Foreword

Organized in 1898, ASTM has grown into one of the largest voluntary standards development systems in the world. ASTM is a not-for-profit organization which provides a forum for producers, users, ultimate consumers, and those having a general interest (representatives of government and academia) to meet on common ground and write standards for materials, products, systems, and services.

From the work of 134 standards-writing committees, ASTM publishes more than 8,500 standards each year. These standards and other related technical information are sold throughout the world.

ASTM Headquarters has no technical research or testing facilities; such work is done voluntarily by 33,000 technically qualified ASTM members located throughout the world. Membership in the Society is open to all concerned with the fields in which ASTM is active. A membership application may be found at the back of this volume. Additional information may be obtained from Member and Committee Services, ASTM, 1916 Race St., Philadelphia, PA 19103; tel. (215) 299-5454.

1992 Annual Book of ASTM Standards

The 1992 *Annual Book of ASTM Standards* consists of 68 volumes, divided among 16 sections, of which this volume is one. It contains approved ASTM standards, proposals, emergency standards, and related material. These terms are defined as follows in the *Regulations Governing ASTM Technical Committees*:

Categories:

standard—as used in ASTM, a document that has been developed and established within the consensus principles of the Society and that meets the approval requirements of ASTM procedures and regulations.

Discussion—The term “standard” serves in ASTM as an adjective in the title of documents, such as test methods or specifications, to connote specified consensus and approval. The various types of standard documents are based on the needs and usages as prescribed by the technical committees of the Society.

proposal—a document that has been approved by the sponsoring committee for publication for information and comment prior to its consideration for adoption as a standard.

Discussion—Complete balloting procedures are not required for proposals.

emergency standard—a document published by the Society to meet a demand for more rapid issuance of a specific standard document.

Discussion—The Executive Subcommittee of the sponsoring committee must recommend the publishing of an emergency standard and the Committee on Standards must concur in the recommendation. Emergency standards are not full consensus documents because they are not submitted to Society ballot.

Types:

The various types of ASTM documents are to provide a flexibility of form, communication, and usage for both the technical committees and the myriad users of ASTM documents. The type of ASTM document that is developed and titled is based on the technical content and intended use, not on the degree of consensus achieved. The three categories of ASTM documents (standard, emergency standard, and proposal) can be of the following forms and types:

classification—a systematic arrangement or division of materials, products, systems, or services into groups based on similar characteristics such as origin, composition, properties, or use.

guide—a series of options or instructions that do not recommend a specific course of action.

Discussion—Whereas a practice prescribes a general usage principle, a guide only suggests an approach. The purpose of a guide is to offer guidance, based on a consensus of viewpoints, but not to establish a fixed procedure. A guide is intended to increase the awareness of the user to available techniques in a given subject area and to provide information from which subsequent evaluation and standardization can be derived.

practice—a definitive procedure for performing one or more specific operations or functions that does not produce a test result. (Compare *test method*.)

Discussion—A practice is not a downgraded test method. Examples of practices include procedures for conducting interlaboratory testing programs or other statistical procedures; for writing statements on sampling or precision and bias; and for selection, preparation, application, inspection, necessary precautions for use or disposal, installation, maintenance, and operation of testing equipment.

specification—a precise statement of a set of requirements to be satisfied by a material, product, system, or service that indicates the procedures for determining whether each of the requirements is satisfied.

Discussion—It is desirable to express the requirements numerically in terms of appropriate units together with their limits.

terminology—a document comprising definitions of terms; descriptions of terms; and explanations of symbols, abbreviations, or acronyms.

test method—a definitive procedure for the identification, measurement, and evaluation of one or more qualities, characteristics, or properties of a material, product, system, or service that produces a test result. (Compare *practice*.)

