Burning of Liquid Mixtures by the Setaflash Apparatus (Open Cup)¹

This standard is issued under the fixed designation D 4206; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

INTRODUCTION

This test method may be used in conjunction with a flash point determination. If the flash point of a mixture of flammable and nonflammable liquids or liquids of widely different flash points is below the upper limit of a flammability classification (for example, 100°F specified by the U.S. Department of Transportation), this test may be conducted to determine the sustained burning characteristics of the mixture.

This test method is a modification of the test for combustibility now incorporated as Schedule 2 of the "Highly Flammable Liquids and Liquified Petroleum Gases Regulation, 1972" of the United Kingdom under The Factories Act, 1961, which is also issued as British Standard BS-3900, Part A-11, Small Scale Test for Combustibility. This sustained burning test was studied and proposed by the ASTM Coordinating Committee for Flash Point and Related Properties. The major purpose of this test is similar to that of the British test—to provide a method for determining the sustained burning characteristics by directly observing this property rather than by deducing them from the flash point.

Scope

1.1 This test method² describes a procedure for determining the sustained burning characteristics of mixtures of flammable and nonflammable liquids and also mixtures containing liquids with widely different flash points.

1.2 This standard should be used to measure and describe the properties of materials, products, or assemblies in response to heat and flame under controlled laboratory conditions and should not be used to describe or appraise the fire hazard or fire risk of materials, products, or assemblies under actual fire conditions. However, results of this test may be used as elements of a fire risk assessment which takes into account all of the factors which are pertinent to an assessment of the fire hazard of a particular end use.

1.3 This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

³ Available from British Standards Institute, 2 Park St., London, England W1A 2BS.

BS-3900, Part A-11, Small Scale Test for Combustibility

3. Summary of Test Method

3.1 A block of aluminum alloy, or other nonrusting metal of suitable heat conductivity, with a concave depression (called the well) is heated to the required temperature of 120°F (49°C). A standard source of flame, capable of being swung over the center of the well and at a given distance from it, is attached to the metal block.

3.2 Two millilitres of the product under test are transferred to the well. After the product has reached the stated temperature, the flame is passed over the well, held there for a specified time, and then removed. The time of sustained burning is then noted.

4. Significance and Use

4.1 Mixtures of flammable liquids and nonflammable liquids, such as an alcohol and water mixture, are classified by the U. S. Government by the definition of flammable liquid based on a closed-cup flash point method. Thus, mixtures may be classed as flammable even though they do not sustain burning. This test method determines the ability of a liquid mixture to sustain burning and, when used with a closed-cup flash point method, indicates the flammability characteristics of the mixture.

5. Apparatus

5.1 *Setaflash Open-Cup Tester*,⁴ or an equivalent tester consisting of a 316 stainless steel block or other nonrusting

⁴ Suitable apparatus is available from Erdco Engineering Corp., 721 Custer Ave., Evanston, IL 60204 or Stanhope-Seta Limited, Park Close, Englefield Egham, Surrey TW20 0XD, England.

block of suitable heat conductivity fitted with a concave depression or well (Note). The metal block has a thermometer embedded in it. A small gas jet on a swivel is attached to the metal block. The exact dimensions of the metal block and its well, the gas jet and its positioning, and the embedded thermometer are shown in Fig. 1 and are specified in Annex A1.

NOTE—While the Setaflash Open Cup Tester is generally made of an aluminum alloy, continued use of it for sustained burning tests may produce a carbon deposit in the well which may be difficult to remove without damaging the aluminum well. The stainless steel well may be cleaned with crocus cloth.

5.1.1 *Gage*—A metal strip, capable of checking the height of the gas jet above the top of the well lip (2.2 ± 0.1 mm).

5.1.2 *Hot Plate*, fitted with a temperature-controlling device or other means of heating the metal block.

5.1.3 *Stopwatch*, or other suitable timing device.⁴

5.2 *Thermometer*,⁴ 32 to 230°F (−5 to 110°C), traceable to the National Institute of Standards and Technology.⁴

5.3 *Graduated Pipet or Hypodermic Syringe*,² capable of delivering 2 ± 0.1 mL.

6. Preparation of Sample

6.1 Obtain a representative sample of the product under test, mixing it thoroughly, especially if it has a tendency to layer, and keep in an airtight container.

6.2 Because of the possibility of loss of volatile constituents, the sample should receive only the minimum treatment

to assure uniformity. After removing the specimen, immediately close the sample container tightly to assure that no volatile flammable components escape from the container. (Otherwise a new sample may be necessary if further testing is required.)

6.3 Do not open containers unnecessarily. Do not make transfers unless the sample temperature is at 100°F (37.8°C) or below, except for samples that are too viscous to be handled at that temperature. In these cases, transfer the samples at the lowest possible temperature at which the sample can be accurately measured into the cup.

6.4 Discard samples in leaky containers.

6.5 Do not store samples in plastic (polyethylene, polypropylene, etc.) bottles, since volatile material may diffuse through the walls of the bottles.

7. Correction for Barometric Pressure

7.1 When the barometric pressure differs from 760 mm Hg (101.3 kPa), determine the temperature at which the test should be conducted by the following equations:

$$F = 120^\circ\text{F} - 0.06(760 - P)$$

$$C = 49^\circ\text{C} - 0.03(760 - P)$$

$$F = 120^\circ\text{F} - 0.42(101.3 - B)$$

$$C = 49^\circ\text{C} - 0.23(101.3 - B)$$

where:

F, C = temperatures to obtain the equivalent of 120°F (49°C) at standard pressure,

P = barometric pressure, mm Hg, and

B = barometric pressure, kPa.

8. Procedure

8.1 Set up the apparatus (see 5.1) in a draft-free area. Place the metal block on the hot plate fitted with a temperature-controlling device or heat the metal block by other suitable means so that the temperature is maintained within $\pm 2^\circ\text{F}$ ($\pm 1^\circ\text{C}$) of the temperature 120°F (49°C) corrected, if necessary, for the difference in pressure from 760 mm Hg (101.3 kPa).

8.2 After the cup is within $\pm 2^\circ\text{F}$ ($\pm 1^\circ\text{C}$) of the correct test temperature, withdraw from the sample container a 2-mL specimen using the graduated syringe or pipet. Transfer the specimen to the well of the tester and immediately start the timing device.

8.3 Light the test flame with the jet in the "off" position away from the well. Adjust the size of the flame so that it is spherical and approximately $\frac{3}{32}$ in. (4 mm) in diameter by matching it to the $\frac{3}{32}$ -in. diameter circle engraved on the surface of the tester.

8.4 After exactly 1 min (0 to +1 s) at which time the test portion will be deemed to have reached the test temperature as indicated by the thermometer embedded in the metal block, swing the test flame into a position exactly over the well. Hold it in this position for exactly 15 s and then return it to the "off" position.

8.5 Observe and time the duration of the burning of the specimen following the return of the flame to the "off" position.

8.6 Repeat the test with a fresh specimen and determine the mean time of burning.

ALL DIMENSIONS IN MILLIMETERS

FIG. 1 Setaflash Tester (Open Cup)

Interpretation of Results

10.1 A product is considered to sustain burning if the specimen (a) ignites when the flame is over the well and burning is sustained for more than 15 s after it is removed, or (b) flashes and burns when the test flame is in the "off" position prior to swinging it over the well.

Report

10.1 Report the following information:

- 10.1.1 Identification of the material under test,
- 10.1.2 Test temperature and barometric pressure in millimetres of mercury (kilopascals),
- 10.1.3 If the specimen burns less than 15 s, the actual time of burning, and
- 10.1.4 Statement of sustained burning characteristics.

Precision

11.1 The precision of this test method will be determined.

ANNEX

A1. Dimensions of Tester

(a) Metal Block Details	Dimensions, mm
Diameter of block	61.5-62.5
Height of block	35.0-38.0
Diameter of flange	94.5-95.5
Flange thickness	3.0 approx.
Height of well "lip" above flange	0.6-1.0
Diameter of well "lip"	41.0 approx.
Spherical radius of well	33.0-33.5
Depth of well	6.2-6.4
Distance from top of block to thermometer hole	16.0-17.0
Thermometer hole diameter	7.0 approx.
(b) Test Gas Jet Details	Dimensions, mm
Outside diameter of jet	3.0-4.0
Jet end tapered to	1.7-2.3
Bore of jet	0.6-0.8
Length of jet (from center of axis to tip)	36.00-36.25
Distance of axis from center of wall	38.00-38.25
Flame gage ring diameter	4.0 ± 0.1
Height of jet above top of well "lip" ^A	2.2 ± 0.1
"Swing" of jet (from stop to stop)	90 ± 1°

^A Adjust with suitable gage.

Standard Test Method for Viscosity by Dip-Type Viscosity Cups¹

This standard is issued under the fixed designation D 4212; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

1. Scope

1.1 This test method covers the determination of viscosity of paints, varnishes, lacquers, and related liquid materials by dip-type viscosity cups. This test method is recommended only for viscosity control work within one plant or laboratory and should not be used to check compliance with specifications.

1.2 Viscosity cups are designed for testing of Newtonian and near-Newtonian liquids. If the test material is non-Newtonian, that is, shear-thinning or thixotropic, another method, such as Test Methods D 2196, should be used.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 1200 Test Method for Viscosity by Ford Viscosity Cup²

D 2196 Test Methods for Rheological Properties of Non-Newtonian Materials by Rotational (Brookfield) Viscometer²

D 4287 Test Method for High Shear Viscosity Using the ICI Cone/Plate Viscometer²

E 1 Specification for ASTM Thermometers³

3. Terminology

3.1 Definitions:

3.1.1 *near-Newtonian liquid*—a liquid in which the variation of viscosity with shear rate is small and the effect on viscosity of mechanical disturbances such as stirring is negligible.

3.1.2 *Newtonian liquid*—a liquid in which the viscosity is independent of the shear stress or shear rate. If the ratio of shear stress to shear rate is not constant, the liquid is non-Newtonian.

4. Summary of Test Method

4.1 The cup is completely immersed in the material to be tested, withdrawn, and the time for the material to flow through a hole in the base of the cup is measured.

5. Significance and Use

5.1 Viscosity is a measure of the fluidity of a material. Viscosity data are useful in the determination of the ease of stirring, pumping, dip coating, or other flow-related properties of paints and related fluids.

5.2 This type of cup is used to measure viscosity because it is easy to use, robust, and may be used in tanks, reservoirs, and reactors.

5.3 There are other types of apparatus for measuring viscosity in the laboratory that provide better precision and bias, including the Ford viscosity cup (Test Method D 1200), and the Brookfield viscometer (Test Methods D 2196).

5.4 Certain higher shear rate devices such as cone/plate viscometers (Test Method D 4287) provide more information about sprayability, roll coatability, and other high-shear rate related properties of coatings.

6. Apparatus

6.1 *Zahn Viscosity Cup*⁴—No. 1 through No. 5 Zahn viscosity cups made of corrosion- and solvent-resistant materials. The capacity of the cup is nominally 44 mL, but may vary from 43 to 49 mL, depending on the manufacturer. A diagram of a Zahn cup is given in Fig. 1. The dimensions, including orifices, are only approximate because the cups are not made to one given specification. Each manufacturer produces a different cup and considerable variation between batches from a given manufacturer has been noted in the past. This is a major reason why Zahn cups should not be referenced in specifications between producer and user. (See Appendix X1 for additional information on Zahn Cups.)

6.1.1 Nominal Zahn cup orifice diameters are listed in Table X1.1. Cup No. 1 with the smallest orifice is used for determining the viscosity of thin-bodied materials. Cup No. 2 is for use with clears, lacquers, enamels, and press-side adjustment of flexographic inks; cups Nos. 3 and 4 are for use with more viscous paints and inks (No. 3 for manufacturing of flexographic inks); and cup No. 5 is used for silk screen inks.

6.2 *Shell Viscosity Cup*⁵—No. 1 through No. 6 Shell viscosity cups made of stainless steel with a capacity of 23 mL and a 1-in. (25-mm) long capillary in the bottom and

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and is the direct responsibility of Subcommittee D01.24 on Physical Properties of Liquid Paints and Paint Materials.

Current edition approved Dec. 30, 1988. Published April 1989. Originally published as D 4212 - 82. Last previous edition D 4212 - 82.

³ Annual Book of ASTM Standards, Vol 14.03.

⁴ Zahn cups may be obtained from Paul N. Gardner Co., P.O. Box 10688, Pompano Beach, FL 33061 and from BYK-Gardner, Inc., Gardner Laboratory, 2435 Linden Lane, Silver Spring, MD 20910. It should be pointed out that cups from these sources are not the same. Paul N. Gardner "Zahn signature" cup viscosities should not be compared to Pacific Scientific or G.E. cup viscosities or to Paul N. Gardner "EZ" cup viscosities.

⁵ Shell cups may be obtained from the Norcross Corp., 255 Newtonville Ave., Newton, MA 02158.

DIMENSIONS IN INCHES
(MILLIMETERS IN PARENTHESES)

NOTE—Dimensions are approximate only and may vary with the manufacturer and from batch to batch

FIG. 1 Zahn Cup

conforming to the dimensions shown in Fig. 2.

6.2.1 Nominal Shell cup orifice diameters are listed in Table X1.1. Cup Nos. 1 through 2½ are recommended for use with reduced rotogravure inks; No. 2 is for use with flexographic inks; Nos. 3 through 4 are used for industrial enamels, lacquers, flexographic, and gravure inks; Nos. 5 and 6 are used for heavy materials.

6.3 Calibration Thermometer—ASTM Saybolt Viscosity Thermometer 17F having a range of 66 to 80°F and subdivisions of 0.2°F, or 17C having a range of 19 to 27°C and subdivisions of 0.1°C, both conforming to the requirements of Specification E 1.

6.3.1 For general operations, any thermometer with 1°C subdivisions may be used.

6.4 Timer—Any timing device may be used provided that the readings can be taken with a discrimination of 0.1 s or better.

7. Test Materials

7.1 The material to be tested should be visibly homogeneous and free from any foreign material or air bubbles.

8. Temperature of Testing

8.1 Measurements should be made at 77°F (25°C) unless otherwise specified. Temperature drift during the test should be kept to a minimum. The viscosities of paints and related materials are highly dependent on temperature. Differences in temperature between measurements can give substantially different viscosities (up to 5 % per °F). For careful work, the temperature should be taken in the efflux stream, but for process control (such as monitoring a dip tank), this is not necessary.

8.2 A temperature correction curve may be constructed for each liquid by plotting viscosity (seconds) against temperature over the expected temperature range. With this curve, a viscosity determined at one measured temperature may be converted quickly to a viscosity at another temperature.

NOTE 1—When dip cups are used for original purposes, that is thinning or monitoring of materials in tanks, coaters, etc., then temperature is not important. This is because the key to good operation is to maintain the fluid within a certain range of dip cup-seconds

FIG. 2 Shell Cup

regardless of the temperature of the plant or lab.

9. Checking and Calibration of Cups

9.1 Cups should be checked in accordance with the procedure described in Appendix X2. The frequency of this depends upon the amount of use and care that the individual cup receives.

9.2 Cups may be calibrated with standard oils according to the procedure in Appendix X3. However, because of the great temperature dependence of the viscosity of standard oils and the lack of adequate temperature control with dip cups, calibration is a difficult and often inaccurate procedure that must be done with great care. Because of the wide variability in Zahn cups, checking rather than calibration is recommended.

10. Procedure

10.1 Choose the proper cup so that the time of efflux will be between 20 and 80 s. See Table 1 for viscosity ranges for the various cups.

10.2 Immerse the cup in the container, which may be a can or beaker, but is more likely to be a thinning or mixing

tank or even a resin reactor. Stir or agitate the fluid well to give uniform temperature and density. Allow the cup to remain in the fluid for 1 to 5 min to attain thermal equilibrium. (Because of their greater mass, Shell cups should remain in the fluid for the full 5 min.)

NOTE 2—Dip cups are not recommended for use with thixotropic (time dependent) materials but if used for them (such as gravure or flexographic inks), more vigorous agitation will be necessary to break up the structure before the measurement is made.

10.3 Lift the cup vertically out of the material in a quick, steady motion. As the top edge of the cup breaks the surface, start the timer. During the time of flow hold the cup vertically no more than 6 in. above the level of the liquid. Stop the timer at the first definite break in the stream at the base of the cup. The efflux time in seconds constitutes the viscosity. It is common to make only a single measurement, but for greater precision and accuracy the mean of two or more measurements should be taken.

11. Care of Cups

11.1 Following each determination, clean the cup with a suitable solvent and a soft brush. Use no metal tools in contact with the instrument as nicks or wear of the drilled orifice affect the accuracy of the cup.

12. Report

12.1 Report the efflux time to the nearest 0.2 s for Zahn or Shell cup No. ____, manufactured by ____, the temperature of the fluid (and where measured, and whether the result is from a single measurement or the mean of two or more measurements).

13. Precision and Bias

13.1 Dip cups are not precision instruments and should

TABLE 1 Approximate Viscosity Ranges, cST (Roughly Corresponding to 20 to 80 s Flow Time)

Cup Number	Zahn Cup	Shell Cup
1 ^A	5-60	2-20
2	20-250	10-50
2 1/2	...	20-80
3	100-800	30-120
3 1/2	...	40-170
4	200-1200	70-270
5	400-1800	125-520
6	...	320-1300

^A The lower limit for the Zahn No. 1 cup is 35 s rather than 20 s.

used for viscosity control at a given location only. However, if comparisons are made, cups from the same manufacturer *must* be used. The following criteria can be used for judging the acceptability of results at the 95 % confidence level:

13.1.1 *Zahn Cups*—Precision was determined on the basis of an interlaboratory test in which six laboratories used new Zahn cups (all from the same set from the same manufacturer) to test eight paints covering a broad range of viscosities. The within-laboratory coefficient of variation was 3.7 % and the between-laboratories coefficient of variation was 11.5 %. Based on these coefficients the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

13.1.1.1 *Repeatability*—Two results, each the mean of two measurements, obtained by the same operator should be considered suspect if they differ by more than 11 % of their mean value.

13.1.1.2 *Reproducibility*—Two results, each the mean of two measurements, obtained by operators in different laboratories should be considered suspect if they differ by more than 33 % of their mean value.

NOTE 3—Since the precision values were obtained under ideal conditions (a single set of cups), reproducibility in practice probably is poorer than that given (perhaps as bad as 50 %).

13.1.2 *Shell Cups*—Precision was determined on the basis of an interlaboratory test in which four laboratories tested seven paints covering a broad range of viscosities. The within-laboratory coefficient of variation was 3.2 % and the between-laboratories coefficient of variation was 6.3 %. Based on these coefficients the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

13.1.2.1 *Repeatability*—Two results, each the mean of two measurements, obtained by the same operator should be considered suspect if they differ by more than 9 % of their mean value.

13.1.2.2 *Reproducibility*—Two results, each the mean of two measurements, obtained by operators in different laboratories should be considered suspect if they differ by more than 18 % of their mean value.

14. Index Terms

14.1 This test method is indexed under the following terms: viscosity; dip cup(s); Zahn cup(s); Shell cup(s); flow cup(s).

APPENDICES

(Nonmandatory Information)

X1. ZAHN CUP DESIGN, MANUFACTURE, AND USE

X1.1 Zahn cups were designed (and made by General Electric) as simple flow property devices for use in dip tanks, flow coat reservoirs, etc. They never were meant to be viscometers or to be used as such. Zahn cup use usually involves thinning or maintaining a coating, adhesive, or ink at a certain consistency (so many Zahn-seconds) regardless of temperature. This is the beauty of dip cups. The operator knows that his or her tank, bath, or coater runs well over a certain range of Zahn-seconds whether the plant temperature is 50°F or 100°F. The operator does whatever is necessary to keep the fluid within the range. He or she does not care what the viscosity is at 25.0°C (77.0°F).

X1.2 Because the Zahn cup patents have long since run out, the cups can be made by anyone. Each manufacturer makes cups that are somewhat different from those made by others. Considerable batch-to-batch difference from any given manufacturer has been seen in the past. Cup variations are not a problem for control of a bath or tank as long as new cups are compared to old ones for the Zahn cup-seconds operating window and a new window is established if necessary. However, cup differences cause great difficulty if cups are used to set producer-user specifications. Comparisons are almost impossible under such conditions.

X2. DIP CUP CHECKING PROCEDURES

X2.1 Because Zahn cups vary with the manufacturer and batch, it is not possible to set up calibration equations that are applicable to all cups. Therefore, the only procedures that are recommended checking a cup against its original efflux time or comparing one cup against another. However, if a cup owner has an absolute compulsion to calibrate a Zahn cup, there are equations available (see X3). Shell cups may be checked by the same procedures as Zahn cups or may be calibrated.

X2.2 *Monitoring Cup Characteristics*—A useful checking technique is to measure the efflux time for a new cup with a given standard oil, then check the cup periodically with the same oil at the same exact temperature to see whether the efflux time has changed. If the time changes drastically (greater than 20 %), the cup should be replaced. If the change is small, the cup can be used as is or a correction can be made in subsequent efflux times of paints or other materials. The correction factor is equal to original oil efflux time divided by the current one. Recommended oils for such tests are given in Table X2.1. The viscosity of oils is very sensitive to temperature variations and, therefore, the temperature of the oil must be controlled closely during testing. It is recommended that the oil be held at the test temperature for at least 15 min prior to testing.

X2.3 *Comparing Cups*—It sometimes is necessary to compare one Zahn cup with another in order to settle a dispute, determine whether a new cup will give similar times to an old one, etc. The most usual technique is to dip both

TABLE X2.1 Viscosity Standards Recommended for Checking Cups

^A Information based on literature of cup manufacturers.

^B Certified kinematic viscosity standards (1-pt samples only) are available from the Cannon Instrument Co., P.O. Box 16, State College, PA 16801. Oils from other sources, having known kinematic viscosities, may also be used.

^C Actual viscosity is noted on the label of the standard.

cups into the same container of standard oil at the same time and pull them out together, timing both of them. The efflux times are compared and a correction factor can be calculated. Sometimes paint or another material is substituted for the oil.

X3. CALIBRATION OF DIP CUPS

X3.1 Select the appropriate standard oil for the cup to be checked (see Table X2.1).

X3.2 Bring the cup and the standard oil to a constant temperature as close as possible to 77.0°F (25.0°C). Determine the time of efflux to the nearest 0.2 s using the procedure detailed in Section 10. Record the temperature of the efflux stream. If it is not 77°F, correct the viscosity of the standard oil to the actual temperature.

X3.3 Convert the time of flow in seconds to kinematic viscosity as follows:

$$V = K(t - c)$$

where:

V = kinematic viscosity, cST

t = efflux time, s, and,

K, c = appropriate constants (from Table X3.1).

X3.3.1 These equations represent linear or relatively linear portions of the overall viscosity-time curves for the cups. The linear equations have been chosen because it is much more straightforward to make time corrections based on linear equations than on nonlinear ones. Zahn cup nonlinear equations that better fit viscosity curves for some

cups better may be found in the literature.^{6,7} No such equations for Shell cups have been published.

X3.4 Calculate the correction factor by dividing the true kinematic viscosity of the standard oil by the kinematic

⁶ Euverard, M., *ASTM Bulletin*, Vol 162, No. 67, October 1950.

⁷ Pierce, P. E., *Journal of Paint Technology*, Vol 42, No. 533, 1969, p. 383.

viscosity calculated from the efflux time. This factor may then be used to correct viscosity readings taken with the cup.

The product of the factor and an efflux time gives a corrected viscosity in Zahn or Shell seconds.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Wet Abrasion Resistance of Interior Paints¹

This standard is issued under the fixed designation D 4213; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers an accelerated procedure for determining the resistance of interior paints to erosion caused by scrubbing.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

- D 562 Test Method for Consistency of Paints Using the Stormer Viscometer²
- D 1193 Specification for Reagent Water³
- D 1475 Test Method for Density of Paint, Varnish, Lacquer, and Related Products²
- D 2369 Test Method for Volatile Content of Coatings²
- D 2486 Test Method for Scrub Resistance of Interior Latex Flat Wall Paints²
- D 2697 Test Method for Volume Nonvolatile Matter in Clear or Pigmented Coatings²
- D 2832 Guide for Determining Volatile and Nonvolatile Content of Paint and Related Coatings²
- D 3450 Test Method for Washability Properties of Interior Architectural Coatings²
- D 3980 Practice for Interlaboratory Testing of Paint and Related Materials²
- E 70 Test Method for pH of Aqueous Solutions with the Glass Electrode⁴

3. Summary of Test Method

3.1 The test paint is applied to a black plastic panel. After conditioning, the coated panel is placed over a glass plate in a washability machine and scrubbed with a fine pore cellulosic sponge and an abrasive medium. The weight of the film eroded is determined by weighing the panel before and after the test, and the volume loss per stated number of cycles is calculated.

4. Significance and Use

4.1 Interior paints often become soiled especially near doorways, windows, and in work and play areas. This test

method covers determination of the relative resistance of different interior paints to erosion when scrubbed.

4.2 Results obtained by this test method do not necessarily represent the scrub resistance of aged paint films, since scrub resistance may change with age.

4.3 Results obtained by this test method also do not necessarily relate to relative ease of soil removal.

5. Apparatus

5.1 Wet Abrasion Test Apparatus.⁵

5.1.1 Accessory Apparatus (Fig. 1).⁵

5.1.1.1 *Sponge Holder*,⁵ sponge and sheet lead weights (total weight 500 ± 10 g).

5.1.1.2 *Glass Plate*, measured to fit.

5.1.1.3 *Gasketed Frame and Clamps*.

5.2 *Film Caster*,⁷ having a 10 mil (250 μ m) clearance and 5.5-in. (140-mm) path width.

5.3 *Balance*, weighing to 1 mg.

5.4 *Oven*, adjusted to 120 to 130°F (50 to 55°C).

6. Reagents and Materials

6.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests unless otherwise specified. Unless otherwise indicated, it is intended that all reagents shall conform to the Specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁸ Other grades may be used provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

6.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water conforming to Type IV of Specification D 1193.

6.3 *Black Plastic Panels*.⁹

6.4 *Masking Tape*.

6.5 *Flannel Cloth*.

⁵ The Gardner Abrasion Tester Model AG 8100 and accessory apparatus, available from BYK-Gardner, Inc., Gardner Laboratory, 2435 Linden Lane, Silver Spring, MD 20910 have been found satisfactory for this purpose. Other straight line wash testers may be adapted to meet the requirements of this test method.

⁶ This holder is also used as a brush holder in Test Method D 2486. It should not be confused with the sponge holder employed in Test Method D 3450.

⁷ The Dow film caster, available from the Gardner Laboratory Div., has been found satisfactory for this purpose.

⁸ "Reagent Chemicals, American Chemical Society Specifications," Am. Chemical Soc., Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY, and the "United States Pharmacopeia."

⁹ Leneta P-121-10N dull black plastic panels, 6½ by 17 in. by 10 mils (165 by 432 by 0.25 mm) in size obtainable from the Leneta Co., P. O. Box 86, Ho-Ho-Kus, NJ 07423, are suitable for the purpose. An equivalent may be used.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.42 on Architectural Finishes.

Current edition approved Dec. 14, 1987. Published February 1988. Originally published as D 4213 - 83. Last previous edition D 4213 - 83.

FIG. 1 Accessory Apparatus for Scrub Test

6.6 Detergent.¹⁰

6.7 Sponge.¹¹ fine pore, uncompressed sponge conforming to U.S. Federal Specification L-S-626, Type II, Fine Pore, Uncompressed.

6.8 Scrub Medium.¹² (Note 1), consisting of the following:

Water, reagent, Type IV	49.4 ^a
Hydroxyethylcellulose ¹³	0.8
Ammonium hydroxide, 28 %	...
Detergent ¹⁰	2.0
Trisodium phosphate, anhydrous	2.0
Silica ¹⁴	45.0
Acetic acid, glacial	0.7 ^b
Preservative ¹⁵	0.1
	100.0

^a Vary to achieve a viscosity from 110 to 120 Krebs Units before use, as measured in accordance with Test Method D 562.

^b Vary to achieve a pH from 9.5 to 10.0 as measured in accordance with Test Method E 70.

¹⁰ Octyl phenoxy polyethoxyethanol containing approximately ten moles of ethylene oxide per mole has been found satisfactory. Triton X-100, obtainable from Rohm and Haas Co., Independence Square, Philadelphia, PA, is representative of this product. An equivalent may be used.

¹¹ Super-Cel Cellulose Sponge, Fine Pore #85, obtainable from American Sponge and Chamois Co., Inc., 47-100 34th St., Long Island City, NY 11101, has been found satisfactory for this purpose. An equivalent may be used.

¹² Laboratory standardized scrub medium is available from the Leneta Co. An equivalent may be used.

NOTE 1—When a referee test is made, prepare fresh medium or use standardized scrub medium from a previously unopened container that is no more than one year old.

6.8.1 Slowly add the hydroxyethylcellulose to the water while stirring mechanically. Stir until uniform and then slowly add 2 to 3 drops of 28 % ammonium hydroxide solution while mixing and continue mixing until the solution turns clear. In the order shown, add the other ingredients separately, stirring continuously. Be sure each item is uniformly dispersed before adding the next one. Add the silica slowly to ensure uniform dispersion. Finally, add the preservative and adjust the pH with glacial acetic acid.

7. Preparation of Apparatus

7.1 *Scrub Test Apparatus*—The scrub machine should be leveled before use and operated at 37 ± 1 cpm. Before each test check the tightness of the motor belt or chain drive and alignment of the cables in both horizontal and vertical planes. Adjust tautness of the cables with the accessory spring scale to approximately 5 lb.

7.2 Cut the sponge to fit the standard brush holder, $3\frac{3}{4}$ by $1\frac{1}{2}$ by $1\frac{1}{2}$ in. (95 by 38 by 40 mm). New sponges should be saturated with reagent water, wrung dry by hand and allowed to equilibrate in a constant temperature and humidity room for 24 h before being cut.

7.3 *Brush Holder*—Add sufficient weight to the holder in the form of sheet lead or other flat weights to total 500 ± 10 g including the sponge.

8. Procedure

8.1 Stir the material under test thoroughly and strain to remove all skins and particles. Clean the top of the glass plate (or preferably suction plate) and both sides of the black plastic panel to be sure they are free of specks. Place the black panel on the plate and tape one end to the plate. Smooth the panel along the plate by rubbing with flannel, creating static electricity to improve adhesion to the plate.

8.2 Drawdown the paint on the panel using the 10-mil (0.25-mm) side of the film caster, starting as close to the taped end of the panel as possible (should be less than $\frac{1}{2}$ in. (13 mm) from the taped end of the panel). The time of application should be fairly slow—3 to 4 s from end to end—to prevent formation of pinholes or holidays in the film. Air dry in a horizontal position for seven days in an open room, preferably kept at $73 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and 50 ± 5 % relative humidity.

8.3 After the specified drying time, cut off the top $\frac{3}{4}$ in. (20 mm) of the panel, preferably with a paper cutter to

¹³ Hydroxyethylcellulose having a molar substitution (MS) value of 1.8 to 2.5 and a viscosity of a 2 % solution in the range of 4400 to 6500 cPs. Cellosize QP-4400, obtainable from Union Carbide Co., Chemicals Div., 270 Park Ave., New York, NY 10017, has been found satisfactory for this purpose, as well as Natrosol 250 MR obtainable from Hercules Inc., 910 Market St., Wilmington, DE 19899.

¹⁴ This silica is an amorphous grade of 99+ % silicon dioxide giving a pH of 6.8 to 7.2 in reagent water. Average particle size is $2.95 \mu\text{m}$ with 92 % being less than $50 \mu\text{m}$ and surface area of $7600 \text{ cm}^2/\text{g}$. Silica No. 22 obtainable from Whittaker, Clark and Daniels, Inc., 100 Church St., New York, NY 10007, has been found satisfactory for this purpose. An equivalent may be used.

¹⁵ 1,3,5 triethyl hexahydro-sym-triazine (Vancide TH) obtainable from R. T. Vanderbilt Co., 30 Winfield St., Norwalk, CT 06855, has been found satisfactory. An equivalent may be used.

ensure a smooth straight edge. The film should now cover the panel uniformly along its entire length, exactly 16 1/4 in. (413 mm). The panel may now be cut in half, *length-wise*, so that duplicate tests can be run. Roll the test panels into the shape of a cylinder to fit the balance pan, fasten the ends together with a paper clip and weigh to 1 mg. Record this as Weight A. Remove the clip and carefully unroll the panel. Save the paper clip for later weighings. Avoid any damage to the film after weighing.

8.4 Clean the glass plate and set it in the pan of the scrub test apparatus. Place the test panel, with painted side up, over the glass plate so that the test area is level. Pre-wet the gasket of the frame (if frame is to be used), and wipe dry before use. Place the frame over the drawdown and clamp in place. Clamps should be tight enough to ensure close contact but not tight enough to cause warping of the panel.

8.5 Place the sponge in reagent water and allow to remain for 30 min. Remove, hand squeeze dry, and insert in the weighted holder. Stir the scrub medium and spread 10 g evenly over the face of the sponge. Place the sponge at the end of the panel and wet the path of the sponge on the panel with 5 mL of water.

8.6 Note counter reading on scrub test apparatus and start the test. Make sure the sponge travels only over the test panel and only over the coated portion of the panel, and that sponge and holder are level during run. If the sponge and carriage tend to tilt sidewise, twist the cable in the direction in which the holder is tilting to impart an opposing torque to the sponge and holder enabling them to ride upright.

8.6.1 **Caution**—Cables should not be twisted more than three or four times. Excessive twisting in the direction opposite to that used to form the cable can cause unraveling of cable strands.

8.7 After each 100 cycles examine the panel for erosion through to the substrate. If cut-through is evident, stop the test and record the number of cycles. Otherwise continue until 400 cycles, at which time add 10 g of stirred medium to the sponge again and 5 mL of water to the panel, and continue testing to a maximum of 1000 cycles. Add 10 g scrub medium and 5 mL deionized water at the end of every 400 cycles.

8.7.1 In instances where cut-through is observed, repeat the test using the other half of the test chart and stop at least 100 cycles short of the previously noted cut-through point. It is important not to erode the film to the point where the substrate shows through since this will cause an erroneous result.

8.8 Rinse off the panel with tap water making sure all scrub medium has been removed, brushing gently with a soft camel hair brush to facilitate removal of the scrub medium. Blot the panel (do not rub) with paper towels, allow to air dry for 30 min, and then place flat in the oven at 120 to 130°F (50 to 55°C) for 30 min. Remove and allow to equilibrate for 15 to 20 min preferably in a conditioned room, or if necessary at ambient conditions surrounding the balance. Roll the panel into a cylinder, clip the edges together with the paper clip used in the initial weighing, and weigh to 1 mg. Record this as Weight B. Then calculate the Erosion Rate C in accordance with 9.1.

8.9 Between runs, rinse the sponge thoroughly to remove as much detergent as possible, soak the sponge in reagent

water before the next test, and then proceed as in 8.5.

8.10 Make three drawdowns from each sample. Test two panels (four tests), then calculate the mean value of C and report this value unless any of the results differ by more than 25 % of the mean. If they do, test the third panel and include the two results in the mean unless one of the results is obviously discrepant, in which case it should be discarded.

NOTE 2—See Table 3 of Practice D 3980 for limits used in rejecting extreme values.

8.11 Determine the density (D) of the paint in g/mL, in accordance with Test Method D 1475.

8.12 Determine the percent nonvolatile by weight, (W), of the paint, in accordance with Test Method D 2369.

9. Calculation

9.1 Determine the total weight loss in milligrams for each panel by subtracting B from A. Divide the weight loss by the number of cycles and multiply by 100 to determine the erosion rate C expressed as milligrams lost per 100 cycles, thus:

$$C = \frac{(A - B) \times 100}{\text{number of cycles}}$$

9.2 Calculate V, the percent nonvolatile by volume of the paint as follows:

9.2.1 *Water-borne Paints*— $V = 100 - D(100 - W)$

9.2.2 *Solvent-borne Paints*— $V = 100 - 1.28D(100 - W)$

9.3 Calculate the erosion rate in terms of wet film volume, thus:

$$\frac{\text{microlitres}}{100 \text{ cycles}} = \frac{100 C}{WD}$$

NOTE 3—This value relates to the whole paint and is thus analogous, though inversely, to the cycles-to-failure values of Test Method D 2486.

9.4 Calculate the erosion rate in terms of dry film volume, thus:

$$\frac{\text{microlitres}}{100 \text{ cycles}} = \frac{CV}{WD}$$

NOTE 4—This value relates to the nonvolatile portion of the paint. The film volume in the equation is exclusive of interstitial air, whether due to vesiculated beads or ordinary porosity.

10. Report

10.1 Report the following information:

10.1.1 Erosion rate of the equivalent wet film in microlitres/100 cycles, as calculated in 9.3.

10.1.2 Erosion rate of the dry film in microlitres/100 cycles, as calculated in 9.4

10.1.3 Number of tests.

10.1.4 Number of cycles at which any erosion to the substrate initially occurred.

10.1.5 Any deviations from the standard procedure.

11. Precision

11.1 In an interlaboratory study of this test method in which operators in six laboratories tested three latex coatings covering a range of pigment volume concentrations, the within-laboratory coefficient of variation was found to be 5.6 % and the between-laboratories coefficient 9.4 %. Based

When these coefficients of variation the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

11.1.1 *Repeatability*—Two results, each the mean of two repeat tests, obtained by the same operator, should be considered suspect if they differ by more than 18 % of the mean.

11.1.2 *Reproducibility*—Two results, each the mean of two repeat tests, obtained by operators in different laborato-

ries, should be considered suspect if they differ by more than 30 % of the mean.

12. Indexing Terms

12.1 This test method is indexed under the following terms: abrasion (of paints/related coatings); interior paints/coatings; resistance—abrasion (of paints/related coatings); resistance—scrubbing; weight—weight loss.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Methods for Evaluating the Degree of Chalking of Exterior Paint Films¹

This standard is issued under the fixed designation D 4214; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

This standard has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

1. Scope

1.1 These test methods cover the evaluation of the degree of chalking on white or lightly tinted exterior paint films. It describes the procedures recommended for transferring the chalk to a fabric or fingertip, which is then compared to photographic reference standards, or in the case of adhesive tapes, compared to a reflectance table or photographic reference standards, to determine the degree of chalking.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

D 662 Test Method for Evaluating Degree of Erosion of Exterior Paints²

D 1150 Single and Multi-Panel Forms for Recording Results of Exposure Tests of Paints^{2,3}

E 97 Test Method for Directional Reflectance Factor, 45-Deg 0-Deg, of Opaque Specimens by Broad-Band Filter Reflectometry²

2.2 Other Document:

Pictorial Standards of Coating Defects⁴

3. Terminology

3.1 Definition:

3.1.1 *chalking*—the formation on a pigmented coating of a friable powder evolved from the film itself at or just beneath the surface.

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.27 on Accelerated Testing.

Current edition approved March 31, 1989. Published June 1989. Originally published as D 4214 - 82. Last previous edition D 4214 - 82 (1987)¹.

² *Annual Book of ASTM Standards*, Vol 06.01.

³ These record sheets may be obtained from ASTM, 1916 Race St., Philadelphia, PA 19103 (request Adjunct Nos. 12-411500-11 and 12-411500-21) and from the Federation of Societies for Coatings Technology, 492 Norristown Rd., Blue Bell, PA 19422.

⁴ Copies of the pictorial photographic reference standards applicable to Test Method D 659 are contained in the publication *Pictorial Standards of Coatings Defects* and may be obtained from the Federation of Societies for Coatings Technology, 492 Norristown Rd., Blue Bell, PA 19422.

4. Significance and Use

4.1 The procedures provide a broader range of techniques and photographic references to evaluate chalking of exterior paints than that in Method D 659 and are thus an extension of that method.

5. Type of Chalking

5.1 Only one type of chalking is recognized, as defined in Section 3.

6. Use of Photographic Reference Standards

6.1 The photographic reference standards that are part of this test method are representative of the degrees of chalking on a paint film. The photographs shown in Figs. 1 and 2 are for illustration purposes only and should not be used for evaluation.

6.2 The use of photographic reference standards illustrated in Figs. 1, 2, 3, and 4 requires the following precautions:

6.2.1 The degree of chalking will vary over any given area. Therefore, an average portion of the coating should be evaluated. On large surfaces, it is recommended that the rating be made at several locations and the mean and range reported.

6.2.2 It is difficult to make readings on a windy day and making readings at such time should be avoided. It should also be noted that rain, snow, or moisture in any form will remove chalk so that readings should be made after a period of clear weather and when the surface is dry.

6.2.3 Chalking and erosion (Note 1) are closely related and erosion is a result of chalking failure. However, the rate of chalking as measured by these test methods, and the rate of erosion may not be comparable because some pigment combinations tend to retain chalk on the surface while other pigment combinations exert a self-cleaning action by natural means.

NOTE 1—For the evaluation of erosion, see Test Method D 662.

6.3 Records may be kept on forms such as shown in Fig. 3, according to Standard D 1150, or other inspection forms. The reporting of the results shall include the information given in Section 10.

6.4 When this test method is referenced in specifications for performance, the permissible degree of chalking is established between the producer and the user.

7. Recommended Procedures—Wood Substrates

7.1 Test Method A—Method D 659:

7.1.1 *Material*—Fabric, as agreed upon between the producer, user, or other interested parties, to rub against the

FIG. 1 Photographic Reference Standard No. 1—Test Method D 659

surface being tested. Black wool felt, velvet, and velveteen have proven particularly effective.

3.1.2 Procedure—Wrap the fabric around the index finger, then apply it with medium pressure to the coating under observation. Rotate the finger through an angle of 90° holding the fabric so it also rotates. Remove the fabric and compare the spot of chalk on it with Photographic Reference Standard No. 1.

7.2 Test Method B—Stroke Method:

7.2.1 *Material*—Fabric as in 7.1.1.

2.2.2 Procedure—Wrap the fabric around the index finger, then make a 3-in. (75-mm) stroke with medium pressure on the coating under observation. Remove the fabric and compare the spot of chalk on it with Photographic Reference Standard No. 1.

3 Test Method C—Wet Finger Method:

7.3.1 Procedure—Moisten a fingertip and with medium pressure make one continuous rub 2 to 2½ in. (50 to 65 mm) in length on the surface under test. Compare the rub-off on the finger with Photographic Reference Standard No. 1. This test method can be used quite effectively by experienced operators and is recommended mainly for on-the-field evaluation when use of one of the other methods is impractical.

Recommended Procedures—Metallic Substrate—Industrial, Automotive, and Coil Coatings

8.1 *Test Method C—Wet Finger Method—See 7.3.*

8.2 Test Method D—Transparent Tape Method:⁵

8.2.1 Materials:

8.2.1.1 *Cellulose Adhesive Tape*,⁶ 1/2 in. (13 mm) wide, pressure-sensitive.

8.2.1.2 *Eraser*, $\frac{3}{4}$ in. (20 mm), wrapped with cellophane

8.2.1.3 *Masking Tape*, ½ in. (13 mm) wide.

8.2.1.4 *Plastic Sheet Protector*, clear.

FIG. 2 Photographic Reference Standard No. 2—Verfinstituut
TNO

8.2.1.5 *Photographic Reference Standard No. 2, TNO.*⁷

8.2.1.6 *Reflectance Standard*, polished black glass.

8.2.1.7 *Reflectance Standard*, white tile.

Permission to include this method is provided as a courtesy of NL Chemicals,
Croff Mills Rd., Hightstown, NJ 08520.

Permacel 404 manufactured by Permacel, Inc., Route 1, New Brunswick, NJ 08903 and Scotch Brand tape No. 600 manufactured by The 3M Company, Packaging Systems, 3M Center, Bldg. 230F267, St. Paul, MN 55144, have been found suitable for the purpose.

⁷ The TNO Method and photographic reference standard are provided as a courtesy of *Verinstituut TNO Paint Research Institute* TNO, Schoemakerstraat 97, Delft, Nederland. The original source of the photographic reference standard illustrated in Fig. 2 is the Paint Research Institute, TNO. The ASTM numerical rating of chalking shown on the photographic reference standard is opposite to the original TNO scale.

NOTE—The cut-out section is for illustration purposes only. The labeling (china marker) may be removed by rubbing the sheet with a clean tissue or cloth.

FIG. 4 Completed Worksheet

mm) cellulose, pressure-sensitive adhesive tape from the roll, place it across the masking strips, and adhere it to the sheet using a 3/4-in. (20-mm) eraser, wrapped with cellophane tape. Label this tape "blank" on the clear plastic sheet cover. A black china marker has been found useful for this purpose.

NOTE 3—The average reflectance measurements of the initial and ending "blank" tapes less the correction value for the clear plastic sheet divided by 100 are used to verify a rating of 10 using Table 1.⁸

8.2.4 Procedure:

8.2.4.1 Apply a 2 in. (50 mm) long piece of 1/2 in. (13 mm) wide tape to the surface being rated. Rub ten times with moderate pressure using the covered eraser, to remove all bubbles and prevent scratching. Remove the tape from the surface and adhere it to the sheet by rubbing with the eraser. Label specimens using a black china marker. Place successive tapes vertically adjacent to previous tapes, separated by 1/8 in. (3 mm). Follow the instructions given in 8.2.3.2, and place the final "blank" tape across the masking tape strips and label "blank" on the clear sheet. When completed, use a razor blade to cut along the inside edges of the masking tape, cutting through the adhesive tapes. The removal of the masking tape will leave only the tapes to be measured and evaluated with the sample number of each tape listed on the

⁸ Kronos-Titan Table for Chalk Rating from Reflectance Reading using the Transparent Tape Method is provided as a courtesy of Kronos-Titan GmbH, Leverkusen, West Germany. The original source of Table 1 is Kronos-Titan GmbH.

>0.366	0

^aThis table is based upon a correlation between tape reflectance measurements and visual evaluations of the same tape compared to the photographic standards prepared by Kronos-Titan.⁸

sheet (see worksheet example in Fig. 4). Before proceeding, check to ensure all sample numbers have been recorded on the sheet.

8.2.4.2 Insert the 1/2-in. (13-mm) aperture and calibrate the reflectometer according to the manufacturer's instructions, setting the reflectometer for zero reflectance using the black reflectance standard and standardizing with the white reflectance standard and record the values. Refer to Test Method E 97 should there be any question on the correct procedure to follow in the calibration of the instrument.

8.2.5 Reflectometer Measurements:

8.2.5.1 Leave the transparent tapes mounted on the clear plastic sheet. Remove the black paper that may have been inserted behind the sheet and fold back the unused portion of the sheet. Measure the reflectance of the clear plastic sheet using the black reflectance standard of the instrument (Note 1) as a backing or background and record its value. Move the sheet until the first tape is exposed to the light source with the adhesive side toward the light and the black reflectance standard behind the area being measured, and record the value.

8.2.5.2 Continue this procedure until ten tapes have been measured, then check reflectance values for the white and black standards. If no changes have occurred, proceed with measurements. If values have changed, restandardize and record values before proceeding to the remaining tapes. Following the final tape measurement, record reflectance values of the clear plastic sheet cover and the white and black reflectance standards.

8.2.5.3 Subtract the mean reflectance value of the sheet from each reading, enter on worksheet form (Fig. 4), or other form used, and determine from Table 1⁸ the chalk rating value of each tape to the nearest 0.5 unit. Record the rating on the worksheet or other form. The worksheet form (Fig. 4),

inserted into the plastic sheet protector with a black background gives a clear permanent record of these measurements and evaluations.

8.2.6 These tape chalks may also be compared to Photographic Reference Standard No. 2 as an alternative procedure.

8.3 Test Method E-TNO Method:

8.3.1 Materials:

8.3.1.1 *Photographic Reference Standard No. 2* for the determination of chalking, consisting of a photograph of five strips of tape mounted on a black background, numbered 0, 2, 4, 6, and 8, and varying in this order from white to almost black. The numerical rating of chalking shown on the photographic reference standard is opposite of the original TNO Scale.

8.3.1.2 *Polyethylene Tape*,⁹ transparent, 1-in. (25-mm) wide.

8.3.1.3 *Black Velvet*, dull black with a short pile and without a tendency to crush, size approximately 8 by 12 in. (200 by 300 mm), mounted on a flat substrate. Place adjacent to the standard for the ratings.

8.3.2 *Procedure*—Apply a piece of tape, approximately 4-in. (100-mm) long, to the coating by uniform gentle pressure of the finger, remove the tape, and lay it with the adhesive side on the piece of velvet. Under diffused light compare the tape on the black velvet with Photographic Reference Standard No. 2, and determine which of the five grades most closely matches the whiteness of the adhering pigment. If the degree of chalking is obviously between two adjacent grades, select the intermediate odd number as the chalk rating.

8.3.3 Chalk ratings may also be determined by following the procedures of 8.2.3 and comparing to the values shown in Table 1. The use of the worksheet form shown in Figs. 3 and 4 may be used as a permanent record.

9. Recommendations

9.1 The procedures recommended for various substrates and coatings are based upon the results obtained in interlaboratory testing. The selection of the method to be used is subject to agreement between producer and user.

10. Report

10.1 A record of the test method used, the rating, panel number, and other pertinent information must be clearly shown on the inspection report for each evaluation. The report form may be in accordance with Standard D 1150 or other form agreed upon between the producer and the user.

10.2 The pertinent information should include: date of inspection, date of exposure start, purchase order number of testing organization, duration, remarks about unusual weather, etc., the name of the person making the inspection, and other information agreed upon between the producer and the seller.

⁹Sellotape 1401, Transparent Polythene Electrical, manufactured by Sellotape Products Ltd., Edgware, Middlesex, England has been found suitable for this purpose.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Qualification of Journeyman Painters for Application of Coatings to Concrete Surfaces of Safety-Related Areas in Nuclear Facilities¹

This standard is issued under the fixed designation D 4227; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

1.1 This practice provides a standard qualifying method for journeyman painters to verify their proficiency and to attain the required quality for application of specified coatings to concrete surfaces in safety-related areas in a nuclear facility.

1.2 Variations or simplifications of the practice set forth herein may be appropriate for special coating work such as maintenance. It is not the intent of this practice to mandate a regular basis for all qualifications.

1.3 Evaluation of the journeyman painter being qualified in accordance with this practice, shall be by qualified agents as specified in 4.1. Reports shall be prepared as specified in Section 5, and qualification as specified in Section 6.

1.4 It is the intent of this practice to judge only the ability of the journeyman painter to apply specified coatings with proper tools and equipment.

1.5 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Definitions

2.1 *journeyman painter*—an individual who has worked in the painting trade sufficiently long enough to master the use of all applicable tools and the materials being applied.

2.2 *qualifying agents*—the designated representatives of the owner or of the coating organization, or both, who have sufficient experience in the practical application and evaluation of coating applied to concrete surfaces of a nuclear facility.

2.3 *governing documents*—technical specifications, jobsite procedures, and reference documents.

Application of Coatings

3.1 This practice requires the journeyman painter to apply the specified coating in conformance to the governing documents to a test area similar to that detailed in Figs. 1 and 2.

3.1.1 *Ceiling Section*—Beginning at the wall line, one 5 by 5-ft (1.5 by 1.5-m) coating.

¹ This practice is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generating Facilities and is the direct responsibility of Subcommittee D33.07 on Application. Current edition approved April 6, 1983. Published June 1983.

FIG. 1 Concrete Ceiling Test Area

3.1.2 *Wall Section*—Beginning at the floor line, one 5 by 5-ft (1.5 by 1.5-m) coating.

3.1.3 *Floor Section*—Beginning at the wall line and connecting with the wall section, one 5 by 5-ft (1.5 by 1.5-m) coating.

3.2 This practice requires the journeyman painter perform the application using the proper technique and application equipment consistent with the governing documents.

3.3 The surfaces of the concrete test area shall be prepared in accordance with the governing documents.

3.4 The journeyman painter shall demonstrate the ability to apply the specified coating to a uniform dry film thickness in accordance with the governing documents, as evaluated by the qualifying agents.

3.5 When desired by the owner, one of the test surfaces may include embedded steel.

3.6 If a coating system specified requires a primer, intermediate, and finish coat, treat each coat as a separate application, allowing a specified drying time before applying each succeeding coat.

3.7 The journeyman painter shall be provided with the following:

FIG. 2 Concrete Wall and Floor Test Area

FIG. 3 Location of Wet-Film Thickness Readings

3.7.1 Information regarding the specified coating material(s), including wet and dry film thickness required, and all other information contained in the governing documents for the coating system being applied.

3.7.2 Coating materials properly mixed in accordance with the governing documents and ready for application.

3.7.3 The necessary equipment for the proper application of the specified coating.

3.7.4 Miscellaneous equipment, brushes, and thinners required for cleaning the equipment after completion of the test.

3.7.5 A practice area to adjust and test the equipment prior to performing the test.

3.7.6 All necessary safety equipment.

3.7.7 Wet-film thickness gage for verifying the coating thickness during application.

3.8 The journeyman painter shall use the wet-film thickness gage furnished to determine coating thickness buildup during application. Material thickness is one of the criteria for evaluation.

4. Evaluation of Coating Application

4.1 Evaluation of the journeyman painter shall be made

by two qualifying agents. Only one qualifying agent can be production-related.

4.2 The qualifying agents shall be capable of answering technical questions requested by the journeyman painter relating to the application of the specified coating material(s). The qualifying agents shall be thoroughly familiar with the specified coating material(s) and acceptance criteria and shall be aware of any difficulties in applying the coating to any surface.

4.3 The qualifying agents shall have a wet-film gage of the same type used by the journeyman painter.

4.4 The qualifying agents shall take approximately 16 wet-film thickness readings on the test areas. These readings shall be recorded as specified in Section 5. The wet-film thickness readings shall be used to verify the specified dry-film thickness requirements and uniformity of application. The number and location of readings shall be as indicated on Fig. 3.

4.5 The journeyman painter and the qualifying agents shall understand the required dry-film thickness range requirements of the governing documents before any coatings are applied.

4.6 The qualifying agent shall inspect the finished surface to verify that it conforms to the requirements of the governing documents. A description of the appearance of the completed applied coating shall be recorded on the form shown in Fig. 4.

5. Report

5.1 The qualifying agents shall use a report form similar to that in Fig. 4 to record wet-film thickness readings specified in 4.4, and the appearance of the completed coating surface as specified in 4.6.

5.2 The qualifying agents and journeyman painter shall sign the report form.

FIG. 5 Qualification Form

3. A copy of the report shall become a permanent part of the quality assurance file for the nuclear project for which the journeyman painter is qualifying.

4. A copy of the report shall be given to the qualifying journeyman painter.

Initial Qualification

7.4.1 The qualifying agents shall prepare a qualification form similar to Fig. 5. The qualification form shall state the coating materials used and the application equipment used in the test.

5.2 The qualifying agents and the journeyman painter shall sign the qualification form.

6.3. A copy of the qualification form shall become a permanent part of the quality assurance file for the nuclear project for which the journeyman painter is qualified.

6.4 A copy of qualification form shall be given to the journeyman painter.

7. Regualification

7.1 The owner or his designated representative may determine the degree of requalification to be permitted, as well as the acceptance of previously qualified journeyman painters based on time interval since the date of the qualification and provided the same coating materials and application procedures are used. Note the acceptance of previous qualification in the quality assurance file for the project.

8. Limited Qualifications—Touch Up and Repair

8.1 Limited qualifications can be accomplished using only areas representative of the actual plant surfaces, even though they do not include all areas represented by Figs. 1 and 2.

9. Limited Qualifications—Brushes, Rollers, Squeegees, or Other Special Tools

9.1 Limited qualifications for special application tools may be required on certain projects. When such limited qualification is performed, the limitations shall be noted on the records for qualification and application.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Qualification of Journeyman Painters for Application of Coatings to Steel Surfaces of Safety-Related Areas in Nuclear Facilities¹

This standard is issued under the fixed designation D 4228; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice provides a standard qualifying method for journeyman painters to verify their proficiency and ability to attain the required quality for application of specified coatings to steel surfaces in safety-related areas in a nuclear facility.

1.2 Variations or simplifications of the practice set forth herein may be appropriate for special coating work such as maintenance or qualifications of equipment suppliers shop personnel. It is not the intent of this practice to mandate a singular basis for all qualifications.

1.3 Evaluation of the journeyman painter being qualified in accordance with this practice, shall be by qualified agents as specified in 4.1. Reports shall be prepared as specified in Section 5, and certification as specified in Section 6.

1.4 It is the intent of this practice to judge only the ability of the journeyman painter to apply specified coatings with the proper tools and equipment.

1.5 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Definitions

2.1 *journeyman painter*—an individual who has worked in the painting trade sufficiently long enough to master the use of all applicable tools and the materials being applied.

2.2 *qualifying agents*—the designated representatives of the owner or of the coating organization, or both, who have sufficient experience in the practical application and evaluation of coatings applied to steel surfaces of a nuclear facility.

2.3 *governing documents*—technical specifications, jobsite procedures, and reference documents.

3. Application of Coatings

3.1 This practice requires the journeyman painter to apply the specified coating in conformance to the governing documents to a test panel similar to that detailed in Fig. 1. This panel is typical of the panel used for qualification, and may be modified to suit site configurations.

3.2 This practice requires the journeyman painter to

perform the application using the proper technique and application equipment consistent with the specified coating materials.

3.3 The surfaces of the test panel shall be prepared in accordance with the governing documents.

3.4 Place the test panel approximately 12 in. (305 mm) above ground level and at approximately 30° from the vertical plane, with the complex side up. This will simulate the types of difficult coating situations encountered by journeyman painters in a nuclear facility.

3.5 The journeyman painter shall demonstrate his ability to apply the specified coating to a uniform dry-film thickness in accordance with the governing documents, as evaluated by the qualifying agents.

3.6 Allow required drying as prescribed by the governing documents prior to taking the dry-film thickness reading of the applied coating. If a coating system specified requires a primer, intermediate, and finish coat, treat each coat as a separate application, allowing a specified drying time before inspecting each completed coat.

3.7 The journeyman painter shall be provided with the following:

3.7.1 Information regarding the specified coating material(s), including wet and dry film thickness required, and all other information contained in the governing documents for the coating system being applied.

3.7.2 Coating materials properly mixed in accordance with the governing documents and ready for application.

3.7.3 The necessary equipment for the proper application of the specified coating.

3.7.4 Miscellaneous equipment, brushes, and thinners required for cleaning the equipment after completion of the test.

3.7.5 A practice area to adjust and test the equipment prior to performing the test.

3.7.6 All necessary safety equipment.

3.7.7 Wet-film thickness gage for testing the coating thickness during application, where applicable.

4. Evaluation of Coating Application

4.1 Evaluation of the journeyman painter shall be made by two qualifying agents. Only one qualifying agent can be production-related.

4.2 The qualifying agents shall be capable of answering technical questions requested by the journeyman painter relating to the application of the specified coating material(s). The qualifying agents shall be thoroughly familiar with the specified coating material(s) and acceptance criteria and shall

¹ This practice is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generating Facilities and is the direct responsibility of Subcommittee D33.07 on Application.

Current edition approved April 6, 1983. Published June 1983.

FIG. 1 Test Panel—Complex Side

aware of any difficulties in applying the coating to any surface.

4.3 The qualifying agents shall have a wet-film gage of the same type used by the journeyman painter, as well as a calibrated magnetic-type dry-film thickness gage.

4.4 The qualifying agents shall take dry-film thickness readings on all areas of the test panel, except nuts and bolts. These readings shall be recorded as specified in Section 5. Dry-film readings may be used to check the journeyman painter's progress during application. The dry-film thickness reading shall be used to verify the specified dry-film thickness requirements and uniformity of application. The number and location of readings shall be as indicated on Fig.

4.5 The journeyman painter and the qualifying agents shall understand the required dry-film thickness range requirements of the governing documents before any coatings are applied.

4.6 The qualifying agent shall inspect the finished surface to verify that it conforms to the requirements of the governing documents. A description of the appearance of the

completed applied coating and dry film thickness shall be recorded on form Fig. 3.

5. Report

5.1 The qualifying agents shall use a report form similar to that in Fig. 2 to record dry-film thickness readings specified in 4.4, and the appearance of the completed coating surface as specified in 4.6.

5.2 The qualifying agents and journeyman painter shall sign the report form.

5.3 A copy of the report shall become a permanent part of the quality assurance file for the nuclear project for which the journeyman painter is qualifying.

5.4 A copy of the report shall be given to the qualifying journeyman painter.

6. Initial Qualification

6.1 The qualifying agents shall prepare a form similar to Fig. 3. The qualification form shall state the coating materials used and the application equipment used in the test.

6.2 The qualifying agents and the journeyman painter shall sign the qualification form.

6.3 A copy of the qualification form shall become a permanent part of the quality assurance file for the nuclear project for which the journeyman painter is qualified.

6.4 A copy of the qualification form shall be given to the journeyman painter.

7. Requalification

7.1 The owner or his designated representative may determine the degree of requalification to be permitted, as well as the acceptance of previously qualified journeyman painters based on time interval since the date of the qualification form and provided the same coating materials and application procedures are used. Note the acceptance of previous qualification in the quality assurance file or the project.

8. Limited Qualifications—Touch Up and Repair

8.1 Limited qualifications can be accomplished using only areas representative of the actual plant surfaces, even though they do not include all areas represented in Fig. 1.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Labeling Art Materials for Chronic Health Hazards¹

This standard is issued under the fixed designation D 4236; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

INTRODUCTION

Uninformed or careless use of some art material products can give rise to health hazards, either acute or chronic, or both. Specific and readily available warnings are needed to help protect users of any age. One way to disseminate such information is to provide appropriate precautionary labeling on art material products.

Labeling for acute health hazards, including those associated with art materials, is being addressed by such requirements as the U.S. Consumer-Product Safety Act, the Federal Hazardous Substances Act, and the like. There are presently no specific national standards for labeling art materials with respect to chronic health hazards.

This practice is intended to provide a standard for developing precautionary labels concerning chronic health hazards related to the use of art materials. It is further intended to have the adaptability necessary to keep labels current with existing scientific and medical knowledge, as well as in conformity with other precautionary labeling requirements, both acute and chronic, thereby avoiding unnecessary confusion by users with respect to other precautionary labeling.

Scope

1.1 This practice describes a procedure for developing precautionary labels for art materials and provides hazard and precautionary statements based upon knowledge that exists in the scientific and medical communities. This practice concerns those chronic health hazards known to be associated with a product or product component(s), when the component(s) is present in a physical form, volume, or concentration that in the opinion of a toxicologist (see 2.1.11) has the potential to produce a chronic adverse health effect(s).

1.2 This practice applies exclusively to art materials packaged in sizes intended for individual users of any age or those participating in a small group.

1.3 Labeling determinations shall consider reasonable foreseeable use or misuse. The responsibility for precautionary labeling rests with the producer or repackager who markets the materials for art or craft use.

1.4 This practice does not specify test methods for determining whether a substance or product presents chronic health hazards.

1.5 This practice does not apply to products appropriately labeled for known chronic health hazards in accordance with chemical substance labeling standards and practices, such as another national consensus standard, existing labeling statutes, regulations, or guidelines.

1.6 Since knowledge about chronic health hazards is incomplete and warnings cannot cover all uses of any product, it is not possible for precautionary labeling to ensure

completely safe use of an art product.

1.7 Manufacturers or repackagers may wish to determine individually or collectively precautionary labeling for art materials in accordance with this practice. Compliance may be certified by a certifying organization. Guidelines for a certifying organization are given in Appendix X1.

1.8 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Terminology

2.1 *Descriptions of Terms Specific to This Standard:*

2.1.1 *analytical laboratory*—a laboratory having personnel and apparatus capable of performing quantitative or qualitative analyses of art materials, which may yield information that is used by a toxicologist for evaluation of potentially hazardous materials.

2.1.2 *art material or art material product*—any raw or processed material, or manufactured product, marketed or represented by the producer or repackager as intended for and suitable for users as defined herein.

2.1.3 *bioavailability*—the extent that a substance can be absorbed in a biologically active form.

2.1.4 *chronic adverse health effect(s)*—a persistent toxic effect(s) that develops over time from a single, prolonged, or repeated exposure to a substance. This effect may result from exposure(s) to a substance that can, in humans, cause sterility, birth defects, harm to a developing fetus or to a nursing infant, cancer, allergenic sensitization, damage to the nervous system, or a persistent adverse effect to any other organ system.

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.57 on Artist Paints and Related Materials.

Current edition approved Sept. 15, 1991. Published November 1991. Originally published as D 4236 - 83. Last previous edition D 4236 - 89.

2.1.5 *chronic health hazard(s)* (hereafter referred to as "*chronic hazard*")—a health risk to humans, resultant from exposure to a substance that may cause a chronic adverse health effect.

2.1.6 *label*—a display of written, printed, or graphic matter upon the immediate container of any art material product. When the product is unpackaged, or is not packaged in an immediate container intended or suitable for delivery to users, the label can be a display of such matter directly upon the article involved or upon a tag or other suitable labeling device attached to the art material.

2.1.7 *producer*—the person or entity who manufactures, processes, or imports an art material.

2.1.8 *repackager*—the person or entity who obtains materials from producers and without making changes in such materials puts them in containers intended for sale as art materials to users.

2.1.9 *sensitizer*—a substance known to cause, through an allergic process, a chronic adverse health effect which becomes evident in a significant number of people on re-exposure to the same substance.

2.1.10 *toxic*—applies to any substance that is likely to produce personal injury or illness to humans through ingestion, inhalation, or skin contact.

2.1.11 *toxicologist*—an individual who through education, training, and experience has expertise in the field of toxicology, as it relates to human exposure, and is either a toxicologist or physician certified by a nationally recognized certification board.

2.1.12 *users*—artists or crafts people, of any age, who create, or recreate in a limited number, largely by hand, works which may or may not have a practical use, but in which aesthetic considerations are paramount.

3. Requirements

3.1 To conform to this voluntary practice the producer or repackager of art materials shall submit art material product formulation(s) or reformulation(s) to a toxicologist for review, such review to be in accordance with Section 4 of this practice. The toxicologist shall be required to keep product formulation(s) confidential.

3.1.1 Unless otherwise agreed in writing by the producer or repackager, no one other than the toxicologist shall have access to the formulation(s); except that the toxicologist shall furnish a patient's physician, on a confidential basis, the information necessary to diagnose or treat cases of exposure or accidental ingestion.

3.2 To conform to this practice, the producer or repackager, upon advice given by a toxicologist in accordance with Section 4 of this practice, shall adopt precautionary labeling in accordance with Section 5 of this practice and based upon generally accepted, well-established evidence that a component substance(s) is known to cause chronic adverse health effects.

3.3 To conform to this practice, labeling shall be parallel to, conform to, and minimally include any labeling practices prescribed by U.S. federal and state statutes or regulations and shall not diminish the effect of required acute toxicity warnings.

3.4 To conform to this practice, the producer or repackager shall supply a poison exposure management informa-

tion source² the generic formulation information required for dissemination to poison control centers or provide a 24-h cost-free telephone number to poison control centers.

3.5 To conform to this practice, the producer or repackager shall have a toxicologist review as necessary, but at least every 5 years, art material product formulation(s) and associated label(s) based upon the then current, generally accepted, well-established scientific knowledge.

3.6 *Statement of Conformance*—"Conforms to ASTM Practice D 4236," or "Conforms to ASTM D 4236," or "Conforms to the health requirements of ASTM D 4236." This statement may be combined with other conformance statements. The purpose of the conformance statement is to inform the purchaser, at the time of purchase, of the product's compliance with the standard. To accomplish this purpose the conformance statement should appear whenever practical on the product; however, it shall also be acceptable to place the statement on one or more of the following: (a) the individual product package, (b) a display or sign at the point of purchase, (c) separate explanatory literature available on request at the point of purchase, (d) a response to a formal request for bid or proposal.

4. Determination of Labeling

4.1 An art material is considered to have the potential for producing chronic adverse health effects if any customary or reasonably foreseeable use can result in a chronic hazard.

4.2 In making the determination a toxicologist(s) shall take into account the following:

4.2.1 Current chemical composition of the art material, supplied by an analytical laboratory or by an industrial chemist on behalf of a manufacturer or repackager.

4.2.2 Current generally accepted, well-established scientific knowledge of the chronic toxic potential of each component and the total formulation.

4.2.3 Specific physical and chemical form of the art material product, bioavailability, concentration, and the amount of each potentially chronic toxic component found in the formulation.

4.2.4 Reasonably foreseeable uses of the art material product as determined by consultation with users and other individuals who are experienced in use of the material(s), such as teachers, or by market studies, unless such use information has previously been determined with respect to the specific art material(s) under review.

4.2.5 Potential for known synergism and antagonism of the various components of the formulation.

4.2.6 Potentially chronic adverse health effects of decomposition or combustion products, if known, from any reasonably foreseeable use of the hazardous art material product.

4.2.7 Opinions of various regulatory agencies and scientific bodies, including the International Agency for Research on Cancer and the National Cancer Institute, on the potential for chronic adverse health effects of the various components of the formulation.

² Two of the larger poison exposure management information sources are: The Rocky Mountain Poison Control Center, West 8th and Cherokee, Denver, CO 80204; and the National Poison Center Network, 125 De Soto St., Pittsburgh, PA 15213.

3 Based upon the conclusion reached in conformance with review determinations set forth herein the toxicologist(s) shall recommend precautionary labeling consistent with Section 5 of this practice.

Labeling Practices

5.1 Signal Word:

5.1.1 When a signal word for an acute hazard(s) is mandated and a chronic hazard(s) exists, the signal word shall be thht for the acute hazard.

5.1.2 When only a chronic hazard(s) exists, the signal word WARNING shall be used.

5.1.3 The signal word shall be prominently visible and set in bold capitals in a size equal to or greater than the statement of potential chronic hazards.

5.2 *List of Potentially Chronic Hazards*—Potentially chronic hazards, as determined under the procedures of Section 4, shall be stated substantially in accordance with the statements listed in Annex A1 of this practice. Potentially chronic hazards noted shall be those that are clinically significant and that might be expected with any reasonably foreseeable use of the art material. The hazards should be grouped in the order of relative descending severity.

5.3 *Name of Chronically Hazardous Component(s)*—All components and known decomposition products of the formulation with a potential for chronic hazards, as determined under the procedures of Section 4, shall be listed prominently. Generically equivalent names may be used.

5.4 *Safe Handling Instructions*—Appropriate precautionary statements as to work practices, personal protection, and ventilation requirements shall be used substantially conforming with those listed in Annex A2 of this practice.

5.5 *List of Sensitizing Components*—To protect users from known sensitizers found within art materials, each label shall contain a list of those sensitizers present in sufficient amounts to contribute significantly to a known skin or respiratory sensitization.

5.6 *Combined Statements*—If an art material contains more than one component capable of causing a chronic adverse health effect, or if a single chemical can cause several different chronic adverse health effects, the potential effects may be combined into one statement.

5.7 *Information Sources*—In addition to an appropriate telephone number, the precautionary label shall contain a statement identifying a source for additional health informa-

tion substantially in conformance with one of the phrases listed below:

5.7.1 For more health information—(24-h cost-free telephone number), or

5.7.2 For further health information call a poison control center.

5.8 *Labeling Content, Product Size*—An art material product(s) in a container larger in size than one fluid ounce (30 mL) (if the product is sold by volume) or one ounce net weight (28 g) (if the product is sold by weight) shall have full precautionary labeling, as generally described in Section 5 of this practice. An art material product(s) in a container equal to or smaller than one fluid ounce or one ounce net weight shall have a label that includes a signal word in conformance with 5.1 of this practice and a list of potentially harmful or sensitizing components in conformance with 5.3 and 5.5 of this practice.

5.9 The information described in Section 5 must appear (1) on the outside container or wrapper, if any, unless it is easily legible through the outside container or wrapper and (2) on all accompanying literature where there are directions for use, written or otherwise. In a case where one or more individual product(s), which require warning labels under Sections 4 and 5, are packed within a point of sale package which obscures the warning statement(s), the point of sale package shall carry the signal word conforming to 5.1 of this practice and the following wording: "Contains: (list hazardous product(s)) that may be harmful if misused. Read cautions on individual containers carefully. Keep out of the reach of children."

5.10 Statements required under Sections 4 and 5 must be in the English language and located prominently in conspicuous and legible type in contrast by topography, layout, or color with other printed matter on the label.

5.11 *Supplemental Information*—Where appropriate, more detailed technical information that relates to chronic hazard(s), such as physical properties, decomposition products, detailed safety instructions, or disposal recommendations, shall be included in supplemental documents, such as Material Safety Data Sheets, technical brochures, technical data sheets etc.

6. Keywords

6.1 art materials; chronic toxicity; craft materials; health labeling; precautionary statements; warning statements

ANNEXES

(Mandatory Information)

A1. CHRONIC HAZARD STATEMENTS

MAY CAUSE STERILITY.
CONTACT MAY CAUSE PERMANENT EYE DAMAGE.
MAY BE HARMFUL BY BREATHING VAPORS/DUSTS.
MAY BE HARMFUL IF SWALLOWED.
MAY BE HARMFUL BY SKIN CONTACT.

MAY PRODUCE BIRTH DEFECTS IN THE DEVELOPING FETUS.
MAY BE EXCRETED IN HUMAN MILK.
MAY CAUSE HARM TO THE NURSING INFANT.
CANCER AGENT! EXPOSURE MAY PRODUCE CANCER.

CANCER AGENT BASED ON TESTS WITH LABORATORY ANIMALS.

POSSIBLE CANCER AGENT BASED ON TESTS WITH LABORATORY ANIMALS.

MAY PRODUCE ALLERGIC REACTION BY INGESTION/INHALATION/SKIN CONTACT.

MAY PRODUCE NUMBNESS OR WEAKNESS IN THE EXTREMITIES.

EXPOSURE MAY CAUSE (SPECIFY THE ORGAN(S)) DAMAGE.

HEATING/COMBUSTION MAY CAUSE HAZARDOUS DECOMPOSITION PRODUCTS.

MAY CAUSE (SPECIFIC EFFECT) OF (SPECIFY ORGAN).

CANCER AGENT! EXPOSURE BY (SPECIFIC ROUTE) MAY PRODUCE CANCER.

MAY CAUSE HARM TO THE DEVELOPING FETUS. EXPOSURE MAY RESULT IN NAUSEA, HEADACHE, CONFUSION OR INSTABILITY.

MAY CAUSE DAMAGE TO RED BLOOD CELLS WITH REDUCED ABILITY TO CARRY OXYGEN.

A2. PRECAUTIONARY STATEMENTS

Keep out of reach of children.
When using do not eat, drink, or smoke.
Wash hands immediately after use.
Avoid inhalation/ingestion/skin contact.
Avoid fumes from combustion.
Keep container tightly closed when not in use.
Store in well-ventilated area.
Wear protective clothing (specify type).
Wear protective goggles/face shield.
Wear NIOSH³-certified mask for dusts/mists/fumes.
Wear NIOSH-certified respirator with an appropriate cartridge for (specify).
Wear NIOSH-certified supplied-air respirator.

Use window exhaust fan to remove vapors and ensure adequate cross ventilation. (Specify explosion-proof if necessary.)

Do not heat above (specify temperature) without adequate ventilation.

Use (specify type) local exhausting hood.

Do not use/mix with (specify material).

Do not dry grind.

Do not spray apply.

If pregnant or contemplating pregnancy, use only under professional supervision.

Avoid using/do not use if pregnant (or contemplating pregnancy).

Not for use by children.

Avoid breathing dust.

Use in glove box.

³ U. S. National Institute of Occupational Safety and Health.

APPENDIX

(Nonmandatory Information)

X1. GUIDELINES FOR A CERTIFYING ORGANIZATION

X1.1 The term certifying organization, as used in these guidelines, refers to an organization or an institute that, after assuring that all provisions are met, certifies that an art material does conform to the labeling requirements of this practice.

X1.2 The certifying body may be funded by member manufacturers, but should include users or their representatives, as well as manufacturers' chemists, on its technical and certifying committees.

X1.3 Representative samples of art materials, labeled as conforming to this practice and bought at retail, should be analyzed at random and from time to time by an analytical laboratory to ensure they are the same as the formulation

used by the toxicologist(s) for determining labeling requirements.

X1.4 The methods used by the toxicologist(s) in review and determination of the need and content of precautionary labeling for potentially chronic adverse health effects should be periodically reviewed by an advisory board composed of not less than three or more than five toxicologists, at least one of whom is certified in toxicology by a nationally recognized certification board.

X1.5 In cases where there is disagreement by participating producers or participating users, with the determination of the toxicologist(s), there should be a method whereby the toxicologist's decision can be presented to the advisory board of toxicologists for arbitration.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Determination of the Decontaminability of Coatings Used in Light-Water Nuclear Power Plants¹

This standard is issued under the fixed designation D 4256; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

Scope

1.1 This test method establishes procedures for determining and ranking the ease of decontaminability of coatings for use in nuclear power plants.

1.2 This standard defines two different test procedures involving differing contaminant contact times and decontaminating media. Procedure A involves a relatively brief radionuclide solution contact time and decontamination using both demineralized water and acid solutions. Procedure B utilizes a seven-day contamination solution contact time and decontamination with ambient temperature water only. Procedure B is more in line with power plant decontamination practices.

1.3 Users of this standard should specify either Procedure A or Procedure B, or both, based upon specific power plant conditions and use requirements.

1.4 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Referenced Documents

- 2.1 *ASTM Standards:*
D 1193 Specification for Reagent Water²
E 522 Method of Calibrating Germanium Detectors for Measurement of Gamma-Ray Emission Rates of Radionuclides³
- 2.2 *American National Standards Institute:*⁴
N512 Protective Coatings (Paint) for the Nuclear Industry

Terminology

- 3.1 *Definitions:*
3.1.1 *decontaminate*—the removal of radionuclides from test panel using prescribed procedures.
3.1.2 *decontamination factor (DF)*—the ratio of the original radioactivity (dpm) to the radioactivity detected after treatment.

¹ This test method is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generating Facilities and is the direct responsibility of Subcommittee D33.11 on Decontamination of Coated Surfaces.

² Current edition approved Feb. 24, 1989. Published June 1989. Originally published as D 4256 - 83. Last previous edition D 4256 - 83.

³ *Annual Book of ASTM Standards*, Vols 06.03 and 11.01.

⁴ Discontinued—see 1983 *Annual Book of ASTM Standards*, Vol 12.02.

⁵ Available from American National Standards Institute, 11 W. 42nd St., 13th floor, New York, NY 10036.

3.1.3 *disintegration of atomic nuclei*—the nuclear transformation characterized by the emission of one or more particles or photons from the nucleus.

3.1.4 *disintegrations per minute (dpm)*—the number of disintegrations occurring in a time period of 1 min.

4. Significance and Use

4.1 Day-to-day operation or a loss-of-coolant accident at a nuclear power plant can give rise to a significant level of radioactive contamination on the walls, floors, and attendant equipment. The ease with which the coated surfaces can be decontaminated could result in considerable reduction in the level of radioactive contamination, thereby mitigating the exposure to plant operating personnel. It is recognized that this test method does not duplicate actual field decontamination procedures, but it does represent comparative test procedures that have been in use for many years. Other tests, designed to be more meaningful in terms of real-life conditions, are under development.

5. Apparatus

5.1 *Radiation Detection Equipment*⁵—Use a gamma-sensitive system composed of the following items:

5.1.1 *Detector*—Use a germanium crystal detector with a resolution of 2.5 keV at 1332 keV or better.

NOTE—See Method E 522 for calibration methods.

5.1.2 *Photomultiplier-Amplifier*.⁶

5.1.3 *Analog-to-Digital Converter (ADC)*.⁷

5.1.4 *Pulse-Height Analyzer*, capable of resolving simple gamma-ray peaks shall be used.

5.2 Mount test specimens so as to give an optimum scanning geometry of the contaminated surface.

5.3 Shield the detector to eliminate excessive background counts.

6. Reagents

6.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chem-

⁵ The most up-to-date information on gamma-ray detectors and accompanying electronics is found in manufacturers' literature. A list of vendors of this equipment can be found in compilations such as the *Guide to Scientific Instruments*, published by the American Association for the Advancement of Science, Washington, DC.

⁶ Teknec Model TC-205, or equivalent, has been found satisfactory for this purpose.

⁷ Nuclear Data Model ND570, or equivalent, has been found satisfactory for this purpose.

ical Society, where such specifications are available.⁸ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

6.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean Type II reagent grade water conforming to Specification D 1193.

6.3 Contaminating Solution:

6.3.1 Use a radioactive contaminant solution of mixed fission products of cobalt-60 and cesium-137, prepared in 8 M nitric acid (HNO₃) and stored in a polyethylene bottle.

6.3.2 The solution shall have a minimum beta-gamma activity of 5×10^6 disintegrations per minute (dpm) per 0.1 mL.

6.4 *Decontaminating Solutions*—The following decontaminating solutions shall be utilized, based upon the procedure selected (Procedure A or Procedure B):

6.4.1 An aqueous mixture of 0.4 M oxalic acid (COOH)₂, 0.05 M sodium fluoride (NaF), and 0.3 M hydrogen peroxide (H₂O₂).

6.4.2 Demineralized water.

7. Preparation of Test Specimens

7.1 *Steel Panels*—Prepare panels in accordance with ANSI N512.

7.2 *Concrete Blocks*—Prepare blocks in accordance with ANSI N512.

8. Test Specimens

8.1 Use a minimum of two test specimens for each coating system.

9. Specimen Contamination

9.1 Degrease the test specimens using the coating manufacturer's approved solvent; place on a level surface inside a laboratory hood and at $24 \pm 3^\circ\text{C}$ until the solvent has evaporated. Maintain a minimum air velocity of 150 ft/min at the face of the hood.

9.2 Transfer a portion of the contaminating solution to a clean polyethylene bottle and immediately adjust to pH 4 with 8 M ammonium hydroxide (NaOH).

9.3 Contamination Procedure A, Evaporate to Dryness:

9.3.1 Immediately transfer a 0.2-mL portion of the pH-adjusted solution to the center of the lower 2-in. section of the test specimen so as to cover an area about 1 cm in diameter.

9.3.2 Allow the specimen to air dry as in 9.1, and place it in a plastic bag approximately 1.5-mil thick.

9.3.3 Position the specimen and bag in the detector chamber and scan, using identical geometry as in 8.2. Record all counts.

9.4 Contamination Procedure B, Seven-Day Contact Time:

9.4.1 Perform contamination using the assembly shown in Fig. 1.

FIG. 1 Top View of Holder for Contamination of Test Specimen in Seven-Day Exposure (Procedure B)

9.4.2 A test specimen is pushed into the positioning aid with its reference corner *R* as shown in Fig. 2. Edges *A* and *B* of the test specimen are brought into close contact with Lines *a* and *b* of the positioning aid, the Contact *B-b* having priority. The test specimen is then pressed against Part *U* containing the silicone rubber ring by fastening the screws until the test specimen is in contact with Part *U* along all of its edges.

9.4.3 The test specimens are contaminated by applying 1 mL of the contaminant solution to the middle of the circle visible through Part *U*.⁸ The holder shall be kept in a horizontal position. If, in the case of highly hydrophobic surface materials, the contaminant does not immediately cover the test circle, the holder may be tilted to enforce sufficient spread of the liquid.

9.4.4 A small petri dish is placed over the test circle on top of Part *U* to prevent evaporation of the contaminant solution.

9.4.5 After seven-days contact time the contaminant solution is sucked off as completely as possible using a pipet. For this purpose it is necessary to tilt the holder. The holder is then inverted. After removing the nuts and Part *L*, lift the test specimen vertically so that distribution of contaminant solution to uncontaminated parts of the test specimen is prevented.

9.4.6 To avoid evaporation effects immediately place the test specimen in a plastic bag. The whole procedure of removing the specimens from their holders and packaging them shall not take more than 12 min.

9.4.7 Position the contaminated specimens and scan as in 9.3.3.

10. Decontamination Procedure

10.1 The decontamination process for Procedure A will

⁸ "Reagent Chemicals, American Chemical Society Specifications," Am. Chemical Soc., Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY, and the "United States Pharmacopeia."

FIG. 2 Cross Section of Holder for Contamination in Seven-Day Exposure (Procedure B)

incorporate ambient water (10.2), ambient acid (10.3), and hot acid (10.4). The decontamination process for Procedure B will incorporate only ambient water (10.2).

10.2 Decontamination With Water:

10.2.1 Place a 600-mL polyethylene beaker containing 400 mL of demineralized water ($24 \pm 3^\circ\text{C}$) and a plastic-covered stirring bar on a magnetic stirrer.

10.2.2 Rigidly suspend the sample in the water to a depth of 2 in. with the contaminated side facing the center of the beaker.

10.2.3 Adjust the speed of the stirrer until the water vortex touches the stirring bar; stir for 10 min.

10.2.4 Remove the sample, rinse the back (uncontaminated side) with water, and air dry the contaminated face as in 9.1.

10.2.5 After the sample has dried, transfer it to a clean plastic bag and scan as before.

10.2.6 The ratio of the original radioactivity (counts per

minute) to the radioactivity detected after the water wash is recorded as the decontamination factor (DF) for the water wash.

10.3 Decontamination With Ambient Acid:

10.3.1 Using the same sample as for 10.2, perform a second decontamination as described in 10.2, except use the acid solution described in 6.4.1 at a temperature of $24 \pm 3^\circ\text{C}$.

10.3.2 The ratio of radioactivity after the water wash to radioactivity after the acid wash is recorded as the DF for the cold acid wash.

10.4 Decontamination With Hot Acid:

10.4.1 Continuing to use the same sample as in 10.3, perform a third decontamination as described in 10.3, except heat the acid to $80 \pm 3^\circ\text{C}$.

10.4.2 The ratio of radioactivity after the cold acid wash to radioactivity after the hot acid wash is recorded as the DF for the hot acid wash.

10.5 The ratio of radioactivity before the water wash to radioactivity after the hot acid wash, with a possible correc-

tion for natural radioactive decay described in 11.1, is recorded as the overall DF.

10.6 Control Sample:

10.6.1 Scan a contaminated, untreated control sample at the time the original and final counts are made on the test specimen.

10.6.2 Record any decrease in radioactivity.

10.6.3 Add this decrease to the value for the radioactivity after the final wash to calculate a corrected DF. The final wash will be with hot acid for Procedure A and with water for Procedure B.

11. Calculation

11.1 Calculate the decontamination factor (DF) (in consistent units) as follows:

$$DF = \frac{\text{original activity}}{\text{activity after treatment}}$$

11.2 Calculate percent removed as follows:

% removed

$$= \frac{\text{original activity} - \text{activity after decontamination}}{\text{original activity}} \times 100$$

$$= \left(1 - \frac{1}{DF}\right) \times 100$$

12. Report

12.1 The report shall include the following:

12.1.1 Procedures and conditions relating to the test specimen preparation,

12.1.2 Decontamination factors for each procedure,

12.1.3 Percent activity removed for each procedure, and

12.1.4 Any deterioration of the coating due to the test procedure.

13. Testing Laboratory

13.1 Testing shall be conducted by an independent testing laboratory. This laboratory shall not be affiliated in any manner with the coating manufacturer without the prior approval of the purchaser.

13.2 The testing laboratory shall be responsible for the documentation, reporting, and certification of all test results.

13.3 The testing laboratory shall be responsible for meeting the quality assurance requirements of the owner.

14. Precision and Bias

14.1 The overall precision and bias of this test method have not been established.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

**Standard Practice for
Design and Use of Safety Alert System for Hazardous Work
Locations in the Coatings and Lining Industry**

This practice covers a safety alert system for hazardous work locations and materials for the coatings and lining application industry. This practice is designed for multi-employer work sites.
Formerly under the jurisdiction of Committee D-33 on Protective Coatings and Lining Work for Power Generation facilities, this practice was discontinued in 1989.

Standard Practice for Surface Cleaning Concrete for Coating¹

This standard is issued under the fixed designation D 4258; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice includes surface cleaning of concrete to remove grease, dirt, and loose material prior to the application of coatings. Procedures include broom cleaning, vacuum cleaning, air blast cleaning, water cleaning, detergent water cleaning, and steam cleaning.

1.2 This practice is not intended to alter the surface profile of the concrete but to clean the surface.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For specific hazard statements, see Section 5.*

2. Referenced Documents

2.1 ASTM Standards:

D 4259 Practice for Abrading Concrete²

D 4260 Practice for Acid Etching Concrete²

D 4262 Test Method for pH of Chemically Cleaned or Etched Concrete Surfaces²

D 4263 Test Method for Indicating Moisture in Concrete by the Plastic Sheet Method²

D 4285 Test Method for Indicating Oil or Water in Compressed Air²

2.2 Other Standard:

ACI-308 Recommended Practice for Curing Concrete³

3. Summary of Practice

3.1 Surface cleaning is intended to provide a clean, contamination-free surface without removing concrete from intact, sound surfaces.

3.2 Acceptable surfaces shall be free of oil, grease, loosely adhering concrete, and other contamination. Fins and projections shall be corrected prior to surface cleaning.

3.3 Air, water cleaning, scrubbing, sweeping, or vacuuming are acceptable cleaning methods. Cleaning agents may also be used to remove oil and grease spots followed by a fresh water rinse.

3.4 Any one or a combination of the listed cleaning procedures may be used to achieve acceptably cleaned

surfaces.

4. Significance and Use

4.1 Surface cleaning is used to prepare concrete surfaces for applying coatings intended for light-duty service.

4.2 Use of this practice alone is not intended where protective systems will be used for continuous or intermittent immersion, mechanical loading, or for protective systems needing optimum bond for satisfactory performance (see Practices D 4259 and D 4260).

5. Cautions

5.1 New concrete shall be cured according to ACI-308 and sufficient additional time allowed for drying.

5.2 Moisture in the concrete may be detrimental to coating adhesion. Moisture content shall be in compliance with coating manufacturer's recommendation (see Test Method D 4263).

5.3 Concrete cure compounds, form release materials, or concrete hardeners not compatible with the coating may require removal by other surface preparation methods as in Practice D 4259.

6. Procedures

6.1 Broom Cleaning:

6.1.1 This procedure is intended to remove most surface dust and other loosely adherent solid contaminants.

6.1.2 Broom cleaning shall consist of sweeping the surface with a clean industrial stiff-bristled broom or similar device. Sweepings shall be removed from the immediate work area.

6.1.3 Broom-cleaned surfaces require additional cleaning using one or more of the surface preparation procedures specified in 6.2 through 6.6.

6.2 Vacuum Cleaning:

6.2.1 This cleaning procedure is intended to remove surface dust and other debris.

6.2.2 Vacuum cleaning shall consist of vacuuming the surface with a heavy-duty type industrial vacuum to provide an essentially dust-free surface.

6.3 Air Blast Cleaning:

6.3.1 This procedure is intended to remove debris, dust, dirt, loosely adherent laitance, and concrete from walls and ceilings and to provide an essentially sound dust-free surface.

6.3.2 Air blast cleaning shall consist of cleaning the surface with a compressed air stream at 80 to 100 psi through a blasting nozzle held approximately 2 ft from the surface.

6.3.3 The air stream shall be free of oil. This may be verified using Test Method D 4285.

6.3.4 Surface cleanliness is dependent upon carrying off air-borne dust before it is redeposited. Vacuum cleaning may be required to remove redeposited dust.

¹ This practice is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generating Facilities and is the direct responsibility of Subcommittee D33.05 on Surface Preparation.

Current edition approved June 24, 1983. Published November 1983.

² Annual Book of ASTM Standards, Vol 06.01.

³ Available from American Concrete Institute, 22400 W. Seven Mile Rd., Detroit, MI 48219.

Water Cleaning:

6.4.1 This procedure is intended to remove dust, dirt, and water-soluble surface contaminants.

6.4.2 Water cleaning shall consist of cleaning the surface with a stream of clean potable water having sufficient pressure to remove dust, dirt, and loose material. When necessary, hand scrub with a stiff-bristled brush.

6.4.3 Prior to water cleaning, provisions shall be made for the removal of wash water and contaminants generated by this cleaning method.

6.4.4 The cleaned surface may be tested for moisture content in accordance with Test Method D 4263 prior to applying coatings.

Detergent Water Cleaning:

6.5.1 This procedure is intended to remove water-soluble surface contaminants and oils, grease, and other emulsifiable materials on the surface.

6.5.2 Detergent water cleaning shall consist of scraping off heavy deposits of grease or oil and cleaning the surface with a stiff-bristled brush using an aqueous solution of detergent or nonsolvent emulsifier. Immediately after treatment, before the surface dries, residues of the cleaning agent shall be removed by thoroughly flushing the surface with clean potable water. Repeat flushing until the pH of the surface water meets the acceptance criteria of Test Method D 4262.

6.5.3 Trisodium phosphate at not less than 4 oz/gal, or proprietary products intended for cleaning concrete, may be used following manufacturers instructions. The effectiveness of trisodium phosphate may be improved with the use of hot water.

6.5.4 Repeat 6.5.2 until water does not bead on the surfaces.

6.5.5 Prior to detergent water washing, provisions shall be made for the removal of wash water and contaminants generated by this cleaning method.

6.5.6 The cleaned surface may be tested for moisture content in accordance with Test Method D 4263.

Steam Cleaning:

6.6.1 This cleaning procedure is similar to detergent water washing, but is more effective for the removal of heavy deposits of grease and oil.

6.6.2 Steam cleaning shall consist of cleaning the surface with a jet of high-pressure steam sufficient to remove contaminants.

6.6.3 Detergents or nonsolvent emulsifying agents intended for use with steam cleaning equipment may be added where required for removal of oil and grease.

6.6.4 When detergents or other emulsifying agents are used, after cleaning and before the surface dries, the surface shall be thoroughly flushed with potable water. Repeat flushing may be necessary to remove cleaning residues.

6.6.5 The surfaces cleaned with detergent or nonsolvent emulsifying agents shall be tested for pH in accordance with Test Method D 4262 and may be tested for moisture content in accordance with Test Method D 4263 prior to applying coatings.

6.6.6 Prior to steam cleaning, provisions shall be made for the removal of water and contaminants generated by this cleaning method.

7. Inspection

7.1 Visually examine the prepared surface for the presence of debris, dust, dirt, oil, grease, loosely adherent concrete, and other contaminants.

7.2 Test surfaces cleaned with detergent or nonsolvent emulsifying agents for pH following Test Method D 4262.

7.3 Moisture content may be determined following Test Method D 4263.

8. Acceptance

8.1 Acceptable surfaces shall be free of oil, grease, loosely adhering concrete, and other contamination.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Standard Practice for Abrading Concrete¹

This standard is issued under the fixed designation D 4259; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice includes surface preparation of concrete to prepare the surface prior to the application of coatings.

1.2 This practice is intended to alter the surface profile of the concrete and to remove foreign materials and weak surface laitance.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For specific hazard statements, see Section 5.*

2. Referenced Documents

2.1 ASTM Standards:

- D 4258 Practice for Surface Cleaning Concrete for Coating²
- D 4263 Test Method for Indicating Moisture in Concrete by the Plastic Sheet Method²
- D 4285 Test Method for Indicating Oil or Water in Compressed Air²
- D 4541 Test Method for Pull-Off Strength of Coatings Using Portable Adhesion Testers²
- 2.2 *Other Standard:*
ACI-308 Recommended Practice for Curing Concrete³

3. Summary of Practice

3.1 This practice is intended to provide a clean, contamination-free, and roughened surface.

3.2 Acceptable surfaces shall be free of laitance, form release agents, curing agents, oil, grease, and other penetrating contaminants. The surface shall be free of fins, projections and loosely adhering concrete, dirt, and dust particles.

3.3 For some applications, a minimum concrete surface strength may be required for proper coating performance.

3.4 Acceptable methods of preparation include abrasive blasting (wet or dry), mechanical abrading, water blasting, and other similar procedures that will alter the surface profile of the concrete.

4. Significance and Use

4.1 This practice is used to prepare concrete for coatings where optimum bond is desired for service conditions such as continuous or intermittent immersion, temperature cycling, or mechanical loading.

5. Cautions

5.1 New concrete shall be cured in accordance with ACI-308.

6. Mechanical Abrading Procedure

6.1 *Suitable Surfaces*—Mechanical abrading is suitable for use on formed surfaces and floors and for the removal of fins and projections.

6.2 *Pre-Surface Preparation:*

6.2.1 Remove grease, oil, and other penetrating contaminants. (See Practice D 4258.)

6.2.2 Concrete surfaces may be wet or dry as appropriate to the type of equipment to be used.

6.3 *Apparatus:*

6.3.1 Typical apparatus covered by this method are rotary impact, vertical impact, and circular grinding equipment.

6.3.2 Use the equipment in accordance with the manufacturer's instructions in an organized manner in order to thoroughly cover the entire surface to be prepared.

6.4 *Appearance of Prepared Surface:*

6.4.1 The intent is to remove sufficient material in order to achieve a sound concrete surface free of laitance, glaze, efflorescence and incompatible concrete curing compounds or form release agents.

6.4.2 The surface shall have a roughened, textured appearance. Aggregate may be exposed. A roughness standard may be established by mutual agreement.

6.4.3 The appearance will vary depending upon the equipment used and type of concrete.

6.5 *Post-Surface Preparation Cleaning*—Clean in accordance with Practice D 4258 to remove loose material.

7. Water Blast Cleaning

7.1 *Suitable Surfaces*—This method is suitable for use on formed surfaces and floors.

7.2 *Pre-Surface Preparation:*

7.2.1 Remove grease, oil, and other penetrating contaminants (see Practice D 4258).

7.2.2 Correct fins and protruding irregularities by mechanical means.

7.2.3 Concrete surface may be wet or dry.

¹ This practice is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generating Facilities and is the direct responsibility of Subcommittee D33.05 on Surface Preparation.

Current edition approved Feb. 26, 1988. Published April 1988. Originally published as D 4259 - 83. Last previous edition D 4259 - 83.

² *Annual Book of ASTM Standards*, Vol 06.01.

³ Available from American Concrete Institute, 22400 W. Seven Mile Rd., Detroit, MI 48219.

8.3 Apparatus—Typical apparatus covered by this method is a piston-type positive displacement pump, high-pressure water blasting unit. The cleaning medium shall be potable water.

8.4 Appearance of Prepared Surface:

8.4.1 The prepared surface shall be clean and free of dust, laitance and efflorescence.

8.4.2 The surface shall have a roughened textured appearance. A roughness standard may be established by mutual agreement.

8.5 Post-Surface Preparation Cleaning—Clean in accordance with Practice D 4258 to remove loose material.

8.6 Abrasive Blast Cleaning Procedure

8.6.1 Pre-Surface Preparation:

8.6.1.1 Remove grease, oil, and other penetrating contaminants (see Practice D 4258).

8.6.1.2 Correct fins and protruding irregularities by mechanical means.

8.6.1.3 Concrete surface may be wet or dry as appropriate to the type of equipment to be used.

8.6.2 Suitable Surfaces—This method is suitable for use on prepared surfaces and floors.

8.6.3 Apparatus:

8.6.3.1 Typical methods are wet or dry open-blast cleaning with nozzles and self-contained recirculating blast-cleaning apparatus.

8.6.3.2 The air stream used for nozzle blast cleaning shall be free of oil. This may be verified using Test Method D 4285.

8.6.3.3 Use the equipment in accordance with the manufacturer's instructions.

8.6.4 Appearance of Prepared Surface:

8.4.1 The intent is to remove sufficient material in order to achieve a sound concrete surface free of laitance, glaze, efflorescence, and incompatible concrete curing compounds or form release agents.

8.4.2 The surface shall have a roughened textured appearance. A roughness standard may be established by mutual agreement.