A new edition of the Book of Standards is published annually because of additions of new standards and significant revisions to existing standards. Approximately 30 % of each volume is new or revised. Each volume contains all actions approved by the Society at least six months before the publication date. New and revised standards approved by the Society between the annual editions of any given volume are made available as separate copies. Users are cautioned to follow the most current issue of a standard except when a specific edition of a standard is cited, for example, as in a contract.

Development and Use of ASTM Standards

ASTM believes that technically competent standards result when a full consensus of all concerned parties is achieved and rigorous due process procedures are followed. This philosophy and standards development system ensure technically competent standards having the highest credibility when critically examined and used as the basis for commercial, legal, or regulatory actions.

ASTM standards are developed voluntarily and used voluntarily. Standards become legally binding only when a government body references them in regulations, or when they are cited in a contract. Any item that is produced and marked as conforming to an ASTM standard must meet all applicable requirements of that standard.

ASTM standards are used by thousands of individuals, companies, and agencies. Purchasers and sellers incorporate standards into contracts; scientists and engineers use them in laboratories; architects and designers use them in plans; government agencies reference them in codes, regulations, and laws; and many others refer to standards for guidance.

Consideration of Comments on ASTM Standards

An ASTM standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of any standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Using the Annual Book of ASTM Standards

The standards are assembled in each volume in alphanumeric sequence of their ASTM designation numbers except for Volumes 11.01, 11.02, and 05.04, which are assembled by subject matter. Volumes 05.03 and 06.03 are assembled first by committee, then in alphanumeric sequence. Each volume has a table of contents, listing the standards in alphanumeric sequence by ASTM designation; and a list by subjects, categorizing the standards according to subject. A subject index of the standards in each volume appears at the back of each volume.

Availability of Individual Standards

Each ASTM standard is available as a separate copy from ASTM. Special quantity prices and discounts can be obtained from Customer Services. When ordering, provide the ASTM standard designation and year of issue, title, quantity desired, and shipping instructions.

Caveat Statements and Policies in Standards

ASTM caveat statements on Safety Hazards and Fire Hazards are required to appear in standards where appropriate. They are located in the scope section of applicable standards. The caveats on General Statement of ASTM Policy and Patents are contained in all standards and located at the end of each standard disclaimer. For more information on the caveats see Section F2 of the Form and Style Manual for ASTM Standards.

ANNUAL BOOK OF ASTM STANDARDS

Listed by Section and Volume

Section 1—Iron and Steel Products

- Volume 01.01 Steel—Piping, Tubing, Fittings
- Volume 01.02 Ferrous Castings; Ferroalloys
- Volume 01.03 Steel—Plate, Sheet, Strip, Wire
- Volume 01.04 Steel—Structural, Reinforcing, Pressure Vessel, Railway
- Volume 01.05 Steel—Bars, Forgings, Bearing, Chain, Springs
- Volume 01.06 Coated Steel Products
- Volume 01.07 Shipbuilding

Section 2—Nonferrous Metal Products

- Volume 02.01 Copper and Copper Alloys
- Volume 02.02 Aluminum and Magnesium Alloys
- Volume 02.03 Electrical Conductors
- Volume 02.04 Nonferrous Metals—Nickel, Cobalt, Lead, Tin, Zinc, Cadmium, Precious, Reactive, Refractory Metals and Alloys
- Volume 02.05 Metallic and Inorganic Coatings; Metal Powders, Sintered P/M Structural Parts

Section 3—Metals Test Methods and Analytical Procedures

- Volume 03.01 Metals—Mechanical Testing; Elevated and Low-Temperature Tests; Metallography
- Volume 03.02 Wear and Erosion; Metal Corrosion
- Volume 03.03 Nondestructive Testing
- Volume 03.04 Magnetic Properties; Metallic Materials for Thermostats, Electrical Heating and Resistance, Contacts, and Connectors
- Volume 03.05 Analytical Chemistry for Metals, Ores, and Related Materials (I): A 751 to E 354
- Volume 03.06 Analytical Chemistry for Metals, Ores, and Related Materials (II): E 356 to latest; Surface Analysis