8.4.3 Some aggregate may be exposed and bug holes shall be opened.

8.5 Post-Preparation Cleaning—Clean in accordance with Practice D 4258 to remove loose material.

9. Inspection

9.1 Visually examine the prepared surface for loose adhering concrete, thin crusts bridging voids, fins, and projections.

9.2 Visually examine the prepared surface for oil, grease, and markings.

9.3 If required, surface strength may be determined in accordance with Method D 4541 or other agreed upon method.

10. Acceptance

10.1 Acceptable surfaces shall be free of laitance, oil, grease, and other materials incompatible with the coating. The surface shall also be free of fins, projections and loosely adhering concrete, dirt, and dust particles.

10.2 The surface shall have a roughened, textured appearance. Aggregate may be exposed. Bug holes shall be opened.

10.3 The roughened textured appearance shall be similar to the roughness standard established by mutual agreement.

10.4 If specified, the treated surface shall meet the surface strength requirements.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Acid Etching Concrete¹

This standard is issued under the fixed designation D 4260; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice includes surface preparation of concrete to prepare the surface prior to the application of coatings.

1.2 This practice is intended to alter the surface profile of the concrete and to remove foreign materials and weak surface laitance.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For specific hazard statements, see Section 5.*

2. Referenced Documents

D 4262 Test Method for pH of Chemically Cleaned or Etched Concrete Surfaces²

D 4263 Test Method for Indicating Moisture in Concrete by the Plastic Sheet Method²

D 4541 Test Method for Pull-Off Strength of Coatings Using Portable Adhesion Testers²

2.2 Other Standard:

ACI-308 Recommended Practice for Curing Concrete³

3. Summary of Practice

3.1 This practice is intended to provide a clean, contamination-free, and roughened surface.

3.2 Acceptable surfaces shall be free of laitance, form release agents, curing agents, oil, grease, and other penetrating contaminants. The surface shall be free of fins, projections, and loosely adhering concrete, dirt, and dust particles.

3.3 For some applications, a minimum concrete surface strength may be required for proper coating performance.

4. Significance and Use

4.1 This practice is used to prepare concrete for coatings where optimum bond is desired for service conditions such

as continuous or intermittent immersion, temperature cycling, or mechanical loading.

5. Cautions

5.1 New concrete shall be cured in accordance with ACI-308.

5.2 Concrete cure compounds, form release materials, or concrete hardeners may require abrading, in accordance with Practice D 4259, as acid etching may not be effective.

5.3 All oil and grease shall be removed in accordance with Practice D 4258 prior to mechanical abrading, abrasive blast cleaning, water blasting, or acid etching.

5.4 Use and disposal of materials should conform to established federal, state, local, and project requirements.

6. Acid Etching Procedure

6.1 Pre-Surface Preparation:

6.1.1 Remove grease, oil, and other penetrating contaminants (see Practice D 4258).

6.1.2 Remove fins and protruding surface irregularities by mechanical means.

6.1.3 Surfaces shall be free of standing water.

6.1.4 Some curing compounds may not be removed by acid etching and will require preparation by mechanical abrading, abrasive blasting, or water blasting in accordance with Practice D 4259.

6.2 Suitable Surfaces:

6.2.1 This method is primarily suited for use on horizontal surfaces.

6.2.2 Other methods of preparation may be more suitable for rough concrete surfaces and walls or overhead surfaces.

6.3 Acid Etching Solutions:

6.3.1 Typical solutions covered by this method are muriatic (hydrochloric), sulfamic, phosphoric and citric acids. Hydrochloric acid shall not be used where chlorides are prohibited.

6.3.2 The acid concentrations of etching solutions may vary, depending on the concrete texture and degree of etching required.

6.3.3 The concrete surface shall be pre-wet with water prior to applying etching solutions. Free-standing water shall be removed. Uniformly apply the etching solution to the wet surface. Polyethylene sprinkling cans are suitable for applying acid solutions. Bubbling should be uniformly evident. If not, this indicates the presence of grease or oil contamination, or both, curing compounds or sealers, or a need to increase the concentration of the acid solution. Scrub the acid wetted surface with a stiff bristle brush.

6.3.4 When the etching solution bubbling begins to subside, flush surfaces to remove reaction products, and inspect for uniform roughening and removal of laitance. Repeat

application of acid to obtain required surface.

6.3.5 After the desired roughening is achieved, thoroughly flush the surface with potable water. Repeated flushing and scrubbing with a stiff-bristled brush may be necessary to remove acid residues.

6.3.6 The acid etched surface shall be tested for pH in accordance with Test Method D 4262 and may be tested for moisture content in accordance with Test Method D 4263 prior to applying coating.

6.4 Appearance of Prepared Surface:

6.4.1 The intent is to remove sufficient material in order to achieve a sound concrete surface free of laitance, glaze, efflorescence, and incompatible concrete curing compounds or form release agents.

6.4.2 The acid etched surface shall be uniformly roughened to a degree similar in appearance to a medium to coarse grade sandpaper. A roughness standard may be established by mutual agreement.

7 Inspection

7.1 Visually examine the prepared surface for loose ad-

hering concrete, thin crusts bridging voids, fins, and projections.

7.2 Visually examine the prepared surface for oil, grease, and markings.

7.3 Test surfaces cleaned by acid etching for pH in accordance with Test Method D 4263.

7.4 If required, surface strength may be determined in accordance with Method D 4541 or other agreed upon method.

8. Acceptance

8.1 Acceptable surfaces shall be free of laitance, oil, grease, and other materials incompatible with the coating. The surface shall also be free of fins, projections, and loosely adhering concrete, dirt, and dust particles.

8.2 The surface shall have a roughened, textured appearance. Aggregate may be exposed. Bug holes shall be opened.

8.3 A roughness standard may be established by mutual agreement.

8.4 If specified, the treated surface shall meet the surface strength requirements.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Surface Cleaning Concrete Unit Masonry for Coating¹

This standard is issued under the fixed designation D 4261; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers surface cleaning of concrete unit masonry to remove dust, dirt, mortar spatter, oil, and grease prior to the application of coatings. Procedures include vacuum cleaning, air-blast cleaning, water cleaning, detergent water wash, steam cleaning, and mechanical cleaning.

1.2 This practice is not intended to alter the surface profile of the concrete masonry units but to clean the surface.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For specific hazard statements, see Section 5.*

2. Referenced Documents

2.1 ASTM Standards:

D 4258 Practice for Surface Cleaning Concrete for Coating²

D 4262 Test Method for pH of Chemically Cleaned or Etched Concrete Surfaces²

D 4263 Test Method for Indicating Moisture in Concrete by the Plastic Sheet Method²

2.2 Other Standard:

ACI Specification 531.7-76 Specification for Concrete Masonry Construction³

3. Summary of Practice

3.1 Surface cleaning is intended to provide a clean, contamination-free surface suitable for the application of coatings.

3.2 Acceptable surfaces shall be free of dust, dirt, mortar spatter, oil, grease, and other contaminants. Mortar joints shall be struck flush or tooled with a round jointer and shall be free of rough edges and nibs (see ACI 531.1-76).

3.3 Vacuum cleaning, air blast cleaning, water cleaning, detergent water wash, steam cleaning, hand tool, and mechanical cleaning are acceptable cleaning methods.

¹ This practice is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generating Facilities and is the direct responsibility of Subcommittee D33.05 on Surface Preparation.

Current edition approved Aug. 17, 1983. Published November 1983.

² Annual Book of ASTM Standards, Vol 06.01.

³ Available from American Concrete Institute, 22400 W. Seven Mile Rd., Detroit, MI 48219.

3.4 Any one or a combination of listed cleaning procedures may be used to achieve acceptably cleaned surfaces.

4. Significance and Use

4.1 Surface cleaning is to be used to prepare concrete unit masonry surfaces for applying coatings intended for light duty service, splash and spillage of water and chemical solutions, radiation exposure, decontamination, and repeated washdowns with alkaline cleaners.

5. Cautions

5.1 Moisture in concrete unit masonry may be detrimental to coating adhesion. Moisture content shall be in compliance with the coating manufacturer's recommendations (see Test Method D 4263 for moisture test method).

6. Procedures

6.1 *Steam Cleaning*—This procedure is intended to remove heavy deposits of grease and oil, as well as other water soluble surface contaminants and emulsifiable materials, with a jet of high pressure steam, in accordance with Practice D 4258.

6.2 *Detergent Water Wash*—This procedure is intended to remove water soluble surface contaminants, oils, grease, and other emulsifiable materials with an aqueous solution of detergent or nonsolvent emulsifier in accordance with Practice D 4258.

6.3 *Water Cleaning*—This procedure is intended to remove dust, dirt, and water soluble contaminants with a stream of water under pressure, in accordance with Practice D 4258.

6.4 Mechanical Tool Cleaning:

6.4.1 The intent of this procedure is to remove mortar spatter, efflorescence, and similar dry, firmly adhering foreign material prior to performing either cleaning operation.

6.4.2 This procedure shall consist of scraping, abrading, brushing, or stoning to dislodge mortar and similar materials from the surface.

6.4.3 Clean in accordance with Practice D 4258 to remove dust and loose particles.

6.5 *Vacuum Cleaning*—This procedure is intended to remove surface dust and other debris by vacuum cleaning in accordance with Practice D 4258.

6.6 *Air Blast Cleaning*—This procedure is intended to remove debris, dust, dirt, and loosely adhering material by air blast cleaning in accordance with Practice D 4258.

7. Inspection

7.1 Visually examine prepared surface for the presence of debris, dust, dirt, oil, grease, loose particles, mortar spatter, and other contaminants.

7.2 Test surfaces cleaned with detergent or non-solvent emulsifying agents for pH in accordance with Test Method D 4262.

7.3 Moisture content may be determined in accordance

with Test Method D 4263.

8. Acceptance

8.1 Acceptable surfaces shall be free of dust, dirt, mortar spatter, oil, grease, and other contaminants.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for pH of Chemically Cleaned or Etched Concrete Surfaces¹

This standard is issued under the fixed designation D 4262; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the procedure for determining the acidity or alkalinity of concrete surfaces prepared by chemical cleaning or etching prior to coatings.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Definition

2.1 *pH*—a measure of the hydrogen ion concentration and indicates whether a solution is acidic, alkaline, or neutral.

3. Significance and Use

3.1 Chemical cleaning or etching is used to prepare concrete for coating.

3.2 Residual chemicals not removed by water rinsing may adversely affect the performance and adhesion of coatings applied over prepared concrete surfaces. It is the intent of this test method to determine that residual chemicals have been removed by measuring the acidity or alkalinity of the final rinsed surface.

4. Apparatus

4.1 *pH Test Paper*, with a minimum range from 1 to 11

pH units with a capability of measuring in increments of 0.5 pH units.

5. Materials

5.1 *Potable Water*, for rinsing chemically cleaned or etched concrete surfaces.

5.2 *Wet Concrete Surface*, following the final water rinse and before the rinse water has completely drained off the surface.

6. Procedure

6.1 Tear off a strip of test paper, wet with test water and after the color develops, compare with color chart to determine pH.

6.2 The pH of the water used for rinsing shall be determined to establish acceptance criteria. Readings shall be taken at the beginning and end of the final rinse cycle.

6.3 At least two surface pH readings shall be taken for each 500 square feet or portion thereof. Readings shall be taken at randomly selected locations immediately following the final rinse and before all the rinse water has drained off the surface.

6.4 Unless otherwise specified, tests shall be conducted in accordance with this procedure.

7. Acceptance Criteria

7.1 The pH readings following the final rinse shall not be more than 1.0 pH lower or 2.0 points higher than the pH of the rinse water (see 6.2) unless otherwise specified.

¹ This test method is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generating Facilities and is the direct responsibility of Subcommittee D33.05 on Surface Preparation.
Current edition approved Aug. 17, 1983. Published November 1983.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Indicating Moisture in Concrete by the Plastic Sheet Method¹

This standard is issued under the fixed designation D 4263; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

⁶¹ NOTE—Editorial changes were made throughout in September 1988.

Scope

1.1 This test method is used to indicate the presence of capillary moisture in concrete.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For specific caution statements, see Section 4.*

Significance and Use

2.1 Capillary moisture in the concrete may be detrimental to the performance of certain coating systems that cannot tolerate moisture on or within the surface boundary.

2.2 This test method is used prior to the application of coatings on concrete.

Materials

3.1 *Transparent Polyethylene Sheet*, commercially available, approximately 4 mils (0.1 mm) thick.

3.2 *Adhesive Tape* that will adhere to the substrate. (Duct tape 2 in. (50 mm) wide is suggested.)

Cautions

4.1 This test method shall be conducted when the surface

This test method is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generating Facilities and is the direct responsibility of Subcommittee D33.05 on Surface Preparation.
Current edition approved Aug. 17, 1983. Published November 1983.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

temperature and ambient conditions are within the established parameters for application of the coating system.

4.2 Avoid direct sunlight, direct heat, or damage to the plastic sheet, as such treatment affects the reliability of the results.

5. Procedure

5.1 Tape a segment of plastic sheet, approximately 18 by 18 in. (457 by 457 mm), tightly to the concrete surface making sure that all edges are sealed.

5.2 Allow the plastic sheet to remain in place a minimum of 16 h.

5.3 After the allowed time has elapsed, remove the plastic sheet and visually inspect the underside of the sheet and the concrete surface of the patch for the presence of moisture.

5.4 Sampling:

5.4.1 *Floors*—One test area per 500 ft² (46 m²) or portion thereof, of surface areas unless otherwise specified.

5.4.2 *Walls and Ceilings*—One test area per 500 ft² (46 m²) or portion thereof, of surface area unless otherwise specified.

5.4.3 The recommended practice is a minimum of one test for each 10 ft (3 m) of vertical rise in all elevation starting within 12 in. (300 mm) of the floor.

6. Report

6.1 Report the presence or absence of moisture.

7. Precision and Bias

7.1 This test method indicates the presence of capillary moisture. No precision or bias has been established for this test method.

Standard Test Method for Indicating Oil or Water in Compressed Air¹

This standard is issued under the fixed designation D 4285; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method is used to determine the presence of oil or water in compressed air used for abrasive blast cleaning, air blast cleaning, and coating application operations.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For specific hazard statements, see Section 4.*

2. Significance and Use

2.1 Clean compressed air is required to prevent contamination of coating materials and surfaces being prepared for coating. This test method is a visual examination technique for determining oil or water in compressed air. Other types of contamination may require additional analytical techniques for detection.

3. Apparatus and Materials

3.1 *Absorbent Collector*, such as white absorbent paper or cloth and rigid backing for mounting absorbent collector, or

3.2 *Nonabsorbent Collector*, such as rigid transparent plastic, approximately $\frac{1}{4}$ in. thick.

4. Cautions

4.1 To avoid false indications prior to testing:

4.1.1 Allow compressed air system to reach operating conditions, and

4.1.2 Allow air to discharge at operating conditions to remove accumulated condensation in the system.

4.2 Fasten the collector material to the rigid backing. Avoid personal contact with the air stream.

5. Sampling

5.1 Conduct the test on discharging air as close to the use point as possible and after the inline oil and water separators.

6. Procedure

6.1 Use either the absorbent or nonabsorbent collector.

6.2 Position the collector within 24 in. of the air-discharge point, centered in the air stream.

6.3 Adjust air discharge so that the collector remains intact during the test. Allow air to discharge onto the collector for a minimum of 1 min.

6.4 Visually examine the collector for the presence or absence of oil or water, or both.

7. Interpretation of Results

7.1 Any indication of oil discoloration on the collector shall be cause for rejection of the compressed air for use in abrasive blast cleaning, air blast cleaning, and coating application operations.

7.2 Any indications of water contamination on the collector shall be cause for rejection of the compressed air for use in those applications where water is detrimental, such as abrasive blast cleaning, air blast cleaning, and coating application operations.

8. Precision and Bias

8.1 No precision or bias statement has been established for this test method.

¹ This test method is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generating Facilities and is the direct responsibility of Subcommittee D33.05 on Surface Preparation. Current edition approved Sept. 30, 1983. Published December 1983.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Determining Coating Contractor Qualifications for Nuclear Powered Electric Generation Facilities¹

Scope

1.1 This practice provides a criteria guide and procedural method to assist utility owners, architects, engineers, contractors, and other selection agencies in determining the overall qualifications of a coating contractor to execute coating work for the primary containment and other safety-related facilities of light-water nuclear power plants.

1.2 The qualification criteria and requirements address the essential basic capability of a contractor to execute nuclear coating work. Obviously, the specific capability to execute those requirements unique to a given project must also be carefully considered. The evaluation procedure contained in this practice is designed to be adaptive to this detailed final qualification process. Variation or simplification of the practice is appropriate for non safety-related areas of nuclear power plants, fossil fueled facilities, and other industrial projects.

1.3 The overall capability of a contractor to successfully execute the varied and complex requirements of nuclear coating work is dependent upon competency in a variety of essential categories.

1.4 The nine evaluation categories described in Sections 3 through 12 detail the specific data to be provided by the contractor as essential to determining qualification status. In addition, a tenth untitled category has been provided on the evaluation work described in Section 12 for inclusion of other information pertinent to a specific project.

1.5 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Referenced Documents

2.1 ASTM Standard:

D 3843 Practice for Quality Assurance for Protective Coatings Applied to Nuclear Facilities²

D 4537 Guide for Establishing Procedures to Qualify and Certify Inspection Personnel for Coating Work in Nuclear Facilities²

2.2 American National Standard:

N 45.2.6 Qualifications of Inspection, Examination, and Testing Personnel for Nuclear Power Plants³

2.3 Other Standard:

¹ This practice is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generation Facilities and is the direct responsibility of Subcommittee D33.07 on Application.

² Current edition approved March 30, 1990. Published May 1990. Originally published as D 4286 - 84. Last previous edition D 4286 - 84.

Nuclear Regulatory Agency 10 CFR 50 Appendix B, Quality Assurance Criteria for Nuclear Power Plants⁴

3. Personnel

3.1 *Home Office Management and Staff*—Resumes of the following types of personnel including educational background, duration and degree of involvement in industrial coating operations, qualifications, registrations, certifications, and specific experience in nuclear coating work.

3.1.1 *Principals and General Management.*

3.1.2 *Engineering Manager.*

3.1.3 *Project Engineers*—List specific nuclear coating work project involvement.

3.1.4 *QA/QC Manager*—List specific qualification/certification credentials per ANSI N45.2.6, or Guide D 4537, or both.

3.2 *General Field Supervision*—Resumes to include specific nuclear coatings work experience.

3.3 *On-Site Project Supervision:*

3.3.1 Total number of personnel qualified for nuclear coatings work, including specific work history.

3.3.2 Total number available in a specific time frame, if appropriate.

4. Contractor Work Experience

4.1 *General Experience*—List of comparable industrial projects, including type (construction or maintenance), form of contract, dollar volume, scope, and duration (start and completion dates) executed during the past five years. Accompanying this listing provide personnel references to include names, titles, locations, and telephone numbers.

4.2 *Nuclear Coating Work Experience:*

4.2.1 List of nuclear projects including type (construction or maintenance), form of contract, dollar volume, scope, and duration, materials, and equipment involved. Accompanying this listing provide personnel references to include names, titles, locations, and telephone numbers.

4.2.2 If the contractor has executed work comparable to the specific evaluation project, submit complete case histories of scope and functions performed to include personnel references for each case.

5. Equipment

5.1 List contractor-owned equipment in the categories listed in 5.1.1 through 5.1.9. Indicate those items required for the specific evaluation project.

5.1.1 Vehicles.

5.1.2 Surface preparation, all types.

5.1.3 Abrasive control and recovery.

5.1.4 Coatings mixing and application, all types.

⁴ Available from Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402.

- 5.1.5 Environmental control and curing.
- 5.1.6 Rigging and enclosure.
- 5.1.7 Safety.
- 5.1.8 Quality control testing instrumentation.
- 5.1.9 Specialized equipment.
- 5.1.9.1 Unique equipment required for the specific project, if applicable.
- 5.1.9.2 Contractor to indicate and provide examples of capability to design and install highly specialized items of equipment, enclosure systems, devices, etc. which have been utilized on previous nuclear coating projects.
- 5.1.10 *Equipment Repair and Replacement Capability*—Contractor to describe standard procedure followed in the event of equipment failure to prevent lost time situations.

6. Quality Assurance

6.1 *Quality Assurance Program*—The contractor shall submit one copy of his quality assurance program that shall conform to 10 CFR 50 Appendix B, ANSI N 45.2.6, Guide D 4537, Practice D 3843, and other applicable documents. The program shall include implementation procedures and sample forms.

6.2 *Quality Assurance/Quality Control*—List number of personnel qualified in accordance with ANSI N 45.2.6 or Guide D 4537, or both, for each of the following:

- 6.2.1 LEVEL III Inspector,
- 6.2.2 LEVEL II Inspector, and
- 6.2.3 LEVEL I Inspector.

7. Training

7.1 Submit training manual for craft and supervisory personnel. If no formal training program exists, the contractor shall submit evidence of procedures and methods utilized.

8. Safety

8.1 Submit copy of corporate safety program. If no formal program exists, the contractor shall submit evidence of safety procedures and work rules.

9. Production/Cost Control

9.1 Submit explanation of methods and procedures utilized to monitor and regulate personnel and equipment productivity.

9.2 Submit sample of actual report forms utilized to record job progress, labor cost analysis, and equipment deployment efficiency.

10. Financial

10.1 Submit documentation to verify financial capability to manage and execute all project requirements. Include the following data:

- 10.1.1 Current financial statement,
- 10.1.2 Trade references, three or more,
- 10.1.3 Bank references, one or more,
- 10.1.4 Bonding capacity, name of bonding company, and name and address of agent, and
- 10.1.5 Current certificate of insurance.

11. Current and Projected Performance Capability (restricted to specific project considerations)

11.1 Submit a statement indicating current commitment status of personnel, equipment, and management capability. The statement shall include analysis of and ability to fulfill requirements in the following categories:

- 11.1.1 Craft personnel,
- 11.1.2 Staff engineering and supervisory personnel,
- 11.1.3 Management personnel,
- 11.1.4 Equipment, and
- 11.1.5 Materials.

12. Contractor Evaluation Work Sheet

12.1 The sample work sheet shown in Fig. 1 is suggested for consolidation of rating and comparison data. Note that there are nine basic rating categories corresponding to the criteria detailed in the text of this practice. Space for an optional tenth category has been provided for owner insertion of other rating data that may be unique to the specific project involved.

12.2 *Rating Values*—Numerical rating values are structured on the following format:

Rating	Value
Excellent	4
Good	3
Average	2
Poor	1
Unsatisfactory	0
No data	0

12.3 *Weighted Category Values*—Each of the ten (includes option) evaluation categories will be assigned a weighted value by the owner in accordance with the specific requirements of the project. The value scale will range from 1 (least critical) to 10 (most critical). The weighted value of each category will be used as a multiplier to determine the overall rating for each contractor in each category.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for High-Shear Viscosity Using the ICI Cone/Plate Viscometer¹

This standard is issued under the fixed designation D 4287; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the viscosity of paints, varnishes, and related products at a rate of shear of $12\,000\text{ s}^{-1}$.

1.2 Paints and varnishes that dry very rapidly may not give reproducible results with this test method. Measurements made at elevated temperatures may also give poor precision due to loss of volatiles and to drying.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability or regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 1210 Test Method for Fineness of Dispersion of Pigment-Vehicle Systems²

D 3925 Practice for Sampling Liquid Paints and Related Pigmented Coatings²

3. Summary of Test Method

3.1 The material to be tested is placed between the cone and plate of an ICI cone/plate viscometer, then subjected to a high shear rate while the viscosity is determined.

4. Significance and Use

4.1 The viscosity value obtained by this test method gives information about the flow properties of the material under application conditions: brushing, spraying, electrostatic disk, or roll coating.

4.2 This test method is suitable for all paints and varnishes whether they are Newtonian in behavior or not. However, due to the narrow gap between the stationary and rotary parts of high-shear viscometers, this test method is more reproducible for paints having finer pigment dispersions as determined by Test Method D 1210.

5. Apparatus

5.1 *ICI Cone/Plate Viscometer*³ (see Fig. 1) with 0 to 10-P

(0 to 1 Pa·s) or 0 to 5-P cone producing a rate of shear of $12\,000\text{ s}^{-1}$. With higher viscosity materials, other cones (0 to 20 P, 0 to 40 P, 0 to 100 P) may be used on agreement between the producer and the user, but it should be noted that these give lower shear rates ($\sim 3000\text{ s}^{-1}$) not truly representative of application conditions. Other cone/plate viscometers may be used on agreement between the producer and the user as long as the same rate of shear is measured and it is approximately $12\,000\text{ s}^{-1}$. However, results may differ from those produced with an ICI cone/plate viscometer.

NOTE 1—The SI units for viscosity are pascal-seconds (Pa·s, 1 Pa·s = 10 P, 1 mPa·s = 1 cP).

6. Reagents and Materials

6.1 *Water or Solvent*—Water or a low viscosity solvent such as xylene or mineral spirits to be used for zeroing the instrument.

6.2 *Mineral Oils*—Three standard mineral oils with known viscosities (certified by an approved laboratory) lying between 10 and 90 % of full scale.⁴

7. Sampling

7.1 Take a representative sample of the product to be tested in accordance with Practice D 3925. If the sample has a tendency to settle or separate on standing, it must be stirred or shaken until homogeneous before a test specimen is taken from it. The specimen must be free of any foreign matter or air bubbles and its volume must be sufficient to cover the portion of the viscometer plate under the cone when the latter is brought into contact with the plate.

8. Preparation of Apparatus

8.1 Zero the apparatus daily when in regular use, or otherwise before use, by following the procedure in Section 9, but using a low viscosity liquid. If the pointer does not indicate zero, it may be adjusted by means of a lever on the left-hand side of the upper part of the instrument housing. If the instrument cannot be zeroed, it should be returned to the supplier for adjustment.

8.2 Verify the calibration of the apparatus by following the procedure in Section 9, but using standard refined mineral oils having Newtonian characteristics and known viscosities.⁴ If the viscometer pointer reads the correct viscosity (or within 5 % of that value) with two or more oils whose viscosities bracket those of specimens to be tested, then the viscometer readings may be used as is. If the

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.24 on Physical Properties of Liquid Paints and Paint Materials.

Current edition approved Oct. 31, 1988. Published December 1988. Originally published as D 4287 - 83. Last previous edition D 4287 - 83.

² *Annual Book of ASTM Standards*, Vol 06.01.

³ ICI cone/plate viscometers are available from BYK-Gardner, Inc., Gardner Laboratory, 2435 Linden Lane, Silver Spring, MD 20910 and from Research Equipment (London) Ltd., 64 Wellington Rd., Hampton Hill, Middlesex TW12 1JX, England.

⁴ Such oils are available from The Cannon Instrument Co., P.O. Box 16, State College, PA 16801.

FIG. 1 ICI Cone/Plate Viscometer

viscometer readings do not give the correct viscosities for the oils, then a calibration curve must be constructed by taking ICI viscometer readings for three oils and plotting measured viscosity versus specified (correct) viscosity for the oils. Subsequent measurements are corrected to true viscosities through use of the curve.

9.3 Check the cones periodically for wear. Replace any cone that shows a definite flattening of the apex. Some users have found it necessary to replace cones every year.

9.4 The determination must be made at a closely controlled temperature of $25 \pm 0.3^\circ\text{C}$ unless otherwise agreed. In order to check the temperature control, carry out the test as outlined in 9.1 with the standard refined mineral oil of the nearest viscosity. Allow the viscometer to run with this oil for 10 min and determine whether the reading decreases. If the decrease is more than 10 %, the apparatus is unsuitable for the determination of viscosities at high rates of shear in accordance with this test method.

NOTE 2—Multitemperature ICI cone/plate viscometers have heating, but not cooling, capabilities. Therefore, runs with these viscometers at 25°C should only be done at room temperatures at or below 22°C to ensure that the plate temperature does not go above 25°C . The

instruments that operate at 25°C only do have cooling capabilities and give better temperature control.

9. Procedure

9.1 With the cone in the down position, turn the instrument on and allow it to warm up for at least 5 min. For a multitemperature instrument, set the dial at 25°C or to an alternatively agreed upon temperature. Raise the cone to the up position. Transfer a suitable amount of the product to be tested to the plate, taking care to avoid the inclusion of air bubbles, and again lower the cone to the down position. Wait for 30 s to allow the specimen to attain the agreed upon temperature.

9.2 Start the cone rotating and record the reading on the scale (Note 3) when the pointer becomes steady.

NOTE 3—Whether the reading gives a direct indication of the viscosity or not, depends on the cone and scale used.

NOTE 4—In some cases it is difficult to judge whether a constant reading has been obtained. However, if the pointer does not become steady after 15 s, record the reading at 15 s and mention the lack of a constant reading in the test report. If highly accurate readings are required, make the readings below 90 % of the scale.

9.3 If the reading does not directly indicate the viscosity, multiply the reading by the appropriate conversion factor or use the appropriate calibration curve to obtain the viscosity.

9.4 Clean both the cone and the plate carefully, employing a cloth or tissue and a suitable solvent. Take care to remove all of the test material and cleaning solvent. Do not use cleaning utensils that may damage the apparatus. *Metal cleaning tools must never be used.*

9.5 Repeat the determination with a second specimen. If the two viscosity determinations differ by less than 7 %, calculate their mean and report as the high shear viscosity for the material. If they differ by more than 7 %, make a third determination. If no two readings are within 7 % of each other, then the material is not suitable for testing by this test method.

10. Report

10.1 Report the following information:

- 10.1.1 Reference to this test method,
- 10.1.2 Type and identification of the product under test,
- 10.1.3 Type of cone used (0 to 5 P, 0 to 10 P, etc.),
- 10.1.4 Rate of shear at which the determination was made (in reciprocal seconds),
- 10.1.5 Temperature at which the determination was made,
- 10.1.6 Test results in poises, reported to the nearest 1 % of the total range, that is, 0.05 P for 0 to 5 P-cones, 0.1 P for 0 to 10 P-cones, etc.,
- 10.1.7 Any deviation, by agreement or otherwise, from the test procedures described, and
- 10.1.8 Date of the test.

11. Precision and Bias⁵

11.1 *Precision*—On the basis of an interlaboratory test of this test method in which eight operators in four laboratories tested six paints ranging in viscosity from 0.8 to 7.9 P, the

⁵ Supporting data are available from ASTM Headquarters. Request RR-D01-1035.

within-laboratory coefficient of variation was found to be 2.2 %, at 40 df. The between-laboratory coefficient of variation was found to be 6.9 % at 34 df. Based on these results, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

11.1.1 *Repeatability*—Two test results, each the mean of two determinations obtained by the same operator, should be considered suspect if they differ by more than 6.3 % relative.

11.1.2 *Reproducibility*—Two results, each the mean of

two determinations, obtained by operators in different laboratories should be considered suspect if they differ by more than 19.9 % relative.

11.2 *Bias*—Bias has not been determined for this test method.

12. Index Terms

12.1 This test method is indexed under the following terms: viscosity—paints/related coatings/materials; viscometer—ICI cone/plate.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Specification for Artists' Oil, Resin-Oil, and Alkyd Paints¹

This standard is issued under the fixed designation D 4302; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

- 1.1 This specification establishes requirements for composition, physical properties, performance, and labeling of artists' oil, resin-oil, and alkyd paints.
- 1.2 This specification covers pigments, vehicles, and additives. Requirements are included for pigment identification, lightfastness, consistency, and drying time.
- 1.3 Table 1 lists some pigments meeting the lightfastness requirements in this specification. In order to identify other pigments that meet these requirements, instructions are given for test specimen preparation. Test methods for determining relative lightfastness are referenced.

E 284 Terminology of Appearance of Materials⁶

3. Terminology

3.1 Definitions:

3.1.1 *Colour Index Name*—consists of the category (type of dye or pigment), general hue, and an assigned number given to a colorant in the Colour Index⁷ as an international identification system.

3.1.1.1 *Discussion*—For example, the Colour Index Name of one phthalocyanine blue pigment is Pigment Blue 15 (PB 15).

3.1.2 *Colour Index Number*—a five-digit number given in the Colour Index that describes the chemical constitution of a colorant.

3.1.2.1 *Discussion*—For example, the Colour Index Number of one phthalocyanine blue pigment is 74160.

3.1.3 Refer to Terminology E 284 for appearance terms used in this specification.

3.2 Descriptions of Terms Specific to This Standard:

3.2.1 *alkali refined oil*—triglyceride oil of vegetable origin that has been treated with alkali to reduce the free acidity by formation of water-soluble salts, subsequently removed by washing.

3.2.1.1 *Discussion*—An appreciable degree of free acidity may cause a greater development of yellowing in a dried film of oil. Most artists' oil paints are ground in alkali refined oil.

3.2.2 *alkyd paint*—paint containing a resin produced by combining a polybasic acid, a polyhydric alcohol, and the fatty acid of a drying vegetable oil. For this specification, the resin produced must be soluble in mineral spirits or turpentine.

3.2.3 *drier (siccative)*—a substance, usually an organometallic compound, that accelerates the rate of drying of an oil paint or oil medium.

3.2.4 *oil paint*—paint containing an alkali refined triglyceride drying oil of vegetable origin.

3.2.5 *resin-oil paint*—paint containing 90 weight % minimum of vehicle solids, vegetable drying oil, and 10 weight % maximum of vehicle solids replaced by gum or resin.

4. Significance and Use

4.1 This specification establishes quality requirements and provides a basis for common understanding among producers, distributors, and users.

4.2 It is not intended that all paints meeting the requirements be identical nor of uniform excellence in all respects.

⁷ *Colour Index*, 3rd ed., 5 Vols and Revisions, The Society of Dyers and Colourists, London, 1971-75. Available from the American Association of Textile Chemists and Colorists, P. O. Box 12215, Research Triangle Park, NC 27709.

TABLE 1 Suitable Pigments List

NOTE—Underlined Information and the lightfastness rating in the table shall be included on every label.

Key:

Lightfastness Category:

Lightfastness I Excellent Lightfastness

Lightfastness II Very Good Lightfastness

Abbreviations Used in Colour Index Names:

NR Natural Red
PB Pigment Blue
PBk Pigment Black
PBr Pigment Brown
PG Pigment Green
PO Pigment Orange
PR Pigment Red
PV Pigment Violet
PW Pigment White
PY Pigment Yellow

Pigment Notations:

(BS) Blue shade
(CC) Concentrated cadmium pigments may contain up to 15 % barium sulfate for color control. Cadmium-barium pigments contain a much higher amount of barium sulfate.
(DL) May darken in strong light
(LF) Lightfast type
(NA) Colour index name or number not assigned
(NR) Not rated as lightfastness I or II
... Not tested
(RS) Red shade
(SM) Sensitive to moisture in direct sunlight
(SS) Sensitive to hydrogen sulfide

^A Applies only to Permanent Red Violet MRS, product of American Hoechst Corp., Coventry, RI 02816. Pigments described as thioindigoids have varying degrees of lightfastness.

Variations in manufacture, not covered by this specification, may cause some artists to prefer one brand over another, either of which may be acceptable under this specification.

5. Labeling Requirements

5.1 Pigment(s) Identification:

5.1.1 Every label shall include for each pigment contained in the paint (1) the information underlined in Table 1 (which includes the Common Name, Colour Index Name, and any additional terms necessary to identify the form of the pigment) and (2) the appropriate Lightfastness Category.

5.1.2 The complete pigment identification given in Table 1, which also includes the Colour Index Number and a simple chemical description, shall be given in an appropriate producer publication. Manufacturers are encouraged to put this complete identification on the container label when label size permits.

5.1.3 The Common Name shall be placed on the front of the label and shall be the name of the paint except as described in 5.1.5 and 5.1.6. Other identification may be

placed elsewhere on the container.

5.1.4 The Colour Index name may be spelled out in full or abbreviated depending on the size of the label. Examples: Pigment Blue 15, or Pig. Blue 15 or PB 15.

5.1.5 *Substituted Pigment*—In the case of substituted pigments, the word "Hue" in equal size letters shall follow in the title, on the front of the tube, immediately after the name of the pigment that has been simulated. Directly below the title, the Common Name of the significant pigment used shall be given in letters no less than the next type size smaller than the title. For example:

COBALT BLUE HUE
(ULTRAMARINE BLUE).

5.1.6 Proprietary names or optional names may be used provided the Common Name(s) given in Table 1 appears on the front of the label directly under the proprietary or optional name in letters no less than the next type size smaller than the proprietary or optional name.

5.1.7 *Mixed Pigments*—Artists' paints containing more than one colorant comply with this specification if all

colored pigments used are on the suitable pigment list (Table 1) and provided the mixture itself has passed all other test requirements in this specification. The lightfastness category shall be that of the least lightfast pigment. This lightfastness category may be changed if these paints are tested for lightfastness in accordance with Test Methods D 4303 and results indicating a different category are submitted to ASTM Subcommittee D01.57 for evaluation.

5.2 Provide on the label:

5.2.1 *Artists' Oil Paints*—Vegetable origin of the oil and method of refinement.

NOTE 1—The type of oil can be identified in accordance with Test Method D 2245.

5.2.2 *Artists' Alkyd Paints*—Type of fatty acid used. If free vegetable oil is used in combination with an alkyd resin, declare this also on the label. State if compatible with artists' oil paints.

NOTE 2—The type of alkyd can be identified in accordance with Practices D 2689.

5.2.3 *Artists' Resin-Oil Paints*—Vegetable origin and method of refinement of the oil and type of resin or gum. If the colors in a resin-oil paint line contain more than one, or different, gums or resins, the identification on the individual labels may uniformly include all of the gums or resins used in the paint line. Example: "Damar or Mastic Gum." State if compatible with artists' oil paints.

NOTE 3—The type of oil can be identified in accordance with Test Method D 2245.

5.3 *Lightfastness*—The label shall contain the word "lightfastness" followed by the appropriate rating, I or II, as given for each pigment in Table 1.

5.3.1 Lightfastness I pigments, when made into paint specimens as described in Section 8 and exposed, tested, and rated in accordance with Test Methods D 4303, shall have a color difference (ΔE^*_{ab}) of 4 or less CIELAB units between the specimens measured before and after exposure.

5.3.2 Lightfastness II pigments, when made into paint specimens as described in Section 8 and exposed, tested, and rated in accordance with Test Methods D 4303, shall have a color difference (ΔE^*_{ab}) of more than 4.0 but not more than 10 CIELAB units between the specimens measured before and after exposure.

5.3.3 Pigments were placed in a lightfastness category on the basis of either known historical performance in art works or the ratings from four lightfastness tests conducted as described in Test Methods D 4303. Results from further tests on these, or other pigments, are solicited by Subcommittee D01.57.

5.3.3.1 The lightfastness category of a pigment shall be changed if results from several further tests conducted in accordance with Test Methods D 4303 and approved by ASTM Subcommittee D01.57, establish a different lightfastness category than the one given in Table 1.

5.3.3.2 Additional pigments shall be placed in Table 1 if they have been tested for lightfastness in accordance with Test Methods D 4303 and the test results submitted to ASTM Subcommittee D01.57 for evaluation, provided the results demonstrate that the pigments have the lightfastness ratings required for Lightfastness I or Lightfastness II, as described above.

5.3.4 For information and to establish nomenclature, pigments in Lightfastness III category are given in Table X1.1 in Appendix X1, but are not to be used in paint conforming to this specification. These pigments have a color difference before and after exposure of more than 8.0 but not more than 16.0 CIELAB units.

5.4 *Contents*—To be expressed in volumetric measure as required by law.

5.5 *Toxicity*—All products and labeling must conform to the Federal Hazardous Substances Act and to Practice D 4236.

5.6 *Statement of Conformance*—"Conforms to ASTM Specification D 4302," or "Conforms to ASTM D 4302," or "Conforms to the quality requirements of ASTM D 4302." This statement may be combined with other conformance statements, such as, "Conforms to the quality and health requirements of ASTM Specification D 4302 and Practice D 4236."

5.7 *Address*—Include on the label (1) the name and address of the manufacturer or importer and (2) the country of manufacture.

6. Quality Assurance for Artists' Oil Paints and Artists' Resin-Oil Paints

6.1 *Conditions Not Covered in This Specification that Affect Artists' Oil and Resin-Oil Paints:*

6.1.1 *Substrate*—Factors such as the texture, gloss, effective pH, porosity, chemical composition, and condition of the substrate will affect gloss, gloss uniformity, drying time, adhesion, and the flexibility of the dried film.

6.1.2 *Environmental Conditions*—Factors such as temperature, humidity, air flow, and light conditions affect application properties, film formation, drying time, and adhesion.

6.1.3 *Storage*—With aging and elevated temperatures, there may be a change in consistency and a separation of oil from the paste paint.

6.2 *Vehicles*—Only vegetable drying oils shall be used in artists' oil paints. Resin-oil paints shall contain 90 weight % minimum of vehicle solids, vegetable drying oil (see Note 1), and 10 weight % maximum of vehicle solids replaced by gum or resin.

6.3 *Pigments*—Pigments to be used in oil paints shall be limited to those listed in the column labeled "Oil" and pigments to be used in resin-oil paints shall be limited to those listed in the column labeled "Resin-Oil" in Table 1. Their lightfastness rating shall be the numeral given in the same row. Those pigments listed as "not tested" shall not be used.

6.4 *Driers*—Driers may be used in minimal amounts in paints that contain a pigment which has a retarding effect on the drying of oil. This is allowed so these paints can conform to the drying requirements of this specification.

6.5 *Inerts*—Minimal amounts of inert pigments may be used to produce desirable working qualities and consistency, to prevent separation, to develop chromatic properties, or to ensure the durability of the paint film.

6.6 *Preparation of Sample*—Empty the contents of a previously unopened container onto a glass slab and mix thoroughly with a spatula to a homogeneous sample.

6.7 *Nonvolatile*—The nonvolatile content shall not be less than 97 weight % for the oil paints and 90 weight % for the

resin-oil paints, as determined by Test Method D 2369.

6.8 *Coarse Particles*—Paints shall be free of oversize particles and shall form a uniform film. The maximum content of coarse particles shall be 1 weight % as determined by Test Methods D 185.

6.9 *Fineness of Dispersion*—On a glass plate, using a spatula, mix the paint with an equal volume of linseed oil until homogeneous. If the paint is very thick, it may be necessary to add a minimum amount of mineral spirits or turpentine to make the paint sufficiently fluid to read the gage accurately. Determine the fineness of dispersion by Test Method D 1210. The maximum allowable grind reading is 1.5 mils (40 μ m).

6.10 *Consistency*—The paste type of paint shall not flow or level when applied with a palette knife.

6.11 *Drying*—Using a film applicator with a 3-mil (75- μ m) clearance, make a uniform drawdown on a lacquer-sealed panel. At a relative humidity of 50 to 75 % and a temperature of 65 to 80°F (18 to 27°C), the dust-free drying time, as determined by Test Methods D 1640, shall not be more than ten days.

6.12 Tinting strength requirements will be included in this specification as appropriate tinting strength standards for individual pigments are established. Test Method D 387 may be used to determine the tinting strength of pigments or paints when all ingredients are known. Test Method D 4838 can be used to determine the relative tinting strength of chromatic paints containing a single pigment and the same vehicle but where other ingredients are unknown.

7. Quality Assurance for Artists' Alkyd Paints

7.1 *Conditions Not Covered in This Specification that Affect Artists' Alkyd Paints:*

7.1.1 *Substrate*—See 6.1.1.

7.1.2 *Environmental Conditions*—See 6.1.2.

7.1.3 *Storage*—With aging and elevated temperatures, there may be a change in consistency and possible solvent loss. Some separation of the medium is also possible.

7.2 *Vehicles*—Only alkyds that are soluble in mineral spirits or turpentine may be used in artists' alkyd paints. Free vegetable drying oils may be included in artists' alkyd paints up to 25 weight % of the vehicle solids.

7.2.1 The amount of yellowing in a vehicle should not exceed the yellowing of a linseed oil paint. To assess excessive yellowing of the alkyd vehicle or alkyd vehicle/drying vegetable oil blend used in alkyd artists' paints, put the vehicle including its usual drier and all additives in the following formula:

	Weight %
Alkyd vehicle under test including driers	22
Mineral spirits	11
Rutile titanium white* (conforming to Type II of Specification D 476)	30
China clay	14
Blanc fixe (conforming to Specification D 602)	22
Anti-skinning agent	1

NOTE 4—More or less mineral spirits may be used for ease of brushing.

* DuPont R900 Rutile titanium dioxide, manufactured by E. I. du Pont de Nemours & Co., 1007 Market St., Wilmington, DE 19898, has been found satisfactory for this purpose.

7.2.2 Prepare a white oil paint using the same titanium white dispersed in alkali refined linseed oil. Make specimens from the alkyd and oil paints as directed in Test Methods D 4303, and expose them to light filtered through glass using Test Method 1 and either Test Method 2 or Test Method 3 as described in the Procedure section of Test Methods D 4303.

7.2.3 Following exposure check that the alkyd specimens are the same or less yellow than the oil specimens exposed by the same test method. (Use Practice D 1729 or Test Method D 2244 to determine amount of yellowing.)

7.3 *Pigments*—Pigments shall be limited to those recommended for use in alkyd paints in the column labeled "Alkyd" in Table 1. Their lightfastness rating shall be the numeral given in the same row. Those pigments listed as "not tested" shall not be used.

7.4 *Driers*—Minimal amounts of driers may be used to allow paints to conform to the drying requirements of this specification.

7.5 *Inerts*—See 6.5.

7.6 *Sampling*—See 6.6.

7.7 *Coarse Particles or Foreign Matter*—See 6.8.

7.8 *Fineness of Dispersion*—On a glass plate, using a spatula, mix the paint with linseed oil in a one-to-one volumetric ratio until homogeneous. If the paint is very thick, it may be necessary to add a minimum amount of turpentine or mineral spirits to make the paint sufficiently fluid to read the gage accurately. Determine the fineness of dispersion in accordance with Test Method D 1210. The maximum allowable grind reading is 1.5 mils (40 μ m).

7.9 *Drying*—Using a film applicator with a 3-mil (75- μ m) clearance, make a uniform drawdown on a lacquer-sealed panel. At a relative humidity from 50 to 75 % and a temperature from 65 to 80°F (18 to 27°C), the dust-free drying time shall be not more than 2 days or less than 30 min.

8. Lightfastness Determination

8.1 If a pigment is not listed in Table 1, test specimens of a paint containing the pigment shall be prepared. These test specimens shall be tested in accordance with the requirements for exposure and evaluation given in Test Methods D 4303.

NOTE 5—A report of the results of these tests may be submitted to Subcommittee D01.57 for inclusion of the pigments in Table 1. The report shall include information on test conditions and instruments used and shall be accompanied by test specimens, which will be returned.

8.2 Materials:

8.2.1 *Aluminum Exposure Panels*⁹ 3 by 6 in. (75 by 150 mm).

8.2.2 *Posterboard*, lightweight, approximately 20 mils (0.5 mm) thick, having a glossy finish on one side.

8.2.3 *White Soya Alkyd Enamels* used to prepare white ground coats.

8.2.4 *White Artists' Paints*—Depending on the vehicle in which the pigments are to be tested:

8.2.4.1 Titanium dioxide yellowing-resistant oil paint,

⁹ The No. A-36 Aluminum Panel, manufactured by The Q-Panel Co., 26200 First St., Cleveland, OH 44145, has been found satisfactory for this purpose.

8.2.4.2 Titanium dioxide yellowing-resistant alkyd paint,

8.2.4.3 Titanium dioxide yellowing-resistant resin-oil paint.

8.2.5 *Spray Apparatus*, for applying ground coats.

8.2.6 *Paint Brush*, 2.5 in. (60 mm) wide for applying ground coats if spray apparatus is not available.

8.2.7 *Soft Hair Brush*, 1 in. (25 mm) wide for applying ground coats to aluminum panels. An oxhair artists' "stroke" brush is suitable.

8.3 *Summary of Method:*

8.3.1 Pigments to be tested are dispersed in the appropriate vehicle and diluted with a standard mixing white of the same type of vehicle until the spectrophotometric measurement of the dried film reads from 35 to 45 % reflectance at the wavelength of maximum absorption for that pigment. Prepared artists' paints of known composition may be tested.

8.4 *Specimen Preparation:*

8.4.1 *Ground Coats:*

8.4.1.1 For two ground coats to be used under oil, alkyd, and resin-oil paints, prepare the following enamel:

	Weight %
Medium oil length soya alkyd, 50 % nonvolatile ¹⁰	20
Rutile titanium chloride ⁸ (conforming to Type II of Specification D 476)	40
Blanc fixe (conforming to Specification D 602)	40
Driers 0.15 % zinc and 0.15 % zirconium as metal on the alkyd nonvolatile	
Sufficient mineral spirits for milling	

8.4.1.2 Mill to a Hegman fineness of 7 as measured by Test Method D 1210. Thin with mineral spirits to appropriate viscosity for spraying or for flow coating by brush.

NOTE 6—These soya alkyd enamels are used for the ground coats because of their color stability, nonabsorbency, adhesion of the specimen coats under humid conditions, and freedom from blistering that occur with an acrylic ground coat under high humidity.

8.4.2 *Application of Ground Coats:*

8.4.2.1 Degrease aluminum substrates before applying the ground coat.

8.4.2.2 Under oil, alkyd, and resin-oil paints, apply two coats of the enamel described in 8.4.1.1 to the aluminum or posterboard supports, either by spraying or by flow coating with a brush. To flow coat the aluminum panels for sun exposure use a 1-in. (25-mm) soft-hair brush. Coat the posterboard to be used for laboratory exposure on the less absorbent, glossy side.

NOTE 7—Coating the posterboard is most conveniently done on the sheet before cutting to size.

8.4.2.3 Allow a minimum of five days drying time following the first coat and two weeks or more before applying the specimen to be tested.

8.4.3 *Mixing Whites for Dilution of Colors:*

8.4.3.1 For oil paints use the following white:

	Weight %
Alkali refined safflower oil	22.5
Aluminum distearate	2.0
Rutile titanium dioxide ⁸ (conforming to Type II of Specification D 476)	30.0
Blanc fixe (conforming to Specification D 602)	39.5
Zinc oxide (conforming to Specification D 79)	6.0

8.4.3.2 Mill to a Hegman fineness of 7 as measured by Test Method D 1210.

8.4.3.3 Keep the viscosity of the mixing white to 250 P or slightly lower.

8.4.3.4 For diluting alkyd paints use the following white containing two alkyd resins:

	Weight %
Medium oil length soya alkyd, ¹⁰ 62 % oil length, 70 % nonvolatile, white spirit as volatile	10
Medium oil length soya alkyd, 62 % oil length, 51 % nonvolatile, mineral spirits as volatile	12
Mineral spirits	11
Rutile titanium dioxide ⁸ (conforming to Type II of Specification D 476)	30
Blanc fixe (conforming to Specification D 602)	16
China clay	14
Anti-skinning agent	1
Zinc oxide (conforming to Specification D 79)	6

8.4.3.5 Mill to a Hegman fineness of 7 as measured by Test Method D 1210.

8.4.3.6 For diluting resin-oil paints, use the following white:

	Weight %
Alkali refined safflower oil	20.7
Aluminum distearate	2
Damar resin dissolved in 3 % mineral spirits (Note 8)	1.8
Rutile titanium dioxide ⁸ (conforming to Type II of Specification D 476)	30
Blanc fixe (conforming to Specification D 602)	39.5
Zinc oxide (conforming to Specification D 79)	6

NOTE 8—The kauri-butanol value of the mineral spirits shall be ≥ 40 as determined by Test Method D 1133.

8.4.3.7 Mill to a Hegman fineness of 7 as measured by Test Method D 1210.

8.4.4 *Preparation of Test Paints:*

8.4.4.1 The pigment to be tested may be milled in a concentrated paste in a resin-oil vehicle. If a prepared resin-oil artists' paint of known composition is available, it may be used for this test.

8.4.4.2 Dilute the pigment paste or paint with the white given in 8.4.3.6 until the spectrophotometric measurement of the dried film shows 35 to 45 % relative reflectance at the wavelength of maximum absorption for that pigment. The wavelength of maximum absorption is located at the point of lowest reflectance on the spectral curve between 420 and 620 nm. If using a tristimulus filter colorimeter, the lowest of the three filter readings is the region of maximum absorption and the dilution should be adjusted so that a reading of 35 to 45 % reflectance is obtained with this filter. The diffuse white reference standard for all measurements should have an absolute reflectance between 97 and 100 %.

8.4.4.3 To obtain this reflectance, use the Kubelka-Munk Single Constant Method described in Appendix X2 or use a trial and error method.

8.4.4.4 Make instrumental readings with the specular reflectance included to minimize the effect on readings of

¹⁰ The following alkyd resins have been found satisfactory for this purpose: All No. 51-5196; McWhorter, DURAMAC 2409; Reichhold, No. 11-035; Amer-Kellog, AROPLAZ 1082 M50.

any change in gloss and to minimize the effect of brush strokes.

8.4.4.5 Use an applicator with a 6-mils (150- μ m) aperture to make a minimum size drawdown, $1\frac{1}{2}$ by $1\frac{1}{2}$ in. (40 by 40 mm), or other minimum size appropriate for the viewing area of the instrument used. Return all recoverable paint to the batch to allow for repeat mixes and measurements.

8.4.4.6 For oil, alkyd, or resin-oil paint, an initial amount of 40 g of white paint is sufficient if specimens are read wet and recoverable paint is returned to the batch. If the instrument provides a way to read wet paint behind glass, and specimens measured this way fall within the accepted range when dry, this method can be used.

NOTE 9—Another suggested method for reading oil paints while wet is to cut from 0.013-mm thick kitchen plastic wrap (such as Saran wrap) the minimum size piece that will protect the instrument and then die-cut a hole in the proper location $\frac{1}{4}$ in. (3.2 mm) smaller than the instrument aperture. Rubbing the plastic several times with a paper towel or tissue imparts sufficient static charge that the protective plastic adheres to the instrument enabling the operator to center the hole on the aperture. The wet oil paint drawdown can then be placed in position, taking care not to disturb the plastic shield.

8.4.4.7 For the initial weights of white stated in 8.4.3.1, 8.4.3.4 and 8.4.3.6 the weighing must be accurate to 0.05 g.

8.4.5 Application of Paints to Panels:

8.4.5.1 Prepare four specimen panels on appropriate substrates for each pigment under test. Two are used in the first lightfastness tests and two are retained in subdued light, one for visual comparisons with the exposed panels and one in case a third test is needed to supplement results from the first two tests, as described in Procedure section Test Methods D 4303.

8.4.5.2 Apply the test paints by brush to the aluminum or posterboard exposure panels described in 8.2, depending on

whether exposure is to be under glass to the sun or to laboratory apparatus.

8.4.5.3 Using the No. 12 artists' flat bristle brush, brush the panels lengthwise, then crosswise, and again lengthwise, this time with a light touch to produce a film as smooth as possible. The mixing whites must be fluid enough to facilitate leveling, but not have excess vehicle that can affect the test. Do not use thinners. Oil-paint brushouts retain minor striations. Apply two coats to all specimen panels to achieve complete opacity.

8.4.5.4 Allow specimens to dry between coats as described in the Procedure section (Dry-Through or Dry-to-Handle Time) of Test Methods D 1640. After recoating, allow specimens to dry hard, as described in the Procedure section (Dry-Hard Time) of Test Methods D 1640, before measuring them prior to exposure. General guidelines for drying times are one to two months to dry hard for oil and resin-oil paints; three days between coats for alkyd paints; and five days after recoating.

8.4.5.5 When testing alkyd paints, prepare and expose a specimen of the mixing white along with the colored specimens diluted with this white. Since the purpose of these lightfastness tests is to evaluate any color change in the pigments, if the white yellows appreciably during exposure, adjust any color change between unexposed and exposed colored specimens to eliminate the effect of this yellowing.

9. Exposure

9.1 Conduct exposure tests in conformance with Test Methods D 4303. Assign lightfastness categories as described in Section 8 of Test Methods D 4303.

10. Keywords

10.1 artists' alkyd paints; artists' oil paints; artists' resin-oil paints; lightfastness; quality requirements; test specimens

APPENDICES

(Nonmandatory Information)

X1. LIGHTFASTNESS III

X1.1 The pigments in Table X1.1 are not sufficiently lightfast to be used in paints that conform to this specification. These pigments are listed here solely to establish

common terminology. They may be satisfactory when used full strength (without dilution) or with extra protection from exposure to light.

TABLE X1.1 Lightfastness III

Colour Index Name	Lightfastness Category		Common Name and Chemical Class	Colour Index Number
	Oil	Alkyd		
PR 83	III	III	Alizarin Crimson; synthetic 1:2 dihydroxyanthraquinone on alumina base	58000
PR 83	III	...	Rose Madder, Alizarin, synthetic 1:2 dihydroxyanthraquinone on alumina base, more dilute than Alizarin Crimson	58000
PR 146	III	...	Naphthol Red, naphthoic arylide	12485
PR 181	III	...	Thioindigoid Magenta, thioindigoid	73360

X2. KUBELKA-MUNK SINGLE CONSTANT METHOD FOR PREPARING PAINT FILMS $40 \pm 5\%$ REFLECTANCE

X2.1 Prepare a mixture of white and colorant in proportions estimated to give a paint having a reflectance of 30 to 40 % at the wavelength of maximum absorption. Calculate the concentration of colorant in white in this batch.

$$C_c = W_c / W_w + W_c$$

where:

C_c = concentration of colorant, and
 W_w and W_c = weight of white and colorant, respectively, used in the batch.

Draw or brush a film of this paint over contrast paper at a thickness sufficient to give complete visual hiding.

X2.1.1 After allowing the film to dry, measure the reflectance of this film at the wavelength of maximum absorption with a spectrophotometer or, if using a colorimeter, the reflectance with the filter that gives the lowest reading (Note X2.1). Calculate the Kubelka-Munk Single Constant Value of this reflectance as follows:

$$(K/S)_m = [1 - (R_m - 0.04)]^2 / 2(R_m - 0.04)$$

where:

$(K/S)_m$ = Kubelka-Munk Value,
 R_m = reflectance measurement of the mixture, made with the specular component included expressed as a decimal value, and
 0.04 = decimal value correction for surface reflectance.

NOTE X2.1—To speed drying, accelerated methods may be used. It is recommended that water-based acrylic paints be warmed to 50 to 55°C or 2 h after 1 h of air drying before measuring the reflectance. Placing the drawdowns of oil paints near fluorescent lamps, for example in the fluorescent light exposure racks described in Annex A1 of Test Methods D 4303, will speed their drying time.

X2.1.2 Calculate the Kubelka-Munk absorption coefficient for unit concentration as follows:

$$K_c = (K/S)_m / C_c$$

where K_c = unit absorption coefficient.

X2.2 Based on the results of the trial mixture, calculate the concentration of colorant in white required to give the desired 35 to 45 % reflectance at the wavelength of maximum absorption as follows:

$$C_d = (K/S)_{40\%} / K_c = 0.4500 / K_c$$

where C_d = concentration of colorant in white predicted to give a paint with the desired 35 to 45 % reflectance value.

X2.3 Adjust the concentration of the trial batch so that the concentration of colorant equals C_d . Determine the changes in colorant concentration, ΔC , as follows:

$$\Delta C = C_d - C_c$$

These changes are positive if the trial batch has a reflectance greater than 40 % and negative if the reflectance is less than 40 %. If ΔC is positive, add more colorant to the trial batch to bring the concentration of colorant to C_d . If ΔC is negative, add more white to bring the concentration of colorant to C_d . Because it may be necessary to add large amounts of white to correct for concentrations of colorant giving reflectance values far below 40 %, it is usually best to prepare a trial batch expected to give a ΔC value that is moderately positive or only slightly negative.

X2.3.1 For the case where ΔC is positive, determine the weight of colorant needed to prepare a second batch as follows:

$$\Delta W_c = W_c - C_d(W_w + W_c) / C_d - 1 \times (L.F.)$$

where:

ΔW_c = weight of colorant to be added to the trial batch to obtain a corrected batch with a colorant concentration of C_d , and

L.F. = loss factor = weight of paint from trial batch used to prepare the corrected batch/weight of paint prepared as trial batch.

The loss factor, L.F., allows for paint removed to prepare drawdowns, loss by transfer to different containers, etc. This term may be neglected if losses are small compared to the batch size. The other terms are as defined in the previous sections of this appendix.

X2.3.2 For the case where ΔC is negative, the weight of white needed to prepare a corrected batch corresponds to,

$$\Delta W_w = W_c - C_d(W_w + W_c) / C_d \times (L.F.)$$

where ΔW_w = weight of white needed to adjust the colorant concentration in the batch to C_d . Other terms are as defined above or in previous sections of this appendix.

X2.4 Prepare a paint film from the adjusted batch. After drying, measure the reflectance at the wavelength of maximum absorption. If this value does not fall within 35 to 45 %, repeat X2.3 through X2.4, where C_d now becomes the C_c for the next batch correction. Normally only a single iteration is necessary and a second batch correction will not be needed.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Methods for Lightfastness of Pigments Used in Artists' Paints¹

This standard is issued under the fixed designation D 4303; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 Three test methods consisting of exposure to light (natural sunlight or simulated sunlight) filtered through glass are described as follows:

- 1.1.1 *Test Method A*—Exposure under glass to the sun,
- 1.1.2 *Test Method B*—Exposure to irradiance from artificial daylight fluorescent lamps, and
- 1.1.3 *Test Method C*—Exposure in xenon-arc lightfastness apparatus.

1.2 These test methods are used to approximate the color change that can be expected over time in pigments used in artists' paints in normal indoor exposure.

NOTE 1—The color changes that result from accelerated exposure may not duplicate the results of normal indoor exposure in a home or gallery. The relative resistance to change, however, can be established so pigments can be assigned to categories of relative lightfastness.

1.3 Lightfastness categories are established to which pigments are assigned based on the color difference between specimens before and after exposure.

1.4 Color difference units are calculated by the CIE 1976 $L^*a^*b^*$ color difference equation.

1.5 These test methods apply to artists' oil, resin-oil, acrylic emulsion, alkyd, and watercolor paints.

1.6 *This standard does not purport to address the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 *Definitions*—Appearance terms used in this standard are defined in Definitions E 284.

4. Summary of Test Methods

4.1 Color measurements are made on specimens that have been prepared as directed in Specification D 4302, D 5067, or D 5098 depending on the vehicle. The measurements are recorded for comparison with readings made after the specimens have been exposed.

4.2 Specimens are exposed to light filtered through glass using at least two of the three test methods described in Section 7.

4.3 The pigments are classified by color difference calculated in accordance with Test Method D 2244.

5. Significance and Use

5.1 The retention of chromatic properties by a pigment over a long period of years is essential in an artistic painting. Accelerated exposure simulates color changes that may reasonably be expected. The producer and the user of artists' paints, therefore, can be apprised of suitable pigments.

6. Apparatus

6.1 *Sun Exposure Facilities* as described in Practice G 24 using an exposure angle of 45°, facing the Equator.

6.2 *Xenon-Arc Lightfastness Apparatus* as described in Practice G 26:

6.2.1 If water-cooled xenon-arc devices are used (Types AH or BH of Practice G 26), use borosilicate glass inner and soda lime outer filters to simulate sunlight filtered through window glass.

6.2.2 If air-cooled xenon-arc devices are used (Types C, D or E of Practice G 26), use the combination of optical filters recommended by the manufacturer to simulate sunlight filtered through window glass.

6.3 *Fluorescent Lamp Lightfastness Apparatus*, using

⁴ Annual Book of ASTM Standards, Vols 06.01, 08.03, and 14.02.

Verilux F48T12VLX/HO lamps⁵ and constructed in accordance with instructions given in Annex A1.

6.4 *Spectrophotometer*, abridged spectrophotometer or colorimeter capable of including specular reflectance in its measurement.

Procedure

7.1 Specimens of pigments to be tested in oil, resin-oil, or alkyd panels shall be prepared as directed in Specification D 4302. Specimens of pigments to be tested in acrylic emulsion paints shall be prepared as directed in Specification D 5098. Specimens of pigments to be tested in watercolors shall be prepared as directed in Specification D 5067.

7.2 Immediately before exposure, measure all test specimens on a spectrophotometer (see Test Method E 1348 or E 1349) or colorimeter (see Test Method E 1347) with the specular reflection included in the measurement and record. These results shall be compared with subsequent readings of the exposed specimens to calculate color difference, or with readings of retained specimens made at the time of visual comparison or before beginning corroborative tests to assure that there has been no color change in the interval.

7.2.1 Read specimen panels always with the striations in the same direction and with panels in the same position. If the design of the instrument allows, three readings at different locations on the panel should be made and the mean calculated. If feasible, mark on the back of the specimen the spot(s) measured, and re-measure these same spots following exposure.

7.2.2 If it is necessary to store specimens in the dark for a period of time, prior to measurement and exposure, those that contain oil in the vehicle shall be placed in subdued light for seven days to eliminate any yellowing of the oil due to storage.

7.3 Expose specimen panels to light passing through glass, either to natural sunlight or to simulated daylight in laboratory apparatus. Oil, resin-oil, alkyd, and acrylic emulsion paint specimens shall be exposed by Test Method A⁶ and other Test Method B or Test Method C. Watercolors and other paints sensitive to moisture shall be exposed by Test Methods B and C.

7.3.1 *Test Method A—Exposure Under Glass to Natural Sunlight:*

7.3.1.1 Mount the specimens on an open type rack and expose at 45° angle to the vertical to a total radiation dose of 1260 MJ/m² in accordance with Practice G 24.

7.3.1.2 For tests in southern Florida expose panels during the months of October through May.

7.3.2 *Test Method B—Exposure to Simulated Daylight (Fluorescent Lamp Type):*

7.3.2.1 Mount the specimens with the test face 3 in. (75

mm) from the plane of the lamps.

7.3.2.2 Unless specified otherwise, expose the specimens to a repeating cycle of 8 h light followed by 4 h dark until the specimen has been exposed to a total radiant energy dose of 1260 MJ/m². Rotate the specimen panels two positions to the right after each 100 MJ/m² dose. This test method takes approximately nine months to complete.

7.3.2.3 Maintain the ambient room temperature at 24 ± 3°C and prevent the test chamber from exceeding room temperature by more than 6°C.

7.3.2.4 Monitor irradiance at the specimen location for total radiation for each rotation period. Measure radiation 1 h after the lamps are turned on and at the end of the period. The mean of these readings in joules per square centimetre (J/cm²) per hour multiplied by the number of hours of radiation gives the J/cm² for that period.

7.3.3 *Test Method C—Exposure to Simulated Daylight (Xenon-Arc Type):*

7.3.3.1 Mount specimens in unbacked holders avoiding positions that place specimens at the extreme top or bottom of the specimen rack.

7.3.3.2 Unless specified otherwise, expose specimens continuously to a total radiant dose of 1260 MJ/m² in accordance with Practice G 26, Test Method C. Maintain the relative humidity in the test chamber at 55 ± 5 % and a black panel temperature of 63 ± 2°C.

NOTE 2—When mutually agreed upon, an alternative dark cycle may be employed in accordance with Test Method D of Practice G 26, optical filter combination (c), and test conditions reported. It has been found that Alizarin Crimson, and possibly other pigments, are affected by a light and dark cycle, owing to the oxidation-reduction effect of titanium dioxide changing valence with the changes from light to dark and vice versa, characteristic of daylight and indoor light.

7.3.3.3 When continuously monitoring irradiance with a narrow bandpass radiometer, the dosage at the monitored wavelength may be calculated knowing the total and spectral irradiance from the lamp operating at a specified wattage, using the equation:

$$Q_{e\lambda} = 3.6 (10^3) t E_{e\lambda} \quad (1)$$

where:

λ = wavelength bandpass expressed in nanometres, nm,

Q_e = radiometric symbol for radiant exposure, J/m²,

$3.6 (10^3)$ = a constant, s/h, for converting hours to seconds,

t = time expressed in hours, h, and

E_e = radiometric symbol for irradiance, W/m².

NOTE 3—1 W = 1 J/s.

NOTE 4—An example is given in Appendix X1.

7.4 Measure test specimens immediately after exposure with specular reflection included in the measurement and record.

7.5 Calculate the color difference between the specimen before exposure and after exposure in accordance with the CIE 1976 L*a*b* color difference equation in Test Method D 2244. State the color change in total color difference units (ΔE^*_{ab}).

7.6 Visually check the exposed specimen against the unexposed specimen of the same paint kept in subdued light, in order to verify that the color difference stated in ΔE^*_{ab} units agrees with visual assessment. Make this check also

⁵ The Verilux lamps manufactured by Verilux, Inc., P.O. Box 1512, Greenwich, CT 06836, are temporarily not available. Other fluorescent lamps that closely simulate daylight may be suitable, and Subcommittee D01.57 seeks information that will allow these fluorescent lamps to be recommended. Lamps should have a correlated color temperature of 6000 ± 500 K and a color rendering index of at least 90 as calculated by Method of Measuring and Specifying Colour-Rendering Properties of Light Sources, International Commission on Illumination (CIE) Publication No. 13.2 (TC-3.2), 1974. Available from the U.S. National Committee for the CIE, c/o Director of Marketing, OEM Division, North American Philips Lighting Corp., Philips Square CN8800, Somerset, NJ 08873.

following any subsequent exposures.

7.7 Since all test methods can produce aberrant results in pigments that are sensitive to some aspect of a particular type of exposure, assign pigments to lightfastness categories based on results from a minimum of two of the methods described in 7.3.1 through 7.3.3. Four exposures are preferred but there may be fewer in many cases using the following procedure:

7.7.1 Unless specified otherwise, expose one specimen inland outdoors under glass to sunlight in southern Florida below 27° latitude following Test Method A and expose the second specimen indoors to simulated daylight following either Test Method B or Test Method C. Place pigment in the appropriate category if both tests indicate the same category and neither result is within $\pm 0.5 \Delta E^*_{ab}$ of the borderline between categories.

7.7.2 If the results from the first two tests place the pigment in different lightfastness categories, or if either of the test results fall within $\pm 0.5 \Delta E^*_{ab}$ of the dividing line between two categories, either assign the pigment to the poorer of the two categories involved or for a more accurate rating, proceed with the third exposure. The third exposure may use either the method not used in the two previous exposures, or may repeat the exposure which gave the poorer result, providing the two test results are within $4 \Delta E^*_{ab}$ of one another. To guard against accepting an aberrant test result, if there is more than $4 \Delta E^*_{ab}$ difference between the first two test results, use the method not employed in the first two tests for the third exposure.

7.7.3 Calculate the mean of the color differences from the three exposures to determine the appropriate lightfastness category unless one of them differs from the nearest test result by more than $4 \Delta E^*_{ab}$, or the mean is within $\pm 0.5 \Delta E^*_{ab}$ of the dividing line between categories. In these cases make a fourth exposure.

7.7.4 For the fourth exposure use the method not previously employed, or if all three methods have been used, for the fourth exposure repeat the method with poorest result, unless the results from that method differs from the nearest other test result by more than $4 \Delta E^*_{ab}$. In this case, discard this one test result. Calculate the mean of the test results from the four exposures, or three exposures if one has been discarded, to determine the lightfastness category.

8. Interpretation of Results

8.1 *Lightfastness I*—Assign pigments that exhibit a mean color change of 4 or less ΔE^*_{ab} to Lightfastness Category I.

8.2 *Lightfastness II*—Assign pigments that exhibit a mean color change of more than 4.0 but not more than 8.0 ΔE^*_{ab} to Lightfastness Category II.

8.3 *Lightfastness III*—Assign pigments that exhibit a

mean color change of more than 8.0 but not more than 16.0 to Lightfastness Category III.

8.4 Since some exposed specimens have lost all color at a color difference of 20 units, additional categories are not appropriate for artists' paints.

9. Report

9.1 *Materials Tested*—Report the pigment tested, the name of the manufacturer, and the vehicle used in the test.

9.2 *Exposure*—Report the methods of exposure and their duration.

9.2.1 For Test Method A, in addition to the requirements of Practice G 24, report the total radiation dose in MJ/m².

9.2.2 For Test Method B, identify the apparatus used, including types and numbers of lamps, specimen to lamp distance, panel rotation sequence, light-dark cycle, method of monitoring radiation, exposure dosage in MJ/m², and test chamber and room temperature.

9.2.3 When using Test Method C, report as directed in Practice G 26.

9.3 *Test Results*—Report ΔE^*_{ab} for each pigment and the lightfastness category to which each is assigned.

10. Precision

10.1 Variation in test results can result from differences in pigment manufacture from time to time within a company, different varieties of a pigment from company to company, specimen preparation, different instruments and instrumental readings, variations in the surface of the specimen and the conditions of exposure. Allowance for these variables is made by requiring more than one test and by establishing lightfastness categories that include a range of color differences.

10.2 To establish the relationship between test methods, sets of 172 paint specimens, 90 in oil and 82 in acrylic emulsion vehicle, were made at the same time by one person and exposed in four sets of lightfastness tests: southern Florida sun filtered through glass, Kansas sun filtered through glass, fluorescent apparatus, and Xenon-arc apparatus.

10.2.1 All four tests placed 73 % of the pigments in the same category. When 12 aberrant test results were dropped from consideration and the third and fourth exposures conducted as required in cases where test results are near the border line between lightfastness categories (see 8.2), all combinations of the test results placed 99 % of the pigments in the same category.

ANNEX

(Mandatory Information for Test Method B)

A1. FLUORESCENT DAYLIGHT LAMP LIGHTFASTNESS APPARATUS

A1.1 The apparatus for exposing paint specimens to fluorescent irradiation is shown in a large size version in Fig. A1.1 and in a smaller version in Fig. A1.2. Figure A1.3 provides the dimensions and arrangement for constructing the larger size apparatus out of materials that are easily available.

A1.2 *Cabinet Construction*—Make framework for the apparatus out of $1\frac{1}{2}$ by $1\frac{1}{2}$ by $\frac{1}{8}$ -in. (40 by 40 by 3.2-mm) aluminum angle available in hardware stores. The supports and the remainder of the enclosure are $\frac{1}{8}$ -in. tempered hardboard. The exposure panel supports, which are also the apparatus sides, are made removable by being fastened by reversed bolts with wing nuts. Coat them on the interior side with a non-yellowing white paint. Four reflectors, which each can hold four fluorescent lamps, are fastened together by the $1\frac{1}{2}$ -in. angles, back to back, to form a square in the center of the cabinet facing the specimens, which are attached to the hardboard panels support as shown in Fig. A1.3. Construct

NOTE—Pyranometer, recorder, and demand readout meter in place.
(a) Four-Bank Fluorescent Exposure Apparatus that Handles One hundred and eight 3 by 6-in. Panels

FIG. A1.1 Apparatus for Exposing Paint Specimens to Fluorescent Irradiation

NOTE—Notice hole for mounting Eppley pyranometer which is attached at right.
(b) Four-Bank Verilux Fluorescent Exposure Apparatus with One Panel Open

FIG. A1.1 Apparatus for Exposing Paint Specimens to Fluorescent Irradiation Continued

the framework so that the lamps are 3 in. (75 mm) from the test specimens. Cut holes in each side adjacent to the center and centered on a panel location to accommodate an Eppley pyranometer. With one panel space missing on each panel bank, the cabinet accommodates 108 test panels.

A1.3 *Irradiation*—The reflector fixtures hold sixteen 48 in. (1.2 m) long high powered Verilux⁶ lamps with a correlated color temperature of 6000 K and a spectral irradiance simulating sunlight.

A1.3.1 Irradiance can be monitored by a spectral radiometer or a filter radiometer which has been calibrated to provide information on the total spectral radiant exposure.

⁶ Verilux F48T12VLX/HO lamps have recessed double contact sockets and use a four gang fixture, Series 152 Industrial Fixture for Four High Output Lamps. Both are manufactured by Verilux, Inc., P.O. Box 1512, Greenwich, CT 06836. The lamps are temporarily not available.

NOTE—Pyranometer, recorder, and demand readout meter in place.

FIG. A1.2 Single-Bank Device of Four Verilux Daylight Fluorescent Lamps that Handles Twenty-seven 3 by 6-in. Panels

A1.3.2 Install a timer, shown as K in Fig. A1.3, to cycle exposure for 8 h of light followed by 4 h of dark.

A1.3.3 Install an electric time meter in the circuit, shown as N in Fig. A1.3 to record the total amount of time the lamps are turned on.

A1.4 *Temperature and Humidity Control*—Install a centrifugal blower unit at the base of the cabinet, shown as I in Fig. A1.3. The air from the blower passes immediately through an air filter O and, after passing through the specimen exposure area, is vented out through the top of the cabinet. The blower furnishes the filtered air draft that keeps the temperature in the cabinet to within 6°C of the ambient

temperature of the room. The small 6°C temperature rise is sufficient to limit the humidity in the cabinet to about 60% relative humidity even when the general humidity is very high. Install a thermometer in the top of the cabinet near the vent and away from any direct illumination from the lights.

A1.5 If preferred, a smaller open apparatus holding a single bank of four Verilux daylight fluorescent lamps may be constructed as shown in Fig. A1.2. A small fan blowing through the unit from one end furnishes the air draft, but otherwise the apparatus must have the same distance between lamps and specimens and the same monitoring equipment described in A1.2 and A1.3.

Fluorescent Daylight Lamp Apparatus Showing One of Four Sides

FIG. A1.3 Dimensions for Constructing Apparatus

APPENDIX

(Nonmandatory Information)

X1. EXAMPLE OF DOSAGE CALCULATION

X1.1 The calculation is as follows:

Given: Total dose, $Q_T = 1260 \text{ MJ/m}^2$

Assume: Total irradiance, $E_t = 1000 \text{ W/m}^2$

Spectral irradiance, $E_\lambda = 0.5 \text{ W/m}^2$

where λ = wavelength of measured spectral irradiance.

$$Q_T = 3.6 (10^3) t E_T$$

$$1260 (10^6) = 3.6 (10^3) t (1000)$$

$$\text{so } t = 1260 (10^6) / 3.6 (10^6) = 350 \text{ h}$$

Thus, if the total irradiance from an energy source remains constant at 1 kW/m^2 , 350 h are required to provide a total dose of 1260 MJ/m^2 .

X1.2 If the spectral irradiance at wavelength, λ , remains

constant, then the spectral irradiation, Q_λ , or the control dosage, is calculated by the equation, as follows:

$$Q_\lambda = 3.6 (10^3) t E_\lambda$$

$$Q_\lambda = 3.6 (10^3) 350 (0.5),$$

$$Q_\lambda = 630 (10^3) \text{ J/m}^2, \text{ or}$$

$$Q_\lambda = 630 \text{ kJ/m}^2.$$

(X1.2)

X1.3 The time required to obtain this dosage may be varied by varying the spectral irradiance. For $E_\lambda = 0.25$, the exposure time will double to 700 h.

X1.4 If the fluorescent lamp system requires nine months to accumulate 1260 MJ/m^2 when the lamps operate two thirds of the time, about 4380 h, then the mean irradiance from the lamps would be:

$$E_T = 1260 (10^6) / 3.6 (10^3) 4.38 (10^3) = 75.1 \text{ W/m}^2 \text{ (X1.3)}$$

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Determining Whether a Material Is a Liquid or a Solid¹

This standard is issued under the fixed designation D 4359; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

Scope

- 1.1 This test method covers the determination of whether a viscous material is a liquid or a solid for regulatory purposes.
- 1.2 The values stated in inch-pound units are to be regarded as the standard.
- 1.3 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Referenced Documents

- D 1 ASTM Standards:
 - D 3925 Practice for Sampling Liquid Paints and Related Pigmented Coatings²
 - E 300 Practice for Sampling Industrial Chemicals³

Summary of Test Method

- 2.1 The material under test is held at 100°F (38°C) in a tightly closed can. The lid is removed and the can inverted. The flow of the material from the can is observed to determine whether it is a solid or a liquid.

Significance and Use

- 3.1 Compliance with regulations often requires the determination of whether a material is a liquid or a solid. A similar test is used by the U. S. Department of Transportation for this purpose.

Apparatus

- 4.1 Can, quart (1 L), friction top with lid, diameter approximately 4 1/4 in. (108 mm), height 4 3/4 in. (120 mm).
- 4.2 Oven, maintained at a temperature of 100°F (38°C).
- 4.3 Tripod or Ring Stand.
- 4.4 Watchglass, tared.
- 4.5 Stopwatch.
- 4.6 Ruler.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.22 on Health and Safety.

² Current edition approved May 25, 1990. Published July 1990. Originally published as D 4359 - 84. Last previous edition D 4359 - 84.

³ Annual Book of ASTM Standards, Vol 06.01.

⁴ Annual Book of ASTM Standards, Vols 06.03 and 15.05.

6. Sampling

- 6.1 Using standard sampling techniques, secure a representative sample from the lot or batch being tested, in accordance with Practices D 3925 or E 300.

7. Test Specimen

- 7.1 If the sample is supplied in a friction top quart can that is at least 85 % full, use the can and material as supplied.
- 7.2 If not, place the material to be tested into the quart can, filling it to at least 85 % and allowing enough ullage for expansion of the material without displacement of the cover. Tightly close the can so that no vapor escapes.

NOTE—The can is considered 85 % filled when the material level is no more than 3/4 in. (20 mm) below the lip of the can.

8. Procedure

- 8.1 Place the can with the material in an oven maintained at 100 ± 5°F (38 ± 3°C). Allow the contents of the can to come to temperature equilibrium (18 to 24 h).
- 8.2 Place the tripod or ring stand on a level surface.
- 8.3 After the material has come to temperature equilibrium take the can from the oven and immediately remove the lid. With the ruler, measure the distance from the surface of the material to the top of the lip of the can and record.
- 8.4 Invert the can onto the tripod or ring stand in a vertical position over the tared watchglass. If a skin has formed on the surface of the material, break the skin prior to inverting the can. Determine the flow of the specimen out of the can at the end of 3 min, by measuring the vertical distance the material has flowed from the lip of the can to the tip of the specimen.
- 8.5 Add the distance from the surface of the material to the top of the lip of the can (8.3) to the distance the material has flowed below the lip of the can (8.4).
- 8.6 If there is an appreciable flow from the can before the 3 min are up, that is, more than 2 in. (50 mm), immediately stop the test and place the can in an upright position.
- 8.7 Collect any free-flowing material onto the tared watchglass and weigh.

9. Interpretation of Results

- 9.1 A material that flows a total of 2 in. (50 mm) or less within 3 min is considered a solid. Otherwise, it is considered a liquid.
- 9.2 If 1 g or more of liquid is collected on the watchglass, the viscous specimen is considered a liquid regardless of its flow characteristics.

10. Precision and Bias

10.1 *Precision*—It is not practical to specify the precision of this procedure as the results of the test are reported only as the state of the material under test.

10.2 *Bias*—Since there is no accepted reference material

suitable for determining the bias, no statement is made.

11. Keywords

11.1 regulations; sample definition; viscous material characterization

Standard Test Method for Apparent Tack of Printing Inks and Vehicles by the Inkometer¹

This standard is issued under the fixed designation D 4361; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

1.1 This test method covers the procedure for determining the apparent tack of printing inks using a mechanical or electronic model of the Inkometer.

1.2 This test method is applicable to paste-type printing inks and vehicles that are essentially nonvolatile under ordinary room conditions.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Terminology

2.1 Descriptions of Terms Specific to This Standard:

2.1.1 *tack*—a function of the force required to split a thin film of a printing ink or vehicle between two rapidly separating surfaces; it is a rheological parameter indicative of internal cohesion of the fluid.

2.1.1.1 *Discussion*—Tack of a printing ink or vehicle is not a fixed number but varies with operating conditions, primarily separation velocity, splitting area, and film thickness. Tack also varies with changes in the rheological properties of the ink or vehicle due to time, temperature, and interactions with the separating surfaces. In practice, one or more of these surfaces usually consist of rubber-like rollers that differ in composition and geometry and whose properties tend to change with age, nature of previously run fluids, type of wash-up solvent, and mechanical flaws. On laboratory instruments, tack readings are also sensitive to the calibration and zero accuracy of the tackmeter employed.

2.1.2 *apparent tack*—a tack reading obtained at a specific set of conditions.

2.1.3 *flying*—the tendency of a printing ink or vehicle to be ejected, as large globules from a roller distribution system.

2.1.3.1 *Discussion*—Flying is generally most severe during rapid roller acceleration such as occurs when switching immediately from zero or a slow speed to a high operating speed.

2.1.4 *misting*—the tendency of a printing ink or vehicle to be ejected as a fine aerosol from a roller distribution system.

2.1.4.1 *Discussion*—Misting is generally most severe at

high operating speeds and with fluids that produce long filaments.

3. Summary of Test Method

3.1 A thin film of the test printing ink or vehicle is applied to the three-roller distribution system of the Inkometer, which operates at speeds comparable to those on production printing presses. Measurement of the frictional torque induced by drag forces in the splitting film provides an arbitrary value for apparent tack. On mechanical models, the torque is determined with a manually balanced lever arm, a direct-reading attachment, or a recorder; on electronic models, with a digital readout, recorder, or printer. Readings are in units of gram-meters (g-m).

3.2 The procedure in this test method is designed to give a single value for apparent tack at a specific set of Inkometer conditions. Typical conditions are as follows: a cooling water temperature of 90°F (32.2°C); a volume of 1.32 mL (film thickness 12.3 μ m) of the test printing ink or vehicle applied to the rollers; an operating speed of 400 r/min for vehicles, 800 r/min for sheet-fed offset inks, and 1200 r/min for web-fed inks; and a reading after 1 min of operation. Alternative conditions may be used by agreement between the supplier and the customer.

3.3 Instructions are also given for calibration of the Inkometer and for minimizing effects of interactions among the rollers, test fluids, and wash-up solvents.

4. Significance and Use

4.1 Tack of printing inks controls their high-speed transfer properties, as manifested by throughput in roll milling, picking of paper during printing, and wet trapping in multicolor printing. Although an apparent tack measurement does not completely predict the transfer performance of an ink or a vehicle, it provides a meaningful parameter for quality control, development, and research.

4.2 A given Inkometer will produce repeatable results on a day-to-day basis only if proper attention is paid to calibration and maintenance procedures and to control of experimental variables referred to in 2.1.1.1.

4.3 Two or more Inkometers may not produce identical apparent tack readings, but if each gives repeatable results, they may be mathematically correlated.

NOTE 1—Besides the Inkometer, a number of three-roller tackmeters are available which differ in design features such as roller weight, geometry, and composition. It cannot be presumed that test results from these other types of tackmeters will either agree or correlate with those from the Inkometer.

This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.56 on Printing Inks. Subcommittee D01.37 on Ink Vehicles assisted in the development of the vehicle portion of this test method.

Current edition approved Oct. 27, 1989. Published December 1989. Originally published as D 4361 - 84. Last previous edition D 4361 - 84.

5. Interferences

5.1 *Inkometer Squeal*—A high pitched whine or squeal may be noted when running high tack fluids or at high rotating speeds, or both. Inkometer squeal may result in instability of the balance beam or direct reading attachment of the mechanical Inkometer or fluctuation of the digital readout of the electronic Inkometer, making definite readings difficult.

6. Apparatus

6.1 *Inkometer*²—one of five models differing in available speeds and type of readout as follows:

6.1.1 *Mechanical Models B-45³, C-45³, or MBC*, operating at fixed speeds of 400, 800 and 1200 r/min on the B-45; 400, 1200, and 2000 r/min on the C-45; and 400, 800, 1200 and 2000 r/min on the MBC. A direct reading attachment² or a recorder² is recommended to supplement the manually operated balance beam.

6.1.2 *Electronic Models 101-A¹ or 101-B*, operating at variable speeds ranging from 100 to 2000 r/min on the 101-A and from 100 to 3000 r/min on the 101-B. A recorder² or printer², or both, are recommended to supplement the digital readout.

NOTE 2—To convert to units of linear speed, multiply Inkometer revolutions per minute by 0.785 to obtain feet per minute or by 0.004 to obtain metres per second.

6.2 *Inkometer Rollers*,² of suitable composition, preferably one set for each major system to be evaluated (see 10.3.1.) A set consists of a top (measuring) roller 3½ in. (79 mm) in diameter and 6½ in. (155 mm) in length, and a vibrator 2.0 in. (51 mm) in diameter and 7¼ in. (184 mm) in length. Together with the fixed brass roller, the total surface area of the distribution system is 166 in.² (0.107 m²). The measuring roller weighs 9.2 lb (4.2 kg) on mechanical models and 9.6 lb (4.4 kg) on electronic models.

6.3 *Ink Pipet*, consisting of a metal cylinder and a metal or TFE-fluorocarbon plunger. Suitable pipets include the fixed-volume Inkometer pipe,² 1.32-mL capacity; and variable volume micropipets,⁴ 2-mL capacity, accurate to 0.01 mL.

6.4 *Stopwatch or Timer*, accurate to 1 s.

6.5 *Ink Knife*, small, free from nicks and rough edges.

6.6 *Manufacturer's Calibration Apparatus*,² for the specific model Inkometer.

7. Reagents and Materials

7.1 *Wash-Up Solvent*, compatible with the test system, fast evaporating, and having minimal effect on the rollers; it should be acceptable environmentally. Hydrocarbon solvents with an initial boiling range of 250 to 350°F (120 to 177°C), a final boiling range of 300 to 400°F (150 to 205°C), a Kauri-Butanol value of 30 to 40 and less than 1 % benzene content are appropriate for many sheet-fed and heat-set

systems. Specific solvents may be required for unique systems.

7.2 *Rags or Wipers*, clean, soft, absorbent, lint-free.

7.3 *Manufacturer's Current Manual*,² for the specific model Inkometer.

8. Hazards

8.1 Never let an ink or a vehicle dry completely on the rollers of the Inkometer.

8.2 **Caution**—Never turn the ZERO button except during the calibration process (see 12.2.1).

8.3 Take care not to damage the rollers during the cleaning process or by leaving them in contact when the instrument is not in use.

8.4 Do not disengage the balance beam of the mechanical Inkometer except when taking a reading.

9. Sampling and Test Specimen

9.1 Carefully select a sample that is free of skin and other contamination and representative of the lot being evaluated. A minimum of 3 to 4 mL is sufficient for two specimens. Transfer to a clean container, protect with skin paper, close and seal.

9.2 When ready to make a run (see 12.3), fill the ink pipet as follows: Transfer 1.5 to 2 mL of sample to a clean glass plate; close and reseal the container. Gently work up with an ink knife but do not aerate. Fill the ink pipet with 1.32 mL of the worked sample (or with a smaller volume (0.5 to 1.0 mL) if a thinner film thickness is desired). Use the ink knife to force the specimen into the cylinder while slowly pulling back the ram. Wipe excess material off the top of the pipet.

NOTE 3—A specimen volume of 1.32 mL, divided by the roller surface area of 0.107 m², gives an initial film thickness of 12.3 µm when distributed uniformly on the roller system of the Inkometer. However, the occurrence of appreciable flying or misting will result in loss of specimen from the rollers. Hence, operating film thickness is unknown.

10. Preparation and Conditioning of the Inkometer

10.1 Locate the Inkometer on a sturdy bench in a draft-free temperature-controlled environment, preferably 73.5 ± 3.5°F (23 ± 2°C). Humidity control is necessary for test samples that are moisture-sensitive or prone to misting.

10.2 Set the Inkometer water bath at 90.0 ± 0.2°F (32.2 ± 0.1°C). All tests are to be run at this temperature. (See also Annex A1.3.)

10.3 Prior to use, ascertain the nature of the test sample for the following reasons:

10.3.1 *Roller conditioning*—Use only an Inkometer having rollers well broken in for the type of test system. The break-in procedure is given in Annex A1.2. A separate set of broken-in rollers is mandatory for radiation curing systems. The necessity for separate sets of broken-in rollers, or for extensive reconditioning when switching among different types of conventional test systems shall be determined in each laboratory.

10.3.2 *Operating speed*—Vehicles are most commonly run at 400 r/min, alternatively at 800 r/min; sheet-fed inks at 800 r/min, alternatively at 400 or 1200 r/min; and web-fed inks at 1200 r/min, alternatively at 800 or 2000 r/min. (The conversion to linear speed is given in Note 2.)

² Available from Thwing-Albert Instrument Company, 10960 Dutton Rd., Philadelphia, PA 19154.

³ No longer manufactured.

⁴ Available from I.G.T. Reptest B.V., 1004 Berlin, Cherry Hill, NJ 08034, Pantone, Inc., 55 Knickerbocker Rd., Moonachie, NJ 07074, or Eastern Scientific, 1459 Lower Ferry Rd., Trenton, NJ 08618.

10.4 Prior to the first use of the day, equilibrate the Inkometer as follows:

10.4.1 Warm up the instrument by activating the water washing system. Engage the two composition rollers and run at the lowest available speed for about 30 min.

10.4.2 Make a conditioning run with a specimen representative of the system to be evaluated. Apply 1 to 1.5 mL of ink or vehicle, and run for 5 to 10 min at the specified speed (see 10.3.2). Clean up as directed in Section 13.

11. Calibration of the Inkometer

11.1 Calibrate the Inkometer before initial use and periodically as needed. First, conduct the necessary steps in 10.3 and 10.4.

11.2 Using the manufacturer's calibration apparatus, follow the directions in the instrument manual.

11.2.1 *Mechanical Models*—Zero and calibrate the balance beam (and direct reading attachment or recorder, if they are to be used) at the test speed specified in 10.3.2.

11.2.2 *Electronic Models*—Zero and calibrate the digital readout (and recorder, if it is to be used) at 1000 r/min. When calibration is completed, check the dry reading at the specified test speed (see 10.3.2).

NOTE 4—The Inkometer can be calibrated at only one speed.

11.3 After each calibration or at regular periods, make a test run with a standard ink or vehicle. (See Annex A1.5.)

12. Procedure for Tack Evaluation

12.1 If necessary, make preparations as in 10.3 and 10.4, and calibrate the Inkometer as in Section 11. If using an electronic model, make sure the motor is preset to the test speed specified in 10.3.2 and the drive is in the LOW mode.

12.2 Engage the rollers and run at the specified test speed. If the dry reading differs from zero by more than ± 0.5 g-m, clean the rollers in accordance with 13.1 or recalibrate in accordance with Section 11.

12.2.1 The dry reading on a properly calibrated instrument is directly related to the condition of the top (measuring) roller; therefore, large deviations from zero are suspect. Usual causes are inadequate cleaning, residual sample or wash-up solvent, or mechanical damage. *Do not push the ZERO button, as doing so will shift the scale. Do not attempt to compensate by subtracting the dry reading from the test reading. Always reclean or recalibrate.* Should large deviations from zero persist, contact the manufacturer about the possibility of serious mechanical damage.

12.3 Turn the Inkometer off, disengage the rollers, and fill the pipet as in 9.2. Transfer its contents to the vibrator in a series of thin ribbons around the middle 5 in. (125 mm) of the roller. Wipe any specimen remaining in the pipet onto a clean place on the same roller. Reengage the rollers.

12.4 Distribute the specimen on the rollers and start the run as follows:

12.4.1 *Mechanical Models C-46 and B-45:*

12.4.1.1 Manually turn the motor coupling about ten revolutions, or until the specimen appears evenly distributed among the three rollers.

12.4.1.2 Set the gears at 400 r/min, start the motor and the stopwatch simultaneously, and let the ink distribute for 15 s. Stop the motor but not the stopwatch.

12.4.1.3 Quickly switch the gears to the test speed (specified in 10.3.2) and immediately restart the motor, noting the time on the stopwatch.

12.4.2 *Mechanical Model MBC:*

12.4.2.1 Place the fingertips against the sides of the brass roller and manually turn about ten revolutions, or until the specimen appears evenly distributed among the three rollers. Do not touch the surface of the rollers.

12.4.2.2 Place the speed control switch at the 150 r/min position. Simultaneously depress the power switch on the Inkometer and start the stopwatch. Let the ink distribute for 15 s.

12.4.2.3 Quickly reposition the speed control switch to the test speed, noting the time on the stopwatch.

12.4.3 *Electronic Models:*

12.4.3.1 Place the fingertips against the sides of the brass roller and manually turn about ten revolutions, or until the specimen appears evenly distributed among the three rollers. Do not touch the surface of the rollers.

12.4.3.2 Depress the DRIVE button and simultaneously activate the stopwatch. Let the ink distribute for 15 s at the automatic LOW speed of 150 r/min.

12.4.3.3 Quickly switch to the test speed (preset in 12.1) by depressing the HIGH/LOW button again, noting the time on the stopwatch.

12.5 After 60 s of running at the test speed, record the apparent tack of the test specimen from the balance beam (see Annex A1.4); direct-reading attachment, or the recorder of a mechanical Inkometer or the digital readout, recorder, or printer of an electronic Inkometer.

12.6 *Optional*—Rather than restrict the test to a single apparent tack determination, valuable information may, in some cases, be gained by continuing the run, taking readings at uniform time intervals (facilitated by the use of a recorder) until the apparent tack begins to decrease. Alternatively, the Inkometer speed may be varied stepwise and a tack reading taken after a specified time at each speed.

12.7 After the run, stop the Inkometer and clean up, as directed in Section 13.

12.8 Make a replicate test with another specimen of the same sample by repeating 12.2 through 12.6. The two tests should agree within the repeatability given in Table 1.

13. Wash-up Procedure

13.1 With the Inkometer running at the lowest speed, apply a small amount of wash-up solvent to the rollers. Remove most of the specimen from the system by placing pads of the clean, soft, absorbent lint-free rags or wipers firmly against the bottom of the brass roller. Repeat this procedure with additional solvent and pads until the rollers are free from ink or vehicle. If any material remains on the edges of the composition rollers, remove very gently with a solvent-moistened rag.

NOTE 5: *Caution*—Remove material directly from the measuring or vibrator rollers with extreme care. Undue pressure will cause uneven wear of the rollers and may place significant strain on the torsion bar of the electronic Inkometer. Use extreme care to ensure that the cleaning pad does not go through the roller nip; otherwise, serious mechanical problems may result and recalibration will be essential.

13.2 Dry the rollers thoroughly by running them in

TABLE 1 Standard Deviation and Precision of Apparent Tack Readings

Samples	Inkometer Type	Speed of Rollers, r/min	Standard Deviation				Repeatability		Reproducibility	
			Within-laboratory		Between-laboratory		1 min	5 min	1 min	5 min
			1 min	5 min	1 min	5 min				
Ink	mechanical	800	0.49	0.47	0.52	0.97	2.0	1.8	2.0	3.8
	electronic	800	0.31	0.46	0.67	1.26	1.2	1.8	2.6	5.0
Vehicles	electronic	400	0.38	0.37	1.30	1.60	1.1	1.0	3.8	4.7
	electronic	800	0.26	...	1.20	...	0.7	...	3.4	...

contact at high speed for a minimum of 5 min or until all of the solvent has evaporated.

13.3 Check the zero reading as in 12.2. Continue cleaning and drying until the dry reading reaches 0 ± 0.5 g-m.

13.4 When the rollers are satisfactorily clean, stop the Inkometer and disengage the measuring and vibrator rollers.

13.5 Clean the pipet, the ink knife, and the glass plate with a solvent-wet rag.

14. Report

14.1 Report the following information:

14.1.1 Complete identification of the sample,

14.1.2 Inkometer model used,

14.1.3 Test speed,

14.1.4 Ambient temperature,

14.1.5 Any modifications to this test method,

14.1.6 Whether significant flying or misting was observed,

14.1.7 Whether Inkometer squeal was noted during the test,

14.1.8 Average apparent tack reading of two determinations, and

14.1.9 Any additional apparent tack readings determined at constant speed-constant time intervals or varying speeds-constant time intervals.

15. Precision and Bias

15.1 Precision:

15.1.1 In an interlaboratory study⁵ of this test method six

inks with a broad range in tack were measured for apparent tack ten times at 1 min and 5 min on mechanical Inkometers in six laboratories and on electronic Inkometers in eight laboratories.

15.1.2 In a separate interlaboratory study⁶ of this test method, four quick-set vehicles and four heat-set vehicles with a broad range in tack were measured in duplicate on two different days at 1 min and 5 min at 400 r/min on electronic Inkometers in six laboratories. The four quick-set vehicles were also measured at 1 min at 800 r/min.

15.1.3 The within-laboratory/ and between-laboratory standard deviations are shown in Table 1. Based on these standard deviations the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

15.1.3.1 *Repeatability*—Two individual results obtained by the same operator should be considered suspect if they differ by more than the values given in Table 1.

15.1.3.2 *Reproducibility*—Two results, each the mean of two readings, obtained by operators in different laboratories should be considered suspect if they differ by more than the values given in Table 1.

15.2 *Bias*—Bias cannot be determined as there are no known methods for measuring actual splitting forces. There are indications that apparent tack measurements from the Inkometer correlate best with transfer performance when a series of test samples is based on the same vehicle chemistry.

16. Keywords

16.1 apparent tack; Inkometer; printing inks; splitting forces; tack; tackmeters; vehicles

ANNEX

(Mandatory Information)

A1. INFORMATION CONCERNING INKOMETERS

A1.1 Routine Maintenance of the Inkometer

A1.1.1 Routine maintenance of the Inkometer is extremely important to the mechanical integrity of the instrument; see the manufacturer's current instruction manual for the specific model.

A1.1.2 The measuring and vibrator rollers may acquire a glazed or shiny appearance with use, depending on the test system and the wash-up solvent. This glaze may result in a significant change in the apparent tack reading of an ink or vehicle. The glaze may be removed by extra cleaning with a strong solvent such as acetone. If not, the composition rollers should be replaced.

A1.2 Breaking-in the Inkometer Rollers

A1.2.1 New Inkometer measuring and vibrator rollers may selectively absorb certain components of some test systems, up to a saturation point, at which point they may be said to be broken in. Until this selective absorption is complete, tack determinations made with these rollers may not be repeatable. Break in new rollers using the following procedure:

A1.2.1.1 Place the rollers on the Inkometer. Choose as break-in samples those representative of the system that will be evaluated on the rollers. Run approximately 1.0 to 1.5 mL of the break-in sample for extended periods of time, wash-up with the solvent to be used, reapply the sample, run, wash-up, etc.

NOTE A1.1—The wash-up is a significant part of the break-in process.

A1.2.1.2 Break-in time may vary from several hours to several days. Reproducible apparent tack readings on standard samples (see A1.5.1), over a period of several days, indicate that the rolls are broken in; they may then be put into routine use.

A1.2.2 A major change in ink systems may adversely affect the Inkometer rollers. When a set of rollers has been used for one system, and it is to be used for another, use this same break-in procedure. The rollers may then no longer be suitable for the original system.

A1.3 Temperature Control of the Inkometer Water Bath

A1.3.1 Extremely precise temperature control of the Inkometer water bath is essential for repeatable apparent tack readings.

A1.3.2 The thermometer furnished with the mechanical Inkometer, and the temperature gage of the electronic Inkometer are accurate to $\pm 0.5^\circ\text{F}$ ($\pm 0.3^\circ\text{C}$).

A1.3.2.1 It may be advantageous to use a Bomb Calorimeter Thermometer ASTM 56F, 66.0 to 95.00°F, with divisions of 0.05°F, or ASTM 56C, 19.00 to 35.00°C, with divisions of 0.02°C, in the Inkometer water bath. Position the thermometer in such a manner that the bottom of the mercury bulb is in line with the return inlet from the brass roller.

A1.3.3 The temperature-control system of the Inkometer is capable of controlling the temperature inside the brass roller within $\pm 0.5^\circ\text{F}$ ($\pm 0.3^\circ\text{C}$).

A1.3.3.1 It may be advantageous, particularly, if high-tack samples are run for extended periods of time, or if the Inkometer is in constant use, to augment the temperature control system with a cold-water cooling coil. A coiled length of 1/4-in. (6.3-mm) outside-diameter copper tubing may be placed in the water-bath reservoir, in the flow area away from the thermometer. The coil is connected to a cold-water tap with a pressure regulator and emptied into a sink or drain.

A1.4 Reading the Mechanical Inkometer Balance-Beam

A1.4.1 In order to take a reading from the balance beam of a mechanical Inkometer, disengage the beam and move the sliding weight until the beam is continuously in balance. Read the scale at the left of the sliding weight, using the scale alignment cutout to facilitate reading.

A1.4.2 Minimization of parallax is necessary for repeatable apparent tack readings. It may be useful to mount a small reflective surface on the beam stop behind the zero indicator and the balance beam. The zero indicator and the zero line on the balance beam are aligned in the reflective surface when an apparent tack reading is being taken.

A1.4.3 Reengage the balance beam immediately after taking the reading.

A1.5 Standard Test Samples

A1.5.1 It may be useful to designate one or more inks or vehicles as standards. Samples that are stable and have a good shelf life without a change in apparent tack reading (for example, tack rated or tack graded) are appropriate. Daily apparent tack readings on these samples ensures that the Inkometer is in calibration and serves as a check on repeatability.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Methods for Hardness of Organic Coatings by Pendulum Damping Tests¹

This standard is issued under the fixed designation D 4366; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

1. Scope

1.1 These test methods cover the use of pendulum damping testers in the determination of hardness of organic coatings that have been applied to acceptably plane rigid surfaces, such as a metal or glass panel.

1.2 Two test methods based on different pendulum types are covered as follows:

1.2.1 Test Method A—König Pendulum Hardness Test

1.2.2 Test Method B—Persoz Pendulum Hardness Test

1.3 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels²

D 1005 Test Methods for Measurement of Dry-Film Thickness of Organic Coatings Using Micrometers²

D 1186 Test Methods for Nondestructive Measurement of Dry Film Thickness of Nonmagnetic Coatings Applied to a Ferrous Base²

D 1400 Test Method for Nondestructive Measurement of Dry Film Thickness of Nonconductive Coatings Applied to a Nonferrous Metal Base²

3. Terminology

3.1 Descriptions of Terms Specific to This Standard:

3.1.1 *König hardness*—time in seconds for the swing amplitude of the König pendulum to decrease from 6 to 3°.

3.1.2 *Persoz hardness*—time in seconds for the swing amplitude of the Persoz pendulum to decrease from 12 to 4°.

4. Summary of Test Methods

4.1 A pendulum resting on a coating surface is set into oscillation (rocking) and the time for the oscillation amplitude to decrease by a specified amount measured. The shorter the damping time, the lower the hardness.

5. Significance and Use

5.1 The pendulum damping test has been found to have

good sensitivity in detecting differences in coating hardness, where hardness is defined as resistance to deformation.

5.2 The two procedures given in these test methods embody the principle that the amplitude of oscillation of a pendulum touching a surface decreases more rapidly the softer the surface. However, these test methods differ in respect to pendulum dimensions, and period and amplitude of oscillation.

5.3 In general, the damping time of the König pendulum is approximately half that of the Persoz pendulum.

5.4 The Persoz pendulum has a greater degree of discrimination than the König for measuring the hardness of soft coatings, but it may not be as suitable for testing hard, slippery films because of its tendency to skid on surfaces with a low coefficient of friction.

5.5 The interaction between the pendulum and the paint film is complex, it depends on both elastic and viscoelastic properties, and it may not be possible to establish a precise relationship between the two types of pendulum tests.

TEST METHOD A—KÖNIG PENDULUM HARDNESS TEST

6. Apparatus

6.1 *König Pendulum Tester*,³ consisting of a stand that supports a pendulum, a test panel, and a pendulum displacement scale. The stand has a stirrup to support the pendulum above the table and a mechanism for shock-free lowering of the pendulum onto the test panel. A typical apparatus is shown in Fig 1.

NOTE 1—Optional features may be the inclusion of an electronic device for automatically timing the oscillation damping and the inclusion of an oscillation counter.

6.2 *König Pendulum*, consisting of an open framework connected by a cross-bar, to the underface of which are two balls, 5 ± 0.005 mm in diameter of hardness 63 ± 3.3 HRC, inset to serve as the fulcrum. The lower end of the framework is formed into a pointer. A weight sliding on a vertical rod attached to the cross-bar is used to counterpoise the pendulum. The total weight of the pendulum shall be 200 ± 0.2 g.

6.3 *Stop Watch*, or other timing device for timing the oscillation damping of the pendulum.

6.4 *Polished Plate (Float) Glass Panel*, for calibrating the pendulum.

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.23 on Physical Properties of Applied Paint Films.

Current edition approved Sept. 15, 1991. Published November 1991. Originally published as D 4366 - 84. Last previous edition D 4366 - 87.

² *Annual Book of ASTM Standards*, Vol 06.01.

³ Pendulum hardness testers meeting the apparatus requirements of this test method may be obtained from BYK-Gardner, Inc., 2435 Linden Lane, Silver Spring, MD 20910, Paul N. Gardner Co., Inc., 316 N.E. First Street, P.O. Box 10688, Pompano Beach, FL 33061-6688 and Zorelco Limited, P.O. Box 25500, Cleveland, OH 44125.

FIG. 1 Apparatus

Calibration

- 7.1 Check the alignment of the pendulum and panel table as follows:
 - 7.1.1 Place the polished glass panel on the panel table and gently bring the pendulum to rest on the surface of the glass. Ensure the pendulum oscillates freely.
 - 7.1.2 Place a spirit level on the glass panel surface. Level the glass panel by means of the adjusting screws at the base of the instrument.
 - 7.1.3 Clean the glass panel by wiping with a soft, lintless cloth wetted with the solvent mixture specified in Practice D 891.
 - 7.1.4 Clean the fulcrum balls by wiping with a soft tissue wetted with solvent. Leave the pendulum in ambient conditions and then bring it to rest on the glass panel.
 - 7.1.5 Check the position of the scale relative to the pendulum pointer. With the pendulum at rest, its pointer should indicate zero on the scale. If the pointer does not indicate zero, move the scale to obtain the correct zero setting.
- 7.2 Check the duration of the pendulum swing on the glass panel.
 - 7.2.1 Deflect the pendulum through 6° , release it and simultaneously start a stopwatch or other timing device.
 - 7.2.2 Determine whether the time for 100 swings of the pendulum falls within 140 ± 2 s.
 - 7.2.3 If the measured time is less than specified, move the weight on the pendulum rod upward. If the measured time is more than specified, move the weight downward. Continue adjustments until the specified time is obtained. If the time cannot be obtained, the instrument should be judged faulty and be repaired.
- 7.3 Check the duration of damping of the pendulum on the glass panel as follows:
 - 7.3.1 Deflect the pendulum through 6° , release it and simultaneously start the stopwatch or other timing device.
 - 7.3.2 Determine whether the time for the amplitude of

swing to decrease from 6 to 3° falls within 250 ± 10 s (corresponding with 172 to 185 pendulum swings).

8. Test Panel Preparation and Conditioning

8.1 Apply uniform coatings of the material to be tested to plane, rigid surfaces, such as metal or glass panels, by one of the procedures given in Test Methods D 823.

8.2 Cure the coated panels under the conditions of humidity and temperature, as agreed upon between the purchaser and seller.

8.3 Measure the thickness of the dry coating in accordance with Test Methods D 1005, D 1186, or D 1400.

NOTE 2—Coating thickness must be controlled closely because the pendulum test results can be affected by thickness variations. A minimum thickness of $25 \mu\text{m}$ is required to minimize substrate effects.

9. Procedure

9.1 Unless otherwise specified, make the hardness determination at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity, after holding the test panels under these conditions for at least 16 h.

9.2 Place the test panel on the panel table and gently bring the pendulum onto the panel surface.

9.3 Deflect the pendulum through 6° , release it and simultaneously start the stopwatch or other timing device.

9.4 Determine the time for the amplitude of swing to decrease from 6 to 3° . This is the König hardness.

9.5 Repeat steps 9.2 through 9.4 on at least two other areas of the test panel.

10. Report

10.1 Report the following information:

- 10.1.1 Mean and range of the König hardness values in sections obtained for the test panel,
- 10.1.2 Manufacturer and model of the hardness tester used,
- 10.1.3 Mean and range of the thickness values obtained for the coating on the test panel, and the method used for determining the thickness,
- 10.1.4 Temperature and relative humidity during the test, and
- 10.1.5 Test panel preparation and conditioning techniques used.

11. Precision⁴

11.1 *Method A—König Pendulum Test*—On the basis of an interlaboratory test of this test method in which operators in four laboratories made three hardness measurements on each of six coated panels covering a wide range of hardness on two days, the within-laboratory coefficient of variation was found to be 3 % with 24 df and the between-laboratories coefficient of variation 8 % with 18 df. Based on these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level.

11.1.1 *Repeatability*—Two results, each the mean of three determinations on a specimen, obtained by the same oper-

⁴ Supporting data are available from ASTM Headquarters. Request RR: D01-1050.

ator should be considered suspect if they differ by more than 8 % of their mean value.

11.1.2 *Reproducibility*—Two results, each the mean of three determinations on a specimen, obtained by operators in different laboratories should be considered suspect if they differ by more than 23 % of their mean value.

TEST METHOD B—PERSOZ PENDULUM HARDNESS TEST

12. Apparatus

12.1 *Persoz Hardness Tester*,⁴ consisting of a stand that supports a pendulum, a test panel, and a pendulum displacement scale. The stand has a stirrup to support the pendulum above the table and a mechanism for shock-free lowering of the pendulum onto the test panel. A typical apparatus is similar to that shown in Fig. 1.

12.2 *Persoz Pendulum*, consisting of an open framework connected by a cross-bar, to the underface of which are two stainless steel balls, 8 ± 0.005 mm in diameter of hardness 59 HRC, inset to form a fulcrum.

12.2.1 *Pointer*, attached to the lower end of the framework, the tip of which shall be 400 ± 0.2 mm below the plane of the fulcrum. The total weight of the pendulum shall be 500 ± 0.1 g.

13. Calibration

13.1 Check the alignment of the pendulum and panel table.

13.1.1 Follow the procedures outlined in 7.1.1 to 7.1.4.

13.2 Check the duration of the pendulum swing on the glass panel.

13.2.1 Deflect the pendulum through 12° , release it and simultaneously start the stopwatch or other timing device.

13.2.2 Determine whether the time for 100 swings of the pendulum falls within 100 ± 0.1 s.

13.2.3 If this value cannot be achieved, reclean the glass panel and the bearing balls of the pendulum, recheck the level of the glass panel, and retest. It is not permissible to adjust the instrument scale at this point.

13.3 Check the duration of damping of the pendulum on the glass panel as follows:

13.3.1 Deflect the pendulum through 12° , release it and simultaneously start the stopwatch or other timing device.

13.3.2 Determine whether the time for the amplitude of swing to decrease from 12° to 4° falls within 400 ± 10 s.

13.3.3 If this value cannot be achieved, repeat the glass panel and instrument checks described in 13.2.3.

14. Procedure

14.1 Unless otherwise specified, make the hardness determination at $23 \pm 2^\circ\text{C}$ and 50 ± 5 % relative humidity, after holding the test panels under these conditions for at least 16 h.

14.2 Place the test panel on the panel table and gently bring the pendulum onto the panel surface.

14.3 Deflect the pendulum through 12° , release it, and simultaneously start the stopwatch or other timing device.

14.4 Determine the time for the amplitude of swing to decrease from 12° to 4° . This is the Persoz hardness.

14.5 Repeat steps 14.2 to 14.4 on at least two other areas of the test panel.

15. Report

15.1 Report the following information:

15.1.1 Mean and range of the Persoz hardness values in seconds obtained for the test panel,

15.1.2 Manufacturer and model of hardness tester used,

15.1.3 Mean and range of the thickness values obtained for the coating on the test panel, and the method used for determining the thickness,

15.1.4 Temperature and relative humidity during the test, and

15.1.5 Test panel preparation and conditioning techniques used.

16. Precision⁴

16.1 *Method B—Persoz Pendulum Test*—On the basis of an interlaboratory test of this test method in which operators in five laboratories made two or three hardness measurements on each of six coated panels (covering a wide range of hardness), the within-laboratory coefficient of variation was found to be 1 % with 24 df and the between-laboratories coefficient of variation 3 % with 12 df. Based on these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level.

16.1.1 *Repeatability*—Two results, each the mean of three determinations on a specimen, obtained by the same operator should be considered suspect if they differ by more than 3 % of their mean value.

16.1.2 *Reproducibility*—Two results, each the mean of three determinations on a specimen, obtained by operators in different laboratories should be considered suspect if they differ by more than 8 % of their mean value.

17. Keywords

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Methods for Acid and Base Milliequivalent Content of Electrocoat Bath¹

This standard is issued under the fixed designation D 4370; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{ε1} NOTE—Editorial changes were made throughout in May 1990.

1. Scope

1.1 These test methods cover the determination of acid and base milliequivalent contents of anodic and cathodic electrocoat baths and their ultrafiltrates.

1.2 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 *ASTM Standard:*
D 1193 Specification For Reagent Water²

3. Summary of Test Methods

3.1 Specimens are titrated with standard acid and alkali solutions respectively. Alternative procedures are given for determining acid and base concentrations potentiometrically or using a pH meter.

4. Significance and Use

4.1 The acid and base concentrations are a measurement of the titratable acidic and alkaline components in the electrocoat baths. These measurements are used for research, production or electrocoat bath process control.

5. Apparatus

5.1 *Automatic Potentiometric Titrator with Stirrer and Recorder*, any model.

5.2 *Analytical Balance*, with sensitivity of 0.1 mg.

5.3 *pH Meter*, any model.

5.4 *Glass and Saturated Calomel Electrodes*.

5.5 *Syringes*, 5-mL disposable.

6. Reagents

6.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.³ Other

grades may be used, provided it is ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

6.2 *Purity of Water*—References to water shall be understood to mean water conforming to Type II of Specification D 1193.

6.3 *Potassium Hydroxide Solution in Methanol*, 0.1 N—Prepare by dissolving 5.6 g of potassium hydroxide (KOH) pellets in 1 L of methanol. Standardize against NIST standard reference material of acid potassium phthalate No. 84 using an automatic potentiometric titrator⁴ to a given end point or, alternatively, to a phenolphthalein end point.

6.4 *Hydrochloric Acid Solution*, 0.1 N—Prepare by mixing about 8.50 mL of concentrated hydrochloric acid (HCl) (1.19 sp gr) into a mixture of 600 mL water and 400 mL methanol. Standardize against 0.1 N potassium hydroxide solution (see 6.3).

6.5 *1,3-Propanediol* (Propylene Glycol) (PG).

6.6 *Tetrahydrofuran* (THF).

6.7 *Reference pH Standard Solutions*—Commercial standards of pH 4.0, 7.0, and 10.0.

7. Sampling and Sample Preparation

7.1 The sample should be obtained while the electrocoat bath is under proper circulation such that a uniform material is obtained. In case of an ultrafiltrate, the material should be thoroughly mixed or stirred prior to sampling to assure uniformity.

7.2 After sampling and prior to removing a test specimen, it is mandatory that the samples be shaken or stirred until they are homogeneous and free of any settled material. This is particularly important if there is a delay between sampling the bath and performing the test. The absence of settled material can be ascertained visually (in a transparent container) or by inserting a spatula, scraping the bottom of the container, and making sure that there is no settled matter. The shaking or stirring of the samples should be carried out up to the moment of taking a specimen; *this Point is Very Important*.

8. Base Concentration Content

8.1 Stir the sample very thoroughly to disperse materials that might have settled to the bottom of the container. With the aid of a syringe, withdraw approximately 5 mL of the

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paint and Paint Materials.

Current edition approved June 28, 1984. Published November 1984.

⁴ Svehla, G., *Automatic Potentiometric Titration*, Pergamon Press, 1978, p. 187.

sample quickly, weigh the full syringe to 0.1 mg, and record this weight as W_1 . Transfer the entire contents of the syringe into a 100-mL beaker. Reweigh the empty syringe to 0.1 mg and record as W_2 . Duplicate the procedure using a second specimen.

8.2 Add approximately 40 mL of THF/PG 80/20 mixture to the specimens in the beakers and cover, preferably with aluminum foil, to minimize evaporation of the solvent mixture.

NOTE 1—In cases where the recommended THF/PG 80/20 mixture causes precipitation of the material, substitute the same amount of an appropriate solvent or solvent mixture to a new specimen. The formation of a precipitate during the titration might foul the electrode system and mask potentiometric changes. Other solvents suitable for dilution are acetone, dimethylformamide, toluene, or methanol. Any other solvent or solvent mixture that does not cause the formation of a precipitate throughout the titration is suitable. In certain instances it may be necessary to run a titration blank and to make the appropriate corrections for the solvent.

8.3 Titrate both specimens with 0.1 N HCl solution using the automatic potentiometric titrator until an end point "break" is reached.⁴ Add approximately 5 mL of additional titrant to complete the curve. A typical titration curve is shown in Fig. 1. Record as V_1 the volume of titrant needed for the end point.

FIG. 1 Potentiometric Titration Curves for the Acid and Base Milliequivalent Content

NOTE 2—If the titration curve does not show an inflection point (end point), back titration with 0.1 N KOH will give an acceptable result.

9. Base Content Calculation

9.1 Calculate the base content as follows:

$$A = \frac{(V_1 \times N_1) \times 100}{(W_1 - W_2)M}$$

where:

A = milliequivalents of base per gram of nonvolatile matter,

V_1 = volume of HCl titrant used, mL,

N_1 = normality of HCl titrant,

W_1 = mass of the syringe filled with sample, mg,

W_2 = mass of the empty syringe after delivery of the specimen, mg, and

M = nonvolatile matter content, %.

10. Acid Concentration Content

10.1 Using a fresh portion of the sample, follow 8.1 and 8.2.

10.2 Titrate both specimens with 0.1 N KOH solution using the automatic potentiometric titrator until an end point break is reached. Add about 5 mL more of titrant to complete the curve. From the curve, determine and record, as V_2 , the volume of titrant needed for the end point.⁴

11. Acid Content Calculation

11.1 Calculate the acid content as follows:

$$A = \frac{(V_2 \times N_2) \times 100}{(W_3 - W_4)M}$$

where:

A = milliequivalents of acid per gram of nonvolatile matter,

V_2 = volume of KOH titrant used, mL,

N_2 = normality of KOH titrant,

W_3 = mass of the syringe filled with sample, mg,

W_4 = mass of the empty syringe after delivery of the specimen, mg, and

M = nonvolatile matter content, %.

12. Base Concentration Content Using a pH Meter

12.1 Proceed in accordance with 8.1 and 8.2.

12.2 Standardize the pH meter at 4.0 and 7.0.

12.3 Titrate both specimens with 0.1 N HCl until a pH of 4.0 is obtained. Make certain that the solutions are well agitated during titration (a magnetic stirrer is recommended). Record volume of titrant, as V_1 , used for each titration. Because electrocoating paints vary greatly, it might be advisable to titrate to a pH value agreed upon between the producer and the user.

13. Base Content Calculation

13.1 Calculate the base content as described in Section 9.

14. Acid Concentration Content Using a pH Meter

14.1 Proceed in accordance with 8.1 and 8.2.

14.2 Standardize the pH meter at 7.0 and 10.0.

14.3 Titrate both specimens with 0.1 N KOH until a pH of 10.0 is obtained. Make certain that solutions are well agitated during titration (a magnetic stirrer is recommended). Record volume of titrant, as V_2 used for each.

5. Acid Content Calculation

5.1 Calculate the acid content as described in Section 11.

6. Precision

6.1 In an interlaboratory study of the test methods, in which six laboratories measured in duplicate on two days four electrocoat samples with acid and base milliequivalents ranging from 0.2 to 0.8, the within-laboratory coefficient of variation, after discarding one result, was found to be 1.4 % relative at 23 df and the between-laboratory coefficient of variation 5.7 % relative at 19 df. Based on these coefficients,

the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

16.1.1 *Repeatability*—Two results, each the mean of duplicate determination, obtained by the same operator on different days should be considered suspect if they differ by more than 4.1 % relative.

16.1.2 *Reproducibility*—Two results, each the mean of duplicate determinations, obtained by operators in different laboratories should be considered suspect if they differ by more than 17 % relative.

17. Keywords

17.1 acid content; base content; electrocoat baths

Standard Test Method for Measuring Electrical Conductivity of Electrocoat Baths¹

This standard is issued under the fixed designation D 4399; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

1. Scope

1.1 This test method covers the determination of the electrical conductivity of electrocoat baths or ultrafiltrate samples using commercially available equipment.

1.2 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 1125 Test Methods for Electrical Conductivity and Resistivity of Water²

D 1193 Specification for Reagent Water³

3. Summary of Test Method

3.1 A specimen is placed in a conductivity cell, or conversely a conductivity cell is placed in an electrocoat material, and the cell is connected to a conductivity bridge. The electrical conductivity is read directly off the meter of the bridge as the instantaneous peak reading.

4. Significance and Use

4.1 The conductivity of electrocoat baths results from the presence of ionic species in the bath, which come from the vehicle and from the presence of impurities present as ionizable acids, bases, salts, or combinations of these. The presence of excessive amounts of ionic impurities is detrimental to the application and performance properties of electrocoating paints. The test is suitable for use in research, production, quality control and electrocoat bath process control.

4.2 Other related methods for determining the electrical conductivity of water are described in Test Methods D 1125.

5. Apparatus

5.1 *Conductivity Bridge*—Battery, or AC/DC line-operated, capable of providing a conductivity reading almost instantaneously.

5.2 *Conductivity Cell*—Dip or fill type, cell constant of 1.0.

5.3 *Thermometer*—Any type capable of 0.5°C accuracy with a -2 to 32°C range.

5.4 *Measuring Vessel*—Any suitable cylindrical container capable of holding sufficient electrocoat sample to cover the electrodes of the conductivity cell, and allowing at least 25 mm between the conductivity cell and the sides of the vessel.

6. Reagents and Materials

6.1 *Purity of Water*—References to water shall be understood to mean water conforming to Type II of Specification D 1193.

6.2 *Cleaning Solvent*—An appropriate solvent for the electrocoat material under measurement.

7. Sampling and Sample Preparation

7.1 The sample should be obtained while the electrocoat bath is under proper circulation so that a uniform sample is obtained. In the case of an ultrafiltrate, the material should be thoroughly mixed or stirred prior to sampling to ensure uniformity.

7.2 After sampling and prior to removing a test specimen, it is mandatory that the samples be shaken or stirred until they are homogeneous and free of any settled material. This is particularly important if there is a delay between sampling the bath and performing the test on the bath materials. The absence of settled material can be ascertained visually (in a transparent container) or by inserting a spatula, scraping the bottom of the container and making sure that there is no settled matter. Shake or stir the sample until specimens are taken for measurement; **THIS POINT IS VERY IMPORTANT.**

8. Procedure

8.1 Calibrate the conductivity cell prior to use following the manufacturer's instructions.

8.2 Rinse the measuring container several times with portions of the electrocoat material under test.

8.3 Take a representative portion of the electrocoat bath or permeate sample and place it in the measuring container. Stir the specimen thoroughly to keep it from settling.

8.4 Adjust the temperature of the specimen to $25 \pm 0.5^\circ\text{C}$. This is very important, since temperature differences cause disagreements in results and are a major source of error in these measurements.

8.5 Immerse the cell in the specimen, and move the cell up and down several times to displace any air bubbles from inside the cell. Hold the cell in a slightly inclined position in the center of the container with the vents at the top of the cell housing beneath the surface of the liquid. If a fill-type cell is used, pour the specimen into the conductivity cell.

8.6 Read and record the conductivity as described in the

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paint and Paint Materials.

Current edition approved May 25, 1990. Published July 1990. Originally published as D 4399 - 84. Last previous edition D 4399 - 85a.

³ Annual Book of ASTM Standards, Vols 06.03 and 11.01.

manufacturer's instructions regarding the use of the instrument. Avoid measuring times longer than 15 s to prevent electrocoat sample deposition on the cell electrodes. Perform a second measurement on another specimen, repeating steps 8.3 and 8.6. Calculate the mean of both measurements.

8.7 Take extreme care to prevent contamination of the sample and equipment. Rinse the cell with deionized water and an appropriate solvent immediately after use. Keep cell clean and do not allow the dry electrocoat sample to accumulate on the interior of the cell.

9. Report

9.1 Report the conductivity in terms of microsiemens (or microohms per centimetre) to the nearest 1 % of the determined conductivity.

10. Precision and Bias

10.1 *Precision*—In an interlaboratory study of this test method, with five laboratories measuring five electrocoat

bath samples with conductivities ranging from 720 to 1750 $\mu\text{S}/\text{cm}$ (microohms/cm), the intralaboratory coefficient of variation was found to be 2.6 % relative at 25 df, and the interlaboratory coefficient of variation 4.2 % relative at 20 df. Based on these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

10.1.1 *Repeatability*—Two results, each the mean of duplicate determinations, obtained by the same operator on different days should be considered suspect if they differ by more than 7.6 % relative.

10.1.2 *Reproducibility*—Two results, each the mean of duplicate determinations, obtained by operators in different laboratories should be considered suspect if they differ by more than 16.5 % relative.

10.2 *Bias*—No bias has been determined for this test method.

11. Keywords

11.1 electroconductivity; electrocoat bath

Standard Test Method for Sag Resistance of Paints Using a Multinotch Applicator¹

This standard is issued under the fixed designation D 4400; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

NOTE—Paragraph 9.3.1.1 was editorially corrected and the year date was changed Oct. 6, 1989.

INTRODUCTION

The multinotch applicator used in this test method is a drawdown blade with a series of notches of successively higher clearance, referred to as the Anti-Sag Meter. See Figs. 1 and 2 for a representative diagram and photograph. The numerical value for sag resistance obtained with this instrument is referred to as the Anti-Sag Index.

Anti-Sag Meters are made with several clearance ranges for different types of coatings (see 5.1). In developing this test method the task group used an instrument with a range from 4 to 24 mils, but this test method is applicable to any clearance range, and results using instruments with overlapping ranges correlate and have equal validity.

This test method covers two procedures. Procedure A was developed in 1962^{2,3} and is referenced in U.S. Federal specifications TT-E-508, TT-E-506, and TT-P-1511. Procedure B is a newer method that obviates concern about the effect of substrate wetting as a possible variable. Numerical values obtained with the two procedures are not necessarily equal, but their rank orders are essentially the same.

A preshear program is essential for a drawdown sag test to duplicate the breakdown in structure that occurs when thixotropic paints are applied by brushout or other practical application methods. The procedures therefore include the preshearing of paints just prior to making test applications.

1. Scope

1.1 This test method covers the laboratory determination of the sag resistance of aqueous and nonaqueous liquid coatings at any level of sag resistance.

1.2 Procedure A is applicable to coatings of any type or color.

1.3 Procedure B is applicable to any type of coating but does not work well with dark colors.

1.4 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Fed. Spec. TT-E-506 Alkyd gloss enamel

Fed. Spec. TT-P-1511 Interior latex gloss and semi-gloss finishes

3. Summary of Test Method

3.1 *Procedure A, Horizontal Stripes*—After preshearing the coating is applied to a test chart with a multinotch applicator. The charts are immediately hung vertically with the drawdown stripes horizontal, similar to rungs of a ladder with the thinnest stripe at the top. After drying in this position, the drawdown is examined and rated for sagging. A typical sag pattern obtained by this procedure is shown in Fig. 3.

3.2 *Procedure B, Vertical Stripes*—Two straight lines are

⁴ *Annual Book of ASTM Standards*, Vol 06.01.

⁵ Available from Standardization Documents Order Desk, Bldg. 4, Section D, 700 Robbins Ave., Philadelphia, PA 19111-5094.

FIG. 1 Diagram of the Medium Range Anti-Sag Meter

FIG. 2 Medium Range Anti-Sag Meter

drawn across a test chart using a suitable marker pen. After preshearing, the coating is applied with a multinotch applicator so that the stripes are perpendicular to the lines. After waiting briefly for the marker ink to migrate through the wet film, the charts are hung vertically with the stripes vertical, similar to the slats of a picket fence, with the thinnest stripe on the left. After drying in this position, the ink lines are examined and rated for sagging. A typical sag pattern obtained by this procedure is shown in Fig. 4.

Significance and Use

4.1 Evaluation of sag resistance is essential in quality control for both producers and purchasers of coatings. Practical application tests are poor in reproducibility while isometric methods, for example Test Methods D 2196, are time-consuming and lack the convincing aspect of actual sagging. This method provides simple and rapid tests, whereby sag resistance is demonstrated by a visible sag pattern, and is rated objectively in terms of numerical values that correlate with brushout test observations.

Apparatus

5.1 *Multinotch Applicator*, Anti-Sag Meter⁶, a drawdown

FIG. 3 Typical Sag Pattern—Procedure A

blade with a series of notches of successively higher clearance. Select a clearance range suitable for the type of coating under test in accordance with Table 1.

5.2 *Test Surfaces*, sealed, smooth-surfaced paper test charts, with sizes and designs as follows:

5.2.1 *Black and White Charts*,⁷ about 7 $\frac{3}{8}$ by 11 $\frac{1}{4}$ in. (193 by 288 mm), the black area comprising about 5 $\frac{1}{2}$ in. (140 mm) centered on the drawdown path. A chart of this design is shown in Figs. 3 and 5.

5.2.2 *Plain White Charts*,⁷ about 7 $\frac{3}{8}$ by 11 $\frac{1}{4}$ in. (193 by 285 mm).

5.2.3 *Plain White Charts*,⁷ about 5 $\frac{1}{2}$ by 11 $\frac{1}{4}$ in. (140 by 285 mm). The use of a chart of this description is shown in Fig. 4.

5.3 *Glass Drawdown Plate*, plus straightedge guide for attachment thereto.

⁷ The following are available from The Leneta Co.:
Black and White Charts, Form 7B.
Plain White Charts, 7 $\frac{3}{8}$ by 11 $\frac{1}{4}$ in., Form WB.
Plain White Charts, 5 $\frac{1}{2}$ by 11 $\frac{1}{4}$, Form WM.
Catch-Papers, Form CP-2.

FIG. 4 Typical Sag Pattern—Procedure B

5.4 *Catch-papers*,⁷ thin sheets of sealed paper, for catching surplus paint at the completion of a drawdown.

5.5 *Fine-Line Marker Pens*—The ink shall be a solvent-based type that wets readily and dries quickly on smooth nonporous surfaces, specifically:

5.5.1 A pen⁸ that applies a hydrophilic ink line for use with water-dispersed coatings.

5.5.2 A pen⁹ that applies an oleophilic ink line for use with solvent-dispersed coatings.

5.6 *Equipment for the Preshearing of Aqueous Coatings:*

5.6.1 *Syringe*, 10-mL, Becton-Dickinson, Luer-Lok disposable plastic type.¹⁰

5.6.2 *Syringe Needle*, 15 g by 1½ in. (40 mm) to fit syringe.

5.6.3 *Syringe Extension Tubing*, clear vinyl, inside diameter ⅛ in. (3.2 mm), outside diameter ⅜ in. (5 mm).

5.7 *Equipment for the Preshearing of Nonaqueous Coatings:*

5.7.1 *Rotary Mechanical Stirrer*, variable speed.

5.7.2 *Circular Mixing Paddle*,¹¹ diameter approximately 1⅞ in. (48 mm).

5.7.3 *Mixing Container*, cylindrical jar or can with capacity of up to 1 pt (500 mL).

6. Procedure A—Horizontal Stripes

6.1 Preparation of Sample:

⁸ "Vis-A-Vis" pens, manufactured by Sanford Pen Company, Bellwood, IL 60104, have been found satisfactory. These are sold at commercial stationers.

⁹ A "Flow Master" refillable pen with a fine line adapter and red Flow Master ink have been found satisfactory. The pen and the ink are sold separately. Both are manufactured by Faber-Castell Pen Corp. Newark, NJ 07107, and are available at commercial stationers.

¹⁰ Luer-Lok is a trademark of Becton-Dickinson, Beaver Brook Rd., Lincoln Park, NJ 07035. Available from distributors of general laboratory supplies.

¹¹ A mixing paddle (Catalog Number PM-70) with a diameter of 1⅞ in. (48 mm) made by Shur-Line Mfg. Co., 2200 Commerce Rd., Lancaster, NY 14086 has been found satisfactory for this purpose. This or equivalent paddles may be purchased at most hardware stores.

TABLE 1 Anti-Sag Meter Types

Type of Coating Under Test	Clearance Range, mils	Range Reference	Number of Clearances
Architectural	3–12	Standard	10
Industrial—OEM.	1–6	Low	11
High build	14–60	High	11
Architectural	4–24	Medium	11

NOTE—Note use of straightedge guide.

FIG. 5 Drawing Down with the Anti-Sag Meter

6.1.1 Stir thoroughly with a spatula in the original container.

6.1.2 Strain if necessary to remove large particles or skins.

6.1.3 Adjust the temperature of the coating to 73.5 ± 3.5°F (23 ± 2°C).

6.2 *Preshearing with Syringe and Needle (Aqueous Coatings):*

6.2.1 Prepare the paint as described in 6.1.

6.2.2 Cut a 2½-in. (60-mm) length of syringe extension tubing and attach it to the syringe.

6.2.3 Press the syringe barrel firmly to expel air, dip the end of the syringe into the coating, pump slightly to expel remaining air, then withdraw 8 mL of coating.

6.2.4 Remove and discard the extension tubing and then attach a syringe needle.

6.2.5 Eject the contents of the syringe in front of the applicator as rapidly as possible, with firm, steady pressure.

6.3 *Preshearing with a Rotary Mechanical Mixer (Nonaqueous Coatings):*

6.3.1 Prepare the paint as described in 6.1 and fill the mixing container slightly more than half. Set the container under the stirrer so that the paddle is about ¼ in. (5 mm) from the bottom.

6.3.2 Mix vigorously for 1 min at a speed sufficient to form a moderate vortex, with the entire contents of the can in rapid circular motion. Rotor speeds of 1300 to 3600 r/min have been found satisfactory, the optimum speed depending on the relative diameters of the mixing paddle and container. For referee tests the operators should agree upon the specific container, paddle, and mixing speed.

6.3.3 Immediately after mixing place about 8 mL of paint in front of the applicator and draw down in accordance with 6.4 (Procedure A) or 7.4 (Procedure B).

6.4.1 Affix a suitable test chart onto the drawdown plate. Use black and white charts in accordance with 5.2.1 for light or moderately dark colored coatings and white charts in accordance with 5.2.2 for very dark coatings.

6.4.2 Fasten the straightedge onto the drawdown plate in suitable position.

6.4.3 Place the Anti-Sag Meter at the far end of the chart, the open side toward the operator and shoulder against the straightedge guide.

6.4.4 If desired, position a catch-paper just underneath the lower edge of the chart.

6.4.5 Preshear in accordance with 6.2 or 6.3 and immediately draw down the coating at a uniform speed of about 6 in. (150 mm)/s, with the applicator pressed against the straightedge to maintain a straight path. See Fig. 5 for illustration of this step.

6.4.6 Immediately hang the chart with the drawdown stripes in a horizontal position like rungs in a standing ladder, the thinnest stripe at the top, and allow to dry in that position. A typical test pattern derived using this procedure is shown in Fig. 3.

6.5 Rating the Drawdown:

6.5.1 When the film is dry, note the notch numbers marked on the Anti-Sag Meter and identify the corresponding stripes accordingly.

6.5.2 Observe the sag pattern, ignoring the bottom stripe, which serves only as a position reference for the stripe above it, and the leading and trailing edges of the drawdown, considering only the central 5½ in. (140 mm) of the blade path. This corresponds to the black area of the black and white chart described in 5.2.1. (See Fig. 3 for a typical sag pattern of this type.)

6.5.3 Select the lowest (thickest) stripe that has resisted crossing the gap to touch the next lower stripe. This is referred to as the index stripe.

6.5.4 Estimate the degree to which the next lower stripe (the post-index stripe) has merged with the one below it, and determine the corresponding addendum fraction, as specified in Table 2.

6.5.5 Multiply the fraction from 6.5.4 by the difference between the index and post-index stripe number to obtain the index addendum.

6.5.6 Add the index addendum to the index stripe number to obtain the Horizontal Anti-Sag Index and record the same.

Procedure B—Vertical Stripes

7.1 Preparation of Sample—Follow procedure in 6.1.

7.2 Preshearing with Syringe and Needle (Aqueous Coatings)—Follow procedure in 6.2.

7.3 Preshearing with a Rotary Mechanical Mixer (Non-aqueous Coatings)—Follow procedure in 6.3.

TABLE 2 Intermediate Ratings

Degree of Merger of Post-Index Stripe	Addendum Fraction
Complete	0.0
Almost complete	0.2
Somewhat more than half	0.4
Half	0.5
Somewhat less than half	0.6
Slight (just touching)	0.8

7.4 Application of Test Coating:

7.4.1 On a plain white test chart as described in 5.2.3, using the appropriate pen described in 5.5, rule two parallel lines about 1½ in. (40 mm) apart, across the intended path of the drawdown blade (see Fig. 4). If desired the operator can prepare a supply of such charts for future use, since the ink line is unaffected by aging.¹²

7.4.2 Affix the ruled test chart onto the drawdown plate and fasten the straightedge in suitable position.

7.4.3 Place the Anti-Sag Meter at the top of the chart, the open side toward the operator and shoulder against the straightedge guide.

7.4.4 If desired, position a catch-paper just underneath the lower edge of the chart.

7.4.5 Preshear in accordance with 6.2 or 6.3 and immediately draw down the coating at a uniform speed of about 6 in. (150 mm)/s, with one arm of the applicator pressed gently against the straightedge to maintain a straight path. This procedure is the same as that referred to in 6.4 and illustrated in Fig. 5.

7.4.6 Fifteen seconds after completing the drawdown, hang the chart with the stripes vertical (like fence pickets), thinnest stripe to the left, and allow to dry in that position. A typical test pattern obtained using this procedure is shown in Fig. 4.

7.5 Rating the Drawdown:

7.5.1 When the film is dry, note the notch numbers marked on the Anti-Sag Meter and identify the corresponding stripes and sag loops accordingly.

7.5.2 Examine Fig. 6 and note the "reference loop," which was selected because it indicates a limited but unambiguous sag movement. By actual measurement this loop represents ¼ in. (1.5 mm) of sagging, which amount can be considered as defining the reference loop.

7.5.3 For each of the two ink lines on the test drawdown, note the loop that shows the same or almost as much sag as the reference loop. This is referred to as the "index" loop. The loop to its immediate right is the "post-index" loop and the corresponding stripes are the "index" and "post-index" stripes.

7.5.4 Estimate the visual difference between the index and reference loops as a fraction (to the nearest fifth or half) of the difference between the index and post-index loops. This is the addendum fraction, permissible values being 0, 0.2, 0.4, 0.5, 0.6, or 0.8.

7.5.5 Multiply the addendum fraction from 7.5.4 by the difference between the index and post-index stripes to obtain the index addendum.

7.5.6 For each ink line, add the index addendum to the index stripe number to obtain the Vertical Anti-Sag Index and record the mean value.

8. Report

8.1 Report the following information:

8.1.1 Procedure A—The Horizontal Anti-Sag Index (HASI) of the coating as recorded in 6.5.6.

8.1.2 Procedure B:

¹² Charts with suitable ink lines are available from The Leneta Co. Refer to Form WM-BL (Blue Line) and Form WM-RL (Red Line) for hydrophilic and oleophilic ink lines respectively.

NOTE—The "reference loop" is 1.5 mm (1/16 in.) deep.

FIG. 6 Sag Loops Obtained with Procedure B

8.1.2.1 The Vertical Anti-Sag Index (VASI) of the coating as recorded in 7.5.6.

9. Precision¹³

9.1 *Correlation*—In an interlaboratory study in which operators in seven laboratories tested six water-reducible paints covering a wide range of sag resistance and in five laboratories tested four solvent-reducible paints covering a wide range of sag resistance, the Spearman Rank Correlation Coefficient was 0.92 for Procedure A and 0.96 for Procedure B versus brushouts (a coefficient of 1.0 indicates perfect agreement in ranking).

9.2 *Sensitivity*—In the interlaboratory study described in 9.1, the sensitivity criterion values have been computed to be 4 for brushouts, 11 for Procedure A, and 13 for Procedure B.

¹³ Supporting data are available from ASTM Headquarters. Request RR: D01-1040.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Thus, Procedures A and B are approximately three times more sensitive to differences in sag resistance than brushouts.

9.3 Precision:

9.3.1 Two interlaboratory tests were conducted to establish the precision of this test method. The first test was that described in 9.1. The second test consisted of operators in five laboratories performing three tests on each of three paints. On the basis of the second interlaboratory test, the within-laboratory pooled coefficients of variations for both water- and solvent-reducible paints were 4.4 % for Procedure A and 5.0 % for Procedure B. On the basis of the first interlaboratory test, the between-laboratory pooled coefficient of variation for Procedure A was found to be 12.4 % for water-reducible paints and 8.8 % for solvent-reducible paints. The between-laboratory pooled coefficient of variation for Procedure B was found to be 8.0 % for water-reducible paints and 6.6 % for solvent-reducible paints. Based on these coefficients of variation, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

9.3.1.1 *Repeatability*—Two results obtained by the same operator for either water-reducible or solvent-reducible paints should be considered suspect if they differ by more than 10.7 % using Procedure A and by more than 13.6 % using Procedure B.

9.3.1.2 *Reproducibility*—Two results obtained by operators in different laboratories using Procedure A should be suspect if they differ by more than 34.4 % for water-reducible paints and 23.4 % for solvent-reducible paints. Two results obtained by operators in different laboratories using Procedure B should be suspect if they differ by more than 23.1 % for water-reducible paints and 19.8 % for solvent-reducible paints.

Standard Practice for Measurement of Wet Film Thickness by Notch Gages¹

This standard is issued under the fixed designation D 4414; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

¹ NOTE—Sections 5 through 10 were editorially renumbered in May 1990.

1. Scope

1.1 This practice describes the use of thin rigid metal notched gages, also called step or comb gages, in the measurement of wet film thickness of organic coatings, such as paint, varnish, and lacquer.

1.2 Notched-gage measurements are neither accurate nor sensitive, but they are useful in determining approximate wet film thickness of coatings on articles where size(s) and shape(s) prohibit the use of the more precise methods given in Methods D 1212.

1.3 This practice is divided into the following two procedures:

1.3.1 *Procedure A*—A square or rectangular rigid metal gage with notched sides is used to measure wet film thicknesses ranging from 0.5 to 80 mils (13 to 2000 μm). Such a gage is applicable to coatings on flat substrates and to coatings on articles of various sizes and complex shapes where it is possible to get the end tabs of the gage to rest in the same plane on the substrate.

1.3.2 *Procedure B*—A circular thin rigid metal notched gage is used to measure wet film thicknesses ranging from 1 to 100 mils (25 to 2500 μm). Such a gage is applicable to coatings on flat substrates and to coatings on objects of various sizes and complex shapes.

1.4 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 ASTM Standard:

D 1212 Methods for Measurement of Wet Film Thickness of Organic Coatings²

3. Summary of Practice

3.1 The material is applied to the articles to be coated and the wet film thickness measured with a notched gage.

3.2 *Procedure A*—A square or rectangular thin rigid metal gage with notched sides, having tabs of varying lengths, is pushed perpendicularly into the film. After removal from the film, the gage is examined and the film thickness is deter-

mined to lie between the clearance of the shortest tab wet by the film and the clearance of the next shorter tab not wetted by the film.

3.3 *Procedure B*—A circular thin rigid metal gage having spaced notches of varying depths around its periphery is rolled perpendicularly across the film. After removal from the film, the gage is examined and the film thickness is determined as being between the clearance of the deepest face wetted and the clearance of the next deepest notch face not wetted by the film.

4. Significance and Use

4.1 Wet film thickness measurements of coatings applied on articles can be very helpful in controlling the thickness of the final dry coating, although in some specifications the wet film thickness is specified. Most protective and high performance coatings are applied to meet a requirement or specification for dry film thickness for each coat or for the completed coating system, or for both.

4.2 There is a direct relationship between dry film thickness and wet film thickness. The wet film/dry film ratio is determined by the volume of volatiles in the coating as applied, including permitted thinning. With some flat coatings the dry film thickness is higher than that calculated from the wet film thickness. Consequently, the results from the notch gage are not to be used to verify the nonvolatile content of a coating.

4.3 Measurement of wet film thickness at the time of application is most appropriate as it permits correction and adjustment of the film by the applicator at the time of application. Correction of the film after it has dried or chemically cured requires costly extra labor time, may lead to contamination of the film, and may introduce problems of adhesion and integrity of the coating system.

4.4 The procedures using notched gages do not provide as accurate or sensitive measurements of wet film thickness as do the Interchemical and Pfund gages described in Methods D 1212. Notch gages may, however, be used on nonuniform surfaces, like concrete block, that are too rough to use the Interchemical and Pfund gages. Also notched gages can be very useful in the shop and field for determining the approximate thickness of wet films over commercial articles where size(s) and shape(s) are not suitable for measurements by other types of gages. Examples of such items are ellipses, thin edges, and corners.

4.5 An operator experienced in the use of a notched gage can monitor the coating application well enough to ensure the minimum required film thickness will be obtained.

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee B01.23 on Physical Properties of Applied Paint Films.

Current edition approved Oct. 26, 1984. Published January 1985.

² Annual Book of ASTM Standards, Vol 06.01.

4.6 Application losses, such as overspray, loss on transfer, and coating residue in application equipment, are a significant unmeasurable part of the coating used on a job and are not accounted for by measurement of wet film thickness.

5. Report

5.1 Report the following information:

5.1.1 The mean and range of the readings taken and the number of readings.

5.1.2 The smallest graduation of the gage used.

6. Precision and Bias

6.1 The precision and bias of Procedure A or B for measuring wet film thickness with notch gages are very dependent on methods of film application, time that the measurement is taken after film application, mechanical condition of the notch gages, and the step range of the gages.

6.2 Generally, the agreement between notch gages is good because they are insensitive to small differences in film thickness, that is the step intervals of the gages are relatively large.

PROCEDURE A

7. Apparatus

7.1 *Notched Gage*, square or rectangular, thin rigid metal plate, with notched sides (see Fig. 1), made from steel or aluminum³ (Note 1). Nonmetallic gages shall not be used.

NOTE 1—Aluminum or aluminum alloy gages are more easily distorted and may exhibit greater wear than steel gages. Gages made of plastic or deformable metal are not suitable.

7.1.1 Each notched side shall consist of a series of tabs (between notches) varying in length and located in a line between two end tabs equal in length and longest in the row.

7.1.2 As an example, the tabs on one row of a gage may differ in length as follows:

By 0.5 mil (13 μm) between 0 and 6 mils (0 to 150 μm),

By 1 mil (25 μm) between 6 and 10 mils (150 to 250 μm),

By 2 mils (50 μm) between 10 and 30 mils (250 to 750 μm), and

By 5 mils (125 μm) over 30 mils (750 μm).

8. Procedure

8.1 Apply the coating material to a rigid substrate and test with the gage immediately. The gage must be used immediately following application of the coating. Some coatings lose solvents quickly and spray application increases the speed. The resulting rapid reduction in wet film thickness can cause misleading readings.

8.2 Locate an area sufficiently large to permit both end tabs of the gage to rest on the substrate in the same plane.

8.3 Push the gage perpendicularly into the wet film so that the two end tabs rest firmly on the substrate at the same time.

8.4 Or, set one end tab firmly on the substrate and lower the gage until the other end tab is firmly in contact with the substrate.

8.5 Remove the gage from the film and examine the tabs.

³ These gages are commercially available from various coating equipment and instrument suppliers.

FIG. 1 Rectangular Notched Gage

The film thickness is determined as being between the clearance of the shortest tab wetted and the clearance of the next shorter tab not wetted by the film.

8.6 Clean the gage immediately after each reading by wiping it on a dry or solvent-dampened cloth so that subsequent readings are not affected. Do not clean with metal scrapers.

8.7 Repeat the procedure in 8.2 through 8.5 for at least three locations on the film. The number of readings required to obtain a good estimate of the film thickness varies with the shape and size of the article being coated, with the operator's experience, and whether one or more of the following problems are encountered:

8.7.1 Some coatings may not wet (leave residue on) some metal gages. However, the film itself may show where contact was made. When reading the gage, look at both the gage and the film itself for verification of the reading.

8.7.2 The gage may slip on the surface. Ignore such readings.

8.7.3 The surface may be coarse and false readings produced. The spot where the gage is used must be as uniform as possible and questionable readings ignored.

8.8 Determine the mean and range of the readings.

PROCEDURE B

9. Apparatus

9.1 *Circular Notched Gage*, thin aluminum disk, with notches of various depths spaced around its periphery (see Fig. 2). Each notch has a recessed flat face. A $\frac{3}{8}$ -in. (10-mm) hole is in the center of the disk.

FIG. 2 Circular Notched Gage

Standard Test Methods for Field Measurement of Surface Profile of Blast Cleaned Steel¹

1. Scope

1.1 These test methods cover the description of techniques for measuring the profile of abrasive blast cleaned surfaces in the laboratory, field, or in the fabricating shop. There are additional techniques suitable for laboratory use not covered by these test methods.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Summary of Method

2.1 The methods are:

2.1.1 *Method A*—The blasted surface is visually compared to standards prepared with various surface profile depths and the mode determined.

2.1.2 *Method B*—The depth of profile is measured using a fine pointed probe at a number of locations and the arithmetic mean determined.

2.1.3 *Method C*—A composite plastic tape is impressed into the blast cleaned surface forming a reverse image of the profile, and the peak to valley height on the tape measured with a micrometer.

3. Significance and Use

3.1 The height of surface profile has been shown to be a factor in the performance of various coatings applied to steel. For this reason, surface profile should be measured prior to coating application to ensure that it meets the specification. The instruments described are readily portable and sufficiently sturdy for use in the field.

NOTE—Optical microscope methods serve as a referee method for surface profile measurement. Profile depth designations are based on the concept of average maximum profile ($\bar{h}$ max); this value is determined by averaging a given number (usually 20) of the highest peak to lowest valley measurements made in the field of view of a standard measuring microscope. This is done because of evidence that coatings performance in any one small area is primarily influenced by the highest surface features in that area and not by the average roughness.²

4. Apparatus

4.1 *Method A*—A profile comparator³ consisting of a number of areas (each approximately one square inch in size), usually side by side, with a different profile or anchor

pattern depth. Each area is marked giving the nominal profile depth in mils or micrometres. Typical comparator surfaces are prepared with steel shot, steel grit, or sand or other nonmetallic abrasive, since the appearance of the profile created by these abrasives may differ. The comparator areas are used with or without magnification of 5 to 10 $\times$.

4.2 *Method B*—A dial gage⁴ depth micrometer fitted with a pointed probe. The probe is machined at a 60° angle with a nominal radius of 50 μ m. The base of the instrument rests on the tops of the peaks of the surface profile while the spring loaded tip projects into the valleys.

4.3 *Method C*—A special tape containing a compressible foam attached to a noncompressible uniform plastic film. A burnishing tool is used to impress the foam face of the tape into the surface to create a reverse replica of the profile that is measured using a spring-loaded micrometer.⁵

5. Test Specimens

5.1 Use any metal surface that, after blast cleaning, is free of loose surface interference material, dirt, dust, and abrasive residue.

6. Procedure

6.1 *Method A:*

6.1.1 Select the comparator standard appropriate for the abrasive used for blast cleaning.

6.1.2 Place the comparator standard directly on the surface to be measured and compare the roughness of the prepared surface with the roughness on the comparator segments. This can be done with the unaided eye, under 5 to 10 $\times$ magnification, or by touch. When using magnification, the magnifier should be brought into intimate contact with the standard, and the depth of focus must be sufficient so that the standard and surface are in focus simultaneously.

6.1.3 Select the comparator segment that most closely approximates the roughness of the surface being evaluated or, if necessary, the two segments to which it is intermediate.

6.1.4 Evaluate the roughness at a sufficient number of locations to characterize the surface as specified or agreed upon between the interested parties. At each location make three evaluations against the comparator and determine the mode. The mode of the three evaluations represents the profile at the specific location, with the mode of all locations representing the profile of the entire surface.

6.2 *Method B:*

6.2.1 Prior to use set the gage to zero by placing it on a piece of plate glass. Hold the gage by its base and press firmly against the glass. Adjust the instrument to zero.

6.2.2 To take readings, hold the gage firmly against the prepared substrate. Do not drag the instrument across the

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.46 on Industrial Protective Painting.

Current edition approved Nov. 14, 1984. Published January 1985.

² John D. Keane, Joseph A. Bruno, Jr., Raymond E. F. Weaver, "Surface Profile for Anti-Corrosion Paints," Oct. 25, 1976. Steel Structures Painting Council, 4400 Fifth Ave., Pittsburgh, PA 15213.

³ Suitable comparators include Keane-Tator Surface Profile Comparator and Clemtex coupons.

⁴ Suitable depth micrometers include the Elcometer Model 123 Surface Profile Gage.

⁵ Suitable replica tape and micrometers include Testex "Press-O-Film" tape and Mitutoyo Model 7326 Spring Micrometer.

surface between readings, otherwise the spring-loaded tip may become rounded.

6.2.3 Measure the profile at a sufficient number of locations to characterize the surface, as specified or agreed upon between the interested parties. At each location make ten readings and determine the mean. Then determine the mean for all the locations and report it as the profile of the surface.

6.3 Method C:

6.3.1 Select the correct tape range for the profile to be measured: coarse, 0 to 2 mils (0 to 50 μm) and extra coarse, 2.5 to 4.5 mils (40 to 115 μm).

6.3.2 Remove the wax paper backing and place the tape on the prepared surface with the foam side down, that is, put the dull side down.

6.3.3 Hold the tape firmly on the surface and rub the circular cut-out portion (approximately $\frac{3}{8}$ in. (6.5 mm) diameter) with the burnishing tool until a uniform gray color appears.

6.3.4 Remove the tape and place it between the anvils of a spring-loaded micrometer. Measure the thickness of the tape

(compressed foam and non-compressible plastic film combined). Subtract the thickness of the noncompressible plastic film to obtain the surface profile.

6.3.5 Measure the profile at a sufficient number of locations to characterize the surface, as specified or agreed upon between the interested parties. At each location make three readings and determine the mean. Then determine the mean for all the locations and report it as the profile of the surface.

7. Report

7.1 Report the range and the appropriate average (mean or mode) of the determinations, the number of locations measured, and the approximate total area covered.

8. Precision

8.1 Precision is under active study.⁶

⁶ Other organizations, such as National Association of Corrosion Engineers (NACE), are currently involved in such studies.

Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Visual Evaluation of Gloss Differences Between Surfaces of Similar Appearance¹

This standard is issued under the fixed designation D 4449; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This method covers the visual evaluation of gloss differences of coating surfaces, using special types of lamps for illumination. It identifies six aspects or types of gloss that one may look for when using the lamp to assess gloss differences between surfaces. It describes the conditions for using the lamps to best identify small differences in each of the six types of gloss. Four levels of visual gloss differences are distinguished.

1.2 While this technique is useful for both weathered and unweathered specimens, it has not been applied to metallics.

1.3 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are for information only.

1.4 *This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 3964 Practice for Selection of Coating Specimens for Appearance Measurements²

E 284 Definitions of Terms Relating to Appearance of Materials³

3. Terminology

3.1 *Definitions*—For definitions of terms used in this method, see Definitions E 284.

3.2 Descriptions of Terms Specific to This Standard:

3.2.1 *directionality of surface*—perceived change of glossy appearance of a surface with rotation of the surface in its own plane (see Fig. 1).

3.2.2 *gloss, distinctness-of-image*—perceived sharpness of images reflected by an object surface (see Fig. 2).

3.2.3 *gloss, of a surface*—perceived directionally selective reflecting properties responsible for the degree to which reflected highlights or images of objects may be seen as superimposed on the surface.

3.2.4 *reflection haze*—cloudy or milky appearance of a

surface adjacent to directions of specular reflection (see Fig. 3).

3.2.5 *sheen*—perceived shininess at a near-grazing angle of incidence for an otherwise matte specimen (difficult to photograph).

3.2.6 *specular gloss*—the relative luminous reflectance factor of a specimen in the specular direction. The luminous reflectance factor is the ratio of the luminous flux reflected from, to that incident on, a specimen for specified solid angles (see Fig. 4).

3.2.7 *texture*—perceived structure, pattern, or topography or combination thereof, of a surface (see Fig. 5).

4. Summary of Test Method

4.1 Test specimens are illuminated by special light sources that provide reflected images suitable for rating the gloss of coating surfaces. Two types of lamps may be used to produce reflected images. Lamp A consists of a modified fluorescent desk lamp covered with screen mesh. Lamp B consists of an incandescent bare filament bulb installed in an adjustable angle fixture.

4.2 Light from the selected lamp illuminates the test specimens. The reflected images reveal specular gloss reflection; the sharpness of the images of the screen or lamp filament reveals the detail and quality of the surface reflection (distinctness of image); and spreading of the reflected light into dark areas, such as the space between fluorescent tubes or near the filament image, reveals the presence of near-specular haze.

5. Significance and Use

5.1 Gloss⁴ is associated with the capacity of a surface to reflect more light in some directions than in others. The directions associated with mirror (or specular) reflection normally have the highest reflectances. Gloss is best seen and analyzed when the surfaces studied are illuminated by a light source that provides strong contrasting patterns of light and dark. Such a light source is described in this test method.

5.2 The simplest concept of gloss is that it corresponds to the mirror-like reflectances of surfaces. However, the distributions and intensities of this surface-reflected light are (for real materials) highly variable and affected by a variety of factors: surface smoothness and contour, refractive index, absorptance, angle of incidence, and (to a generally small extent) wavelength. From the great variety of surfaces

⁴ For a more detailed account of gloss, its measurement, and relationship to appearance generally, see R. S. Hunter, *The Measurement of Appearance*, Wiley-Interscience New York, NY 1975.

NOTE—The left panel is free of directionality. The right panel is highly directional because of buffing marks.

FIG. 1 Reflection of Bright Incandescent Lamp in Two Panels

NOTE—The panels exhibit a difference in distinctness-of-reflected image.

FIG. 2 Two White Porcelain Enamel Panels

Reflection patterns met in materials of commerce, it has been possible to identify seven surface-reflection criteria or "types of gloss" regularly used by skilled technologists for intercomparing and rating their products for gloss. Six of the seven criteria, or "types of gloss," are identified in the section on definitions. The seventh, luster or contrast gloss, is seldom of

concern to the coatings industry.

6. Apparatus

6.1 *Lamp A*—The recommended apparatus is constructed by modifying a conventional fluorescent desk lamp that has two 15-W, 18-in. (450-mm) tubes. Figure 6 is a photograph;

Standard Test Method for Pigment Content of Paints by Low-Temperature Ashing¹

This standard is issued under the fixed designation D 4451; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

¹ NOTE—Keywords were added editorially in July 1991.

Scope

1.1 This test method covers the pigment content of paints and several traffic marking materials (thermoplastic and preformed tape) by low-temperature furnace ashing. Some organic pigments may be lost by this method and some water moisture contained in pigments will be lost.

1.2 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Referenced Documents

2.1 ASTM Standards:

D 3723 Test Method for Pigment Content of Water-Emulsion Paints by Low-Temperature Ashing²

E 180 Practice for Determining the Precision of ASTM Methods for Analysis and Testing of Industrial Chemicals³

3. Summary of Test Method

3.1 The specimen is transferred to a tared porcelain dish, dried (if necessary) at 105°C, and heated on a burner. The dish and specimen are transferred to a muffle furnace and heated at 450°C. The dish and specimen are reweighed and the pigment (ash) content calculated.

4. Apparatus

- 4.1 Muffle Furnace, maintained at 450°C $\pm$ 25°C.
- 4.2 Circulating Oven, maintained at 105°C $\pm$ 2°C.
- 4.3 Porcelain Dishes, 90-mm diameter.
- 4.4 Plastic Disposable Syringe, 10-mL capacity.
- 4.5 Burner, meker type.

5. Reagents

5.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chem-

ical Society, where such specifications are available.⁴

5.2 Toluene.

6. Procedure

6.1 Liquid Paint:

6.1.1 Mix the sample until homogeneous, preferably on a mechanical shaker. If air bubbles become entrapped in the paint, stir it by hand.

6.1.2 Draw slightly more than 10 g of the paint under test into a 10-mL syringe and weigh to 0.1 mg. Transfer about 5 mL toluene to a porcelain dish tared with a paper clip for use as a stirrer. Add 10 g of the material into the toluene. Reweigh the syringe to 0.1 mg and calculate the specimen weight. Mix well on a magnetic stirrer. Place the dish in the oven at 105°C for 30 min.

6.1.3 Remove and heat at the lowest temperature possible over a meker burner in a fume hood. Do not leave the dish on the burner after the flame has subsided. Transfer to the muffle furnace and proceed as in 6.4.

6.2 *Preformed Traffic Marking Tape*—Cut about a 10-g square of the product. Remove the adhesive by pulling it off or by using an appropriate solvent. Save the beads that are knocked off by this process and weigh with the tape. Dry the specimen for 30 min at 105°C to remove the solvent. Cool in a desiccator. Weigh the specimen along with the loose beads to 0.1 mg into a tared porcelain dish. Heat in a fume hood at the lowest temperature of a meker burner in a furnace hood until the material catches fire. Do not leave the dish on the burner after the flame has subsided. Transfer to the muffle furnace and proceed as in 6.4.

6.3 *Thermoplastic Traffic Marking Material*—This material may be delivered in block or powdered form. Transfer about 400 g of the sample to a quart container and heat in a forced draft oven at 400°F until completely melted (may take as long as 4 h). Stir vigorously until well mixed. Pour about 10 g of the sample into an aluminum dish and let it cool. Remove the 10 g wafer from the aluminum dish and weigh to 0.1 mg. Transfer to a tared porcelain dish. Heat the dish at the lowest temperature of a meker burner in a fume hood until the specimen catches fire. Do not leave the dish on the burner after the flame has subsided. Transfer to a muffle furnace and proceed as in 6.4.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Materials.

Current edition approved Jan. 25, 1985. Published December 1985.

³ Annual Book of ASTM Standards, Vol. 15.05.

⁴ "Reagent Chemicals. American Chemical Society Specifications," Am. Chem. Soc., Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY and the "United States Pharmacopeia."

6.4 Place the porcelain dish in a muffle furnace in a fume hood at 450°C (see Test Method D 3723). Heat overnight or until no further carbonaceous material is noted. Cool in a desiccator and reweigh the dish plus the residue to 0.1 mg. Calculate the residue as percent pigment or, in the case of thermoplastic material and preformed tape, as pigment and beads.

7. Calculation

7.1 Calculate the percent pigment, P , as follows:

$$P = C - A/S \times 100$$

where:

C = weight of dish and specimen after ignition in furnace, g,

A = weight of dish alone, g, and

S = specimen weight used, g.

8. Precision

8.1 The precision estimates are based on an interlaboratory study in which one operator in 7 different laboratories

analyzed in duplicate on two days six samples of commercial whole paint or thermoplastic material containing 50 to 80 % pigment. The results were analyzed statistically in accordance with Practice E 180 and the within-laboratory coefficient of variation was found to be 0.10 % relative at 36 df and the between-laboratories coefficient of variation 0.25 % relative at 30 df. Based on these coefficients the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

8.1.1 *Repeatability*—Two results, each the mean of duplicate determinations, obtained by the same operator on different days should be considered suspect if they differ by more than 0.28 % relative.

8.1.2 *Reproducibility*—Two results, each the mean of duplicate determinations, obtained by operators in different laboratories should be considered suspect if they differ by more than 0.72 % relative.

9. Keywords

9.1 ignition, pigment; low temperature ashing; pigment content of paints

Standard Test Method for Determination of Dichloromethane and 1,1,1-Trichloroethane in Paints and Coatings by Direct Injection into a Gas Chromatograph¹

This standard is issued under the fixed designation D 4457; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

¹ NOTE—Keywords were added editorially in July 1991.

Scope

1.1 This test method covers the determination of total amount of dichloromethane or 1,1,1-trichloroethane, or both, in paints and coatings. It has been evaluated for cellulose nitrate, alkyd, vinyl, and styrene-butadiene systems. It has not yet been evaluated for other formulations, but is believed to be applicable. The established working range of this test method is from 31 to 65 % for 1,1,1-trichloroethane and 32 to 78 % for dichloromethane. There is no reason to believe it will not work outside of these ranges. The presence of 1-propanol in paints and coatings requires the use of a different internal standard. (See also Practice E 260.)

1.2 This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. Specific hazard statements are given in Section 7.

Referenced Documents

2.1 ASTM Standards:

E 180 Practice for Determining the Precision Data of ASTM Methods for Analysis and Testing of Industrial Chemicals²

E 260 Practice for Packed Column Gas Chromatography³

Summary of Test Method

3.1 Anhydrous 1-propanol (see 10.5) is added as an internal standard to suitable aliquot of the whole paint. The aliquot is then diluted with dimethylformamide and injected onto a gas chromatographic column containing a porous polymer packing that separates dichloromethane and 1,1,1-trichloroethane from other volatile compounds.

Significance and Use

4.1 Use of 1,1,1-trichloroethane and dichloromethane, which do not measurably contribute to the atmospheric oxidant level, is a way for industry to meet government or

other regulations on volatile organic compounds. This test method is designed to determine the content of these halohydrocarbon solvents in paints and coatings. That content can subsequently be used in calculating the volatile organic compound content of a coating.

5. Apparatus

5.1 *Chromatograph*, any gas-liquid chromatographic instrument equipped with a thermal conductivity detector and capable of being temperature programmed (see Table 1). Optionally, a flame ionization detector may be used if the sample is diluted so that no more than 1000 ppm each of dichloromethane and 1,1,1-trichloroethane is present in the injected specimen.

5.2 *Recorder*, a recording potentiometer with a full-scale deflection of 10 mV, a full-scale response time of 2 s or less, and a maximum noise of ± 0.03 % of full scale.

5.3 *Pre-Column*, 40 in. (100 mm) long by $\frac{1}{8}$ in. (3.2 mm) outside diameter stainless steel, packed with glass wool, fitted on the entrance end of the column to retain any nonvolatile materials and minimize sludge buildup in the column.

5.4 *Column*, 4 ft (1.22 m) long by $\frac{1}{8}$ in. (3.2 mm) outside diameter stainless steel, packed with 80/100 mesh (150 to 180 μ m) porous polymer packing material,⁴ or other suitable material.

5.5 *Liquid Charging Devices*, such as microsyringes of 5- μ L or 10- μ L capacity, cleaned with acetone or other suitable solvent. Visually inspect for plugs or cracks before and after each injection.

5.6 *Vials*, 25-mL to minimize head space, capable of being septum sealed.⁵

6. Reagents and Materials

6.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests, unless otherwise specified (as in 6.7). Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁶ Other grades may be used

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paint and Paint Materials.

Current edition approved July 16, 1985. Published October 1985.

³ Annual Book of ASTM Standards, Vol 14.01.

⁴ Porapak R[®], available from Waters Associates, Inc., Milford, MA, has been found satisfactory for this purpose.

⁵ Mininert valves, available from The Pierce Chemical Co., Box 117, Rockford, IL 61105, have been found satisfactory for this purpose.

⁶ "Reagent Chemicals, American Chemical Society Specifications," Am. Chem. Soc., Washington, DC. For suggestions on the testing of reagents not listed by the

provided it is first ascertained that the reagent is of sufficient high purity to permit its use without lessening the accuracy of the determination.

6.2 *Carrier Gas*, helium of 99.995 % or higher purity. High purity nitrogen may also be used.

6.3 *Dimethylformamide (DMF)*, reagent grade.

6.4 *1-Propanol*, gas chromatography spectrophotometric quality (see 10.5).

6.5 *1,1,1-Trichloroethane* (see 6.7).

6.6 *Dichloromethane* (see 6.7).

6.7 *Halogenated Hydrocarbon Stabilizers*—All commercial grades of these halogenated hydrocarbons contain stabilizers. Either obtain the same solvent used in the coating for use as the standard, or find the type and quantity of stabilizer specified for use in the solvent of interest and add the appropriate quantity to the pure solvent.

7. Hazards

7.1 Dimethylformamide is harmful if inhaled or absorbed through skin. Use only with adequate ventilation. Avoid contact with skin, eyes, and clothing.

8. Preparation of Apparatus

8.1 *Column Conditioning*—The packed column is installed in the gas chromatographic unit leaving the exit end disconnected from the detector. This will prevent any contamination of the detector with the column bleed. Set the helium flow rate at 30 mL/min if a 1/8 in. (3.2 mm) outside diameter column is used. Purge the column 5 to 10 min before heating. Heat the column from room temperature to 200°C at 5°C/min and hold this temperature for at least 12 h (overnight). At the end of this period of time, heat the column to 240°C at a 5°C/min rate and hold this temperature for several hours. The maximum temperature for this packing is 250°C. Cool the column to 100°C and reheat to 240°C at 5°C/min to observe the column bleed. Optimum conditioning of this column may take several cycles of the heating program before a good recorder baseline is achieved. Conditioning of any column other than that suggested (5.4) should be in accordance with the manufacturer's recommendations.

8.2 Install the column in the chromatograph and use the information in Table 1 as a guide to establish the conditions required to give the desired separation. Allow sufficient time for the instrument to reach equilibrium as indicated by a stable recorder baseline. Adjust the carrier-gas flow to a constant rate. Before each calibration and series of determinations (or daily), condition the column at 200°C for 1 h with carrier-gas flow.

9. Calibration

9.1 *Preparation of Standards*—All standards, as well as samples and blanks, should be at a constant temperature. The given order of ingredient addition should be observed to minimize loss of volatile ingredients.

9.1.1 Weighing to 1.0 mg, add 16.0 g of dimethylformamide to a vial capable of being septum sealed. Add 2.0

TABLE 1 Typical Instrument Conditions

Detector	thermal conductivity
Column	4 ft (1.22 m) by 1/8 in. (3.2 mm) outside diameter packed with 80-100 mesh porous polymer packing
Temperature, °C	
Injection port	200
Detector block	250
Column	
Initial	100
Final	230 (for 8 min)
°C/min	8
Carrier gas	helium
Flow rate, mL/min	30
Specimen size, µL	1

g of 1,1,1-trichloroethane, 2.0 g of 1-propanol (see 10.5) and 2.0 g of dichloromethane. Seal the vial with a crimp-on or septum seal.

9.2 Determine the retention time of each component by injecting small amounts either separately or in known mixtures. The components should elute close to the typical retention times given in Table 1 and the chromatograms should closely approximate those shown in Fig. 1.

9.3 The area under each peak of the chromatogram is considered a quantitative measure of the corresponding compound. The relative area is proportional to concentration if the detector responds equally to all the sample components. The response to different components is generally significantly different for both flame ionization and thermal conductivity detectors and especially for flame ionization detectors. This difference in detector response may be corrected by use of relative response factors obtained by injecting and measuring the response of known blends. For precise and accurate determination of the halogenated

hydrocarbons inject a 1 μ L specimen of the standard in accordance with the preparation in 9.1. Calculate the response factors relative to unity for the halogenated hydrocarbons.

10. Procedure

10.1 Keep all samples, blanks, and standards at a constant temperature. Observe the given order of ingredient addition to minimize loss of volatile ingredients. Shake paints, then sample from the middle of the container.

10.2 Weighing to 1.0 mg, add 16.0 g of dimethylformamide and 5.0 g of the paint to a vial capable of being septum sealed. Add 2.0 g of 1-propanol (see 10.5). Seal the vial with a crimp-on or septum seal.

10.3 Shake the vial. Then to facilitate settling, centrifuge using a low speed centrifuge at 1000 rpm for 5 min.

10.4 Inject a 1- μ L specimen of the supernatant from the prepared solution onto the chromatographic column, in accordance with the conditions established in 8.2. Record the peaks of all components.

10.5 If the composition of the paint is unknown, test for the presence of 1-propanol. Prepare a blank, omitting the 2.0 g of 1-propanol in 10.2, and inject a 1- μ L specimen. To this blank add 2.0 g of 1-propanol and inject a 1- μ L specimen. Then compare peak response to that from the test solution. If 1-propanol is present in the paint, substitute a different internal standard. Other possible internal standards include alcohols, esters, and hydrocarbons.

10.6 If the composition of the paint is unknown, establish whether peaks interfering with 1-propanol or the halogenated hydrocarbons are present by using both the column specified in 5.4 and a second column that yields different retention times.⁷

11. Calculation

11.1 Measure the area of all peaks (Note) and multiply each area by the appropriate attenuation factor to express the peak areas on a common basis.

NOTE—Peak areas may be determined by any method that meets the precision requirements of Section 12. Electronic integration is recommended for best results.

11.2 Calculate the percent halogenated hydrocarbon in the paint as follows:

$$RF_i = \frac{W_i}{A_i}$$

where:

RF_i = corrected peak response for i^{th} component, area units,

W_i = weight of i^{th} component in the standard solution, g, and

A_i = chromatographic peak area for the i^{th} component in the standard solution, area units,

then:

$$CH \text{ wt } \% = \frac{RF_{CH} \times A_{CH} \times IS_{amt}}{RF_{IS} \times A_{IS} \times W} \times 100$$

⁷ Packings from the Porapak series and the Chromosorb Century series may be satisfactory for this purpose. However, it is the responsibility of each analyst to check for interferences from paints or the internal standard chosen, or both, and to choose a column that gives symmetrical peaks.

where:

CH wt % = chlorinated hydrocarbon, weight %,

RF_{CH} = response factor for the chlorinated hydrocarbon in the standard solution, area units,

A_{CH} = area of the chlorinated hydrocarbon peak in the test solution, area units,

IS_{amt} = weight of internal standard added to the paint, g,

RF_{IS} = response factor for the internal standard in the standard solution, area units,

A_{IS} = area of the internal standard peak in the test solution, area units, and

W = specimen weight, g.

12. Precision and Bias⁸ (see also Practice E 180)

12.1 Precision:

12.1.1 *1,1,1-Trichloroethane*—On the basis of an inter-laboratory test of this test method in which one operator in each of eight laboratories tested three coatings containing from 31 to 65 % 1,1,1-trichloroethane (theoretical), the within-laboratory coefficient of variation was found to be 1.01 % relative at 20 degrees of freedom and the between-laboratories coefficient of variation was found to be 2.72 % relative at 17 degrees of freedom. Based on these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

12.1.1.1 *Repeatability*—Two results, each the mean of duplicate runs, obtained by the same operator should be considered suspect if they differ by more than 3.0 % relative.

12.1.1.2 *Reproducibility*—Two results, each the mean of duplicate runs, obtained by operators in different laboratories should be considered suspect if they differ by more than 8.1 % relative.

12.1.2 *Dichloromethane*—On the basis of an inter-laboratory test of this test method in which one operator in each of eight laboratories tested two coatings containing from 32 to 78 % dichloromethane (theoretical), the within-laboratory coefficient of variation was found to be 0.98 % relative at 14 degrees of freedom and the between-laboratories coefficient of variation was found to be 5.16 % relative at 12 degrees of freedom. Based on these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

12.1.2.1 *Repeatability*—Two results, each the mean of duplicate runs, obtained by same operator should be considered suspect if they differ by more than 3.0 % relative.

12.1.2.2 *Reproducibility*—Two results, each the mean of duplicate runs, obtained by operators in different laboratories should be considered suspect if they differ by more than 17.92 % relative.

12.2 *Bias*—Determination of a bias statement for this test method is not practical at this time.

13. Keywords

13.1 chlorinated hydrocarbons in paints by gas chromatograph; dichloromethane, in paints; exempted solvent in paints; gas chromatograph, halohydrocarbon; 1,1,1-trichloroethane, in paints

Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Methods for Measuring Static Friction of Coating Surfaces¹

This standard is issued under the fixed designation D 4518; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 These test methods cover the determination of the resistance to sliding on coating surfaces by measuring the static friction.

1.2 Two test methods are described as follows:

	Sections
Method A—Inclined Plane Test.....	8 to 13
Method B—Horizontal Pull Test.....	14 to 19

1.3 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 *ASTM Standard:*

D 823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels²

3. Terminology

3.1 *Definition:*

3.1.1 *static friction*—the force required to start the test sled moving, divided by the mass of the sled.

4. Summary of Test Methods

4.1 With the inclined plane test (Test Method A), a weighted sled is placed on a test specimen and the specimen is gradually inclined from the horizontal until the sled begins to slide. The tangent of this angle of inclination is reported as the static friction.

4.2 With the horizontal pull test (Test Method B), a weighted sled is placed on a horizontal test specimen and is pulled across the specimen. The static friction is reported as the force required to start the sled moving, divided by the mass of the sled.

5. Significance and Use

5.1 The friction characteristics of coating surfaces can be important to the use of the coatings. For example, low friction of exterior can coatings is beneficial to the flow of the cans on production lines. Also low friction of interior pipeline coatings is beneficial to the flow of materials

through pipes. On the other hand, low friction of floor coatings can be hazardous to foot traffic.

5.2 Under some conditions, measurement of the static friction can be used to evaluate the slip resistance of coatings under use conditions. However, results can be extremely dependent on the type of coating surface and the type of sliding unit used.

5.3 The tendency for footwear to slip may be influenced by foreign materials or lubricants on the shoe materials or on the walking surfaces. Also, these test methods do not incorporate all the directional forces involved in the walking process. Consequently, levels of slip resistance as determined by these test methods may not predict a person's resistance to slipping when walking on various surfaces.

5.4 The best precision and sensitivity are obtained when stainless steel is used as the facing of the sliding unit. In some tests where a leather facing is used, poor precision is obtained because of the inability to control the uniformity of its surface during the test. The use of a hard synthetic rubber facing provides somewhat better precision.

5.5 These test methods provide for static friction measurements when the sled facing and the coating surfaces are wet with water. Results from such tests must be treated with caution because frequently the static friction values obtained for wet, smooth coatings are higher than those obtained for the same surfaces dry. This is because, when stationary at the beginning of the test, the sled contact can produce a "suction cup" effect on a wet surface. Measurements performed on wet coatings with rough surfaces have been more satisfactory.

5.6 A test procedure is offered that eliminates the "suction cup" effect of wet surfaces. The wet sled is dropped onto the wet coating surface at the start of the test.

5.7 Results obtained by these test methods may be extremely sensitive to the age of the test coating because the blooming action of additives or plasticizers is often time-dependent. It may be meaningless to compare slip and frictional properties of test coatings applied at different times unless this effect is being studied.

5.8 The measurement of static friction may be influenced by the length of time that the sled rests on the test specimen before motion is initiated.

5.9 Static friction measurements have been useful in evaluating (1) the suitability of coatings for the exterior of cans, (2) the slipperiness of floor polishes, and (3) the slip resistance characteristics of footwear on floor tiles and floor coatings. Also, static friction measurements have been useful in determining the effect of coating additives (for example waxes, silicones) on the slipperiness of coating surfaces.

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.23 on Physical Properties of Applied Paint Films.

Current edition approved Sept. 15, 1991. Published November 1991. Originally published as D 4518 - 85. Last previous edition D 4518 - 90.

² *Annual Book of ASTM Standards*, Vol 06.01.

6. Test Specimens

6.1 Apply test coatings in accordance with Test Methods D 823 to substrates of at least 4 in. (100 mm) in width and length. The substrates may be of glass, steel, aluminum, or other appropriate material that remains smooth and plane after the test coating has been applied and cured at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity for 7 days, unless otherwise specified. Prepare at least two test panels for each coating.

6.2 Take care during application of the test coating to minimize entrainment of dust and particulate matter in the surface of the coating. Extreme care is required when handling the panels, even after sufficient cure. The surface should be kept free of all dust, lint, fingerprints, or any foreign matter that may change the characteristics of the surface.

7. Conditions for Testing

7.1 Test the coated test specimens under one or more of the following conditions as agreed upon by the purchaser and the seller:

7.1.1 Both sled facing and coating surfaces dry at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$).

7.1.2 Both the sled face and the coating surface wet with water containing a slight amount of wetting agent at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$). Sea water containing a slight amount of wetting agent may be used when it is appropriate. A wetting solution consisting of 1 mL of surfactant³ added to 200 mL of water has been found to be satisfactory.

7.1.3 One or both of the above at $35.5 \pm 3.5^\circ\text{F}$ ($2 \pm 2^\circ\text{C}$).

TEST METHOD A—INCLINED PLANE TEST

8. Apparatus

8.1 *Inclined Plane*, having a smooth, incompressible surface, at least 1 in. (25 mm) wider than the sliding unit and of sufficient length to allow the test sled to move by gravity at least 0.5 in. (12 mm), provided with clamps for the test specimen, and an inclinometer to indicate the angular displacement of the plane to within 0.5° .

NOTE 1—A suitable apparatus is shown in Fig. 1. It may be assembled from items obtained from laboratory instrument supply houses.

8.2 *Test Sleds*—Alternative sleds that may be used are:

8.2.1 *Stainless Rounded Edge Steel Block*, with a highly polished plane lower surface 3 by 3 in. (75 by 75 mm) in area and a mass of 1.8 lb (0.82 kg) to provide a pressure of 0.2 psi (1.4 kPa) when horizontal.

8.2.2 *Stainless Steel Block*, with a plane lower surface of 3 by 3 in. (75 by 75 mm) and a mass of 1.8 lb (0.82 kg). Adhered to the lower surface is a $\frac{1}{4}$ -in. (6-mm) thick vulcanized neoprene rubber having a Shore "A" hardness of 65 ± 5 . A screw eye or other means to attach the sled to the force-measuring device is provided.

8.3 *Inclinometer*—Means to smoothly increase the inclination of the plane from the horizontal through an arc of at

FIG. 1 Schematic of Inclined Plane Apparatus

least 45° at a rate of $1.5 \pm 0.5^\circ/\text{s}$.

NOTE 2—Procedures found suitable for smoothly increasing the inclination of the plane are (1) pulling the top of the plane upward with a motor driven dip coater and (2) pushing the top of the plane upward with a laboratory jack equipped with a hand crank.

9. Preparation of Apparatus

9.1 Preparation of Sled Facing:

9.1.1 If a synthetic rubber facing is used on the test sled, it must be preconditioned by light sanding before each determination.

9.1.2 Place a sheet of 400A wet or dry silicon carbide abrasive paper on a flat surface. Sand the synthetic rubber facing by rubbing it gently back and forth over the paper four times. Repeat at 90° to the first direction. Wipe the surface of the synthetic rubber facing with a clean, dry cloth to remove dust or loose material from the surface.

10. Procedure

10.1 Level the plane so it is horizontal when the inclinometer reads zero.

10.2 Clamp the test specimen to the plane. Recheck the levelness of the panel in two directions (along the length of the panel and across the panel at 90° to the first measurement).

10.3 Dry Surfaces:

10.3.1 Center the sled on the test coating. Immediately commence inclining at a rate of $1.5 \pm 0.5^\circ/\text{s}$. When the sled starts to move, stop the inclinometer immediately and read the angle of displacement at the moment the sled starts to move.

10.3.2 Return the plane to a level position and make two additional tests on the test specimen as described in 8.3.

10.4 For Wet Surfaces:

10.4.1 Check levelness of plane and test panel according to procedures given in 10.1 and 10.2.

10.4.2 Wet the test coating surface and the sled facing with the prescribed solution. Apply the solution with a soft brush. Make certain that all surfaces are completely wet.

10.4.3 Set the plane of the angle of displacement deter-

³ A surfactant such as Aerosol OT manufactured by American Cyanamid Co., Chemical Group, One Cyanamid Plaza, Wayne, NJ 07470, has been found suitable for this purpose.

TABLE 1 Precision Values Obtained in 1987 Round-Robin Test of Test Method D 4518

Inclined Plane Test				Dry Surfaces		
Type of Sled Surface	Standard Deviation		Coefficient of Variation	Degree of Freedom	Maximum Allowable Difference	
	Angle of Inclination	Static Friction			Angle of Inclination	Static Friction
Polished Steel	3.6	0.08	23 %	14	10.9	0.24
Abraded Steel	3.7	0.08	10 %	13	11.3	0.24

Interlaboratory						
Type of Sled Surface	Standard Deviation		Coefficient of Variation	Degree of Freedom	Maximum Allowable Difference	
	Angle of Inclination	Static Friction			Angle of Inclination	Static Friction
Polished Steel	4.2	0.09	28 %	32	12.1	0.26
Abraded Steel	4.0	0.09	20 %	32	11.5	0.26
Neoprene	4.2	0.21	17 %	19	12.4	0.62

measured for the dry coating surface in 10.3.1.

10.4.4 From a height of 1/2 in. (12 mm), drop the sled onto the coating surface. Determine if the sled begins to slide.

10.4.5 Change the angle of the slide, and after rewetting coating and sled surfaces, repeat dropping the sled. Continue in this manner until the plane angle at which the sled starts to slide is determined.

10.4.6 Return the plane to the initial position of 10.4.3 and repeat 10.4.4 and 10.4.5.

11. Calculation

11.1 Calculate the mean of the three measurements on the test specimen. Determine the trigonometric tangent of the mean angle, which is the static friction value.

12. Report

12.1 Report the following information for the coated panels tested:

12.1.1 Temperature and humidity during curing and at the time of testing,

12.1.2 Type of facing used on the test sled,

12.1.3 Whether facing and coating surface were wet or dry,

12.1.4 Inclination angle determined for each measurement,

12.1.5 Static friction value for each measurement, and

12.1.6 Mean static friction value for the replicate panels.

13. Precision

13.1 An interlaboratory study of Test Method A (Inclined Plane Test) in which one operator in each of four laboratories, using sled surfaces of neoprene, polished steel and mildly abraded steel, tested the dry surfaces of eight coated panels with a wide range of slip resistance. The intralaboratory and interlaboratory standard deviations were found to be as shown in Table 1. Based on these standard deviations, the following criteria should be used for judging, at the 95 % confidence level, the acceptability of results:

13.1.1 *Repeatability*—Two results obtained by the same operator should be suspect if they differ by more than the maximum allowable difference given in Table 1.

13.1.2 *Reproducibility*—Two results obtained by operators in different laboratories should be considered suspect if they differ by more than the maximum allowable difference given in Table 1.

13.2 Comparison of inclined plane results are shown in Table 2.

TABLE 2 Comparison of Inclined Plane Results Obtained with Stationary and Dropped Sleds on Panel Surfaces

Panel	Sled	Surface	Angle of Slide, °		Static Friction	
			Sled Stationary	Sled Dropped	Sled Stationary	Sled Dropped
A	Steel	Dry	12	12	0.21	0.21
	Neoprene		27	31	0.50	0.61
	Steel	Wet	...	14	...	0.25
	Neoprene		...	32	...	0.61
B	Steel	Dry	20	25	0.35	0.46
	Neoprene		47	34	1.07	0.68
	Steel	Wet	...	19	...	0.34
	Neoprene		...	26	...	0.49
C	Steel	Dry	17	26	0.31	0.49
	Neoprene		36	41	0.73	0.86
	Steel	Wet	...	19	...	0.23
	Neoprene		...	26	...	0.56
D	Steel	Dry	20	25	0.35	0.46
	Neoprene		47	34	1.07	0.68
	Steel	Wet	...	15	...	0.27
	Neoprene		...	29	...	0.56
G	Steel	Dry	20	20	0.35	0.35
	Neoprene		38	32	0.80	0.61
	Steel	Wet	...	19	...	0.34
	Neoprene		...	26	...	0.49
H	Steel	Dry	25	22	0.46	0.39
	Neoprene		14	36	0.96	0.74
	Steel	Wet	...	13	...	0.23
	Neoprene		...	18	...	0.32

13.3 Bias cannot be determined since there is no standard for slipperiness or slip resistance.

TEST METHOD B—HORIZONTAL PULL TEST

14. Apparatus⁴

14.1 *Test Base*, a horizontal plane surface of a smooth, incompressible material (metal, wood, plate glass, or plastic) having a width at least 1 in. (25 mm) wider than the test sled (14.2) with means of leveling it in two directions. This base serves as a support for the rest of the mechanism and the test specimen. When placed on a solid support, it must be free of vibration.

14.2 *Test Sleds*—Alternative sleds that may be used are:

14.2.1 *Stainless Steel Block*, with a highly polished lower plane surface of 3 by 3 in. (75 by 75 mm) and a mass of 1.8 lb (0.82 kg) to provide a pressure of 0.2 psi (1.4 MPa) on the horizontal surface. A screw eye or other means to attach the sled to the force-measuring device is provided.

14.2.2 *Steel Block*, with a smooth lower surface of 3 by 3 in. (75 by 75 mm) in area and a mass of 1.8 lb (0.82 kg). Adhered to the lower surface is a 1/4-in. (6-mm) thick vulcanized neoprene rubber having a Shore "A" hardness of 65 ± 5 . A screw eye or other means to attach the sled to the force-measuring device is provided.

14.2.3 *Steel Block*, having a smooth lower surface 4 by 5 in. (100 by 125 mm) in area and a thickness of 1 to 1.5 in. (25 to 40 mm). Adhered to the lower surface is vulcanized neoprene rubber having a Shore "A" hardness of 65 ± 5 and a thickness of 1/8 in. (3 mm). The total mass of the sled with the rubber facing shall be 6.0 ± 0.5 lb (2.7 ± 0.2 kg).

14.3 *Mechanical Power Unit*—Means for moving the test sled horizontally over the test specimen or the test specimen under a fixed test sled under the following conditions:

14.3.1 For the sleds described in 14.2.1 and 14.2.2, a speed of 6.0 ± 1.0 in./min (150 ± 25 mm/min) shall be provided and a sled (or panel) travel of 4 in. (100 mm).

14.3.2 For the sled described in 14.2.3, a speed of 12 ± 1 in. (300 ± 25 mm)/min shall be provided and the sled (or panel) allowed to travel 4 in. (100 mm).

14.3.3 *Force Measuring Device*—Means for measuring the force to 0.01 lb (0.04 N) required to move or restrain the test sled.

NOTE 3—A force gage⁵ that can be preset to display the highest force encountered is desirable.

NOTE 4—Figure 2 illustrates a suitable apparatus. There are various commercial instruments available but some require modification to meet the requirements of these test methods.

15. Preparation of Apparatus

15.1 Preparation of Sled Facing:

15.1.1 If a synthetic rubber facing is used on the test sled, it must be preconditioned by light sanding before each determination.

15.1.2 Place a sheet of 400A wet or dry silicon carbide abrasive paper on a plane surface. Sand the synthetic rubber facing by rubbing it gently back and forth over the paper four

⁴ A facing of heel material such as Neolite, with a Shore "A" hardness of 95 ± 5 may be used if appropriate.

⁵ Chatillon dynamometer gages, available from Chatillon, Inc., 83-30 Kew Garden Rd., Kew Garden, NY 11415, have been found suitable for this purpose.

FIG. 2 Schematics for Two Horizontal Plane Instruments.

times. Repeat at 90° to the first direction. Wipe the surface of the synthetic rubber facing with a clean, dry cloth to remove dust or loose material from the surface.

16. Procedure

16.1 Select the test sled and traverse the speed appropriate for the type of test desired:

16.1.1 The test sled described in 14.2.2 with a traverse speed of 6 in. (150 mm)/min is recommended if the best precision of measurement on a smooth coating is desired.

16.1.2 The test sled described in 14.2.2 with a traverse speed of 6 in. (150 mm)/min is recommended if it is desired to measure the resistance of a smooth coating to the slipping of a rubber shoe heel or sole.

16.1.3 The test sled described in 14.2.3 with a traverse speed of 12 in. (300 mm)/min is recommended if it is desired to measure the resistance of a rough coating to the slipping of a rubber shoe heel or sole.

16.2 Clamp the test specimen to the base. Position the test sled and connect it to the power unit or force gage. Fasten the inelastic linkage (cable or chain) to the test sled and connect to the power unit or the force gage.

16.3 As soon as possible after positioning the sled, start the power unit, taking care to maintain tautness in the linkage as the power unit takes up the load.

16.4 Record the force required to just begin motion of the test slide; that is, the maximum force value recorded.

16.5 For the evaluation of smooth coatings, make two additional determinations on the test specimen as described in 16.1 through 16.4. For the evaluation of rough coatings, make four additional determinations on the test specimen.

17. Calculation

17.1 Calculate the mean of the force value obtained for the replicate determinations.

17.2 Divide the mean force by the mass of the test sled. This is the static friction value.

18. Report

18.1 Report the following information for the coated panels tested:

- 18.1.1 Temperature and humidity during curing and testing,
- 18.1.2 Whether facing and coating surfaces were dry or wet,
- 18.1.3 Mass of test sled used,
- 18.1.4 Type of facing used on the test sled,
- 18.1.5 Traverse speed of sled used,
- 18.1.6 Static friction value for each coated panel, and

18.1.7 Mean static friction value for the replicate panels.

19. Precision and Bias

19.1 An interlaboratory test will be conducted to determine the precision and bias of this test method. Tests conducted by several laboratories have shown that this measuring technique has sufficient sensitivity and precision to differentiate coatings exhibiting significantly different sliding friction characteristics.

20. Keywords

20.1 coating surface slipperiness; horizontal pull slipmeter test; inclined plane; static friction

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Guide for Establishing Procedures to Qualify and Certify Inspection Personnel for Coating Work in Nuclear Facilities¹

This standard is issued under the fixed designation D 4537; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide delineates the requirements for development of procedures for the qualification of personnel who perform inspection of coating work. These activities are accomplished to verify conformance to specified requirements for nuclear facility coatings work whose satisfactory performance is required in order not to compromise systems used to mitigate the consequences of postulated accidents.

1.2 This guide provides a uniform interpretation of the requirements in ANSI/ASME N45.2.6-1978 for the inspection of coating work in nuclear facilities.

1.3 This guide meets the intent of ANSI/ASME NQA-1.

1.4 It is the intent of this guide to provide a recommended basis for qualification, not to mandate a singular basis for all qualifications. Variations or simplifications of the qualifications described in this guide are appropriate for special coating work outside of safety-related areas.

1.5 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ANSI/ASME Standards:

ANSI/ASME N45.2.6 Qualifications of Inspection, Examination, and Testing Personnel for Nuclear Power Plants²

ANSI/ASME NQA-1 Quality Assurance Program Requirements for Nuclear Facilities.²

3. Terminology

3.1 Description of Terms Specific to This Standard

3.1.1 *certification*—written documentation of qualification.

3.1.2 *coating work inspection*—a phase of quality control which, by means of examination, observation, or measurement, determines the conformance of coating work to predetermined quality requirements.

3.1.3 *qualifications*—skills, training, and experience required for personnel to perform properly the duties and

execute the responsibilities of the appropriate certification level.

3.1.4 *training*—the program developed to ensure that personnel receive the knowledge and skills necessary for qualification.

4. Significance and Use

4.1 The requirements of this guide apply to personnel who perform inspections of coating work during (1) fabrication, (2) receipt of items at the construction site, (3) construction, (4) pre-operational and startup testing, and (5) operational phases of nuclear facilities.

4.2 It is the responsibility of each organization participating in the project to ensure that only those personnel within their respective organizations who meet the requirements of this guide are permitted to perform inspection activities covered by this guide.