Section 4—Construction

- Volume 04.01 Cement; Lime; Gypsum
- Volume 04.02 Concrete and Aggregates
- Volume 04.03 Road and Paving Materials; Pavement Management Technologies
- Volume 04.04 Roofing, Waterproofing, and Bituminous Materials
- Volume 04.05 Chemical-Resistant Materials; Vitrified Clay, Concrete, Fiber-Cement Products; Mortars; Masonry
- Volume 04.06 Thermal Insulation; Environmental Acoustics
- Volume 04.07 Building Seals and Sealants; Fire Standards; Building Constructions
- Volume 04.08 Soil and Rock; Dimension Stone; Geosynthetics
- Volume 04.09 Wood

Section 5—Petroleum Products, Lubricants, and Fossil Fuels

- Volume 05.01 Petroleum Products and Lubricants (I): D 56–D 1947
- Volume 05.02 Petroleum Products and Lubricants (II): D 1949–D 3601
- Volume 05.03 Petroleum Products and Lubricants (III): D 3602–latest; Catalysts
- Volume 05.04 Test Methods for Rating Motor, Diesel, and Aviation Fuels
- Volume 05.05 Gaseous Fuels; Coal and Coke

Section 6—Paints, Related Coatings, and Aromatics

- Volume 06.01 Paint—Tests for Formulated Products and Applied Coatings
- Volume 06.02 Paint—Pigments, Resins, and Polymers; Cellulose
- Volume 06.03 Paint—Fatty Oils and Acids, Solvents, Miscellaneous; Aromatic Hydrocarbons

LISTED BY SECTION AND VOLUME

Section 7—Textiles

- Volume 07.01 Textiles (I): D 76–D 3219
- Volume 07.02 Textiles (II): D 3333–latest

Section 8—Plastics

- Volume 08.01 Plastics (I): C 177–D 1600
- Volume 08.02 Plastics (II): D 1601–D 3099
- Volume 08.03 Plastics (III): D 3100–latest
- Volume 08.04 Plastic Pipe and Building Products

Section 9—Rubber

- Volume 09.01 Rubber, Natural and Synthetic—General Test Methods; Carbon Black
- Volume 09.02 Rubber Products, Industrial—Specifications and Related Test Methods; Gaskets; Tires

Section 10—Electrical Insulation and Electronics

- Volume 10.01 Electrical Insulation (I)—D 69–D 2484
- Volume 10.02 Electrical Insulation (II)—D 2518–latest
- Volume 10.03 Electrical Insulating Liquids and Gases; Electrical Protective Equipment
- Volume 10.04 Electronics (I)
- Volume 10.05 Electronics (II)

Section 11—Water and Environmental Technology

- Volume 11.01 Water (I)
- Volume 11.02 Water (II)
- Volume 11.03 Atmospheric Analysis; Occupational Health and Safety
- Volume 11.04 Pesticides; Resource Recovery; Hazardous Substances and Oil Spill Responses; Waste Management; Biological Effects

Section 12—Nuclear, Solar, and Geothermal Energy

- Volume 12.01 Nuclear Energy (I)
- Volume 12.02 Nuclear (II), Solar, and Geothermal Energy

Section 13—Medical Devices and Services

- Volume 13.01 Medical Devices; Emergency Medical Services

Section 14—General Methods and Instrumentation

- Volume 14.01 Analytical Methods—Spectroscopy; Chromatography; Computerized Systems
- Volume 14.02 General Test Methods, Nonmetal; Laboratory Apparatus; Statistical Methods; Appearance of Materials; Durability of Nonmetallic Materials
- Volume 14.03 Temperature Measurement