4.3 The organization(s) responsible for establishing the applicable requirements for activities covered by this guide shall be identified, and the scope of their responsibility shall be documented. Delegation of this responsibility to other qualified organizations is permitted and shall be documented.

4.4 It is the responsibility of the organization performing these activities to specify the detailed methods and procedures for meeting the requirements of this guide, unless they are otherwise specified in the contract documents.

5. General Requirements for Inspection Personnel

5.1 Provisions shall be made for the indoctrination of personnel as to the technical objectives of the project, the codes and standards that are to be used, and the quality assurance elements that are to be employed.

5.2 The need for formal training programs shall be determined, and such training activities shall be conducted as required to qualify personnel who perform inspections. On-the-job participation shall also be included in the program, with emphasis on first-hand experience gained through actual performance of inspections.

5.3 A candidate's qualifications for certification shall be initially determined by a suitable evaluation of the candidate's education, experience, training, examination results, and capability demonstration.

5.4 The job performance of coating work inspection personnel shall be reevaluated at periodic intervals not to exceed three years. Reevaluation shall be by evidence of continued satisfactory performance or redetermination of capability in accordance with 5.3. If, during this evaluation or at any other time, it is determined by the responsible organization that the capabilities of an individual are not in

¹ This guide is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generation Facilities and is the direct responsibility of Subcommittee D33.04 on Inspection.

accordance with the qualifications specified for the job, that person shall be removed from that activity until the required capability has been demonstrated.

5.5 Any person who has not been actively engaged in the performance or supervision of coating work inspection for a period of one year shall be reevaluated in accordance with 5.3.

6. Functional Qualifications of Inspectors

6.1 All physical inspection activities can be performed by certified Level I, Level II, or Level III inspectors.

6.2 *Level I Coatings Inspector*, shall be capable of the following:

6.2.1 Implementing and recording all inspections required by the applicable procedures.

6.2.2 Verifying instrument calibration.

6.2.3 Performing hold point inspections in accordance with the applicable procedures.

6.3 *Level II Coatings Inspector*, shall be capable of the following:

6.3.1 Performing all of the duties and responsibilities of a Level I coatings inspector.

6.3.2 Planning and supervising inspections, initiating and reviewing inspection procedures, and evaluating the adequacy of activities.

6.3.3 Reviewing, organizing, and approving results of inspections.

6.3.4 Monitoring the performance of and supervising the work of Level I coatings inspectors.

6.3.5 Training and verifying the qualifications of Level I coatings inspectors for certification.

6.3.6 Initiating changes to quality procedures.

6.3.7 Implementing the Quality Assurance Program if assigned that authority by company policy or the Quality Assurance Program.

6.4 *Level III Coatings Inspector*, shall be capable of the following:

6.4.1 Carrying out all of the duties and responsibilities of a Level II coatings inspector.

6.4.2 Certifying Level I, Level II, and other Level III coatings inspectors.

6.4.3 Responsible for evaluating the adequacy of programs used to train coatings inspectors.

6.4.4 Responsible for authorizing Level II coatings inspectors to carry out training and examination duties:

6.4.5 Responsible for approving all safety-related inspection procedures.

7. Physical Qualifications of Inspectors

7.1 Each inspector shall be examined annually to ensure natural or corrected near-distance visual acuity in at least one eye. The individual shall read the J-1 letters on a Standard Jaeger Test Chart, or equivalent, at a distance of not less than 12 in. with one or both eyes, uncorrected or corrected.

7.2 Each candidate shall be examined for color preception using the Ishihara Test or the Farnsworth D-15 Test when being certified or recertified. If a candidate does not pass the Red/Green Sensitive Ishihara Test, the candidate may take the Farnsworth D-15 Test.

7.3 If a candidate does not pass the Farnsworth D-15 Test the candidate may be evaluated by a licensed medical practitioner to provide the necessary data to determine the candidate's color perception. Individuals certified after an

evaluation by a licensed medical practitioner may only be certified to perform inspection work that is within the candidate's color perception capability.

7.4 The examinations required by 7.1 and 7.2 shall be administered by a licensed medical practitioner or a person familiar with the tests involved. The results of vision tests shall be documented on a Vision Test Record (Fig. 1 or equivalent form).

7.5 The responsible organization shall identify any other physical qualifications required to perform the assigned inspection duties. Inspectors requiring the identified physical qualifications shall have them confirmed by examinations at intervals not to exceed one year.

8. Education, Training, and Experience Qualifications

8.1 Candidates for certification as coatings inspectors shall have sufficient education, experience, and training to ensure an understanding of the principles and procedures in those areas of inspection, examination, and testing activities for which they are being considered for certification.

8.2 *Level I Coatings Inspectors*, shall, as a minimum, meet one or more of the following requirements:

ORGANIZATIONAL TRAINING RECORD

NAME: _____
(Last) (First) (Middle Initial)

TRAINING COURSES, SEMINARS, LECTURES, ETC.

Given by and Date	Description of Training	Test Score	Pass/Fail	Initials

FIG. 3 Sample Organization Training Record

8.2.1 High school graduation plus six months of related experience in equivalent inspection activities.

3.2.2 Completion of college level work leading to an associate Degree or higher, plus three months of related experience in equivalent inspection activities.

8.3 *Level II Coatings Inspectors*, shall, as a minimum, meet one or more of the following requirements:

8.3.1 High school graduation plus one year of satisfactory performance as a Level I coating inspector in the corresponding inspection activity.

8.3.2 High school graduation plus three years of related experience in equivalent inspection activities.

8.3.3 Completion of college level work leading to an associate Degree plus one year of related experience in equivalent inspection activities.

3.3.4 Four-year college graduation plus six months of related experience in equivalent inspection activities.

8.4 *Level III Coatings Inspectors*, shall meet one or more of the following requirements:

8.4.1 High school graduation plus six years of satisfactory performance as a Level II coatings inspector in the corresponding inspection activity.

8.4.2 High school graduation plus ten years of related experience in equivalent inspection activities; or high school graduation plus eight years experience in equivalent inspection activities, with at least two years as a Level II coatings inspector. The candidate shall have at least two years associated with nuclear facilities or sufficient training to be knowledgeable of the quality assurance requirements for nuclear coating work.

8.4.3 Completion of college level work leading to an Associate Degree and seven years of related experience in equivalent inspection activities. The candidate shall have at least two years of this experience associated with nuclear

_____ has complied with, and successfully passed, all of the applicable requirements of the referenced Standard Guide.

EXAMINATION SCORES

GENERAL PORTION _____
SPECIFIC PORTION _____
PRACTICAL PORTION _____

I certify that the above statements are correct and recommend certification as a Level _____ Coatings Inspector.

RECOMMENDED BY

NAME: _____
Type or print followed by signature
TITLE: _____

The above statement and recommendation have been reviewed for conformance to the requirements of the referenced Standard, and are correct. This individual is certified as Level _____ coatings inspector in accordance with the referenced Standard Guide.

CERTIFIED BY

Type or print name followed by signature
(must comply with 11.3 of the Standard Guide)

FIG. 4 Sample Record of Certification

facilities or sufficient training to be knowledgeable of the quality assurance requirements for nuclear coating work.

8.4.4 Four-year college graduation plus five years of related experience in equivalent inspection activities. The candidate shall have at least two years of this experience associated with nuclear facilities or sufficient training to be knowledgeable of the quality assurance requirements for nuclear coating work.

8.5 Compliance with the requirements of 8.1, 8.2, 8.3, and 8.4 shall be documented on an Education and Experience Record (Fig. 2 or equivalent form).

8.6 Training leading to certification or recertification as a qualified coatings inspector shall be documented on an Organizational Training Record (Fig. 3 or equivalent form).

9. Examination

9.1 Each candidate for coatings inspector shall be given an

examination covering the general, specific, and practical aspects of coatings inspection. The general and specific portions of the examination may be written, in the form of a personal interview, or a combination of both. The examination results shall be documented in accordance with 11.1.

9.1.1 The general portion of the examination shall cover the basic principles of quality assurance and coating work inspection.

9.1.2 The specific portion of the examination shall cover specific coating work requirements and inspection procedures.

9.1.3 The practical portion of the examination shall cover the use of coating work inspection equipment and inspection procedures.

9.1.4 All parts of the examination for a Level I or Level II coatings inspector shall be administered by a Level III

coatings inspector or a duly authorized Level II coatings inspector.

9.1.5 Examinations for a Level III coatings inspector shall be administered by a certified Level III coatings inspector or by the responsible organization's management.

10. Performance

10.1 Personnel assigned the responsibility and authority to perform functions covered by this guide shall have, as a minimum, the appropriate level of capability given in Section 6. When a single inspection requires implementation by a team or group, personnel not meeting the requirements of this Guide may be used in data-taking assignments or in plant or equipment operation provided they are supervised or overseen by a qualified individual participating in the inspection.

10.2 A certified coatings inspector shall submit annually a summary of coatings related inspection/testing activities performed between certification anniversary dates in order to maintain the validity of the certification. This summary for a Level I or Level II coatings inspector shall be reviewed by a certified Level III coatings inspector or his designee, signed and placed in the coatings inspector's certification file. The summary review for a Level III coatings inspector shall be conducted by another certified Level III coatings inspector or the responsible organization's management, signed and placed in the inspector's certification file.

10.3 Any certified coatings inspector not performing coatings related inspection/testing work between certification anniversary dates shall be recertified in accordance with 11.2, after it is reconfirmed that the inspector's capabilities meet the requirements of this guide.

11. Certification of Inspectors

11.1 Level I and Level II coatings inspection certifications are valid for a period not to exceed three years. Level III coatings inspector certifications are valid for a period not to exceed five years. Coatings inspectors are certified after review of the candidate's qualifications for compliance with this guide. The examiner shall document the interview of the candidate and the review of the candidate's capabilities, education, experience, vision records, training records, and applicable examination records. Certifications are documented on a Record of Certification (Fig. 4 or equivalent form).

11.2 Coatings inspectors shall be recertified as required by 11.1 after evaluation of their work record. Individual work records shall show evidence of continuing satisfactory performance.

11.3 Level I and Level II coatings inspectors are certified or recertified by a certified Level III coatings inspector. Level III coatings inspectors are certified or recertified by the responsible organization's management or by a certified Level III coatings inspector.

11.4 Certification by a given employer shall be considered revoked when employment is terminated.

12. Records

12.1 A personnel qualification records file shall be established and maintained by the employer. Collection, storage, and control of records required by this guide shall be in accordance with the requirements of the responsible organization and appropriate specifications.

13. Keywords

13.1 certified coatings inspector; coatings inspection; coatings inspector; inspector certification; Level II Coatings Inspector; Level III Coatings Inspector; nuclear coatings inspector; qualified coatings inspector

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Terminology Relating to Protective Coating and Lining Work for Power Generation Facilities¹

This standard is issued under the fixed designation D 4538; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

- alligatoring**—*in protective coatings*, surface cracking of coating film having an appearance similar to alligator hide.
- certification**—*in protective coatings*, the written documentation of the qualification of personnel or material.
- checking**—*in protective coatings*, the formation of slight breaks in a coating film that do not penetrate to the underlying surface.
- coating applicator**—*in protective coatings*, an organization or individual responsible for applying a protective or decorative coating.
- coating system**—*in protective coatings*, a protective film consisting of one or more coats, applied in a predetermined order by prescribed methods.
- coating work**—*in protective coatings*, an all-inclusive term to define all operations required to accomplish a complete coating job; construed to include materials, equipment, labor, preparation of surfaces, control of ambient conditions, application of coating systems, and inspection.
- cobwebbing**—*in protective coatings*, the formation of fine filaments (cobwebs) or partly dried coating, during spray application.
- cracking**—*in protective coatings*, the formation of breaks in a coating film that extend through to the underlying surface.
- cratering**—*in protective coatings*, the formation of round depressions in a coating film that do not expose the previous coat or the substrate.
- crawling**—*in protective coatings*, a defect in which a wet coating film recedes from a small area to form an uneven surface shortly after application.
- crazing**—*in protective coatings*, the formation of a criss-cross pattern of minute cracks on the surface of a coating film.
- delamination**—*in protective coatings*, a separation of one coat from another coat within a coating system; or from the substrate.
- deviation**—*in protective coatings*, a departure of a characteristic from established procedures or from specified requirements.
- drips**—*in protective coatings*, the small drops of coating that collect on the edge of the coated work.
- dry spray**—*in protective coatings*, a rough, powdery, non-coherent film produced when an atomized coating partially dries before reaching the surface.
- flaking**—*in protective coatings*, the detachment of small pieces of the coating film.
- foreign matter**—*in protective coatings*, insoluble foreign particles such as sand, lint, dust, and dirt that get mixed with the coating material before, during, or after application; causing the formation of raised specks in the dried film.
- hairline crack**—*in protective coatings*, a very fine crack (having a hairlike appearance) that is visible on the surface of a dried coating film.
- heavy-centered spray pattern**—*in protective coatings*, an uneven spray pattern having more coating in the center, and less at the edges.
- intercoat contamination**—*in protective coatings*, the presence of foreign matter between successive coats.
- mudcracking**—*in protective coatings*, a particular pattern of cracking in a coating with the appearance of a dried mud puddle (see cracking and checking).
- orange peel**—*in protective coatings*, the dimpled appearance of a dried coating film resembling the surface of an orange.
- pinhole**—*in protective coatings*, minute holes through a coat or coats that expose an underlying coat or the substrate.
- pinholes**—small pore-like flaws in a coating that extend entirely through the applied film and have the general appearance of pin pricks when viewed by reflected light (see Definitions D 16²).
- qualification**—*in protective coatings*: The characteristics or abilities gained through training or experience, or both, that enable an individual to perform a required function.
- wrinkling**—*in protective coatings*, the formation of a surface appearance in a coating film resembling the skin of a prune.

Standard Guide for Testing Interior Latex Semigloss and Gloss Paints¹

This standard is issued under the fixed designation D 4540; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

Scope

1.1 This guide covers the selection and use of procedures for testing latex semigloss or gloss paints intended for use on interior walls or trim. The test methods included are listed in Tables 1 and 2.

1.2 The latex semigloss and gloss paints covered by this guide are intended for application by brushing, rolling, spraying, or other means, on plaster, masonry surfaces, wood, wallboard, previously painted surfaces and other interior architectural surfaces.

1.3 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 Definitions:

3.1.1 For definitions of terms used in this guide, see Terminology D 16.

4. Conditions Affecting Latex Semigloss and Gloss Paints

4.1 *Substrate Type*—The substrate to be painted can affect not only the application properties and the physical properties of a latex paint, such as gloss and uniformity, but may also be a factor in determining the type of latex paint to be used.

4.2 *Substrate Condition*—Dirty, alkaline, or water-soluble surfaces may affect the practical requirements and performance of these paints.

4.3 *Application Properties*—The application properties of paints are affected by temperature, humidity, and the texture and porosity of the surface to be painted. Application is also affected by the type and quality of equipment used.

5. Selection of Tests

5.1 Many conditions affect interior latex semigloss and gloss paints, so that different types of latex paints have been developed specifically to meet the requirements of these various conditions. Although the recommended test methods in Tables 1 and 2 cover most of the properties of such paints, all of the tests may not be required for each paint. If a paint is to be used only in a warm climate for instance, then freeze-thaw tests or low temperature coalescence tests need not be considered.

5.2 The purchaser should first determine which properties a latex paint must have and then select only the test methods that will measure or evaluate those properties. After selecting the desired tests, the purchaser should determine which of these properties are the most important and establish the appropriate requirements or specifications for obtaining the desired properties. Since paint properties frequently tend to oppose each other, some properties may need to be attenuated if others are to be accentuated. This balance of properties must be considered when selecting the tests and establishing their requirements. A normal range of values is indicated in many of the tests methods.

5.3 This guide does not indicate relative importance of the various tests nor does it recommend specific values for each test, since the properties that are important to one purchaser may not be important to another.

6. Sampling

6.1 Prior to sampling, the condition of the container should be established since damage to it may cause evaporation or skinning of the pigment or other undesirable effects in the coating. Determine the condition of the coating in accordance with 7.1 and 7.2.

6.2 Sample in accordance with Practice D 3925. Determine the weight per gallon in accordance with Test Method D 1475. Repeat this procedure until successive readings agree within 0.2 lb (90 g) or as agreed upon between purchaser and seller. Samples for testing may then be taken.

TABLE 1 List of Test Methods by Properties

Test Method	Section	ASTM Test Method	Federal Test Method Standard No. 141
Liquid Paint Properties:			
Condition in container	7.1		3011
Coarse particles and foreign matter	7.2	D 185	
Density (weight per gallon)	7.3	D 1475	
Fineness of dispersion	7.4	D 1210	
Odor	7.5		
Color compatibility	7.6		
Package Stability:	7.7	D 1849	
Accelerated heat-aged stability	7.7.1		
Freeze-thaw stability	7.7.2	D 2243	
Microorganism resistance	7.7.3	D 2574	
pH stability	7.7.4	E 70	
Sampling	6	D 3925	
Settling	7.7.5	D 869	
Paint Application and Film Formation:			
Application properties	8.1		4541
Application by brush	8.1.1		2141
Application by roller	8.1.2		2112
Application by spray	8.1.3		2131
Drying time	8.2	D 1640	
Low-temperature coalescence of paints	8.3	D 3793	
Producing uniform thickness of films	8.4	D 823	
Touch-up uniformity	8.5	D 3928	
Rheological Properties:			
Leveling	9.1	D 4062	
Low shear viscosity (consistency)	9.2	D 562	
High shear viscosity (ICI cone and plate viscosity)	9.3	D 4287	
Sag resistance	9.4	D 4400	
Rheological properties, non-Newtonian liquids	9.5	D 2196	
Appearance of Dry Paint Film:			
Color difference by visual evaluation	10.1	D 1729	
Color difference using instrumental measurements	10.2	D 2244	
Hiding power	10.3	D 344, D 2805	
Specular gloss	10.4	D 523	
Properties of Dry Paint Film:			
Block Resistance	11.1		
Efflorescence of paint film	11.2	D 1736	
Efflorescence from substrate	11.3		
Flexibility	11.4	D 522	
Film porosity	11.5	D 3258	
Print resistance	11.6		
Scrubability (wet abrasion)	11.7	D 4213 or D 2486	
Stain removal (washability)	11.8	D 3450	
Wet adhesion	11.9		
Analysis of Paint:			
Chemical analysis	12.1		
Nonvolatile content	12.2	D 2369	
Volatile organic compound (VOC)	12.3	D 3960	

6.3 Specify the identification codes. A 1 U.S. gallon (or 4-L) sample is usually sufficient for the recommended tests but for guidance in selecting a sampling plan, consult Practice E 105.

7. Liquid Paint Properties

7.1 *Condition in the Container*—Thickening, settling, and separation are undesirable and objectionable if the paint cannot be reconditioned with a reasonable amount of stirring. The referenced method covers procedures for determining changes in properties of paints after storage. Deter

Volatile organic compound (VOC)	12.3	D 3960	
Wet adhesion	11.9		

mine the condition in the container in accordance with Method 3011 of Federal Test Method Standard No. 141. (See also 7.7 on Package Stability.)

7.2 Coarse Particles and Foreign Matter:

7.2.1 Paints must be free of coarse particles to form uniform films of good appearance, a typical maximum being weight % of total paint. The specified test with a 325-mesh (45- μ m) screen and water as the wash liquid gives the percent of these particles in a latex paint. Determine coarse particles and foreign matter in accordance with Test Methods D 185.

7.2.2 Another test method used in industry to determine whether coarse particles are present in a dry film is to scrape the surface of the film with a spatula or metal edge of a ruler. Any particles larger than 325 mesh (45 μ m) can be clearly seen after the surface has been scraped.

7.3 Density (Weight per Gallon)—The density as mea-

sured by weight per gallon (kilograms per litre) is used to assure product uniformity from batch to batch. It does not necessarily measure the quality of a paint. In the referenced method, the density is expressed as the weight in pounds per U.S. gal (or kg/L) of the paint at a specified temperature. Most interior semigloss and gloss paints have densities of about 10 to 12 lb/gal (1.2 to 1.4 kg/L). Determine density in accordance with Test Method D 1475.

7.4 Fineness of Dispersion:

7.4.1 The more finely a pigment is dispersed, the more efficiently it is being used. One method for measuring the degree of dispersion (commonly referred to as "fineness of grind") is to draw the material down a calibrated tapered groove varying in depth from 4 to 0 mils (100 to 0 μ m). The Hegman scale is one commonly accepted measurement method. The point at which the continuous groupings of particles or agglomerates, or both, protrude through the surface of the liquid is taken as the fineness reading. Lower readings in mils or micrometres or higher readings in Hegman units indicate better fineness dispersion. Measure fineness of dispersion in accordance with Test Method D 1210.

7.4.2 The referenced method was designed primarily for coatings with good fineness of dispersion such as enamels. Most interior semigloss and gloss latex paints have a fineness of about 7.5 to 5 Hegman (6 to 40 μ m).

7.5 Odor—One of the advantages of latex paints is that they do not have odors characteristic of solvent-reducible coatings. However, other ingredients, such as ammonia, may be used that might also be objectionable in confined spaces. Thus, interior latex paints should be tested for odor acceptability. Determine whether the paint has an unpleasant or irritating odor during application or drying.

7.6 Color Compatibility—A test method to determine how well colorants can be dispersed in paints so that the paint will have uniformity of color when applied is in preparation and will be included in the guide when adopted by ASTM.

7.7 Package Stability—Since paints cannot normally be used immediately after manufacture they must remain stable in the can for some time. At normal temperatures, most latex paints can be stored for over a year with little change in properties. Although indications of long term package stability can usually be obtained in several days or weeks at an elevated temperature, such as 140°F (60°C) or 122°F (50°C), occasionally the results of the accelerated test do not agree with those at prolonged normal storage conditions. The referenced method predicts the change in consistency and certain other properties in packaged latex paint when stored at temperatures above freezing. Determine package stability in accordance with Test Method D 1849.

7.7.1 Heat Stability—Heating is used to accelerate changes in viscosity with time and to predict their affect on other properties. An excessive increase or decrease in viscosity after heat-aging is unacceptable. There is a general correlation between short-term high temperature oven stability and long-term shelf storage at ambient temperature. This test is meant to predict which paints will not be stable when stored by customers or consumers under elevated temperature for a short period of time or at room temperature for a longer period of time. After heat-aging, such

properties as viscosity, flow, gloss, pH drift, foam resistance, color uniformity, and wet adhesion are usually rechecked versus room temperature-aged controls.

7.7.2 Freeze-Thaw Stability—Water-reducible paints may be subjected to freezing conditions during shipping and storage. Suitably stabilized paints will resist several cycles of freezing and thawing without showing deleterious changes such as coagulation, graininess, or excessive viscosity increase. Many latex paints will increase in viscosity but can still be considered satisfactory if other properties that may be affected by a higher viscosity, such as leveling and brushability, are satisfactory. Determine freeze-thaw stability in accordance with Test Method D 2243.

7.7.3 Microorganism Resistance—Bacteria in a latex paint can cause gassing, putrefactive or fermentative odors, and loss of viscosity. Determine if the paint contains living bacteria or if it is resistant to attack by bacteria in accordance with Test Method D 2574.

7.7.4 pH—Latex paints with low (acidic) pH can corrode metal containers. pH may vary from about 5 to 10 depending upon the type of latex used and general formulation. pH does not determine the quality of a latex paint and should only be used to assure product uniformity. However, a change in pH during storage may indicate poor stability and unacceptable change in the properties of a paint. Determine pH in accordance with Test Method E 70.

7.7.5 Settling—Latex paints are generally resistant to hard settling, but do at times show separation and soft settling. The referenced method covers the degree of pigment suspension and ease of remixing a shelf-aged sample of paint to a homogeneous condition suitable for the intended use. Determine settling in accordance with Method D 869.

8. Paint Application and Film Formation

8.1 Application Properties—Determine the ease with which a paint can be applied to various wall surfaces with brush, roller, or spray equipment, in accordance with Method 4541 of Federal Test Method Standard No. 141. Application properties are generally compared to a standard, or described by requirements in a product specification.

8.1.1 Brush Application—Brushed films should be smooth and free of seeds and on vertical surfaces should show no sagging, color streaking, or excessive brush marks. The specified method covers the determination of the brushing properties of coatings. The test is subjective although those experienced in the art can produce quite consistent results, particularly in the evaluation of "drag" properties. Determine brushing properties in accordance with Method 4321 of Federal Test Method Standard No. 141.

8.1.2 Roller Application—Walls are frequently painted with rollers that produce slight stipple effects. Determine the ease with which a paint can be roller applied in accordance with Method 2112 of Federal Test Method Standard No. 141. Since roller foam and roller spatter are often serious problems when latex paints are roller applied, these properties can also be determined in the test method for roller application. The amount of foam produced, the time that it takes for the bubbles to break, and the number of craters that remain after the bubbles have broken can be determined by visual examination of the test panel. Roller spatter can be

determined by placing a strip of paper or a panel at the bottom of the test panel to catch the paint spatters from the roller. The degree to which a paint will spatter when roller applied can be determined by the density of the paint spatter.

8.1.3 Spray Application—Interior coatings are sometimes applied by spray. Both air and airless spray are used on commercial work. Determine the spray application properties in accordance with Method 2131 of Federal Test Method Standard No. 141. The method can be modified to include application by airless spray equipment.

8.2 Drying Properties—The drying time of an interior latex paint is important in determining when a freshly painted room can be put back to use. Under average conditions most semigloss and gloss latex paints are dry to touch in 1 to 2 h when the water has evaporated from the film. Because of the glycols usually present in these paints, it is prudent to recoat after at least an 18-h dry. Ultimate properties may take a few days to develop for some latex paints while others may require a few weeks depending on the composition. Determine the drying time in accordance with Test Methods D 1640.

8.3 Low-Temperature Coalescence of Paints—The referenced test method determines how well the latex particles in a paint will fuse together or coalesce, to form a continuous film at low temperatures. Determine low-temperature coalescence in accordance with Test Method D 3793.

8.4 Producing Films of Uniform Thickness—The following method covers the preparation of various films of uniform thickness essential in conducting tests. Prepare films in accordance with Test Methods D 823.

8.5 Touch-Up Uniformity—After paint has dried, areas where less material was applied sometimes become noticeable. If the paint has suitable touch-up properties, additional paint can be applied to these areas only, instead of refinish the complete wall. The color, gloss, and leveling of the touched-up areas and the previously painted area should be uniform. Differences in these properties are often caused by short wet edge time, poor leveling on recoat and pigment orientation or floatation during and after application. Determine touch-up properties in accordance with Test Method D 3928.

9. Rheological Properties

9.1 Leveling—Leveling is an important factor when uniform surfaces are to be produced as it affects hiding power and appearance. Brush marks and imperfections are much more conspicuous in semigloss and gloss paints than they are in flat paints. The referenced method covers the leveling characteristics of liquid coatings. Evaluate leveling in accordance with Test Method D 4062.

9.2 Low Shear Viscosity (Consistency)—Paints of a given type should fall within a stated consistency range for satisfactory reproduction of a specific formula. While consistency is an important property, it does not determine the quality of a paint and should be used mainly to ensure product uniformity. In the referenced method, consistency is defined as the load in grams to produce a specified rate of shear. Although the consistency of most latex wall paint is about 150 to 300 g, a much wider range is possible because of the wide variations in rheological properties of these paints. Two paints of the same consistency may have quite different

ological properties since this is only a measure of their shear viscosity. Optimized application properties are generally used to determine the optimum consistency. Measure the consistency in accordance with Test Method D 562.

10.3 High Shear Viscosity (ICI Cone and Plate Viscosity)—The shear rate for this measurement (10 000 reciprocal seconds) is similar to that occurring during brush application, and the viscosity measured at this shear rate therefore is related to brush drag, which is in turn related to spreading and film build. Measure the high shear viscosity in accordance with Test Method D 4287.

10.4 Sag Resistance—This is an important property particularly for semigloss and gloss latex paints because sagging results in unsightly film appearance. Measure the sag resistance in accordance with Test Methods D 4400.

10.5 Rheological Properties, Non-Newtonian Liquids—Rheological properties are related to application and leveling properties of the liquid paint. The referenced methods cover the determination of rheological properties and are particularly suited for use with paints that display thixotropic characteristics. They actually measure viscosity under different shear rates. Determine rheological properties in accordance with Test Methods D 2196 or D 4287, or both.

10. Appearance of Dry Film

10.1 Color Differences by Visual Evaluation—Visual comparison of color is fast and often acceptable although numerical values are not obtained. The referenced method covers the spectral, photometric, and geometric characteristics of light source, illuminating and viewing conditions, size of specimens, and general procedures to be used in the visual evaluation of color differences of opaque materials. Determine color differences in accordance with Practice D 1729.

10.2 Color Differences Using Instrumental Measurements—The differences in color between a product and its standard can be measured by instrument. Generally, the standard is agreed upon by the purchaser and the seller and may also be required if a product specification is involved. Color instruments provide numerical values that can be compared to subsequent measurements. The referenced method covers the instrumental determination of small color differences observable in daylight illumination between nonmetameric, opaque surfaces such as coated specimens. If metamerism is suspected, visual evaluation (see 10.1) should be used to verify the results. Calculate in accordance with Test Method D 2244 the color differences that have been measured instrumentally.

10.3 Hiding Power (Dry Opacity)—Hiding power is the measure of the ability of a paint to hide the substrate. It is, however, dependent upon uniform film thickness that is influenced by flow and leveling. Test Method D 344 is a practical test in which paint is applied with a brush, film thickness is approximately measured, opacity is evaluated and usually compared to a standard paint, and results are affected by flow and leveling application properties of the paint. Test Method D 2805 is considered to be a more precise and accurate test that does not need a material paint standard. Paint is applied with an applicator bar to minimize the effects of flow and leveling, film thickness is rigorously measured, and opacity is instrumentally evaluated. Deter-

mine hiding power in accordance with Test Methods D 344 or D 2805.

10.4 Specular Gloss—The method given, using the 20° geometry for high gloss paints and 60° geometry for semigloss paints, is useful in characterizing the direct appearance of gloss and semigloss paints. According to the *Paint/Coatings Dictionary*,⁷ the semigloss range is usually 35 to 70 using the 60° geometry. Full gloss is usually above 70 using the 60° geometry. Although paints with good uniformity of appearance are often paints of lower gloss and paints with good cleanability are often ones with higher gloss, this is not always the case, and the gloss of a paint should not be used as a measure of other paint properties. Determine the gloss at 20° and 60°, as appropriate, gloss in accordance with Test Method D 523.

11. Properties of Dry Film

11.1 Block Resistance—This is an important property of an interior semigloss or gloss since it is the resistance of the painted surfaces to stick together when stacked or placed in contact with each other. An interior paint often comes in contact with itself especially in the cases of doors, windows and drawers and sometimes sticks to itself (blocks) depending on the hardness of the coating, the pressure, temperature, humidity, and duration of time the surfaces are in contact.

11.2 Efflorescence of the Paint Film—The referenced method measures efflorescence that comes from the paint itself, not from the substrate. Few interior latex paints effloresce due to improvements in latex and latex paint formulations. Salt formation is produced by specific conditions of temperature and humidity if a paint contains sufficient solid water-soluble material to cause a noticeable deposit on the film. Determine efflorescence resistance in accordance with Test Method D 1736.

11.3 Efflorescence from Substrate—Cementitious substances may contain sufficient solid water-soluble materials to cause a surface deposit through leaching and evaporation.

11.4 Flexibility—Elongation is a measure of the flexibility of a paint film. Most interior latex paints can be bent over a 1/8-in. (3.2-mm) mandrel without affecting the film. Determine elongation in accordance with Test Methods D 522.

11.5 Film Porosity—The more porous a paint is, the worse will be its cleanability and enamel holdout. Determine film porosity in accordance with Test Method D 3258.

11.6 Print Resistance—The ability of a coating to resist printing is important because its appearance is adversely affected if the surface texture is modified by contact with another surface particularly one with a pattern. Interior gloss and semigloss systems on window sills and other horizontal surfaces often have flower pots placed on them that may tend to leave a permanent impression from the pressure. This tendency for a paint film to "print" is often a function of the hardness of the coating, the pressure, temperature, humidity, and duration of time that the painted surface is in contact with the object.

⁷ Available from Federation of Societies for Coatings Technology, 492 Norristown Rd., Blue Bell, PA 19422.

11.7 Scrubbability—The ability of an interior finish to resist scrubbing is an important property. The referenced method provides a measure of the wet abrasion resistance of a film. However, wet abrasion resistance is not necessarily a measure of how well soils or stains can be removed since some paints have good scrubability but poor stain cleanability because they are porous. Determine the scrubability in accordance with Test Method D 4213 or D 2486. A control paint should always be tested at the same time because of the variability of the method.

11.8 Stain Removal (Cleanability)—The ability to remove marks satisfactorily without damaging the film is an important property of interior finishes. Determine stain removal in accordance with Test Method D 3450.

11.9 Wet Adhesion—It is essential that an interior finish adhere tightly to a given substrate or primer under the wet conditions of washing or scrubbing.

12. Analysis of Paint

12.1 Chemical Analysis—If a specification requires certain raw materials or certain components in a given amount, then chemical analysis is required to determine whether the specified materials are present and in what amounts. Analysis does not necessarily establish paint quality that can also be greatly affected by manufacturing techniques. Most ASTM analytical methods apply to solvent-based coatings. However, some of them can be adapted for analysis of latex paints.

12.2 Volatile Content—The percent of volatile matter is a

measure of the amount of a liquid coating lost as it dries. This quantity is not necessarily indicative of the quality of a coating. It is useful, however, for determining the similarity of two batches. The referenced method covers the determination of the volatile content by weight of solvent- and water-reducible coatings. The quantity determined subtracted from 100 % gives the nonvolatile content. Determine volatile content in accordance with Test Method D 2369.

12.3 Volatile Organic Compound (VOC) Content—Several local jurisdictions in California have adopted air pollution controls that severely limit the amount of solvent (Volatile Organic Compound (VOC) content) permitted in architectural coatings, including interior latex gloss and semigloss paints. Since these paints may contain solvents such as coalescents and cosolvent wet edge aids, it is essential that these products not exceed the established VOC limits. Determine VOC content in accordance with Practice D 3960.

13. Field Testing

13.1 Although many of the recommended test methods attempt to simulate conditions under which latex semigloss and gloss wall paints are applied, it is not possible to accurately simulate all possible conditions. Testing latex semigloss and gloss wall paints under field conditions is recommended for the final evaluation of suitability.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Pull-Off Strength of Coatings Using Portable Adhesion Testers¹

This standard is issued under the fixed designation D 4541; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

¹ NOTE—Editorial changes were made throughout in April 1989.

Scope

1.1 This test method covers a procedure and apparatus for evaluating the pull-off strength (commonly referred to as "adhesion") of a coating by determining either the greatest perpendicular force (in tension) that a surface area can bear before a plug of material is detached, or whether the surface remains intact at a prescribed force (pass/fail). Failure will occur along the weakest plane within the system comprised of the test fixture, adhesive coating system, and substrate and will be exposed by the fracture surface. This test method maximizes tensile stress as compared to the shear stress applied by other methods such as scratch or knife adhesion and results may not be comparable.

1.2 This test method uses a class of apparatus known as pull-off adhesion testers.² They are portable and capable of applying a concentric load and counter load to a single surface so that coatings can be tested even though only one side is accessible. Measurements are limited by the strength of adhesion bonds between the loading fixture and the specimen surface or the cohesive strength of the substrate.

1.3 This test can be destructive and spot repairs may be necessary.

1.4 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For specific hazard statements, see Notes 2 and 3.*

N 512 Protective Coatings (Paints) for the Nuclear Industry⁴

2.3 ISO Standard:

4624 Paints and Varnish—Pull-Off Test for Adhesion⁴

3. Summary of Test Method

3.1 The general pull-off test is performed by securing a loading fixture (dolly) normal (perpendicular) to the surface of the coating with an adhesive. After the adhesive is cured, a testing apparatus is attached to the loading fixture and aligned to apply tension normal (perpendicular) to the test surface. The force applied to the loading fixture is then gradually increased and monitored until either a plug of coating material is detached, or a specified value is reached. When a plug of material is detached, the exposed surface represents the plane of limiting strength within the system. The nature of the failure is qualified in accordance with the percent of adhesive and cohesive failures, and the actual interfaces and layers involved. The pull-off strength is computed based on the maximum indicated load, the instrument calibration data, and the original surface area stressed (see Fig. 1).

4. Significance and Use

4.1 The pull-off strength (commonly referred to as adhesion) of a coating is an important performance property that has been used in specifications. This test method serves as a means for uniformly preparing and testing coated surfaces, and evaluating and reporting the results. This test method is applicable to any portable apparatus meeting the basic requirements for determining the pull-off strength of a coating.

5. Apparatus

5.1 *Adhesion Tester*, commercially available, or comparable apparatus specific examples of which are listed in Annexes A1 and A2 (see Fig. 1):

5.1.1 *Loading Fixtures*, having a flat surface on one end that can be adhered to the coating and a means of attachment to the tester on the other end.

5.1.2 *Detaching Assembly* (adhesion tester), having a central grip for engaging the fixture.

⁴ Available from American National Standards Institute, 11 W. 42nd St., 13th Floor, New York, NY 10036.

FIG. 1 Schematic of Pull-Off Adhesion Tester

5.1.3 *Base*, on the detaching assembly, or an annular bearing ring if needed for uniformly pressing against the coating surface around the fixture either directly, or by way of an intermediate bearing ring. A means of aligning the base is needed so that the resultant force is normal to the surface. If shims are required when a bearing ring is employed, place them between the tester base and bearing ring rather than on the coating surface.

5.1.4 Means of moving the grip away from the base in as smooth and continuous a manner as possible so that a torsion free, co-axial (opposing pull of the grip and push of the base along the same axis) force results between them.

5.1.5 *Timer*, or means of limiting the rate of stress to less than 150 psi/s (1 MPa/s) so that the maximum stress is obtained in less than about 100 s. A timer would be the minimum equipment when used by the operator along with the force indicator in 5.1.6.

5.1.6 *Force Indicator and Calibration Information*, for determining the actual force delivered to the loading fixture.

5.2 *Solvent*, or other means for cleaning the loading fixture surface. Finger prints, moisture, and oxides tend to be the primary contaminants.

5.3 *Fine Sandpaper*, or other means of cleaning the coating that will not alter its integrity by chemical or solvent attack. If any light sanding is anticipated, choose only a very fine grade abrasive that will not introduce flaws or leave a residue.

5.4 *Adhesive*, for securing the fixture to the coating that does not affect the coating properties. Two component

epoxies⁵ and acrylics⁶ have been found to be the most versatile.

5.5 *Magnetic or Mechanical Clamps*, if needed, for holding the fixture in place while the adhesive cures.

5.6 *Cotton Swabs*, or other means for removing excess adhesive and defining the adhered area. Any method for removing excess adhesive that damages the surface, such as scoring, must generally be avoided since induced surface flaws may cause premature failure of the coating.

5.7 *Circular Hole Cutter* (optional), to score through to the substrate around the loading fixture.

6. Test Preparation

6.1 The method for selecting the coating sites to be prepared for testing depends upon the objectives of the test and agreements between the contracting parties. There are, however, a few physical restrictions imposed by the general method and apparatus. The following requirements apply to all sites:

6.1.1 The selected test area must be a flat surface large enough to accommodate the specified number of replicate tests. The surface may have any orientation with reference to gravitational pull. Each test site must be separated by at least the distance needed to accommodate the detaching appa-

⁵ Araldite Adhesive, available from Ciba-Geigy Plastics, Duxford, Cambridge, CB2 4QA, England, Scotch Weld Adhesive 1838B/A, available from 3M, Adhesive Coatings and Sealers Div., 3M Center, St. Paul, MN 55144, and Hysol Epoxy Patch Kit 907, available from Hysol Div., The Dexter Corp., Willow Pass Rd., Pittsburg, CA 94565, have been found satisfactory for this purpose.

⁶ Versilac 201 and 204 with accelerator, available from Lord Corp., Industrial Adhesive Div., 2010 W. Grandview Blvd., P.O. Box 10038, Erie, PA 16514, have been found satisfactory for this purpose.

status. The size of a test site is essentially that of the secured loading fixture. At least three replications are usually required in order to statistically characterize the test area.

6.1.2 The selected test areas must also have enough perpendicular and radial clearance to accommodate the apparatus, be flat enough to permit alignment, and be rigid enough to support the counter force.

6.2 Since the rigidity of the substrate affects pull-off strength results and is not a controllable test variable in field measurements, some knowledge of the substrate thickness and composition should be reported for subsequent analysis of laboratory comparisons. For example, steel substrate of less than 1/8-in. (3.2-mm) thickness may reduce pull-off strength results compared to 1/4 in. (6.4 mm) thick panels.

6.3 Subject to the requirements of 6.1, select representative test areas and clean the surfaces in a manner that will not affect integrity of the coating or leave a residue. Surface abrasion may introduce flaws and should generally be avoided. A light abrasive should only be used if needed to remove loose or weakly adhered surface contaminants.

6.4 Clean the loading fixture surface as indicated by the apparatus manufacturer. Failures at the fixture-adhesive interface can often be avoided by treating the fixture surfaces in accordance with an appropriate ASTM standard practice for preparing metal surfaces for adhesive bonding.

NOTE 1—Practices D 2651 and D 3933 are typical of well-proven methods for improving adhesive bond strengths to metal surfaces.

6.5 Mix the adhesive in accordance with the adhesive manufacturer's recommendations, applying the adhesive between the fixture and the surface to be tested using a method preferred by the adhesion-tester manufacturer. Carefully remove the excess adhesive from around the fixture.

NOTE 2: Caution—Movement, especially twisting, can cause tiny bubbles to coalesce into large holidays that constitute stress discontinuities during testing.

6.6 Based on the adhesive manufacturer's recommendations and the anticipated environmental conditions, allow enough time for the adhesive to set up and reach the recommended cure. During the adhesive set and early cure stage, a constant contact pressure should be maintained on the fixture. Magnetic or mechanical clamping systems work well, but systems relying on tack, such as masking tape, should be used with care to ensure that they do not relax with time and allow air to intrude between the fixture and the test area.

6.7 Scoring around the fixture violates the fundamental in-situ test criterion that an unaltered coating be tested. If scoring around the test surface is employed, extreme care is required to prevent micro-cracking in the coating. Such cracks may cause failures at diminished strengths. Scored samples constitute a different test, and this procedure should be clearly reported with the results.

6.8 Note the approximate temperature and relative humidity during the time of test.

Test Procedure

7.1 Select an adhesion-tester with a detaching assembly having a force calibration spanning the range of expected values along with its compatible loading fixture. Mid-range measurements are usually the best, but before proceeding,

read the manufacturer's operating instructions.

7.2 If a bearing ring or comparable device (5.1.3) is to be used, place it concentrically around the loading fixture on the coating surface.

7.3 Carefully connect the central grip of the detaching assembly to the loading fixture without bumping, bending, or otherwise prestressing the sample and connect the detaching assembly to its control mechanism, if necessary. For nonhorizontal surfaces, the detaching assembly should be manually supported so that its weight does not contribute to the force exerted in the test.

7.4 Align the device according to the manufacturer's instructions and set the force indicator to zero.

NOTE 3: Caution—Proper alignment is critical. If shims are needed for fixed alignment devices, report the manner in which used.

7.5 Increase the load to the fixture in as smooth and continuous a manner as possible, at a rate of less than 150 psi/s (1 MPa/s) so that failure occurs or the maximum stress is reached in about 100 s or less.

7.6 Record the force attained at failure or the maximum force applied.

7.7 If a plug of material is detached, label and store the fixture for qualification of the failed surface in accordance with the procedure in 8.3.

7.8 Report any departures from the procedure such as possible misalignment, hesitations in the force application, etc.

8. Calculation and Interpretation of Results

8.1 Use the instrument calibration factors to convert the indicated force for each test into the actual force applied in units of pounds-force (1 N = 0.1 kgf).

8.2 Compute the relative stress applied to each coating sample as follows:

$$X = 4F/d^2\pi$$

where:

X = greatest mean pull-off stress applied during a pass/fail test, or the pull-off strength achieved at failure. Both have units of psi (MPa = 1 N/mm²).

F = highest force applied to the test surface as determined in procedure in 8.1, and

d = equivalent diameter of the original surface area stressed having units of inches (or millimetres). This is usually equal to the diameter of the loading fixture.

8.3 For all tests to failure, estimate the percent of adhesive and cohesive failures in accordance to their respective areas and location within the test system comprised of coating and adhesive layers. A convenient scheme that describes the total test system is outlined in procedures in 8.3.1 through 8.3.3. (See ISO 4624.)

8.3.1 Describe the specimen as substrate A , upon which successive coating layers B , C , D , etc., have been applied, including the adhesive, Y , that secures the fixture, Z , to the top coat.

8.3.2 Designate cohesive failures by the layers within which they occur as B , C , etc., and the percent of each.

8.3.3 Designate adhesive failures by the interfaces at which they occur as A/B , B/C , C/D , etc., and the percent of each.

8.4 Erratic errors should be dropped. Unpredictable errors

may result if alignment of the apparatus is not normal to the surface, from poor definition of the area stressed due to improper preparation of the adhesive, poorly defined glue lines and boundaries, holidays in the adhesive caused by voids, inclusions, improperly prepared surfaces, or sliding or twisting the fixture during the initial cure. Scratched or scored samples may contain stress concentrations leading to premature fractures. These should be retested at adjacent areas.

8.5 Further information relative to the interpretation of the test results is given in Appendix A1.

9. Report

9.1 Report the following information:

9.1.1 Brief description of the general nature of the test, such as, field or laboratory testing of the general type of coating as applied to a given substrate, etc.

9.1.2 Temperature and relative humidity and any other pertinent environmental conditions during the test period.

9.1.3 Apparatus used, fixed or self-aligning, which includes: apparatus manufacturer and model numbers, loading fixture type and dimensions, and bearing ring type and dimensions.

9.1.4 Description of the test system, if possible, by the indexing scheme outlined in 8.3 including: product identity and generic type for each coat and any other information supplied, the substrate identity (thickness, type, orientation, etc.), and the adhesive used.

9.1.5 Test results.

9.1.5.1 Date, test location, testing agent.

9.1.5.2 For pass/fail tests, stress applied along with the result, for example, pass or fail and note the plane of any failure (see ANSI N512).

9.1.5.3 For tests to failure, all values computed in 8.2 along with the nature and location of the failures as specified in 8.3, or, if only the average strength is required, report it along with the statistics.

9.1.5.4 If corrections of the results have been made, or if certain values have been omitted such as the lowest or highest values or others, reasons for the adjustments and criteria used.

9.1.5.5 For any test where scoring was employed, indicate it by placing a footnote superscript beside each data point affected and a footnote to that effect at the bottom of each page on which such data appears. Note any other deviations from the procedure.

10. Precision and Bias

10.1 The precision and bias is primarily dependent upon the accuracy of the force measurement, the alignment of the device, and the care exercised in preparation and testing.

10.2 Since no standard for pull-off strength of coatings has been developed prior to this test method, precision and bias statements will be developed in round-robin testing.

11. Keywords

11.1 adhesion; adhesive strength; bond strength; coatings cohesion; cohesive strength; paints; pull-off strength

ANNEXES

(Mandatory Information)

A1. FIXED-ALIGNMENT ADHESION TESTERS—ELCOMETER MODEL 106 ADHESION TESTER (Fig. A1.1)⁷

A1.1 Apparatus:

A1.1.1 This is a fixed-alignment portable tester.

A1.1.2 The tester is comprised of detachable aluminum loading fixtures having a flat conic base that is 0.8 in. in diameter on one end for securing to the coating, and a circular T-bolt head on the other end, a central grip for engaging the loading fixture that is forced away from a tripod base by the interaction of a handwheel (or nut), and a co-axial bolt connected through a series of Belleville washers, or springs in later models, that acts as both a torsion relief and a spring that displaces a dragging indicator with respect to a scale.

A1.1.3 The force is indicated by measuring the maximum spring displacement when loaded. Care should be taken to see that substrate bending does not influence its final position or the actual force delivered by the spring arrangement.

A1.1.4 The devices are available in four ranges: from 0 to 500, 0 to 1000, 0 to 2000, and 0 to 4000 psi (35, 70, 140 and 280 kgf/cm²).

A1.2 Procedure:

A1.2.1 Center the bearing ring on the coating surface concentric with the loading fixture. Turn the hand wheel or nut of the tester counter-clockwise, lowering the grip so that it slips under the head of the loading fixture.

A1.2.2 Align or shim the three instrument swivel pads of the tripod base so that the instrument will pull perpendicularly to the surface at the bearing ring.

A1.2.3 Take up the slack between the various members and slide the dragging (force) indicator located on the tester to zero.

A1.2.4 Firmly hold the instrument with one hand. Do not allow the base to move or slide during the test. With the other hand, turn the handwheel clockwise using as smooth and constant a motion as possible. Do not jerk or exceed a stress rate of 150 psi/s (1 MPa/s) which is attained by allowing in excess of 7 s/1000 psi stress. If the 2000 or 4000 psi models are used, the handwheel is replaced with a nut requiring a wrench for tightening. The wrench must be used

FIG. A1.1 Elcometer Model 106 Adhesion Tester

in a plane parallel to the substrate so that the loading fixture will not be removed by a shearing force or misalignment thus negating the results. The maximum stress must be reached within about 100 s.

A1.2.5 The pulling force applied to the loading fixture is increased to a maximum or until the system fails at its weakest locus. Upon failure, the scale will rise slightly, while the dragging indicator retains the apparent load. The apparatus scale indicates an approximate stress directly in pounds per square inch, but may be compared to a calibration curve.

A1.2.6 Record the highest value attained by reading along the bottom of the dragging indicator.

⁷ Manufactured by Elcometer Instruments, Ltd., Edge Lane, Droylston, Manchester M35 6UB, England.

A2. SELF-ALIGNING ADHESION TESTERS—SEMICRO PNEUMATIC ADHESION TESTER (Fig. A2.1)⁸

A2.1 Apparatus:

A2.1.1 This is a self-aligning tester, although a non-self-aligning pneumatic apparatus is in use in Europe.⁹ It is portable and has a common pressure source and measuring system that controls a choice of different range detaching assemblies.

A2.1.2 The apparatus is comprised of: (1) detachable loading fixtures having a flat cylindrical base that is 0.5 in. (13 mm) in diameter on one end, for securing the coating, and $\frac{3}{8}$ UNC threads on the other end; (2) a central grip for engaging the loading fixture through an annular base that is forced away from the grip by the interaction of a self-aligning seal; and (3) a pressurized gas that enters the device through a flexible hose connected to a pressurization rate controller and a pressure gage (or electronic sensor).

A2.1.3 The force is indicated by the maximum gas pressure when loaded, which is not displacement dependent, and can be directly calibrated.

A2.1.4 The detaching assemblies are available in four standard ranges in multiples of two from 0 to 500 psi (3.5

MPa) to 0 to 4000 psi (28 MPa). Special ranges to 10 000 psi (70 MPa) are available.

A2.1.5 The standard System 2000 is a fully automated electronic monitoring and control system of briefcase size that can be used with any detaching assembly. Special manually controlled pneumatic devices can be ordered.

A2.2 Procedure:

A2.2.1 Position the annular ring on the coating concentric with the fixture, and loosely engage the fixture via the central threaded grip. Leave at least $\frac{1}{32}$ -in. (0.8-mm) clearance between the detaching assembly and the annular ring so that the seal can protrude enough to align itself when pressurized.

A2.2.2 Make the appropriate pneumatic connections, and adjust the pressure.

A2.2.3 Initialize the system by nulling the force indicator and introducing a small amount of gas in order to set the seal and align the device.

A2.2.4 If the device is fully automated, select the desired rate of load and set the mode switch to its run position; otherwise, manually control the gas pressure to the device so that the rate of stress does not exceed 150 psi/s (1 MPa/s) yet reaches its maximum within 100 s.

A2.2.5 Record both the maximum pressure attained and the appropriate force or stress multiplier for the specific detaching assembly.

⁸ Manufactured by SEMicro Corp., 15817 Crabbs Branch Way, Rockville, MD 20855.

⁹ Saberg Apparatus, available from Scandinavian Paint and Printing Inc., Research Institute, Copenhagen, Denmark.

FIG. A2.1 SEMicro Pneumatic Adhesion Tester

APPENDIX

(Nonmandatory Information)

X1. STRESS CALCULATION

X1.1 The stress computed in 8.2 is equal to the uniform pull-off strength of the analogous rigid coating system if the applied force is distributed uniformly over the critical locus at the instant of failure. For any given continuous stress distribution where the peak-to-mean stress ratio is known, the uniform pull-off strength may be approximated as:

$$U = XR$$

where:

U = uniform pull-off strength, representing the greatest force that could be applied to the given surface area, psi (MPa),
 X = measured in-situ pull-off strength calculated in 8.2, psi (or MPa) and
 R = peak-to-mean stress ratio.

It is important to note that a difference between these pull-off strengths does not necessarily constitute an error;

rather the in-situ measurement simply reflects the actual character of the applied coating system with respect to the analogous "ideal" rigid system.

X1.2 An error is introduced if the alignment of the apparatus is not normal to the surface. An approximate correction by the peak-to-mean stress ratio is:

$$R = (1 + 0.14 az/d),$$

where:

z = distance from the surface to the first gimbal or the point at which the force and counter force are generated by the action of the driving mechanism, in. (mm),
 d = diameter of the loading fixture, in. (mm),
 a = angle of misalignment, degrees (less than 5), and
 R = maximum peak-to-mean stress ratio for the misaligned rigid system.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Determination by Atomic Absorption Spectroscopy of Titanium Dioxide Content of Pigments Recovered From Whole Paint¹

This standard is issued under the fixed designation D 4563; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^e) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Keywords were added editorially in February 1991.

1. Scope

1.1 This test method covers the atomic absorption (AA) analysis of titanium dioxide content in pigments recovered from whole paint. It is applicable to quality control situations where the same type of product is repeatedly analyzed.

1.2 *This standard does not purport to address the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. Specific hazard statements are given in Section 7.*

2. Referenced Documents

2.1 ASTM Standards:

- D 1193 Specification for Reagent Water²
- D 1394 Test Methods for Chemical Analysis of White Titanium Pigments³
- E 180 Practice for Determining the Precision Data of ASTM Methods for Analysis and Testing of Industrial Chemicals⁴
- E 288 Specification for Volumetric Flasks⁵

3. Significance and Use

3.1 This test method may be used in quality control laboratories when the repeated analysis of titanium dioxide in similar paints may be required. Reagents and time are kept to a minimum when this test method is used in place of wet chemical analysis such as in Test Methods D 1394. However, reproducibility and repeatability are not as good as in Test Methods D 1394.

4. Summary of Test Method

4.1 The specimen is prepared for analysis by ashing at 450°C followed by digestion with sulfuric acid and ammo-

nium sulfate as in Methods D 1394. The titanium content is determined by atomic absorption spectroscopy using a specimen similar to that previously analyzed by the Aluminum Reduction Method in Test Methods D 1394.

4.2 By utilizing the pigment analyzed in Test Methods D 1394 as an atomic absorption standard, several hundred TiO₂ determinations can be made. The AA technique is much faster than the technique in Test Methods D 1394 for multiple determinations and uses only acids. This keeps reagents and time to a minimum.

5. Apparatus

- 5.1 *Atomic Absorption Spectrophotometer*, consisting of:
 - 5.1.1 Atomizer and nitrous oxide burner,
 - 5.1.2 Gas-pressure regulator and metering devices for nitrous oxide and acetylene,
 - 5.1.3 Titanium hollow cathode lamp with regulated constant-current supply,
 - 5.1.4 Monochromator and associated optics,
 - 5.1.5 Photosensitive detector connected to an electronic amplifier,
 - 5.1.6 Readout device.
- 5.2 *Muffle Furnace*, capable of maintaining 450 ± 25 °C.
- 5.3 *Circulating Oven*, maintained at 105 ± 2°C.
- 5.4 *Porcelain Dishes*, 90-mm diameter.
- 5.5 *Plastic Disposable Syringe*, 10-mL capacity.
- 5.6 *Agate Mortar and Pestle*, 95-mm outside diameter.
- 5.7 *Wide-Mouth Erlenmeyer Flask*, 500-mL capacity.
- 5.8 *Hot Plate*, with variable surface temperature control from 10°C above ambient to 370°C accurate to within ±5°C.
- 5.9 *Burner*.
- 5.10 *Volumetric Flask*, 1000 mL, plastic (see Specification E 288).
- 5.11 *Paint Shaker*.
- 5.12 *Weighing Bottles*, wide-mouth, with an external fitting cap, and no larger than necessary for required amount of sample.
- 5.13 *Desiccator*.

6. Reagents

6.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chem-

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Materials.

Current edition approved Jan. 31, 1986. Published March 1986.

² *Annual Book of ASTM Standards*, Vols 06.03 and 11.01.

³ *Annual Book of ASTM Standards*, Vol 06.02.

⁴ *Annual Book of ASTM Standards*, Vol 15.05.

⁵ *Annual Book of ASTM Standards*, Vol 14.02.

Society, where such specifications are available.⁶ Other grades may be used, provided it is first ascertained that the reagent is of sufficient high purity to permit its use without reducing the accuracy of the determination.

6.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water conforming to Type II of Specification D 1193.⁷

6.3 *Ammonium Hydroxide* (sp gr 0.90)—Concentrated ammonium hydroxide (NH₄OH).

6.4 *Ammonium Sulfate* (NH₄)₂SO₄.

6.5 *Hydrochloric Acid* (sp gr 1.19)—Concentrated hydrochloric acid (HCl).

6.6 *Hydrofluoric Acid* (HF)—Approximately 49 %.

6.7 *Standard Pigment Solution*.

6.7.1 Following the procedure in Section 9 recover the pigment from a paint that is similar to the unknown specimen. Analyze the extracted pigment for TiO₂ content in accordance with the Aluminum Reduction Method in Test Methods D 1394 and record the percent TiO₂ found in the pigment.

6.7.2 Following the procedure in 12.1 through 12.5 take a specimen of the pigment extracted in 6.7.1 into solution. Store this solution for no more than 3 months in a plastic bottle marked with the percent TiO₂ as determined in 6.7.1.

6.8 *Sulfuric Acid* (sp gr 1.84), concentrated sulfuric acid (H₂SO₄).

6.9 *Toluene*.

Hazards

7.1 *Concentrated Hydrofluoric Acid*—Make certain to observe manufacturer's recommended precautions for handling.

7.2 *Warning*—Nitrous oxide and acetylene can cause explosions, if not used properly. See the supplier's manual of instructions for the atomic absorption instrument for proper operation with these gases.

Calibration and Standardization

8.1 Operational instructions for atomic absorption spectrophotometers vary with different models. Consult the manufacturer's literature for establishing optimum conditions for the specific instrument used.

8.2 Turn the instrument on and set the wavelength to the 353-nm titanium line. Apply the recommended current to the titanium hollow cathode lamp. Allow the instrument to warm up for about 15 min and set the proper slit width. Adjust the gas pressures and ignite the burner in accordance with instructions for using nitrous oxide and acetylene.

8.3 Aspirate the water to rinse the atomizer chamber from 10 to 15 min until the burner head achieves temperature equilibrium. Set the instrument reading to zero while doing this. While aspirating the working standard from 6.7.2 set the instrument to the percent TiO₂ (determined in 6.7.1). Aspirate the water and reset the instrument to ZERO. Repeat this procedure until the readings become stable.

⁶ "Reagent Chemicals, American Chemical Society Specifications," Am. Chem. Soc., Washington, DC. For suggestions on testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards" by Joseph E. Ingham, D. Van Nostrand Co., Inc., New York, NY, and the "United States Pharmacopeia."

8.3.1 Expanding the scale of a spectrophotometer increases the noise level of the readout system. Therefore, if expanding the scale to make the readout indicate 60 % TiO₂ has this effect, do not use any expansion. For instance, it is not necessary to make the instrument read 60 for 60 % TiO₂ standard. It may read 30. If 60 % equals 30, a pigment giving a reading of 25 would have a TiO₂ content of 50 %.

PIGMENT CONTENT

9. Procedure

9.1 Mix the samples until homogenous, preferably on a mechanical shaker. If air bubbles become entrapped in the sample, stir by hand.

9.2 Draw approximately 5 g of the paint under test into a 10-mL syringe and weigh to 1 mg. Transfer, by dropwise addition, between 2.0 and 4.0 g of the specimen to a tared porcelain dish containing either 2 mL of water (for water-borne paint) or 2 mL of toluene (for solvent-borne paint). Reweigh the syringe to 1 mg. Swirl the dish during the addition of the paint and continue to swirl until the specimen is completely dispersed. If a water-borne paint tends to agglomerate or form lumps that cannot be dispersed, a drop or two of concentrated NH₄OH may help the dispersement. If the lumps persist, discard the specimen, and prepare a new one. Prepare a duplicate specimen in the same manner.

9.3 Dry the specimens at 110°C for 30 min and then drive off the remaining solvent or water at the lowest temperature possible using a Meker burner (under a hood). Do not leave the dishes on the burners after the flames have subsided.

9.4 Transfer the dried specimens to a muffle furnace and heat at 450 ± 25°C for at least 1 h and until no further char is evident. Leave the furnace door slightly open after first inserting the dishes to allow smoke and possibly flames to escape making certain the furnace is well vented.

9.5 Remove the dishes from the muffle furnace, cool in a desiccator, and weigh.

9.6 Grind the pigment to pass through an 80-mesh screen.

10. Calculation

10.1 Calculate the percent pigment content as follows:

$$P = \frac{C - W_1}{W_2} \times 100$$

where:

P = pigment content, %

C = weight of the dish and specimen after ignition, g.

W_1 = weight of the dish alone, g.

W_2 = specimen weight used, g.

11. Precision and Bias (see Practice E 180)⁷

11.1 In an interlaboratory study of this test method in which operators in each of seven laboratories made duplicate analyses on different days and one operator in one laboratory made duplicate analyses on one day and a single analysis on the second day on a water-borne flat wall paint, a solvent-

⁷ Supporting data are available from ASTM Headquarters. Request RR: D01-1046.

borne semi-gloss enamel and a solvent-borne house paint containing 33, 38.5, and 37 % pigment, respectively, the pooled within-laboratory standard deviation was found to be 0.07 % absolute with 21 df. The pooled between-laboratories standard deviation was 0.22 % absolute with 21 df. One laboratory's results for one day were discarded because the duplicates differed significantly and another laboratory's results for one day because the range differed significantly from all other ranges for Coating 1 and a third laboratory's results for one day because it differed significantly from the other day's results and those from all other laboratories for Coating 2. Based on these standard deviations the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

11.1.1 *Repeatability*—Two results, each the mean of duplicates, obtained by the same operator should be considered suspect if they differ by more than 0.21 % absolute at pigment contents of 33 to 39 wt %.

11.1.2 *Reproducibility*—Two results, each the mean of duplicates obtained by operators in different laboratories, should be considered suspect if they differ by more than 0.66 % absolute at the same pigment content levels.

TITANIUM DIOXIDE CONTENT

12. Procedure

12.1 Determine the dry weight of two weighing bottles with caps. In accordance with Table 1 select the appropriate specimen weight and place the approximate amount of recovered pigment in each weighing bottle.

12.2 Dry the specimens in the open weighing bottles for 2 h at 105°C. Cool in a desiccator. After cooling, cap the weighing bottles and weigh as rapidly as possible.

12.3 Transfer the dry specimens to 500-mL wide-mouth Erlenmeyer flasks. Reweigh bottles and caps and record weights of specimens transferred (W_4 in equation in 13.1 and 13.2).

12.4 To the 500-mL flasks, which now contain the specimens, add 8 g $\pm$ 0.001 g of $(\text{NH}_4)_2\text{SO}_4$, 50 mL of concentrated H_2SO_4 and 5 drops of concentrated HNO_3 . Mix well by swirling the flasks. Heat on a hot plate until dense white fumes are evolved. Continue heating over a hot flame until solutions are complete (usually requires not more than 5 min of boiling), or until it is apparent that the residues are composed of SiO_2 or siliceous matter. Cool and add 100 mL of water with extreme caution.

TABLE 1 Specimen Weight Requirement

Expected TiO_2 on pigment, %	Specimen Weight, mg ^a
0 to 19	1000
20 to 29	500
30 to 39	330
40 to 49	250
50 to 59	200
60 to 69	160
70 to 79	140
80 to 89	130
90 to 100	110

^a Equivalent to about 60 ppm Ti in the final solution.

12.5 Quantitatively transfer the contents of the flasks including any insoluble matter to 1000-mL plastic volumetric flasks (see Specification E 288). Add 50 mL of HCl and 30 mL of HF . Allow to cool to room temperature and then fill to the mark with water. Stopper and mix well. Transfer the solutions to plastic bottles (because of the HF) and store for no more than 3 months for analysis by AA. Solutions must be filtered through a Whatman 42 paper before being aspirated.

12.6 Calibrate the instrument in accordance with Section 8 and aspirate the solutions in the following order:

- 1—water (set to ZERO)
- 2—working standard (set to percent TiO_2)
- 3—specimen (read)
- 1—water (set to ZERO)
- 2—working standard (set to percent TiO_2)
- 3—specimen (read)

This MUST be repeated until the readings are stable.

13. Calculation

13.1 Calculate the percent TiO_2 in the pigment as follows:

$$\text{TiO}_2, \% = \frac{C \times W_3}{W_4}$$

where:

C = reading of specimen (number 3 in 12.6),

W_3 = standard pigment weight in 6.7.1, g, and

W_4 = specimen pigment weight in 12.3, g.

13.2 Calculate the percent TiO_2 in the whole paint as follows:

$$\text{TiO}_2, \% = \frac{P \times W_3 \times A}{W_4}$$

where:

A = pigment calculated in 10.1, %, and

P , W_3 , and W_4 = same as in 13.1.

14. Precision and Bias (see Practice E 180)⁷

14.1 In an interlaboratory study of this test method in which operators in each of eight laboratories analyzed on different days a water-borne flat wall paint, a solvent-borne semi-gloss enamel and a solvent-borne house paint, respectively containing 28.8, 56.8, and 42.8 weight % titanium dioxide in the pigment, the pooled within-laboratory standard deviation was found to be 0.65 % absolute with 22 degrees of freedom. The pooled between-laboratories standard deviation was 1.31 % absolute with 20 degrees of freedom. One duplicate value from one laboratory was discarded because the range differed significantly from all other duplicate ranges for Coating 1, one day's result from another laboratory because the range differed significantly from all other ranges and both day's results from a third laboratory were discarded because the mean differed significantly from all other laboratory means for Coating 2, and one duplicate value was discarded from the same laboratory as with Coating 1 because the range differed significantly from all other duplicate ranges for Coating 3. Based on these standard deviations, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

14.1.1
ates of
spect if
contents
14.1.2
uplicate

14.1.1 *Repeatability*—Two results, each the mean of duplicates obtained by the same operator, should be considered suspect if they differ by more than 1.91 % absolute at TiO_2 contents of 28 to 57 weight % of the pigment.

14.1.2 *Reproducibility*—Two results, each the mean of duplicates, obtained by operators in different laboratories

should be considered suspect if they differ by more than 3.68 % absolute at the same levels of TiO_2 content.

15. Keywords

15.1 atomic adsorption spectroscopy; percent pigment by ignition; titanium dioxide, analysis of

Standard Test Method for Measuring Apparent pH of Electrocoat Baths¹

This standard is issued under the fixed designation D 4584; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^{e1}) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Keywords were added editorially in January 1991.

1. Scope

1.1 This test method covers the measurement of the free hydrogen ion concentration of electrocoat baths and their ultrafiltrates.

1.2 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 1193 Specification for Reagent Water²

D 1293 Test Methods for pH of Water³

E 70 Test Method for pH of Aqueous Solutions with the Glass Electrode⁴

E 180 Practice for Determining the Precision Data of ASTM Methods for Analysis and Testing of Industrial Chemicals⁴

3. Summary of Test Method

3.1 A specimen of a well-agitated electrocoat bath is placed in a stirrer-equipped container and the pH measured with a pH meter and associated glass and reference electrodes.

4. Significance and Use

4.1 The pH is the measure of the free hydrogen ion concentration of a sample, and it indicates whether an electrocoat bath is acidic, neutral, or basic. Since pH measurements of good precision are made in aqueous solutions, it is suggested that the pH measurements of electrocoat baths are only semi-quantitative, and therefore such measurements should be referred to as apparent pH measurements.

4.2 The pH of electrocoat paints is used for research, production, and quality control or electrocoat bath process control.

4.3 Other related methods for determining the pH of water or aqueous systems are described in Test Methods D 1293 and E 70.

5. Apparatus

5.1 pH Meter,

5.2 Glass and Reference Electrodes.

NOTE—Due to the polarity of electrocoat materials it is desirable to use a separate set of electrodes for each bath polarity, cathodic and anodic, because a bath of opposite polarity poisons the electrodes. A desired practice is to rinse the electrodes after each measurement with an appropriate solvent for the electrocoat material.

5.3 Thermometer, capable of 0.5°C accuracy with a -2 to 32°C range.

6. Reagents

6.1 *Reference Standard Solutions*, commercial standards of pH 4.0, 7.0, and 10.0.

6.2 *Purity of Water*—References to water shall be understood to mean water conforming to Type II of Specification D 1193.

7. Sampling and Sample Preparation

7.1 The sample should be obtained while the electrocoat bath is under proper circulation so that a uniform material is obtained. In case of an ultrafiltrate, the material should be thoroughly mixed or stirred prior to sampling to assure uniformity.

7.2 After sampling and prior to removing a test specimen it is mandatory that the sample be shaken or stirred until it is homogeneous and free of any settled material. This is particularly important if there is any delay between the sampling of the bath and the preparation of the specimens for the test. The absence of settled material can be ascertained visually (in a transparent container) or by inserting a spatula, scraping the bottom of the container to make sure that there is no settled matter. Shake or stir the samples until specimens are taken for measurement; *this point is very important.*

8. Procedure

8.1 *Standardization*—Turn on the pH meter and allow it to warm up. Wash the electrodes with a stream of water. Use the pH meter manufacturer's instructions to calibrate the electrodes with buffer solutions of pH 4 and 7 for cationic systems and 7 and 10 for anionic systems. Rinsing the electrodes thoroughly after each calibration. The reference buffer solutions should thoroughly match the temperature of the samples to be measured within 2°C.

8.2 Apparent pH Measurement:

8.2.1 Place a suitable quantity of a well-mixed electrocoat specimen in a clean and dry container equipped with a stirrer (preferably magnetic). Operate the stirrer fast enough to avoid separation of the paint but slow enough to prevent splashing or vortexing. Allow the temperature of the

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paints and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Materials.

Current edition approved April 23, 1986. Published June 1986.

³ *Annual Book of ASTM Standards*, Vol 11.01.

⁴ *Annual Book of ASTM Standards*, Vol 15.05.

specimen to come to equilibrium (that is, the temperature should show a drift of less than 0.5°C/min). Record the temperature, and dial in the temperature correction on the pH meter. Place the electrodes in the specimen and determine the pH value in accordance with the pH meter manufacturer's instructions. Record the pH value and the temperature of the specimen.

8.2.2 Run two successive specimens of the electrocoat bath sample; the pH value should be within 0.1 units/min and should show drifts of less than 0.1 units/min. If these drift limits are not met, check the pH meter and repeat the whole procedure.

9. Precision and Bias

9.1 In an interlaboratory study of the test method, with five laboratories measuring five electrocoat bath samples with pH ranging from 2.6 to 8.0, the intralaboratory standard deviation (in accordance with Practice E 180) was

found to be 0.03 units at 25 df, and the interlaboratory coefficient of variation was 0.08 units at 20 df. Based on these standard deviations, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

9.1.1 *Repeatability*—Two results, each the mean of duplicate determinations, obtained by the same operator on different days should be considered suspect if they differ by more than 0.1 units.

9.1.2 *Reproducibility*—Two results, each the mean of duplicate determinations, obtained by operators in different laboratories should be considered suspect if they differ by more than 0.3 units.

9.1.3 *Bias*—Bias cannot be determined for this test method.

10. Keywords

10.1 electrocoat baths, pH; pH measurement; ultrafiltrates, pH

Standard Practice for Testing Water Resistance of Coatings Using Controlled Condensation¹

This standard is issued under the fixed designation D 4585; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^e) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Paragraph 7.3 was corrected editorially in June 1988.

1. Scope

1.1 This practice covers basic principles and operating procedures for testing water resistance of coatings using controlled condensation. Condensation is produced by exposing one surface of a coated specimen to a heated, saturated mixture of air and water vapor, while the reverse side of the specimen is exposed to the cooling effect of room temperature air. This practice is derived from research of the Cleveland Society for Coatings Technology.²

1.2 This practice is limited to the methods of obtaining, measuring, and controlling conditions and procedures of controlled condensation tests. It does not specify specimen preparation, specific test conditions, or evaluation of results.

NOTE 1—Alternative practices for testing water resistance of coatings include Practices D 870, D 1735, and D 2247.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

G 53 Practice for Operating Light- and Water-Exposure Apparatus (Fluorescent UV-Condensation Type) for Exposure of Nonmetallic Materials⁶

3. Summary of Practice

3.1 Water vapor is generated by heating a pan of water at the bottom of the test chamber. The specimens form the roof or walls of the test chamber so that the back sides of the specimens are exposed to the cooling effects of room temperature air. The resulting heat transfer causes vapor to condense on the test specimens as liquid water saturated with air.

3.2 The temperature and amount of condensate forming on the specimens is controlled by the test temperature and the room temperature. The test specimens are inclined so that condensate runs off the test surface by gravity and is replaced by fresh condensate in a continuous process during the condensate cycle.

3.3 Exposure conditions are varied by selecting: (a) the temperature of the test, (b) the duration of the test, and (c) periodic drying of the specimens. Testing may be conducted at temperatures from 100 to 180°F (38 to 82°C). Any effects such as color change, blistering, loss of adhesion, softening, or embrittlement are observed and reported.

4. Significance and Use

4.1 Water can cause degradation of coatings, so knowledge of how a coating resists water is helpful in predicting its service life. Failure in a condensation test may be caused by a number of factors including a deficiency in the coating itself, contamination of the substrate, or inadequate surface preparation. The test is therefore useful for evaluating

⁴ *Annual Book of ASTM Standards*, Vols 02.05 and 06.01.

⁵ *Annual Book of ASTM Standards*, Vol 14.02.

⁶ *Annual Book of ASTM Standards*, Vols 06.01 and 14.02.

FIG. 1 Controlled Condensation Apparatus

FIG. 2 Apparatus Cross Section

coatings alone or complete coating systems.

4.2 Condensation tests of coatings are used for specification acceptance, quality control, and research and development of coatings and substrate treatments. These tests usually result in a pass or fail determination but the degree of failure also may be measured. A coating system is considered to pass if there is no evidence of water-related failure after a specified period of time.

4.3 Results obtained from the use of condensation tests in accordance with this practice should not be represented as being equivalent to a period of exposure to water in the natural environment, until the degree of quantitative correlation has been established for the coating or coating system.

4.4 The test is usually conducted on metal or wood specimens with the coating facing the inside of the chamber. However, it is possible to test the blister resistance of house paints on wood specimens by mounting the uncoated wood surface facing the inside of the chamber.

4.5 This practice can be used for corrosion tests particularly if the specimens are periodically dried. While corrosion products will drain into the water bath, they are not carried into the vapor that condenses on the test specimens.

5. Apparatus⁷

5.1 *Test Chamber* (see Figs. 1 and 2), consisting of insulated side walls mounted on a base, test specimen racks attached to the side walls, a heated water pan, and provisions for controlling and indicating the vapor temperature within the chamber. Vents, approximately 0.10 to 0.20 in. (3 to 5 mm) wide, shall be provided to admit room air at the bottom of the test chamber.

NOTE 2—The apparatus described in Practice G 53 may be used if the ultraviolet lamps specified in Practice G 53 are turned off.

5.2 Specimens shall form the roof of the test chamber. If the specimens cannot completely fill all the openings, blank panels shall be used. Specimens shall be inclined from 15 to 75° from the horizontal and arranged so that condensate is returned to the water pan without dripping on other specimens.

5.3 *Water Supply*, with water level control.

5.4 *Water Heater*, preferably located under the water pan, controlled by a thermostat with the sensing element located in the water.

5.5 *Thermometer*, with the stem extending into the air-

water vapor mixture in the test chamber.

5.6 *Program Timer, Blower, and Air Heater*, (optional) fitted to the chamber to provide periods of drying on a fixed schedule.

6. Test Specimens

6.1 This practice does not cover the preparation of test specimens. The substrate composition and surface preparation, specimen preparation, and the number of specimens should be agreed upon prior to testing.

NOTE 3—Applicable methods for the preparation of test panels and substrates are given in Methods D 609 and Practices D 1730. Test Methods D 823 cover application techniques for the production of uniform films.

7. Procedure

7.1 Fill the water pan to a depth of approximately 1 in. (25 mm) with water. The quality of the water in the pan does not affect the test since the evaporation and condensation process yields distilled water, but the use of tap water can result in the accumulation of residues in the water pan.

7.2 Fill all spaces in the specimen holder rack with specimens or corrosion-resistant blank panels. Mount coated metal panels with the coating to be tested facing the inside of the chamber. Coated wood specimens may be mounted in the same way.

7.2.1 Blister tests to simulate the effects of water vapor migration from inside a frame house are mounted with the uncoated side of the wood specimen facing the inside of the test chamber.

7.2.2 Seal all cracks between specimens and holes in specimens with tape or metal strips. Condensate may seal small openings but cracks larger than 0.04 in. (1 mm) and holes larger than 0.08 in. (2 mm) in diameter can cause water vapor loss and local temperature variation.

7.3 Adjust the thermostat to maintain the desired temperature of the saturated air and water vapor mixture. Vapor temperatures of 100, 120, or 140°F (38, 49, or 60°C) are suggested. Other temperatures may be used provided that the

⁷ Apparatus from Q-Panel Co., 26200 First St., Cleveland, OH 44145 has been found satisfactory for this purpose. Equivalent apparatus may be used.

temperature is reported in conformance with Section 8. To ensure adequate condensation, maintain a 20°F (11°C) temperature differential between the room and the vapor.

7.4 Operate the chamber continuously unless otherwise specified or agreed. The removal of specimens for inspections during operation is permitted. When removing a specimen for inspection, replace it with a blank so that the test conditions are not altered.

7.5 Cyclic operation with alternating periods of condensation and drying may be used. Automatic drying requires the apparatus described in 5.6. For manual drying of specimens, remove them from the apparatus. Drying periods should be at least 4 h long.

7.6 Conclude the test after a specified period of time or after effects from exposure to water are noted.

7.7 Remove specimens at the conclusion of the test. Do not leave the specimens in the apparatus at the conclusion of the test as the specimens can remain wet for hours, or even days, when the apparatus is turned off.

7.8 Wipe the test specimens dry. Rate specimens for changes in color, blistering, etc. Evaluate specimens no less than 5 min and no more than 10 min after removal from test, as the effects from water exposure can change within a short time. Remove only as many specimens as can be rated within the specified time.

NOTE 4—The 0 to 10 scale described in ASTM STP 500⁸ is preferred for rating. Relevant procedures for evaluating water effects are described in Methods D 610 and D 2616, and Test Methods D 714, D 3359, and D 3363.

7.8.1 If possible, rate the specimens again after they have been removed from the test for a recovery period long enough that moisture absorbed within the specimen dries out and the specimens reach moisture equilibrium with room air. A recovery period from 12 to 24 h is generally sufficient. The post-recovery rating allows evaluation of the permanent effects of the exposure as distinct from the transient effects, and is especially important for evaluation of color and gloss.

8. Report

8.1 Report the following information:

- 8.1.1 Sample identification.
- 8.1.2 Results of the evaluation(s).
- 8.1.3 Reference to Practice D 4585.
- 8.1.4 Hours of test duration.
- 8.1.5 Description of any cyclic operations.
- 8.1.6 Condensation temperature.
- 8.1.7 Special conditions of test or any deviations in test procedure.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Conducting Tests on Paint and Related Coatings and Materials Using a Fluorescent UV-Condensation Light- and Water-Exposure Apparatus¹

This standard is issued under the fixed designation D 4587; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

1 This practice covers the selection of test conditions in Practice G 53 to be employed for exposure testing of paint and related coatings and materials.

2 *This standard does not purport to address all of the problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

G 53 Practice for Operating Light- and Water-Exposure Apparatus (Fluorescent UV-Condensation Type) for Exposure of Nonmetallic Materials⁵

3. Significance and Use

3.1 Organic coatings on exterior exposure are subjected to attack by degrading elements of the weather, particularly ultraviolet light, oxygen, and water. This practice may be used for evaluating the behavior of films exposed in apparatus that produces ultraviolet radiation, high temperatures, and water condensation on the films. This apparatus is used to make an early materials comparison of the exterior exposure quality of paints. However, light sources, such as the fluorescent UV lamp, that emit a significant amount of radiation at wavelengths shorter than those in natural sunlight, may cause results that lead to unrealistic evaluations of weathering properties.

3.2 As no single light exposure apparatus, with or without water, can be specified as a direct simulation of natural exposure, this practice does not imply expressly, or otherwise, a specific correlation with outdoor exposure. It has, however, been useful in many instances.

3.3 Since climatic conditions vary with respect to time,

³ Annual Book of ASTM Standards, Vol 14.02.

⁴ Annual Book of ASTM Standards, Vols 02.05 and 06.01.

⁵ Annual Book of ASTM Standards, Vols 06.01 and 14.02.

geography, and topography, it may be expected that the effects of natural exposure will vary accordingly. All materials are not affected equally by the same environment. Results obtained by use of this practice should not be represented as equivalent to those of any outdoor weathering test unless the degree of quantitative correlation has been established for the material in question.

3.4 Variations in results may be expected when operating conditions among similar type instruments vary within accepted limits of this standard procedure.

4. Test Specimens

4.1 Unless otherwise agreed upon, choose panels that meet the applicable base panel requirements specified in Standards D 358, D 609, D 1730, D 1731, D 1732, or D 2092. Select panel sizes suitable for exhibiting the failure mode to be observed.

4.2 Apply the coatings to flat panels with the base panel material, method of application, coating system, film thickness, and method of drying consistent with the anticipated end use, or as mutually agreed upon between the producer and the user. If it's not possible to test *flat* samples, you may need to take special precautions to ensure that (1) the sample holders seal behind the samples so that the water vapor does not escape from the test chamber, and (2) the closest part of the samples to the UV lamps is at the 50-mm distance specified in Practice G 53. If part of the sample is closer to the lamps, it will be subject to more intense UV exposure.

4.3 Unless otherwise agreed upon, coat test panels in accordance with Test Methods D 823 and measure the film thickness in accordance with an appropriate procedure selected from Test Methods D 1005, D 1186, or D 1400. Nondestructive methods are preferred because panels so measured do not need to be repaired.

4.4 Unless otherwise specified, before exposing coated panels in the apparatus, condition them at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity for one of the following periods in accordance with the type of coating:

Baked coatings	24 h
Radiation-cured coatings	24 h
All other coatings	7 days minimum

5. Apparatus

5.1 *Fluorescent UV/Condensation Apparatus*, complying with Practice G 53.⁶

6. Procedure

6.1 Place panels within the 8.25 by 35.35-in. (210 by 900-mm) area as described in Practice G 53. Reposition the panels on a regular schedule as described in Practice G 53 to minimize any effects from temperature or UV light variation. When the test specimens do not completely fill the racks, fill the empty spaces with blank non-rusting panels to maintain the test conditions within the chamber.

6.2 Use the test conditions specified by mutual consent or required by a product quality specification. Some test conditions in current use for testing paint and related

coatings and materials are:

A = 8 h UV/70°C followed by 4 h CON/50°C for automotive coatings,

B = 4 h UV/60°C followed by 4 h CON/50°C for general metal coatings,

C = 4 h UV/60°C followed by 20 h CON/60°C for exterior wood coatings,

D = 8 h UV/60°C followed by 4 h CON/45°C for industrial maintenance coatings,

E = other test temperatures and time cycles that conform to the Procedure section of Practice G 53.

where:

UV = ultraviolet light (lamps) only, and

CON = condensation conditions only.

NOTE 1—Temperatures are black panel temperatures measured in the panel rack.

6.3 Program the selected test conditions and operate the apparatus continuously within the limits specified in Practice G 53. Service the apparatus in accordance with Practice G 53.

NOTE 2—Variations in results can occur as the result of not changing lamps in accordance with the manufacturer's instructions.

7. Periods of Exposure

7.1 Use one of the following methods to determine the duration of the exposure under this practice:

7.1.1 A mutually agreed upon specified number of total hours.

7.1.2 The number of total hours of exposure required to produce a mutually agreed upon amount of change in either the test specimen or an agreed upon standard sample.

8. Evaluation of Results

8.1 Evaluate conditions of exposed test specimens by means of one or more of the following standards: D 523, D 610, D 659, D 660, D 661, D 662, D 714, D 772, D 1654, D 1729, D 2244, D 2616, D 4214 and E 97. Select methods in accordance with product use requirements.

8.2 Because of possible variations in results as described in 3.4, no reference should be made to results obtained from tests conducted in the apparatus using this practice unless accompanied by Section 9 or unless otherwise specified in a reference procedure.

9. Report

9.1 Report the following information:

9.1.1 Manufacturer and model of fluorescent UV/condensation apparatus.

9.1.2 Manufacturer's designation for the fluorescent UV lamp and the relative spectral energy distribution of the lamp. This may be accomplished by listing the manufacturer's designation, wavelength (nm) where peak emission occurs, and the wavelength near low cut-off where 1 % of peak emission occurs.

9.1.3 Exposure cycle, for example, 4 h UV/60°C, 4 h CON/50°C.

9.1.4 Total exposure time.

9.1.5 Results of panel evaluation (see 8.1).

9.1.6 Identification of standard used for comparative evaluation, if any.

⁶ Apparatus and lamps from Q-Panel Co., 26200 First St., Cleveland, OH 44145 and from Atlas Electric Devices Co., 4114 N. Ravenswood Ave., Chicago, IL 60613, have been found suitable for this purpose.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Guide for Determining the Presence of and Removing Microbial (Fungal or Algal) Growth on Paint and Related Coatings¹

This standard is issued under the fixed designation D 4610; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

1. Scope

1.1 This guide describes techniques used for determining the presence of fungal or algal growth on paint and related coatings and methods for removal of such growth prior to recoating.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 2022 Method for Sampling and Chemical Analysis of Chlorine-Containing Bleaches²

D 3274 Test Method for Evaluating Degree of Surface Disfigurement of Paint Films by Microbial (Fungal or Algal) Growth or Soil and Dirt Accumulation³

3. Significance and Use

3.1 Microbial growth is a major cause of discoloration and deterioration of paint films. This guide describes techniques used to distinguish fungi and algae from other surface contaminants.

3.2 Repainting a surface contaminated with fungi or algae generally causes more rapid infestation of the new paint than repainting a surface from which fungal or algal growth has been removed. This guide describes methods for removing fungal or algal growth prior to repainting.

4. Reagents

4.1 *Sodium Hypochlorite*, approximately 5 % aqueous (NaOCl) as commercial household bleach. Because sodium hypochlorite decomposes on exposure to heat and sunlight and becomes ineffective, use only fresh material. See Method D 2022 for methods of sampling and chemical analysis.

4.2 *Trisodium Phosphate*, or non-ammonia-containing laundry detergent.

5. Procedures

5.1 *Determining the Presence of Fungal or Algal Growth on Paint:*

5.1.1 *Chemical*—Apply a drop of 5 % aqueous sodium hypochlorite solution (common household bleach) to the area suspected of being contaminated with fungal or algal growth. Fungal or algal discoloration will normally bleach within 60 s. Discoloration that does not bleach is probably dirt. For further confirmation do visual and subculture tests.

5.1.2 The following procedures should preferably be used by persons who have had basic microbiological training:

5.1.2.1 *Visual*—Examine the surface using magnification from 10 to 100 $\times$ to distinguish among fungal, algal, or dirt disfigurement in accordance with Test Method D 3274.

5.1.2.2 *Subculture*—Apply a prepared petri dish containing a raised convex surface of nutrient agar culture medium⁴ directly to the surface to be sampled and exert moderate pressure. Replace the cover and incubate for at least 72 h at 95°F (35°C). Examine the agar surface visually as in 5.1.2.1.

NOTE 1—The culture medium must contain the nutrients necessary for growth of algae and fungi.

5.2 *Removal of Fungal and Algal Growth on Paint:*

5.2.1 Wash the surface with a solution of approximately 5 % trisodium phosphate in water or a solution at approximately 2 % laundry detergent in water.

5.2.2 Thoroughly rinse the surface with water to remove residual trisodium phosphate or detergent.

5.2.3 Wash the surface with a solution of 1 part by volume of sodium hypochlorite 5 % aqueous solution and 3 parts by volume of water.

NOTE 2—The solution should be allowed to remain on the surface from 10 to 15 min.

NOTE 3—The sodium hypochlorite solution and the 2 % laundry detergent solution may be combined 1:1 by volume in one treatment if desired.

5.2.4 Thoroughly rinse the surface with water to remove residual sodium hypochlorite.

5.2.5 If agreed upon by the parties involved, reinspect the surface in accordance with 5.1 to ensure that there has been adequate removal. Refer to the coating manufacturer's literature for recommended drying time before recoating.

Standard Specification for Design and Fabrication of Flue Gas Desulfurization System Components for Protective Lining Application¹

This standard is issued under the fixed designation D 4618; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the design and fabrication of metal components for Flue Gas Desulfurization (FGD) equipment, including absorbers, tanks, chimney liners, ductwork and associated equipment that are to be lined for corrosion or abrasion resistance, or both.

1.2 *Limitations*—This specification does not cover structural performance of FGD components. It is intended only to define the design considerations for successful application and performance of protective linings for FGD system components.

1.3 This specification represents the minimum requirements for lining work. In cases where the manufacturer's instructions and recommendations differ from this specification, these differences must be resolved before fabrication is started.

1.4 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are for information only.

1.5 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Design/Engineering Requirements

2.1 Rigidity:

2.1.1 The components shall be designed so that the interior metal surfaces are sufficiently rigid for the intended lining materials. Manufacturer's recommendations for maximum strains or deflection limits for the lining material shall be followed.

2.1.2 The weight of the lining system shall be considered in the structural design of the component.

2.1.3 The design shall consider the effects of pressure, wind, seismic and other design loads.

2.1.4 Vibration may cause flexing or high surface strains on the lining. This is of particular concern to rigid lining materials and shall be minimized.

2.1.5 Special consideration shall be given to all areas of potentially excessive strain such as unsupported bottom areas, oil-canning, out of roundness, sidewall-to-bottom joints, etc.

2.1.5.1 Where a component is on a concrete foundation, grouting shall be done if necessary to correct unsupported bottom areas.

2.1.5.2 Sand fill shall not be used for bottom support unless provisions are made to assure that the sand cannot be lost due to erosion.

2.2 Accessibility:

2.2.1 All interior surfaces of the components shall be designed to be readily accessible for surface preparation and lining application.

2.2.1.1 All fillets and corners shall be accessible for proper welding and grinding.

2.2.2 The minimum manway size for a working entrance during lining application shall be 36 in. (900 mm) in diameter or 24 in. (600 mm) width by 36 in. (900 mm) height.

2.2.2.1 Closed components shall have a minimum of two manways, one near the top and one near the bottom, preferably located 180° apart to facilitate adequate ventilation for workers.

2.2.2.2 Additional or larger openings may be required to facilitate ventilation and material handling. The lining material applicator should be consulted for specific requirements.

2.3 Shell Penetrations:

2.3.1 All connections or openings in the vessel or component shall be flush with the interior wall. Inlet nozzle shall extend into vessels if incoming fluids can be detrimental to lining materials. Any exterior or interior connection shall be flanged in order to facilitate linings.

2.3.2 The maximum length of flanged nozzles, 4 in. (100 mm) and greater in diameter, shall not exceed the dimensions in Table 1.

2.3.2.1 Only 4 in. (100 mm) diameter and larger nozzles shall be used for maximum reliability of the lining system.

2.3.2.2 As an alternative to lined nozzles, compatible prefabricated, reinforced plastic, ceramic or alloy metal inserts (sleeves) may be used if they offer superior corrosion and abrasion protection. Lining shall overlap onto prefabricated liners.

TABLE 1 Maximum Length of Nozzles

Nominal Nozzle Size, in. (mm)	Maximum Nozzle Length— Shell to Face of Flange, in. (mm)
4 (100)	8 (200)
6 (150)	12 (300)
8-24 (200-600)	16 (400)
24-36 (600-900)	24 (600)
Over 36 (900)	any length

¹ This specification is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generation Facilities and is the direct responsibility of Subcommittee D33.09 on Protective Linings for FGD Systems.

Current edition approved Feb. 20, 1987. Published April 1987.

2.3.3 Lining thickness may dictate changes in nozzle dimensions to achieve design flow rates.

2.4 Appurtenances Inside Components:

2.4.1 The requirements in Sections 2 and 3 apply to any appurtenances that are being lined and installed inside a lined component, such as agitators, anti-swirl baffles, gaging devices, internal piping, ladders, and support brackets.

2.4.2 If appurtenances inside the component cannot be lined, they shall be made of corrosion-resistant materials. If alloys are used, the lining shall carry over the welded area onto the alloy a minimum of 3 in. (76 mm). Some linings may require special designs to protect the edge of the lining. Bolted connections are used, dielectric insulation shall be provided.

2.4.3 Heating elements shall be attached with a minimum clearance of 6 in. (150 mm) from the surface of the lined component. Greater clearance may be required to protect the lining from excessive temperature conditions depending on

the temperature of the element.

2.4.4 Special precautions shall be taken in lined components where severe abrasion/impingement damage may occur. Precautionary design measures, such as wear plates, brick liners or added coating thickness, shall be considered when necessary.

2.5 Structural Reinforcement Members and Supports:

2.5.1 Structural reinforcement members (stiffeners) shall be installed on the vessel exterior, wherever necessary. However, if such members are installed internally they shall be fabricated of simple closed shapes such as round bars, pipe, or box beams for ease of applying the lining material.

2.5.2 The use of box beams or pipe for internal supports is recommended. The use of angles, channels, I-beams and other complex shapes shall be avoided wherever possible. If they must be installed internally, these members shall be fully seal welded and the edges ground to a 1/8 in. (3 mm) minimum radius.

2.5.3 If closed chambers are formed with internal box beams or pipes, they shall be vented to the atmosphere at the lowest point, so that pressures are not developed during operation and possible curing procedures and so that corrosion, due to localized lining failures, can be observed early.

3. Fabrication

3.1 Welds:

3.1.1 All internal welds to be lined shall be continuous without imperfections such as weld slag, weld splatter, rough surfaces, undercutting, high peaks, porosity, sharp corners, sharp edges and inadequate thickness (see Fig. 1).

3.1.2 The degree of weld preparation prior to lining depends on the type of lining to be applied. The lining manufacturer must be consulted for specific requirements for weld preparation during the design of the component and prior to start of fabrication.

3.1.3 Use of weld display samples before and after grinding may be of help to the component fabricator in supplying acceptable welds with a minimum required rework. All welds shall be inspected prior to lining. Whenever possible, shop welds shall be inspected in the fabricator's shop.

3.1.3.1 All weld areas shall be inspected before and after blast cleaning. Pinholes, pits, blind holes, porosity, undercutting or similar depressions are not permissible in the finished surface.

3.1.4 Weld splatter shall be removed. Chipping may be utilized only if followed by grinding for the required surface finish.

3.1.4.1 The use of non-silicone, anti-splatter coating applied adjacent to weld areas is suggested. This coating shall be of a type that can be removed by the final blast cleaning.

3.1.5 After inspection, all undercuts and pinholes shall be eliminated by welding or grinding. All rough welds shall be ground to remove sharp edges. Chipping may be used to remove sharp edges if followed by grinding.

3.1.6 All edges and similar abrupt contours shall be rounded off by grinding or machining to a 1/8-in. (3 mm) minimum radius.

3.1.7 Fillets and changes in contour shall be ground to a 1/8-in. (3-mm) minimum radius where required for the selected lining material. Any grinding done on welds, edges,

FIG. 1 Weld Fabrication for Lining Application

FIG. 2 Joint Fabrication for Lining Application

and fillets shall be done carefully to eliminate potential problems caused by gouging of the parent metal.

3.1.8 All internal and external welding shall be completed prior to any lining application.

3.2 Joints:

3.2.1 All welds shall be continuous. Intermittent or spot welding is not permitted (see Fig. 2).

3.2.2 Riveted joints shall not be used. Internal bolted joints shall not be used except to avoid welding on an already lined surface. In this case, corrosion resistant alloy or nonmetallic bolts shall be used.

3.2.3 If bolts are used to facilitate installation or welding, or both, of a component, they shall be removed and holes plug welded before lining application.

3.2.4 Lap welded joints shall be avoided whenever possible. Where they are necessary, the interior lap shall be a full fillet weld and finished as in accordance with 3.1.6.

3.2.5 Expansion joints and bolted flanged duct or shell joints require special lining consideration. Bolted flange joint surfaces shall be lined before assembly. Special consideration shall be given during erection and fit-up so as not to damage the lining.

3.2.5.1 If alloy flanges are used at expansion joints, the design must allow for the lining system to be applied over the alloy by 3 in. (75 mm). Some linings may require special designs to protect the leading edge.

3.3 During and after the lining of the equipment, no welding shall be allowed on the interior or exterior surfaces.

3.4 Signs shall be hung or stenciled on the exterior surface of the equipment designating the following: LINED EQUIPMENT, DO NOT BURN OR WELD. They shall be visible from all elevations and sides of the equipment.

4. Drawing Notes

4.1 All lined surfaces should be clearly identified on all detail and arrangement drawings.

FIG. 2 (Continued) Joint Fabrication for Lining Application

4.2 The following note shall appear on appropriate detail and arrangement drawings: All surfaces to be lined shall meet the requirements of ASTM Specification D 4618.

CORNER JOINTS

Standard Practice for Inspection of Linings in Operating Flue Gas Desulfurization Systems¹

This standard is issued under the fixed designation D 4619; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

1. Scope

1.1 This practice describes procedures for conducting inspections of the conditions of various linings in operating Flue Gas Desulfurization (FGD) system components.

1.2 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* For specific hazard statements, see Section 7.

2. Significance and Use

2.1 Periodic inspections are essential to evaluate lining performance, to detect existing damage potential problems, and to plan scheduled maintenance. The frequency of these inspections may diminish or increase with time depending upon lining performance.

3. Recordkeeping

3.1 Lining condition will depend on the operating conditions experienced by the lining systems. Records of these conditions that are maintained by the owner/operator should be evaluated for potential effects upon the linings. These may include:

- 3.1.1 Dates of lining installation and initial operation,
- 3.1.2 Solution/gas temperatures in lined components,
- 3.1.3 Solution/gas chemistry (pH, composition),
- 3.1.4 Start up/shut down dates,
- 3.1.5 Gas velocities and particulate loading, and
- 3.1.6 Ambient conditions.

3.2 Any known change in the process criteria or modifications of the physical design shall be identified and dated.

3.3 All past history pertaining to the lining systems should be available during the inspection process. They may include:

- 3.3.1 Copies of existing lining specifications and installation procedures.
- 3.3.2 Quality control documents of the existing lining installation.
- 3.3.3 Copies of previous inspection reports.
- 3.3.4 Documentation pertaining to any maintenance of existing lining systems.

4. Inspection Team

4.1 The owner/operator should select a team of experienced personnel to conduct the inspection. Personnel representing the following may be included:

- 4.1.1 Owner's representative,
- 4.1.2 Lining manufacturer,
- 4.1.3 Lining applicator,
- 4.1.4 Equipment designer,
- 4.1.5 Architect engineer,
- 4.1.6 Third party inspectors, and
- 4.1.7 System designer.

5. Pre-Inspection Procedure

5.1 Prior to conducting an inspection of the lining, the owner/operator shall ensure that the following services and equipment are provided.

5.1.1 *Safety*—The inspection team shall verify that the equipment being inspected has been made safe for entry. This shall include lockout procedures for related equipment such as, but not limited to, the boiler, dampers, valves, fans, and pumps.

5.1.2 *Lighting*—Sufficient lighting shall be provided to assure general lighting of the overall area plus localized high intensity lights for close visual observation or taking of photographs, or both. The lighting fixtures shall be equipped with a safety guard to minimize breakage and injury.

5.1.3 *Access to Lining Surfaces*—The access equipment must meet all safety requirements of OSHA and the owner/operator. The equipment must be capable of placing the inspectors close enough to the lining surface to perform all inspection procedures.

5.1.4 *Cleaning*—Selected lining surfaces to be inspected shall be cleaned of any deposits or buildup that will obscure examination of the lining. The cleaning procedure selected must not cause damage to the lining.

5.1.5 *Ventilation*—Provisions must be made to assure that adequate fresh air is provided in all FGD components being inspected. If some components are on line, provisions must be taken to adequately isolate such components.

6. Hazards

6.1 All safety requirements of OSHA and the owner/operator, must be met when performing all inspection operations. Residues, including acids, heavy metals, or other hazardous materials, may be present in deposits, on the lining surfaces, or in the atmosphere. Precautions shall be taken to protect personnel. Confined entry safety requirements shall be adhered to where applicable.

¹ This practice is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generation Facilities and is the direct responsibility of Subcommittee D33.09 on Protective Linings for FGD Systems.

Current edition approved Aug. 15, 1991. Published October 1991. Originally published as D 4619 - 86. Last previous edition D 4619 - 86.

Inspection Procedures

7.1 The inspection should include visual examination, photographic examination, mapping of potential problem areas, specific destructive or nondestructive testing, and removal (if required) of representative samples for analysis (see Table 1).

7.2 Temperature may influence observed or tested lining parameters, such as crack width, hardness, and adhesion. During inspection, temperature of the lining surface and the interior and exterior ambient temperatures of the component should be measured and recorded.

7.3 Other parameters important to the inspection should be discussed with the parties involved and agreed to prior to the inspection.

Report

8.1 The owner/operator shall designate who is responsible for the preparation of an inspection report.

8.2 Report the following information:

8.2.1 Pertinent background information contained in Section 3,

8.2.2 Date(s) of inspection,

8.2.3 Participants and their affiliation,

8.2.4 Documentation of inspection,

8.2.5 Photographs, as applicable,

8.2.6 Mapping of problem areas,

8.2.7 Test results, and

8.2.8 Conclusions and recommendations.

9. Repairs

9.1 If repairs of the lining are required, the owner/operator or his representative shall prepare specific repair specifications or procedures, or both, with the input of the lining manufacturer(s), the applicator(s), and others as necessary.

9.2 These specifications or procedures, or both, may be prepared in advance or as a result of the inspection.

Standard Test Method for Measuring Paint Spatter Resistance to Roller Application¹

This standard is issued under the fixed designation D 4707; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the tendency of a paint to spatter when applied with a paint roller to a substrate.

1.2 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 3924 Specification for Standard Environment for Conditioning and Testing Paint, Varnish, Lacquer, and Related Materials²

D 3925 Practice for Sampling Liquid Paints and Related Pigmented Coatings²

2.2 Other Document:

Photographic Standards of Paint Roller Spatter³

3. Summary of Test Method

3.1 The test paint is applied to a black plastic panel by draw-down. The coated plastic panel is immediately mounted on an essentially vertical surface above a sheet of paper used to catch any spatter. A specially designed notched spool roller (see 5.1) is rolled through the film following a defined procedure, tending to generate spatter. Any spatter falls upon the spatter catch paper, and after drying is rated against the photographic standards.

4. Significance and Use

4.1 Paint spatter generated by roller application is dependent on the properties of both the paint being applied and the paint roller cover used for the application. To eliminate the influence of the paint roller cover as a variable, and thus restrict the spatter-inducing variable to the paint under test only, the paint roller cover is replaced by a standard notched spool roller to generate spatter by a mechanism that simulates that of a paint-applying roller cover.

4.2 Although most of the development work to establish this test method was undertaken using latex paints, sufficient

work was also done to show its applicability to solvent-reducible paints.

4.3 Tests during the development of this test method showed that the spattering properties of paints, like other physical properties, may in time change. Therefore, the results of this test are valid only for the time when the test is run.

5. Apparatus

5.1 *Notched Spool Test Roller* (Fig. 1).⁴

5.2 *Glass Plate*, at least 9 by 19 in. (230 by 485 mm) by $\frac{1}{8}$ in. (6 mm) thick.

5.3 *U-shaped Film Caster*,⁵ having a 7-mil (175- μ m) clearance by $5\frac{1}{4}$ in. (135 mm) wide.

5.4 *Mechanical Metronome*, with swinging arm.

6. Materials

6.1 *Black Plastic Panels*,⁶ $6\frac{1}{2}$ by 17 in. (165 by 430 mm).

6.2 *Flannel Cloth*.

6.3 *Masking Tape*, 1 in. (25 mm) wide.

6.4 *Spatter Catch Paper*, 18 by 18 in. (455 by 455 mm).

This paper can be any convenient paper to which the spatter droplets will adhere and of a color to contrast with the color of the paint under test.

7. Sampling and Conditioning

7.1 Sample the material in accordance with Practice D 3925.

7.2 Prior to testing, the samples shall be conditioned in accordance with the standard atmosphere described in Specification D 3924. The testing shall take place under the same conditions.

8. Procedure

8.1 Clean the top of the glass plate and both sides of the black plastic panel to ensure that they are free of specks. Place the black plastic panel on the glass plate and tape the narrow end at the top to the glass plate. Smooth the panel along the plate to ensure a close fit.

8.2 Stir the paint under test thoroughly and strain to remove all skins and particles. Place the film caster with the

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.42 on Architectural Finishes.

Current edition approved May 29, 1987. Published July 1987.

² *Annual Book of ASTM Standards*, Vol 06.01.

³ Copies of the pictorial photographic standards are contained in *Pictorial Standards of Coatings Defects* and may be obtained from the Federation of Societies For Coatings Technology, 492 Norristown Rd., Blue Bell, PA 19422.

⁴ The E-Z Paint Notched Spool Test Roller, obtainable from the Precision Gage and Tool Co., 28 Volkenand Ave., Dayton, OH 45410, has been found suitable for this purpose.

⁵ The Dow film caster, available from BYK-Gardner, Inc., Gardner Laboratory, 2435 Linden Lane, Silver Spring, MD 20910, has been found suitable for this purpose.

⁶ Leneta P-121-10N dull black plastic panels $6\frac{1}{2}$ by 17 in. by 10 mil (production tolerance: ± 1 mil) (165 by 432 by 250 μ m) in size, obtainable from the Leneta Co., P.O. Box 86, Ho-Ho-Kus, NJ 07423, are suitable for the purpose.

Dimensions

		in.	mm
A	Flange thickness	0.063 ± 0.005	1.60 ± 0.13
B	Space between flanges	0.343 ± 0.005	8.71 ± 0.13
C	Total diameter	1.600 ± 0.015	40.16 ± 0.38
D	Diameter under notches	1.400 ± 0.015	35.56 ± 0.38
E	Hole diameter	0.281 ± 0.005	7.14 ± 0.13

FIG. 1 Notched Spool Roller

0-mil (175- μ m) side down immediately below the taped portion of the black plastic panel. Turn on the metronome, adjusted for 80 beats/min. Into the well formed by the film caster, pour sufficient paint so that the well is filled from corner to corner. Draw down the paint the full length of the black plastic panel, until the film caster is fully beyond the far edge. The rate of application should be fairly slow, 3 to 4 s from end to end, to prevent pinholes or holidays in the paint film.

8.3 Immediately upon completion of the draw-down, remove the black plastic panel from the glass plate, keeping the masking tape intact, and tape, with the long direction vertical, to a surface that is vertical or nearly vertical (within 5° of vertical, top sloping away from the operator) with the bottom of the black plastic panel about 1 in. (25 mm) above the laboratory bench or table (Fig. 2). It is desirable that the surface under the black plastic panel be firm but with a little resilience. A backing of 1/4-in. (6-mm) thick pasted fiberboard⁷ is ideal as very hard surfaces make proper performance of the test difficult. Center the spatter catch paper on the laboratory bench or table under the black plastic panel.

⁷ Upson or universal board, manufactured by Domtar Gypsum Co., P. O. Box 508, Lockport, NY 14094, and available at most lumberyards, has been found suitable for this purpose.

8.4 Using the clean, notched spool roller, start in one of the upper corners and roll downward and upward through the paint film. Always keep the notched spool in contact with the black plastic panel, not removing the roller from the film when changing directions. Make ten passes in each direction (20 passes total), $15 \pm 1/2$ in. (380 ± 15 mm) per pass, progressively moving sideways from one edge of the film to the other (Fig. 3). Each pass should coincide with a beat of the metronome and the motion should be continuous, not jerky. Try to emulate the motion of the metronome, using the metronome for accurate timing (practice the motion with the metronome to gain the necessary rhythm and timing), since the speed of the rolling of the notched spool roller through the paint film has been found to be the only variable significantly affecting the results of the test. Make sure that all four flanges of the notched spool roller are within the draw-down area at all times. Use sufficient pressure to maintain constant contact between the notched spool roller and the black plastic panel. Note that as long as constant contact is maintained, pressure variations have not been found to noticeably affect the results.

8.5 Remove the spatter catch paper and lay it in a suitable place to dry.

8.6 Repeat the test with a second plastic panel after cleaning the apparatus.

FIG. 2 Test Set-Up Schematic

9. Grading Procedure

9.1 Carefully cut an area $7\frac{1}{2}$ by $9\frac{1}{2}$ in. (190 by 240 mm) out of the front edge (edge nearest the paint) of the spatter catch paper. The $7\frac{1}{2}$ -in. side will be the front edge. Center the area with respect to the spatter so a maximum of spatter is on this sheet (Fig. 4).

9.2 Using the photographic standards numbered 1, 3, 5, 7, and 9 for comparison, rate each test with a number from 0 (low spatter resistance) to 10 (no spatter), interpolating as needed for ratings 2, 4, 6, and 8.

NOTE—Figures 5 through 9 are duplications thereof for sample purposes, not meant to be used for test grading purposes.

9.3 In rating the paints using the photographic standards, consider the population of spatter droplets of greater importance than the average size of the spatter droplets.

9.4 If the ratings of two tests do not agree within 1 unit, repeat until such precision is obtained.

10. Precision and Bias

10.1 A precision and bias statement is in development.

Standard Practice for Preparation of Uniform Free Films of Organic Coatings¹

This standard is issued under the fixed designation D 4708; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers the preparation of free films of organic coatings for use in determining the physical properties of the coatings. Procedures are given for preparing free films on four alternative substrates. These substrates are dental foil, treated FEP (fluorinated ethylene-propylene) sheet, silicone coated paper, and halo-silane coated glass plates.

1.2 This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. A specific hazard statement is given in 6.1.

2. Referenced Documents

2.1 ASTM Standards:

- D 823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels²
- D 1005 Test Methods for Measurement of Dry-Film Thickness of Organic Coatings Using Micrometers²
- D 1653 Test Methods for Water Vapor Permeability of Organic Coating Films²
- D 2370 Test Method for Tensile Properties of Organic Coatings²

3. Summary of Test Method

3.1 Free films are prepared by depositing a uniform wet coating of the test material on a release substrate. The applied films are dried or baked, cut into appropriate size for the intended physical property test, and then stripped from the release substrate.

4. Significance and Use

4.1 Free films are required for conducting tests to evaluate the tensile properties (Test Method D 2370) and moisture vapor permeability (Test Methods D 1653) of organic coatings.

4.2 The tin foil/mercury amalgamation procedure should be used only in cases where FEP and paper substrates cannot accommodate wetting or high-temperature baking conditions.

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.23 on Physical Properties of Applied Paint Films.

Current edition approved Sept. 15, 1991. Published November 1991. Originally published as D 4708 - 87. Last previous edition D 4708 - 87.

² Annual Book of ASTM Standards, Vol. 06.01.

5. Apparatus

5.1 *Equipment*, for applying films of uniform thickness as described in Test Methods D 823.

5.2 *Micrometer Film Thickness Gage*, as described in Test Methods D 1005.

5.3 Alternative Release Substrates:

5.3.1 *Dental Tin Foil*, preferably 1-mil (25- μ m) thick.³

5.3.2 *Sheet of FEP*,⁴ preferably 2-mils (50- μ m) thick, coated with a thin film of a dry lubricant.⁵

5.3.3 *Sheet of Silicone Coated Paper*, preferably 5-mil (125- μ m) thick.⁶

5.3.4 *Glass Plates*, coated with halo-silane compound.

5.4 *Precision Specimen Cutter*, having a double blade with a foot to hold the sample.⁷

NOTE 1—Other substrates that may be suitable are 10-mil (250- μ m) thick polyethylene, photographic paper, polished steel, and fluoropolymer coated metal panels.

6. Hazards

6.1 *Mercury*—This practice involves the use of an OSHA-designated hazardous substance, mercury. For information on the potential hazards and guidance relative to use, consult the supplier's Material Safety Data Sheet. Mercury is a toxic metallic liquid. Its vapors are extremely hazardous. Small amounts of spilled mercury can vaporize sufficiently at room temperature to exceed the TVL of the vapor. Use with adequate ventilation (in a hood) or wear a respirator, and clean up spills immediately. Wear gloves when handling mercury. Containers should be kept closed. Droplets of mercury can be picked up by using a small glass pipet connected to a suction flask with a rubber hose.

7. Procedure

7.1 Prepare the free films by one of the following procedures:

7.1.1 Dental Tin Foil Substrate:

7.1.1.1 Apply each material to be tested to a strip of

³ Dental tin foil available from Yates and Bird, Chicago, IL 60610 has been found suitable for this purpose.

⁴ Teflon FEP 2-mil film thickness (Card No. 03111, Item #29499) available from E.I. du Pont de Nemours & Co., Inc., Wilmington, DE 19898, has been found suitable for this purpose.

⁵ Dry lubricant (MS-122 Fluorocarbon Release Agent) available from Miller-Stephenson Chemical Co., Danbury, CT 06810, has been found suitable for this purpose.

⁶ Silicone coated release paper Form RP-1K, size 8 3/4 by 11 3/4 in., available from the Leneta Co., P.O. Box 86, Ho-Ho-Kus, NJ, has been found suitable for this purpose.

⁷ The JDC Precision Sample Cutter manufactured by Thwing-Albert Instrument Co., 10960 Dutton Rd., Philadelphia, PA 19154, has been found suitable for this purpose.

dental tin foil. First, mount the foil on a smooth glass plate on which there may be placed a small pool of high-boiling liquid. Spread the foil out to a smooth flat surface by means of a rubber squeegee, which may be useful in holding the foil in close contact with the glass. Apply a uniform wet film of the material to the foil by one of the procedures given in Test Methods D 823.

NOTE 2—Use a liquid that is known to have little or no effect on the test coating. In many cases a light mineral oil would be suitable.

NOTE 3: Caution—Exercise care at all times to prevent the high-boiling liquids used in mounting the foil from coming in contact with the test film as these liquids may soften the film. For instance, the foil should be cleaned before amalgamation since any liquid remaining on the back of the foil and the test film will float on the bath of mercury.

7.1.1.2 Dry the applied films at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity, or bake under conditions mutually agreeable to the producer and the user. Dry film thicknesses must not vary by more than the specified or agreed-upon tolerance of the average film thickness and must not contain visible flaws. Most films with a thickness of less than 2.0 mil (50 μm) are very difficult to handle.

7.1.1.3 When required for further treatment such as weathering, remount the coated foil on a convenient smooth, flat substrate such as a glass or steel panel. In this case, a high boiling liquid (Note 2) may be used to hold the foil in close contact with the substrate over extended periods of time.

7.1.1.4 Age or expose the coated foil to conditions mutually agreed upon. At the end of the specified or agreed upon period, remove the foil-backed film from the glass or metal substrate and cut the specimens to size using a sharp knife or a precision specimen cutter.

NOTE 4—To prepare specimens for tensile property tests a precision specimen cutter must be used to ensure nick-free edges on the specimens. Even with this instrument, it is necessary to cut each specimen independently, allowing at least $\frac{1}{2}$ in. (50 mm) of waste between specimens.

7.1.1.5 Place the foil-backed specimen film side up on a pool of mercury to remove the foil by amalgamation. After amalgamation is completed, pick up an end of the floating film with tweezers, and carefully brush the unsupported film free of mercury and amalgam with a soft camel hair brush.

7.1.2 FEP Substrate:

7.1.2.1 Apply each material to be tested to a treated sheet of FEP. First, cover a smooth, flat polished glass plate with a sheet of FEP. Coat the sheet uniformly with a light coat of a dry fluoro-carbon lubricant and allow to dry for 24 h at standard conditions. Then apply a uniform wet coating of the test material on the sheet by one of the procedures given in Test Methods D 823.

7.1.2.2 Dry the applied films in $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ humidity, or bake under conditions mutually agreeable to the producer and the user. Dry film thicknesses must not vary by more than the specified or agreed upon tolerances of the average film thickness and must be free of visible flaws. Most films with a thickness of less than 2.0 mil (50 μm) are very difficult to handle.

7.1.2.3 When required for further treatment such as weathering, remount the coated sheet on a convenient smooth, flat substrate such as a glass or steel panel.

7.1.2.4 Age or expose the coated sheet to conditions mutually agreed upon. At the end of the aging or exposure period, remove the sheet-backed film from the glass or metal substrate and cut the specimens to size using a sharp knife or the precision cutter (Note 4). Carefully strip the coating film from the sheet substrate.

7.1.3 Silicone Coated Paper:

7.1.3.1 Apply each material to a sheet of silicone coated paper. First, cover a smooth, flat substrate with a sheet of a silicone-coated release paper. Then apply a film of the material under test, dry or cure, expose or treat if required, and prepare test specimens as described in 7.1.2.

7.1.4 Halo-silane Coated Glass Plates—Apply each material to a glass plate coated with a halo-silane compound. First, coat a glass plate with a thin film of a halo-silane compound and dry. Then apply a film of the material under test, dry or cure, expose or treat if required, and prepare test specimens as described in 7.1.2.

8. Keywords

8.1 dental tin foil substrate; film; halo-silane coated glass plates; lacquer; organic coatings; paints and related coatings; polyhexafluoropylene (FEP) substrate; silicone-coated paper; substrates; surface preparation; tension (tensile) properties; tests; vapors; varnishes

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Guide for Testing Industrial Water-Reducible Coatings¹

This standard is issued under the fixed designation D 4712; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide covers the selection and use of procedures for testing water-reducible coatings, both pigmented and clear, utilizing synthetic latices, synthetic resin emulsions, or water-reducible alkyds. The methods included are listed in Table 1. Where more than one standard is listed for the same characteristic, no attempt is made to indicate superiority of one standard over another. Selection of the standards to be followed must be governed by experience and the requirements in each individual case, together with agreement between producer and user.

1.2 This guide covers the testing of liquid coatings as applied by conventional spray, airless spray, electrostatic spray, dip, fancoat, flowcoat, roller coat, and curtain coat.

1.3 This guide includes procedures relating to proper and safe packaging, shipping and receiving, and storage and handling during use and application.

1.4 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Terminology

3.1 Definitions:

3.1.1 For definitions of terms used in this guide, refer to definitions D 16.

Significance and Use

4.1 This compilation of standards is intended to provide assistance in selecting appropriate tests for evaluating water-reducible coatings and for determining what characteristics should be considered for a given end use. Either single-coat operations or multicoat systems may be addressed by the proper selection of tests. Results from the various tests are not all necessarily useful in evaluating the performance of different systems for various end uses. The list can be useful to those developing coatings and coating systems and to those seeking coating systems for products.

Equipment

5.1 Use the equipment as specified in each standard.

General Requirements

6.1 Tests and observations shall be at standard laboratory conditions as specified in Specification D 3924 unless otherwise specified or agreed upon by the producer and user.

Sampling and Specimen Preparation

7.1 Sample the water-reducible coatings in accordance with Practice D 3925.

7.2 Prepare specimens as required for the specific tests on the liquid coating and the dry coating.

8. Conditions Affecting Performance

8.1 Practical requirements and performance of water-reducible coatings may vary with:

8.1.1 Type of substrate.

8.1.2 Substrate condition, for example, porosity, hardness, smoothness, flexibility, etc.

8.1.3 Type, quality, and suitability of the surface treatment or primer used under the water-reducible coating and the time before coating application.

8.1.4 Application methods and techniques.

8.1.5 Contaminants on the surface of the substrate.

8.1.6 Environmental conditions such as temperature and relative humidity.

8.1.7 Damage to container, size, and type of container.

8.1.8 Storage variables, for example storage time, excessive temperature fluctuations that may cause physical or chemical change. Special needs arise due to carbon dioxide absorption, dissolved metal compatibility, and ultrafiltration treatments.

9. Liquid Coatings Properties

9.1 *Condition in Container*—Thickening, settling, and separation are undesirable and objectionable if a liquid coating cannot be reconditioned and made suitable for application with a reasonable amount of stirring. The referenced method covers procedures for determining changes in properties after storage. Determine the condition in the container in accordance with Method 3011.1 of U.S. Federal Test Method Standard No. 141c.

9.2 *Coarse Particles and Foreign Matter*—To form uniform films of good appearance, the liquid coating must be free of coarse particles as agreed upon between the producer and the user, a typical maximum being 1 % by weight of the total paint. Determine coarse particles and foreign matter in accordance with Test Methods D 185.

9.3 *Density or Weight Per Gallon*—The density as measured by weight per gallon is used to help assure product uniformity from batch to batch. In the referenced test method, the density is expressed as the weight in pounds avoirdupois of 1 U.S. gal or the weight in kilograms of 1 L of the paint at a specified temperature. A calibrated weight-per-gallon cup is used. Determine the density in accordance with Test Method D 1475.

9.4 *Fineness of Dispersion*—The more finely a pigment is dispersed, the more efficiently it is being used. One test method for measuring the degree of dispersion (commonly referred to as "fineness of grind") is to draw the material down a calibrated, tapered groove in a hardened steel block with the groove varying in depth from 4 to 0 mils (100 to 0 μ m). The point at which continuous groupings of particles or agglomerates, or both, protrude through the surface of the liquid is taken as the fineness reading. Lower readings in mils or μ m or higher readings in Hegman units indicate better fineness of dispersion. Determine fineness of dispersion in accordance with Test Method D 1210.

9.5 *Pigment Suspension*—The amount and type of settling is an indication of how well the pigments remain in suspension and how easily settled pigment can be remixed. Determine degree of settling in accordance with Test Method D 869.

9.6 *Viscosity*—Viscosity refers to the flow resistance of a fluid and should fall within an agreed-upon range. Viscosities of Newtonian fluids (constant viscosity regardless of shear rate) may be measured with a Ford Cup. Viscosities of non-Newtonian materials should be measured at two or more speeds with a Brookfield rotational viscometer. Determine viscosity in accordance with Test Methods D 1200 or D 2196.

9.7 *Consistency*—Consistency is a less precise term than viscosity for evaluating the flow properties of a material. In the referenced test method, consistency is defined as the load in grams required to produce a specific rate of rotation in a specimen using the Stormer Viscometer. This is a one-speed test method and is not recommended for paints that show shear thinning or thixotropy. Determine consistency in

¹⁴ Annual Book of ASTM Standards, Vol 15.05.

TABLE 1 List of Test Methods by Properties

Test Method	Section	ASTM Standard	Federal Test Method Standard 141
I. Liquid Coating Properties:			
Coarse particles and foreign matter	9.2	D 185	...
Condition in container	9.1	...	3011.1
Conductivity	9.14	D 1125 or D 4399	...
Consistency	9.7	D 562	...
Density or weight per gallon	9.3	D 1475	...
Fineness of dispersion	9.4	D 1210	...
Flash point	9.13	D 56, D 93 or D 3278	...
Freeze-thaw stability	9.9	D 2243	...
Microorganism resistance	9.11	D 2574	...
pH	9.8	E 70	...
Package stability	9.10	D 1849	...
Pigment suspension	9.5	D 869	...
Surface tension	9.12	...	...
Viscosity	9.6	D 1200 or D 2196	...
II. Application and Film Formation:			
Panel preparation	10.1	D 609, D 1730, D 1731, D 1732, D 2082, D 2201	...
Drying properties	10.2.2	D 1640	...
Leveling properties	10.3	D 4062, D 2353	...
Low temperature coalescence	10.5	D 3793, D 2354	...
Spray properties	10.2.1	...	2131.1, 4331.1
Touch-up	10.6	D 3928	...
Uniform film preparation	10.4	D 823	...
Wet film thickness	10.3	D 1212	...
III. Appearance of Dry Film:			
Color difference by visual evaluation	11.1.1	D 1729, D 2616	...
Color difference by instrumental evaluation	11.1.2	D 2244 and D 3134	...
Color description by visual evaluation	11.1.3	D 1535	...
Color description by instrumental evaluation	11.1.4	D 2244	...
Gloss	11.2	D 523	...
Hiding power	11.3	D 344, D 2605	...
IV. Properties of Dry Film:			
Abrasion resistance	12.1	D 658, D 968, D 4060	...
Adhesion	12.2	D 2197, D 3359	...
Elongation	12.3	D 522, D 1737, D 3281	...
Exterior exposure	12.4	...	...
Blistering	12.4.1	D 714	...
Chalking	12.4.2	D 659	...
Checking	12.4.3	D 660	...
Cracking	12.4.4	D 661	...
Erosion	12.4.5	D 662	...
Flaking	12.4.6	D 772	...
Rusting	12.4.7	D 610, D 2933	...
Accelerated weathering	12.4.8	D 822, D 3361, D 4587	...
Corrosive environments	12.4.9	D 1654	...
Hardness	12.5	D 1474	...
Impact resistance	12.6	D 2794, D 3170	...
Resistance to various forms of water	12.8	...	...
Water immersion	12.8.1	D 870	...
Water fog	12.8.2	D 1735	...
Humidity resistance	12.8.3	D 2247	...
Moisture vapor permeability	12.8.4	D 1653	...
Salt spray	12.8.5	B 117, B 287	...
Humidity-thermal cycling	12.8.6	D 2246	...
Filiform corrosion	12.8.7	D 2803	...
Condensation	12.8.8	D 4585	...
Detergent resistance	12.8.9	D 2248	...
Resistance to chemicals	12.7	D 1308, D 1540, D 3023	...
Overbaking	12.9	D 2454	...
Print resistance	12.10	D 2091	...
Reporting results	12.4.10	D 1848	...
Dry film thickness	12.11	D 1186, D 1400	...
V. Analysis of Paint:			
Volatile content	13.2	D 2369	...
Volume of nonvolatile	13.3	D 2697	...
Weight of nonvolatile	13.3	D 2369	...
Pigment content	13.4	D 2371	...
Identification of vehicle solids	13.6	D 3168	...

accordance with Test Method D 562.

9.8 pH—The pH of a water-reducible coating depends on the type of vehicle used and the general formulation. It may vary from about 4 to 10. A change in pH during storage may indicate poor stability or a change in properties of a water-reducible coating. Determine pH in accordance with Test Method E 70.

9.9 Freeze-Thaw Resistance—Water-reducible coatings may be subjected to freezing conditions during shipping and storage. Suitably stabilized paints will resist several cycles of freezing and thawing without showing deleterious changes. The referenced method covers the determination of the extent to which water-reducible coatings retain their original consistency and freedom from lumps when subjected to freezing and subsequent thawing. Determine freeze-thaw resistance in accordance with Test Method D 2243.

9.10 Package Stability—Since liquid coatings cannot normally be used immediately after manufacture, they must remain stable in the package for some time. The referenced test method covers the change in consistency and in certain related properties that may take place in packaged water-reducible coatings when stored at a temperature above room temperature. Determine package stability in accordance with Test Method D 1849, at a temperature and for a period of time agreed upon by the purchaser and the seller.

NOTE—Although there is no ASTM or Federal test method for determining gassing during normal storage, special containers may be necessary to vent any spontaneous pressure buildup.

9.11 Microorganism Resistance—Microorganisms in water-reducible coatings can cause gassing, putrefaction or fermentation odors, and loss of viscosity. Determine if the liquid coating contains living bacteria and if it is resistant to attack by bacteria in accordance with Test Method D 2574.

9.12 Surface Tension—Although there is no ASTM or Federal test method for determining surface tension of liquid coatings, this is an important property of a water-reducible resin or coating. If surface tension is too high, poor pigment and substrate wetting may occur, leading to cratering, low gloss, or other surface defects. The most common methods for measuring the surface tensions of coatings probably are the ring pull method and drop weight method. For a comprehensive discussion of these and other aspects of surface tension, see *Paint Flow and Pigment Dispersion*.¹⁶

9.13 Flash Point—Nearly all water-borne coatings are incapable of sustaining combustion, but many do contain volatile solvents whose vapors can ignite if near open flame. Because they do give flash points, water-borne coatings must be tested for flash point temperature to conform with many government regulations concerning transportation, labeling, packaging, etc. Determine flash point in accordance with Test Methods D 56, D 93 or D 3278.

9.14 Conductivity—Conductivity is an important factor in the application of some water-borne coatings. Test Methods available for determining conductivity are D 1125 (specifically Methods A and B) and D 4399.

10. Application and Film Formation

10.1 Panel Preparation—Select a substrate as agreed upon

by the producer and the user. Prepare panels for testing the coating in accordance with Test Methods D 609, D 1730, D 1731, D 1732, D 2201, or D 2092. The preparation of plastics for paint testing is covered in Practice D 3002.

10.2 Application Properties—Determine the ease with which the liquid coating can be applied to various surfaces with brush, spray, or other application equipment. Application properties are generally compared to a standard, or described by requirements in a product specification. Application properties are related to such characteristics as kinematic viscosity, non-Newtonian rheology, surface tension, shear sensitivity, micelle stability, electrical resistivity, erosion abrasiveness, conductivity, heat capacity, and corrosiveness.

10.2.1 Sprayed Film Application—Liquid coatings can be applied by spray. Determine the spray application properties in accordance with Method 2131.1 of Federal Test Method Standard No. 141. The method can be modified to include application by airless spray equipment.

10.2.2 Drying Properties—The drying time of water-reducible coatings is important in determining when the applied coatings can be handled or packed. Also, inadequate drying of the film may result in poor film and poor appearance and, if used on an exterior surface, rain, dew, or snow may cause a nonuniform appearance. Determine drying time in accordance with Test Method D 1640, or as agreed upon by producer or user.

10.3 Leveling Properties—Leveling is an important factor when uniform surfaces are to be produced, as it affects hiding and appearance. The referenced methods cover the laboratory determination of the relative leveling characteristics of liquid coatings. Determine the leveling characteristics in accordance with Test Method D 4062. Measure wet film thickness in accordance with Test Method D 1212.

10.4 Producing Films of Uniform Thickness—The following test method covers the preparation of various films of uniform thickness essential in conducting tests. Prepare films in accordance with Test Methods D 823.

10.5 Low Temperature Coalescence of Paints—A test method to determine how well the latex particles in coating will fuse together or coalesce to form a continuous film at low temperature is described in Test Method D 3793. A test for the minimum film formation temperature is described in Test Method D 2354.

10.6 Touch-Up—For many coating systems it is important to be able to repair damage sustained during production, delivery, or after delivery. A coating can be tested by applying it with a small nylon bristle brush or air brush to a small section of a panel previously coated with it. When the touch-up area has dried, it is examined to see if it differs significantly from the initial coating. Determine the ability to touch up the coating in accordance with Test Method D 3928. Test the adhesion of the original and touch-up areas in accordance with Test Methods D 3359 or other agreed-upon test method.

11. Appearance of Dry Film

11.1 Color—The color of a water-reducible coating may be specified independently or as the color-difference with respect to another color that is usually the standard. Visual and instrumental methods are both applicable. An opaque

¹⁶ Patton, T., *Paint Flow and Pigment Dispersion*, 2nd Ed., Wiley-Interscience, New York, 1979, pp. 205-246.

film is preferred that may be prepared by making one or more applications of water-reducible coating onto a black and white substrate until the substrate is completely obscured. Each application should be performed in a normal manner with respect to application method, drying, and film thickness.

11.1.1 *Color Differences by Visual Evaluation*—Visual comparison of color is fast and often acceptable although numerical values are not obtained. The referenced standard covers the spectral, photometric, and geometric characteristics of light source, illuminating and viewing conditions, size of specimens, and general procedures to be used in the visual evaluation of color differences of opaque materials. Determine color difference by visual evaluation in accordance with Practice D 1729 or Test Method D 2616.

11.1.2 *Color Differences of Opaque Material by Instrumental Evaluation*—Color difference between a product and the standard can be measured by an instrument. Generally, the tolerance is agreed upon by the purchaser and the seller and may also be required if a product specification is involved. Color instruments provide numerical values that can be subsequently compared to later measurements. The referenced method covers the instrumental determination of small color differences observable in daylight illumination between nonfluorescent, nonmetameric, opaque surfaces such as coated specimens. If metamerism is suspected, visual evaluation (10.1.1) should be used to verify the results. Make instrumental measurement of color difference in accordance with Method D 2244. Tolerances are discussed in Recommended Practice D 3134.

11.1.3 *Color Description by Visual Evaluation*—In some cases it is necessary to specify or identify a color instead of a color difference from some standard. Various color atlases are available, the most common being the Munsell System. Describe or identify the Munsell color in accordance with Method D 1535.

11.1.4 *Color Description by Instrumental Evaluation*—Instrumental measurements involve the determination of CIE tristimulus values, X, Y, and Z, from which other color coordinates such as L^* , a^* , b^* , or L , a , b values may be calculated or obtained directly with some instruments. Describe or identify in accordance with Method D 2244.

11.2 *Gloss*—Water-reducible coatings vary in gloss and the end use determines whether the gloss should be high, semi-gloss, eggshell, or flat. Determine the gloss in accordance with Test Method D 523 using 20, 60, or 85° geometry as appropriate.

11.3 *Hiding Power (Dry Opacity)*—Hiding power is the measure of the ability of a paint to hide the substrate. It is, however, dependent upon uniform film thickness which is influenced by flow and leveling. Test Method D 344 is a practical test in which paint is applied with a brush, film thickness is approximately measured, and opacity is evaluated visually as compared to a standard paint. Results are affected by flow and leveling application properties of the paint. Test Method D 2805 is considered to be a more precise and accurate test that does not need a material paint standard. Paint is applied with an applicator bar to minimize the effects of flow and leveling, film thickness is rigorously measured, and opacity is instrumentally evaluated. Determine

hiding power in accordance with Test Methods D 344 or D 2805.

12. Properties of Dry Film

12.1 *Abrasion Resistance*—Abrasion resistance is a measure of the ability of a dried coating to withstand wear and marring from objects rolled or pulled across the surface. Determine abrasion resistance in accordance with Test Method D 658, D 968, or D 4060 (see methods to determine the applicability for interlaboratory use).

12.2 *Adhesion*—Adhesion is the property of the coating that resists removal from the substrate when scraped. Test Methods D 2197 covers the use of a scrape adhesion tester and a parallel groove adhesion tester. In Test Methods D 3359 cuts are made in the film and pressure-sensitive tape applied and removed. Determine adhesion in accordance with Test Methods D 2197 or D 3359.

12.3 *Elongation*—Elongation is a measure of the flexibility of coating films. Determine elongation in accordance with Test Methods D 522, D 1737, or D 3281.

12.4 *Exterior Exposure*—If the paint is intended for exterior exposure, tests may be run in accordance with Method D 1014, and Standard D 1150 and evaluated by the following methods:

12.4.1 *Blistering*—Determine the degree of blistering in accordance with Test Method D 714.

12.4.2 *Chalking*—Determine the degree of chalking in accordance with Method D 659.

12.4.3 *Checking*—Determine the degree of checking in accordance with Test Method D 660.

12.4.4 *Cracking*—Determine the degree of cracking in accordance with Test Method D 661.

12.4.5 *Erosion*—Determine the degree of erosion in accordance with Test Method D 662.

12.4.6 *Flaking*—Determine the degree of flaking in accordance with Test Method D 772.

12.4.7 *Rusting*—Determine the degree of rusting in accordance with Test Methods D 610 or D 2933.

12.4.8 *Accelerated Weathering*—Determine the resistance to accelerated weathering in accordance with Test Method D 822, D 3361, or D 4587.

12.4.9 *Corrosive Environment*—Determine the resistance to corrosive environment in accordance with Test Method D 1654.

12.4.10 *Reporting of Results*—The reporting of results can often be helped by reference to the classifications prescribed in Classification D 1848.

12.5 *Hardness*—Hardness is a measure of the ability of a dried coating to resist indentation. Determine hardness in accordance with Test Method D 1474.

12.6 *Impact Resistance*—An important property of a water-reducible coating is its ability to withstand a striking blow or impingement. Determine the impact resistance in accordance with Test Methods D 2794 or D 3170.

12.7 *Resistance to Chemicals*—An important property of a water-reducible coating is its ability to resist spotting, softening, or removal when subjected to household chemicals or strong cleaners. Determine resistance to chemicals in accordance with Test Methods D 1308 or D 1540 or Practice D 3023.

12.8 *Resistance to Various Physical Forms of Water*—

The ability of a dried coating to resist water in many different forms is an especially important property of water-reducible coatings.

12.8.1 *Water Immersion*—Determine the resistance to water absorption in accordance with Practice D 870.

12.8.2 *Water Fog*—Determine the resistance to water fog in accordance with Practice D 1735.

12.8.3 *Humidity Resistance*—Determine the resistance to 100 % relative humidity in accordance with Practice D 2247.

12.8.4 *Moisture Vapor Permeability*—Determine the resistance to moisture vapor transmission in accordance with Test Method D 1653.

12.8.5 *Salt Spray*—Determine the resistance to salt spray (fog) in accordance with Methods B 117 or B 287.

12.8.6 *Humidity-Thermal Cycling*—Determine the resistance to humidity-thermal cycling in accordance with Test Method D 2246.

12.8.7 *Filiform Corrosion*—Determine the resistance to filiform corrosion in accordance with Test Method D 2803.

12.8.8 *Condensation*—Determine the resistance to condensed water such as dew in accordance with Practice D 4585.

12.8.9 *Detergent Resistance*—Determine the resistance to detergent solution in accordance with Practice D 2248.

12.9 *Overbaking*—The ability of a coating to withstand a baking temperature moderately higher than initial bake or for a longer period of time is an important property. Measure the resistance to overbaking by Practice D 2454.

12.10 *Print Resistance*—Print resistance is the ability of a dried coating to withstand pressure from a textured surface without any noticeable marking on the coating. Measure print resistance in accordance with Test Method D 2091.

12.11 *Dry Film Thickness*—There are several methods currently being used for determining dry film thickness. Depending on the substrates being used, the following test methods should be considered: D 1005, D 1186, D 1400, and D 2691.

13. Analysis of Paint

13.1 *Chemical Analysis*—If a specification requires certain raw materials or certain components in a given amount, then chemical analysis is required. Chemical analysis deter-

mines whether the specified components are present, and if they are, in what amounts. It does not necessarily establish quality, which can also be greatly affected by manufacturing techniques. Most ASTM analytical methods, such as Method D 215, apply to solvent-type coatings. However, some of these can be adapted for analysis of water-reducible coatings.

13.2 *Volatile Content*—The percent of volatile matter indicates the water and organic solvent released from the film as it dries. This quantity subtracted from 100 % gives the nonvolatile content. Determine the volatile content in accordance with Test Method D 2369.

13.3 *Nonvolatile Content*—The percent of nonvolatile matter indicates the amount of material present that can be converted to the desired film. Determine the weight percent of nonvolatile in accordance with Test Method D 2369. Determine the volume percent of nonvolatile in accordance with Test Method D 2697.

13.4 *Pigment Content*—Although the referenced method describes the procedure for quantitative separation of the vehicle from the pigment in solvent-reducible coatings, it can be adapted for water-reducible coatings to determine the weight percent pigment in the paint. Determine the pigment content in accordance with Test Method D 2371.

13.5 *Pigment Analysis*—The analysis of pigment may be required if the product is covered by a specification, or if it is agreed upon between the producer and the user. Analyze the pigment in accordance with methods appropriate for the constituents present or specified.

13.6 *Identification of Vehicle Solids*—The suggested method covers the qualitative characterization or identification of separated paint vehicle solids by infrared spectroscopy. It is useful in detecting uniformity, batch to batch, and the presence of adulterants. Characterize vehicle solids in accordance with Practice D 3168.

14. Keywords

14.1 alkyds; appearance of materials; application properties; brush application; color; curtain coat; dip application; electrostatic spray; emulsion vehicles; exterior exposure; fancoat; film formation rates; flowcoat; instrumental evaluation; opaque film; paints and related coatings; paints, water-base; roller coat; spray method; visual examination; water-reducible coatings.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Methods for Nonvolatile Content of Printing Inks, Resin Solutions, and Vehicles¹

This standard is issued under the fixed designation D 4713; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^e) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Paragraphs 3.2 and 11.1.2 were editorially corrected in May 1988.

1. Scope

1.1 These test methods cover the determination of weight content of nonvolatile matter in two types of printing inks.

1.2 Test Method A is applicable to heatset-type printing inks and resin solutions; solvents in such systems typically have initial boiling points in the range from 240 to 275°C (470 to 535°F) and vapor pressures less than 0.2 mm Hg.

1.3 Test Method B is applicable to liquid-type printing inks and vehicles based on aqueous or organic solvents that evaporate readily at ordinary room temperatures.

1.4 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

NOTE 1—Test Method A (for heatset systems) specifies a specimen film thickness that is much thinner than those produced by related test methods; one exception is Test Method B in Test Method D 1259, which is recommended as a referee test.

NOTE 2—Test Method B (for liquid ink systems) is similar to Test Method D 2369 except that a solvent is not required for spreading the test specimen.

2. Referenced Documents

2.1 ASTM Standards:

D 1259 Test Methods for Nonvolatile Content of Resin Solutions²

D 2369 Test Method for Volatile Content of Coatings³

E 1 Specification for ASTM Thermometers⁴

E 145 Specification for Gravity-Convection and Forced-Ventilation Ovens⁵

E 691 Practice for Conducting an Interlaboratory Study to Determine the Precision of a Test Method⁶

3. Summary of Test Methods

3.1 *Test Method A—Heatset Systems.* A 0.15-g specimen is mechanically spread in a 57-mm weighing dish to a nominal thickness of 80 ± 10 g/m² and heated in a forced

ventilation oven at 110°C for 3 h.

3.2 *Test Method B—Liquid Ink Systems.* A 0.5-g specimen is dispensed into a 57-mm weighing dish by means of a disposable syringe, mechanically spread out, and heated in an oven at 110°C for 1 h.

4. Significance and Use

4.1 Nonvolatile content of printing inks is useful for specification acceptance between the supplier and the purchaser.

4.2 In order to obtain accurate results for heatset systems within the specified 3-h heating time, the specimen film thickness must be less than 100 g/m², and the oven must have forced ventilation. Thickness of the specimen film is less critical for liquid ink systems.

5. Apparatus

5.1 *Balance*, accurate to 1 mg.

5.2 *Oven*, forced-ventilation type conforming to Type IIB in Specification E 145 and maintained at $110 \pm 2^\circ\text{C}$.

5.3 *Thermometer*, bulb-type, capable of reading $110 \pm 2^\circ\text{C}$, such as Thermometer 88C prescribed in Specification E 1.

5.4 *Weighing Dish*, such as an aluminum foil dish 57 mm wide, the lid of a 1-lb ink can 94 mm wide, or other flat-bottomed container. The bottom of the container must not have a trough or depression into which the test material might collect.

5.5 *Spatula*, or small ink knife.

5.6 *Spreading Device*, one per weighing dish, of heat-stable material, such as a glass stirring rod or thick L-shaped wire.

5.7 *Forceps*,

5.8 *Desiccator*,

5.9 *Syringe*⁷ (for liquid ink systems only), single-use 2 to 5-mL capacity without needle, or other weighing device listed in the Apparatus section of Test Method D 1259.

6. Reagents

6.1 *Toluene*, technical grade.

7. Preparations of Equipment and Sample

7.1 Check the levelness of shelving in the oven; adjust, if necessary. Lay the thermometer on shelf with the bulb at the place where the samples will be placed. Adjust oven controls

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.56 on Printing Inks.

⁷ Available from any scientific supply house.

until thermometer reads $110 \pm 2^\circ\text{C}$. If air flow is adjustable, set control dampers at 50 %.

7.2 Wear disposable gloves prior to handling weighing dish, spreading device, or syringe in order to minimize contamination by moisture from hands.

7.3 Measure diameter of bottom of weighing dish in millimetres. For example, a catalogue listing of 57 mm refers to the top diameter, whereas the bottom diameter may be only 50 mm. The bottom diameter must be used in the calculations of weight per unit area in 9.3.

7.4 Mark weighing dishes with a suitable notation. Rinse with toluene and heat in oven at 110°C for $\frac{1}{2}$ h.

7.5 Thoroughly mix ink in container to ensure that the sample is uniform. Close can after removing specimen. Reseal when finished.

8. Procedure

8.1 Test Method A—Heatset Systems:

8.1.1 For each specimen, tare to the nearest milligram two weighing dishes each with a spreading device. Retain spreading device throughout the test.

8.1.2 Transfer a representative portion of the sample to the tip of a spatula and dab about 0.15 ± 0.02 g around the bottom of each 57-mm dish, or 0.43 ± 0.02 g if a 94-mm can lid is used. Quickly reweigh and calculate the weight per unit area in accordance with 9.3. If in excess of 100 g/m^2 , discard and weigh out a new specimen.

8.1.3 With spreader, smooth out the specimen into a reasonably uniform film covering the entire bottom of the dish. High viscosity inks may require a few drops of a suitable solvent to aid in spreading out the film.

8.1.4 Place the dishes in the forced draft oven at 110°C for 1 h. Remove dishes from oven, cool in desiccator, and reweigh.

8.2 Test Method B—Liquid Ink Systems:

8.2.1 Tare weighing dishes as in 8.1.1. Transfer 2 to 4 mL of representative sample to syringe and weigh. Dispense a 0.5 ± 0.1 g specimen from the syringe to a 57-mm dish, or 1.5 ± 0.1 g to a 94-mm can lid. Immediately spread out as in 8.1.2. Reweigh syringe.

8.2.2 Repeat 8.2.1 with second dish.

8.2.3 Place dishes in forced draft oven at 110°C for 1 h. Remove dishes from oven, cool in desiccator, and reweigh.

9. Calculation

9.1 Calculate content of nonvolatile matter as follows:

$$NVM, \% = (W/S) \times 100$$

where:

W = specimen weight after heating, g.

S = initial specimen weight, g.

9.2 Optional: The percent of volatile matter may be calculated by difference as follows:

$$VM, \% = 100 - NVM \%$$

9.3 Calculate initial weight/area of each specimen:

$$W/A = 1\,000\,000\,S/3.14\,R^2, \text{ g/m}^2$$

where:

W = weight,

A = area, and

R = radius of dish bottom, mm = diameter/2.

NOTE 3—For a dish with a 50-mm bottom diameter, weight/area = 510 S. For a can lid with a 94-mm bottom diameter, weight/area = 1450 S.

10. Report

10.1 Report *NVM* to the nearest 0.1 % as the mean of replicate determinations.

10.2 Optional: Report *VM* to the nearest 0.1 %.

10.3 Report the mean weight per unit area of the initial specimens to the nearest gram per square metre.

11. Precision and Bias

11.1 Precision:

11.1.1 *Test Method A—Heatset Systems*. An interlaboratory⁸ study was conducted in which one operator in each of five laboratories tested in duplicate on each of two days four heatset printing inks, of which two were low *NVM* (about 50 %) and two were high *NVM* (about 60 %). The round-robin data were analyzed according to Practice E 691. There were no outliers. The within-laboratory pooled standard deviation was found to be 0.44 % absolute at 12 degrees of freedom, and the between-laboratories pooled standard deviation was 2.0 % absolute at 16 degrees of freedom. Based on these standard deviations, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

11.1.1.1 *Repeatability*—Two results, each the mean of two runs obtained by one operator, should be considered suspect if they differ by more than 1.2 % absolute.

11.1.1.2 *Reproducibility*—Two results, each the mean of two runs obtained by operators in different laboratories, should be considered suspect if they differ by more than 5.7 % absolute.

11.1.2 *Test Method B—Liquid Ink Systems*. See Precision section of Test Method D 2369.

11.2 *Bias*—In the interlaboratory study of heatset inks described in 11.1, the mean values for *NVM* agreed with the calculated values within 1 % absolute.

12. Indexing Terms

12.1 These test methods are indexed under the following terms: Heatset-type printing inks, ink, nonvolatile matter content, ovens, printing inks, resin solutions, solvents, and vehicles.

⁸ Supporting data are available from ASTM Headquarters, 1916 Race St., Philadelphia, PA 19103. Request RR D01-1053.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Standard Test Method for Measuring MEK Resistance of Ethyl Silicate (Inorganic) Zinc-Rich Primers by Solvent Rub¹

This standard is issued under the fixed designation D 4752; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

1. Scope

1.1 This test method describes a solvent rub technique for assessing the MEK resistance of ethyl silicate (inorganic) zinc-rich primers. The MEK resistance of some two-component ethyl silicate zinc-rich primers has been shown to correlate well with the cure of the primer as determined by diffuse reflectance infrared spectroscopy.² The technique can be used in the laboratory, field, or in the fabricating shop.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* Specific hazard statements are given in Section 6.

2. Referenced Documents

2.1 ASTM Standards:

D 740 Specification for Methyl Ethyl Ketone³

D 1186 Test Methods for Nondestructive Measurement of Dry Film Thickness of Nonmagnetic Coatings Applied to a Ferrous Base⁴

3. Description of Term Specific to This Standard

3.1 *double rub*—a back-and-forth motion over the test area of approximately 2 in. (50 mm).

4. Significance and Use

4.1 Ethyl silicate zinc-rich primers cure by the reaction of the vehicle with moisture thereby providing a binder. As relative humidity and temperature vary during the day, so does the rate of cure. A certain minimum degree of cure is necessary prior to topcoating. It has been shown that the degree of cure of ethyl silicate zinc-rich primers can be measured by the chemical changes occurring using diffuse reflectance infrared spectroscopy.² This solvent rub test has been shown to correlate well with the infrared spectroscopic results of two-component ethyl silicate inorganic zinc systems.

4.2 The cure rating required for the application of specific topcoats must be agreed upon before the test method is used.

5. Reagents and Materials

5.1 *Methyl Ethyl Ketone* (MEK), in accordance with Specification D 740.

5.2 *Cotton Cheesecloth*.

5.3 *Squeeze Bottle*.

6. Precautions

6.1 Methyl ethyl ketone is a flammable liquid. Its vapors form explosive mixtures in air. Repeated or prolonged contact can cause drying of the skin. Consult supplier's Material Safety Data Sheet(s) for specific hazard information.

7. Procedure

7.1 Select areas on the primer surface at least 2 in. (50 mm) long on which the tests will be run. Measure the dry film thickness of the primer in the selected areas in accordance with Test Methods D 1186.

7.2 Clean the surface first with fresh water to remove loose material.

7.3 Immediately fold the cheesecloth into a pad containing four thicknesses of the cloth. Saturate the cloth to a dripping wet condition with the methyl ethyl ketone.

7.4 Rub the test area with the saturated cloth, exerting moderate pressure with the thumb, using a 2-in. (50-mm) long stroke that encompasses the test area.

7.5 Continue rubbing the surface with the MEK saturated pad, wetting the pad as necessary without lifting it from the surface, until either the metal substrate is exposed or 50 double rubs have been completed. Record the number of rubs when the substrate is exposed.

7.6 Select an adjacent area to be used as a control. Repeat 7.1 through 7.5, except use a dry cheesecloth to establish the effect of burnishing without the influence of MEK.

TABLE 1 Scale for Resistance Rating

Resistance Rating	Description
5	No effect on surface; no zinc on cloth after 50 double rubs
4	Burnished appearance in rubbed area; slight amount of zinc on cloth after 50 double rubs
3	Some marring and apparent depression of the film after 50 double rubs
2	Heavy marring; obvious depression in the film after 50 double rubs
1	Heavy depression in the film but no actual penetration to the substrate after 50 double rubs
0	Penetration to the substrate in 50 double rubs or less

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Material and is the direct responsibility of Subcommittee D01.46 on Industrial Protective Coatings.

Current edition approved Nov. 27, 1987. Published January 1988.

² Starr, T. L., Henton, L. E., Lewis, W. S., and Rideout, F. A., "Improved Field Reliability of High Performance Coating Systems: Phase II—Develop Procedures and Criteria in Critical Performance Areas," available from Steel Structures Painting Council, 4400 Fifth Ave., Pittsburgh, PA 15213.

³ Annual Book of ASTM Standards, Vol 06.03.

⁴ Annual Book of ASTM Standards, Vol 06.01.

7 Inspect the test areas and the cheesecloths. Rate the results in accordance with Table 1.

Report

8.1 Report the following information:

- 8.1.1 Dry film thickness of the primer.
- 8.1.2 Elapsed time between the application of the primer and the running of the tests.
- 8.1.3 Number of tests conducted.
- 8.1.4 Resulting ratings.
- 8.1.5 In the case of a zero rating, number of double rubs required to expose the substrate.
- 8.1.6 *Field and Fabricating Shop Tests*—Identification of

the area or piece tested.

9. Precision and Bias

9.1 Since no standard for measuring the MEK resistance of ethyl silicate zinc-rich primers has been developed prior to this test method, precision and bias statements will be developed in round-robin testing.

10. Indexing Terms

10.1 This test method is indexed under the following terms: curing characteristics, double rub method, drying or curing, ethyl silicate (inorganic) primer, methyl ethyl ketone, MEK (methyl ethyl ketone) resistance, primer, solvent rub method, visual examination, and zinc-rich primer.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Determination by X-ray Fluorescence Spectroscopy of Titanium Dioxide Content in Paint¹

This standard is issued under the fixed designation D 4764; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of titanium dioxide content in liquid paint. This test method is applicable to both water-reducible and solvent-reducible paints.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. Specific hazards statements are given in Section 7.*

2. Referenced Documents

- 2.1 *ASTM Standards:*
 - D 476 Specification for Titanium Dioxide Pigments²
 - D 1193 Specifications for Reagent Water³
 - D 1394 Test Methods for Chemical Analysis of White Titanium Pigments²
 - D 2369 Test Method for Volatile Content of Coatings⁴
 - D 3925 Practice for Sampling Liquid Paints and Related Pigmented Coatings⁴
 - D 3980 Practice for Interlaboratory Testing of Paint and Related Materials⁴
 - D 4563 Test Method for Determination by Atomic Absorption Spectroscopy of Titanium Dioxide Content of Pigments Recovered from Whole Paint⁴
 - E 180 Practice for Determining the Precision Data of ASTM Methods for Analysis and Testing of Industrial Chemicals⁵

3. Summary of Method

3.1 Paint containing a known amount of titanium dioxide is used as the reference standard. A solution of tetraethylammonium bromide in 2-ethoxyethanol is added to the standard paint and to each paint being analyzed. Drawdown films of the standard and test paint are made on thin plastic sheets. The intensities of key X-ray fluorescence peaks of titanium and bromine are measured. The titanium dioxide content is determined by comparing the ratio of the intensities of titanium and bromine peaks in the test paint and the standard. Differences in the nonvolatile content of the paints

are taken into account in the calculation of results.

4. Significance and Use

4.1 Titanium dioxide pigments are components with high refractive index that significantly influence the opacity, color, durability, and other properties of coatings. This test method for determining titanium dioxide content is quicker and easier to use than Test Methods D 1394, a wet chemical analysis method for pigments. It is conveniently applicable to single samples and to large numbers of samples. Only a single relatively stable reagent used to prepare standards and paints under test need be stored. Drawdown specimens used as standards, once prepared, can be stored indefinitely and used repeatedly.

5. Apparatus

5.1 *X-ray Fluorescence Spectrometer*, suitable for measurement of the baseline corrected intensity of the $K\alpha$ lines of titanium and of bromine. For spectrometers equipped with a tungsten or chromium target and a lithium fluoride (200) analyzing crystal, these lines are observed at 2θ angles of 86.09° and 29.97° , respectively.

NOTE 1—Follow the recommendations of the manufacturer of the instrument used. Use operating conditions that ensure that the count rate for bromine and titanium are within the linear response range of the detector. Although the base operating conditions and count rate may be different for different instruments, these differences will not affect the outcome of the analysis.

5.2 Paint Shaker.

5.3 *Film Applicator*, to produce a 3-mil (75- μm) wet film thickness.

5.4 *Plastic Sheet*,⁶ with no interfering X-ray fluorescence peaks and not attacked by paint solvent.

5.5 *Perforated Suction Plate*, or other flat surface.

5.6 *Vials and caps*, 20 mL.

6. Reagents

6.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests, unless otherwise specified. It is intended that all reagents conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society

¹ This test method is under the jurisdiction of ASTM Committee D01 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Materials.

Current edition approved Feb. 26, 1988. Published April 1988.

⁵ *Annual Book of ASTM Standards*, Vol 15.05.

⁶ Leneta P-121-10N dull black plastic panels 6½ by 17 in. by 10 mils (165 by 432 by 0.25 mm) in size, available from Leneta Co., P.O. Box 576, Ho-Ho-Kus, NJ 07423, have been found suitable for this purpose.

where such specifications are available.⁷ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

6.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water that conforms to the requirements of Type II of Specification D 1193.

6.3 *2-ethoxyethanol*, purified grade.

6.4 *Tetraethylammonium Bromide*, internal standard solution—Into a 100-mL volumetric flask weigh approximately 10.80 g of tetraethylammonium bromide (TEAB) to 0.1 mg. Dissolve the TEAB in 2-ethoxyethanol, fill the flask to the mark with 2-ethoxyethanol, and mix thoroughly. (TEAB dissolved in 2-ethoxyethanol can be used as an internal standard for both water-reducible and solvent-reducible paint. However, water may be substituted for 2-ethoxyethanol, if only water-reducible paint is to be analyzed.)

Hazards

7.1 As exposure to excessive quantities of x-radiation is injurious to health, X-ray producing equipment can be dangerous to both the operator and persons in the immediate vicinity unless safety precautions are strictly observed. Therefore, users should avoid exposing any parts of their bodies, not only to the direct beam, but also to secondary or scattered radiation that occurs when an X-ray beam strikes or passes through any material. It is strongly recommended that users check the degree of exposure by film carried on them or by the use of dosimeters and that blood counts be made periodically. Before utilizing the equipment, all persons designated or authorized to operate X-ray instrumentation or supervise its operation, should have a full understanding of its nature and should also become familiar with established safe exposure factors by a careful study of the National Bureau of Standards Handbook "X-ray Recommendations of the International Roentgen Ray Committee on X-ray Protection,"⁸ the manufacturer's instruction manual, and other standard publications on the subject. Inquiries should be made of state agencies as to existing requirements.

Specimen Preparation

8.1 Thoroughly mix and sample each paint in accordance with Practice D 3925. Prepare duplicate specimens of the standard paint, which contains a known concentration of titanium dioxide, and each test paint using the following procedure. Into a 20-mL vial weigh approximately 7.00 g of paint to 1 mg. Pipet 2 mL of TEAB internal standard solution (see 6.4) into the paint and thoroughly mix.

8.2 Place a plastic sheet on the perforated suction plate. On the plastic sheet make a 3.0-mil (75- μ m) thick drawdown of the liquid paint. Air dry the drawdown film overnight. Cut

TABLE 1. Instrument Conditions

	Ti K α	Br K α
Analyzer crystal	LIF	LIF
Counter	Flow or Scintillation	Scintillation
Collimator	Fine	Coarse
Order	First	First
Tube KV/ma	10/5	50/24
Time, s	20	20
Peak, 2 θ , °	86.00	29.97
Background, 2 θ , °	85.00	29.00

from the drawdown on the plastic sheet a disk of a size appropriate for the specimen holder of the spectrometer.

8.3 Determine the percent nonvolatile content of each paint at 110°C in accordance with Test Method D 2369 if the information is not already available.

9. Procedure

9.1 Turn on the spectrometer and allow it to stabilize thoroughly before beginning collection of results. With the aid of the manufacturer's literature, select spectrometer settings to permit measurement of the intensity of the K α peaks of titanium and bromine. For instruments equipped with an X-ray tube with a tungsten or chromium target, the settings prescribed in Table 1 may be used as guidelines (Note 1).

9.2 Place the disk in the specimen holder in such a way that the coated side of the sheet is turned toward the incident X-rays. Before measuring the specimens, record the background spectrum in the ranges of the K α peaks of titanium and bromine, including at least 10° on each side. Check the spectra for the presence of interfering peaks and select for each peak an angle for background measurement where interference is at a minimum.

9.3 At the selected angles measure the background intensities and the intensities of the K α peaks of titanium and bromine in counts per second (c/s). Determine the net intensity, c/s, of each peak by subtracting the background count from the peak count.

10. Calculation

10.1 Use the values of the standard paint of known TiO₂ content to calculate K_r , the reference intensity ratio of titanium relative to bromine in the film, defined as:^{9,10}

$$K_r = \frac{\frac{B}{B+N}}{\frac{T}{T+N}} \times \frac{I_b}{I_t} = \frac{B}{T} \times \frac{I_t}{I_b}$$

where:

B = TEAB used in making film, g,

= TEAB used, g, $\times \frac{2 \text{ mL}}{100 \text{ mL}}$ = TEAB used, g, $\times \frac{1}{50}$

T = TiO₂ in film, g,

= paint used, g, $\times$ (% TiO₂ in dry paint/100) $\times$ % nonvolatile matter/100,

= paint used, g, $\times$ % TiO₂ in liquid paint/100,

⁷ "Reagent Chemicals, American Chemical Society Specifications," Am. Chemical Soc., Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY, and the "United States Pharmacopeia."

⁸ Available from National Bureau of Standards, National Center for Standards, Gaithersburg, MD 20899.

⁹ Chung, F. H., "A New Approach to Quantitative Multi-element X-ray Fluorescence Analysis," *Advances in X-ray Analysis*, 19, 1976, p. 81.

¹⁰ Chung, F. H., Lentz, A. J., and Scott, R. W., "A Versatile Thin Film Method for Quantitative X-ray Emission Analysis," *X-ray Spectrometry*, 3(4), 1974, p. 172.

= paint used, g, $\times$ weight fraction of TiO_2 in liquid paint,
 N = nonvolatile matter (from paint) in film, g,
 = paint used, g, $\times$ % nonvolatile matter/100,
 = paint used, g, $\times$ % weight fraction of nonvolatile matter,
 I_b = intensity of bromine peak, c/s, and
 I_t = intensity of titanium peak, c/s.
 Therefore

$$K_t = \frac{B}{W} \times \frac{1}{50X} \times \frac{I_t}{I_b}$$

where:

W = paint used, g, and

X = weight fraction of TiO_2 in liquid paint.

Calculate the mean of the K_t values obtained from the two disks coated with the standard paint and use in the calculation in 10.2.

10.2 Calculate the percent TiO_2 in the test paint, P , as follows:

$$P = \frac{2 \times B \times I_t}{K_t \times W \times I_b}$$

where the symbols are defined as in 10.1.

10.3 Sample Calculation:

10.3.1 Reference intensity ratio, K_t ,

Standard paint—12.8 % TiO_2 in liquid paint,

Standard solution—10.347 g TEAB in 100-mL solution,

Film—2 mL of standard solution in 7.25 g of liquid standard paint, and

X-ray intensity: $I_b = 4396$ c/s, $I_t = 1804$ c/s.

$$K_t = \frac{10.347}{7.252} \times \frac{1}{(50)(0.128)} \times \frac{1804}{4396} = 0.0915$$

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

The mean of duplicate analyses is $K_t = 0.0916$.

10.3.2 TiO_2 content of test paint,

Data:

Film—2 mL of standard solution in 7.186 g wet paint, and

X-ray intensity: $I_b = 4272$ c/s, $I_t = 2569$ c/s

$$P = \frac{10.347}{7.186} \times \frac{2}{0.0916} \times \frac{2569}{4272} = 18.9 \%$$

11. Precision and Bias

11.1 In an interlaboratory study of this test method, one operator in each of five laboratories analyzed on two days two samples of latex house paint and two samples of solvent-reducible house paint. The mean weight percent titanium dioxide in samples Number 1 through 4 was, respectively, 3.64, 19.1, 7.44, and 15.8 %. The pooled within-laboratory coefficient of variation was 2.39 % with 19 degrees of freedom and the pooled between-laboratories coefficient of variation 4.47 % with 15 degrees of freedom, after discarding one duplicate value from one laboratory because the range differed significantly from all other duplicate ranges for paint sample Number 2. Based on these coefficients of variation, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

11.1.1 *Repeatability*—Two results, each the mean of duplicate determinations, obtained by the same operator on different days should be considered suspect if they differ by more than 7.08 % relative.

11.1.2 *Reproducibility*—Two results, each the mean of duplicate determinations, obtained by operators in different laboratories should be considered suspect if they differ by more than 13.5 % relative.

Standard Practice for Continuity Verification of Liquid or Sheet Linings Applied to Concrete Substrates¹

This standard is issued under the fixed designation D 4787; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

1.1 This practice covers procedures that may be used to allow the detection of discontinuities in nonconductive linings with thicknesses exceeding 20 mils (0.5 mm) applied to concrete substrates.

1.2 Discontinuities may include pinholes, internal voids, holidays, cracks, and conductive inclusions.

1.3 This practice utilizes high-voltage spark testing in conjunction with a continuous conductive membrane.

NOTE—For further information on discontinuity testing refer to Nace standard RP0188-88.

1.4 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For a specific hazard statement, see Section 6.*

2.1 ASTM Standards:

D 149 Test Method for Dielectric Breakdown Voltage and Dielectric Strength of Solid Electrical Insulating Materials at Commercial Power Frequencies²

2.2 NACE Standards:³

RP0188-88 NACE Standard Practice Discontinuity (Holiday) Testing of Protective Coatings

Terminology

3.1 Description of Terms Specific to This Standard:

3.1.1 *discontinuity*—a localized lining site that has a dielectric strength less than a determined test voltage.

3.1.2 *conductive underlayment*—a continuous layer applied to the prepared concrete surface prior to the application of a nonconductive lining layer(s) that will allow high voltage spark testing for discontinuities in the lining.

3.1.3 *spark-over*—at a certain electrical voltage and distance from a grounded surface a spark from a high-voltage testing instrument will jump across the space.

3.1.4 *high voltage spark tester*—a high voltage electrical detector used to locate discontinuities in nonconductive

linings applied to conductive substrates.

3.1.5 *test voltage*—that electrical voltage established which will allow a discontinuity at the thickest lining location site to be tested, but which will not damage the lining. The test voltage must always be set well below the dielectric breakdown strength of the lining. This voltage should normally be recommended by the lining manufacturer. The dielectric breakdown voltage strength of a solid can be determined by Test Method D 149.

4. Summary of Practice

4.1 This practice allows for high voltage electrical detection of discontinuities in new linings applied to concrete substrates through the utilization of a continuous conductive underlayment applied to the prepared concrete surface prior to the application of the nonconductive lining layer(s).

5. Significance and Use

5.1 The electrical conductivity of concrete is primarily influenced by the presence of moisture. Other factors which affect the continuity of concrete include the following:

- 5.1.1 Presence of metal rebars,
- 5.1.2 Cement content and type,
- 5.1.3 Aggregate types,
- 5.1.4 Admixtures,
- 5.1.5 Porosity,
- 5.1.6 Above or below grade elevation,
- 5.1.7 Indoor or outdoor location,
- 5.1.8 Temperature and humidity, and
- 5.1.9 Age of concrete.

5.2 The electrical conductivity of concrete itself may be successfully used for high-voltage continuity testing of linings applied directly with no specific conductive underlayment installed. However, the voltage required to find a discontinuity may vary greatly from point to point on the structure. This variance may reduce the test reliability to an unacceptable level.

5.3 Although the most common conductive underlayments are liquid primers applied by trowel, roller, or spray, and which contain carbon or graphite fillers, others may take the form of the following:

- 5.3.1 Sheet-applied graphite veils,
- 5.3.2 Conductive polymers,
- 5.3.3 Conductive graphite fibers,
- 5.3.4 Conductive metallic fibers, and
- 5.3.5 Conductive metallic screening.

5.4 Liquid-applied conductive underlayments may be desirable as they can serve to address imperfections in the concrete surface and provide a better base for which to apply the lining.

¹ This practice is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generation Facilities and is the direct responsibility of Subcommittee D33.04 on Inspection.

Current edition approved Sept. 30, 1988. Published November 1988.

² Annual Book of ASTM Standards, Vol 10.01.

³ Available from National Association of Corrosion Engineers, P.O. Box 218340, Houston, TX 77218.

5.5 This practice is intended for use with new linings applied to concrete substrates. It may also be applicable for linings previously tested by this practice and subsequently placed in service. However, consideration must be given to potential changes to the electrical properties of the conductive and nonconductive layers comprising the system.

5.6 The user may consider this practice when performance requirements of the lining in a specified chemical environment requires assurance of a lining free of discontinuities.

5.7 Factors affecting the dielectric properties and test voltage shall be considered. Some factors are the curing time of liquid-applied linings; the possible presence of electrically conductive fillers or solvents, or both; the possible presence of air inclusions or voids; and the compatibility of conductive underlayments with the specified lining.

6. Apparatus

6.1 *High Voltage Spark Tester*—An electrical detector with a voltage rating in excess of 900 V. The detector is to consist of an electrical energy source, an exploring electrode, a ground connection, and ground wire. The detector shall be equipped with a visual or audible indicator, or both.

6.1.1 *Electrical Energy Source*—Either a-c, d-c, or pulsating d-c type with the appropriate test voltage.

6.1.2 *Exploring Electrode*—The full length shall be capable of maintaining continuous contact with the surface being inspected.

6.1.3 *Ground Wire*, stranded 14 to 16 gage copper wire.

6.1.4 *Visual or Audible Indicators*, or both, to signal a closed electrical circuit. Such signals shall be essential for testing the underlayment for electrical conductivity and for exposing discontinuities in the lining after it has been applied.

7. Hazards

7.1 Solvents retained in the applied conductive underlayment may create an explosive environment as well as produce erroneous results.

8. Conductive Underlayments

8.1 The conductive underlayment shall not rely on the concrete substrate's electrical properties.

8.2 The specified lining shall be compatible with the specified conductive underlayment.

8.3 Application:

8.3.1 The finished conductive underlayment surface shall be relatively smooth. The conductive underlayment shall be considered part of the lining system and must be installed in accordance with the manufacturer's latest published instructions.

8.3.2 Visually verify that the conductive underlayment covers the entire area to be lined. Breaks at expansion joints and construction joints are allowable unless otherwise specified.

8.4 Verification of Underlayment Conductivity:

8.4.1 The surface of the applied conductive underlayment shall be clean, dry, free of oil, grease, dirt, or other contaminants and be sufficiently cured in accordance with the manufacturer's latest published instructions at the time

the high-voltage spark testing is performed. (Warning—See Section 7.)

8.4.2 Verify the operation of the high-voltage test instrument in accordance with Section 9.

8.4.3 Adjust the high-voltage test instrument in accordance with Section 10.

8.4.4 Ground the test instrument to the installed underlayment or other appropriate ground. If electrical isolation across an expansion joint is encountered, the ground wire must be moved to an appropriate ground in the same section being tested.

8.4.5 Place the exploring electrode on a nonconductive spacer so that an air gap between the surface of the underlayment and the electrode is equal to the maximum thickness of the lining.

8.4.6 The underlayment is conductive if a spark-over is emitted and the visual or audible indicator, or both, on the test instrument is activated.

8.4.7 Test Sampling:

8.4.7.1 A minimum of four test points shall be used for the first 100 ft.² Test points shall be approximately equally spaced within the test area. At least one additional test point shall be used for every 500 ft.² thereafter.

8.4.7.2 Test points most distant from the ground connection shall be included in the test sampling.

8.4.8 The specified lining shall not be applied until the conductivity of the underlayment has been verified.

9. Verifying Operation of High-Voltage Spark Tester

9.1 Test electrical source for proper voltage output.

9.2 Follow the equipment manufacturer's operating instructions for verifying the operation of the high voltage tester.

9.3 If the tester fails to signal, it shall be considered defective.

10. Adjustment of High-Voltage Spark Tester for Verifying Conductivity of Underlayment

10.1 Establish the test voltage based on the maximum specified thickness of the nonconductive lining, its dielectric strength, and the lining manufacturer's recommendations.

10.2 Following the equipment manufacturer's instructions, set and check the test voltage established in 10.1.

11. Application of the Lining or Coating

11.1 Apply the specified lining in accordance with governing specifications.

12. Adjustment of High Voltage Spark Tester for Verifying Conductivity of the Applied Lining

12.1 Select the proper test voltage to provide reliable spark-over to locate a holiday under normal test conditions. The voltage selected must jump an air gap equal to the maximum specified dry film thickness of the lining being tested and not arc through the lining at the minimum specified dry film thickness.

12.2 Adjust the tester to the test voltage established in 12.1 as follows:

12.2.1 Connect a high-voltage voltmeter or a spark-gap calibrator between the electrode and the ground wire.

12.2.2 Switch the detector to the ON position.

12.2.3 Perform field checking of the test voltage with the electrode placed against the surface of the lining since the exploring electrode voltage may be reduced by the slight current flow to the lining.

12.2.4 If required, compare measured voltage with the selected test voltage. Depending on the type of tester, adjust to the selected voltage $\pm 5\%$.

12.2.5 Switch the detector to the OFF position.

12.2.6 Disconnect the voltmeter or spark-gap calibrator.

3. High Voltage Spark Testing for Verifying Continuity of Applied Lining

13.1 The surface of the applied lining shall be clean, dry, free of oil, grease, dirt, or other contaminants and be sufficiently cured in accordance with the manufacturer's latest published instructions at the time the high-voltage

spark testing is performed (**Warning**—See Section 7).

13.2 Attach the ground wire from the instrument ground terminal to the conductive underlayment or appropriate ground in the same manner as was required in 8.4.4. Make contact with the exploring electrode at a known discontinuity to verify that the instrument is properly grounded. For each ground location, make contact with a known discontinuity. Conduct this test periodically during the test.

13.3 With the exploring electrode in continuous contact with the lining surface, move it over the entire surface of the lining at a rate of 1 ft/s (0.3 m/s) maximum in a sweeping motion with overlapping passes to ensure that the entire surface has been subjected to the test.

13.4 Identify discontinuities that require repair with a compatible marker.

13.5 Completely test the lining one time only. Repair all defects found in the lining and retest only those repaired areas.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Bond Strength of Thermoplastic Traffic Marking Materials¹

This standard is issued under the fixed designation D 4796; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

1. Scope

1.1 This test method provides an instrumental means for the determination of thermoplastic traffic marking material bond strengths using cement bricks and steel cubes.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

C 109 Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or 50-mm Cube Specimens)²

C 881 Specification for Epoxy-Resin-Base Bonding Systems for Concrete³

D 883 Definition of Terms Relating to Plastics⁴

E 284 Terminology Relating to Appearance of Materials⁵

F 412 Terminology Relating to Plastic Piping Systems⁶

3. Terminology

3.1 *Definitions*—Definitions are in accordance with Definitions D 883, E 284, and F 412, unless otherwise indicated.

3.2 Descriptions of Terms Specific to This Standard:

3.2.1 *cement brick*—a brick formed by mixing cement and fine sand together and allowing to harden.

3.2.2 *thermoplastic*—traffic marking (same as 3.2.3).

3.2.3 *thermoplastic traffic marking*—a highly filled 100 % total solids highway marking system that when heated to a molten state can be extruded or sprayed onto a road surface and when cooled forms a solid durable delineator.

4. Summary of Test Method

4.1 The thermoplastic specimen is prepared for this test by first melting a sample to its application temperature under continuous agitation. The specimen is then applied to the specified cement brick by a hot drawdown blade. Two

steel cubes are then immediately placed onto the hot thermoplastic line and the excess thermoplastic trimmed away from around the two steel cubes. After the trimming is complete, the steel cubes are removed. A heated steel cube is bonded with epoxy to the square of thermoplastic and allowed to cure overnight before determining the bond strength on a Dillon dynamometer or similar device.

5. Significance and Use

5.1 The function of this test method is to provide numerical instrumental results indicating the cohesive or adhesive, or both, bond strength of thermoplastic traffic marking to a specified cement brick substrate.

5.2 The use of this test method allows the user and manufacturer to control the quality of the product and make inferences about the performance of the thermoplastic traffic marking product. Results from these tests also provide information helpful in researching and developing thermoplastic traffic marking materials.

5.3 Strict adherence to the procedures outlined is necessary for precision of the test method. Under no conditions should the bond strength be accepted unless there is conformance to 9.14. Precise results are obtained only when one steel block is epoxied to the thermoplastic traffic marking on the cement brick.

6. Types of Separation in Bond Strength Tests

6.1 *Thermoplastic to Steel Cube Separation*—This type of separation occurs where there is an insufficient bond between the thermoplastic and steel cube probably due to insufficient coverage of the epoxy adhesive.

6.2 *Thermoplastic to Thermoplastic Separation*—This type of separation is caused by internal cohesive failure of the thermoplastic. This separation is acceptable when it exceeds the specified bond strength.

6.3 *Thermoplastic to Cement Brick Separation*—This type of separation is caused by the failure of the bond between the thermoplastic specimen and the cement brick.

6.4 *Cement Brick to Cement Brick*—This type of separation is caused by the internal cohesive failure of the brick. This is due, in most cases, to a bond between the thermoplastic and cement brick that exceeds the cohesive strength of the cement brick. This separation is not acceptable when the bond strength values are lower than specified.

7. Apparatus

7.1 *Agitator Blade*, 6 in. (15 cm) long with a 1/2-in. (1-cm) steel shaft and a 1 3/4 by 1 in. by 1/8-in. (4.5 by 2.5 by 0.3-cm) straight horizontal steel blade.

7.2 *Capped Bolts*, two, 3/8 in. (16 mm) in size.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.44 on Traffic Coatings.

FIG. 1 Bond Strength Testing Apparatus

7.3 *Cement Bricks*, 3½ by 2 by 7½ in. (9 by 5 by 19 cm) in size with a compressive strength of 3000 to 5000 psi (Note 1).

NOTE 1—Concrete bricks conforming to Test Method C 109 have been used but proved more variable due to migration of a thin veneer of cement to the top of the brick making determinations erratic. The cement bricks may be obtained from local block plants. The term "cement" brick is common for the industry and is used in this test method extensively.

NOTE 2—The unit should be fitted with a steel frame to hold the cement brick for testing.

7.4 *Dynamometer*,⁷ with a capacity of 6000 lbs in 25-lb divisions having a pull-rate capability of ¼ in./min. (Note 2) (See Figs. 1, 2, 3, and 4).

7.5 *Draw Down Blade*, 2 by 1 by 4 in. (5 by 2.5 by 10 cm) in size capable of laying down a .125 mil (0.125 in.) wet thermoplastic film 2 in. wide.

7.6 *Drill Press*, or other apparatus capable of agitating the thermoplastic during meltdown to the application temperature at 600 to 800 r/min in the jacketed electric pots.

7.7 *Epoxy Resin and Hardener*, Type I or II, Grade 2, Class C in accordance with Specification C 881.

7.8 *Hot Plate*, capable of maintaining 537°C.

7.9 *Gravity Convection Oven*, capable of maintaining 260°C.

7.10 *Electric Pots, Jacketed*, for heating and melting the thermoplastic to 218°C.

7.11 *Spatulas*, for cutting, stirring, and shaping the thermoplastic.

7.12 *Steel Cubes*, two, 2 by 2 by 2 in. (5 by 5 by 5 cm) in size threaded in the center of one side for a ⅝-in. (16-mm) capped bolt.

8. Sampling

8.1 Samples may be obtained by an appropriate quartering or riffle sampling method where deemed necessary

⁷ A Dillon Dynamometer available from Weigh-Tranex, 1000 Armstrong Drive, P.O. Box 1000, Fairmount, MN 56031, or equivalent, has been found suitable for this purpose.

FIG. 2 Tension Bed

considering the physical form of the material.

9. Procedure

9.1 Under continuous agitation melt a specimen of the thermoplastic to be tested to a temperature of 218°C. If the specimen is a dry powder mix, allow the specimen to cool to

FIG. 3 Load Plate (2 Required)

FIG. 4 Coupling Hitch

193°C under continuous agitation and reheat under agitation to 218°C.

NOTE 3—Dry powder mixed thermoplastic must be conditioned to ensure a homogeneous melt necessary for consistent results. Premelted block thermoplastic does not require this conditioning. The specimen may be melted on a hot plate set at 537°C or in a jacketed electric pot. Continuous agitation is necessary to prevent scorching and settling. If the specimen is melted in an oven set at 260°C, the specimen must be agitated every 15 min until 218°C is reached.

9.2 Heat the draw down blade to 218°C.

9.3 Obtain a dry room temperature cement brick that has been brushed or textured on the side to be coated with thermoplastic.

9.4 Heat one 2 by 2 by 2 in. (5 by 5 by 5 cm) steel cube in an oven or on a hot plate to 49°C for 2 h prior to making the thermoplastic draw down on the cement brick.

9.5 When the thermoplastic specimen is melted to 218°C under continuous agitation, remove the agitator blade from the thermoplastic.

9.6 Remove the draw down blade from the hot plate and immediately place it on the cement brick and make the draw down the full length of the brick with the melted thermoplastic on the brushed or rough textured side of the brick.

9.7 Immediately place two room temperature steel cubes on the thermoplastic approximately 1 in. from each end of the brick and trim the plastic from around the two steel cubes before the plastic cools and hardens.

9.8 Remove the steel cubes by hand and allow the thermoplastic to cool for 1 h.

9.9 Prepare the epoxy solution using the proper resin and hardener ratio and mix thoroughly.

9.10 Remove the steel cube heated to 49°C from the oven and place a small amount of epoxy on the heated cube. Place the steel cube on the thermoplastic square and rub to ensure an even coating and good adhesion. To ensure an even coating, remove the steel cube from the thermoplastic square and visually inspect the square and cube and then replace the steel cube on the square and rub. Do not allow any excess epoxy solution to flow from the steel cube and thermoplastic square onto the cement brick.

NOTE 4—Only one steel cube can be epoxied at a time to the thermoplastic on the brick because the shock of the first pull will cause a premature release of the second thermoplastic square.

9.11 Place a weight such as a cement brick on the steel cube epoxied to the thermoplastic square and allow to cure for a minimum time of 8 h.

9.12 Screw the 5/8-in. (15.9-mm) capped bolt into the steel cube epoxied to the thermoplastic and place the brick into the steel frame mounted onto the dynamometer.

9.13 Set the dynamometer to zero and pull the steel cube at 1/4 in./min.

9.14 Two tests are run on each brick. Separations involving at least 80 % of the thermoplastic area to the cement brick, thermoplastic to thermoplastic, and cement brick to cement brick are acceptable for reporting bond strengths.

10. Calculations

10.1 Calculate the bond strength as follows:

10.1.1 Average the readings obtained in 9.13 if the conditions in 9.14 are met.

10.1.2 Divide the average reading obtained by 4. The result is the bond strength in pounds per square inch.

10.1.3 If one of the two tests fails then that test is repeated until the conditions of 9.14 are met.

11. Report

11.1 Report the following information:

11.1.1 The type of separation and bond strength, the batch number, color, and type of thermoplastic.

11.1.2 The determination of the area of separation is subjective. The area not involved in the separation is usually attached to the steel cube or cement brick.

12. Precision and Bias

12.1 *Precision*—No general statement of precision can be made because of lack of sufficient data at this time.

12.2 *Bias*—No statement of bias can be prepared for this test method since there is no absolute method for use as a comparative basis.

12.3 Experience dictates that test results with ± 50 psi are acceptable.

13. Index Terms

13.1 This test method is indexed under the following terms: thermoplastic—traffic marking; bond strength; cement brick.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Methods for Chemical and Gravimetric Analysis of White and Yellow Thermoplastic Traffic Marking Containing Lead Chromate and Titanium Dioxide¹

This standard is issued under the fixed designation D 4797; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 These test methods cover procedures for the chemical and gravimetric analysis of white and yellow thermoplastic traffic marking containing lead chromate and titanium dioxide pigment.

1.2 The analytical procedures appear in the following order:

	Sections
Percent Binder	10
Percent Glass Beads (Note 1)	11
Percent Titanium Dioxide	12
Percent Lead Chromate and Analysis of Chrome Yellow and Chrome Orange Pigments (Note 2)	13

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

NOTE 1—Test for 1.50 glass spheres only.

NOTE 2—This modified analysis of chrome yellow and chrome orange pigments must be used because the heat resistant chrome yellows in the thermoplastic cannot be analyzed by Test Method D 126.

2. Referenced Documents

2.1 ASTM Standards:

- D 126 Test Methods for Chemical Analysis of Yellow, Orange, and Green Pigments Containing Lead Chromate and Chromium Oxide Green²
- D 883 Definitions of Terms Relating to Plastics³
- D 1193 Specification for Reagent Water⁴
- D 1394 Test Methods for Chemical Analysis of White Titanium Pigments²
- F 412 Terminology Relating to Plastic Piping Systems⁵

3. Terminology

3.1 *Definitions*—Definitions are in accordance with Definitions D 883 and F 412, unless otherwise indicated.

3.2 Descriptions of Terms Specific to This Standard:

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Materials.

Current edition approved Oct. 31, 1988. Published December 1988.

³ Annual Book of ASTM Standards, Vols 08.01 and 08.04.

⁴ Annual Book of ASTM Standards, Vols 06.03 and 11.01.

⁵ Annual Book of ASTM Standards, Vol 08.04.

3.2.1 *ash*—the inorganic components of thermoplastic traffic marking including the pigment, glass spheres, and filler.

3.2.2 *binder*—the organic components of thermoplastic traffic marking that bind the pigments, glass spheres, and filler together as a unit.

3.2.3 *filler*—the inorganic components of thermoplastic traffic marking not including the pigments or glass spheres.

3.2.4 *pigment*—titanium dioxide and lead chromate colorants.

3.2.5 *thermoplastic*—See *thermoplastic traffic marking*.

3.2.6 *thermoplastic traffic marking*—a highly filled 100 % total solids highway marking system that when heated to a molten state can be extruded or sprayed onto a road surface and when cooled forms a solid durable delineator.

4. Summary of Test Method

4.1 The thermoplastic material is prepared for the described test methods by melting a sample to its application temperature under continuous agitation. The specimen is then poured into round patties on a clean tin plate or baking pan. The patties are then broken into pieces for ignition in a muffle furnace. The percent binder is calculated from the ashed specimen and the various tests for glass spheres, titanium dioxide, and lead chromate pigment are performed on the ashed residue. The tests for pigment type or glass spheres may be run on the same ashed specimen. Specimen selection and preparation are the same for each sample tested.

5. Significance and Use

5.1 The function of these test methods is to define the percent of binder, glass, titanium dioxide, and lead chromate present in the composition of the thermoplastic traffic marking as defined by the applicable specification for the manufacture of a specific thermoplastic traffic marking.

6. Apparatus

- 6.1 Balance, analytical, accurate to 0.1 mg.
- 6.2 Buret, 10 mL, 0.1-mL divisions.
- 6.3 Buret, 50 mL, 0.1-mL divisions.
- 6.4 Crucibles, 30 mL, porcelain.
- 6.5 Desiccator.
- 6.6 Erlenmeyer flask, 500 mL.
- 6.7 Furnace (Muffle), capable of maintaining 1100°C.
- 6.8 Hot plate, capable of maintaining 537°C.
- 6.9 Jones Reductor.

6.10 *Mortar and Pestle*, glazed ceramic or other impervious type.

6.11 *Oven*, capable of maintaining 260°C.

6.12 *Sieve*, 3 in., 45- μ m (No. 325) (metal).

7. Reagents

7.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁶ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

7.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water as defined by Type IV of Specification D 1193.

7.3 *Alcohol*—Ethyl alcohol 95 %.

7.4 *Potassium Chloride* (KCl).

7.5 *Potassium Hydroxide Solution*—Dissolve 50 g of potassium hydroxide (KOH) in 100 mL of freshly distilled water.

7.6 *Potassium Iodide* (KI).

7.7 *Potassium Permanganate Solution* (KMnO₄) (0.1N).

7.8 *Sodium Thiosulfate, Standard Solution* (Na₂S₂O₃ · 5H₂O) (0.1 N).

7.9 *Starch (Soluble) Indicator Solution*—Dissolve 10 g of soluble starch in 1 L of deionized or distilled water.

7.10 *Hydrochloric Acid Solution* (HCl) (1+2).

7.11 *Hydrochloric Acid, Concentrated* (HCl).

8. Sampling

8.1 Samples may be obtained by an appropriate quartering or riffle sampling method where deemed necessary considering the physical form of the material.

9. Preparation of Specimens

9.1 Melt a sample of approximately 1000 g of thermoplastic traffic marking to 210 to 218°C under continuous agitation on a hot plate set at 537°C or stir every 15 min in an oven set at 260°C.

9.2 Flow the sample out on a smooth clean surface and allow it to cool to room temperature. Patties 1/8 in. (3 mm) thick will facilitate breaking up specimens for the described analysis.

9.3 Break the specimen into small pieces and weigh 10 g to the nearest 0.1 mg into a 30-mL weighed crucible.

9.4 Cover the crucible and place into a muffle furnace preheated to 540°C and ash for 1 h or until no carbonaceous materials remain.

9.5 Remove the crucible with the ashed remains of the specimen and place into a desiccator and cool to room temperature.

⁶ "Reagent Chemicals, American Chemical Society Specifications," Am. Chemical Soc., Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY, and the "United States Pharmacopeia."

10. Percent Binder

10.1 Procedure:

10.1.1 Weigh the crucible and ash (see Section 9) to the nearest 0.1 mg and calculate the percent of organic binder *D* as follows:

$$D = [1 - (S/W)] \times 100$$

where:

S = ashed weight of thermoplastic specimen, g, and

W = weight of thermoplastic specimen, g.

11. Percent Glass Beads

11.1 *Interferences*—Acid-insoluble fillers will affect the glass-sphere analysis and must be removed by some physical separation method or accounted for quantitatively, or both.

11.2 Procedure:

11.2.1 Weigh the crucible and ash (see Section 9) to 0.1 mg and calculate the percent ash.

11.2.2 After the ashed material has been weighed, transfer the ash to a mortar and pestle and grind with minimal pressure to reduce the ash to a fine grained consistency without crushing the beads. Carefully transfer the ashed contents into a 400-mL beaker.

11.2.3 Add to the ash approximately 150 mL of cold 1+2 HCl and stir occasionally until the effervescence has ceased completely.

11.2.4 Place the beaker on a hot plate preheated to approximately 260°C and boil for 20 min under continuous agitation to dissolve all acid-soluble filler pigments.

11.2.5 Remove the beaker from the hot plate, and while hot, immediately dilute the contents with 150 mL of cold water. Allow the beads to settle. Decant the water carefully so as not to lose any glass beads.

11.2.6 Continue diluting with 150-mL aliquots of water and decanting until the water is nearly clear. Then transfer the residue into a weighed 3-in. 45- μ m (No. 325) sieve and wash with 500 mL of cold water.

11.2.7 Dry the sides and the bottom of the sieve with a paper towel and dry for 1 h in a gravity oven preheated to 100°C.

11.2.8 Place the sieve in a desiccator and cool to room temperature. Weigh the sieve and glass beads to 0.1 mg and calculate the percent beads *G* as follows:

$$G = (B/W) \times 100$$

where:

B = weight of the glass beads, g, and

W = weight of thermoplastic specimen, g.

12. Percent Titanium Dioxide

12.1 Procedure:

12.1.1 Weigh the crucible and ash (see Section 9) to 0.1 mg and calculate the percent of ash which is also equal to the percent filler (pigments and beads).

12.1.2 After weighing the above ashed materials, carefully transfer the ash to an agate or similar impervious-type mortar. Grind the ash to a consistent fine powder except for the glass beads. The pulverized ash must be stirred each time specimens are taken to weigh the prescribed amount for the analysis.

12.1.3 Weigh 1 ± 0.1 g of ash for the titanium analysis.

12.1.4 Proceed with the titanium analysis as described in Test Methods D 1394. The Jones Reductor or aluminum reduction method may be used.

12.1.5 At the end of the digestions described in Test Methods D 1394, filter the undigested materials through a 3-in. 45- μ m (No. 325) sieve with hot water. This will prevent clogging of the Jones Reductor. This step is not necessary if the aluminum reduction method is used.

12.1.6 Calculate the percent of titanium dioxide (TiO_2) from the total ash weighed. The result gives the percent of TiO_2 in the total thermoplastic specimen.

12.1.7 Calculate the percent ash A as follows:

$$A = (S/W) \times 100$$

where:

S = weight of ash, g, and

W = weight of thermoplastic specimen used, g.

12.1.8 Calculate the percent of total TiO_2 in the T based on percent ash:

$$T = 0.08 AMN/CS_a$$

where:

A = ash (pigment + filler + beads), %,

S_a = weight of ash used, g,

M = amount of 0.1 N potassium permanganate (KMnO_4) solution used, mL, (see the paragraph on titration with KMnO_4 solution of the Procedure section of the Jones Reductor Method of Test Methods D 1394),

N = normality of KMnO_4 used,

C = correction factor for TiO_2 pigment used (usually 1.0). This represents the purity of the pigment if specified, and

0.08 = weight of TiO_2 per 1 mL of 1 N KMnO_4 , g.

13. Percent Lead Chromate

13.1 Procedure:

13.1.1 Weigh the crucible and ash (see Section 9) to 0.1 mg and calculate the percent of ash.

13.1.2 After weighing the above ashed materials, carefully transfer the ash to an agate or similar impervious type mortar and grind the ash to a consistent fine powder except for the glass beads. The pulverized ash must be stirred when specimens are taken to weigh the prescribed amount for the analysis.

13.1.3 Weigh 1 ± 0.1 g of the ash for the lead chromate (PbCrO_4) analysis.

13.1.4 Analyze the dry ash as follows:

13.1.4.1 Transfer the ashed specimen to a 500-mL Erlenmeyer flask. Add 6 mL of the (KOH) solution (see 7.5) and 10 mL of distilled water. Heat until dissolved. Do not allow to dry. To the hot solution add 50 g of KCl. Dilute with water to 200 mL and swirl until dissolved. Add 16 mL of HCl slowly. Add 10 g of KI and titrate with the standard sodium thiosulfate solution (see 7.7) using the starch solution (see 7.8) as the indicator. Titrate to a green endpoint.

NOTE 3—A 10-mL buret may be used since the titrant required is small for most thermoplastic analysis.

13.1.5 Calculate the percent ash A as follows:

$$A = (S/W) \times 100$$

where:

S = weight of gas, g, and

W = weight of the thermoplastic specimen used, g.

13.1.6 Calculate the percent of total PbCrO_4 in the sample (binder + filler) L based on percent ash as follows:

$$L = 0.1077 AMN/CS_a$$

where:

A = ash (pigment + filler + beads), %,

C = correction factor for PbCrO_4 pigment used (for example, 90 to 100 %, normally 1.0). This represents the purity of the pigment if specified,

M = amount of 0.1 N sodium thiosulfate solution used, mL,

N = normality of sodium thiosulfate used, and

S_a = weight of ash used, g.

14. Precision and Bias

14.1 No general statement of precision can be made because of lack of sufficient data at this time.

14.2 No statement of bias can be prepared for this test method since there is no absolute method for use as a basis for comparison.

15. Index Terms

15.1 This test method is indexed under the following terms: glass spheres (in traffic paint); lead chromate; titanium dioxide; thermoplastic traffic marking material.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Practical Washability of Organic Coatings¹

This standard is issued under the fixed designation D 4828; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the relative ease of removal of common soil and stains from interior coatings by manual or mechanical washing with a sponge and a liquid or powder cleanser.

1.2 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 1193 Specification for Reagent Water²

D 3450 Test Method for Washability Properties of Interior Architectural Coatings³

D 3924 Specification for Standard Environment for Conditioning and Testing Paint, Varnish, Lacquer, and Related Materials³

3. Summary of Test Method

3.1 The test material is applied to a plastic panel and allowed to dry for 7 days or as mutually agreed. Soilants or stains, or both, are applied to the film. The film is washed for up to 100 cycles using a sponge and a liquid or powder cleanser. After rinsing and drying, the panel is evaluated for the degree of soil or stain removal, difference in erosion, and any change in gloss/sheen or color between the washed and unwashed area.

4. Significance and Use

4.1 Interior architectural paints are subjected in use to soiling by dirt or other stains. This test method provides a way to assess relative ease of soil or stain removal from a paint film using materials common to households. This test method includes a way to evaluate the film for washability properties and changes in appearance. Thus, a formulator may evaluate the effects of composition on the washability properties of a paint. Users may also compare the ease of soil removal from difference paints that are tested, preferably at the same time.

5. Apparatus

5.1 *Sponge and Holder.*⁴

5.2 *Soil and Stain Applicator* (see Fig. 1).

5.3 *Weight*, 100 g.

5.4 *Balance*, weighing accurately to 0.1 g.

5.5 *Doctor or Bird Film Applicator*, having a 7-mil (0.18-mm) clearance by 6-in. (150-mm) film width.

5.6 *Glass Plate*, 17½ by 6½ by ¼ in. (455 by 165 by 6.3 mm).

5.7 *Washability Machine.*⁵

5.8 *Black Plastic Panels.*⁶

5.9 *Masking Tape.*

5.10 *Straightedge*, approximately 17 in. (430 mm) in length.

5.11 *Cotton Tipped Swabs.*

5.12 *Medicine Droppers.*

5.13 *Suction Plate*, for drawdowns.

6. Reagents and Materials

6.1 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water as defined by Type IV of Specification D 1193.

6.2 *Soil and Staining Medium*—Examples found acceptable for use with this test method include, but are not limited to pencil, crayon, mercurochrome, ball-point pen, waterborne felt-tip markers, lipstick and mineral-oil-borne soilant as outlined in Test Method D 3450.

6.3 *Cleaning Media*—Examples found acceptable for use with this test method include, but are not limited to, commercial liquid cleansers, laboratory standardized liquid cleaners as outlined in Test Method D 3450, and powder cleansers. Powder cleansers containing chlorine may effect the color of the washed portion of the test panel.

7. Preparation of Apparatus

7.1 *Washability Machine*—Level the apparatus before use and operate at 37 ± 1 cpm. (A cycle consists of a complete forward and reverse stroke.)

7.2 *Sponge and Holder*—Add sufficient weight to the

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.42 on Architectural Finishes.

Current edition approved Oct. 15, 1991. Published December 1991. Originally published as D 4828 - 88. Last previous edition D 4828 - 88.

² *Annual Book of ASTM Standards*, Vol 06.03 and 11.01.

³ *Annual Book of ASTM Standards*, Vol 06.01.

⁴ A sponge, 3 by 3¼ by 1¼ in. (75 by 95 by 45 mm), Part No. AG-8116, and a metal holder, Part No. AG-8115, available from BYK-Gardner, Inc., 2435 Linden Lane, Silver Spring, MD 20910 or a sponge, Part No. WA 2222, and metal holder, Part No. WA 2220, available from the Paul N. Gardner Co., 316 N. E. First Street, Pompano Beach, Florida 33060-6699 have been found acceptable for this purpose. An equivalent may be used.

⁵ Washability machine, Model AG-8100, available from BYK-Gardner, Inc. or Model WA 2037D, available from the Paul N. Gardner Co., have been found suitable for this purpose. Other straight-line wash testers may be adapted to meet the requirements of this test method.

⁶ Leneta P-121-10N dull black plastic panels, 17 by 6½ in. by 10 mils (430 by 165 by 0.25 mm), available from the Leneta Co., P.O. Box 86, Ho-Ho-Kus, N.J. 07423, are suitable for this purpose. An equivalent may be used.

prior to 100 cycles, stop and record the number of cycles before proceeding to 8.8.

8.7 Mechanical Method:

8.7.1 Place the sponge and holder at one end of the panel so that its long axis is parallel to the length of the panel (see Fig. 2). Attach to the cable of the washability machine. Allow the sponge to travel a maximum of 100 cycles. If all the soils or stains are removed prior to 100 cycles, stop and record the number of cycles before proceeding to 8.8.

8.8 Remove the test panel and evaluate the condition of each soil or stain in the path of the sponge and rate as follows:

- 0—No change from original intensity (depth) of soil or stain,
- 3—Slight change from original, but readily visible,
- 5—Moderate change from original, slightly visible,
- 7—Large change from original, barely visible, and
- 10—All soil and stain removed.

If a difference exists between a pair of lines, report the lower rating of the pair. When a soil or stain is removed prior to 100 cycles, assign a rating of 10 and note the number of cycles in which each soilant or stain was removed.

8.9 Rinse the panel with running tap water and remove any clinging particles of cleaning medium by gently moving the palm of the hand over the path the sponge followed during the washing cycle. Blot the panel and allow to dry. Rate the washed area relative to the unwashed areas for gloss or color change and erosion as given below:

Gloss Change	Color Change	Erosion
N—None	N—None	N—None
I—Increase	SD—Slightly darker	S—Slight
II—Large increase	CD—Considerably darker	M—Moderate
D—Decrease	SL—Slightly lighter	
DD—Large decrease	CL—Considerably lighter	

9. Report

9.1 Report the following information:

- 9.1.1 Type of soilant(s), stain(s), washing medium(s) and washing method used and the results obtained in 8.8 and 8.9,
- 9.1.2 Any soils or stains that were removed in less than 100 cycles, and
- 9.1.3 Any deviation from the recommended procedure.

10. Precision and Bias

10.1 *Precision*—On the basis of interlaboratory tests in which operators in seven laboratories using the manual washing method, tested four coatings including solvent- and waterborne systems covering a range of pigment volume concentrations, the following criteria should be used for judging the acceptability of the results at the 95 % confidence level:

10.1.1 *Repeatability*—Two results obtained by the same operator should be considered suspect if they differ by more than 20 % of their mean rating with the powder cleaner and 40 % with the liquid cleanser.

10.1.2 *Reproducibility*—Results obtained from the four round robins indicate that the manual method is not suitable for between laboratory evaluations.

10.1.3 A precision and bias statement for the mechanical method is being developed.

10.1.4 *Bias*—Bias cannot be determined for this test method.

11. Keywords

11.1 cleansability; soil/dirt resistance; stain resistance; washability; wet abrasion resistance

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Standard Test Method for Detection of Lead in Paint by Direct Aspiration Atomic Absorption Spectroscopy¹

This standard is issued under the fixed designation D 4834; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

Scope

1.1 This test method is intended as a screening test to determine if the solids in a paint contain more than 0.06 % lead. The test described can differentiate between 0.05 and 0.06 %. Paints giving a result greater than 0.05 % should be analyzed quantitatively for lead using Test Method D 3335. This test method provides a more definitive and reliable screening test than Test Method D 3618.

1.2 There is no reason to believe that higher levels of lead could not be determined by this test method provided that appropriate dilutions and adjustments in specimen size and reagent quantities are made.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

D 1193 Specification for Reagent Water²
D 2832 Guide for Determining Volatile and Nonvolatile Content of Paint and Related Coatings³
D 3335 Test Method for Low Concentrations of Lead, Cadmium, and Cobalt in Paint by Atomic Absorption Spectroscopy³
D 3618 Test Method for Detection of Lead in Paint and Dried Paint Films³

Summary of Test Method

3.1 A weighed quantity of the paint sample is diluted (solvent-reducible paints in methyl isobutyl ketone and water-reducible paints in water) and then aspirated into the burner of an atomic absorption spectrometer. Lead content of the paint is determined from a calibration plot of absorbance versus concentration, prepared from standard coatings containing known amounts of lead.

Significance and Use

4.1 Current U.S. regulations restrict the amount of lead that may be present in consumer paint products to less than 0.06 % based on the total solids. This test method provides a

rapid means for screening paints to determine compliance with those regulations. The test method may be adjusted to meet regulations with a different limit on lead content.

5. Apparatus

5.1 *Atomic Absorption Spectrophotometer*, consisting of an atomizer and either a single- or a three-slot burner, gas pressure regulating and metering devices for air and acetylene, lead source lamp with a regulated constant-current supply, a monochromator and associated optics, a photosensitive detector connected to an electronic amplifier, and a readout device.

5.2 *Volumetric Flasks*, 50 mL.

6. Reagent and Materials

6.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests unless otherwise specified. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁴ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

6.2 *Purity of Water*—Unless otherwise indicated, reference to water shall be understood to mean reagent water conforming to Type II of Specification D 1193.

6.3 *Methyl Isobutyl Ketone (MIBK)*, technical grade.

6.4 *Standard Paints*—Prepare at least 3 standard paints by adding accurately weighed quantities of an analytically assayed compatible lead compound to a solvent-reducible or water-reducible paint that has been analyzed by Test Method D 3335 and shown to contain less than 10 ppm of lead. Determine the nonvolatile content of the base paint and choose quantities of the lead compound so that the lead concentrations of the standard paints will be approximately 300, 600, and 900 $\mu\text{g/g}$ based on the nonvolatile content.

7. Calibration and Standardization

7.1 Prepare at least three solvent-reducible or water-reducible standard paint specimens (see 6.4) that bracket the expected lead concentration in the sample to be tested. Following the procedure in 8.2 dilute the standards for aspiration.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Materials.

⁴ Reagent Chemicals, American Chemical Society Specifications, Am. Chemical Soc., Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY, and the "United States Pharmacopeia."

7.2 Operational instructions for atomic absorption spectrophotometers vary with different models. Consult the manufacturer's literature for establishing optimum conditions for the specific instrument used.

7.3 Turn the instrument on and set the wavelength to the 283.3-nm lead line. Apply the current recommended by the manufacturer to the lead source lamp. Allow the instrument to warm up for about 15 min and set the slit width. Adjust the air and acetylene pressure or flow rates and ignite the burner in accordance with the manufacturer's instructions. A background corrector should be used.

7.4 Aspirate each of the diluted standard paints and record the corresponding absorbance readings. Aspirate MIBK or water, as appropriate, between standards.

NOTE 1: Caution—It is important that MIBK or water be aspirated immediately after each diluted standard paint to minimize fouling of the aspirator/nebulizer system which could change the aspiration rate and absorbance reading. Continued response for lead while aspirating MIBK or water may indicate contamination of the burner head with pigment and require cleaning of the burner head.

NOTE 2—To be certain that the diluted paint specimen remains homogeneous during aspiration, the flask containing the specimen may be stirred continuously with a small magnetic stirring bar.

7.5 Construct a calibration curve on linear graph paper by plotting the absorbance readings versus micrograms of lead present in each diluted standard paint as follows:

$$A = (B \times D \times E)$$

where:

A = lead present, μg ,

B = lead in standard paint based on nonvolatile content (see 6.4), $\mu\text{g/g}$,

D = weight of standard paint, g, and

E = nonvolatile portion of standard paint, %.

8. Procedure

8.1 Mix the paint to be tested until homogeneous, preferably on a mechanical shaker. Determine the nonvolatile content in accordance with the appropriate test method selected by consulting Guide D 2832.

8.2 Prepare at least two replicate specimens by weighing by difference from a weighing bottle or disposable syringe to 0.1 mg, $0.5 \pm 0.02\text{-g}$ quantities of the paint being tested, into 10 mL volumetric flasks. Dilute to the mark with MIBK, if the paint is solvent reducible, or with water, if it is water reducible. Mix thoroughly.

NOTE 3—Adjustment of specimen size and dilution volume may be made as required for linear calibration and reasonable response for the instrument used as well as for differing lead content limits.

8.3 Aspirate the diluted paint specimens *immediately* (Caution—See Note 1) after mixing and measure the absorbance (see Note 2). Aspirate MIBK or water, as appropriate between specimen aspirations. Determine the micrograms of lead present from the calibration curve.

NOTE 4—For maximum accuracy, calibration and standardization (See Section 7) should be completed just prior to aspirating the diluted paint specimen.

9. Calculation

9.1 Calculate the mean concentration of lead in the nonvolatile portion of the paint specimen as follows:

$$L = (C \times 100)/(NV \times S)$$

where:

L = lead in nonvolatile portion of the paint specimen, ppm ($\mu\text{g/g}$),

C = lead in the aspirated specimen solution (8.3), μg ,
100 = factor derived from multiplying the numerator by 100 (to convert NV used to a whole number) and 10⁶ (to obtain ppm) and multiplying the denominator by 10⁶ (to convert grams of specimen to micrograms),

NV = nonvolatile portion of paint specimen, %, and

S = weight of specimen, g.

10. Report

10.1 Report the lead concentration expressed on the nonvolatile content of the paint sample.

11. Precision and Bias⁵

11.1 *Precision*—The precision estimates are based on an interlaboratory study in which five different laboratories analyzed in duplicate on 2 days, three samples of solvent reducible paints and three samples of water-reducible paints containing from 464 to 742 ppm lead. The within-laboratory coefficient of variation was found to be 3.34 % relative at 24 df and the between-laboratories coefficient of variation was 6.72 % relative at 18 df. Based on these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

11.1.1 *Repeatability*—Two results, each the mean of duplicate determinations, obtained by the same operator on different days should be considered suspect if they differ by more than 9.76 % relative.

11.1.2 *Reproducibility*—Two results, each the mean of duplicate determinations, obtained by operators in different laboratories should be considered suspect if they differ by more than 19.96 % relative.

11.2 *Bias*—Bias is under investigation.

12. Index Terms

12.1 This test method is indexed under the following terms: spectroscopy—atomic adsorption; lead content—paint; lead screening test.

Standard Test Method for Determining the Relative Tinting Strength of Chromatic Paints¹

This standard is issued under the fixed designation D 4838; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

1.1 This test method describes the determination of the absorption tinting strength of a chromatic test paint relative to that of a standard or reference paint of the same chemical type. The procedures are based on dilution of the paints with a standard mixing white paint, followed by instrumental measurement and calculation. Provision is made for correcting the results for small differences in hue or chroma, or both, between the test and reference chromatic paints.

1.2 This test method is intended for the comparison of paints containing the same type of vehicle (acrylic, alkyd, or oil) and single-pigment colorants of the same Colour Index² name and number. The amounts of the pigment and of the other components of the paint need not be known.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2.1 ASTM Standards:

- D 1640 Test Methods for Drying, Curing, or Film Formation of Organic Coatings at Room Temperature³
- D 4303 Test Methods for Lightfastness of Pigments Used in Artists' Paints³
- E 284 Definitions of Terms Relating to Appearance of Materials⁴
- E 308 Method for Computing the Colors of Objects by Using the CIE System⁴
- E 1164 Practice for Obtaining Spectrophotometric Data for Object-Color Evaluation⁴

Terminology

3.1 Definitions:

3.1.1 *tinting strength*—measure of the effectiveness with which a unit quantity of a colorant alters the color of a material. For scattering and absorbing colorants (pigments),

both absorption and scattering tinting strength must be specified.

3.1.2 *tinting strength, absorption*—relative change in the absorption properties of a standard white material when a specified amount of an absorbing pigment, black or chromatic, is added to it.

DISCUSSION—This is the common definition of tinting strength; however, this definition of the term can be misleading. For example, the tinting strength of a yellow colorant depends on its scattering as well as its absorption. Its tinting strength as determined from a mixture with white provides no information about its behavior when mixed with low-scattering colorants, such as a black.

3.1.3 *tinting strength, scattering*—relative change in the scattering properties of a standard black material (with no white pigment present) when a specified amount of a white or chromatic scattering pigment is added to it.

3.1.4 For other definitions, see Definitions E 284.

3.2 Descriptions of Terms Specific to This Standard:

3.2.1 *drawdown*—a layer of paint deposited on a substrate by use of a drawdown bar to evaluate the characteristics of the paint.

3.2.2 *drawdown bar*—a bar designed to deposit a specified thickness of wet paint film uniformly on a specified test panel or other substrate.

4. Summary of Test Method

4.1 Chromatic paints are diluted with white paint to obtain mixtures that will produce a drawdown having 35 to 45 % reflectance factor at the wavelength of maximum absorption.

4.2 Drawdowns of these mixture paints are produced at complete hiding.

4.3 The drawdowns are measured to obtain tristimulus filter readings R , G , B either directly or by computation from CIE tristimulus values X , Y , Z .

4.4 One of the samples is designated the standard, and the percents of tinting strength, % TS, of the others are calculated relative to that of the standard. Provision is made for correcting this tinting strength for small differences in hue, chroma, or both, between the standard and the test specimen, and for obtaining an average tinting strength and a range.

5. Significance and Use

5.1 Tinting strength may be one factor in judging the relative economic value of paints, since pigment concentration contributes to strength in a major way; other factors are formulation and color development in grinding. The user may also select products for other properties, such as

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.57 on Artist Paints and Related Materials.

Current edition approved June 24, 1988. Published November 1988.

³ *Annual Book of ASTM Standards*, Vol 06.01.

⁴ *Annual Book of ASTM Standards*, Vol 14.02.

transparency, that are accompanied by different tinting strengths. The results of this test method may be used for production control or quality comparisons.

5.2 The product with the greatest or the least tinting strength may not be the most desirable for a given artistic use. For example, low tinting strength may lead to the need to use an excessively high pigment concentration to obtain a desired color effect, and this may lead to defects in the dry paint film.

5.3 This test method applies only to single-pigment paints. The tinting strength of paints that contain two or more chromatic pigments with different optical properties cannot be evaluated by this test method.

5.4 The term "similar chemical type" used in 1.1 does not limit the ingredients in the paints to identity, but refers to compatibility in the case of vehicles and to similarity in the case of pigment types.

5.5 While the instrumental evaluation of tinting strength is described, visual comparisons can also be used, with lower precision, and should be made to provide confirmation of the instrumental and computational results.

5.6 If the sample and standard are widely different in appearance when prepared at the same ratio of chromatic to white paint, another sample should be prepared to bring the two closer in appearance, to obtain the most accurate results.

5.7 The quantities of chromatic and white paints mixed must be accurately known, on either a weight or a volume basis, but the concentration of pigment in the chromatic paint need not be known.

5.8 When the paints being compared have the same vehicle and pigment (same Colour Index name and number) the values of uncorrected tinting strength from 9.1 and corrected tinting strength from 9.2 should be nearly the same. If they are not, an average of the two tinting strengths is recommended as the best estimate of the true value, and a range provides a measure of the magnitude of the uncertainty, which is due to differences in hue or chroma, or both, between the paints.

5.9 Strictly speaking, the Kubelka-Munk-type analysis of this test method should not be applied to the tristimulus filter readings used, but only to spectral data. For the purposes of the relative comparisons of this test method, however, the errors introduced by the calculations used cancel to an adequate degree.

6. Apparatus and Materials

6.1 *Laboratory Balance*, top-loading, having a sensitivity of 0.01 g.

6.2 *Drawdown bars*, capable of producing smooth paint films with wet-film thicknesses between 0.003 and 0.010 in. (0.075 and 0.25 mm).⁵

6.3 *Opacity charts*, sealed-paper type with black and white areas.⁶

6.4 *Color-Measuring Instrument*, either a spectrophotometer providing 1931 CIE tristimulus values X , Y , Z for CIE

standard illuminant C , or a tristimulus colorimeter providing either such tristimulus values or colorimeter readings R , G , B .

6.5 *Mixing White Paint*, prepared as described in the Specimen Preparation, Mixing Whites for Dilution of Colors section of Test Method D 4303. Alternatively, a commercial titanium-dioxide white artists' paint may be used. The mixing white paint must be made with the same vehicle type (acrylic, alkyd, or oil) as the paints to be tested.

7. Specimen Preparation

7.1 Obtain representative samples of the chromatic paints to be tested. For tube paints, expel the entire contents of the tube and mix thoroughly before sampling.

7.2 Determine the approximate amount of chromatic paint to be added to 20 g of mixing white paint to obtain a drawdown with 35 to 45 % reflectance factor at the wavelength of maximum absorption. If the amount of chromatic paint is not known in advance, consult the tables in Appendix X1. For pigments other than those listed, use as the general guideline the addition of 5 g of chromatic paint containing an inorganic pigment or 1 g of chromatic paint containing an organic pigment to the 20 g of mixing white paint.

NOTE 1—Appendix X1 of Test Method D 4303 describes a method for computing the necessary adjustments in quantities required. Additional trials are needed to obtain the desired level of reflectance factor.

7.3 Weigh out the chromatic and mixing white paints to the nearest 0.01 g, and mix thoroughly.

7.4 Prepare drawdowns by placing the paint mixture at one end of an opacity chart and pulling the drawdown bar smoothly through the paint and across the chart. Paste paints should be spread with a spatula or palette knife over the entire chart area to be covered before pulling the bar down the chart.

7.5 Allow the drawdowns to reach the dry-to-touch time as described in the Procedure section of Test Method D 1640. Acrylic paints should dry in air overnight. Alkyd paints may require 5 days to dry. Oil paints may require 20 months to dry.

7.6 Determine whether each drawdown is at complete hiding by measuring the portions of it over the black and over the white areas of the chart to determine tristimulus value Y or colorimeter reading G . If the quotient Y_B/Y_W or G_B/G_W , where the subscripts refer to measurements over black and white, respectively, is greater than 0.98, the drawdown can be considered at complete hiding. If the drawdown is not at complete hiding, prepare a thicker drawdown or a drawdown made with multiple coats of paint, one over another.

NOTE 2—At the required dilution with white, a drawdown bar with an aperture of 0.006 in. (0.15 mm) will usually make a drawdown at complete hiding. In the cases of some acrylic paints and a few oil paints it may be necessary to increase the aperture to 0.010 in. (0.25 mm) to obtain complete hiding. If this leads to a slow-drying film or a film that is wrinkled when dry, multiple coats can be applied by depositing a second 0.006 in. (0.15 mm) coat, drawing down at a right angle to the first coat. After this coat dries, a third coat can be applied if necessary by using a shorter bar that rides over the previous coats.

⁵ Suitable drawdown bars can be obtained from the Paul N. Gardner Company, Inc., P.O. Box 10688, Pompano Beach, FL 33061-6688, or BYK-Gardner, Inc., Gardner Laboratory, 2435 Linden Lane, Silver Spring, MD 20910.

⁶ Leneta 2A charts, available from the Leneta Co., Box 576, Ho-Ho-Kus, NJ 07423, and the Morest Co., 211 Center St., New York, NY 10013, have been found satisfactory for this purpose.

Procedure

8.1 Obtain values of R , G , B for each sample by either of the two following procedures.

8.1.1 Measure the drawdown with a spectrophotometer or tristimulus colorimeter to determine 1931 CIE tristimulus values X , Y , Z for CIE standard illuminant C . Follow Practice E 1164 and Method E 308. If hemispherical (integrating-sphere) geometry is used, measure with the specular component excluded.

8.1.2 If a colorimeter that is direct reading in R , G , B is used, measure these quantities.

8.2 If X , Y , Z are measured, calculate R , G , B by use of the following equations:

$$R = (X/0.98 - 0.2Z/1.18)/0.8 \quad (1)$$

$$G = Y \quad (2)$$

$$B = Z/1.18 \quad (3)$$

NOTE 3—The use of the 1931 CIE system (and standard observer) and standard illuminant C is specified because all known tristimulus colorimeters that are direct reading in R , G , B measure for these conditions. If values of X , Y , Z are obtained by spectrophotometry, the 1964 CIE system and other CIE standard illuminants may be used. Equations 1 to 3 are specific to the conditions, and must be replaced by the appropriate equations if other conditions are specified.⁷ The article referenced also discusses correcting the measured values for surface reflections.

Calculation

9.1 Calculate uncorrected relative tinting strength, % TS_{UC} as follows:

9.1.1 Using decimal-fraction values of R , G , B , calculate Kubelka-Munk-type ratios of absorption coefficient, K , to scattering coefficient, S :

$$(K/S)_R = (1 - R)^2/2R \quad (4)$$

$$(K/S)_G = (1 - G)^2/2G \quad (5)$$

$$(K/S)_B = (1 - B)^2/2B \quad (6)$$

9.1.2 Calculate the pigment concentration term C_P :

$$C_P = Q_c/(Q_c + Q_w) \quad (7)$$

where:

Q_c = quantity of chromatic paint, g,

Q_w = quantity of white paint, g.

NOTE 4—If it is desirable to use volume rather than weight as the basis for comparison of tinting strengths, determine the densities of the paints and compute the volumes of the weighed samples. Calculate C_P by use of Eq 7 using volumes instead of weights.

9.1.3 Calculate normalized values of (K/S) , denoted N , as follows:

$$N_R = (K/S)_R/C_P \quad (8)$$

$$N_G = (K/S)_G/C_P \quad (9)$$

$$N_B = (K/S)_B/C_P \quad (10)$$

9.1.4 Select one of the specimens to be denoted the standard and assigned the value of 100 % tinting strength. The tinting strength of the remaining specimens will be

determined relative to that of the standard.

9.1.5 Select the value of N to be used in the calculation of % TS_{UC} by one of the following three methods:

9.1.5.1 Select N based on the visually determined color of the specimen: For blue and green specimens, select N_R ; for purple and red specimens, select N_G ; and for yellow and orange specimens, select N_B . Relabel the selected value N_{1SPEC} and N_{STD} for the specimens and the standard, respectively. Relabel the remaining two values of N as N_{2SPEC} and N_{3SPEC} for the specimens and N_{2STD} and N_{3STD} for the standard.

9.1.5.2 If the specimen color cannot be classified accurately in 9.1.5.1, select the lowest value of N as N_1 . The same selection must be made for the standard and all specimens to be compared. Relabel the values of N as in 9.1.5.1.

9.1.5.3 If the values of N_R and N_B for the specimen are both low and approximately equal, follow the procedure in Annex A1 to select N and calculate the tinting strength.

9.1.6 Calculate % TS_{UC} as follows:

$$\% TS_{UC} = 100 (N_{1SPEC}/N_{1STD}) \quad (11)$$

9.2 Calculate tinting strength corrected for differences in hue and chroma, % TS_C , by use of the following equations:

$$d_{SPEC} = N_{2SPEC} + N_{3SPEC} \quad (12)$$

$$d_{STD} = N_{2STD} + N_{3STD} \quad (13)$$

$$D = (d_{SPEC} - d_{STD})/2 \quad (14)$$

$$\% TS_C = 100 (N_{1SPEC} - D)/N_{1STD} \quad (15)$$

9.3 Calculate average tinting strength, % TS_{AV} , and range E as follows:

$$\% TS_{AV} = (\% TS_{UC} + \% TS_C)/2 \quad (16)$$

$$E = \pm (\% TS_{UC} - \% TS_C)/2 \quad (17)$$

10. Report

10.1 Report the following information:

10.1.1 Complete identification of the specimens, including brand and color name, date of manufacture, and lot number if available.

10.1.2 Name of color-measuring instrument used, method of standardization, and other information required in the Report section of Practice E 1164 and Methods E 308.

10.1.3 Date of test.

10.1.4 Test results for % TS_{UC} , % TS_C , or % TS_{AV} , and range.

11. Precision and Bias⁸

11.1 Based on interlaboratory intercomparisons, the results of this test method agree to within ± 6 % on an absolute basis.

12. Index Terms

12.1 This test method is indexed under the following terms: artists' paints; chromate coatings; tinting strength.

⁷ Johnston-Feller, R. M., and Bailie, C. W., "Determination of the Tinting Strength of Chromatic Pigments," *Journal of Coatings Technology*, Vol 54, No. 892, 1982, pp. 43-56.

⁸ Supporting data are available from ASTM Headquarters. Request RR:D01-1057.

ANNEX

(Mandatory Information)

A1. Procedure for Pigments with Two Separated Absorption Maxima

A1. The tinting strength of pigments, such as chromium oxide green, for which both N_R and N_B are low and approximately equal, must be calculated by the following equations:

$$\text{NUM} = (N_{R,\text{SPEC}} + N_{B,\text{SPEC}})/2 \quad (\text{A1.1})$$

$$\text{DENOM} = (N_{R,\text{STD}} + N_{B,\text{STD}})/2 \quad (\text{A1.2})$$

$$D = (N_{G,\text{SPEC}} + N_{G,\text{STD}})/2 \quad (\text{A1.3})$$

$$\% \text{TS}_{\text{UC}} = 100 \text{ NUM/DENOM} \quad (\text{A1.4})$$

$$\% \text{TS}_{\text{C}} = (\text{NUM} - D)/\text{DENOM} \quad (\text{A1.5})$$

Standard Test Method for Total Carbon and Organic Carbon in Water by Ultraviolet, or Persulfate Oxidation, or Both, and Infrared Detection¹

This standard is issued under the fixed designation D 4839; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

1.1 This test method covers the determination of total carbon (TC), inorganic carbon (IC), and total organic carbon (TOC) in water, wastewater, and seawater in the range from 1 mg/L to 4000 mg/L of carbon.

1.2 This test method was used successfully with reagent water spiked with sodium carbonate, acetic acid, and pyridine. It is the user's responsibility to ensure the validity of this test method for waters of untested matrices.

1.3 This test method is applicable only to carbonaceous matter in the sample that can be introduced into the reaction zone. The syringe needle or injector opening size generally limit the maximum size of particles that can be so introduced.

1.4 In addition to laboratory analyses, this test method may be applied to stream monitoring.

1.5 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3.1 Definitions:

3.1.1 For definitions of terms used in this test method, refer to Specification D 1129.

3.2 Description of Terms Specific to This Standard:

3.2.1 *inorganic carbon (IC)*—carbon in the form of carbon dioxide, carbonate ion, or bicarbonate ion.

3.2.2 *total organic carbon (TOC)*—carbon in the form of organic compounds.

3.2.3 *total carbon (TC)*—the sum of IC and OC.

3.2.4 *refractory material*—that which cannot be oxidized completely under the test method conditions.

4. Summary of Test Method

4.1 *Fundamentals*—Carbon can occur in water as an inorganic and organic compound. This test method can be used to make independent measurements of IC, TOC, and TC, and can also determine IC by the difference of TC and TOC, and TOC as the difference of TC and IC.

4.2 The essentials of this test method are: (a) removal of IC, if desired, by acidification of the sample and sparging by carbon-free gas; (b) conversion of remaining carbon to CO₂ by action of persulfate, aided either by elevated temperature or ultraviolet (UV) radiation; (c) detection of CO₂ that is swept out of the reactor by a gas stream; and (d) conversion of detector signal to a display of carbon concentration in mg/L. A diagram of suitable apparatus is given in Fig. 1.

5. Significance and Use

5.1 This test method is used for determination of the carbon content of water from a variety of natural, domestic, and industrial sources. In its most common form, this test method is used to measure organic carbon as a means of monitoring organic pollutants in industrial wastewater. These measurements are also used in monitoring waste treatment processes.

5.2 The relationship of TOC to other water quality parameters such as chemical oxygen demand (COD) and total oxygen demand (TOD) is described in the literature.³

6. Interferences and Limitations

6.1 The oxidation of dissolved carbon to CO₂ is brought about at relatively low temperatures by the chemical action of reactive species produced by hot or UV-irradiated persulfate ions. Even if oxygen is used as the sparging gas, it makes a much lower contribution to oxidation than in high-temperature (combustive) systems. Not all suspended or refractory material may be oxidized under these conditions; analysts should take steps to determine what recovery is being obtained. This may be done by several methods: (a) by monitoring reaction progress to verify that oxidation has been completed; (b) by rerunning the sample under more vigorous reaction conditions; (c) by analyzing the sample by

¹ This test method is under the jurisdiction of ASTM Committee D-19 on Water and is the direct responsibility of Subcommittee D19.06 on Methods for Analysis for Organic Substances in Water.

Current edition approved June 24, 1988. Published September 1988.

³ Handbook for Monitoring Industrial Wastewater, Section 5.3, U.S. Environmental Protection Agency, August 1973, pp. 5-12.

FIG. 1 Diagram of Apparatus

an alternative method known to result in full recovery; or (d) by spiking samples with known refractories and determining recovery.

6.2 Chloride ion tends to interfere with oxidative reaction mechanisms in this test method, prolonging oxidation times and sometimes preventing full recovery. Follow manufacturer's instructions for dealing with this problem. See Appendix XI for supporting data.

6.3 Homogenizing or sparging of a sample, or both, may cause loss of purgeable organic compounds, thus yielding a value lower than the true TOC level. (For this reason, such measurements are sometimes known as nonpurgeable organic carbon (NPOC)). The extent and significance of such losses must be evaluated on an individual basis. This may be done by comparing the TOC by difference (TC-IC) with the direct TOC figure, that is, that obtained from a sparged sample. The difference, if any, between these TOC figures represents purgeable organic carbon (POC) lost during sparging. Alternatively, direct measurement of POC can be made during sparging, using optional capabilities of the analyzer.

6.4 Note that error will be introduced when the method of difference is used to derive a relatively small level from two large levels. For example, a ground water high in IC and low in TOC will give a poorer TOC value as (TC-IC) than by direct measurement.

7. Apparatus

7.1 *Homogenizing Apparatus*—A household blender is generally satisfactory for homogenizing immiscible phases in water.

7.2 *Sampling Devices*—Microlitre-to-millilitre syringes are typically required for this test method. Alternatives include manually operated or automatically operated sampling valves. Sampling devices with inside diameters as small as 0.15 mm may be used with samples containing little or no particulate matter. Larger inside dimensions such as 0.4 mm will be required for samples with particulate matter.

NOTE 1—See 6.1 concerning oxidation of particulate matter.

7.3 *Apparatus for Carbon Determination*—This instrument consists of reagent and sample introduction mechanism, a gas-sparged reaction vessel, a gas demister or dryer, or both, an optional CO₂ trap, a CO₂-specific infrared detector, a control system, and a display. Fig. 1 shows a diagram of such an arrangement.

7.3.1 Sparging requires an inert vessel with a capacity of at least double the sample size with provision for sparging with 50 to 100 mL/min of carbon free gas. This procedure will remove essentially all IC in 2 to 10 min, depending on design.

7.3.2 *Oxidation*—The reaction assembly contains reagent and sample introduction devices, and a reactor vessel with sparging flow of carbon-free gas. The vessel may be heated by an external source, and may contain a UV lamp. The reaction vessel and sparging vessel (see 6.3.1) may be combined.

7.3.3 *Gas Conditioning*—The gas passing from the reactor is dried, and the CO₂ produced is either trapped and later released to the detector, or routed directly to the detector through a chlorine-removing scrubber.

7.3.4 *Detector*—The CO₂ in the gas stream is detected by a CO₂-specific nondispersive infrared (NDIR) detector.

7.3.5 *Presentation of Results*—The NDIR detector output is related to stored calibration data and then displayed as milligrams of carbon per litre.

8. Reagents and Materials

8.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society,⁴ where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficient purity to permit its use without lessening the accuracy of the determination.

8.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water conforming to Specification D 1193, Type I or Type II. The indicated specification does not actually specify inorganic carbon or organic carbon levels. These levels can affect the results of this test method, especially at progressively lower levels of the carbon content in the samples to be measured. Where inorganic carbon in reagent water is significant, CO₂-free water may be prepared from reagent water by acidifying to pH 2, then sparging with fritted-glass sparger using CO₂-free gas (time will depend on volume and gas flow rate, and should be determined by test). Alternatively, if the carbon contribution of the reagent water is known accurately, its effect may be allowed for in preparation of standards and other solutions. CO₂-free water should be protected from atmospheric contamination. Glass containers are required for storage of water and standard solutions.

8.3 *Acid*—Various concentrated acids may be used for acidification of samples and of the oxidizing reagent. Acids such as phosphoric (sp gr 1.69), nitric (sp gr 1.42), or sulfuric (sp gr 1.84) are suitable for most applications. Sulfuric acid

⁴ "Reagent Chemicals, American Chemical Society Specifications," American Chemical Society, Washington, DC. For suggestions on the testing of reagents not listed by the A.C.S., see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY and the "United States Pharmacopeia."

should be used in the form of a 1 + 1 dilution, for safety reasons. Hydrochloric acid is not recommended.

8.4 Organic Carbon, Standard Solution (2000 mg/L)—Choose a water-soluble, stable reagent grade compound, such as benzoic acid or anhydrous potassium hydrogen phthalate ($\text{KHC}_8\text{H}_4\text{O}_4$). Calculate the weight of compound required to make 1 L of organic carbon standard solution; for example, $\text{KHC}_8\text{H}_4\text{O}_4 = 0.471$ g of carbon per gram, so one litre of 2 g/L of standard requires 2/0.471, or 4.25, grams of KHP. Dissolve the required amount of standard in some CO_2 -free water in a 1-L volumetric flask, add 1 mL of acid, and dilute to volume. This stock solution, or dilutions of it, may be used to calibrate and test performance of the carbon analyzer.

8.5 Persulfate Solution—Prepare by dissolving the appropriate weight of potassium or sodium persulfate in 1 L of water, to produce the concentration specified by the instrument manufacturer. If specified, add 1 mL of phosphoric acid (sp gr 1.69) and mix well. Store in a cool, dark place. Recipes for this reagent solution may be modified by manufacturers to meet the needs of specific applications, for example, high chloride samples.

8.6 Gas Supply—A gas free of CO_2 and of organic matter is required. Use a purity as specified by the equipment manufacturer. The use of oxygen is preferred for the UV-persulfate method, and nitrogen or helium is preferred if a CO_2 trap is used between reactor and detector.

9. Sampling and Sample Preservation

9.1 Collect the sample in accordance with Specification D 1192 and Practice D 3370.

9.2 To preserve samples for this analysis, store samples in glass at 4°C. To aid preservation, acidify the samples to a pH of 2. It should be noted that acidification will enhance loss of inorganic carbon. If the purgeable organic fraction is important, fill the sample bottles to overflowing with a minimum of turbulence and cap them using a fluoropolymer-lined cap, without headspace.

9.3 For monitoring of waters containing solids or immiscible liquids that are to be injected into the reaction zone, use a mechanical homogenizer or ultrasonic disintegrator. Filtering or screening may be necessary after homogenization to reject particle sizes that are too large for injection. Volatile organics may be lost. See 6.3.

9.4 For wastewater streams where carbon concentrations are greater than the desired range of instrument operation, dilute the samples as necessary.

10. Instrument Operation

10.1 Follow the manufacturer's instructions for instrument warmup, gas flows, and liquid flows.

11. Calibration

11.1 Use the stock solution of 2000 mg/L of carbon, and various dilutions of it, for calibration.

NOTE 2—Dilutions should be made with CO_2 -free water (see 8.2).

11.2 Calibration protocols may vary with equipment manufacturers. However, in general, calibrate the instrument in accordance with the manufacturer's instructions, and use standards to verify such calibration in the specific range of

interest for actual measurements. Plots of standard concentration versus instrument reading may be used for calibration or to verify linearity of response.

11.3 Establish instrument blank according to the manufacturer's instructions.

12. Procedure

12.1 Mix or blend each sample thoroughly and carry out any necessary dilution to bring the carbon content within range of the instrument.

12.2 If inorganic carbon is to be measured directly, inject the sample into the analyzer under appropriate conditions.

12.3 If inorganic carbon is to be removed by sparging prior to sample introduction, acidify to approximately pH 2 with concentrated acid (if not already done) and sparge with an appropriate flow of gas. Samples with high alkali content or buffer capacity may require larger amounts of acid. In such cases, incorporate this dilution into the calculation. If incomplete sparging of CO_2 from IC is suspected, sparge and analyze the sample and then repeat the procedure until appropriate conditions are established. In difficult conditions, use of a fritted-glass sparger may help.

12.4 To measure TOC, inject an appropriate volume of the sample into the analyzer. If external sparging is required to remove IC, inject a sparged sample for the TOC measurement. See 6.3.

12.5 To measure TC, inject an appropriate volume of unsparged sample.

13. Calculation

13.1 Read carbon values directly from a digital display or printer, or both.

14. Precision and Bias⁵

14.1 Collaborative Test—This test method was evaluated by sending seven identical sample to each of ten laboratories and asking them to measure TOC and TC exactly in accordance with this test method. Three of the ten laboratories did not make the TC measurement. One of the samples consisted of laboratory reagent water. The other six were of that water spiked to various levels with acetic acid, pyridine, and sodium carbonate. TC levels ranged from 0.6 to 2 000 mg/L, and TOC levels from 0.3 to 1 700 mg/L. An *F* test at 95 % confidence level showed no significant difference between the results of the five laboratories using UV-persulfate oxidation and those of the five laboratories using hot persulfate. Consequently, results were pooled for further analysis.

14.2 Removal of Outliers—Application of outlier tests specified in Practice D 2777 – 85 resulted in the elimination of one laboratory's TC and TOC results. In addition, three laboratories did not perform the TC analysis, so the effective number of laboratories was six for the TC measurement. Five of their individual results were later eliminated by outlier test. In the TOC determination, one additional laboratory failed the outlier test, leaving a total of eight. Three individual results were later eliminated.

⁵ Supporting data are available from ASTM Headquarters. Request RR: D-19-1130.

FIG. 2 Precision Versus Amount Recovered

14.3 *Precision*—Separate determinations of precision were made for TC and TOC measurements:

$$\text{For TC: } S_r = 0.03x + 0.3$$

$$S_o = 0.01x + 0.2$$

$$\text{For TOC: } S_r = 0.08x + 0.1$$

$$S_o = 0.04x + 0.1$$

where:

x = the recovered C concentration, mg/L,

S_r = overall precision, and

S_o = single-operator precision.

Fig. 2 shows a log-log plot of the overall and single-operator precision of all TC and TOC measurements not eliminated by outlier tests.

14.4 *Bias*—Fig. 3 plots “amount added” against “amount found,” with overall precision shown as an error bar. Bias significant at the 95 % level (student’s t -test) is flagged. Water that was used as one of the samples is omitted, since no value equivalent to “amount added” is available. The contribution of the carbon in the water to the spiked samples was allowed for before analysis of bias. In general, bias is positive, with the values running from 1 % to 25 % of the amount added, with no particular pattern evident. Of the twelve bias measurements, ten were below 10 %. Users of this test method should make their own determination of bias.

14.5 *Matrix Effects*—Participants were asked to measure the TC and TOC levels in a water sample of their choice, and

FIG. 3 Bias: Amount Added Versus Amount Recovered

then to spike the sample with one of the study samples and to measure the sample again. The chosen samples were: sink waste; DI water with KHP; soil solution; tap water with added IC; plant waste stream; synthetic sewage, and anion resin brine wash. TC recoveries averaged 86 % (range from 74 % to 92 %), and TOC, 82 % (from 47 % to 92 %). The negative bias, versus the positive bias noted in 14.4, can reflect incomplete oxidation of spiking compounds in the presence of other organics, errors introduced by sample handling, or other effects. In any event, no one matrix was studied in sufficient depth to provide an answer. Users of this test method should conduct their own experiments to determine recovery in their particular circumstances.

14.6 The quality assurance (QA)/quality control (QC) portion of this test method has not been completely established at this time. It is the intent of Subcommittee D19.06 that procedures be incorporated into this test method that require a minimum level of QC. These procedures will require, at minimum, a method startup check and ongoing performance checks. The analysts performing this test method will be required to measure their performance against the performance level achieved by the laboratories that participated in the ASTM round-robin study done on this test method. These formal QC procedures will be incorporated at such time as they have been officially accepted by the Society. See Practice D 4210.

APPENDIX

(Nonmandatory Information)

X1. RECOVERIES OF VARIOUS COMPOUNDS FROM CHLORIDE-CONTAINING SOLUTIONS WITH UV-PERSULFATE OXIDATION

TABLE X1.1 Percent Recovery

Analyte	No Mercuric Reagent	With Mercuric Reagent
Potassium hydrogen phthalate	90.5	101.2
Urea	101.1	...
Methanol	96.6	99.3
Nicotinic acid	91.0	97.9
Pyridine	88.6	98.0
Proline	86.0	92.2

Standard Test Method for Erosion Testing of Antifouling Paints Using High Velocity Water¹

This standard is issued under the fixed designation D 4938; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of erosion rates for marine antifouling paint systems immersed in flowing natural seawater.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For a specific hazard statement, see Section 7.*

2. Referenced Documents

2.1 ASTM Standards:

D 823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels³

D 1889 Test Methods for Turbidity of Water⁴

D 2200 Pictorial Surface Preparation Standards for Painting Steel Surfaces³

2.2 U.S. Military Specifications:⁵

MIL-P-24441 Paint, Epoxy-Polyamide

DOD-P-24647 Paint, Antifouling, Ship Hull (Metric)

DOD-P-24655 Paint, Underwater Hull, Anticorrosion (Metric)

3. Summary of Test Method

3.1 Steel panels coated with the antifouling paint system under evaluation are positioned in a high velocity water channel, similar to the type shown in Figs. 1 to 3, parallel to the path of the flowing water.

3.2 Exposure conditions shall include at least one series of test panels evaluated at the standard water velocity of 12 m/s and shall specify the length of time, temperature, salinity, and pH. Additional velocities may be conducted at the discretion of the customer.

3.3 Color photographs and coating thickness measure-

ments shall be taken prior to exposure, at specified time intervals, and repeated at the end of the test for comparison purposes.

4. Significance and Use

4.1 This test method is intended to measure the erosion rates of ablative antifouling paint systems exposed to flowing water at velocities designed to subject the paint system to shear stresses experienced in service.

4.2 Measurement of erosion rates are necessary to help in the assessment of ablative antifouling paint film thicknesses required for fouling control between scheduled drydockings of ships, in the selection of materials, in producing quality assurance, and in understanding the performance mechanism.

4.3 The test data is intended to serve as a guide for predicting the service life of ablative antifouling paints in order to calculate the necessary paint thickness to fit specified deployment cycles. Erosion rates of antifouling paints in service will vary depending on such factors as: berthing location, geographic area of operation, salinity, pH, and temperature of seawater. It should also be recognized that some areas of the ship are subject to different erosion rates.

4.4 The degree of correlation between results obtained from this test method and shipboard service has not been determined.

5. Apparatus

5.1 Water Channel:

5.1.1 High velocity flowing water in a contained channel, similar to the type shown in Figs. 1 to 3, is used to induce hydrodynamic shear stresses on painted panels to determine erosion rates of ablative antifouling paints.

5.1.2 The basic apparatus consists of a four-walled channel, rectangular in cross section, through which natural seawater flows at varying linear velocities to simulate ships' speeds.

5.1.3 All wetted materials supplying seawater to and within the channel shall be nonmetallic with the following exceptions:

5.1.3.1 Channel circulating pump impellers.

5.1.3.2 Thermowells.

5.1.3.3 Channel flow orifice plate.

5.1.4 One section of the channel shall permit testing of the panels at a standard test velocity of 12 m/s. All sections of the channel shall provide flow with fully formed turbulent characteristics. A minimum Reynolds number of 1 000 000 shall be achieved in each velocity test section. The Reynolds number, R , is calculated as follows:

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.45 on Marine Coatings.

Current edition approved April 28, 1989. Published June 1989.

³ Annual Book of ASTM Standards, Vol 06.01.

⁴ Annual Book of ASTM Standards, Vol 11.01.

⁵ Available from Standardization Documents Order Desk, Bldg. 4 Section D, 700 Robbins Ave., Philadelphia, PA 19111-5094, Attn: NPODS.

$$R = (D \times V \times P)/U$$

where:

- D = equivalent diameter = $4 \times (\text{area of flowing liquid/wetted perimeter})$, m,
- V = velocity, in m/s,
- P = density of medium, kg/m^3 , and
- U = viscosity, P/s.

For a channel with a rectangular cross section and a test panel placed in the middle of the channel, the equivalent diameter would be calculated as follows:

$$4 \times [(A \times B)/(2A + 2B)]$$

where:

- A = width of channel from side wall to panel face, m, and
- B = height of channel, m.

5.2 *Erosion Rate Determination*—Erosion rates of ablative antifouling paints are determined by using noneroding reference points and measured in accordance with Section 8 with the following equipment:

- 5.2.1 Microtome or encapsulating/polishing equipment.
- 5.2.2 Microscope with photomicrographic capability.

5.3 *Seawater Requirements:*

5.3.1 Seawater will be circulated through the channel at a constant rate permitting testing at different flow velocities as shown in 9.3.

5.3.2 Natural seawater shall be continuously supplied to the channel during operation to eliminate stagnation or concentration effects. During operation of the channel the following data shall be obtained and recorded on a daily basis:

- 5.3.2.1 Seawater circulating rate.
- 5.3.2.2 Seawater salinity and pH.
- 5.3.2.3 Incoming seawater temperature and the channel seawater temperature.

5.3.3 Provisions shall also be made for supplying filtered seawater to the channel. A suitable filter is one which can reduce turbidity to $\frac{1}{2}$ Jackson Turbidity Unit in accordance with Test Method D 1889.

5.3.4 As a minimum, the seawater chemistry in the channel, averaged over the course of the test run, shall be within the limits specified below:

	Maximum	Minimum
Salinity, ppm	35 000	27 000
pH	8.3	7.6

5.4 *Test Panels:*

5.4.1 Steel test panels conforming to Specification A 569/569M shall be used in the channel. The panels shall measure 18.75 cm high, 15 cm long, and 1.25 cm thick. The painted test panels shall be subjected to a double sided exposure with both sides exposed to similar hydrodynamic conditions.

5.4.2 Test panels painted in accordance with Test Methods D 823 are positioned vertically and parallel to the flowing water to simulate shear stresses experienced by paints on the ship's underwater hull.

5.4.3 The coating systems shall be applied in accordance with the manufacturer's instructions for both the anti-corrosion and the antifouling paints.

5.5 *Operation*—The channel shall be operated on a continuous basis during the test period except for downtime for panel inspection and seawater filtering system backwashes.

The total running time of the test is defined as the total hours of actual channel operation under fully flowing conditions.

6. Application of Paints

6.1 Antifouling paints under evaluation may be applied by spray over a primer from the same manufacturer in accordance with the manufacturer's directions or over 9 mils of epoxy polyamide paint conforming to Military Specification MIL-P-24441 with an appropriate tie-coat if necessary. Application shall be in accordance with Test Methods D 823.

7. Hazards

7.1 Antifouling paints contain toxic materials that could cause skin and eye irritation on contact and adverse physiological effects if ingested or inhaled. In the preparation of panels and the application of various types of antifouling paints, the use of appropriate protective clothing and equipment is required consistent with local, state, and federal government regulations and recognized industrial and technical standards. Spills, overspray, and unused material shall not be flushed down the drain but shall be disposed of as hazardous waste.

8. Procedure

8.1 Abrasive blast a minimum of three test panels for each system being evaluated to near-white metal, Sa 2½ in accordance with Pictorial Standard D 2200, to obtain a 1.0 to 3.0 mils (25 to 75 μm) surface profile.

8.2 Apply an epoxy anticorrosion primer in accordance with Military Specifications DOD-P-24655 and MIL-P-24441, or the manufacturer's recommendations, whichever applies.

8.3 Apply an antifouling topcoat in accordance with Military Specification DOD-P-24647 or the manufacturer's recommendations, whichever applies.

8.4 Apply additional coats of antifouling paint in accordance with Military Specification DOD-P-24647 or the manufacturer's instructions, whichever applies. The last coat shall dry for a minimum of 7 days before any erosion testing.

8.5 Both sides of the painted test surfaces are provided with noneroding reference (NER) points before immersion in the test environment. The NER is an insoluble, tightly adherent vinyl or other suitable, compatible coating 2 ± 0.5 cm/diameter applied in the center of the panel which will blanket a portion of the eroding surface. The NER preserves the original outer surface of the antifouling and thus offers a reference for comparison with the eroded surface during later microscopic examination.

8.6 Take film thickness measurements before and after testing (see 5.2).

8.7 Panels are to be photographed prior to starting the test for comparison with photographs taken at the conclusion of the test.

8.8 A specimen of exposed antifouling paint is carefully removed for examination in a single flake which includes a fragment of the noneroding reference. This specimen is mounted for microscopic analysis in a suitable medium such as paraffin wax or epoxy resin. Care is required to ensure that the specimen is not damaged by solvent attack or heat evolution during this encapsulation.

8.9 Specimens are prepared for examination by micro-

FIG. 1 High Velocity Flow Channel

FIG. 2 Simplified Schematic of Flow Channel

tome sectioning or by abrasive polishing to a plane surface.

8.10 Subsequent microscopic examination yields the typical image shown in Figs. 4 and 5. The material lost during the duration of the test is clearly shown as measurement d in Fig. 4. An actual photomicrograph is shown in Fig. 5.

9. Calculation

9.1 The material loss is expressed as the erosion rate of the ablative antifouling paint.

9.2 The erosion rate is calculated by dividing the micrometers of surface erosion by the duration of the test expressed in months at a specified speed.

W, mm	Velocity, m/s
50	18
60	15
75	12
100	9
150	6
300	3

FIG. 3 Cross-Section View of Test Panel Mounted in Flow Channel (Low Velocity Section)

9.2.1 Example—A 20- μ m erosion in 3 months equals 6.7 μ m/month.

9.3 The speed of the water in the channel expressed in metres per second is correlated to a ship's speed expressed in

FIG. 4 Illustration of Material Lost During Testing

Tests in accordance with the following table:

Speed in Channel, m/s	Speed, knots
3	5.8
6	11.7
9	17.5
12	23.3
15	29.1
18	35.0

9.3.1 Example—A typical erosion rate is reported as 6.7 mm/month at 17.5 knots, etc.

10. Report

10.1 The final test report shall include the following data:

10.1.1 List of the paints tested,

FIG. 5 Actual Microphotograph

- 10.1.2 Test duration—date started and date ended,
- 10.1.3 Thickness readings before and after exposure. Report total paint film loss at the standard test velocity and any auxiliary test velocities,
- 10.1.4 Daily measurements of the seawater temperature, salinity, and the pH,
- 10.1.5 Speed of test water correlated to knots,
- 10.1.6 Observation of the overall condition of painted panel, and
- 10.1.7 Initial and final photographs of the test panels.

Standard Test Method for Conductimetric Analysis of Water Soluble Ionic Contamination of Blasting Abrasives¹

This standard is issued under the fixed designation D 4940; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method describes a procedure for rapid evaluation of abrasives for the presence of ionic contamination by determining the total concentration of water soluble ionic contaminants by means of a conductivity test.

1.2 This test method does not identify the ionic species present nor provide quantitative results on each species.

1.3 This test method is based on a volume comparison among abrasives of similar sizes. A volume comparison is more closely related to surface area of the abrasives than is a weight comparison.

1.4 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

- 2.1 *ASTM Standards:*
D 1193 Specification for Reagent Water²
E 832 Specification for Laboratory Filter Papers³

3. Summary of Test Method

3.1 Abrasive and pure water are combined into a slurry that is stirred to leach the soluble salts from the abrasive. This slurry is filtered and conductance of the filtrate is measured. The conductivity, which is related to the concentration of soluble ionic materials contaminating the abrasive surface, is calculated from the conductance and the cell constant.

4. Significance and Use

4.1 By-product abrasives manufactured from slags that are air cooled or quenched with pure water, normally contain low concentrations of ionic materials as do mined mineral abrasives. However, slags quenched with seawater or other contaminated water, contain high amounts of ionic material as does seashore sand. This contamination of the abrasive can transfer to the steel surfaces being blasted, where it may accelerate corrosion. This test is useful in establishing the cleanliness of the abrasive at the jobsite.

4.2 This test method provides a value that indicates the concentration of total water soluble ions in accordance with their electrolytic mobility. Thus, it provides an indication of ionic corrosion potential.

NOTE 1—A typical value of conductivity for a high level of contamination is 500 $\mu\text{mho/cm}$. A typical value for a low level of contamination is 50 $\mu\text{mho/cm}$.

5. Apparatus

5.1 *Conductivity Bridge and Cell*—Any commercial conductivity bridge and conductivity cell having a range of at least 5 $\mu\text{mho/cm}$ to 1 000 000 $\mu\text{mho/cm}$ and temperature compensation capability is satisfactory. Either a dip-type, pipet-type, or cup-type cell may be used. A means of adjusting for temperature or controlling the temperature is essential. While some instruments have an adjustment to compensate for temperature, one means is to use a 25°C constant temperature bath. Another method is to stir the solution with a clean thermometer while the vessel is warmed or cooled by an external source.

NOTE 2—If temperature compensation or control is not followed correctly, an error of approximately 2 % per degree of temperature deviation from 25°C can be introduced. The deviation of conductivity with temperature in the range of 18°C is reported to be 0.0216 % per degree for chloride ions and 0.0227 % per degree for sulfate ions.

5.2 *Filter Paper*, conforming to Specification E 832, Type 1, Class C, to keep silt from fouling the surfaces of the conductivity cell.

6. Reagents and Materials

6.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society where such specifications are available.⁴ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

6.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water as defined by Type IV of Specification D 1193.

6.3 *Potassium Chloride* (KCl or 0.02 N KCl solution).

¹ This specification is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.46 on Industrial Protective Coatings.

Current edition approved April 28, 1989. Published June 1989.

⁴ "Reagent Chemicals, American Chemical Society Specifications," Am. Chemical Soc., Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY, and the "United States Pharmacopeia."

7. Sampling

7.1 Sampling shall be as follows unless otherwise agreed upon between the purchaser and the seller. Take two 1-L samples of abrasive at random from different packages of each lot, batch, day's pack, or other unit of production in the shipment. When no markings distinguishing between units of production appear, take samples from the different packages in the ratio of two samples for each 10 000 lb (5000 kg), except that for shipments of less than 10 000 lb, take two samples. Test the samples separately.

8. Calibration and Standardization

8.1 Determination of Cell Constant:

8.1.1 The conductivity cell will come with a predetermined constant. This constant should be checked periodically, one method being as follows:

8.1.1.1 Prepare a standard solution such as a 0.0005 *N* solution of KCl by diluting a 0.02 *N* KCl solution with water or by dissolving 0.0372 g of KCl (heated before weighing for 1 h at 105°C) in water, followed by dilution to 1 L. Cool and measure the conductance at 25°C as described in Section 9. Calculate the cell constant, K_{25} , as follows:

$$K_{25} = (C_s/C_m)$$

where:

C_m = conductance, measured at 25°C (see 10.1), μmho , and
 C_s = conductivity, 72 $\mu\text{mho/cm}$ (from Table 1).

NOTE 3—In general the cell constant is not greatly affected by variations in the strength of the KCl solution, but, for greater accuracy, measurements should be made at or near the specific conductivity of the solution to be measured and at values that utilize the middle range of the scale of the conductivity bridge, using the same multiplier tap.

8.1.2 Table 1 gives values of specific conductivities for corresponding KCl solution concentrations which are useful for abrasive testing.

9. Procedure

9.1 Preparation of a Slurry Filtrate:

9.1.1 Rinse beakers, stirring rods, and funnels with reagent water until tests show the rinse water has a conductivity of 5.0 $\mu\text{mho/cm}$ or less.

9.1.2 Add 300 mL of water to 300 mL of abrasive and stir for 1 min with a stirring rod. Let stand for 8 min and then stir again for 1 min.

9.1.3 Filter sufficient supernatant liquid for tests, discarding the first 10 mL of the filtrate. The amount of supernatant liquid filtered shall be sufficient to cover the cell.

9.1.4 Rinse the conductivity cell in reagent water until the rinse water is a cleanliness of 5.0 $\mu\text{mho/cm}$ or less.

9.1.5 Rinse the conductivity cell two or three times with the filtrate then determine conductance at 25°C in accordance with the operating instructions of the instrument. Use

successive portions of the sample until a constant value is obtained.

10. Calculation

10.1 Calculate the specific conductivity of the abrasive as follows:

$$C_s = C_m \times K_{25}$$

11. Report

11.1 Report the following information:

11.1.1 The calibration value of the cell constant (both as measured and as predetermined and supplied with the conductivity cell), the date, and the name of the person checking the calibration.

11.1.2 The material, date, readings and mean in $\mu\text{mho/cm}$ along with name of person conducting the tests and identification of the apparatus.

12. Precision and Bias⁵

12.1 *Precision*—On the basis of five replicate interlaboratory tests of this test method in which three operators in three laboratories analyzed, in duplicate, six blasting abrasives containing ionogenic contamination, the within-laboratory coefficient of variation after rejecting results from one set of replicate tests as outliers, was found to be 1.7 % with 20 degrees of freedom (df) and the between-laboratory standard deviation coefficient of variation was found to be 7.4 % with 15 df. Based on these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

12.1.1 *Repeatability*—Two results, each the mean of two runs obtained by the same operator should be considered suspect if they differ by more than 5 % relative.

12.1.2 *Reproducibility*—Two results, each the mean of two runs, obtained by operators in different laboratories should be considered suspect if they differ by more than 22 % relative.

12.2 Bias:

12.2.1 Bias can be present because of the mobility of various ions. The hydrogen ion has a much greater mobility than the hydroxyl ion or other ions so that at low pH's the conductivity will be relatively higher than at high pH's for the same ionic concentration. However, the bias introduced by this factor is in the proper direction. That is, high conductivity due to a lower pH of the contamination would normally indicate greater corrosion potential.

12.2.2 A bias may be introduced by extraneous contamination or from reduced sensitivity of instruments for low levels of contamination in the range of conductivity between 0 and 30 $\mu\text{mho/cm}$.

Standard Practice for Preparing Drawdowns of Artists' Paste Paints¹

This standard is issued under the fixed designation D 4941; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers the production of uniform films of artists' tube paints and other nonflowing pigmented paints using paint applicators designed for less viscous paints.

1.2 Information on how to achieve opaque specimens from these paints is included.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 16 Terminology Relating to Paint, Varnish, Lacquer, and Related Products²

D 4838 Test Method for Determining the Relative Tinting Strength of Chromatic Paints³

E 1164 Practice for Obtaining Spectrophotometric Data for Object-Color Evaluation⁴

3. Terminology

3.1 **Definitions**—See Definitions D 16 for definitions of terms used in this practice.

3.2 Descriptions of Terms Specific to This Standard:

3.2.1 **drawdown bar**—a metal applicator with a specified gap designed to deposit a wet paint film uniformly on a specified test panel (for example, an opacity chart) or other substrate.

3.2.2 **drawdown**—a layer of paint deposited on a substrate by use of a drawdown bar for the evaluation of paint characteristics.

4. Summary of Practice

4.1 The paint is spread over the area of the test panel to be covered by the drawdown and the bar is pulled down with pressure just sufficient to avoid lifting of the bar from the chart surface.

4.2 Test panels are allowed to dry in a dust-free environment.

4.3 If complete hiding (opacity) is needed and not produced by a single paint film, a second film is applied at a 90°

angle to the first. If required, additional layers may be applied using a narrower drawdown bar.

5. Significance and Use

5.1 Quality standards for artists' paints require the evaluation of various appearance characteristics of paint films. Tinting strength determination (Test Method D 4838) specifically requires the preparation of drawdowns for colorimetric measurement. Other evaluations such as color designation, transparency, gloss, and color difference measurements also require drawdown samples.

5.2 Artists' tube paints have a paste consistency that makes the use of traditional film application methods difficult, especially for drying oil paints.

5.3 Artists' paints vary in two properties important to the preparation of films, that is, transparency and drying time. Colorimetric determination and some other types of evaluation require paint specimens that completely hide the substrate. Very transparent paints require such a thick film to produce complete hiding that drying times are excessively long or the specimen surface is blemished. When complete hiding is necessary, this practice is designed to provide opaque films without these defects through application of a series of thin film.

6. Apparatus

6.1 **Drawdown Bars**, two, of different widths with a clearance of 0.006 in. (0.152 mm). Recommended widths are 3 in. (7.6 cm) and 6 in. (15.2 cm). The second bar is required to prepare drawdowns with more than two layers. Wire wound drawdown bars have been found to be unsuitable.⁵

6.2 **Drawdown Charts**, sealed paper type, half black and half white if transparency is being evaluated or opacity is necessary.⁶

7. Procedure

7.1 Attach chart to a firm, smooth, level plane surface using tape, a vacuum plate, or a clamp. Label the chart with the identity of the specimen and other data as required.

7.2 Mix paint sample thoroughly using two spatulas. Tube paints that have separated should be expelled completely and mixed.

NOTE 1—The use of coated freezer wrapping paper as a mixing surface simplifies clean up. The same paper can be used for weighing

¹ This specification is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.57 on Artist Paints and Related Materials.

Current edition approved April 28, 1989. Published June 1989.

⁵ Suitable drawdown bars can be obtained from the Paul N. Gardner Co., P.O. Box 10688, Pompano Beach, FL 33061-6688; or BYK-Gardner, Inc., Gardner Laboratory, 2435 Linden Lane, Silver Spring, MD 20910.

⁶ Suitable charts can be obtained from The Leneta Co., Box 576, Ho-Ho-Kus, NJ 07423.

FIG. 1 Preparation for Drawdown

specimens when required as in the tinting strength determination (Test Method D 4838).

7.3 Using a spatula, spread the paint, in a thickness exceeding the bar's gap clearance, over the entire area to be covered by the drawdown. Do not cover the area to be contacted by the supporting feet of the wider of the two bars. Starting at the top of the chart and using the wider bar, draw the bar down over the paint in an even motion applying sufficient pressure to ensure that the resistance of the viscous paint does not raise the feet of the bar from the surface. When using oil paints the motion should be slow enough to allow for the high viscosity. Acrylic paints, which have short drying times, should be applied immediately after mixing to avoid premature film formation.

7.4 After drying in a horizontal position for 15 min, specimens may be hung in a vertical position in a dust-free area to complete the drying. Allow 24 h for acrylic and alkyd paints and 48 h or longer for oil paints until dry to touch.

7.5 Examine the specimen for surface defects and discard if unacceptable.

7.6 If complete hiding is required, compare, either visually or instrumentally, the lightness of the paint on the black portion of the chart with that on the white. For instrumental evaluation, follow the procedures given in Practice E 1164 to determine CIE Y for each portion, then calculate the contrast ratio of the paint film on the two portions of the chart ($CIE Y_{black}/CIE Y_{white}$). A contrast ratio of 0.98 or higher is considered opaque.

7.6.1 If opacity is not sufficient, rotate the chart through a

FIG. 2 Three Overlapping Drawdowns

90° angle and deposit a second film using the wider bar to repeat the procedure in 7.3 through 7.5. If additional layers are required, repeat this sequence using the narrower bar. Be careful each time that the feet of the drawdown bar ride on the surface of the combined lower layers. See Figs. 1 and 2.

NOTE 2—The most transparent paints studied were found to require three coats; however, in some instances, such as with alizarin crimson oil paint, it may not be practical to obtain complete hiding.

Standard Test Methods for Water Pickup of Lithographic Printing Inks and Vehicles in a Laboratory Mixer¹

This standard is issued under the fixed designation D 4942; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

1.1 These test methods cover two procedures for determining the amount of water picked up by lithographic printing inks in a laboratory mixer.

1.2 Test Method A covers single-point water pickup; Test Method B covers the rate of water pickup. Both test methods are applicable to any printing ink and vehicle intended for the lithographic printing process.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Summary of Test Method

2.1 These test methods utilize a laboratory mixer for beating water or other agreed upon fluid into the test ink.

2.2 For single-point water pickup (Test Method A), 50 mL of water is normally added to 50 g of ink and mixed in for 5 min. The water picked up is determined from volumetric measurements of free water.

2.3 For rate of water pickup (Test Method B), water is added to 50 g of ink in increments of 20 mL and mixed in for 1 min or more over a cumulative time period totaling 10 min. The water taken up by the ink after each mixing interval is determined gravimetrically.

Significance and Use

3.1 The lithographic printing process requires that some dampening solution be emulsified into the ink. These test methods provide a rapid means for determining water pickup under laboratory conditions. Test results may be useful for specification acceptance between the supplier and the customer.

3.2 In order that results be comparable, the tests must be run at the same temperature and with the same type and quantity of liquid added prior to mixing.

3.3 The emulsions obtained in these test methods are of larger particle size than those typically produced in printing shops. Because of these and other variables in the printing process, water pickup results do not by themselves predict lithographic printing performance.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.56 on Printing Inks.

Current edition approved April 28, 1989. Published June 1989.

4. Apparatus

4.1 *Laboratory Mixer*,² such as a Duke Ink-Water Emulsification Tester² equipped with a stainless steel specimen bowl 83 mm wide and 88 mm high, mixer blades that rotate at 90 r/min, and a timing device.

4.2 *Balance*, accurate to 0.1 g, 600-g capacity.

4.3 *Palette knives*, two.

4.4 *Thermometer*, quick response.

4.5 *pH Meter* (optional).

4.6 *Conductivity Meter* (optional).

4.7 *Graduated Cylinder*, 50 or 100-mL.

5. Reagents and Materials

5.1 *Water*—Deionized or distilled water, preferably having a pH of 5.0 to 7.0 (100 to 200 mL per sample); alternatively, fountain solution or other aqueous medium as agreed upon between the supplier and the customer may be used.

5.2 *Cleanup Materials*—Naphtha and rags or tissues.

6. Test Specimen

6.1 A minimum of 100 g is sufficient for two determinations. Before removing ink from the can, stir or otherwise ensure that the ink specimen is representative. Close the can and replace sealing tape immediately after each ink removal.

7. Conditioning

7.1 Condition the instrument, water, and ink samples in a constant temperature room or bath, preferably at $23 \pm 1^\circ\text{C}$.

7.2 Prior to use, check the alignment of the mixer blades. With the power switch of the mixer in the off position, set the clean bowl into the turntable and engage the locking pin firmly into the slot in the side of the turntable. Tilt the mixer head back and insert the blades, marked left and right, into their respective holders. Lower the mixer head. If the blades hit the side or bottom of the bowl, return the instrument to the manufacturer for realignment.

8. Test Method A—Single Point Water Pickup (by Volumetry)

8.1 Program the counter of the mixer for 5 min mixing time (450 revolutions).

8.2 *Optional*—If the first run of the day, pour test water into a beaker. Measure pH, conductivity, and temperature at the beginning of testing.

8.3 Weigh or tare the clean dry mixing bowl. Add $50 \pm$

² Available from Duke Custom Systems, 8371 Highway 49, Pleasant View, TN 37146.

0.1 g of the ink to the center of the bowl.

8.4 Pour 50 mL of water (from 8.2) into a graduated cylinder. If the ink is expected to pick up more than 100 % water, use 100 mL of water. Adjust the volume to ± 0.5 mL. Add the entire contents to the bowl.

8.5 With the mixer head tilted back insert the clean blades, marked left and right, into their respective holders. Lock the bowl on the turntable. Lower the mixer head. Press the counter reset button, making sure that 450 is displayed on the face of the counter.

8.6 Turn the mixer on. Examine contents of the bowl as mixing progresses. If 50 mL of water had been added and all of it disappears into the ink, stop, discard the ink in the bowl, clean up, and start over from 8.3, adding 100 mL of water in 8.4. The latter quantity must also be used for all other inks in the series under study.

NOTE 1—With some inks, water pickup is affected by the amount of water added prior to mixing. When 50 mL is insufficient, do not simply add another 50 mL during the run, as test results may differ significantly from those obtained by adding 100 mL at the outset.

8.7 When the mixer stops, turn the power switch off. Tilt the head out of the ink, detach the mixing blades, and add to the bowl.

8.8 Remove the bowl from the turntable and, holding the blades at the side of the bowl, decant the free water into a graduated cylinder. Run the blades *very slowly* through the ink in the bowl. Decant additional free water into the cylinder.

NOTE 2—Do not knock the bowl to force free water from the surface. Always handle the bowl gently to avoid breaking the emulsion.

8.9 Record the returned water level to 0.5 mL.

8.10 *Optional*—Measure the temperature, pH, and conductivity of the returned water. Note the appearance of the water and the consistency of the ink and the appearance of the returned water.

8.11 Discard ink left in the bowl. Clean the bowl and the mixer blades with tissue wetted with naphtha. Discard the returned water and rinse the cylinder clean.

8.12 Repeat 8.3 through 8.10 with a second specimen of the same ink.

9. Test Method B—Rate of Water Pickup (by Gravimetry)

9.1 Program the counter for the first interval of the mixing cycle.

NOTE 3—A commonly used cycle is 1-min intervals (90 revolutions) times ten determinations. Intervals need not be uniform, for example, 1, 2, 3, 5, and 10 min (90 times 3 plus 180 plus 450 revolutions).

9.2 *Optional*—Measure water properties in accordance with 8.2.

9.3 Weigh or tare the clean dry mixing bowl and blades on the balance. Add 50 ± 0.1 g of ink to the center of the bowl.

9.4 Lock the bowl on the platform of the mixer. With the mixer head raised, carefully insert the blades into their respective holders. If ink on one blade touches the upper parts of the other blade or the side of the bowl, carefully remove the ink with two palette knives and transfer to the bottom of the bowl. Lower the mixer head.

9.5 Pour 100 mL of water (from 8.2) into a beaker. Meter out 20 mL and add to the bowl.

9.6 Press the counter reset button, making sure that the

desired number of revolutions is displayed on the face of the counter. Turn the mixer on. Examine the contents of the bowl as mixing progresses. If all liquid disappears into the ink, add more as needed to maintain a layer of excess water on the surface of the ink.

NOTE 4—Few specimens will take up more than 20 mL of water within a 1-min mixing interval. If a high-water pickup specimen is being run and the mixing interval is longer than 1 min, another 20 mL should be added prior to each subsequent minute of mixing time.

9.7 When the mixer stops, turn the power switch off. Detach the mixing blades and add to the bowl.

9.8 Remove the bowl from the turntable and, holding the blades at the side of the bowl, decant the free water into the beaker containing the unused water. Run the blades *very slowly* through the ink in the bowl. Decant additional free water into the beaker (see Note 2).

9.9 Weigh the mixing bowl and contents, including the blades.

9.10 Using a palette knife, transfer the ink from the walls to the center of the bowl. Return the bowl to the mixer. Replace the blades as in 8.4.

9.11 For the next mixing interval, swirl the beaker in order to mix the returned and unused water. Meter out 20 mL and add to the bowl. Press the counter reset (or change the counter) and turn the power on. Add more water if needed to maintain an excess layer (see Note 4).

9.12 When the mixer stops, repeat 9.7 through 9.11 until the cumulative mixing time totals at least 10 min.

9.13 *Optional*—At the end of the run, make measurements in accordance with 8.10.

9.14 Discard the ink left in the bowl. Clean the bowl and the mixer blades with tissue wetted with naphtha. Discard returned water and rinse the beaker clean.

9.15 Repeat 9.3 through 9.14 with another specimen of the same ink.

10. Calculation

10.1 Calculate water pickup, P , as follows:

10.1.1 *Test Method A—Volumetric:*

$$P = (V_1 - V_2) \times 2$$

where:

P = water pickup, % or mL water/100 g ink,

V_1 = volume of water added, mL, and

V_2 = volume of returned water, mL.

10.1.2 *Test Method B—Gravimetric:*

$$P = (W - S) \times 2$$

where:

P = water pickup, % or g water/100 g ink,

W = weight of the specimen plus water picked up after each mixing interval, g, and

S = weight of initial specimen, g.

NOTE 5—The conversion from water pickup of the ink to water content, C , of the emulsion is $C = P/(100 + P)$. Units are percent or grams of water per 100 grams of emulsion.

11. Report

11.1 Report the following information:

11.1.1 The percent water pickup to the nearest whole number as the mean of the two determinations, the cumulative mixing time, and a description of the water used for

testing (for example, tap water, deionized water, or type of fountain solution).

11.1.2 If rate of water pickup was determined, plot the percent of water pickup versus the cumulative mixing time.

11.1.3 *Optional*—The mean temperature, changes in pH, conductivity, appearance of the water, and the change in consistency of the ink.

12. Precision and Bias

12.1 Precision:

12.1.1 *Test Method A*—An interlaboratory study of single-point water pickup by Test Method A was conducted in which one operator in each of eleven laboratories tested in duplicate on each of two days three lithographic printing inks ranging in 5-min water pickup from 50 to 65 %. One company was found to be an outlier and was deleted from the analysis. The within laboratory pooled standard deviation was found to be 1.58 % absolute (millilitre of water per 100 grams of ink) at 9 degrees of freedom (df), and the between laboratories pooled standard deviation was 7.1 % absolute at 30 df. Based on these standard deviations, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

12.1.1.1 *Repeatability*—Two results, each the mean of two runs obtained by one operator, should be considered suspect if they differ by more than 4.5 % absolute.

12.1.1.2 *Reproducibility*—Two results, each the mean of two runs obtained by operators in different laboratories, should be considered suspect if they differ by more than 20 % absolute.

12.1.2 *Test Method B*—In an interlaboratory study of rate

of water pickup by Test Method B, water pickup values at 2½, 5, 7½ and 10 min were determined twice on one day by one operator in each of nine laboratories on six inks. The inks ranged in water pickup from 40 to 52 % at 2½ min and from 65 to 100 % at 10 min. After rejecting 12 out of 156 replicated test values as outliers, the within laboratory pooled standard deviation was found to be 1.58 % absolute (grams of water per 100 grams ink) with 97 df and the between laboratory standard deviation 3.73 % absolute with 86 df. Based on these standard deviations, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

12.1.2.1 *Repeatability*—Repeatability cannot be determined as both runs were conducted on the same day.

12.1.2.2 *Reproducibility*—Two water pickup curves, each the mean of two runs, obtained by operators in different laboratories should be considered suspect if they differ by more than 10.5 % absolute.

12.2 *Bias*—Bias cannot be determined because there are no standard materials. The poorer interlaboratory precision of Test Method A compared to Test Method B is believed to be caused by the fact that the gross quantity of water added at one time is picked up as large globules which make it difficult for different operators to release free water in the same manner.

13. Keywords

13.1 lithographic printing inks; printing inks; inks; vehicles; water pickup; water content; emulsification; fountain solution; mixers

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Standard Test Method for Blocking Resistance of Architectural Paints¹

This standard is issued under the fixed designation D 4946; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

¹ NOTE—Paragraphs 6.5, 7.2, and 7.5 were editorially corrected in October 1990.

1. Scope

1.1 This test method describes an accelerated procedure for evaluating the face-to-face blocking resistance of trades sales paints. This is not to be confused with blocking resistance Test Method D 3003 which is concerned with blocking of industrial coatings on metal substrates, nor with Test Method D 2793 which is concerned specifically with wood product finishes and reports results on a satisfactory or not satisfactory basis, rather than by the degree of blocking tendency as in this test method.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 2793 Test Method for Blocking Resistance of Organic Coatings on Wood Substrates²

D 3003 Test Method for Pressure Mottling and Blocking Resistance of Organic Coatings on Metal Substrates²

3. Terminology

3.1 Definition:

3.1.1 *blocking*—The undesirable sticking together of two painted surfaces when pressed together or placed in contact with each other for an extended period of time.

4. Summary of Test Method

4.1 Dried paint films are placed face-to-face and a pressure of about 1.8 psi (127 g/cm²) is applied. These paint films are put into an oven for 30 min to make the test more stringent. After cooling, the blocked panels are peeled apart. The degree of blocking is rated subjectively for tack or seal using a series of standard descriptive terms corresponding to numerical ASTM values of 10 to 0.

5. Significance and Use

5.1 Dry paint often comes in contact with itself especially in window and door areas and, depending on its hardness,

the pressure, temperature, humidity, and duration of time the surfaces are in contact, sometimes sticks to itself (blocks). This stringent test method can be used to compare and rate subjectively the resistance of paints to blocking.

6. Apparatus

6.1 *Conditioned Room*, at 65 to 85°F (18 to 29.5°C) and 40 to 60 % relative humidity.

6.2 *Sealed Paper Test Charts*, approximately 7.5 by 11 in. (190 by 280 mm).³

6.3 *Applicator Blade*, 5 to 6 in. (13 to 15 cm) wide, 6 mil clearance.

6.4 *Oven*, 115 to 125°F (48 to 52°C).

6.5 *Rubber Stoppers*, No. 8, 1.25 in. (3.2 cm) smaller diameter.

6.6 *Weights*, 1000 g.

6.7 *Scissors*.

6.8 *Aluminum Tray or Pan*, flat.

7. Procedure

7.1 Cast the paint to be tested on a sealed test chart using the applicator blade. Condition coated panels in the conditioned room for seven days. All painted panels should be kept free of grease, oil, or fingerprints since these will affect block resistance.

7.2 After the panels have been conditioned, cut out six 1½ by 1½-in. (3.8 by 3.8-cm) sections from the painted chart. Start the cut at least ½ in. (1.3 cm) away from the edge of the drawdown.

7.3 Place the cut sections with the paint surfaces face-to-face for each paint to be tested.

7.4 The weights, stoppers, and tray should be temperature equilibrated in the oven prior to running the test.

7.5 Place the face-to-face specimens in the oven on a flat aluminum tray. Place a No. 8 stopper on top, with the small diameter in contact with the specimens, then place a 1000-g weight on top of the stopper. This results in a pressure of 1.8 psi (127 g/cm²) on the specimens. One weight and stopper is to be used for each specimen to be tested. It is recommended that "pass" and "fail" paint controls be used in each test run and that the tests be run in triplicate.

7.6 After exactly 30 min, take the stoppers and weights off the test specimens and remove them from the oven. Allow them to cool for ½ h in the conditioned room before determining the block resistance.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.42 on Architectural Finishes.

Current edition approved May 26, 1989. Published July 1989.

² Annual Book of ASTM Standards, Vol 06.01.

³ Form WB available from The Leneta Co., P.O. Box 86, Ho-Ho-Kus, NJ 07423 has been found satisfactory for this purpose.

7.7 After cooling, separate the specimens by peeling them apart with a slow and steady force at about 180° from each other forming a "T" pattern during beginning of the separation. It is necessary to put the specimen next to the ear while separating to actually hear the degree of tack. Rate for blocking resistance on a scale of 0 to 10 (see 8.2).

8. Interpretation of Results

8.1 Blocking resistance is rated on a scale of 10 to 0, which corresponds to a subjective tack (sound of separation when peeled) or seal (the complete sticking together) rating determined by the operator. This rating system is defined in 8.2 in the appropriate descriptive terms. The degree of seal is the estimated area on the specimens where the paint surfaces adhere and some of the paper tears away from the chart when peeled.

8.2 Blocking Resistance Ratings:

Blocking Resistance Numerical Ratings	Type of Separation	Performance
10	no tack	perfect
9	trace tack	excellent
8	very slight tack	very good

Blocking Resistance Numerical Ratings	Type of Separation	Performance
7	very slight to slight tack	good to very good
6	slight tack	good
5	moderate tack	fair
4	very tacky; no seal	poor to fair
3	5 to 25 % seal	poor
2	25 to 50 % seal	poor
1	50 to 75 % seal	very poor
0	75 to 100 % seal	very poor

9. Report

9.1 Report the blocking resistance rating determined in accordance with 8.2.

10. Precision

10.1 Data are unavailable for a conventional precision statement. However, based on actual laboratory experience, with experienced operators, the repeatability is estimated to be plus or minus one blocking resistance unit. Numerical values may differ from operator to operator but relative ranking should be about the same. As in many tests the precision improves with practice.

11. Keywords

11.1 blocking; blocking resistance; sticking; tack

Standard Test Method for Determination of the Upper Layer Separated from a Viscous Liquid¹

This standard is issued under the fixed designation D 4948; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

1. Scope

1.1 This test method covers the determination of the amount of liquid separated as an upper layer in a 24-h period from viscous solutions or dispersions that contain dispersed solids such as paints, enamels, pigmented lacquers, adhesives, polishes, and other similar materials.

NOTE—The amount of clear liquid that separates during this test is one of the criteria in the United Nations Recommendations on the Transportation of Dangerous Goods² for the placement of flammable viscous liquids into packing groups related to flash points (See 4.1).

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

- 2.1 *ASTM Standard:*
D 3925 Practice for Sampling Liquid Paints and Related Pigmented Coatings³

3. Summary of Test Method

3.1 A measured amount of the material to be tested is placed in a graduated cylinder and allowed to stand undisturbed for 24 h. The volume percent of the separated top layer is then determined.

4. Significance and Use

4.1 The United Nations Committee of Experts on the Transport of Dangerous Goods in their recommended regulations place materials having a flash point below 73.5°F (23°C) in Packing Group II. However, if viscous substances such as paint and related coatings, adhesives, polishes, etc., meet certain requirements, they can be placed in Group III along with materials having a flash point between 73.5 and 140°F (23 and 60.5°C). One of the requirements is that less than 3 % of clear liquid separates from the bulk of the material when subjected to this test method.

4.2 At the present time most international regulatory bodies such as the International Civil Aviation Organization

(ICAO) and the International Maritime Organization (IMO) use the U.N. Recommendations. It is anticipated that most national transportation regulatory bodies will adopt the U.N. Recommendations as their regulations for control of transportation of hazardous materials. At present the United States permits the transshipment of hazardous materials through the United States to other countries under regulations of the IMO and ICAO.

5. Apparatus

5.1 *Graduated Cylinder*,⁴ 100-mL, glass-stoppered, 250-mm total height and 30-mm inside diameter.

5.2 *Constant Temperature Cabinet or Room*, at 73.5 ± 3.5°F (23 ± 2°C).

6. Sampling

6.1 Obtain a uniform quart sample of the material using standard methods for sampling in accordance with Practice D 3925.

7. Conditioning

7.1 Store the sample or a representative portion at a constant temperature of 73.5 ± 3.5°F (23 ± 2°C) until the sample reaches a uniform temperature of 73.5°F (23°C).

8. Procedure

8.1 Thoroughly stir the sample to obtain uniform consistency and, in the case of materials containing particles, uniform dispersion of these particles.

8.2 Immediately pour 100 mL of the sample into the graduated cylinder. Insert a stopper and leave the cylinder undisturbed at 73.5 ± 3.5°F (23°C) for 24 h.

8.3 After 24 h, measure the volume of any upper separated layer and determine the percent of the separated layer compared to the total volume of the specimen.

9. Calculation

9.1 Calculate the volume percent of the clear upper liquid layer P_c as follows:

$$P_c = (V_c/V_m) \times 100$$

where:

V_c = volume of the clear upper liquid layer, mL, and
 V_m = total volume of the 100-mL specimen, mL.

⁴ A graduated cylinder, Catalog No. 2982-100, available from Corning Glass Works, Corning, NY 14831, has been found satisfactory for this purpose.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.22 on Health and Safety.

Current edition approved May 26, 1989. Published July 1989.

² *Transport of Dangerous Goods: Recommendations of the Committee of Experts on the Transport of Dangerous Goods*, United Nations, 3rd ed., New York, 1984.

³ *Annual Book of ASTM Standards*, Vol 06.01.

10. Report

10.1 Report the volume percent of the separated clear liquid to within 0.5 %.

11. Precision and Bias

11.1 The precision of this test method will be determined.

11.2 Bias cannot be determined since no standards are available.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Comparison of the Brush Drag of Latex Paints¹

This standard is issued under the fixed designation D 4958; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method is a standardized brushout procedure for comparing the brush drag of architectural type latex paints.

1.2 With slight modifications this test method is also applicable to solvent paints.

1.3 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

- D 1475 Test Method for Density of Paint, Varnish, Lacquer and Related Materials²
- D 3924 Specification for Standard Environment for Conditioning and Testing Paint, Varnish, Lacquer and Related Materials²
- D 3925 Practice for Sampling Liquid Paints and Related Pigmented Coatings²
- D 4287 Test Method for High-Shear Viscosity Using the ICI Cone/Plate Viscometer²

3. Terminology

3.1 **Definitions**—See *Paint/Coatings Dictionary*³ for definition of terms used in this test method.

3.1.1 *brush-drag*—resistance encountered when applying a coating by brush.

4. Summary of Test Method

4.1 A 2-in. (50-mm) polyester brush is used to apply the test paint on a 1.076-ft² (1000-cm²) test area. The application is made at a spreading rate of 400 ft²/gal (9.82 m²/L) and is completed in 30 to 35 s. The degree of brush drag is rated subjectively using a series of standard descriptive terms corresponding to numerical values of 1 to 10. The rank order of a set of samples is thereby established.

5. Significance and Use

5.1 As the brush drag of a paint increases, any natural tendency on the part of the painter to overspread the paint is

reduced. When all other factors are held constant, increased brush drag will result in greater film thickness with consequent improvement in durability and hiding. Conversely, sometimes it might be preferred to have a lesser degree of brush drag for easier application (that is, the amount of time and effort in applying a paint to a specific area is reduced with a lesser degree of brush drag).

5.2 This test method provides a standardized brushout procedure for the evaluation of brush drag as an alternative to customary informal ad hoc procedures. Its objective is to maximize the reliability and precision with which this characteristic may be determined.

NOTE 1—The brush drag of paints is directly related to their high-shear viscosity. There is generally good rank order agreement between results obtained by this method and Test Method D 4287. The sensitivity of this brushout method has been found sufficient to distinguish between brushabilities corresponding to high-shear viscosity differences not lower than 0.3 poise (0.03 Pa.s). Round robin data show that rank order agreement between the brushout and viscometric methods is poor when latex and solvent paints are part of the same comparison group. This is the result of these two paint types having markedly different rheological properties that affect the relative perception of brush drag.⁴

6. Apparatus

6.1 *Brush*, 2-in. (50-mm) polyester filament, 2¼-in. (70-mm) length-out, ⅞ in. (14 mm) thick, with a chiseled tip.

NOTE 2—All tests of a given series of paints, within or between laboratories, should be carried out with commercially identical brushes.

6.2 *Stopwatch*.

6.3 *Balance*, capable of weighing accurately to 0.1 g.

6.4 *Test charts*, with a sealed surface, having 1.076 ft² (1000 cm²) of test area.⁵

7. Sampling and Conditioning

7.1 Sample in accordance with Practice D 3925.

7.2 Condition the samples in accordance with the Conditioning and Testing section of Specification D 3924.

7.3 All testing should be performed under the same conditions.

8. Procedure

8.1 Do not change operators during the running of a series of specimens, since this will invalidate any conclusions as to rank order.

8.2 Determine the density in pounds per gallon of the paint sample in accordance with Test Method D 1475.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.42 on Architectural Finishes.

Current edition approved Oct. 15, 1991. Published December 1991. Originally published as D 4958 - 89. Last previous edition D 4958 - 89.

² *Annual Book of ASTM Standards*, Vol 06.01.

³ Available from Federation of Societies for Coatings Technology, 492 Norristown Rd., Blue Bell, PA 19422.

⁴ Supporting data are available from ASTM Headquarters. Request RR: D01-1072.

⁵ Leneta Form 8H-BW, obtainable from The Leneta Co., P.O. Box 86, Ho-Ho-Kus, NJ 07423, has been found satisfactory for this purpose.

8.3 Multiply the density by 1.221 to obtain the weight of paint in grams to apply on the specified test chart to obtain a spreading rate of 400 ft²/gal (9.82 m²/L).

8.4 *Conditioning of the Brush:*

8.4.1 Soak the brush in clean water, then spin rapidly to remove the water from the bristles as completely as possible.

8.4.2 In order to equalize the amount of paint contained on the brush, dip the brush into the can to take up a normal brush load and paint out approximately 1/2 ft² (0.05 m²) of a reasonably well sealed surface (for example, any previously painted test chart).

8.4.3 Repeat 8.4.2 utilizing another dry surface.

8.5 Place the test chart on the balance and weigh the correct amount of paint as calculated in 8.3 directly onto the center of the card.

8.6 Immediately tape the card onto a hard, flat surface, start the stopwatch, and proceed to spread the paint using the previously conditioned 2-in. (50-mm) brush. Using long, steady brush strokes, alternately parallel and perpendicular to the edge of the chart, cover the test area uniformly and completely in 30 to 35 s.

8.7 Immediately assign and record a brush drag rating according to the following series of qualitative descriptive terms, first characterizing it by a verbal description, and then by the corresponding number.

- 1—Very slight
- 2—Slight
- 3—Slight to moderate
- 4—Moderate
- 5—Moderate to considerable
- 6—Considerable
- 7—Considerable to pronounced
- 8—Pronounced
- 9—Very pronounced
- 10—Extreme

8.8 Thoroughly clean the brush with warm water and spin to remove excess water between tests.

8.9 Repeat 8.2 through 8.8 for each specimen in the set

and rate the specimen as the mean of the two results.

8.10 If more than one specimen has the same rating, brush out the similarly rated specimens again, in close comparison. If small differences are perceived, then indicate these by assigning intermediate decimal values. If no difference is found then the original ratings stand.

9. Interpretation of Results

9.1 Tabulate the paints in order of their brush drag ratings, showing verbal descriptions and numerical ratings in separate columns.

9.2 In a fourth rank order column, rank the paints from 1 to *n* (least to most brush drag), where *n* is the total number of paints in the series.

9.3 Paints with the same qualitative ratings should be assigned multiple rank numbers, with the mean of those numbers shown in parentheses, for example, 3 to 4 (3.5), 5 to 7 (6). The mean ranking value (in parentheses) is used to calculate an average ranking value when the same series of paints is ranked by more than one operator.

10. Report

10.1 Report the brush drag ranking as determined in Section 9.

11. Precision and Bias

11.1 In an interlaboratory study of this test method in which five coatings varying widely in brush drag were ranked by one operator in each of nine laboratories, two operators in one laboratory, and three operators in another laboratory, the coefficient of concordance (agreement in ranking) was found to be 0.84, reflecting the fact that seven of the fourteen operators agreed perfectly and four others reversed one of two adjacent pairs. The coefficient is statistically significant at the 99.9 % confidence level.

11.2 Bias has not been determined for this test method.

12. Keywords

12.1 brush drag; high shear viscosity; brushability; ease of brushing; drag

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Standard Test Method for Evaluation of Color for Thermoplastic Traffic Marking Materials¹

This standard is issued under the fixed designation D 4960; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the instrumental determination of color of thermoplastic traffic marking materials in the CIE 1931 system.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

3. Terminology

3.1 **Definitions**—Definitions are in accordance with Definitions D 883, E 284 and F 412, unless otherwise indicated.

3.2 Descriptions of Terms Specific to This Standard:

3.2.1 **thermochromism**—a color hue change that takes place in the thermoplastic material due to temperature changes.

3.2.2 **thermoplastic traffic marking material**—a highly filled 100 % total solids highway marking material that when heated to a molten state can be extruded or sprayed onto a road surface and when cooled forms a solid, durable delineator.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is under the direct responsibility of Subcommittee D01.44 on Traffic Coatings.

Current edition approved June 30, 1989. Published August 1989.

² Annual Book of ASTM Standards, Vol 08.01.

³ Annual Book of ASTM Standards, Vols 06.01 and 14.02.

⁴ Annual Book of ASTM Standards, Vol 14.02.

⁵ Annual Book of ASTM Standards, Vol 08.04.

4. Summary of Test Method

4.1 The thermoplastic specimen is prepared for this test by melting a sample to its application temperature under continuous agitation and then pouring it into a TFE-fluorocarbon coated pan, to form a patty of approximately 3 in. (7.6 cm) in diameter. The patty is allowed to cool to room temperature before measuring the color. Color measurements are made on the flat side or the top side of the thermoplastic patty.

NOTE 1—No significant color differences are encountered in reading the top or bottom of the patty.

5. Significance and Use

5.1 This test method provides a standard procedure for the determination of color of thermoplastic traffic marking materials. This test method can be used in conjunction with specifications to determine the uniformity of thermoplastic traffic marking materials from batch to batch and that produced by various suppliers.

5.2 There is a slight variation in color standards and colorimeters. This test method is only applicable when results are reported with the instrument model designation and white color calibration standard identification information.

6. Sampling

6.1 Samples may be obtained by an appropriate quartering or riffle sampling method where deemed necessary considering the physical form of the material.

7. Apparatus

7.1 **Agitator Blade**, 6 in. (15 cm) long with a 1/2-in. (1-cm) steel shaft and a 1 3/4 by 1 by 1/8-in. (4.5 by 2.5 by 0.3-cm) straight horizontal steel blade.

7.2 **Drill Press**, or other apparatus capable of agitating the thermoplastic marking material in the electric pots at 600 to 700 r/min during meltdown to the application temperature.

7.3 Heating Equipment:

7.3.1 **Gravity Convection Oven**, capable of maintaining 260°C, for melting the thermoplastic traffic marking.

7.3.2 **Hot Plate**, capable of maintaining 537°C.

7.3.3 **Insulated Electric Pots**, for heating and melting the thermoplastic traffic marking materials.

7.4 **Color Measuring Instrument**, conforming to all requirements of Test Method E 97, Practices E 179 and E 1164, and Method E 308 (geometry 45°/0°, illuminant C, 2° observer).

7.5 **Spatulas**, for stirring the thermoplastic traffic marking

during meltdown on the hot plate or in the gravity convection oven.

7.6 TFE-fluorocarbon Baking Pans or Uncoated Pint Can Lids, for forming 3-in. (7.6-cm) diameter patties.

8. Procedure

8.1 Taking care to prevent scorching of the material, melt a 1000 ± 50 -g sample of the thermoplastic marking material to a temperature of 218°C under continuous agitation, by one of the following means:

8.1.1 On a hot plate set at 537°C and using a spatula as the means of agitation.

8.1.2 In an insulated electric pot with a heat setting sufficient to reach the test temperature and with agitation of 600 to 700 r/min from an electric drill press or other suitable means.

8.1.3 In an oven set at 260°C with agitation by stirring with a spatula after the first 15 min and thereafter at 15-min intervals. The first stirring at 15 min is critical to prevent scorching of the thermoplastic marking material. The sample must be completely wet in on the first stir to ensure even melting and complete blending of the components of the thermoplastic material.

8.2 Pour the thermoplastic sample into a clean, TFE-fluorocarbon-lined pan, to form a 3-in. (7.6-cm) diameter patty. If a TFE-fluorocarbon pan is not available, pour the sample into an uncoated pint tin lid to form a 3-in. diameter patty. Before pouring the patty, the sample must be agitated well to prevent settling of the components and to provide a smooth homogeneous surface for color measurement.

8.3 Allow the patty to cool to room temperature for a minimum of 30 min and not to exceed 45 min.

NOTE 2—A 30 ± 5 -min conditioning of the patty negates the initial effects of thermochromism.

8.4 Calibrate the color measuring instrument with a white calibration color standard according to the instructions supplied by the manufacturer.

8.5 Remove the patty from the TFE-fluorocarbon pan and read the color measurement values from the flat smooth side. If a pint tin lid is used then read the top of the patty. Without removing the patty from the sample port immediately take three readings. Record only the third reading for each Y, x, and y value to further compensate for any thermochromism of the thermoplastic marking material.

8.6 A small port adapter, if available, for the color measuring instrument of approximately $\frac{3}{4}$ in. (19 mm) may be used to negate the effects of geometry and texture when reading the patties. This will measure in between small surface imperfections characteristic of thermoplastic traffic marking.

9. Report

9.1 Report the following information:

9.1.1 The formula code, batch number, formula type, and color for each patty read.

9.1.2 The type of color measuring instrument used and the identification of the white color calibration standard, and

9.1.3 The exact cooling period and values Y, x and y for each sample.

10. Precision and Bias

10.1 No general statement of precision can be made because of lack of sufficient data at this time.

10.2 No statement of bias can be prepared for this test method since there is no absolute test method for use as a comparative basis.

11. Keywords

11.1 thermoplastic traffic marking; color measurement.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Wet-to-Dry Hiding Change¹

This standard is issued under the fixed designation D 5007; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

1. Scope

1.1 This test method covers the determination of the change in hiding power of an architectural coating during drying, by visual evaluation of the wet and dry film.

1.2 This test method is not recommended for colors other than white and tints.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 2805 Test Method for Hiding Power of Paints by Reflectometry²

D 3924 Specification for Standard Environment for Conditioning and Testing Paint, Varnish, Lacquer, and Related Materials²

3. Terminology

3.1 Descriptions of Terms Specific to This Standard:

3.1.1 *hiding index, h_s* —the Spreading Index at a standard film opacity. In this test method the latter is a visual contrast standard prepared by applying a semi-opaque white coating on a black and white hiding-power chart to give a contrast ratio of 0.98 which is just short of complete hiding, and is the conventional so-called *full hiding* end point in photometric hiding-power methods such as Test Method D 2805. Refer to the hiding indices of the wet and dry films as h_{sw} and h_{sd} respectively.

3.1.1.1 *Discussion*—Since this test method is intended to measure hiding-power difference rather than hiding power itself, a 98 % contrast ratio standard is not required. It is necessary only that the same standard be used for measuring both wet and dry films. See 3.1.8.1. For this purpose the standard needs to lie within the contrast range of both the wet and dry stripes, which will be true of the 98 % contrast-ratio standard for most commercial paints. With paints of unusually low hiding, a lower contrast standard may be required, which can be simply one of the stripes taken from a drawdown of the test paint.

3.1.2 *hiding power*—the spreading rate of a paint applied uniformly on a standard black and white hiding power chart

to give a standard degree of contrast just short of complete hiding.

3.1.2.1 *Discussion*—In reflectometry the standard contrast for hiding power measurements is generally accepted as the contrast ratio $C = 0.98$, which with white and light tinted coatings is equivalent to a visual color difference of about 0.75 CIELAB units. That amount of color difference can reasonably be described as “just-short-of complete-hiding.” Since this is a visual method it employs a visual comparator as a standard, which is a hiding power chart with a white coating applied at a contrast ratio of 0.98.

3.1.3 *logicator*—a multi-notch applicator with clearances, and corresponding wet film thicknesses and spreading rates, in equal percentage steps.

3.1.4 *logicator scale*—a scale whose values are in direct, linear relationship with the logarithms of corresponding spreading rates. A specified change in scale value represents the same percentage change in spreading rate over any part of such a scale.

3.1.5 *spreading index, h* —the spreading rate expressed in logicator scale units (LU) as described in 3.1.4 and 4.1.7.

3.1.6 *spreading rate, H* —the area covered per unit quantity of coating. (In this test method the quantity is volumetric).

3.1.7 *TG19 logicator*—a logicator designed for this test method with eight notches numbered at four-unit intervals on a scale from 20 to 48, the notch clearances ranging from 2.65 to 10.4 mils (67 to 264 μm) corresponding to wet film thicknesses from 1.46 to 5.7 mils (37 to 145 μm) and spreading rates from 280 to 1100 ft^2/gal (6.9 to 27 m^2/L), with one scale unit representing a change of 5 % and the four-unit interval between notches a cumulative change of 21.55 % in the clearance and corresponding film thicknesses and spreading rates. Refer to this scale unit as a logicator unit (LU). (See Fig. 1.)

3.1.7.1 *Discussion*—The percentage difference between notches is calculated as $(1.05^4 - 1) \times 100 = 21.55$. This percentage is applicable precisely to the notch clearances and approximately to their related wet-film thicknesses and spreading rates. The detailed relationships between scalar value and the notch clearance, wet film thickness, and spreading rate are given in Tables 1 and 2.

3.1.8 *wet-to-dry hiding change (WDHC)*—the difference in the Hiding Index of a paint between the wet and the dry state, expressed in logicator units (LU) as follows:

$$\text{WDHC} = \Delta h_s = h_{sd} - h_{sw}$$

3.1.8.1 *Discussion*—The WDHC is unchanged if the contrast level of the hiding standard is varied, because the resultant changes in the two hiding power values will be proportional and their ratio therefore constant.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.42 on Architectural Finishes.

Current edition approved October 27, 1989. Published December 1989.

² Annual Book of ASTM Standards, Vol 06.01.

FIG. 1 Diagram of the Leneta TG19 Logicator

3.1.8.2 Discussion—The WDHC is unaffected by deviations from the estimated film thickness/clearance ratio T/N (see Note, Table 1), because the ratio of the two recalculated hiding-power values is unchanged.

Summary of Test Method

4.1 The test paint is applied with a TG19 Logicator on a logicator test chart (see 6.2 and Fig. 2) and the drawdown examined in comparison with an agreed hiding standard immediately after application and again after drying.

4.2 The scale numbers of the wet and dry stripes that match the standard in contrast are recorded as the Wet Hiding Index, h_{sw} , and the Dry Hiding Index h_{sd} .

4.3 The difference between the wet and dry hiding indices is recorded as the wet-to-dry hiding change WDHC.

4.4 If desired, the percent change in hiding power corresponding to the WDHC value is calculated and reported.

Significance and Use

5.1 Many architectural paints, particularly white and light tints, change significantly in film opacity as they dry. An increase in hiding is sometimes associated with porosity and poor film integrity with conventionally formulated coatings. A decrease can result in a disappointing paint job. The wet-to-dry hiding change is therefore a property of great practical importance.

5.2 This test method can be used in paint specifications and as a short, simple procedure for evaluation and quality control.

Apparatus

6.1 TG19 Logicator³—A multi-notch, varied-clearance applicator designed specifically for this test method (see 3.1.7 and Fig. 1).

6.2 Logicator Test Charts³—Black and white hiding charts with a chevron-stripe pattern and scale numbers printed at the top corresponding to the paint stripes applied by the Logicator (see Fig. 2).

6.3 Vacuum Plate, for holding the chart flat while the drawdown is made.

6.4 Visual Hiding Standard⁴—A narrow stripe cut from a logicator test chart on which a durable glossy white coating had been applied to obtain a contrast ratio of 0.98. The stripe

TABLE 1 Equations Relating the Logicator Scale Value or Spreading Index, h , to the Notch Clearance, N , Wet Film Thickness, T , and Spreading Rate, H

NOTE—The relationships involving T and H are based on a presumed T/N ratio of 0.55, which ratio is approximate and somewhat variable, depending on coating rheology, drawdown technique, and clearance.

Inch-Pound Units (mils, ft ² /gal):	Metric Units (μ m, m ² /L):
$N = 1.05^{68-h} = 27.6 + 1.05^h$	$N = 25.4 \times 1.05^{68-h} = 701 + 1.05^h$
$h = 68 - 47.2 \log N$	$h = 134.3 - 47.2 \log N$
$T = 0.55 N = 15.18 + 1.05^h$	$T = 0.55 N = 385.5 + 1.05^h$
$h = 55.75 - 47.2 \log T$	$h = 122.05 - 47.2 \log T$
$H = 105.7 \times 1.05^h$	$H = 2.594 \times 1.05^h$
$h = 47.2 \log H - 95.52$	$h = 47.2 \log H - 19.54$

is mounted on a blank card for convenient handling, as illustrated in Fig. 3.

Procedure

7.1 Prepare a hiding standard as described in 6.4, or use the standard supplied with the logicator test charts.

NOTE 1—Strong colors were measured according to this test method using standards prepared with the self-same coatings. Some measurements were also made using the regular white standard. Due to poor correlation in these tests it was decided to exclude strong colors from the scope of the test method. However, should measurements with such colors be attempted anyway, it is of interest to note that the white standard apparently served as well for that purpose as a standard made with the identical color.

7.2 Place a test chart on the vacuum plate. Then place the logicator at the top of the chart with its arms extending toward the operator.

7.3 Spread about 6 mL of the test paint evenly in front of the logicator, then draw down the full length of the chart (about 10 in. (254 mm)) at a uniform speed such that the total drawdown time is about 2.5 to 3 s.

7.4 Promptly after film application, determine the Wet Hiding Index (h_{sw}) in accordance with 7.5.

7.5 Observation of the Hiding Index (h_s):

7.5.1 Place the chart vertically in a well-illuminated glare-free location.

7.5.2 Hold the hiding standard next to the chart and identify by number the stripe that the standard matches in contrast. This number is the Hiding Index.

7.5.3 If there is no exact match and it is difficult to decide which of two adjacent stripes is matched more closely, record their mean as the Hiding Index. However, if the standard is perceived as closer to one or the other of the two stripes, then report the Hiding Index as one more than the lower or one less than the higher, as the case may be.

7.6 Immediately after determining the Wet Hiding Index (h_{sw}), place the drawdown horizontally in a well-ventilated, dust-free location, as specified in Specification D 3924, and allow to dry for 40 to 48 h. Then repeat 7.5 to determine the Dry Hiding Index (h_{sd}).

7.7 Make drawdowns in triplicate and calculate the mean index value to 0.1 units. Individual values that deviate from the mean by more than 1.5 units should be discarded and the test repeated.

Calculation

8.1 Subtract the Wet Hiding Index, h_{sw} from the Dry

^A Boldface values refer to notches in TG19 Logicator.

^B Target values are significant to one decimal place.

^C Based on wet film thickness estimated at 55 % of clearance.

Hiding Index, h_{SD} , to obtain the wet-to-dry hiding change (WDHC), Δh_s , as follows:

$$WDHC = \Delta h_s = h_{SD} - h_{SW}$$

The value for WDHC is positive for an increase and negative for a decrease in hiding. To avoid possible misunderstanding write the sign of the change (+ or -) in every case.

8.2 If desired, calculate the corresponding percent change in wet-to-dry hiding power as follows:

$$WDHC\% = (1.05^{WDHC} - 1) \times 100$$

9. Report

9.1 Report the following information:

9.1.1 The Wet-to-Dry Hiding Change (WDHC) in logicator units (LU) to one decimal place, as described in 8.1, and

9.2 If desired, the percent change in conventional hiding power (WDHC%), calculated as shown in 8.2.

10. Precision and Bias

10.1 In an interlaboratory study of this test method, two operators in each of two laboratories and one operator in each of six laboratories, tested in triplicate five coatings with

a wide range in wet-to-dry hiding change. Since the test was not repeated, the repeatability data is only for replicates. On this basis the intralaboratory standard deviation was 0.77 LU with 85 df and the interlaboratory standard deviation was 1.97 LU with 39 df. Based on these standard deviations the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

10.1.1 *Repeatability (Replicate)*—Three replicates by the same operator should be considered suspect if they differ by more than 2.6 LU.

10.1.2 *Reproducibility*—Two results, each the mean of triplicates, obtained by different operators should be considered suspect if they differ by more than 5.7 LU.

10.2 *Bias*—This test method has no bias because there is no criterion for the property it measures more valid than the test method itself.

NOTE 2—In the statistical analysis results were discarded on the following basis: (1) all results from one operator who appeared to be less sensitive than the other operators in detecting differences among triplicates, (2) one replicate result from one laboratory because the triplicate range was significantly higher than for other laboratories, and (3) all three results from the same laboratory for another paint, because the mean differed significantly from other means for that paint.

11. Keywords

11.1 hiding power; wet-to-dry hiding change

FIG. 2 Logicator Test Application

NOTE—For illustration only. Shading is not accurate.

FIG. 3 Visual Hiding Standard

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Evaluating and Comparing Transfer Efficiency Under Laboratory Conditions¹

This standard is issued under the fixed designation D 5009; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

1.1 This test method covers the evaluation and comparison of the transfer efficiency of spray-applied coatings under controlled laboratory conditions.

1.2 This test method has been shown to yield excellent intralaboratory reproducibility. Interlaboratory precision is poorer and is highly dependent on closely controlled air flow in the spray booth, the rate at which the paint is delivered to the part, and other variables suggested in the test method.

1.3 Limitations:

1.3.1 This laboratory procedure only indicates the direction of the effect of spray variables on transfer efficiency. The magnitude of the effect is determined only by specific plant experience.

NOTE 1—This laboratory procedure requires specific equipment and procedures. For those laboratories that do not have access to the type of equipment required a more general laboratory procedure is being prepared as Procedure B.

1.4 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For specific hazard statements, see Section 7 and Notes 2 and 3.*

2. Referenced Documents

2.1 ASTM Standards:

D 1200 Test Method for Viscosity by Ford Viscosity Cup²

D 2369 Test Method for Volatile Content of Coatings²

2.2 National Fire Protection Association Documents³

NFPA 33 Spray Application Using Flammable and Combustible Materials

NFPA 86 Standard for Ovens and Furnaces

3. Terminology

3.1 Descriptions of Terms Specific to This Standard:

3.1.1 *conveyor speed*—the speed of the conveyor in centimeters per minute during the test.

3.1.2 *fluid mass flow rate*—the mass flow rate of paint in grams per minute during the test.

3.1.3 *mass of foil*—the weight of each target foil in grams before being painted.

3.1.4 *mass of foil plus paint solids*—the weight of each target foil in grams after being painted and baked.

3.1.5 *mass of paint solids*—the difference in the mass of the foils before painting and the mass of the foils after painting and baking. This is the sum of the mass of the foil plus paint solids less the sum of the mass of the foil.

3.1.6 *transfer efficiency*—the ratio of the mass of the paint solids deposited on the foil to the mass of the paint solids sprayed during the test expressed as a percent.

3.1.7 *weight percent solids*—the solids content in percent of the total weight of a sample of the paint used during the test.

4. Summary of Test Method

4.1 Metal panels covered with preweighed aluminum foil are conveyed in a spraybooth past a fixed spraygun. The coated foils are then baked to remove volatile matter. The transfer efficiency is calculated on a weight basis using the solids content and quantity of the paint sprayed and the amount of solids on the coated aluminum foil target.

5. Significance and Use

5.1 Subject to the limitations listed above, the procedure can be used as a research tool to optimize spray equipment and paint formulations as well as to study the relative effect on transfer efficiency of changing operating variables, spray application equipment, and types of coatings.

6. Apparatus

6.1 *Laboratory Scale*, accurate to ± 0.001 g for weight percent solids determination.

6.2 *Platform Scale*, accurate, or equivalent, to ± 0.01 g for mass of foil, mass of foil plus paint, and mass flow rate instrumentation calibration.

6.3 *Mass Flow Rate Meter*, or mass flow rate determination method, accurate to $\pm 2\%$ of the mass flow rate to be used during the test.

6.4 *Conveyor Timer* or conveyor timing method, accurate to $\pm 1\%$ of the conveyor speed to be used during the test. The equipment may consist of photoelectric cells or limit switches used in conjunction with a digital timer or timing marks on the conveyor used in conjunction with a stopwatch. Take at least two readings with a stopwatch and average the readings.

6.5 *Targets*, consisting of a set of ten steel panels 6 in. (15.2 cm) wide by 0.0625 in. (0.15875 cm) with 0.25-in.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.55 on Factory-Applied Coatings on Preformed Products.

Current edition approved October 27, 1989. Published December 1989.

² *Annual Book of ASTM Standards*, Vol 06.01.

³ Available from National Fire Protection Assn., Battery March Park, Quincy, MA 02269.

(0.635-cm) radius corners. A minimum panel length of 48 in. (121.9 cm) should be used. The length of the panel should be set so that a minimum of 12 in. (30.4 cm) above and below the spray pattern is achieved.

6.5.1 It is essential to do this so that the entire height of the spray pattern is effectively captured.

6.6 *Aluminum Foil*, medium temper or equivalent, 1.5 mil (0.0037 cm) thick.

6.7 *Back-Draw Water Wash Spray Booth*, or equivalent. The booth should be a minimum of 6 ft (1.8 m) wide and capable of up to 120 ft/min (0.61 m/s) air velocity in the middle at the plane of the target. If a dry filter booth is used, filters should be changed as necessary to maintain uniform air velocity.

6.8 *Adjustable Rate Overhead Conveyor System*, capable of hanging targets as specified, and capable of up to 40 ft/min (0.20 m/s) or the maximum speed desired by the user.

6.9 *Forced Draft Curing Oven*, of sufficient size for curing targets, and capable of achieving and maintaining the cure temperatures specified by the paint supplier. All ovens should conform to NFPA 86.

6.10 *Curing Rack*.

6.11 *Stopwatch*.

6.12 *Air Velocity Measurement Equipment*.

6.13 *Humidity and Temperature Measurement Equipment*.

6.14 *Compressed Air Supply*.

7. Hazards

7.1 For specific hazard information and guidance, consult the supplier's Material Safety Data Sheet (MSDS) for the materials used.

8. Procedure

8.1 Set up the spray apparatus paint supply and the mass flow measurement equipment in accordance with the manufacturer's instructions.

8.1.1 In accordance with Chapter 9-11 of NFPA 33, all electrically conductive objects in the spray area, except those objects required by the process to be at high voltage, shall be adequately grounded.

8.2 Agitate paint in a closed container at least 30 min before any paint samples are taken.

8.3 Using an airtight container take a paint grab sample from the paint pot in accordance with Practice D 3925.

8.4 Determine and record the following from the paint sample:

8.4.1 Viscosity determined in accordance with Test Method D 1200.

8.4.2 Weight percent solids determined in accordance with Test Method D 2369. If the baking temperature in Test Method D 2369 is inadequate, use the manufacturers recommended cure schedule.

8.4.3 Resistivity for the samples being applied electrostatically (An ASTM method is under development).

8.5 Set up the conveyor speed measuring equipment.

8.6 Cut the aluminum foil to dimensions of 15 in. (38 cm) by approximately 50 in. (127 cm) or 2 in. (5 cm) longer than the length of the target panel.

8.7 Consecutively number each precut foil strip before weighing using a permanent marking pen.

FIG. 1 Foil Attachment Technique

8.8 Weigh each test foil strip and record the uncoated weight and the foil number.

8.9 Attach the preweighed, labeled test foil to six targets using the technique shown in Fig. 1. Attach the unlabeled foil on four scavenger targets as shown in Fig. 1.

8.10 Mount the foil covered targets in consecutive order as shown in Fig. 2, with the foil seam on each target facing away from the spray gun.

8.10.1 If electrostatic equipment is being used the resistance shall be less than $1 \text{ by } 10^6 \Omega$ between the target and the earth ground in accordance with Chapter 9-8 of NFPA 33.

8.11 Adjust the following equipment operating parameters to the values desired for testing:

8.11.1 Paint fluid pressure (kilopascals) at spray gun.

8.11.2 Atomizing air pressure (kilopascals) at spray gun.

8.11.3 Rotating atomizer head speed (revolutions per minute) with and without paint fluid flow.

8.11.4 Operating voltage (kilovolts) if electrostatic equipment is used.

8.11.5 Ambient air temperature (degree Celsius).

8.11.6 Paint fluid temperature (degree Celsius).

8.11.7 Booth air velocity (feet per minute).

8.11.8 Relative humidity (percent).

8.11.9 Spray gun to target distance (centimeters).

NOTE 2: Precaution—If electrostatic equipment is being used, the gun-to-target distance shall be at least twice the sparking distance in accordance with Chapter 9-7 of NFPA 33.

8.11.10 Conveyor speed (centimeters per second).

8.11.11 Fluid mass flow rate (grams per minute).

8.11.12 Set the cure time and temperature in accordance with the manufacturer's instructions.

FIG. 2 Target Configuration for Transfer Efficiency Determination

8.12 For electrostatic spray equipment, measure the operating voltage and adjust it according to the manufacturer's instructions.

8.13 Turn on the spray booth and conveyor. At least 15 s before the first scavenger target passes in front of the gun, turn on the paint spray equipment. Maintain uniform paint flow during the test.

8.13.1 If mass flow measurement is used, begin the flow measurement at the leading edge of the first scavenger target and stop the mass flow measurement at the trailing edge of the last scavenger target.

8.13.2 If mass flow measurement equipment is not available use the following technique. Just before turning on the spray booth and the conveyor, spray the gun into a preweighed covered plastic container for a minimum of 30 s.

NOTE 3: Precaution—In addition to other precautions, turn off all high voltage to electrostatic spray guns to prevent personal injury.

8.13.3 Immediately weigh the container with paint, calculate the flow rate, and record the result. Just after turning off the spray booth and conveyor, repeat this procedure. Average the two results to obtain the average flow rate for the test.

NOTE 4—A gallon plastic bottle with the top cut off to conveniently fit around the front of the gun is recommended to use with the above procedure. A large plastic beaker covered with plastic wrap with a hole punched in the center of the plastic wrap works also.

Turn off all air sources to the spray gun before using the above procedure to prevent paint splattering out of the container.

8.14 Record the following data:

8.14.1 Application Equipment:

8.14.1.1 Paint fluid pressure (kilopascals) at the spray gun,

8.14.1.2 Atomizing air pressure (kilopascals) at the spray gun,

8.14.1.3 Rotating atomizer head speed (revolutions per minute) with and without paint fluid flow, and

8.14.1.4 Operating voltage (kilovolts) if electrostatic equipment is used.

8.14.2 Spray Booth and Conveyor:

8.14.2.1 Ambient temperature (degrees Celsius),

8.14.2.2 Paint fluid temperature (degrees Celsius),

8.14.2.3 Booth air velocity (foot per minute),

8.14.2.4 Relative humidity (percent),

8.14.2.5 Spray gun to target distance (centimeters),

8.14.2.6 Conveyor speed (centimeters per minute), and

8.14.2.7 Fluid mass flow rate (grams per minute).

8.15 After the paint flow and the conveyor are stopped, remove the painted targets from the conveyor and ensure that no paint is lost. Measure the wet film thickness to ensure that the proper amount of paint has been applied and record the wet film thickness.

8.16 Securely hang the coated targets on oven racks so all painted surfaces are exposed for uniform drying. Insert the racks into the oven and bake at the recommended manufacturer's cure schedule.

8.17 Remove the targets from the oven and let cool.

8.18 Remove the foil from each target, weigh and record the coated weight, the foil number, the percent vertical film coverage, and the dry film thickness at the center of the spray pattern.

8.19 The mass of the paint solids deposited is the difference in the total weight of the foils before painting and the total weight of the foils after painting and baking.

9. Calculation

9.1 Calculate the transfer efficiency using the following equation:

$$T = (100 \times C \times P) / (F \times S \times W)$$

where:

T = transfer efficiency, %

C = conveyor speed, cm/min,

P = mass of paint solids deposited, g,

F = fluid delivery rate, g/min,

S = weight percent solids expressed as a decimal, and

W = effective target width, 30.48 cm.

10. Report

10.1 Report the following information:

- 10.1.1 Transfer efficiency results,
- 10.1.2 Type of spray equipment,
- 10.1.3 Type of paint applied,
- 10.1.4 Paint application conditions, and
- 10.1.5 Conditions of test other than those specified in the procedure section of this test method.

11. Precision

11.1 This test method is derived from a study and report of transfer efficiency measurements conducted for the U. S. Environmental Protection Agency.⁴ The procedure described was subjected to round-robin evaluation following ASTM guidelines. The procedure was used at eight laboratories and results were obtained using conventional airless,

electrostatic air spray, and conventional air spray equipment. Statistical treatment of the results for the test sites and spray equipment type (gun) yields the following transfer efficiency results:

Type of Gun	Variance	Standard Deviation
<i>Conventional airless:</i>		
Within laboratory	1.22	1.10
Between laboratory	26.41	...
Gun	6.22	...
Total	33.85	5.82
<i>Electrostatic Air Spray:</i>		
Within laboratory	3.63	1.91
Between laboratory	72.02	...
Gun	13.01	...
Total	88.66	9.42
<i>Conventional Air Spray:</i>		
Within laboratory	2.30	1.50
Between laboratory	42.90	...
Gun	0.88	...
Total	46.08	6.79

12. Keywords

12.1 laboratory method; spray applied coatings; transfer efficiency

⁴ Development of Proposed Standard Test Method for Spray Painting Transfer Efficiency, Vols I and II, EPA Publication Nos. EPA-600/2-88-026a and EPA-600/2-88-026b, Environmental Protection Agency, Research Triangle Park, NC.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Guide for Testing Printing Inks and Related Materials¹

This standard is issued under the fixed designation D 5010; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide covers a list of test methods, practices, and specifications that can be used for the testing and evaluation of printing inks, printed ink films, and substrates used in their production (see Table 1).

1.2 This guide includes methods that were developed to test paints, paint films, and substrates, but may be adapted for use in testing printing inks and printed matter. Tests on raw materials and analytical methods in general have not been included.

NOTE 1—For the purpose of this guide, clear coatings such as overprint varnishes are classed as printing inks.

1.3 Other ASTM standards not specified here may also be applicable.

2. Terminology

2.1 Definitions:

2.1.1 *printing ink*—a colored or pigmented liquid or paste composition that dries to a solid film after application as a thin layer by printing machinery.

2.1.1.1 *Discussion*—Printing inks may contain vehicles, colorants, waxes, solvents, and other additives. Bulk inks are tested for dispersion, tinting strength, density, heat and storage stability, rheology, and printing properties.

2.1.2 *printed ink film*—thin layer of a printing ink deposited onto a substrate by means of a laboratory or production printing press, occasionally by a drawdown or roll-out technique. Printed matter is the usual medium by which inks are tested for appearance properties, drying, and resistance to various agents.

2.1.3 *printing substrate*—material onto which ink is deposited in the production of printed matter. Printing substrates include paper, paperboard, plastic film, glass, and metallic surfaces. In this guide, standards relating to substrates are largely restricted to properties associated with appearance and printability.

3. Test Categories

3.1 For convenience in selection, the test methods, practices, and specifications, listed in this guide are classified into three groups by type of printing process and in subgroups indicating whether the test is conducted on a bulk ink, a printed ink film, or a substrate (see Table 2). The group is given in the left column preceding the test method reference. The classification are as follows:

3.1.1 Group 1—Applicable in General:

Class A—Bulk inks.

Class B—Printed ink films.

Class C—Substrates.

3.1.2 Group 2—Applicable to Low Viscosity or Liquid Inks Associated With Flexography or Gravure:

Class A—Bulk inks.

Class B—Printed ink films.

Class C—Substrates.

3.1.3 Group 3—Applicable to High Viscosity or Paste Inks Associated With Letterpress, Lithography, or Silk Screen:

Class A—Bulk inks.

Class B—Printed ink films.

Class C—Substrates.

4. Precision and Bias

4.1 If available, precision for each test method listed can be found in the latest revision of that test method.

5. Keywords

5.1 printed matter; printing inks; printing substrates; test methods and practices (tabulation of)

¹ This guide is under the jurisdiction of the ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.56 on Printing Inks.

Current edition approved May 15, 1991. Published July 1991.

ASTM Designation	Volume	Title
D 16	06.01 06.02 06.03	Terminology Relating to Paint, Varnish, Lacquer, and Related Products
D 56	05.03 06.03	Test Method for Flash Point by Tag Closed Tester
D 93	04.09 05.01 06.03	Test Method for Flash Point by Pensky-Martin Closed Tester
D 185	06.01	Test Methods for Coarse Particles in Pigments, Pastes, and Paints
D 344	06.01	Test Method for Relative Dry Hiding Power of Paints by the Visual Evaluation of Brushouts
D 523	06.01	Test Method for Specular Gloss
D 528	15.09	Test Method for Machine Direction of Paper and Paperboard
D 562	06.01	Test Method for Consistency of Paints Using the Stormer Viscometer
D 644	15.09	Test Method for Moisture Content of Paper and Paperboard by Oven Drying
D 685	15.09	Method for Conditioning Paper and Paperboard Products for Testing
D 724	15.09	Test Method for Surface Wettability of Paper (Angle-of-Contact Method)
D 780	15.09	Test Method for Printing Ink Permeation of Paper (Castor Oil Test)
D 869	06.01	Test Method for Evaluating the Degree of Settling of Paint
D 918	15.09	Test Method for Blocking Resistance of Paper and Paperboard
D 971	05.01 10.03	Test Method for Interfacial Tension of Oil Against Water by the Ring Method
D 1200	06.01	Test Method for Viscosity by Ford Viscosity Cup
D 1210	06.01	Test Method for Fineness of Dispersion of Pigment-Vehicle Systems
D 1259	06.02	Test Methods for Nonvolatile Content of Resin Solutions
D 1310	05.01 06.03	Test Method for Flash Point and Fire Point of Liquids by Tag Open-Cup Apparatus
D 1316	06.01	Test Method for Fineness of Grind of Printing Inks by the NPRI Grindometer
D 1331	15.04	Test Methods for Surface and Interfacial Tension of Solutions of Surface-Active Agents
D 1353	06.03	Test Method for Nonvolatile Matter in Volatile Solvents for Use in Paint, Varnish, Lacquer, and Related Products
D 1474	06.01	Test Methods for Indentation Hardness of Organic Coatings
D 1475	06.01	Test Method for Density of Paint, Varnish, Lacquer, and Related Products
D 1535	06.01	Test Method for Specifying Color by the Munsell System
D 1544	06.01 06.02 06.03	Test Method for Color of Transparent Liquids (Gardner Color Scale)
D 1545	06.01	Test Method for Viscosity of Transparent Liquids by Bubble Time Method
D 1590	11.01	Test Methods for Surface Tension of Water and Waste Water
D 1640	06.01	Test Methods for Drying, Curing, or Film Formation of Organic Coatings at Room Temperature
D 1644	06.01	Test Methods for Nonvolatile Content of Varnishes
D 1647	06.01	Test Methods for Resistance of Dried Films of Varnishes to Water and Alkali
D 1653	06.01	Test Methods for Water Vapor Permeability of Organic Coating Films
D 1725	05.02	Test Method for Viscosity of Resin Solutions
D 1729	06.01	Practice for Visual Evaluation of Color Differences of Opaque Materials
D 1849	06.01	Test Method for Package Stability of Paint
D 1963	06.03	Test Method for Specific Gravity of Drying Oils, Varnishes, Resins, and Related Materials at 25/25°C
D 2066	06.01	Test Methods for Relative Tinting Strength of Printing Ink Dispersions
D 2091	06.01	Test Method for Print Resistance of Lacquers
D 2196	06.01	Test Methods for Rheological Properties of Non-Newtonian Materials by Rotational (Brookfield) Viscometer
D 2243	06.01	Test Method for Freeze-Thaw Resistance of Water-Borne Coatings
D 2244	06.01	Test Method for Calculation of Color Differences from Instrumentally Measured Color Coordinates
D 2248	06.01	Practice for Detergent Resistance of Organic Finishes
D 2337	06.01	Test Method for Freeze-Thaw Stability of Multicolor Lacquers
D 2369	06.01	Test Method for Volatile Content of Coatings
D 2482	15.09	Method for Wax Pick Test for Surface Strength of Paper
D 2574	06.01	Test Method for Resistance of Emulsion Paints in the Container to Attack by Microorganisms
D 2578	08.02	Test Method for Wetting Tension of Polyethylene and Polypropylene Films
D 2616	06.01 14.02	Test Method for Evaluation of Visual Color Difference with a Gray Scale
D 2620	06.01	Test Method for Light Stability of Clear Coatings
D 2794	06.01	Test Method for Resistance of Organic Coatings to the Effects of Rapid Deformation (Impact)
D 2805	06.01	Test Method for Hiding Power of Paints by Reflectometry
D 3134	06.01	Practice for Establishing Color and Gloss Tolerances
D 3258	06.01	Test Method for Porosity of Paint Films
D 3278	06.03	Test Methods for Flash Point of Liquids by Setflash Closed-Cup Apparatus
D 3359	06.01	Test Methods for Measuring Adhesion by Tape Test
D 3363	06.01	Test Method for Film Hardness by Pencil Test
D 3424	06.01	Method of Evaluating the Lightfastness of Printed Matter
D 3732	06.01	Practice for Reporting Cure Times of Ultraviolet-Cured Coatings
D 3825	05.03	Test Method for Dynamic Surface Tension by the Fast Bubble Technique
D 3828	05.03	Test Method for Flash Point by Setflash Closed Tester
D 3924	06.01	Specification for Standard Environment for Conditioning and Testing Paint, Varnish, Lacquers, and Related Materials
D 3925	06.01	Practice for Sampling Liquid Paints and Related Pigmented Coatings
D 3928	06.01	Test Method for Evaluation of Gloss or Sheen Uniformity
D 3934	06.03	Test Method for Flash/No Flash Test—Equilibrium Method by a Closed-Cup Apparatus

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Conducting Tests on Paints and Related Coatings and Materials Using Enclosed Carbon-Arc Light and Water Exposure Apparatus¹

This standard is issued under the fixed designation D 5031; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

1.1 This practice covers accelerated exposure testing of paint, varnish, lacquer, and related products. The apparatus types available are single enclosed carbon arcs (Types H and EH) and twin enclosed carbon arcs (types D and DH). Both types are manufactured with or without automatic humidity control.² Table 1 describes commonly used test conditions. Interlaboratory comparisons *must* only be made using the same device type and test conditions.

1.2 The procedures described in this practice were previously included in Practice D 822, which covered the use of both filtered open flame and enclosed carbon arcs for testing paints, varnishes, lacquers, and related products.

NOTE 1—Another procedure for exposing these products is covered by Practice D 3361, in which the specimens are subjected to radiation from an unfiltered open-flame carbon arc that produces much higher levels of short wavelength radiation than filtered open-flame or enclosed carbon arcs. Only automatic humidity controlled open-flame carbon-arc apparatus (Type EH) is applicable to Practice D 3361.

1.3 *This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* For specific hazard statements, see Section 4.

TABLE 1 Cycles Commonly Used for Testing Paints, Varnishes, Lacquers, and Related Coatings in Enclosed Carbon-Arc Devices

Cycle Description	Black Panel Temp. ^A °F (°C)	Typical Uses
102 min light	145 ± 5	general coatings ^B
18 min light and water spray	(63 ± 2.5)	
18 h using:		general coatings
102 min light	145 ± 5	
18 min light and water spray	(63 ± 2.5)	
6 h at 95 ± 4 % relative humidity with no water spray	75 ± 3	original equipment manufactured coatings
48 min light	145 ± 5	
12 min light and water spray	(63 ± 2.5)	exterior pigmented paints
4 h light	145 ± 5	
4 h water spray	(63 ± 2.5)	exterior wood stains and clears
12 h light	145 ± 5	
12 h water spray	(63 ± 2.5)	marine enamels
8 h light	145 ± 5	
10 h light and water spray	(63 ± 2.5)	
6 h water spray		

^A Unless otherwise indicated, black panel temperature during light only portion of the cycle.

^B Historical convention has established this as a very commonly used test cycle.

3. Significance and Use

3.1 This practice is intended to evaluate coating films for their stability to ultraviolet light and moisture. If the spectral power distribution of the light source used for exposure tests does not adequately simulate that for terrestrial solar radiation, it may produce a different type of degradation and distort the ranking of materials obtained in outdoor exposures. Figures 1 and 2 compare representative spectral power distributions of a twin enclosed carbon arc with that of terrestrial sunlight.

3.2 No single operating procedure for light-exposure apparatus with or without water can be specified as a direct simulation of natural exposure. This practice does not express, or imply, a specific correlation with outdoor exposure.

3.3 Since natural environments vary with respect to climate, geography, and topography, it may be expected that the effects of natural exposures will vary accordingly. Furthermore, all materials are not affected equally by the same environment. Therefore, results obtained by use of this practice should not be represented as equivalent to those of any natural weathering test until the degree of correlation has been empirically established for the material in question.

3.4 Variations in results are possible between instruments of the same type operating within the accepted limits of this practice. It is recommended that results obtained using this practice be compared with those for a control or reference material that is mutually agreed upon by the interested parties.

3.5 All references to exposures in accordance with this practice must include a complete description of the test cycle used in addition to the type of device used.

NOTE—The enclosed carbon-arc irradiance was measured at the sample plane at a position centered between the two carbon arcs. Sunlight was measured in Phoenix, AZ, at the summer solstice with clear sky at solar noon using a double grating monochromator (1-nm bandpass) with a quartz cosine receptor on an equatorial follow-the-sun mount. Because of momentary fluctuations in intensity due to flickering of the carbon-arc flame, the spectral power distribution shown in this figure is relative and is not to be used to calculate or estimate total radiant exposure for tests in enclosed carbon-arc devices.

FIG. 1 Representative Spectral Power Distributions (250–400 nm) for Twin Enclosed Carbon Arcs and Terrestrial Sunlight

NOTE—Measurements were made as described in Fig. 1. Because of momentary fluctuations in intensity due to flickering of the carbon-arc flame, the spectral power distribution shown in this figure is representative and is not meant to be used to calculate or estimate total radiant exposure for tests in enclosed carbon-arc devices.

FIG. 2 Representative Spectral Power Distributions (300–350 nm) for Twin Enclosed Carbon Arcs and Terrestrial Sunlight

4. Hazards

4.1 **Precaution**—In addition to other precautions, never look directly at the carbon arc because ultraviolet radiation can damage the eye. Most carbon-arc machines are equipped with door safety switches, but users of old equipment must be certain to turn the OPERATE switch OFF before opening the test-chamber door.

4.2 The burning carbon rods used in these devices become very hot during use. Make sure to allow at least 15 min for the arcs to cool after the device is turned off before

attempting to change the carbon rods. Avoid inhaling ash dust when changing carbon rods.

5. Test Specimens

5.1 Apply the coating to flat (plane) panels with the substrate, method of preparation, method of application, coating system, film thickness, and method of drying consistent with the anticipated end use, or as mutually agreed upon between the producer and user.

5.2 Panel specifications and methods of preparation include but are not limited to Methods D 609, Specification D 358, or Practices D 1730. Select panel sizes suitable for use with the exposure apparatus.

5.3 Coat test panels in accordance with Test Methods D 823 and measure the film thickness in accordance with an appropriate procedure selected from Test Methods D 1005, D 1186, or D 1400. Nondestructive methods are preferred because panels so measured need not be repaired.

5.4 Prior to exposing coated panels in the apparatus, condition them at $73 \pm 3^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity for one of the following periods in accordance with the type of coating:

Baked coatings	24 h
Radiation-cured coatings	24 h
All other coatings	7 days

NOTE 2—The procedures and specifications described in 5.2 through 5.4 are recommended but others may be used if agreed upon by all interested parties.

6. Procedure

6.1 Mount the test specimens both above and below a horizontal plane at the center of the single arc or centered between the two enclosed carbon arcs. When the exposure interval does not exceed 24 h, locate each specimen equidistant from the horizontal plane at the center of the single arc or centered between the arcs.

6.2 To ensure uniform exposure conditions for all specimens, reposition them vertically within their holders in a sequence that will provide each specimen with equivalent exposure periods in each location. For exposure intervals not exceeding 100 h, reposition specimens daily. For longer exposures, reposition specimens weekly. Other methods of achieving uniform total irradiation may be employed if mutually agreed upon between all concerned parties.

6.3 Table 1 lists test-cycle conditions commonly used for evaluation of paints, varnishes, lacquers, and related coatings.

6.4 It is recommended that the temperature of the water used for specimen spray be $60 \pm 9^\circ\text{F}$ ($16 \pm 5^\circ\text{C}$). Water used

for specimen spray must meet the purity levels specified in Practice G 23 in order to avoid unrealistic water spotting.

6.5 When mutually agreed upon, cycles other than those listed in Table 1 may be used. The term *cycle* is defined as the set of exposure conditions (light, light plus water spray, dark periods) that are repeated.

7. Periods of Exposure

7.1 Use one of the following methods to determine the duration of the exposure under this practice:

7.1.1 A mutually agreed upon specified number of total hours.

7.1.2 The number of total hours of exposure required to produce a mutually agreed upon amount of change in either the test specimen or an agreed upon control or reference material.

8. Evaluation of Specimens After Exposure

8.1 Evaluate or rate changes in exposed test specimens in accordance with Test Methods D 523, D 610, D 659, D 660, D 661, D 662, D 714, D 772, D 2244, D 2616, D 4214, E 97, and Practice D 1729. Consider product use requirements when selecting appropriate methods.

8.2 Evaluate test specimens by ranking their performance relative to a control or reference material exposed at the same time.

8.3 Plot properties of test specimens and controls as a function of exposure time and compare rate of change with that of the control or reference material. When this method of evaluation is used, the control or reference material must be exposed at the same time and in the same device as the test specimens.

8.4 Other methods for evaluating test specimens may be used if mutually agreed on by all interested parties.

9. Report

9.1 Report the following information:

9.1.1 Complete description of exposure procedure used, including:

9.1.1.1 Light/light plus water/dark cycle used, type of device used (single or twin enclosed carbon arc),

9.1.1.2 Operating black panel temperature during all portions of exposure cycle,

9.1.1.3 Operating relative humidity, and

9.1.1.4 Temperature of water used for water spray.

9.1.2 Total hours of test.

9.1.3 Test specimen preparation.

9.1.4 Identification of controls used.

9.1.5 Results of evaluation test or tests performed on specimens and control or standard samples.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Methods for Field Identification of Coatings¹

This standard is issued under the fixed designation D 5043; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 These test methods cover procedures and portable apparatus for determining the generic type of coating films most likely to be encountered on structures. The coating can either be weathered from exposure or be freshly applied.

1.2 Most commonly used coatings can be divided into the broad categories and subgroups shown in Table 1 on the basis of the nonvolatile component (generic types) of their vehicle (film forming resin, binder). Although the curing of some coatings involves more than one process and coatings may contain more than one type of resin, they can usually be assigned to one of the basic classes and generic types listed in Table 1.

1.3 For field exposed coatings, it is suggested that these test methods be used as part of a complete evaluation of a coated surface as it is frequently helpful to consider the environment of exposure and how the coating has performed in the environment when drawing conclusions from these tests.

1.4 These test methods will not result in the identification of components of a coating beyond general classification of the coating by generic type and are not appropriate if more detailed analysis is required, for example, as a part of failure analysis or to identify between different manufacturers of the same type of coating. They also may not be definitive enough to identify complex systems that include multiple layers of different generic types of coatings.

1.5 The evaluation of results is quite subjective. Practice and experience are required to minimize misinterpretation. Repeat tests may be required.

1.6 None of the tests is to be taken alone as grounds for identifying the generic type. Only the combination of results from several or all of the tests are to be used in conclusions regarding generic types.

1.7 *This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* For specific hazard statements, see Notes 8, 9, and 11.

2. Summary of Test Methods

2.1 Samples of coatings films are tested with solvents and chemicals and subjected to pyrolysis to provide evidence of their generic type. Figure 1 shows a flow chart for suggested order of tests and classification of results.

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.46 on Industrial Protective Coatings.

Current edition approved April 27, 1990. Published June 1990.

3. Significance and Use

3.1 Information about the generic type of coating on a surface is required to select compatible coatings for repainting and can be used when evaluating the performance of a coating in an environment in decisions on upgrading or replacing a coating system. These test methods provide information on generic type, can be performed in the field by personnel with limited laboratory experience, and require a minimum of equipment and materials.

4. Sampling

4.1 The sample of coating can be obtained by chipping or scraping with a knife or by sanding and then brushing the material into a specimen container or clean envelope. Care should be taken not to cut into substrates, such as plastic or asphalt, that contain polymeric or bituminous materials. Small portions of untreated wood, masonry, or steel do not ordinarily interfere with the tests. Some tests can be conducted directly on the coating surface. If a liquid sample of coating is to be evaluated, a film of the coating should first be cast on a glass plate or similar surface from which it can conveniently be removed after drying.

NOTE 1—To develop familiarity with the subjective evaluations that follow, it is good practice to make films of known resin composition by applying control paints to glass plates or similar surfaces from which they can be readily removed after drying.

5. Pyrolysis

5.1 *Summary of Test Method*—A sample of coating placed in a small test tube is burned over a hot flame. The way the coating burns and the odor and other characteristics of the fume generated are recorded. The Beilstein test identifies the presence of chlorinated and other halogens. In coatings, chlorine-containing material is most often encountered. For coatings not containing halogens, the odor is recorded.

5.2 Apparatus:

5.2.1 *Flame Source*, including butane or propane utility torch. (Lighters do not provide a hot enough flame.)

5.2.2 *Test Tubes*—A suitable size is 10 by 75 mm (disposable culture tubes).

5.2.3 *Copper Wire*—A length of single-strand 16 to 18 gauge. AWG copper electrical wire, stripped of insulation sufficiently far that melted insulation cannot interfere with the test, is satisfactory. Leave about 6 in. of insulation as a heat insulator or provide a wrapping or handle for protection from heat.

5.2.4 *Lead Acetate Paper*.

5.2.5 *Test Tube Clamp*.

5.3 Procedure:

5.3.1 Put a small specimen of coating, preferably of one

TABLE 1 Classification of Coatings Frequently Used

Basic Class	Examples
Drying or baking (oxidizing) paint and enamel	unmodified drying oil oleoresinous (oil-modified, alkyd, epoxy ester, phenolic and other resins)
Lacquer (drying by solvent evaporation)	vinyl (poly(vinyl chloride-vinyl acetate)) poly(vinyl butyral) chlorinated rubber styrene-butadiene rubber and similar rubbers bituminous (coal tar, asphalt) cellulose nitrate poly(vinyl acetate) acrylic styrenated acrylic epoxy
Glass (drying by evaporation of water)	
Chemically curing single package and multi-component coating	bituminous epoxy urethane polyester silicates and cement flame-sprayed silicones
Inorganic	
Cellulosic	

piece, in the test tube and hold the tube briefly in the hot flame. Limit flame contact to the end of the test tube immediately around the specimen. As the specimen begins to burn, observe the nature of deterioration and identify coating type as follows:

Observation	Identification
Change in shape; possible change in color; continued heating causes sample to glow red; rapid deterioration, almost explosive in nature; charring	inorganic cellulose nitrate, or similar some vinyl-type coatings

NOTE 2—Melting, bubbling, and charring are common with most generic types and not definitive.

5.3.2 Continue heating until fume (smoke) fills the test tube. Most fumes are white or near-white; slight condensation of a clear liquid on the upper test tube wall is sometimes observed. Other observations and identifications include:

Observation	Identification
Dark fume; clear brown liquid condensate	possibly epoxy
Very dark, possibly sooty fume; dark condensate	bituminous

NOTE 3—Bituminous coatings may be asphalt, coal tar, or combinations. The test is not definitive.

NOTE 4—Silicone coatings will form an ash upon pyrolysis at 800°C. Such temperatures are outside the scope of this test.

5.3.3 *Beilstein Test*—Conduct the Beilstein test by first heating the bare copper wire in the flame until no color is imparted to the flame. Insert the heated wire into hot fume in the test tube briefly (1 to 2 s). Withdraw the copper wire from the test tube and immediately hold it in the flame again. Observe the flame over the copper wire for color and make identifications as follows:

Observation	Identification
No color	no chlorine or chloride (or other halogen) content
Traces of green color	chloride contaminants from environment or minor component of coating
Strong green color	chlorinated resin or chlorinated resin modifier

With practice, the intensity of the green flame can be used to determine whether the chlorine containing component is major or minor.

5.3.3.1 *Example 1*—A very intense, relatively long-lasting repeatable green flame indicates chlorinated rubber or vinyl coating.

FIG. 1 Suggested Test Flow Chart for Coatings Identification

5.3.3.2 *Example 2*—An intense or moderately intense relatively short-lived green flame, which may or may not be repeated, indicates chlorinated plasticizer in a nonchlorinated resin binder.

NOTE 5—Although fluorinated resins also give a positive Beilstein test, they are less likely to be encountered in industrial applications than chlorinated resins.

NOTE 6—If the sample includes hydrated material, for example, concrete or plaster, water will be liberated by burning and will condense on the wall of the test tube. Halogen liberated from the paint will be absorbed into the condensate. The copper wire must be brought into contact with the condensate to avoid a false negative.

NOTE 7—Those experienced with the Beilstein test may prefer to run it on a specimen not subjected to pyrolysis.

5.3.4 *Odor Test*—Conduct the odor test *only* if the Beilstein test is negative (no green flame).

NOTE 8: *Warning*—Hot chlorine or fluorine-containing fumes are extremely irritating and potentially hazardous. Tip the test tube so that the fumes flow toward the open end of the tube. Gently wave a hand over the mouth of the test tube and carefully smell the odor of the fumes as they dissipate from the mouth of the test tube. Avoid overexposure to the fumes.

5.3.4.1 Indications are subjective, but the following classes can be assigned:

Observation	Identification
Oily	oleoresinous
Very sweet	acrylic latex
Vinegary; acetic acid	poly(vinyl acetate)
Burning hair	epoxy, epoxy ester, bituminous epoxy
Burning rubber	polysulfide
No strong odor	inorganic, cementitious
Acrid (biting) odor, with sooty or tarry smoke	bituminous

5.3.5 Use the lead acetate paper to verify the presence of a sulfide component by holding a piece of moistened lead acetate paper over or in the mouth of the test tube. A sulfur-containing component is present if the paper rapidly darkens.

6. Solubility Tests

6.1 Chemically cured, inorganic, and aged oleoresinous coatings are not resolvable in the solvents originally used in producing the coatings. Lacquers and some latex coatings are resolvable and the strength of the solvent required to cause the coating to dissolve can be used to classify the coating.

6.2 *Reagents*—Solvents used, listed in order of increasing power of solvency (that is, ability to dissolve a resin), are as follows:

6.2.1 *Denatured Ethanol (Ethyl Alcohol)*:

6.2.2 *Mineral Spirits (Petroleum Spirits)*—Aliphatic hydrocarbon solvent with typical Kauri-Butanol value (KB) of 25 to 45.

6.2.3 *Xylene (Xylol)*—Aromatic hydrocarbon solvent with typical KB of 98.

6.2.4 *Methyl Isobutyl Ketone (MIBK, 4-Methyl-2-Pentanone)*.

6.2.5 *Acetone (Dimethyl Ketone, 2-Propanone)*.

6.3 *Procedure*:

6.3.1 Although a stirring rod or a gloved finger-tip can be used, the test is best done by a finger-rub technique on the coating film itself. The sensations perceptible by touch are valuable in interpreting results. Alternatively, the solubility tests may be done by soaking portions of the film in solvents,

in which case porcelain spot plates and glass stirring rods can be used.

NOTE 9: *Warning*—These solvents can cause skin irritation and dermatitis. Minimize time of contact of solvents with skin and discontinue use if irritation occurs.

6.3.2 *Finger-Rub Test*—Beginning with ethanol, dampen a fingertip and rub the surface of the film briskly in a circular motion 5 to 10 mm (1/4 to 1/2 in.) in diameter. Renew the test solvent frequently as required. Continue rubbing at least 30 s or until definite effects are observed. Continue with each solvent in increasing power of solvency by cleaning the fingertip in each succeeding solvent before using that test solvent and selecting a new spot on the film or an untested chip of paint for each solvent used.

NOTE 10—If the coating film on the test surface is chalky, the first finger-rub test done with ethanol will liberate much of the chalk, which will dry quickly on the finger as a powder. Repeating the test will reveal much less or no color and the test surface will appear unchanged. If chalk is liberated, use ethanol to clean the test spot for subsequent solvent tests.

6.3.3 *Solvent-Soak Test*—The full series of solvents can be run concurrently. Place five chips in a spot plate dish and pour a small amount of each solvent over one of the chips. Periodically stir the solvent and rub the chip with a stirring rod until definite changes occur. Add additional solvent, if necessary due to evaporation, and observe extent of discoloration of the solvent and whether the chip softens, breaks apart, swells, dissolves, or a combination thereof. Note whether a color different from the color of the topcoat is imparted to the solvent, indicating dissolution of an intermediate or primer coat. If portions of the chip dissolve or discolor the solvent, soak up the solvent with a paper towel and add fresh solvent if undissolved chip remains. If no further effect occurs, wash the remainder of the chip by gentle swirling, soak up the solvent, allow the chip to dry, and proceed with pyrolysis or other tests.

NOTE 11: *Precaution*—Do not attempt to burn a solvent-wet chip or heat solvent in a test tube, as the liquid may suddenly boil, possibly causing burns or loss of specimen.

6.3.4 Observe the effects of rubbing or soaking and classify as follows (the results for the soaking test are more difficult to interpret than for the finger-rub test):

6.3.4.1 No effect or small amount of color transfer to the fingertip or rod (due to chalk or film surface abrasion while rubbing).

6.3.4.2 Softening of the film, with resin rolling into small balls under the fingertip or rod.

6.3.4.3 True solubility with film dissolving, becoming sticky, and transferring in relatively large liquified quantity to the fingertip or rod.

6.3.5 Succeeding layers in a coating system may be individually tested if they are visually different; for example, colored topcoat, white or grey intermediate coat, and brown or red primer coat. To test visually different layers, repeatedly rub the spot with an effective solvent and wipe away dissolved coating periodically until a sublayer of different color is clean, then continue the test with the effective solvent on the sublayer. If that solvent is ineffective, repeat the test on the same spot with the next stronger solvent in the series. If that solvent is effective, repeat the test on a new

men or area, and when the sublayer is uncovered, allow solvent to evaporate, then test the coating with the next solvent in the series, continuing up the series until solubility is again observed. If a sublayer of coating is not affected by any solvent in the series, that layer may be removed and collected by chipping or scraping for a solubility test.

2. Interpretation of Results:

2.1 **No Effect with Any Solvent**—Chemically cured, aged (aged) oleoresinous, or inorganic.

NOTE 12—With prolonged contact, oleoresinous coatings may soften or wrinkle. Absence of wrinkling, however, is not indicative of absence of oleoresinous coatings.

2.2 **Breaks Up or Dissolves in Ethanol**—Latex coating poly(vinyl butyral).

NOTE 13—Latex coatings are normally not soluble in mineral spirits but are only slightly affected in the short time of the test by xylene and MIBK (resulting in surface slickness). Ethanol will not dissolve any common coating type in this test, but it may affect considerable color transfer from weathered epoxy films. Bituminous emulsions do not break up or dissolve in ethanol.

2.3 **Dissolves in Mineral Spirits**—Asphalt coatings and other coatings other than chlorinated rubber and vinyls. Acceptable resins include styrene-butadiene, styrene-acrylate, and similar resins, but do not include polymers such as neoprene which are not normally used in solvent resistant coatings.

NOTE 14—Lacquer coatings other than chlorinated rubber and vinyls contain chlorinated plasticizers that give a positive Beilstein test.

NOTE 15—Some coal tar coatings strongly discolor mineral spirits but are not significantly dissolved by the solvent.

2.4 **Dissolves in Xylene but Not in Mineral Spirits**—Coal tar coatings and chlorinated rubber-based coatings. Frequently associated with solution of a chlorinated rubber is the ability of the resin to "string" between surface of film and finger when the finger is pulled away from the coating.

2.5 **Dissolves in MIBK but Not in Xylene**—Poly(vinyl chloride-vinyl acetate) solution coatings.

NOTE 16—Vinyls may soften with resultant "resin roll" in the finger-rub test with xylene. Some vinyls, modified with polymers such as ethylene, may not readily dissolve in MIBK, but feel slick with little color transfer in the finger-rub test and may swell up to 2½ times without dissolving in the MIBK soak test. They may also feel similarly with some color transfer in xylene.

NOTE 17—Latex binders merely soften in the short time the test is

2.6 It may be possible to further differentiate between asphalt and coal tar coatings using acetone. Soak a chip of bituminous coating in a test tube of acetone for several minutes. Agitate gently and observe for extent of discoloration. Asphalts only very slightly discolor acetone while coal tars strongly discolor it, but there can be intermediate degrees of discoloration that do not permit discrimination. It is not possible by simple methods to differentiate between a solvent-borne (cutback) and water-borne (emulsion) bituminous coating.

Test for Polyester Coatings

1 This test identifies polyester-based coatings from the

group of chemically cured coatings that are not affected by the solubility test.

7.2 Apparatus:

7.2.1 Test Tube.

7.2.2 Medicine Droppers.

7.3 Reagents:

7.3.1 Potassium Hydroxide in Methanol.

7.3.2 Hydroxylamine Hydrochloride Solution in Methanol, 10 %.

7.3.3 Ferric Chloride Solution, saturated in distilled water.

7.3.4 Hydrochloric Acid, 3 %.

7.3.5 Warm Water, 125°F (50°C).

7.4 **Procedure**—Place a small quantity of the film sample in a test tube. Add 10 drops of potassium hydroxide solution and 6 drops of hydroxylamine hydrochloride solution. Place the test tube in a container of warm water for 2 min. Add 10 drops of hydrochloric acid and one drop of ferric chloride solution.

7.5 Interpretation of Results:

Observation	Identification
Muddy violet color	dicastic polyester is present
Absence of color or light yellow color	dicastic polyester is not present

8. Test for Epoxy Coatings

8.1 All common epoxy coatings give positive results in this test. Epoxy ester coatings may also give positive results.

8.2 Apparatus:

8.2.1 **Ashless or Low-Ash Filter Paper**, 90 to 110-mm diameter.

8.2.2 Medicine Droppers.

8.3 Reagent:

8.3.1 Sulfuric Acid, concentrated.

8.4 **Procedure**—Support the filter paper off surfaces that may be damaged or could cause interference in the test. A watch glass can be used to support the paper. Place a specimen of coating in the filter paper. Place 2 or 3 drops of sulfuric acid directly on the coating. Place 1 or 2 drops of acid elsewhere on the filter paper not in contact with the coating. Let stand for 1 to 2 min. Carefully hold and tilt the filter paper toward the vertical until the acid runs down the paper away from the specimen. Wait 10 to 30 s or until there is development of color in the acid itself, not on the coating.

8.5 Interpretation of Results

Observation	Identification
Development of red to violet color in the acid	presence of epoxy
Absence of color in the acid	coating is not epoxy

8.5.1 If red to violet color develops in the drop of acid not in contact with the specimen, then the paper is contaminated or was placed on an epoxy or epoxy-coated surface. Discard and repeat the test. A very slight pink color may develop in the acid. This is not a positive result. Bitumen-filled epoxies may discolor the acid enough to mask color development. If the acid stream is discolored brown to black, carefully rinse the filter paper briefly in water or under running water if available. Color from a positive test will remain in the filter paper after the discoloration is washed off. The filter paper itself will be charred brown by the acid and eventually dissolve. The color of a positive test should occur early enough to be seen before the paper chars.

9. Test for Pigments that Contain Lead and Hexavalent Chromium

9.1 Summary of Test Method:

9.1.1 Knowledge of the presence of pigments that contain lead and hexavalent chromium in an existing coating system may be important in a decision on whether the coating system is to be retained and recoated or on the method of removal and disposal of the coating system residue.

9.1.2 Pigments that contain lead or hexavalent chromium, or both, may be used both in primers as rust-inhibitive pigments and in topcoats as weather-resistant colored pigments. Depending on the ease with which a coating system can be separated, topcoats and primer coats may be individually tested for lead or hexavalent chromium, or both.

9.1.3 The presence of lead and hexavalent chromium containing pigments can be qualitatively determined in the field with the following two tests. Both tests can be done directly on the coated surface or on chips or dust of the coating placed in the well of a spot plate.

9.2 *Apparatus*—Glass beakers, jars or bottles, porcelain spot plates, sandpaper, razor blade or knife.

9.3 Reagents:

9.3.1 *Sodium Sulfide Powder or Crystals.*

9.3.2 *Hydrochloric Acid, concentrated.*

9.3.3 *Diphenylcarbohydrazide Powder.*

9.3.4 *Phosphoric Acid, concentrated (85 %).*

9.3.5 *Acetone.*

9.3.6 *Denatured Ethanol.*

9.3.7 *Distilled or Deionized Water.*

9.4 Preparation of Test Solutions:

9.4.1 A solution of sodium sulfide in water is used to test for presence of lead. Prepare the solution by dissolving 1.5 g of sodium sulfide in 20 mL of distilled water and adding hydrochloric acid dropwise while swirling the solution until a white precipitate forms and remains with continued swirling (pH should be about 8). A proportionally smaller or larger amount of solution can be made up. The solution loses strength with age. Test the solution by placing a drop on a strip of lead acetate paper and observing the paper for the development of the black color of lead sulfide. If color development does not occur, discard the solution and make a fresh one.

9.4.2 A solution of 1,5-diphenylcarbohydrazide is used to test for the presence of hexavalent chromium. Prepare the solution using the following or proportionally smaller amounts of ingredients. Dissolve 0.5 g of 1,5-diphenylcarbohydrazide in a mixture of 20 mL acetone and 20 mL ethanol in a beaker, warming the beaker in warm water if necessary to facilitate solution. Carefully add 20 mL of phosphoric acid to 20 mL of cold distilled water in a separate container. Slowly add the acetone-ethanol mixture to the dilute acid solution and mix thoroughly by swirling. The 1,5-diphenylcarbohydrazide solution is not stable. It

may be stored for short periods of time in an opaque glass bottle but is best prepared just prior to use. The solution can be tested by placing a drop on a material known to contain a hexavalent chromium pigment. If a blue to violet color does not rapidly develop in the drop of solution, discard the solution and prepare a fresh solution.

9.5 Procedure:

9.5.1 Abrade two separate spots on the coating film with sandpaper or knife if the tests are to be done on the coating surface. Alternatively, abrade one spot of the coating and collect the dust and flakes in two wells of a spot plate. Abrasion of the film is required to expose pigments in an aged, weathered film.

9.5.2 On one abraded spot or on the specimen in one well of the spot plate, place 1 or 2 drops of sodium sulfide solution. Development of a black or dark grey color on the film or flakes indicates the presence of lead. Lack of color development indicates less than 0.1 % by weight lead (approximate practical limit of sensitivity of this test procedure).

9.5.3 Metals other than lead give a positive sulfide test but may not be common to coatings or usually do not interfere in this test in the form present. If there is doubt, laboratory testing beyond the scope of this test method is required to confirm the presence of lead.

9.5.4 On one abraded spot or to the second well of the spot plate place 1 or 2 drops of 1,5 diphenylcarbohydrazide solution. Rapid development of blue to violet color in the solution droplets indicates the presence of hexavalent chromium.

9.6 *Interpretation of Results*—The combination of results from the two tests, together with consideration of the color of the coating, may be used to establish more definitely the pigments that are present, as shown in the following scheme, which is not all inclusive:

Observation	Identification
Positive for lead, negative for chromium	pigment is red lead, white lead, or lead suboxide (white)
Negative for lead, positive for chromium	pigment is zinc or strontium chromate (yellow)
Positive for lead, positive for chromium	chrome yellow, chrome green, chrome orange, or molybdate orange (all color pigments containing lead chromate) or basic lead silichromate (orange-red inhibitive pigment)

10. Precision and Bias

10.1 Precision cannot be determined for these test methods because the variability of coatings on a surface does not permit the collection of reliably uniform samples and because few specimens will be tested from one particular coating.

10.2 Bias cannot be established for these test methods because accepted reference standards are not available.

11. Keywords

11.1 coatings; field; generic resin; identification

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Resin Solution Dilutability¹

This standard is issued under the fixed designation D 5062; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^{e1}) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Keywords were added editorially in March 1991.

1. Scope

1.1 This test method covers a titrametric/gravimetric determination of resin solution dilutability which gives a numerical value for the overall solubility of the resin expressed as percent dilutability.

1.2 This test method is applicable only if the test solution is of sufficient clarity to allow accurate visual judgement of the end point and of low enough viscosity for efficient mixing to take place.

1.3 This test method is primarily for, but not limited to, resins used in the printing ink industry.

1.4 The percent solvent tolerance of a resin can be determined using this test method if the solvent in the resin solution and the dilution solvent are the same.

1.5 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

- 2.1 *ASTM Standards:*
 - D 1725 Test Method for Viscosity of Resin Solutions²
 - E 1 Specification for ASTM Thermometers³

3. Terminology

3.1 Definition of Term Specific to This Standard:

3.1.1 *resin solution dilutability*—the maximum amount of diluent tolerated to reach a defined degree of turbidity; beyond this point, resin precipitation will occur.

4. Summary of Test Method

4.1 A sample of resin solution is weighed into a glass beaker that is placed over a piece of 10 point print (standard newspaper print).

4.2 The dilution solvent is added slowly from a buret until the newsprint can no longer be read (cloud point) when viewed from the top of the beaker.

4.3 The percent dilutability is calculated by weight.

5. Significance and Use

5.1 This test method provides a means for resin producers and users as well as solvent and varnish manufacturers to rate various types of resins for solubility by assigning a numerical dilutability value. This percent dilutability value can be used to differentiate resin types for end users and can be utilized as a quality control tool by resin manufacturers.

5.2 When running a series of these tests the same lot or batch of dilution solvent must be used throughout to ensure reproducible results.

6. Apparatus

6.1 *Glass Beaker*, 150-mL (51-mm diameter, 79-mm height).

6.2 *Graduated Buret*, 50 mL.

6.3 *Constant Temperature Water Bath* at 25°C.

6.4 *Thermometer*, 0 to 40°C range with subdivisions of 0.5°C conforming to Specification E 1.

6.5 *Magnetic Stirring Bar and Stirring Plate or Stirring Rod*.

6.6 *Sheet of Newsprint*, with 10-point (Note), No. 3 old-style type, lower case letters 1.5-mm high with normal spacing, upper and lower case with no italicized or bold letters.

NOTE—The term point is derived from the American Point System. 72 points = 1 in.

7. Reagents and Materials

7.1 *Resin Solution*—A resin solution prepared in such a way as to provide an accurate percent solids and to have sufficient clarity to allow accurate visual judgment of the cloud point. The solution must also have low enough viscosity at 25°C to allow efficient mixing during the addition of the dilution solvent.

7.2 *Dilution Solvent*—The dilution solvent for this test is typically, but not limited to, a hydrocarbon. The dilution solvent should have minimal loss by evaporation at room temperature.

8. Procedure

8.1 Preparation of Resin Solution:

8.1.1 The resin solution may be prepared by either heating the resin/solvent combination as described in Test Method D 1725, or dispersing using a high-speed mixer such as a blender. Please note results may vary dependent on method of preparation.

8.1.2 The ratio of resin to solvent in the preparation should correspond as much as possible to the intended end

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.37 on Ink Vehicles.

Current edition approved May 25, 1990. Published July 1990.

² *Annual Book of ASTM Standards*, Vol 06.02.

³ *Annual Book of ASTM Standards*, Vol 14.03.

use of the material, but should be chosen to avoid difficulty in effecting solution at a low enough viscosity for efficient mixing during dilution.

8.1.3 The precision of weighing the resin and solvent should ensure a maximum deviation of $\pm 1\%$ in the desired concentration. This percent solids must not be altered during resin solution preparation by solvent loss.

8.2 Weigh a 150-mL glass beaker with the magnetic stirrer bar or stirring rod. Record this tare weight as W_1 .

8.3 Accurately weigh 10 ± 0.1 g of the resin solution into the beaker. Record this sample weight as W_2 .

8.4 Place the beaker in a 25°C constant temperature bath until the resin solution reaches $25 \pm 1^\circ\text{C}$ as measured with the thermometer specified in 6.4.

8.5 Prepare the dilution solvent by bringing it to a temperature of $25 \pm 1^\circ\text{C}$ before adding it to the buret.

8.6 Place the beaker over the piece of 10-point print and begin adding solvent slowly (5 to 6 mL/min) while stirring. Ensure that the sample temperature remains at $25 \pm 1^\circ\text{C}$, which may require periodic return of the beaker to the water bath. If the sample has started to form a haze it should not be returned to the water bath.

8.7 Observe the 10-point print from the top of the beaker looking through the solution.

8.8 If the resin solution begins to cloud, add solvent slowly one drop at a time while continuing to mix. Do not return the sample to the water bath at this point. If more than 100 g is required, the resin solution can be considered infinitely soluble unless otherwise specified in an agreement between the purchaser and supplier.

8.9 The end point is reached when the 10-point print cannot be read looking through the solution from the top of the beaker.

8.10 Record the final weight of the beaker and its contents (W_3).

8.11 Record the sample temperature at the end point.

9. Calculation

9.1 Calculate the percent resin solution dilutability, D , as follows:

$$D = \frac{W_3 - (W_1 + W_2)}{W_2} \times 100 \quad (1)$$

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

9.2 Calculate the percent solvent tolerance of the resin, S , (percent resin solids at cloud point) as follows:

$$T = \frac{[W_2 \times (S/100)]}{W_2 + [W_3 - (W_1 + W_2)]} \times 100 \quad (2)$$

where S = resin in solution, %.

10. Report

10.1 Report the following information:

10.1.1 The identification of the resins and the solvent in the solution as well as the dilution solvent,

10.1.2 The method used to prepare the resin solution,

10.1.3 The percent solids of the resin solution, and

10.1.4 The percent resin dilutability value and operating conditions including air temperature, relative humidity, initial resin solution temperature, final resin solution temperature, initial dilution solvent temperature, and final dilution solvent temperature.

11. Precision

11.1 An interlaboratory study was conducted in which one operator in each of eight laboratories determined the percent dilutability of two common resin solutions and two dilution solvents completed in duplicate on two different days. The pooled within-laboratory standard deviation was found to be 3.25 % of the value measured with 12 df. The between-laboratory standard deviation was 7.63 % of the value measured with 28 df. Based on these standard deviations, the following criteria should be used for judging the acceptability of results at the 95 % confidence level.

11.2 *Repeatability*—Two results, each the mean of duplicate determinations, obtained by the same operator should be considered suspect if they differ by more than 9.19 % of the value measured.

11.3 *Reproducibility*—Two results, each the mean of duplicate determinations obtained by operators in different laboratories, should be considered suspect if they differ by more than 23.38 % of the value measured.

12. Keywords

12.1 dilutability value; percent dilutability; printing ink resins; resins; resin solution cloud point; resin solution dilutability; solvent tolerance

Standard Guide for Use of Certification of Coating Conformance Form¹

This standard is issued under the fixed designation D 5063; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This certification of coating conformance form provides procurement information concerning products being furnished in accordance with a specific coating specification and additional requirements contained in the purchase order (see Fig. 1).

1.2 The completed form can be utilized to help evaluate the acceptability of the paint being furnished.

2. Referenced Documents

Standard Practice for Conducting a Patch Test to Assess Coating Compatibility¹

This standard is issued under the fixed designation D 5064; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers the procedures for testing coating compatibility when maintenance of an in-place coating system is being contemplated. It does not cover procedures for assessing the integrity of the existing coating to determine if it can be repainted, nor does it establish the compatibility of the maintenance coating system with the substrate or corrosion products. The practice is intended for use in the field.

NOTE 1—Pass-Fail Criteria (for example, adhesion requirements) are not established by this practice. These should be established by the user or specifier with input from the supplier.

1.2 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

- D 1186 Test Methods for Nondestructive Measurement of Dry Film Thickness of Nonmagnetic Coatings Applied to a Ferrous Base²
- D 1400 Test Method for Nondestructive Measurement of Dry Film Thickness of Nonconductive Coatings Applied to a Nonferrous Metal Base²
- D 3359 Test Methods for Measuring Adhesion by Tape Test²
- D 4138 Test Method of Measurement of Dry Film Thickness of Protective Coating Systems by Destructive Means²
- D 4414 Practice for Measurement of Wet Film Thickness by Notch Gages²

3. Terminology

3.1 *Definitions*—For definitions of terms used in this practice, refer to the Federation of Societies for Coatings Technology (FSCT) *Paint/Coatings Dictionary*.³

4. Summary of Test Method

4.1 The materials under test are applied to the previously painted surface after proper surface preparation. After the appropriate time has elapsed, the test patch is examined for

visual defects and adhesion is determined.

5. Significance and Use

5.1 In performing maintenance of a coating system, the new coating being applied must be compatible with the existing coating. While general guides exist which indicate compatibility of different generic types of coatings, differences in manufacturer's formulation and the condition of the in-place coating will affect compatibility.

6. Procedure

6.1 Select test locations for evaluation that properly characterize differences in configuration of the structure and exposure, that is, vertical versus horizontal surfaces and bold versus sheltered exposure. A minimum of three test locations with one test patch in each is recommended.

6.2 The size of each test patch will be determined by the size and configuration of the test locations. Each test patch shall be as large as possible, with a minimum size of 10 ft² (0.93 m²) recommended.

6.3 Clean the surface of the test areas using the methods specified for the maintenance painting procedure (Note 2). Alternative methods of preparation may also be evaluated in separate, adjacent tests.

NOTE 2—This test method assesses compatibility with the existing coating only and does not apply to areas where the substrate is exposed by the methods of preparation.

6.4 Measure the existing coating thickness in accordance with Test Methods D 1186, D 1400, or D 4138, as appropriate for the substrate.

6.5 Measure the ambient conditions and surface temperature and assure the conditions are within the limits specified by the coatings manufacturer for the product being tested.

6.6 Apply the test coating to the thickness recommended for the particular job. Use the application technique as intended for use on the full-scale job. If agreed upon between the purchaser and the seller, the method of coating application may be different from that used on the job, that is, brush application of the test patch even though spray application will be used on the job. However, this can cause some error and is not generally recommended.

6.7 Immediately after application, measure the wet-film thickness in accordance with Practice D 4414. Make corrections to the application, if necessary, by either applying more material if the expected dry-film thickness is low or applying another test patch if the expected dry-film thickness is above the recommended maximum. Inspect each patch for application defects such as runs, sags, and holidays. If such defects cannot be corrected as a part of the initial application process, prepare a new test patch.

6.8 After the coating has dried, measure the dry-film

thickness in accordance with Test Method D 1186, D 1400, or D 4138.

NOTE 3—When using Test Methods D 1186 or D 1400, the dry film thickness is the difference in average thickness of the coating system less the average thickness of the in-place coating.

6.9 Allow the coating to cure or weather prior to testing. Cure durations are defined as long term and short term. Long-term curing provides the most reliable assessment of compatibility. Short-term curing provides for more rapid evaluation of results.

6.9.1 *Long-Term Curing*—Curing for as long a time as possible, with a minimum of six months preferred. Curing should span seasonal weather changes.

6.9.2 *Short-Term Curing*—Curing at the following minimum times based on average daily (24 h) temperatures:

50°F (10°C)	70°F (21°C)	90°F (32°C)
14 days	10 days	7 days

6.10 After curing, examine the total surface of each test patch for wrinkling, blistering, mudcracking, checking, cracking, peeling, lifting, and disbonding. Measure or rate

the adhesion in a minimum of five locations per test patch in accordance with Test Methods D 3359.

6.11 Examine the test patches for the defects noted in 6.10 on a regular schedule, discounting rust caused by previous tests such as adhesion measurements and destructive film thickness measurements.

7. Report

7.1 Report the following information:

7.1.1 The identity of the structure tested, the location and size of the test patches, the identity of the test coating, the method and grade of surface preparation, and the method of coating application.

7.1.2 For each test patch, the dry film thickness measurements and average of the in-place coating, the dry film thickness measurements and average of the test coating, the elapsed time for each evaluation, the visual defects noticed, and the results of adhesion tests.

8. Keywords

8.1 coating; coating compatibility; coating test patch; paint; paint compatibility; test patch

Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Guide for Assessing the Condition of Aged Coatings on Steel Surfaces¹

This standard is issued under the fixed designation D 5065; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide provides general guidelines for a detailed assessment of the condition of aged coatings on steel structures and the extent of rust breakthrough of the coated surface. Additional assessment may be required to support coating failure analyses or other job specific needs.

1.2 This guide does not address the problem of determining the structural condition of a steel substrate. It provides procedures to determine the percent of the surface rusted, but not the severity, condition, or cause of such rusting.

NOTE 1—A more comprehensive condition assessment procedure, Practice F 1133, based upon two sets of visual standards, one for level and one for extent of deterioration, has been developed for determining the condition of coatings on ship hulls.

1.3 This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

SSPC-PA-2 Measurement of Dry Paint Thickness with Magnetic Gages

3. Summary of Practice

3.1 This practice for assessing the condition of coatings consists of identifying general types of components of a structure and assessing each separately for commonly occurring modes of coating deterioration and rust breakthrough of the coating using visual standards and simple evaluation tools. A form for recording the results of the assessment procedure (Fig. 1) is provided.

4. Significance and Use

4.1 Assessment of the condition of aged coated surfaces strengthens decisions on when coating maintenance is required, aids in the selection of effective coating maintenance procedures, and provides a means to characterize performance of coating systems.

5. Procedure

5.1 Survey the structure to (1) determine the general types of unique components (for example, for fuel tanks the components may be shell, roof, ladders, and piping) and the service exposure environment for each, (2) visually identify areas having a typical level of coating deterioration and rust breakthrough for each component and (3) identify areas having a much greater visual level of deterioration than typical and unique environmental conditions that may correspond to these areas (for example, bridge expansion joints). Record a description of the components and their general environment on an inspection form and describe areas having greater deterioration, as well as any unique associated environments in the remarks column. A suggested general format for data collection is shown in Fig. 1. Modification of the form (for example, adding or deleting specific items) will be required for each specific application.

5.2 Based upon the knowledge of what constitutes typical deterioration for each component as determined in the initial survey, examine the condition of the coating on a representative sample of each component. Rate the condition of the coatings using the appropriate ASTM visual standard for rust breakthrough (Test Methods D 610), blistering (Test Method D 714), peeling (use Test Methods D 610 to report amount), chalking (Test Methods D 4214), and cracking/checking (Test Method D 660) of the coating film. Record the rating in the appropriate column of the report form for each

^A Rusting corresponds to Test Methods D 610, that is, that observed upon visual inspection of the coated surface while underfilm condition corresponds to substrate condition under an intact coating as described in Section 4.

FIG. 1. Example 1 Report Form

component. Determine and record the type of peeling, for example, intercoat delamination. Rate the condition in enough areas to ensure that for each component the coating evaluation is representative of the condition over the entire structure. If additional areas of greater deterioration are detected during this assessment, make note of them in the remarks column.

NOTE 2—For the purpose of an initial general assessment, cracking and checking can be assessed as one type of failure, using the pictorial standards in Test Method D 660 to define type and extent.

5.3 When rusting beneath an intact coating film is suspected, examine the condition of the underlying substrate. Remove apparently intact coatings using chemical strippers or closely spaced parallel knife cuts. For structural steel, determine the type of previous surface preparation from the presence of millscale or profile. Identify evidence of corrosion from the presence of pits, black anodic spots or corrosion scale, or from results of a test for ferrous ion using potassium ferriferrocyanide paper. Record the results of the examination on the report form.

5.4 Using one of the procedures described in Test Methods D 1186, determine the coating thickness in enough areas of each component to ensure a representative measure. Record the measured thicknesses.

5.5 Using one of the procedures described in Test Methods D 3359 or D 4541, determine coating adhesion in enough areas of each component to ensure a representative measure. Record the adhesion reading and the type of procedure and equipment used.

NOTE 3—The number of areas in which coating thickness and adhesion is measured will depend upon the desired precision of the measurement. More measurements would be made on structures in which precise knowledge of the thickness and adhesion of the coating is required. SSPC-PA-2 states the required number of thickness measurements as a function of coating area for conformance of thickness to a specification.

5.6 If required for a maintenance decision, identify the generic type(s) of the existing coating film component from records or using the procedure in Test Method D 5043. To the extent possible, each layer of the film should be characterized.

6. Report

6.1 Prepare an inspection report. Figure 1 provides an example of the types of information to be included.

7. Keywords

7.1 assessment; coatings; condition; field; paint; weathered

Standard Test Method for Determination of the Transfer Efficiency Under Production Conditions for Spray Application of Automotive Paints— Weight Basis¹

This standard is issued under the fixed designation D 5066; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method provides procedures for determination of the transfer efficiency (using a weight method) under production conditions for in-plant spray application of automotive paints.

1.2 The transfer efficiency is calculated from the weight of the paint solids sprayed and that deposited on the painted part. The recommended approach involves painting the part directly. Also described is an alternative approach for painting parts covered with aluminum foil.

1.3 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. Specific hazard statements are given in 10.9.*

EPA Federal Reference Method 24—Determination of Volatile Matter Content, Water Content, Density, Volume Solids, and Weight Solids, of Surface Coatings⁴

3. Terminology

3.1 Descriptions of Terms Specific to This Standard:

3.1.1 *paint*—the liquid material that is applied onto the part to cover or coat the surfaces.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.55 on Factory Applied Coatings on Preformed Products.

Current edition approved May 15, 1991. Published July 1991. Originally published as D 5066 - 90. Last previous edition D 5066 - 90.

² Annual Book of ASTM Standards, Vol 06.01.

³ Available from Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402. Refer to EPA 450/3-88-018 dated December 1988. This protocol makes reference to the determination of production spray transfer efficiency.

⁴ Available from Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402. Refer to CFR 40, Part 60, Appendix A.

3.1.2 *transfer efficiency*—the ratio of the weight of paint solids deposited to the total weight of paint solids used during the application process, expressed as a percent.

3.1.3 *paint weight solids content*—the weight of the non-volatile materials in the liquid paint material divided by the total weight of the paint, times 100, determined by Test Method D 2369.

3.1.4 *paint density*—the mass of a unit volume of the liquid paint material at any given temperature, determined by Test Method D 1475.

3.1.5 *satellite paint supply system*—a smaller, paint-circulating system separate from the main production paint-circulating supply system capable of supplying paint under the same conditions.

4. Summary of Test Method

4.1 The weight of the part to be painted is determined before and after the paint application process. The weight of liquid paint used per part is determined from material usage and part processing records. The determined weight solids content of the paint material is determined and used to calculate the paint solids sprayed per part. The transfer efficiency of the process is calculated by dividing the weight of paint solids deposited by the weight of the paint solids sprayed.

5. Significance and Use

5.1 This test method is specifically directed at the spray painting of automobile car and light duty truck bodies. The general principles are applicable to the painting of other automotive parts.

5.2 This test method may also be used to measure transfer efficiency in full-sized painting facilities simulating production conditions and operations.

6. Interferences

6.1 Limitations include the ability of the weighing device to determine accurately the weight of the paint solids deposited on the part and the capability of accurate measurement of the amount of paint sprayed (see Section 7).

6.2 It may be difficult to cover the surface of complex shaped parts with aluminum foil (see 11.6.11).

7. Apparatus

7.1 *Tension Load Cells*, with upper/lower transition pieces.

7.1.1 1500-lb (682 kg) capacity with 0.05-lb (0.02 kg) precision for weighing automobile body and support frame.

7.1.2 500 to 800-lb (227 to 364-kg) capacity with 0.05-lb (0.02 kg) precision for weighing mix tanks or automobile components.

7.1.3 A safety cable is required for upper to lower transition.

7.2 *Electronic Digitizer/Readout*, readability of 0.05 lb (0.02 kg) and special filtering.

7.2.1 The electronic digitizer/readout shall meet OIML International Organization of Legalized Metrology specifications.⁵

7.3 *Voltage Regulator*.

7.4 *Swivel Devices*, as required.

7.5 *Rule and Calipers* for measuring diameter of paint supply tank shaft, etc.

7.6 *Sample Containers*, clean and airtight for paint material.

7.7 *Lifting Device and Support Frame Apparatus* to lift body.

7.7.1 Total weight must not exceed capacity of load cell or scale.

7.8 *Standard Calibration Weight*, approximately 2 lb (0.9 kg).

7.9 *Measure Stick*, Starret precision spring tempered, satin chrome finish, 36 in. (91.4 cm), with 4R graduations, or equivalent.

Paint Usage Measurement Procedures

8.1 Transfer efficiency measurement requires that accurate measurements be made of the quantity of paint material used in the application process during the time period associated with the coating of specific vehicles or parts. Two general procedures are applicable for accurately measuring paint usage.

8.1.1 The preferred procedure is to determine the weight of paint used during the application study period. Under typical production conditions, such weighing may be difficult, due to the large number of applicators requiring paint supply from a common tank. If a separate, isolated paint supply tank is used in the test; it is important to control paint viscosity, temperature, and flow rate consistent with the regular production system (see 9.1).

8.1.2 Where direct paint usage measurement by weight is not practical, an alternative procedure for determining paint usage by volume is suggested. This procedure involves measuring the drop in paint level in the paint supply tank during the test. To provide sufficient accuracy, it may be necessary to paint a "block" (isolated group) of similar vehicles or parts from the paint supply system while usage measurements are taken. Typically, this may require painting approximately 30 vehicles (see 9.2).

9. Paint Usage Determination by Weight Procedure

9.1 This procedure for determining paint usage during the test is preferred when a satellite paint supply system is available for the process to be tested. With this procedure, it is usually easier to isolate paint usage for measurement purposes, and accurate results can be obtained with a smaller

number of vehicles or parts (see 9.1.1).

9.1.1 At least 5.0 lb (2.27 kg) of paint material must be used during the test with the specified weighing equipment.

9.2 Before a satellite paint supply system can be used, it must be demonstrated that the system is capable of supplying the paint at sufficient volume and pressure to maintain normal process conditions (fluid deliveries of the spray devices) and that the paint can be maintained at a representative temperature and viscosity for the duration of the test period. These requirements can best be assured by mounting the satellite tank on a load cell or scale and directly piping it into the production supply system of the spraybooth. For this procedure the requirements are as follows:

9.2.1 Level and calibrate a weighing device (see Section 7) for weighing the satellite supply tank.

9.2.2 If an electronic weighing device is used, it must be turned on long enough to achieve stability, following the manufacturer's directions. All weighing devices must be situated to minimize disturbance from vibration or air movement.

9.2.3 Introduce the paint material, reduced to spraying viscosity, into the tank to be weighed. Before the test is conducted, be certain that fluid flows are properly set, that all supply and return lines are filled with the paint, and that no leaks are present in the piping system.

9.2.4 Shut off the agitator to minimize vibration during the weighing of the system.

9.2.5 Calibrate the weighing device in accordance with manufacturer's instructions. Weigh and tare a lifting frame, if used to support the satellite paint supply tank.

9.2.6 Weigh the satellite paint supply tank before the test vehicles or parts are run. Flexible connections are required to minimize strain. Carefully note the configuration of the tank so that the same configuration is used for both initial and the final weighing (that is, hose connections, height, etc.). Weigh the tank until 2 consecutive measurements are obtained within the measurement error of the weighing system ± 0.05 lb (0.02 kg). Average the two readings. The satellite tank may be left on the weighing device during the painting operation to monitor painting usage on a continuous basis.

9.2.7 After painting the test vehicles or parts, reweigh the satellite paint supply tank in accordance with 9.2.5 and 9.2.6.

9.2.8 Obtain representative paint samples immediately after completion of the test for solids and density analysis.

10. Paint Usage Determination by Tank Level Measurement (Volume Procedure)

10.1 This procedure for determining the paint usage requires that the drop in the liquid level in the system supply tank be measured accurately. This procedure is applicable with either a satellite system or a main-mix room supply system. A sufficient number of parts must be processed in the test block to provide at least a 3-in. (7.6-cm) drop in the liquid level in the paint supply tank. Careful measurement is critical to the overall accuracy of the transfer efficiency test. This procedure consists of the following:

10.1.1 Accurately measure the inside diameter of the paint supply tank(s) to be used for the various test materials. If the agitator shafts, fill pipes, or any other objects are located in the measurement zone, the occupied volume of

⁵ Electronic digitizer, Model 5322, available from Sterling Scale Co., 20950 Boening, Southfield, MI 48075, has been found suitable for this purpose.

these items must be determined and subtracted from the total volume. Careful selection of the section of the tank for the test measurement will minimize the difficulty of this task. The measurements are used to develop a conversion factor between level drop and volume of paint.

10.1.2 Most main paint supply systems consist of two tanks connected together to maintain the material supply. During the test, the paint supply tank must be isolated. Check to ensure that there is no leakage or overflow between the two tanks and that the directional valves for paint return function properly. Make sure that these checks are made just prior to and after the test, and are done by measuring the volume in both tanks.

10.1.3 Place the test paint, which has been reduced to spraying viscosity, into the paint supply tank to be measured. No material additions or reductions may be made to the tank during the test. Before the test is conducted, make certain that valving is set so that paint is being drawn from the test tank and returned to the test tank, and that all air has been removed from the delivery system.

10.1.4 With satellite paint supply tank systems, special care must be taken to ensure that all fluid lines are completely filled.

10.1.5 Prior to taking the volume measurement, turn off any agitation within the tank that will interfere with the measuring process and then turn it back on after the measurement.

10.1.6 Record the tank levels before and after the test. Take the initial reading just prior to the first test vehicle or part of the block that enters the first application station in the tested process. Take the final reading just after the last vehicle or part has left the last application area in the tested process.

10.1.7 With clearcoat (or other paint materials that cannot be isolated to a specific block of cars due to other connected operations such as repair), take the initial reading as the first vehicle or part in the test block enters the first station applying clearcoat. Take the final reading when the vehicle after the last job in the test block enters the first station, applying clearcoat (the same point at which the initial reading was taken). If this is not done, the block size for clearcoat will be different from the block size for basecoat (this is acceptable but must be accurately reflected in the calculations).

10.1.8 The measurements are to be taken to the nearest $\frac{1}{16}$ in. with a measuring stick with $\frac{1}{16}$ -in. (1.6-mm) or less graduations. Measurements are made from the top of the tank to the top of the liquid level at least 3 to 4 in. (7.6 to 10.2 cm) from the sides of the tank. The top of the tank is to be determined by laying a straight edge across the top of the tank in the same position for each measurement.

NOTE—Caution—Any measuring instruments used in this procedure must be effectively grounded before contacting the coating tank or coating liquid surface. Review all measuring instruments for suitability and resistance to the paint solvents prior to the test.

10.1.9 It may be necessary to provide two-way radio communication between the mix-room monitor and the tested process operation to coordinate the measurement process and timing.

10.1.10 Obtain representative paint samples immediately

after completion of the test for density and solids determinations.

11. Paint Solids Deposited Measurement Procedure

11.1 To determine the transfer efficiency, it is necessary to determine both the weight of paint solids sprayed per vehicle or part and the weight of paint solids actually deposited onto the object in the tested process. These are obtained by weighing vehicles or parts incorporated in the same sample (block) used to obtain the paint usage measurement.

11.2 *Vehicle or Part Weighing Procedure*—The weight of paint solids deposited during the application process is determined by weighing the vehicle(s) or part(s) prior to and after the paint is applied and baked. At least two vehicles or parts are required to be tested. A control part is also run and weighed before and after the application process. No paint is applied to the control part in the process. The control is required to determine weight loss from miscellaneous materials (primarily sealants and plastics applied prior to the tested process) that may occur in the drying oven. The difference in the weight of the measurement vehicles adjusted for the weight loss in the control vehicle or part, is the weight of paint solids applied in the tested process.

11.3 Weighing of the parts requires the use of a precision weighing device and digitizer as described in 7.1 and 7.2. A lifting frame and hoist are required to support the test vehicle. The measurement site(s) must be selected to avoid disturbance caused by air movement or production activities and to allow convenient removal of the test vehicles or parts from the production line and their subsequent replacement to the production line. Fork trucks or other mechanical handling aids along with sufficient manpower to move the vehicle bodies into and out of the weighing frame will be required.

11.3.1 Passenger car bodies generally will weigh 800 to 900 lb (364 to 409 kg). Since the maximum capacity of the specified load cell is 1500 lb (682 kg), the weight of the lifting frame and rigging must be kept to less than 600 lb (273 kg) or a higher capacity load cell with the specified accuracy must be utilized.

11.4 It is critical that the vehicles or parts be allowed to cool completely to room temperature prior to weighing. Closely monitor heavy-metal sections (usually around the door frames) as these areas will cool more slowly than exterior body surfaces. If during the weighing process there is any doubt that the vehicle or part is fully cooled, weigh the test part and allow it to stand 15 to 20 min and weigh again. If a weight increase of more than 0.05 lb (0.02 kg) is noted, allow the body to cool an additional 15 to 20 min and repeat the weighing procedure. Repeat this process until consistent weights are obtained.

11.5 Check that all accessories and miscellaneous materials (hangers, spacers, etc.) remain in the same position (either on or off) for both the initial and final weighings.

11.6 Weighing Procedure:

11.6.1 Turn on the weighing device and digitizer and allow them to warm up in accordance with the manufacturer's instructions.

11.6.2 Zero the instrument in accordance with manufacturer's instructions.

11.6.3 Attach the lifting frame to the load cell. Lift and

the frame until two consecutive readings within 0.05 (2 kg) are obtained. Record this tare weight, W_t .

11.6.4 Mount a completely cooled vehicle or part into the frame. Lift the test unit until it is completely clear of the carrier and fully suspended by the load cell. If the test does not hang level, adjust the suspension point on the frame and recheck for proper tare weight. If necessary, calibration weights may be used to help level the test but be certain to include this weight in the initial tare weight.

11.6.5 Allow the suspended vehicle or part to completely stabilize (usually 2 to 3 min). Be certain that nothing is touching the test unit or suspension frame and record the weight, W_i .

11.6.6 Add a standard calibration weight to the suspended vehicle or part and check for instrument accuracy. Recalibrate the system if a discrepancy is noted.

11.6.6.1 Select the calibration weight to represent the estimated increase in weight of the vehicle or part in the weighing process.

11.6.7 Lower the vehicle or part back onto the carrier to remove the weight from the load cell. Relift the vehicle or part, as just indicated until two consecutive readings within 0.05 lb (0.02 kg) are obtained. Record the weight of two consecutive initial weights, that is W_i for part and $W_{c,i}$ for the control.

11.6.8 Remove the first body and repeat 11.6.5 through 11.6.7 for the other vehicles and the weight loss control vehicle (if included in this test run). Between test measurements and after the last unit is weighed, resuspend the empty weighing frame and verify the tare weight, W_t .

11.6.9 Apply the paint to the specified vehicles or parts, allowing the control unit to proceed through the spraybooth oven uncoated.

11.6.9.1 Considerable care must be taken in handling the weighed units to eliminate any weight gain or loss due to handling, parts addition, parts removal, or miscellaneous items.

11.6.10 After the vehicles or parts have been painted and dried in the oven, allow them to cool to room temperature and then reweighing. Repeat the weighing procedure in 11.6.1 through 11.6.8 and record the weights, $W_{f,i}$ for the coated part (1) and $W_{c,f}$ for the control.

11.6.11 *Foiled Part Procedure*—The procedure is identical to that described in 11.2 except that aluminum foil is applied to the vehicle or part. All the surfaces to be painted are covered with foil as smoothly and tightly as possible to ensure that the covered surface is representative of the area painted in the normal production environment.

12. Measurement of Other Paint Usage

12.1 When the measurement of paint used cannot be completely isolated to the application process under test because of the process and facilities arrangement, it may be necessary to obtain an estimate of paint solids deposited from the same paint supply system in the nonisolated operations (such as repair, etc.). With this estimated value, the total paint solids deposited in the main process can be directly correlated to the amount of paint used in calculating the resultant transfer efficiency. Such a correlation can be established by either making a separate estimate or measurement of the paint used

or the paint solids deposited outside the tested process. The amount of material involved should be small (less than 5 %) relative to the total paint used or deposited.

12.2 While an estimate of paint used is generally preferred, in practice it is usually easier to obtain an estimate of the amount of paint solids deposited onto the test unit. For repair type operations, an estimate of paint solids applied may be obtained by counting the number of panels repaired while the test block is being processed and multiplying by the square feet per panel and the average film build applied (determined from measurements or historical data). This technique works well since almost all repairs involve complete body panels for which data can readily be obtained.

13. Analysis of Paint Samples

13.1 Make the following analytical determinations for each paint sample obtained:

13.1.1 *Weight Fraction Solids*, in accordance with Test Method D 2369 per EPA Federal Reference Method 24.

13.1.2 *Paint Density*, in accordance with Test Method D 1475.

13.2 These determinations are required to calculate transfer efficiency. Obtain separate determinations for each paint material used in each test.

14. Calculations and Report Submission

14.1 Upon completion of the test and receipt of the paint analytical results, the transfer efficiency calculations can be made in accordance with the following procedure:

14.2 Calculate the average weight gain of the vehicle or part, corrected for the weight gain or loss of the control unit.

$$G_{avg} = \frac{\text{Sum}[W_f - W_i]}{n} - [W_{c,f} - W_{c,i}] \quad (1)$$

where:

G_{avg} = average weight gain, lb (kg),

W = weight, lb (kg),

W_f = final weight, lb (kg),

W_i = initial weight, lb (kg),

n = number of test units coated,

c = control,

$W_{c,f}$ = final weight of control vehicle or part, lb (kg), and

$W_{c,i}$ = initial weight of control vehicle or parts, lb (kg).

14.3 Calculate the average amount of paint used during the test period by either the weight procedure or the volume procedure.

14.3.1 *Weight Procedure* (see Section 9):

$$P_{avg} = [P_i - P_f]/m \quad (2)$$

where:

P_{avg} = average weight of paint used during the test, lb (kg),

P_i = initial weight, lb (kg),

P_f = final weight, lb (kg), and

m = number of units measured.

14.3.2 *Volume Procedure* (see Section 10):

$$P_{avg} = (V \times P)/m \quad (3)$$

where:

V = volume of paint used during the test,

D = paint density in accordance with Test Method D 1475, and

m = number of units measured.

14.4 Calculate the average paint solids used during the test period.

$$S_{avg} = P_{avg} \times F \quad (4)$$

where:

S_{avg} = average weight of paint solids used during the test, lb (kg), and

F = weight fraction solids in the paint material from Test Method D 2369.

14.5 Calculate the transfer efficiency T result.

$$T = G_{avg}/S_{avg} \times 100 \quad (5)$$

15. Precision and Bias

15.1 *Precision*—Engineering estimates based on error assumptions indicate an accuracy of $\pm 5\%$ can be expected for typical automotive painting operations.

15.2 *Bias*—Since there is no accepted reference procedure suitable for determining the bias for this test method, no statement on bias is being made.

16. Keywords

16.1 automotive painting; production method; spray-applied; transfer efficiency.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Specification for Artists' Watercolor Paints¹

This standard is issued under the fixed designation D 5067; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (^e) indicates an editorial change since the last revision or reappraisal.

^{e1} NOTE—Table X1.1 was editorially corrected in March 1991.

This specification establishes requirements for composition, physical properties, performance, and labeling of watercolor paints.

This specification covers pigments, vehicles, and additional requirements are included for pigment identification, fineness, and consistency.

Table 1 lists some pigments meeting the lightfastness requirements in this specification. In order to identify other pigments that meet these requirements, instructions are given for test specimen preparation. Test methods for determining relative lightfastness are referenced.

D 284 Terminology of Appearance of Materials³

Terminology

Definitions:

1.1 **Colour Index Name**—consists of the category (type of dye or pigment), general hue, and an assigned number added to a colorant in the Colour Index⁴ as an international identification system.

1.1.1 **Discussion**—For example, the Colour Index name of one phthalocyanine blue pigment is Pigment Blue 15 (PB 15).

1.2 **Colour Index Number**—a five-digit number given in the Colour Index that describes the chemical constitution of a colorant.

1.2.1 **Discussion**—For example, the Colour Index

Number of one phthalocyanine blue pigment is 74160.

3.1.3 Appearance terms used in this standard are defined in Terminology E 284.

3.2 Descriptions of Terms Specific to this Standard:

3.2.1 **watercolor paint**—a pigment dispersion in a water soluble gum/resin vehicle that dries water soluble and is intended primarily for transparent applications.

4. Significance and Use

4.1 This specification establishes quality requirements and provides a basis for common understanding among producers, distributors, and users.

4.2 It is not intended that all paints meeting the requirements be identical nor of uniform excellence in all respects. Variations in manufacture, not covered by this specification, may cause some artists to prefer one brand over another, either of which may be acceptable under this specification.

5. Labeling Requirements

5.1 Pigment(s) Identification:

5.1.1 Every label shall include for each pigment contained in the paint (1) the information underlined in Table 1 (which includes the Common Name, Colour Index Name, and any additional terms necessary to identify the form of the pigment) and (2) the appropriate Lightfastness Category.

5.1.2 The complete pigment identification given in Table 1, which also includes the Colour Index Number and a simple chemical description, shall be given in an appropriate producer publication. Manufacturers are encouraged to put this complete identification on the container label when label size permits.

5.1.3 The Common Name shall be placed on the front of the label and shall be the name of the paint except as described in 5.1.5 and 5.1.6. Other identification may be placed elsewhere on the container.

5.1.4 The Colour Index Name may be spelled out in full or abbreviated depending on the size of the label. Example: Pigment Blue 15, or Pig. Blue 15 or PB 15.

5.1.5 **Substituted Pigments**—In the case of substituted pigments, the word "Hue" in equal size letters shall follow in the title, on the front of the tube, immediately after the name of the pigment that has been simulated. Directly below the title, the Common Name of the significant pigment used shall be given in letters no less than the next type size smaller than the title. For example:

COBALT BLUE HUE
(ULTRAMARINE BLUE).

5.1.6 Proprietary names or optional names may be used

¹This specification is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.57 on Artist Paints and Related Materials.

TABLE 1 Suitable Pigments List

Note—Underlined information and the lightfastness category in the table shall be included on every label.

Key:

Lightfastness Category:

Lightfastness I Excellent Lightfastness
Lightfastness II Very Good Lightfastness

Abbreviations Used for Colour Index Names:

NR Natural Red
PB Pigment Blue
PBk Pigment Black
PBr Pigment Brown
PG Pigment Green
PO Pigment Orange
PR Pigment Red
PV Pigment Violet
PW Pigment White
PY Pigment Yellow

Pigment Notations:

(CC) Concentrated cadmium pigments may contain up to 15 % barium sulfate for color control. Cadmium-barium pigments contain a much higher amount of barium sulfate.
(NA) Colour Index name or number not assigned.
(SM) Sensitive to moisture in direct sunlight.

Colour Index Name	Lightfastness Category	Common Name and Chemical Class	Colour Index Number
Watercolors			
YELLOWS			
PY 3	II	Arylide Yellow 10G, with option of adding the name Hansa Yellow Light, arylide yellow	11710
PY 31	I	Barium Chromate Lemon, barium chromate	77103
PY 34	I	Chrome Yellow Lemon, lead chromate and lead sulfate	77600
PY 35	I	Cadmium Yellow Light, concentrated cadmium zinc sulfide (CC) (SM)	77205
PY 35:1	I	Cadmium-Barium Yellow Light, cadmium zinc sulfide coprecipitated with barium sulfate (SM)	77205:1
PY 37	I	Cadmium Yellow Medium or Deep, concentrated cadmium sulfide (CC) (SM)	77199
PY 37:1	I	Cadmium-Barium Yellow Medium or Deep, cadmium sulfide coprecipitated with barium sulfate (SM)	77199:1
PY 40	II	Aureolin, with option of adding the name Cobalt Yellow, potassium cobaltinitrite	77357
PY 42	I	Mars Yellow, with option of adding the name Yellow Iron Oxide, synthetic hydrated iron oxide	77492
PY 42	I	Mars Orange, synthetic hydrated iron oxide	77492
PY 43	I	Yellow Ochre, natural hydrated iron oxide	77492
PY 97	IIA	Arylide Yellow FGL, arylide yellow	11767
ORANGES			
PO 20	I	Cadmium Orange, concentrated cadmium sulfo-selenide (CC)	77202
PO 20:1	I	Cadmium-Barium Orange, cadmium sulfo-selenide coprecipitated with barium sulfate	77202:1
PO 62	I	Benzimidazolone Orange H5G, monoacetolone	NA
REDS			
PR 101	I	Indian Red, synthetic red iron oxide (bluish hue)	77491
PR 101	I	Light or English Red Oxide, synthetic red iron oxide (yellowish hue)	
PR 101	I	Mars Red, with option of adding the name Red Iron Oxide, synthetic red iron oxide	77491
PR 101	I	Mars Violet, with option of adding the name Violet Iron Oxide, synthetic iron oxide (violet hue)	77015
PR 101	I	Venetian Red, synthetic iron oxide (yellowish hue)	77491
PR 104	I	Chrome Orange, lead chromate and lead molybdate	77605
PR 108	I	Cadmium Red Light, Medium, or Deep, concentrated cadmium-seleno sulfide (CC)	77202:1
PR 108:1	I	Cadmium-Barium Red Light, Medium, or Deep, cadmium seleno-sulfide coprecipitated with barium sulfate	77202:1
PURPLES			
PV 14	I	Cobalt Violet, cobalt phosphate, cobalt ammonium phosphate	77360
PV 15	I	Ultramarine Red, complex silicate of sodium and aluminum with sulfur	77362
PV 15	I	Ultramarine Violet, complex silicate of sodium and aluminum with sulfur	77007
PV 16	I	Manganese Violet, manganese ammonium pyrophosphate	77007
PV 19	IIA	Quinacridone Violet, quinacridone violet b	77742
BLUES			
PB 15	IIA	Phthalocyanine Blue, copper phthalocyanine	74160
PB 27	I	Prussian Blue, with the option of adding the name Milori Blue, ferriammonium ferrocyanide	77510
PB 28	I	Cobalt Blue, oxides of cobalt and aluminum	77346
PB 29	I	Ultramarine Blue, complex silicate of sodium and aluminum with sulfur	77007
PB 33	I	Manganese Blue, barium manganate with barium sulfate	77112
PB 35	I	Cerulean Blue, oxides of cobalt and tin	77368
PB 36	I	Cerulean Blue, Chromium, oxides of cobalt and chromium	77343
GREENS			
PG 7	I	Phthalocyanine Green, chlorinated copper phthalocyanine	74260
PG 17	I	Chromium Oxide Green, anhydrous chromium sesquioxide	77268
PG 18	I	Viridian, hydrous chromium sesquioxide	77269
PG 19	I	Cobalt Green, oxides of cobalt and zinc	77335

TABLE 1 Continued

Pigment Index Number	Lightness Category	Common Name and Chemical Class	Colour Index Number
	Watercolors		
BROWNS			
PBr 7	I	Burnt Sienna, calcined natural iron oxide	77492
PBr 7	I	Burnt Umber, calcined natural iron oxide containing manganese	77492
PBr 7	I	Raw Sienna, natural iron oxide	77492
PBr 7	I	Raw Umber, natural iron oxide containing manganese	77492
BLACKS			
PBk 6	I	Lamp Black, nearly pure amorphous carbon	77266
PBk 7	I	Carbon Black, nearly pure amorphous carbon	77266
PBk 8	I	Ivory Black, amorphous carbon produced by charring animal bones	77267
PBk 9	I	Gray Hydrated Aluminum Silicate, hydrated aluminum silicate	77017
PBk 19	I		
WHITES			
PW 4	I	Zinc White, zinc oxide with option of adding the name Chinese White	77947

These pigments were put into the lightfastness II category pending results of retesting.

provided the Common Name(s) given in Table 1 appears on front of the label directly under the proprietary or optional name in letters no less than the next type size smaller than the proprietary or optional name.

5.1.7 *Mixed Pigments*—Artists' paints containing more than one colorant comply with this specification if all colored pigments used are on the suitable pigment list (Table 1) and provided the mixture itself has passed all other test requirements in this specification. The lightfastness category shall be that of the least lightfast pigment. This lightfastness category may be changed if these paints are tested for lightfastness in accordance with Test Methods D 4303 and results indicating a different category are submitted to ASTM Subcommittee D01.57 for evaluation.

5.2 Provide on the label the identification of the gum/medium used.

5.3 *Lightfastness*—The label shall contain the word "lightfastness" followed by the appropriate rating, I or II, as given for each pigment in Table 1.

5.3.1 Lightfastness I pigments, when made into paint specimens as described in Section 7 and exposed, tested, and rated in accordance with Test Methods D 4303, shall have a color difference (ΔE^*_{ab}) of 4 or less CIELAB units between the specimens measured before and after exposure.

5.3.2 Lightfastness II pigments, when made into paint specimens as described in Section 7 and exposed, tested, and rated in accordance with Test Methods D 4303, shall have a color difference (ΔE^*_{ab}) of more than 4.0 but not more than 10 CIELAB units between the specimens measured before and after exposure.

5.3.3 Pigments were placed in a lightfastness category on the basis of either known historical performance in art works or the ratings from four lightfastness tests conducted as described in Test Methods D 4303. Results from further tests on these, or other pigments, are solicited by Subcommittee D01.57.

5.3.3.1 The lightfastness category of a pigment shall be changed if results from several further tests conducted in accordance with Test Methods D 4303 and approved by ASTM Subcommittee D01.57, establish a different lightfastness category than the one given in Table 1.

5.3.3.2 Additional pigments shall be placed in Table 1 after they have been tested for lightfastness in accordance

with Test Methods D 4303 and the test results submitted to ASTM Subcommittee D01.57 for evaluation, provided the results demonstrate that the pigments have the lightfastness ratings required for Lightfastness I or Lightfastness II, as described above.

5.3.4 For information and to establish nomenclature, pigments in Lightfastness III category are given in Table X1.1 in Appendix X1, but are not to be used in paint conforming to this specification. These pigments have a color difference before and after exposure of more than 8.0 but not more than 16.0 CIELAB units.

5.4 *Toxicity*—All products and labeling must conform to the Federal Hazardous Substances Act and to Practice D 4236.

5.5 *Statement of Conformance*—"Conforms to ASTM Specification D 5067," or "Conforms to ASTM D 5067," or "Conforms to the quality requirements of ASTM D 5067." This statement may be combined with other conformance statements, such as, "Conforms to the quality and health requirements of ASTM Specification D 5067 and Practice D 4236."

5.6 *Address*—Include on the label (1) the name and address of the manufacturer or importer and (2) the country of manufacture.

6. Quality Assurance for Artists' Watercolor Paints

6.1 *Conditions not Covered in This Specification That Affect Artists' Watercolor Paints:*

6.1.1 *Substrate*—The effective pH of the paper used will affect the long-term color of the applied watercolor.

6.1.2 *Environmental Conditions*—Factors such as temperature, humidity, airflow, and light conditions affect application properties, drying time, and adhesion.

6.1.3 *Storage*—With aging and elevated temperatures there may be a change in consistency and a discernible separation of vehicle.

6.2 *Vehicles*—Only water soluble gums/resins shall be used.

6.3 *Pigments*—Pigments used in watercolors shall be limited to those in Table 1. Their lightfastness rating shall be the numeral given in the same row.

6.4 *Additives*—Thickeners, preservatives, surfactants, and humectants may be used to achieve consistency, prevent

microbe deterioration, and control application results.

6.5 *Inerts*—Inerts shall only be used to produce desirable working qualities.

6.6 *Preparation of Sample*—For paste and fluid paints, empty the contents of the previously unopened container onto a glass slab and mix thoroughly with a spatula to a homogeneous sample. For cake paints, take a piece of the cake on a glass slab and add water and mix until a homogeneous paint is formed.

6.7 *Coarse Particles*—Paints shall be free of oversize particles and shall form a uniform film. The maximum content of coarse particles shall be 1 weight % as determined by Test Methods D 185.

6.8 *Fineness of Dispersion*—Determine the fineness of dispersion by Test Method D 1210. For paste paint, on a glass plate, using a spatula, mix the paint with an equal volume of water until homogeneous. The maximum allowable grind reading is 1.5 mils (40 μm).

6.9 *Consistency*—Paints shall be smooth and easily solubilized with water to a homogeneous color.

6.10 *Freeze-Thaw Stability*—Using a freezer that has a temperature of 20°F (−7°C) or lower, subject the paint to five freeze-thaw cycles. A freeze-thaw cycle shall consist of freezing the paint to a solid state (minimum of 18 h) and then thawing the paint to room temperature (minimum of 5 h). The paint shall then meet the requirements of 6.7, 6.8, and 6.9.

7. Lightfastness Determination

7.1 If a pigment is not listed in Table 1, test specimens of a watercolor containing the pigment shall be prepared. These test specimens shall be tested in accordance with the requirements for exposure and evaluation given in Test Methods D 4303.

NOTE—A report of the results of these tests may be submitted to Subcommittee D01.57 for inclusion of the pigments in Table 1. The report shall include information on test conditions and instruments used and shall be accompanied by the test specimens (which will be returned).

7.2 Materials:

7.2.1 *Filter Paper*, 15.0-cm diameter, ashless.⁵

7.2.2 *Drawdown Bar* with 3-mil (75- μm) aperture.

7.2.3 *Posterboard*, lightweight, approximately 20 mils (0.5 mm) thick, having a glossy finish on one side.

7.2.4 *Distilled Water*.

7.2.5 *Acrylic Latex Adhesive*.

7.3 Preparation of Test Paints:

7.3.1 The pigment to be tested may be milled in a soft

paste consistency. If a prepared artists' paint of known composition is available it may be used for this test instead of preparing a standard.

7.3.2 Dilute the watercolors with water and drawdown on paper until the spectrophotometric measurement of the dry paint shows from 35 to 45 % reflectance at the wavelength of maximum absorption for that pigment. The wavelength of maximum absorption is located at the point of lowest reflectance on the spectral curve between 420 and 620 nm. If using a tristimulus filter colorimeter, the lowest of the three filter readings is the region of maximum absorption and the dilution should be adjusted so that a reading of 35 to 45 % reflectance is obtained with this filter. The diffuse white reference standard for all measurements should have an absolute reflectance between 97 and 100 %.

7.3.3 Use an applicator with a 3-mil (75- μm) aperture to make a drawdown on the filter paper. Tape the filter paper to a smooth surface such as a piece of glass. Place the drawdown bar just above the upper edge of the paper so it is ready to use. Pour a small amount of the diluted paint, which is thoroughly mixed, onto the top of the filter paper. Using the drawdown bar, draw the paint down, running the excess off the edge of the filter paper at the bottom. Quickly untape the filter paper and hang it to dry at room temperature. There will be a dark puddle area where the paint was originally applied, but the remaining part of the paper will be uniform in color for use in obtaining spectrophotometric measurements.

7.3.3.1 Prepare four specimen panels for each pigment under test. Two are used in the first lightfastness tests and two are retained in subdued light, one for visual comparisons with the exposed panels and one in case a third test is needed to supplement results from the first two tests, as described in Test Methods D 4303.

7.3.3.2 Apply the test paints to the filter paper as described in 7.3.3. The panels should be air dried for 2 h and then put in an oven at 50°C for overnight drying.

7.3.3.3 Cut the uniform color section of the filter paper drawdown panel into 1½-in. (38-mm) square panels. Adhere the panels to the light posterboard (see 7.2.3) using a thin coat of an acrylic-latex adhesive. The size of the posterboard shall conform to the dimensions of the exposure equipment test racks.

8. Exposure

8.1 Conduct exposure tests, calculate mean color difference, and assign pigments to lightfastness categories as described in Test Methods D 4303.

9. Keywords

9.1 lightfastness; quality requirements; specimen preparation; watercolors

⁵ Whatman No. 42 Filter Paper, available from Fisher Scientific, 711 Forbes Ave., Pittsburgh, PA 15219, has been found satisfactory for this purpose.

APPENDIX

(Nonmandatory Information)

X1. LIGHTFASTNESS III

The pigments in Table X1.1 are not sufficiently common terminology. They may be satisfactory when used fast to be used in paints that conform to this specifica- full strength (without dilution) or with extra protection from These pigments are listed here solely to establish exposure to light.

TABLE X1.1 Lightfastness III

—Underlined information and the lightfastness category in the table shall be included on every label.

Notations:

Lightfast type

Colour Index name or number not assigned

Colour Index Name	Lightfastness Category	Common Name and Chemical Class	Colour Index Number
RY1:1	III	Arylide Yellow G, with option of adding the name Hansa Yellow Medium, arylide yellow	11680
RY74 (LF)†	III	Arylide Yellow 5GX, with option of adding Hansa Yellow 5GX, arylide yellow	11741
RY110	III	isoindolinone Yellow R, tetrachloroisoindolinone	NA
RB106	III	Vermilion, mercuric sulfide	77766
RB112	III	Naphthol AS-D, naphthol AS-D	12370
RB122	III	Quinacridone Magenta, quinacridone	73915

Editorially corrected.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Preparation of Paint Brushes for Evaluation¹

This standard is issued under the fixed designation D 5068; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice describes the preparation of paint brushes for evaluation.

1.2 This practice is applicable to paint brushes 2 to 4 in. (50 to 100 mm) in width.

1.3 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Summary of Practice

2.1 Using a paint chosen for the evaluation, the brush to be tested is repeatedly loaded with this paint and brushed out over a specified area in a specified application time.

3. Significance and Use

3.1 Until a paint brush is fully wetted with paint, only part of the paint loaded onto the brush can be transferred to the surface being painted. By properly preparing the brush before using, the amount of paint delivered to the surface can be made more uniform and reflect real use.

4. Apparatus

- 4.1 *Container*, to hold paint, for example, a quart can.
- 4.2 *Test Brush*, 2 to 4 in. (50 to 100 mm) in width.

5. Materials

- 5.1 *Test Paint*.
- 5.2 *Brush-Out Panels*, or other typical panels to be used.²
- 5.3 *Masking Tape*, to secure the panel to a flat surface.

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.61 on Paint Application Tools.

Current Edition Approved May 25, 1990. Published July 1990.

² Any smooth type panel, for example, upson boards, can be used. A Leneta 8H-BW Chart, available from The Leneta Co., P. O. Box 86, Ho-Ho-Kus, NJ 07427, has been found satisfactory for this purpose.

6. Procedure

6.1 Secure the brush-out panel with masking tape to a flat, smooth, horizontal surface.

6.2 Dip the test brush into the specified paint to the depth shown below:

Brush Width, in. (mm)	Depth, in. (mm)
2 and 2½ (50 and 62.5)	1½ (38)
3 and 3½ (75 and 87.5)	1¾ (45)
4 (100)	2 (50)

6.3 Hold the brush at the specified depth in the paint for 10 s. Remove and hold the brush vertically for 30 s allowing any excess paint to drain.

6.4 After the drain period, immediately apply paint to the specified initial area on the brush-out panel as indicated below:

Brush Width, in. (mm)	Initial Area, cm ²
2 and 2½ (50 and 62.5)	250
3 to 4 (75 to 100)	500

6.5 Application time shall be 15 s for 2 and 2½-in. (50 and 62.5-mm) brushes and 20 s for 3 to 4-in. (75 to 100-mm) brushes.

6.6 Repeat this procedure three times.

6.7 Maintain the level of paint in the container. Keep the angle of the handle and displacement of the filaments of the test brush uniform throughout the entire series. When applying paint, always displace the test brush filament about one third to one half of the filament length and maintain the handle perpendicular to the paint-out surface.

6.8 When applying paint, always start in the middle of the area to be painted with each loading. This leaves the excess paint in the middle where it is easiest to spread to the area being covered and will result in a more uniform coverage (see Fig. 1).

7. Keyword

- 7.1 brush preparation

FIG. 1 Paint Application

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing, you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Preparation of Paint-Roller Covers for Evaluation¹

This standard is issued under the fixed designation D 5069; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice describes the preparation or breaking-in of paint-roller covers for evaluation.

1.2 This practice is applicable to paint-roller covers having nap lengths up to $\frac{1}{2}$ in. (13 mm).

1.3 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Summary of Practice

2.1 Using the paint chosen for the evaluation, the paint-roller cover to be tested is repeatedly and generously loaded with paint and painted out over the same area of approximately 4 to 6 ft (0.4 to 0.6 m²) until it is saturated with paint, that is, the paint-roller cover cannot pick up any more paint, nor apply any more paint to the area being used for break-in.

3. Significance and Use

3.1 Until a paint-roller cover is saturated with paint, only part of the paint loaded onto the paint-roller cover can be transferred to a surface being painted. The remainder of the paint is absorbed into the fabric of the paint-roller cover. The amount of paint absorbed by a paint-roller cover is inversely proportional to the amount already present within the paint-roller cover. By saturation of the paint-roller cover before testing, quantitative inaccuracies of the amount of paint delivered to a surface are eliminated.

3.1.1 Using a saturated paint-roller cover enables the user to apply paint at controllable spreading rates.

3.1.2 Using a saturated paint-roller cover affords reproducibility when repeating a test.

4. Apparatus

4.1 *Paint Tray.*

4.2 *Paint Roller Frame*, of the same size as the paint-roller cover being prepared.

5. Materials

5.1 *Paint*, to be used in test.

5.2 *Primed or Painted Surface*, to be used for the roller cover break-in.

6. Procedure

6.1 Place the paint-roller cover on the frame.

6.2 Load the paint-roller cover with the paint from the tray by rolling the paint-roller cover over the surface of the tray so that just the nap is submersed. See Fig. 1.

6.3 Roll out the roller cover on the surface being used for break-in in an upward and downward motion in no larger an area than 2 ft (0.6 m) high by the width of the roller cover.

6.4 Reload the paint-roller cover with paint and roll out in the same manner over the same area. Do not increase the area except as necessary to control excess dripping of paint.

6.5 Repeat the above procedure as necessary until the following conditions are met:

6.5.1 Reloading the paint-roller cover does not result in increased paint pickup.

6.5.2 There is so much paint on the surface being used that the fully loaded paint-roller cover cannot transfer any more paint to the surface.

6.5.3 When the above conditions are met, there will be so much paint on the roller cover that constant movement (turning over) is necessary to prevent dripping, and the panel will show profuse sagging of the paint. About six roller-cover loadings are usually necessary to achieve this.

6.6 The roller cover is now prepared for immediate testing.

Standard Test Method for Determining Amount of Volatile Organic Compound (VOC) Released from Solventborne Automotive Coatings and Available for Removal in a VOC Control Device (Abatement)¹

This standard is issued under the fixed designation D 5087; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the amount of volatile organic compound (VOC) released from applied solventborne automotive coatings that is available for delivery to a VOC control device. This is accomplished by measuring the weight loss of a freshly coated test panel subjected to solvent evaporation or baking in a laboratory simulation of the production process.

1.2 This test method is applicable to the VOC released from flashoff and baking operations after the paint has been applied.

1.3 This test method is applicable to solventborne automotive coating materials and is intended to represent or simulate the production process. The same general principles apply to waterborne coatings that contain volatile organic compounds (VOC), although specific procedural details are not presented herein to differentiate between VOC and water.

1.4 *This standard does not purport to address the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2.2 EPA Standard:

EPA Federal Reference Method 24—Determination of Volatile Matter Content, Water Content, Density, Volume Solids, and Weight Solids, of Surface Coatings, 40 CFR, Part 60, Appendix A⁵

EPA 450/3-88-018, PB89152276—Protocol for Determining the Daily Volatile Organic Compound Emission Rate of Automobile and Light Duty Truck Topcoat Operations⁶

3. Summary of Test Method

3.1 This test method simulates the loss of VOC from a freshly coated surface by using the difference in weight of a coated test panel before and after baking. Metal test panels are subjected to a simulation of the production coating process including application, flashing, and baking. The weight loss value obtained is then related to the volume of solids deposited on the test panel to compute the number of pounds of VOC per gallon (grams per litre) of solids applied that is available at the inlet of the VOC control device.

3.2 The information needed to determine the amount of VOC available for removal by the VOC control device is determined by identification of the points in the production process at which coated objects would enter flashoff/baking zones whose effluents are vented to the VOC control device.

4. Significance and Use

4.1 This test method provides basic engineering data that may be used to determine the amount of VOC available for delivery at the inlet of a VOC control device (particularly for the automobile industry).⁷ Typically, the procedure is useful for establishing the quantity of VOC that is evolved from the coating in the baking oven and available to be incinerated, although the same procedure can be followed for other forms of VOC abatement (that is, carbon, adsorption, etc.).

4.2 This test method may be adaptable for use directly in a production environment if all the critical factors (for

⁴ Annual Book of ASTM Standards, Vol 14.02.

⁵ Available from Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402.

⁶ National Technical Information Services, 5285 Port Royal Rd. Springfield, VA 22151.

⁷ United States Environmental Protection Agency Protocol for Determining the Daily Volatile Organic Compound Emission Rate of Automobile and Light Duty Truck Topcoat Operations, Ref EPA 450/3-88-018 dated December 1988. This protocol provides for VOC emissions reduction credit for abatement processes.

expressed in pounds (grams) VOC per gallon (litre) solids applied:

11.1.1 The weight of coating solids deposited, W_s , is equal to the coated panel weight after full bake minus the panel weight before coating application as follows:

$$W_s = W_3 - W \quad (3)$$

or

$W_s = W_2 - W$ if W_2 represents a fully cured paint film.

where:

W_s = weight of coating solids deposited, lb (g),

W_2 = weight of panel at point which exhaust air is no longer vented to VOC control device,

W_3 = weight of panel with fully baked paint film, and

W = weight of initial unpainted test panel.

11.1.2 Determine the weight of VOC available for abatement control (W_A) by taking the difference in the weight of the panel representing the point in the process at which the exhaust air is vented to the control device (W_1) and the weight of the panel at the point where the exhaust air is no longer vented to the VOC control device (W_2) as follows:

$$W_A = W_1 - W_2 \quad (4)$$

where:

W_A = weight of VOC available for control, lb (g),

W_1 = weight of panel at point at which exhaust air is first vented to VOC control device, and

W_2 = weight of panel at point at which exhaust air is no longer vented to VOC control device.

11.1.3 Calculate the pounds VOC available for control per gallon of coating solids applied, C_L , by combining the weight of VOC available (W_A), weight of coating solids applied (W_s) and the coating solids density (D_{CS}) as follows:

$$C_L = \left(\frac{W_A}{W_s} \right) \times D_{CS} \quad (5)$$

where:

C_L = VOC loading lb/gal (g/L),

W_A = VOC available for removal, lb,

W_s = coating solids applied, lb, and

D_{CS} = coating solids density, lb/gal (g/L).

NOTE 2—Coating materials must be the specific formulations (as-applied condition) used in the process for which the VOC loading to the VOC control device, is to be determined.

12. Precision and Bias

12.1 *Precision*—The precision of the procedure in this test method is being determined.

12.2 *Bias*—Since there is no accepted reference procedure suitable for determining the bias for the procedure in this test method, no statement on bias is being made.

13. Keywords

13.1 automotive coatings; solvent release; VOC abatement

Standard Test Method for Determination of the Nonvolatile Content in Silanes, Siloxanes and Silane-Siloxane Blends Used in Masonry Water Repellent Treatments¹

This standard is issued under the fixed designation D 5095; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

1.1 This test method describes a procedure for the determination of the nonvolatile content (N_v) of silanes, siloxanes, and blended silane-siloxane materials used in masonry water repellent treatments and is applicable to both solvent- and water-borne materials.

1.2 This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate health and safety practices and determine the applicability of regulatory limitations prior to use. For a specific hazard statement, see Section 7.

Referenced Documents

- 2.1 *ASTM Standards*:
D 1193 Specification for Reagent Water²
D 3980 Practice for Interlaboratory Testing of Paint and Related Materials³
E 145 Specification for Gravity-Convection and Forced-Ventilation Ovens⁴

Summary of Test Method

3.1 A designated quantity of test material is weighed into a preweighed aluminum dish containing the catalyst solution, mixed, allowed to stand for 60 min at room temperature, and then heated in an oven at $110 \pm 5^\circ\text{C}$ for 60 min. The nonvolatile content of the test material is calculated by subtracting the solids of the catalyst solution from the total solids by weight of the test solution.

Significance and Use

4.1 This test method is used to determine the nonvolatile content of silanes, siloxanes, and silane-siloxane blended materials used in masonry water-repellent treatments. It can be used for the purpose of calculating the volatile organic compound (VOC) content of these materials under specified test conditions.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.47 on Masonry Treatments.

Current edition approved Sept. 15, 1991. Published November 1991. Originally published as D 5095 - 90. Last previous edition D 5095 - 90.

³ *Annual Book of ASTM Standards*, Vol 06.01.

⁴ *Annual Book of ASTM Standards*, Vol 14.02.

5. Apparatus

5.1 *Aluminum Dishes*, 58-mm diameter by 18-mm high with a smooth (planar) bottom surface. Precondition the dishes for 30 min in an oven at $110 \pm 5^\circ\text{C}$ and store in a desiccator prior to use.

5.2 *Forced Draft Oven*, Type IIA or Type IIB as specified by Specification E 145.

5.3 *Syringes*, 1-mL and 5-mL.

5.4 *Analytical Balance*, capable of weighing to 0.1 mg.

6. Reagents

6.1 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water as defined by Type IV of Specification D 1193.

6.2 *p-Toluenesulfonic Acid*, monohydrate.⁵

6.3 *Alcohol*, technical grade ethanol or isopropanol.

7. Hazards

7.1 In addition to other precautions, provide adequate ventilation, consistent with accepted laboratory practice, to limit the accumulation of solvent vapors.

8. Procedure

8.1 *Catalyst Solution*—Prepare a catalyst solution containing a mixture of 0.5 % *p*-Toluenesulfonic acid in either ethanol or isopropanol. Thoroughly mix the solution. Prepare sufficient catalyst solution to perform all tests.

8.1.1 The nonvolatile content of the test material can be calculated only if the same catalyst solution is used throughout the test. Each time a new batch of catalyst solution is used, its nonvolatile content must be determined.

8.2 Determine the nonvolatile matter, in triplicate, of the catalyst solution as follows:

8.2.1 Weigh an aluminum dish to 0.1 mg. Record the weight as W_1 .

8.2.2 Using a 5-mL syringe, weigh 3 ± 1.0 g, to 0.1 mg, by difference, of the catalyst solution into the preweighed aluminum dish. Record the weight of catalyst solution as W_2 .

8.2.3 Heat the aluminum dish containing the catalyst solution in a forced draft oven for 60 min at $110 \pm 5^\circ\text{C}$.

8.2.4 Remove the dish from the oven and immediately place in a desiccator. Seal the desiccator and allow the dish to cool to ambient temperature.

⁵ Solutions of *p*-Toluenesulfonic acid in isopropanol may be obtained from King Industries, Science Road, Norwalk, CT 06852.

8.2.5 Reweigh the dish to 0.1 mg. Record the weight as W_2 .

8.2.6 Calculate the nonvolatile matter of the catalyst solution, N_c , in accordance with 9.1.

8.3 Determine the percent nonvolatile content, in triplicate, of the test specimen as follows:

8.3.1 Thoroughly mix the test materials before use.

8.3.2 Weigh an aluminum dish to 0.1 mg. Record the weight as W_4 .

8.3.3 Using a 5-mL syringe, weigh 3 ± 1.0 g, to 0.1 mg, by difference, of the catalyst solution into the preweighed aluminum dish. Record the weight as W_6 .

8.3.4 Using a 1-mL syringe, weigh 1.0 ± 0.1 g, to 0.1 mg, by difference, of the test specimen into the weighing dish containing the catalyst solution. Record the weight of the test specimen as S .

8.3.4.1 Weighings must be done quickly to limit weight loss due to volatilization. If there is insufficient moisture present when testing solvent-borne silane materials, it is advisable to add up to 0.3 g of reagent grade water to the dish containing the mixture of catalyst and test solutions.

8.3.5 Gently swirl the dish to mix the materials. Allow the materials to stand at room temperature for 60 min.

8.3.6 Heat the dish containing the mixture of catalyst and test solutions in a forced-draft oven for 60 min at $110 \pm 5^\circ\text{C}$.

8.3.7 Remove the dish from the oven and immediately place in a desiccator. Seal the desiccator and allow the dish to cool to ambient temperature.

8.3.8 Reweigh the aluminum dish to 0.1 mg and record the weight as W_5 .

8.3.9 Calculate the nonvolatile content, N_s , of the test specimen in accordance with 9.2.

9. Calculation

9.1 Calculate the nonvolatile matter, N_c , in the catalyst solution as follows:

$$N_c = (W_2 - W_1)/W_3 \quad (1)$$

where:

N_c = nonvolatile matter of catalyst solution expressed as a decimal fraction,

W_1 = weight of aluminum dish, g,

W_2 = weight of dish plus catalyst solution after heating, g, and

W_3 = weight of catalyst solution before heating, g.

9.2 Calculate the nonvolatile content, N_s , in the test specimen as follows:

$$N_s = 100 \frac{[(W_5 - W_4) - (W_6)(N_c)]}{S}$$

where:

N_s = nonvolatile content of test specimen, percent,

W_4 = weight of the aluminum dish, g,

W_5 = weight of aluminum dish plus the catalyzed material after heating, g,

W_6 = weight of catalyst solution used in test specimen before heating, g,

N_c = nonvolatile matter of catalyst solution, decimal fraction, (average of two determinations), and

S = weight of test specimen before heating, g.

10. Report

10.1 Report the following information:

10.1.1 The average values obtained for the nonvolatile content of the catalyst solution, N_c .

10.1.2 The average values obtained for the percent nonvolatile content of the test specimen, N_s .

11. Precision and Bias

11.1 The precision estimated for this test method is based on an interlaboratory study in which one operator in each of five laboratories tested in triplicate on two different days four water repellent materials containing between 14 to 65% nonvolatiles. The results were analyzed statistically in accordance with Practice D 3980. The intralaboratory standard deviation was found to be 0.283% absolute with 17 df and the interlaboratory coefficient of variation 7.02% relative with 16 df. Based on the standard deviation and coefficient of variation, the following criteria should be used for judging at the 95% confidence level, the acceptability of results.

11.1.1 *Repeatability*—Two results, each the mean of triplicates, obtained by the same operator should be considered suspect if they differ by more than 0.84% absolute.

11.1.2 *Reproducibility*—Two results, each the mean of triplicates, obtained by operators in different laboratories should be considered suspect if they differ by more than 7.02% relative.

11.2 *Bias*—Bias has not been established for this test method.

12. Keywords

12.1 masonry water repellents; nonvolatile matter content; silanes; siloxanes

Standard Specification for Artists' Acrylic Emulsion Paints¹

This standard is issued under the fixed designation D 5098; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

1.1 This specification establishes requirements for composition, physical properties, performance, and labeling of artists' acrylic emulsion paints.

1.2 This specification covers pigments, vehicles, and additives. Requirements are included for pigment identification, lightfastness, consistency, and drying time.

1.3 Table 1 lists some pigments meeting the lightfastness requirements in this specification. In order to identify other pigments that meet these requirements, instructions are given for test specimen preparation. Test methods for determining relative lightfastness are referenced.

1.4 The values stated in inch-pound units are to be regarded as standard. The SI units given in parentheses are for information only.

- E 284 Terminology of Appearance⁵

Terminology

3.1 Definitions:

3.1.1 *colour index name*—consists of the category (type of color or pigment), general hue, and an assigned number given

to a colorant in the Colour Index⁶ as an international identification system.

3.1.1.1 *Discussion*—For example, the Colour Index Name of one phthalocyanine blue pigment is Pigment Blue 15 (PB 15).

3.1.2 *Colour Index Number*—a five-digit number given in the Colour Index that describes the chemical constitution of a colorant.

3.1.2.1 *Discussion*—For example, the Colour Index Number of one phthalocyanine blue pigment is 74160.

3.1.3 Appearance terms used in this specification are defined in Terminology E 284.

3.2 Descriptions of Terms Specific to This Standard:

3.2.1 *acrylic emulsion paint*—paint containing a stable aqueous dispersion of polymers or copolymers of acrylic acid, methacrylic acid, esters of these acids, or acrylonitrile; sometimes termed latex, acrylic latex, or polymer emulsion paint.

3.2.2 *glycols*—general term for dihydric alcohols used to provide freeze-thaw stability in acrylic and other water-based vehicle systems.

4. Significance and Use

4.1 This specification establishes quality requirements and provides a basis for common understanding among producers, distributors, and users.

4.2 It is not intended that all paints meeting the requirements be identical nor of uniform excellence in all respects. Variations in manufacture, not covered by this specification, may cause some artists to prefer one brand over another, either of which may be acceptable under this specification.

5. Labeling Requirements

5.1 Pigment(s) Identification:

5.1.1 Every label shall include for each pigment contained in the paint the information underlined in Table 1 which includes the Common Name, Colour Index Name, and any additional terms necessary to identify the form of the pigment.

5.1.2 The complete pigment identification given in Table 1, which also includes the Colour Index Number and a simple chemical description, shall be given in an appropriate producer publication. Manufacturers are encouraged to put this complete identification on the container label when label size permits.

5.1.3 The Common Name shall be placed on the front of the label and shall be the name of the paint except as

TABLE 1 Suitable Pigment List

Note—Underlined information and the lightfastness rating in the table shall be included on every label.

Key:

Lightfastness Category:

Lightfastness I Excellent Lightfastness

Lightfastness II Very Good Lightfastness

Abbreviations used in Colour Index Names:

PB Pigment Blue
PBk Pigment Black
PBr Pigment Brown
PG Pigment Green
PO Pigment Orange
PR Pigment Red
PV Pigment Violet
PW Pigment White
PY Pigment Yellow

Pigment Notations:

(CC) Concentrated cadmium pigments may contain up to 15 % barium sulfate for color control. Cadmium-barium pigments contain a much higher amount of barium sulfate.
(DL) May darken in strong light
(LF) Lightfast type
(NA) Colour Index name or number not assigned
(RS) Red shade
(SM) Sensitive to moisture in direct sunlight
(SS) Sensitive to hydrogen sulfide

	I	Mars Violet, with option of adding the name Violet Iron Oxide, synthetic iron oxide (violet hue)	77015
	I	Venetian Red, synthetic iron oxide (yellowish hue)	77491
	I	Light Red, calcined yellow ochre	77492
	I	Vermilion, mercuric sulfide (DL)	77766
	I	Cadmium Red Light, Medium, or Deep, concentrated cadmium-seleno sulfide (CC)	77202.1
	I	Cadmium-Barium Red Light, Medium, or Deep, cadmium seleno-sulfide coprecipitated with barium sulfate	77202.1
	II	Naphthol AS-D, naphthol AS-D	12370
	I	Cadmium Vermillion Red Light, Medium or Deep, concentrated cadmium mercury sulfide (CC)	77201
	I	Cadmium-Barium Vermillion Red Light, Medium or Deep, cadmium mercury sulfide coprecipitated with barium sulfate	77201.1
	I	Naphthol Red, naphthol	NA
	I	Quinacridone Magenta, γ quinacridone	73915
	II	Perylene Vermillion, perylene	71145
	I	Perylene Red, perylene	77137
	I	Brominated Anthranthrone, brominated anthranthrone	58300
F3RK-70	I	Naphthol Red, naphthol carbanilide	12475
F5RK	II	Naphthol Crimson, naphthol carbanilide	12475
	I	Benzimidazolone Maroon, benzimidazolone	71513
	I	Perylene Maroon, perylene	71130
	I	Thioindigold Magenta, thioindigold	73360
	I	Naphthol AS, naphthol AS	12467
	I	Perylene Red, perylene	71140
	I	Quinacridone Red, γ quinacridone red	NA
	I	Pennone Red Deep, pennone	71100
	I	Quinacridone Scarlet, quinacridone red	NA
	I	Quinacridone Yellow Red, quinacridone red γ	73902
	I	Quinacridone Red, γ quinacridone red	73900
PURPLES			
	I	Ultramarine Red, complex silicate of sodium and aluminum with sulfur	77007
	I	Ultramarine Violet, complex silicate of sodium and aluminum with sulfur	77007
	I	Quinacridone Violet, quinacridone violet b	73900
23 (RS)	II	Dioxazine Purple, carbazole dioxazine	51319
	I	Isoviolanthrone Violet, isoviolanthrone	60010
BLUES			
	I	Phthalocyanine Blue, copper phthalocyanine	74160
	I	Phthalocyanine Blue, metal free phthalocyanine	74100
	I	Indanthrone Blue, indanthrone	69810
	I	Cobalt Blue, oxides of cobalt and aluminum	77346
	I	Ultramarine Blue, complex silicate of sodium and aluminum with sulfur	77007
	I	Manganese Blue, barium manganate with barium sulfate	77112
	I	Cerulean Blue, oxides of cobalt and tin	77368
	I	Cerulean Blue, Chromium, oxides of cobalt and chromium	77343
	I	Indanthrone Blue, indanthrone	69800
GREENS			
	I	Phthalocyanine Green, chlorinated copper phthalocyanine	74260
	I	Green Gold, with option of adding the name Nickel Azo Yellow, nickel chelated azo	12775
	I	Chromium Oxide Green, anhydrous chromium sesquioxide	77288
	I	Cobalt Green, oxides of cobalt and zinc	77335
	I	Green Earth or Terra Verde, natural green	77009
	I	Phthalocyanine Green, chlorinated and brominated phthalocyanine	74265
	I	Light Green Oxide, oxides of nickel, cobalt, and titanium	77377
BROWNS			
	I	Mars Brown, with option of adding the name Brown Iron Oxide, synthetic brown iron oxide or mixtures of synthetic iron oxides	77499
	I	Burnt Sienna, calcined natural iron oxide	77492
	I	Burnt Umber, calcined natural iron oxide containing manganese	77492
	I	Raw Sienna, natural iron oxide	77492
	I	Raw Umber, natural iron oxide containing manganese	77492

TABLE 1 Continued

Colour Index Name	Lightfastness Category	Common Name and Chemical Class	Colour Index Number
	Acrylic		
BLACKS			
PBk 6	I	Lamp Black, nearly pure amorphous carbon	77266
PBk 7	I	Carbon Black, nearly pure amorphous carbon	77266
PBk 9	I	Ivory Black, amorphous carbon produced by charring animal bones	77267
PBk 11	I	Mars Black, with option of adding the name Black Iron Oxide, synthetic black iron oxide	77499
WHITES			
PW 4	I	Zinc White, zinc oxide	77947
PW 6	I	Titanium White, titanium dioxide (rutile or anatase) with option of including some barium sulfate or zinc oxide	77891

* Applies only to Permanent Red Violet MRS, product of American Hoechst Corp., Coventry, RI 02616. Pigments described as thioindigoids have varying degrees of lightfastness.

described in 5.1.5 and 5.1.6. Other identification may be placed elsewhere on the container.

5.1.4 The Colour Index Name may be spelled out in full or abbreviated depending on the size of the label. Example: Pigment Blue 15, or Pig. Blue 15 or PB 15.

5.1.5 *Substituted Pigments*—In the case of substituted pigments, the word "Hue" in equal size letters shall follow in the title, on the front of the tube, immediately after the name of the pigment that has been simulated. Directly below the title, the Common Name of the significant pigment used shall be given in letters no less than the next type size smaller than the title. For example:

COBALT BLUE HUE
(ULTRAMARINE BLUE).

5.1.6 Proprietary names or optional names may be used provided the Common Name(s) given in Table 1 appears on the front of the label directly under the proprietary or optional name in letters no less than the next type size smaller than the proprietary or optional name.

5.1.7 *Mixed Pigments*—Artists' paints containing more than one colorant comply with this specification if all colored pigments used are on the suitable pigment list (Table 1) and provided the mixture itself has passed all other test requirements in this specification. The lightfastness category shall be that of the least lightfast pigment. This lightfastness category may be changed if these paints are tested for lightfastness in accordance with Test Methods D 4303 and results indicating a different category are submitted to ASTM Subcommittee D01.57 for evaluation.

5.2 Provide on the label identification of polymer used in the paint.

NOTE 1—The type of polymer can be identified by using Practice D 3168.

5.3 *Lightfastness*—The label shall contain the word "Lightfastness" followed by the appropriate rating, I or II, as given for each pigment in Table 1.

5.3.1 Lightfastness I pigments, when made into paint specimens as described in Section 7 and exposed, tested, and rated in accordance with Test Method D 4303, shall have a color difference (ΔE^*_{ab}) of 4 or less CIELAB units between the specimens measured before and after exposure.

5.3.2 Lightfastness II pigments, when made into paint specimens as described in Section 7 and exposed, tested, and rated in accordance with Test Methods D 4303, shall have a color difference (ΔE^*_{ab}) of more than 4.0 but not more than

8.0 CIELAB units between the specimens measured before and after exposure.

5.3.3 Pigments were placed in a lightfastness category on the basis of either known historical performance in art works or the ratings from four lightfastness tests conducted as described in Test Methods D 4303. Results from further tests on these, or other pigments, are solicited by ASTM Subcommittee D01.57.

5.3.3.1 The lightfastness category of a pigment shall be changed if results from several further tests conducted in accordance with Test Methods D 4303 and approved by ASTM Subcommittee D01.57, establish a different lightfastness category than the one given in Table 1.

5.3.3.2 Additional pigments shall be placed in Table 1 after they have been tested for lightfastness in accordance with Test Methods D 4303 and the test results submitted to ASTM Subcommittee D01.57 for evaluation, provided the results demonstrate that the pigments have the lightfastness ratings required for Lightfastness I or Lightfastness II, as described in 5.3.1 and 5.3.2.

5.3.4 For information and to establish nomenclature, pigments in Lightfastness III category are given in Table X1.1 in Appendix X1, but are not to be used in paint conforming to this specification. These pigments have a color difference before and after exposure of more than 8.0 but not more than 16.0 CIELAB units.

5.4 *Toxicity*—All products and labeling must conform to the Federal Hazardous Substances Act and to Practice D 4236.

5.5 *Statement of Conformance*—"Conforms to ASTM Specification D 5098," or "Conforms to ASTM D 5098," or "Conforms to the quality requirements of ASTM D 5098." This statement may be combined with other conformance statements, such as, "Conforms to the quality and health requirements of ASTM Specification D 5098 and Practice D 4236."

5.6 *Address*—Include on the label (1) the name and address of the manufacturer or importer and (2) the country of manufacture.

6. Quality Assurance for Artists' Acrylic Emulsion Paints

6.1 *Conditions not Covered in This Specification that Affect the Quality of Artists' Acrylic Emulsion Paints:*

6.1.1 *Substrate*—Factors such as the texture, gloss, effective pH, porosity, chemical composition, and condition of the substrate will affect gloss, gloss uniformity, drying time,

hesion, and the flexibility of the dried film.

6.1.2 *Environmental Conditions*—Factors such as temperature, humidity, air flow, and light conditions affect application properties, film formation, drying time, and adhesion.

6.1.3 *Storage*—Factors such as aging, and high and low temperatures may cause changes in consistency.

6.2 *Vehicles*—Only acrylic polymer emulsions or acrylic polymer emulsions may be used (see Note 1).

6.3 *Pigments*—The pigments shall be limited to those recommended for use in acrylic emulsion paints in the list of pigments in Table 1. Their lightfastness rating shall be the numeral given in the same row.

6.4 *Additives*—Surfactants, preservatives, defoamers, glycol solvents, and thickeners may be used to achieve aging stability, to control foaming, to ensure freeze-thaw stability of film coalescence, and to obtain a desired consistency.

6.5 *Inerts*—Inerts shall be included only to adjust product gloss or sheen, or to produce desirable working qualities.

6.6 *Preparation of Sample*—Empty the contents of a previously unopened container onto a glass slab and mix thoroughly with a spatula to a homogeneous sample.

6.7 *Coarse Particles*—Paints shall be free of oversize particles and shall form a uniform film. The maximum content of coarse particles shall be 1 weight % as determined by Test Methods D 185.

6.8 *Fineness of Dispersion*—Determine the fineness of dispersion by Test Method D 1210. For paste paint: on a glass plate, using a spatula, mix the paint with an equal volume of water until homogeneous. The maximum allowable grind reading is 1.5 mils (40 μ m).

6.9 *Consistency*—Paints shall be smooth and creamy. The paste type of paint shall not flow or level when applied with a palette knife.

6.10 *Freeze-Thaw Stability*—Using a freezer that has a temperature of 20°F (−7°C) or lower, subject the paint to five freeze-thaw cycles. A freeze-thaw cycle shall consist of freezing the paint to a solid state (minimum of 18 h) and then thawing the paint to room temperature (minimum of 5 h). The paint shall then meet the requirements of 6.7, 6.8, and 6.9.

6.11 *Drying*—Use a 6-mil (150- μ m) clearance film applicator to make a uniform drawdown on a lacquer-sealed panel. At a relative humidity of 50 to 75 % and a temperature of 65 to 80°F (18 to 27°C), the dust-free drying time, determined in accordance with Test Method D 1640, shall be not less than 10 min.

6.12 *Tinting strength requirements* will be included in this specification as appropriate tinting strength standards for individual pigments are established. Test Method D 387 may be used to determine the tinting strength of pigments or tints when all ingredients are known. Test Method D 4838 may be used to determine the relative tinting strength of aromatic paints containing a single pigment and the same vehicle but where other ingredients are unknown.

Lightfastness Determination

7.1 If a pigment is not listed in Table 1, test specimens of paint containing the pigment shall be prepared. These test specimens shall be tested in conformance with the requirements for exposure and evaluation given in Test Methods D 4303.

NOTE 2—A report of the results of these tests may be submitted to ASTM Subcommittee D01.57 for inclusion of the pigments in Table 1. The report shall include information on test conditions, instruments used, and be accompanied by the test specimens, which will be returned.

7.2 Materials:

7.2.1 *Aluminum Exposure Panels*,⁷ 3 by 6 in. (75 by 150 mm).

7.2.2 *Posterboard*, lightweight, approximately 20 mils (0.5 mm) thick, having a glossy finish on one side.

7.2.3 *Titanium Dioxide Acrylic Emulsion Paint*.

7.2.4 *Spray Apparatus*, for applying ground coats.

7.2.5 *Paint Brush*, 2.5 in. (60 mm) wide for applying ground coats if spray apparatus is not available.

7.2.6 *Soft Hair Brush*, 1 in. (25 mm) wide for applying ground coats to aluminum panels. An oxhair artist's "stroke" brush is suitable.

7.3 Specimen Preparation:

7.3.1 Ground Coats:

7.3.1.1 For the first ground coat under acrylic emulsion paints, prepare the following enamel:

	Weight %
Medium oil length soya alkyd, 50 % nonvolatile ⁸	20
Rutile titanium dioxide ⁹ (conforming to Type II of Specification D 476)	40
Blanc fixe (conforming to Specification D 602)	40
Driers: 0.15 % zinc and 0.15 % zirconium as metal on the alkyd nonvolatile	
Sufficient mineral spirits for milling	

7.3.1.2 Mill to a Hegman fineness of 7 as measured by Test Method D 1210. Thin with mineral spirits to appropriate viscosity for spraying or for flow coating by brush.

7.3.2 For the second ground coat for acrylic emulsion paints, prepare the following enamel:

	Weight %
Medium oil length soya alkyd, 50 % nonvolatile ⁸	40
Rutile titanium dioxide ⁹ (conforming to Type II of Specification D 476)	30
Colloidal silica ¹⁰	30
Driers: 0.15 % zinc and 0.15 % zirconium as metal on the alkyd nonvolatile	
Sufficient mineral spirits for milling	

7.3.2.1 The colloidal silica may be dispersed separately in mineral spirits using a high-speed mixer and added to the milled alkyd-titanium pigment paste. Mill to a Hegman fineness of 7 as measured by Test Method D 1210. Use sufficient mineral spirit for proper application.

NOTE 3—These soya alkyd enamels are used for the ground coats because of their color stability, nonabsorbency, adhesion of the specimen coats under humid conditions, and freedom from blistering that can occur with an acrylic ground coat under high humidity.

⁷ The No. A-36 aluminum panel manufactured by Q Panel Co., 26200 First St., Cleveland, OH 44145, has been found satisfactory for this purpose.

⁸ The following alkyd resins have been found satisfactory for this purpose: Cargill, No. 5196; JMC McWhorter, DURAMAC 2419; Reichhold, No. 11-035; and Spencer-Kellog, AROPLAZ 1082 M50.

⁹ DuPont R900 rutile titanium dioxide, available from E.I. du Pont de Nemours & Co., 1007 Market St., Wilmington, DE 19898, has been found satisfactory for this purpose.

¹⁰ Syloid 308, available from Davison Chemical, Div. W.R. Grace Co., PO Box 2117; Baltimore, MD 21203, has been found satisfactory for this purpose.

7.3.3 Application of Ground Coats:

7.3.3.1 Degrease aluminum substrates before applying the ground coat.

7.3.3.2 Apply one coat of the enamel described in 7.3.1.1, followed by one coat of the enamel described in 7.3.2. To flow coat the aluminum panels for sun exposure use a 1-in. (25-mm) soft hair brush. Coat the posterboard to be used for laboratory exposure on the less absorbent, glossy side.

NOTE 4—Coating the posterboard is most conveniently done on the whole sheet before cutting to size.

7.3.3.3 Allow a minimum of five days drying time following the first coat and two weeks or more after applying the second coat and before applying the paint to be tested.

7.4 Mixing Whites for Dilution of Colors:

7.4.1 Use a white containing the same emulsion and additives as the formulation in which the pigment is incorporated if possible.¹¹ The following basic composition has been found satisfactory:

	Weight %
Acrylic emulsion nonvolatile	23 to 24
Rutile titanium dioxide ⁹ (conforming to Type II of Specification D 476)	34.6

7.4.1.1 Keep the viscosity of the mixing white to 250 P or slightly lower.

7.5 Preparation of Test Paints:

7.5.1 The pigment to be tested may be milled in a compatible paste for acrylic emulsion. If a prepared artists' paint of known composition is available, it may be used for this test instead of preparing a dispersion.

7.5.2 Dilute the pigment paste or paint with the white containing the same type of vehicle until the spectrophotometric measurement of the dried film shows 35 to 45 % relative reflectance at the wavelength of maximum absorption for that pigment. The wavelength of maximum absorption is located at the point of lowest reflectance on the spectral curve between 420 and 620 nm. If using a tristimulus filter colorimeter, the lowest of the three filter readings is the region of maximum absorption and the dilution should be adjusted so that a reading of 35 to 45 % reflectance is obtained with this filter. The diffuse white reference standard for all measurements should have an absolute reflectance between 97 and 100 %.

7.5.2.1 To obtain this reflectance, use the Kubelka-Munk

Single Constant Method described in Appendix X2 or use a trial and error method.

7.5.3 Make instrumental readings with the specular reflectance included to minimize the effect on readings of any change in gloss and to minimize the effect of brush strokes.

7.5.4 Use an applicator with a 6-mil (150- μ m) aperture to make a minimum size drawdown, 1½ by 1½ in. (40 by 40 mm), or other minimum size appropriate for the viewing area of the instrument used. Return all recoverable paint to the batch to allow for repeat mixes and measurements.

7.5.5 For acrylic emulsion paints, 80 g of white paint is needed since paint used in the drawdown is lost.

7.5.6 For the initial weights of white stated in 7.5.4 and 7.5.5, the weighing must be accurate to 0.05 g.

7.6 Application of Paints to Panels:

7.6.1 Prepare four specimen panels on appropriate substrates for each pigment under test. Two are used in the first lightfastness tests and two are retained in subdued light, one for visual comparisons with the exposed panels and one in case a third test is needed to supplement results from the first two tests, as described in Test Methods D 4303.

7.6.2 Apply the test paints by brush to the aluminum panel if exposure is to be under glass to the sun or by brush to the posterboard panel if exposure is to be to laboratory apparatus.

7.6.3 Using the No. 12 artist's flat bristle brush, brush the panels lengthwise, then crosswise, and again lengthwise, this time with a light touch to produce a film as smooth as possible. The mixing whites must be fluid enough to facilitate leveling, but not have excess vehicle that can affect the test. Do not use thinners. Apply two coats to all specimen panels to achieve complete opacity.

7.6.4 Allow specimens to dry between coats as described in the Procedure section (Dry-Through or Dry-to-Handle Time) of Test Methods D 1640. After recoating, allow specimens to dry hard, as described in the Procedure section (Dry-Hard Time) of Test Methods D 1640, before measuring them prior to exposure. Acrylic paints can be recoated the next day and read two days after recoating.

8. Exposure

8.1 Conduct exposure tests, calculate mean color difference, and assign pigments to lightfastness categories as described in Test Methods D 4303.

9. Keywords

9.1 artists' acrylic paints; lightfastness; quality requirements; test specimens

¹¹ If the acrylic vehicle composition of the paint is unknown, Rhoplex AC-234, from Rohm & Haas Co., Independence Mall W., Philadelphia, PA 19105, is compatible with most acrylic emulsion paints.

APPENDIXES

(Nonmandatory Information)

X1. LIGHTFASTNESS III

The pigments in Table X1.1 are not sufficiently fast to be used in paints that conform to this specification. These pigments are listed here solely to establish

common terminology. They may be satisfactory when used full strength (without dilution) or with extra protection from exposure to light.

TABLE X1.1 Lightfastness III

Colour Index Name	Lightfastness Category	Common Name and Chemical Class	Colour Index Number
PR 17	III	Naphthol Red AS-D, naphthol	12390
PR 146	III	Naphthol Red, naphtholic arylide	12485
PY 23BS	III	Dioxazine Purple, carbazole dioxazine	51319
PG 8	III	Hooker's Green, ferric-nitroso-beta-naphthol	10006

X2. KUBELKA-MUNK SINGLE CONSTANT METHOD FOR PREPARING PAINT FILMS $40 \pm 5\%$ REFLECTANCE

X2.1 Prepare a mixture of white and colorant in proportion estimated to give a paint having a reflectance of 30 to 40 % at the wavelength of maximum absorption. Calculate the concentration of colorant in white in this batch as follows:

$$C_c = W_c/W_w + W_c$$

where:
 C_c = concentration of colorant, and
 W_c = weight of white and colorant, respectively, used in the batch.

Now or brush a film of this paint over contrast paper at a thickness sufficient to give complete visual hiding.

X2.1.1 After allowing the film to dry, measure the reflectance of this film at the wavelength of maximum absorption with a spectrophotometer or, if using a colorimeter, the reflectance with the filter that gives the lowest reading (see Note X2.1). Calculate the Kubelka-Munk Single Constant value of this reflectance as follows:

$$(K/S)_m = [1 - (R_m - 0.04)]^2 / 2(R_m - 0.04)$$

where:
 $(K/S)_m$ = Kubelka-Munk Value,
 R_m = reflectance measurement of the mixture, made with the specular component included expressed as a decimal value, and
 0.04 = decimal value correction for surface reflectance.

NOTE X2.1—To speed drying, accelerated methods may be used. It is recommended that water-based acrylic paints be warmed to 50 to 55°C for 2 h after 1 h of air drying before measuring the reflectance. Placing drawdowns of oil paints near fluorescent lamps, for example in the fluorescent light exposure racks described in Annex A1 of Test Methods D303, will speed their drying time.

X2.1.2 Calculate the Kubelka-Munk absorption coefficient for unit concentration as follows:

$$K_c = (K/S)_m / C_c$$

where K_c = unit absorption coefficient.

X2.2 Based on the results of the trial mixture, calculate the concentration of colorant in white required to give the

desired 35 to 45 % reflectance at the wavelength of maximum absorption as follows:

$$C_d = (K/S)_{40\%} / K_c = 0.4500 / K_c$$

where C_d = concentration of colorant in white predicted to give a paint with the desired 35 to 45 % reflectance value.

X2.3 Adjust the concentration of the trial batch so that the concentration of colorant equals C_d . Determine the changes in colorant concentration, ΔC as follows:

$$\Delta C = C_d - C_c$$

These changes are positive if the trial batch has a reflectance greater than 40 % and negative if the reflectance is less than 40 %. If ΔC is positive, add more colorant to the trial batch to bring the concentration of colorant to C_d . If ΔC is negative, add more white to bring the concentration of colorant to C_d . Because it may be necessary to add large amounts of white to correct for concentrations of colorant giving reflectance values far below 40 %, it is usually best to prepare a trial batch expected to give a ΔC value that is moderately positive or only slightly negative.

X2.3.1 For the case where ΔC is positive, the weight of colorant needed to prepare a second batch is,

$$\Delta W_c = W_c - C_d(W_w + W_c) / C_d - 1 \times (L.F.)$$

where:

ΔW_c = weight of colorant to be added to the trial batch to obtain a corrected batch with a colorant concentration of C_d , and

L.F. = "loss factor" = weight of paint from trial batch used to prepare the corrected batch/weight of paint prepared as trial batch.

The loss factor, L.F., allows for paint removed to prepare drawdowns, loss by transfer to different containers, etc. This term may be neglected if losses are small compared to the batch size. The other terms are as defined in the previous sections of this appendix.

X2.3.2 For the case where ΔC is negative, the weight of white needed to prepare a corrected batch corresponds to,

$$\Delta W_w = W_c - C_d(W_w + W_c) / C_d \times (L.F.)$$

where ΔW_w = weight of white needed to adjust the colorant concentration in the batch to C_d . Other terms are as defined above or in previous sections of this appendix.

X2.4 Prepare a paint film from the adjusted batch. After drying, measure the reflectance at the wavelength of max-

imum absorption. If this value does not fall within 35 to 45 %, repeat X2.3 through X2.4, where C_d now becomes the C_c for the next batch correction. Normally only a single iteration is necessary and a second batch correction will not be needed.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Preparatory Surface Cleaning of Architectural Sandstone¹

This standard is issued under the fixed designation D 5107; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

1.1 This practice covers non-abrasive surface cleaning of architectural sandstone to remove grease, dirt, loose material, and surface deposits such as soot, fly ash, hydrocarbon residues, and algae and other biological growth in preparation for the application of water repellent coatings. Procedures include broom cleaning, vacuum cleaning, air blast cleaning, water cleaning (and detergent water cleaning), and chemical cleaning.

1.2 **Limitations**—This practice is intended to clean architectural sandstone without damaging it or altering the surface profile.

1.3 *This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* For specific hazard statements, see Section 4.

Referenced Documents

- 2.1 **ASTM Standards:**
 C 119 Definitions of Terms Relating to Natural Building Stones²
 D 4262 Test Method for pH of Chemically Cleaned or Etched Concrete Surfaces³
 D 4263 Test Method for Indicating Moisture in Concrete by the Plastic Sheet Method³
 D 4285 Method for Indicating Oil or Water in Compressed Air³

Significance and Use

3.1 Surface cleaning is necessary to prepare architectural sandstone surfaces for application of coatings intended for water repellent protection. Surface cleaning of the sandstone substrate helps to ensure proper adhesion of the coating.

3.2 Use of procedures described in this practice may not be adequate where protective systems will be used for continuous or intermittent immersion or mechanical loading.

Hazards

4.1 Moisture in the architectural sandstone may be detrimental to coating adhesion or (in some cases) cure. Moisture content shall be in compliance with coating manufacturer's

recommendation. See also Test Method D 4263.

4.2 Localized staining (for example efflorescence and metallic staining) and previously applied coatings or preservative treatments not compatible with the treatment may require removal by other surface preparation methods.

4.3 Water cleaning, detergent water cleaning, and chemical cleaning should not be performed at temperatures below 40°F.

4.4 Many chemical cleaning products contain acids and should be handled according to manufacturers' recommendations. Use and disposal of materials should conform to established federal, state, local, and project requirements.

4.5 If pressure washing equipment is employed for water cleaning or for flushing the surface with detergent water cleaning or chemical cleaning, the minimum effective pressure should be used. Avoid excessive pressures that could damage the sandstone substrate.

5. Procedure

5.1 Air blast, water, scrubbing, sweeping, or vacuuming are acceptable cleaning methods. Chemical cleaning agents may be used to remove surface deposits such as soot, fly ash, and hydrocarbon residues not removed by any of the above methods. Chemical cleaning should be preceded and followed by a thorough fresh water rinse.

5.2 Existing conditions of the substrate will determine the selection of appropriate procedure(s). Prior to the initiation of cleaning, small test areas should be cleaned in inconspicuous areas by the selected procedure to determine effectiveness.

5.3 The six types of cleaning procedures are described below. One or more of the procedures may be required to remove contaminants from the sandstone surface:

5.3.1 **Broom Cleaning**—Removes most loosely adherent solid contaminants.

5.3.1.1 Working from top to bottom, sweep the surface with a clean industrial stiff-bristled broom or similar device. Remove sweepings from the immediate work area.

5.3.1.2 Clean broom-cleaned surfaces again using one or more of the surface preparation procedures specified in 5.3.2 through 5.3.6.

5.3.2 **Vacuum Cleaning**—Removes surface dust and other debris.

5.3.2.1 Vacuum the surface with a heavy-duty type industrial vacuum to provide an essentially dust-free surface.

5.3.3 **Air Blast Cleaning**—Removes debris, dust, dirt, loosely adherent architectural sandstone, and laitance from walls to provide an essentially sound, dust-free surface.

5.3.3.1 Clean surface with a compressed-air stream through a blasting nozzle held at an oblique angle approximately 2 ft (0.6 m) from the surface. Air stream pressure

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.47 on Masonry Treatments.

Current edition approved Nov. 21, 1990. Published January 1991.

² Annual Book of ASTM Standards, Vol 04.08.

³ Annual Book of ASTM Standards, Vol 06.01.

should not exceed 100 psi (689 kPa).

5.3.3.2 Before initiating air-blast cleaning, verify that the air stream is free of oil in accordance with Test Method D 4285.

5.3.3.3 Surface cleanliness is dependent upon carrying off airborne dust before it is redeposited. Vacuum cleaning may be required to remove redeposited dust.

5.3.4 *Water Cleaning*—Removes dust, dirt, and water-soluble surface contaminants.

5.3.4.1 Clean the surface with a stream of clean potable water, aimed at an oblique angle approximately 2 ft (0.6 m) from the surface, having sufficient pressure to remove dust, dirt, and loose material without damaging the substrate. When necessary, hand scrub with a nonmetallic stiff-bristled fiber brush.

5.3.4.2 Prior to water cleaning, make provisions for the removal of wash water and contaminants generated.

5.3.4.3 If necessary, test the cleaned surface for moisture content in accordance with Test Method D 4263 prior to applying coatings.

5.3.5 *Detergent Water Cleaning*—Removes water-soluble surface contaminants and oils, grease, and other emulsifiable materials on the surface.

5.3.5.1 Scrape off heavy deposits of grease or oil and prewet the surface with potable water. Clean the surface with a nonmetallic stiff-bristled fiber brush, using an aqueous solution of detergent or nonsolvent emulsifier. Immediately after treatment, before the surface dries, remove residues of the cleaning agent by thoroughly flushing the surface with clean potable water. Repeat flushing until the pH of the surface water meets the acceptance criteria of Test Method D 4262.

5.3.5.2 Repeat 5.3.5.1 until water does not bead on the surfaces.

5.3.5.3 Prior to detergent water washing, make provisions for the removal of wash water and contaminants generated.

5.3.5.4 If necessary, test the cleaned surface for moisture content in accordance with Test Method D 4263.

5.3.6 *Chemical Cleaning*—This procedure is similar to detergent water washing, but involves the use of proprietary chemical cleaning compounds (generally hydrofluoric and phosphoric acids) for the removal of surface deposits such as

soot, fly ash, and hydrocarbon residues.

NOTE—In some cases, removal of heavy soiling may require use of alkaline pretreatment prior to acidic cleaning.

5.3.6.1 Chemical cleaning using acidic products is generally not recommended for calcareous sandstones. (See Definitions C 119.)

5.3.6.2 Protect all adjacent materials and surrounding areas as recommended by the manufacturer of the proprietary chemical cleaning compound.

5.3.6.3 Prior to chemical cleaning, provide for application to small test area to determine effectiveness. Make provisions for the removal of water and contaminants generated during full-scale cleaning operations.

5.3.6.4 Before applying the chemical cleaning compound, prewet the surface thoroughly with potable water to prevent absorption of the cleaning solution within the pores of the masonry.

5.3.6.5 Apply a dilute solution of a proprietary cleaning compound to the pre-wet surface as recommended by the manufacturer. Leave the cleaning solution on the surface for a prescribed dwell period (usually less than 5 min).

5.3.6.6 Immediately following the dwell period, and before the surface dries, flush thoroughly to wash chemical cleaning compounds from the surface, then rinse thoroughly from bottom to top. (Rinsing from bottom to top helps to avoid surface streaking.) Repeat flushing may be necessary to remove cleaning residues.

5.3.6.7 *Evaluation*—Visually examine the prepared surface to evaluate removal of debris, dust, dirt, oil, grease, loosely adherent sandstone building stone, and other contaminants. Test the surfaces cleaned with proprietary chemical cleaning compounds for pH in accordance with Test Method D 4262 and if necessary test for moisture content in accordance with Test Method D 4263 prior to applying coatings.

5.4 Surface cleaning is intended to provide a clean, contamination-free surface without damaging or removing architectural sandstone from intact, sound surfaces. Acceptable surfaces shall be free of oil, grease, loosely adhering sandstone, and other contamination such as dirt, soot, fly ash, and hydrocarbon residues.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

Standard Test Method for Organotin Release Rates of Antifouling Coating Systems in Sea Water¹

This standard is issued under the fixed designation D 5108; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

This test method covers the laboratory determination of the rate at which organotin expressed as tributyltin (TBT) released from an antifouling (AF) coating in synthetic sea water using graphite furnace atomic absorption spectrophotometry (GF-AAS). This does not exclude the use of other analytical methodology for measurement of organotin in sea water such as gas chromatography.

2 The values stated in SI units are to be regarded as standard. The inch-pound units given in parentheses are for information only.

3 *This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety practices and to determine the applicability of regulatory limitations prior to use.* For specific hazard statements, see Section 7.

Referenced Documents

1.1 ASTM Standards:

- D 1141 Specification for Substitute Ocean Water²
- D 1212 Methods for Measurement of Wet Film Thickness of Organic Coatings³
- D 4138 Test Method for Measurement of Dry Film Thickness of Protective Coatings by Destructive Means³

Summary of Test Method

1.1 The candidate paint system is applied to cylindrical specimens. The coated specimens are placed in a tank of synthetic sea water where the tin levels are kept low by circulating the sea water through a carbon filter. At specified intervals, each specimen is placed in 1500 mL of unused sea water and is rotated for 1 h. The rate of tributyltin release from the paint is determined by measuring tributyltin concentrations in the sea water.

1.2 Analysis of sea water for tributyltin is conducted by extracting the organotin with toluene, washing with sodium hydroxide, and measuring for total tin using (GF-AAS).

Significance and Use

1.1 This test method is designed to provide a laboratory procedure to measure changes in the release rates of solvent

soluble tin (tributyl- and triphenyltin) that occur during a period of immersion under specified conditions of constant temperature, pH, salinity, and low heavy-metal concentrations in the surrounding sea water. Quantitative measurement of the release rate is necessary to help in selection of materials, in providing quality assurance, and in understanding the performance mechanism.

4.2 This test method serves only as a guide for organotin release rates in service. Organotin release rates of antifouling (AF) paint systems in service can vary over the life of the coating system depending on the formulation and the environment. Differences in berthing locations, operating schedules, length of service, condition of paint-film surface, temperature, pH, and salinity can affect results. Results obtained may not necessarily reflect actual tributyltin release rates that will occur in service, but provide reliable comparisons of the release rate characteristics of different antifouling formulations.

4.3 This test method will serve to characterize the early release rate pattern, as well as estimate the steady state release, of tributyltin from both self-polishing copolymer and free-association antifouling paints.

5. Apparatus

5.1 *Release-Rate Measuring Container*—A 2-L (nominal ½ gal) polycarbonate container,⁴ approximately 13.5 cm (5.5 in.) in diameter and 19 cm (7.5 in.) high, fitted with three polycarbonate rods approximately 6 mm (nominal ¼ in.) in diameter to serve as baffles. Rods shall be evenly spaced on the inside circumference of the container to prevent swirling of water with the test cylinder during rotation. The rods will be secured to the container walls using acetone or methylene chloride.

5.2 *Constant Temperature Bath*—A temperature controlled water bath capable of maintaining a temperature of $25 \pm 2^\circ\text{C}$ into which one or more release rate measuring test containers can be placed.⁵

5.3 *Holding Tank*—A container of such dimensions so as to permit immersion of four or more test cylinders; must be equipped with a system to continuously circulate synthetic sea water in the tank through a carbon filter. The rate of water flow and the size of the carbon filter should be selected to maintain tributyltin concentrations below 100 µg/L. Flow

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paints and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.45 on Marine Coatings.

Current edition approved Dec. 5, 1990. Published February 1991.

³ Annual Book of ASTM Standards, Vol 06.01.

⁴ A Nalgene Container, available from Cole-Palmer, 7425 N. Oak Ave., Chicago, IL 60648, catalog number R-6761-20, or equivalent, has been found satisfactory for this purpose.

⁵ Boekel Water Baths, Models 148003 and 148004 available from Boekel Industries Inc., 509-T Vine St., Philadelphia, PA 19106, or equivalent, have been found satisfactory for this purpose.

rates should generally be set to obtain 2 to 8 turnovers per h. The size and geometry of the tanks as well as the positioning of the inflow and outflow ports for the water circulation system should be selected to obtain a slow, relatively uniform flow of synthetic sea water past all test cylinders in the tank. Maintain the pH of the synthetic sea water between 7.8 and 8.2, and the salinity between 30 and 35 parts per thousand (ppt). The tank shall be provided with heaters to maintain the temperature between 21 and 27°C (70 and 81°F).

5.4 Test Cylinders—Approximately 6.4 cm (nominal 2½ in.) outside diameter polycarbonate pipe coated with a 10-cm band of AF paint around the exterior circumference of the test cylinder to provide 200 cm² of paint film that can be immersed and freely rotated in the release rate measuring container. Seal the bottom of the test cylinder with a polycarbonate disc using acetone, methylene chloride, or a polycarbonate cement so as to form a watertight joint. Do not coat the bottom 1 to 2 cm of the test cylinder. The test cylinder shall be of such height so that a rotating device can be attached to rotate the cylinder and the upper open end of the cylinder is above the level of the test container immersion liquid to prevent entry of the immersion liquid into the test cylinder.

5.5 Test Cylinder Rotating Device—The device shall be capable of rotating the test cylinder in the release rate measuring container at 60 ± 5 r/min. No part of the device shall be immersed in sea water.⁶

5.6 Centrifuge Tubes, 50-mL capacity, with screw closures⁷ (or disposable bottles, culture tubes, separatory funnels, etc.) made of polycarbonate, TFE fluorocarbon, or borosilicate glass.

5.7 Mechanical Shaker, with appropriate holders.

5.8 Dispensers, automatic or repeating, for reagents.

5.9 Pipets, with disposable polypropylene tips.

5.10 Graphite Furnace, atomic absorption spectrophotometer (GF-AAS) with automatic sampler.

5.11 pH Meter, with a mercury/mercurous chloride (Hg/Hg₂Cl₂) electrode.

5.12 Appropriate Volumetric Flasks.

6. Reagents and Materials

6.1 Synthetic Sea Water—Substitute ocean water in accordance with Section 6 of Specification D 1141 or a proprietary equivalent with a salinity of 30 to 35 ppt.

6.2 Extraction Solvent—Toluene, spectrograde or equivalent.

6.3 Tributyltin Standards—Prepare standards using a stock solution of tributyltin chloride (reagent grade, minimum 96 % pure) in methanol (suggested concentration of approximately 10 mg/L). The standards are acidified with acetic acid (less than pH 4) to obtain a stable solution.

6.4 Hydrochloric Acid (HCl) (10 % aqueous solution).

6.5 Hydrochloric Acid (HCl) (0.1N).

6.6 Nitric Acid (HNO₃) (10 % aqueous solution) can be used in place of HCl to clean labware.

6.7 Sodium Hydroxide (NaOH) (3 % aqueous solution).

6.8 Sodium Hydroxide (NaOH) (0.1N).

6.9 All reagents and cleaning agents used must be tin-free.

7. Hazards

7.1 Warning—Antifouling paints contain toxic materials that could cause skin and eye irritation on contact and adverse physiological effects if ingested or inhaled. In the preparation of test specimens and the application of various types of paints, the use of appropriate protective clothing and equipment is required consistent with local, state, and federal government regulations, and recognized industrial and technical standards. Spills, overspray, and unused material should not be flushed down the drain, but should be disposed of as hazardous waste.

7.2 See antifouling paint supplier's Material Safety Data Sheet.

8. Calibration and Standardization

8.1 Prepare three standards throughout the range of the quantification limit to 100 µg of tin per litre by dilution in toluene of a stock solution of tributyltin chloride (96 % pure) in methanol. Include one standard with a concentration of approximately 50 µg of tin per litre. An alternate range of concentrations may be used when appropriate.

8.2 Prepare synthetic sea water spiked with three concentrations of TBT in the range of 10 to 50 µg of tin per litre by spiking with stock solution of tributyltin chloride in methanol. When the concentration of tin extracted in toluene exceeds 100 µg/L appropriate dilution should be employed to keep it within the limits of the calibration curve (0 to 100 µg/L).

8.3 Operate the graphite furnace in accordance with manufacturer's instructions. Optional conditions are described in Appendix X1.

8.4 Analyze the following:

8.4.1 At the beginning of each instrument run, perform analysis of the toluene blank and standards in toluene in order to establish that the response of the instrument is linear. Plot separate calibration curves for each analysis of the standards (peak height absorbance versus tin concentration), and calculate the slope, intercept, and coefficient of determination for each curve using least squares regression or another appropriate procedure.

8.4.2 Sea Water Blank—Extract and analyze as specified for test samples to establish baseline.

8.4.3 Spiked Sea Water Samples—Extract and analyze as specified for test samples to determine extraction efficiency. Recovery must be 90 to 110 %.

8.4.4 If changing the graphite tube during a run is necessary, the blank and standards in toluene should be analyzed to ensure proper response and linearity before continuing the sample analysis.

8.5 Determine the tin concentration of individual test samples with reference to the 50 µg/L calibrating standard analyzed immediately after those test samples.

9. Procedure

9.1 Organotins have a strong tendency to adsorb on certain glass or plastic surfaces. Therefore, all labware (glass or polycarbonate) used for organotin release measurements

⁶ A six-paddle stirrer, Model 300, manufactured by Whitaker Medical Mfg. Co., Phipps and Bird Div., 8741 Landmark Rd., Richmond, VA 23228, or equivalent, has been found satisfactory for this purpose.

⁷ Oak Ridge Tubes, available from Cole-Parmer, or equivalent, have been found satisfactory for this purpose.

be treated as follows: clean thoroughly by soaking in HCl or HNO₃ for a minimum of 6 h. Rinse labware thoroughly with distilled water and allow to dry. Cleaning also be accomplished by soaking in concentrated HCl for 24 h. Prepare all samples, blanks, and standards in labware prepared in this manner. Disposable materials (pipet tips, centrifuge tubes, etc.) do not have to be acid-washed before use. Prepare the exposure surfaces (200 cm²) of three replicate test cylinders to provide a suitable surface for application of the paint system to be applied. Mask the surfaces to remain uncoated (including the bottom 1 to 2 cm of the interior circumferential surface of the test cylinder).

3 Paints shall be manufactured a minimum of seven days prior to testing. Also, test paints shall not be allowed to expire beyond the manufacturer's recommended shelf life. Proper storage conditions during aging, that is, sealed in a container commonly used for sale and held at 20 to 30°C.

4 Apply one or more coats of antifouling paint to the interior circumferential surface of a test cylinder to produce a band of AF paint with an exposure surface of 200 cm² and a minimum dry film thickness of 100 µm (4 mils). Follow manufacturer's instructions with respect to mixing and drying. At a minimum, mechanically shake until the paint appears homogeneous. Apply using a sponge applicator or brush as recommended by the manufacturer. If the paint is marketed only in spray cans, then apply as a spray. After the final application allow the paint to dry for 7 ± 1 days at 23 to 25°C.

5 Estimate the initial dry film thickness using a suitable nondestructive method such as Method D 1212. If the leaching tests exceed 6 months measure the film thickness at the conclusion of the test. Methodology for the final measurement can be either that used for the initial measurement or Test Method D 4138. If a nonstandard method is used, make several film thickness measurements for each cylinder and estimate the variability of the determination. Film thickness should remain greater than 50 µm throughout the test. For tests of long duration, the initial thickness may need to be greater than 100 µm to maintain a thickness greater than 50 µm throughout the test.

6 Place all cylinders in a single batch in a holding tank after the 7-day drying period. A batch consists of one or more sets of three replicate cylinders coated with a test paint and one control (unpainted) cylinder. The painted surface on the cylinders must be completely submerged. Cylinders must be stationary and positioned so that sea water moving through the tank will flow around each cylinder.

7 Monitor the pH (using a pH meter with a calomel electrode) and the temperature of the synthetic sea water in the holding tank daily. Adjust the pH if necessary using either 0.1N NaOH or 0.1N HCl. Quantitate salinity every 14 days and adjust if necessary. Determine TBT concentrations weekly. When TBT levels increase, change the carbon filter before the TBT concentration exceeds 100 µg/L. More frequent monitoring of synthetic sea water may be necessary in some instances to maintain the specified environmental conditions.

8 After 1, 3, 7, 10, 14, 21, 24, 28, 31, 35, 38, 42, and 45 days, transfer all cylinders in given batch into individual measuring containers containing 1500 mL of fresh synthetic sea water. Randomly assign cylinders (control and painted)

to measuring containers at each leaching. When transferring cylinders, lift the cylinder out of the holding tank, allow sea water to drain off, install the cylinder into the rotating device, and submerge the painted area into the sea water. Immediately start rotation of the cylinder at 60 ± 5 r/min, and continue rotation for 60 min. When transferring the cylinders, do not touch or in any way damage the paint film, and do not allow the paint surface to dry. The transfer should be completed as quickly as possible (generally, in less than 5 min).

9.9 If testing beyond the minimum (45 days) length requirement is desired, the study may be extended to 73 days. During the extended test, remove the cylinders from the holding tank every 3 to 4 days to make a measurement of the leach rate.

9.10 At the completion of the cylinder rotation, immediately remove the cylinder from the measuring tank and return it to the holding tank. Pipet a 25-mL subsample of the sea water into a 50-mL centrifuge tube containing sufficient 10% HCl to reduce the pH to ≤4.0. If the number of samples from the leach measuring steps exceeds the daily analysis capacity, the samples may be refrigerated and stored in the acidified state in a sealed container for up to 14 days. Clean the measuring containers using appropriate procedures (distilled water or acid wash) before reuse.

9.11 Partition acidified sea water samples with 10 mL of toluene (15 min shaking on a mechanical shaker). Remove most of the toluene and wash it with 5 mL of a 3% aqueous NaOH solution (10 min shaking). Pipet off (or separate using a separatory funnel) the organic phase and analyze for total tin content by GF-AAS. The toluene extract can be stored sealed in the dark at 4°C for up to 24 h before analysis.

10. Calculation

10.1 Calculate the concentration of the TBT cation in the sea water of the measuring container as follows:

$$C_{TBT} = (C \times E \times F) / S$$

where:

C_{TBT} = concentration of TBT cation (µg/L),
 C = concentration of tin in the toluene extraction (µg/L),

E = volume of toluene = 10 mL,

F = correction factor to convert tin to TBT = 2.5, and

S = aliquot of sea water analyzed = 25 mL.

This equation can be simplified as follows if the prescribed volume of sea water and toluene are used:

$$C_{TBT} = (C_{Sn} \times 10 \times 2.5) / 25 \\ = C_{Sn}$$

10.2 Calculate the release rate by the following formula:

$$R = (C_{TBT} \times V \times D) / (T \times A)$$

where:

R = release rate (µg/cm²/day),

D = 24 h/day,

V = 1.5 L, volume of sea water in measuring container,

T = 1 h during which cylinder is in measuring container, and

A = 200 cm² surface area of paint film.

This formula can be simplified as follows:

$$R = (C_{\text{TBT}} \times 1.5 \times 24) / (1 \times 200) \\ = C_{\text{TBT}} \times 0.18$$

10.3 Calculate the 14-day cumulative release of TBT cation as follows:

$$R = R_1 + (2 \times R_3) + (4 \times R_7) + (3 \times R_{10}) + (4 \times R_{14})$$

where:

R = 14-day cumulative release, $\mu\text{g}/\text{cm}^2 \cdot 14$ days, and R_1, R_3, R_7, R_{10} , and R_{14} = release rates for sampling days 1, 3, 7, 10, and 14, respectively, $\mu\text{g}/\text{cm}^2$ per day.

10.4 Calculate the average release rate ($\mu\text{g}/\text{cm}^2$ per day) by averaging individual release rate measurements taken from day 21 through the last day of sampling (day 45 through day 73). If values at day 21 are high and it is suspected that the release had not reached pseudo steady-state conditions, then compare the release rate at day 21 to the mean for all release rates from day 21 through the termination of testing (45 to 73 days). If the release rate exceeds the mean by two or more standard deviations, then the release rate may be excluded from the average. If the day 21 release rate is excluded, the day 24 release rate may be

evaluated by the same procedure.

11. Report

11.1 Report the following information:

11.1.1 Report the concentration in micrograms per litre of TBT cation in the sea water of the measuring tank and the rate of TBT cation release (micrograms per square centimetre per day) for each sampling time (give values for individual replicates as well as the mean). Plot the rate of TBT release as a function of time (use linear axes). Also report the 14-day cumulative release and the average release rate.

12. Precision and Bias

12.1 Precision and bias for this test method have not been determined.

13. Keywords

13.1 antifouling coating system; organotin; release rate; TBT; tributyl tin

X4. DESCRIPTION OF PROPOSED TESTING APPARATUS

X4.1 A 200 cm² organotin antifouling paint film of a minimum 100 μ m thickness is applied to the curved surface of a polycarbonate cylinder closed at one end. This cylinder is suspended with its closed end immersed within and concentric with a larger polycarbonate cylinder holding

synthetic sea water. The coated internal cylinder is rotated about its axis at 60 ± 5 r/min in order to produce a peripheral speed of about 1 knot. In practice, the commercially available polycarbonate "multipurpose jars" described in this test method will hold 1500 mL of synthetic sea water.

NOTE 1—Test Container Dimensions:

Capacity, L	2
Inside diameter, cm	12.7
Outside diameter, cm	13.3
Height (without cover), cm	19

NOTE 2—Rotating Test Cylinder Dimensions:

D = approximately 7 cm (2 1/2 in. nominal),
H = 12 cm min,
L = 10-cm coated section, and
X = 1-cm uncoated band.

FIG. X4.1 Dimensions of Testing Apparatus (Container and Cylinder)

2.2 Other Standards:

American Concrete Institute, ACI 301 Specifications for Structural Concrete for Buildings⁶
SSPC-SP-1, 2, 3, 5, 6, 7, 10, or 11⁷

3. Significance and Use

3.1 This specification provides uniform requirements for the preparation of test samples used for qualification testing of coatings used in nuclear power plant construction and maintenance.

4. Steel Samples

4.1 Sample size shall be a minimum of 2 in. wide by 4 in. long by $\frac{1}{8}$ in. thick. Edges and corners may be rounded. A $\frac{1}{4}$ in. diameter hole suitably located may be in the test panel as appropriate for the test samples in Test Methods D 3911, D 3912, D 4082 and D 4256.

4.1.1 For Test Method D 4541 the minimum size shall be 3 in. wide by 5 in. long by $\frac{1}{4}$ in. thick.

4.2 All panels should be carbon steel, meeting the requirements of Specification A 36.

4.3 Surface preparation shall be in accordance with SSPC-SP 10 for qualification testing. Other surface preparation as required by the project or specific conditions may be used when testing for evaluation over surfaces other than SSPC-SP 10, such as SSPC-SP 1, 2, 3, 5, 6, 7, or 11.

5. Concrete Blocks

5.1 Applicable to Test Methods D 3911, D 3912, D 4082, D 4256 and D 4541. The minimum size shall be 2 in. by 2 in. deep by 4 in. long. The edges may be chamfered up to $\frac{1}{4}$ in. maximum.

5.2 Composition shall be as follows:

Cement	Specification C 150, Type II	7 sacks/yd ³
Gravel	Specification C 33, size $\frac{3}{4}$ in.	45 % by volume
Sand	Specification C 33	55 % by volume
Air-entraining admixture	Specification C 260	As recommended 4 to 7 %
Water-reducing admixture	Specification C 494	As recommended
Pozzolan	Specification C 618	As recommended to 15 % amount
Water, demineralized or distilled		3 in. slump

¹ This specification is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generation Facilities and is the direct responsibility of Subcommittee D33.02 on Service and Material Parameters. Current edition approved Dec. 12, 1990. Published January 1991.

⁴ Annual Book of ASTM Standards, Vol 04.01.

⁵ Annual Book of ASTM Standards, Vol 06.01.

⁶ Available from American Concrete Institute, P.O. Box 19150, Detroit, MI 48219.

⁷ Surface Preparation Standards are available from Steel Structures Painting Council, 4400 5th Ave., Pittsburgh, PA 15213-2683.

		Nominal 1 Cubic Foot Batch
Cement	Specification C 150, Type II low alkali	22.2 lb
Gravel	Specification C 33, Size $\frac{3}{4}$ in.	45.3 lb
Sand	Specification C 33	55.5 lb
Air-entraining ad- mixture	Specification C 260	31 mL
Pozzolan	Specification C 618	2.2 lb
Water-reducing admixture (Type A)	Specification C 494	As recommended by the manufac- turer
Water, demineral- ized or distilled		As required to pro- duce 3-in. slump (approximately)

5.3 Blocks shall be cast horizontally in forms using release agents that are compatible with the coatings to be used. The top surface, as cast, shall be given a broom finish, unless otherwise specified. The block surface is to be covered with plastic during the first 24 h to simulate water curing unless a curing compound is included in the testing.

5.4 The block shall be removed from the form after 24 h and wet cured in accordance with ACI 301 or Practice C 192.

5.5 If a curing compound is to be used, apply the compound to the broom finished surface immediately after finishing and to all other surfaces of the block within 2 h after its removal from the form.

5.6 Allow the block to cure for 28 days in accordance with ACI 301 before application of the coating system unless otherwise specified.

5.7 After curing, remove loose material on the broom finish surface by light wirebrushing. Remove loose material on the cast surfaces by blowing with air (80 to 100 psi) unless otherwise specified, such as Practices D 4258, D 4259, or D 4260.

5.8 All surfaces of the blocks shall be coated in accordance with Test Method D 3912. The upper and/or lower ends of the blocks shall be left uncoated for all other testing.

5.9 A suitable hanger compatible with the testing apparatus shall be affixed at the mid-point of the upper end of the block where applicable.

5.10 Large bug-holes, rock pockets and other coating defects may be simulated by drilling holes to test coating systems for patching surface defects.

6. Miscellaneous Materials

6.1 Follow 4.1 and 4.3 for metallic materials such as

aluminum, galvanized steel, and other metals.

6.2 Follow 5.1 and 5.3 for castable materials such as grout, fireproofing, and other castables.

7. Abrasion Test Samples

7.1 Substrate material for abrasion testing shall be of a size in accordance with Test Method D 4060 and shall be aluminum or steel and of a thickness to maintain a flat surface after surface preparation.

7.2 Surface preparation shall be compatible with coating to be tested.

8. Application

8.1 All test samples shall be coated with the full coating system including any applicable fillers. The manufacturer's latest published application instructions shall be followed for mixing and coating application unless otherwise specified. Any special procedures or conditions shall be noted in the documentation including thinning, mixing, drying/curing times, force curing, aging between coats/systems, intermediate surface preparations or other special procedures or conditions.

8.2 The film thickness range shall be representative of the specified work for which the testing is being conducted.

8.3 Test samples for maintenance painting test programs may include simulated aging of the existing coating, intermediate surface preparation and wide ranges of coating film thicknesses. Field conditions should be duplicated as close as possible including coating application methods that may differ from the manufacturer's published data.

9. Documentation

9.1 The procedures and conditions used for the test sample preparation shall be documented. As a minimum the documentation shall include preparation times and dates, surface preparation details, coating sequence and individual dry film thickness ranges of each coat, total thickness range, environmental conditions, and product batch identification.

9.2 Record all deviations from the procedures called for in this specification, that is, all items allowing "unless otherwise specified" that are different than those described.

10. Keywords

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Scope

1.1 This guide covers coating systems for concrete and steel in nuclear power plants.

This guide covers coating systems for concrete and steel in nuclear power plants. It is the responsibility of the user to ensure that the coating system is suitable for the intended application.

Standard Guide for Use of Protective Coating Standards in Nuclear Power Plants¹

This standard is issued under the fixed designation D 5144; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

INTRODUCTION

Protective coatings (paints) have been used extensively in the nuclear industry to protect the surfaces of facilities and equipment from corrosion and contamination by radioactive nuclides in accordance with ALARA. In the absence of a standard method of selecting, testing, and evaluating coatings, many sites evaluated paints by empirical tests to determine which were useful in their particular operation. Understandably, the methods of testing were not uniform throughout the industry. It has been very difficult, consequently, to compare the results obtained at one site with those obtained at another. Standard tests whereby industrial (nuclear) users of paints systematically prepare specimens and subject them to selected evaluations, thus permitting uniform comparisons, are advantageous, internationally as well as domestically.

The designer of light water-moderated nuclear reactor systems must consider the possibility of a Design Basis Accident (DBA) and the subsequent events which might lead to the release or expulsion of a fraction of the fission-product inventory of the core to the reactor containment facility. Engineered safety features, principally a reactor containment facility, are provided to prevent the release of fission products to the biological environment during and after this improbable event. The design, fabrication, quality assurance, and testing of these engineered safety features ensure reliable operation and safety under all anticipated conditions.

Large areas of the reactor-containment facility are painted with a protective coating. If severe delamination, peeling, or flaking causes significant portions of the coating to be discharged into the common water reservoir (primary containment sump), the performance of the safety systems could be seriously compromised by the plugging of strainers, flow lines, pumps, spray nozzles, and core coolant channels.

The safety requirement for protective coatings is to ensure that failure of the coatings under DBA conditions does not adversely affect the performance of post-accident fluid systems. Therefore, coatings must be qualified to the environmental exposures anticipated during normal plant operation, and during DBA and other upset conditions.

This guide is the result of a comprehensive examination of the experience and data that have been developed on protective coatings in the nuclear industry over approximately 40 years. Standards pertaining to nuclear coatings have historically been covered by ANSI N5.12, N101.2, and N101.4. Responsibility for updating, rewriting, and issuing appropriate ANSI replacement standards has been transferred to ASTM, specifically ASTM Committee D-33, on Protective Coating and Lining Work for Power Generation Facilities.

Quality assurance in the nuclear industry is a mandatory requirement for all aspects of safety related nuclear coatings work. The objective of this guide is to provide a common basis on which to define and specify the performance requirements for the coatings which will be used in Service Level I and II areas of a nuclear facility. Proposed Regulation 10CFR50.65 (Draft Rule November 28, 1988) defines the requirements for an effective program for maintenance of nuclear power plants. This guide may be used both for coatings applied to new nuclear power plants and to facilitate implementation of the coating aspects of 10CFR50.65.

Scope

1.1 This guide provides a common basis on which protective coatings for the surfaces of light water-moderated nuclear power generating facilities may be qualified and

selected by reproducible evaluation tests. This standard also provides guidance for application and maintenance of protective coatings. Under the environmental operating and accident conditions of nuclear power generation facilities, encompassing Pressurized Water Reactors (PWR's) and Boiling Water Reactors (BWR's), coating performance may be affected by exposure to any one, all, or a combination of the following conditions: ionizing radiation; contamination by radioactive nuclides and subsequent decontamination

¹ This guide is under the jurisdiction of ASTM Committee D-33 on Protective Coating and Lining Work for Power Generation Facilities and is the direct responsibility of Subcommittee D33.02 on Service and Material Parameters. Current edition approved Jan. 8, 1991. Published March 1991.

processes; chemical and water sprays; high-temperature high-pressure steam; and abrasion or wear.

3. Terminology

3.1 *Definitions*—Definitions for use with this guide are shown in Definitions D 4538 or other applicable standards.

3.2 Descriptions of Terms Specific to This Standard:

3.2.1 *ALARA*—the concept of reducing radiation exposure to personnel to levels "as low as is reasonably achievable," as defined in the USNRC Regulation Guide 8.8, and 10CFR20.1(C).

3.2.2 *Coating Service Level I*—areas where coating failure could adversely affect the operation of post-accident fluid systems and, thereby, impair safe shutdown. With few exceptions, *Coating Service Level I* applies to coatings inside primary containment.

3.2.3 *Coating Service Level II*—areas where coating failure could impair, but not prevent, normal operating performance. The function of *Coating Service Level II* coatings is to provide corrosion protection and decontaminability in those areas outside primary containment subject to radiation exposure and radionuclide contamination.

4. Significance and Use

4.1 This guide addresses the concerns of Regulation Guide 1.54 and Standard Review Plan 6.1.2, and the

⁴ *Annual Book of ASTM Standards*, Vol 04.07.

⁵ Available from American National Standards Institute, 11 W. 42nd St., 13th Floor, New York, NY 10036.

⁶ Available from the U.S. Government Printing Office, Washington, DC 20402.

replacement of ANSI Standards N5.12, N101.2, and N101.4. This guide covers coating work on previously coated surfaces as well as bare substrates. The entire document applies to all painting work in Service Level I areas. Applicable sections of this guide may be used to evaluate and select protective coatings for Service Level II areas.

Preparation of Test Specimens

All test samples used for qualification testing of coatings shall be prepared in accordance with Specification D 3912.

Radiation Tolerance Tests

Coating film resistance to radiation exposure shall be evaluated in accordance with Test Method D 4082.

Decontamination Test

The relative decontaminability of the coating shall be evaluated by Test Method D 4256.

Certain coatings may contaminate more readily than others, and the responses to decontamination treatments also vary. In some cases, the desired level of decontamination may be achieved merely by cleaning the coating surface; in other cases, decontamination may be achieved only by partial or complete removal of the coating. The decontamination test described gives a method of evaluating the relative ease of decontamination of a coating system. The higher the overall Decontamination Factor (DF), the easier the coating will be to decontaminate.

Physical Properties

8.1 Adhesion—Panels shall be tested for adhesion in accordance with Method D 4541. A minimum of two panels shall be tested for each coating system. If the size of the test specimen is less than 3 in. by 5 in., an annular bearing ring should be used to ensure full contact of the tester legs to the test specimen.

8.1.1 Minimum adhesion shall be 200 psi, consisting of three adhesion tests on each test panel.

8.2 Abrasion Resistance—Abrasion resistance characteristics of coating systems for floors and other surfaces where abrasion is a factor shall be determined in accordance with Test Method D 4060.

8.2.1 Weight loss shall not exceed 175 mg/1000 cycles when a CS-17 Wheel is used with a 1000-g load.

Chemical Resistance Tests

9.1 Test specimens shall be tested in accordance with Test Method D 3912.

9.2 The specific chemicals to be used should be selected to characterize the anticipated exposure; the chemicals indicated in Test Method D 3912 are shown only as examples and are not mandatory.

10. Fire Evaluation Tests

10.1 Flame Spread Tests—Flame-spread tests, when required, shall be conducted and evaluated in accordance with Test Method E 84. The permissible flame-spread and smoke generation, when tested on a noncombustible substrate, shall not exceed the limits set by the nuclear power generating facility.

10.2 The coating systems should be tested to cover the specified film thickness range (or greater) since the flame-spread and smoke density can vary with film thickness. Smoke density is significant where a coating is utilized in enclosed spaces and smoke generation can reduce visibility and prevent effective fire fighting operations. Historic test data indicates that most coatings applied at less than 25 mils dry film thickness over noncombustible substrates and tested in accordance with Test Method E 84 demonstrate flame-spread values below 25.

11. DBA Testing

11.1 The test specimen shall be tested and evaluated in accordance with Test Method D 3911.

12. Surface Preparation, Coating Application, and Inspection for Shop and Field Work

12.1 It is recommended that the *Manual of Coating Work for Light-Water Nuclear Power Plant Primary Containment and Other Safety-Related Facilities Guide*,⁷ prepared by ASTM Subcommittee D01.43, be reviewed in the course of nuclear coating work.

12.2 Surface preparation for steel, concrete, and previously coated surfaces shall be at least as good as that used in the qualification testing of the coating system intended for use.

12.3 Coating application shall be in accordance with the job specifications and the coating manufacturer's latest published instructions. Journeymen painter qualification shall meet the requirements of the applicable quality assurance (QA) program, Practices D 4227 and D 4228. Coating dry film thickness shall be in the range used in the qualification testing of the coating system.

12.4 Coatings work shall be inspected by coatings inspectors qualified and certified in accordance with the applicable QA program and Guide D 4537. Inspections shall be documented to provide a record of the coatings work.

12.5 Maintenance painting work shall follow the requirements of 12.2, 12.3, and 12.4. The maintenance painting specifications shall take into consideration the plant environment in which the coating work must be accomplished. Maintenance painting work qualification testing should be based on proposed surface preparation, coating application methods, and film thickness ranges, all of which may be different than the original design qualification work.

13. Quality Assurance

13.1 A quality assurance program for Service Level I coating work shall be established in accordance with Practice D 3843. Quality assurance requirements may also be established for Service Level II coating work based on criticality.

Standard Test Methods for Nonvolatile and Pigment Content of Electrocoat Baths¹

This standard is issued under the fixed designation D 5145; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

Scope

These test methods cover the characterization of electrocoat baths through the determination of nonvolatile content of inorganic pigment content.

This standard does not purport to address the safety hazards associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

Referenced Documents

ASTM Standards:

- D 1193 Specifications for Reagent Grade Water²
- D 2832 Guide for Determining Volatile and Nonvolatile Content of Paint and Related Coatings³
- D 180 Practice for Determining the Precision Data of ASTM Methods for Analysis and Testing of Industrial Chemicals⁴

Summary of Test Method

Two specimens are accurately weighed into aluminum weighing dishes. The dishes are placed in an oven at 110°C for 1 h, reweighed to obtain the nonvolatile matter content and, if required, placed in a muffle furnace at 500°C for 2 h and weighed a third time to obtain the inorganic pigment content.

Significance and Use

4.1 The nonvolatile content and pigment content are measures of total solids and inorganic pigment solids, respectively, in electrocoat paints. In addition to production quality control, these properties are important in maintaining electrocoat baths in the optimum range.

4.2 Other test methods for determining nonvolatile content of paint and paint related materials are described in Method D 2832.

Apparatus

- 5.1 *Analytical Balance* with a sensitivity of 0.1 mg.
- 5.2 *Aluminum Weighing Dishes*, 57 mm in diameter and 7 mm deep. These commercial dishes may contain a lubricant used during their manufacture. This should be removed by heating the aluminum dishes on a hot plate at

300°C until vapors are no longer visible. Store the dishes in a desiccator until needed.

- 5.3 *Syringes*, 5-mL, disposable variety.
- 5.4 *Oven* circulating, maintained at $110 \pm 2^\circ\text{C}$.
- 5.5 *Muffle Furnace*, maintained at $500 \pm 15^\circ\text{C}$.

6. Reagents

6.1 *Purity of Water*—References to water shall be understood to mean water conforming to Type II of Specification D 1193.

7. Sampling and Sample Preparation

7.1 Obtain the sample while the electrocoat bath is under proper circulation so a uniform sample is obtained. In the case of a ultrafiltrate sample, the material should be thoroughly mixed or stirred prior to drawing the sample, thereby ensuring uniformity.