Section 15—General Products, Chemical Specialties, and End Use Products

- Volume 15.01 Refractories; Carbon and Graphite Products; Activated Carbon
- Volume 15.02 Glass; Ceramic Whitewares
- Volume 15.03 Space Simulation; Aerospace and Aircraft; High Modulus Fibers and Composites
- Volume 15.04 Soap; Polishes; Leather; Resilient Floor Coverings
- Volume 15.05 Engine Coolants; Halogenated Organic Solvents; Industrial Chemicals
- Volume 15.06 Adhesives
- Volume 15.07 End Use Products
- Volume 15.08 Fasteners
- Volume 15.09 Paper; Packaging; Flexible Barrier Materials; Business Imaging Products

Section 00—Index

- Volume 00.01 Subject Index and Alphanumeric List

ANNUAL BOOK OF ASTM STANDARDS

Listed by Subjects

SUBJECT	VOLUME	SUBJECT	VOLUME
Acoustics, Environmental	04.06	Glass	15.02

Contents

1992 ANNUAL BOOK OF ASTM STANDARDS, Volumes 06.01, 06.02, and 06.03

STANDARDS RELATING TO PAINT—TESTS FOR FORMULATED PRODUCTS AND APPLIED COATINGS; PIGMENTS, RESINS AND POLYMERS; CELLULOSE; FATTY OILS AND ACIDS, MISCELLANEOUS; AROMATIC HYDROCARBONS

A complete Subject Index begins on p. 1133

This contents includes only those standards included in these books and those standards that appeared previously that have been superceded or discontinued within the past five years. Since the standards in these books are arranged in alphanumerical sequence, no page numbers are given in this contents.

The alphanumerical sequence in Volume 06.03 is divided into two sections, separating the standards of Committee D-1 and D-16.

In the serial designations prefixed to the following titles, the number following the dash indicates the year of original adoption as standard or, in the case of revision, the year of last revision. Thus, standards adopted or revised during the year 1992 have as their final number, 92. A letter following this number indicates more than one revision during that year, that is 92a indicates the second revision in 1992, 92b the third revision, etc. Standards that have been reapproved without change are indicated by the year of last reapproval in parentheses as part of the designation number, for example, (1992). A superscript epsilon indicates an editorial change since the last revision or reapproval—e1 for the first change, e2 for the second change, etc.

PAINT AND RELATED COATINGS AND MATERIALS

	VOLUME
\$B 117 - 90	Method of Salt Spray (Fog) Testing 06.01
B 287 - 74 (1980) ^{e1}	Method of Acetic Acid-Salt Spray (Fog) Testing (Discontinued 1988†—Replaced by Practice G 85) 06.01

D 234 - 82 (1991) ^{e1}	Specification for Raw Linseed Oil 06.03
\$D 235 - 87 ^{e1}	Specification for Mineral Spirits (Petroleum Spirits) (Hydrocarbon Dry Cleaning Solvent) 06.03

§ Approved for use by agencies of the Department of Defense and, if indicated on the standard, replaces corresponding Federal or Military document. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

† Although this standard has been officially withdrawn from Society approval, a brief description is included for information only.

CONTENTS, VOLUMES 06.01, 06.02, AND 06.03

D 237 - 91	Specification for Orange Shellac and Other Lacs	06.02
D 260 - 86 (1990)	Specification for Boiled Linseed Oil	06.03
D 261 - 75 (1987) ^{e1}	Specification for Iron Blue Pigment	06.02
D 262 - 81 (1987) ^{e1}	Specification for Ultramarine Blue Pigment	06.02
D 263 - 75 (1987)	Specification for Chrome Oxide Green Pigment	06.02
D 267 - 82 (1987) ^{e1}	Specification for Gold Bronze Powder	06.02
§D 268 - 90	Methods of Sampling and Testing Volatile Solvents and Chemical Intermediates for Use in Paint and Related Coatings and Materials	06.03
D 269 - (1987) ^{e1}	Test Method for Toluene-Insoluble Solid Matter in Rosin (Chiefly Sand, Chips, Dirt, and Bark)	06.03
§D 279 - 87 (1991) ^{e1}	Test Methods for Bleeding of Pigments	06.02
§D 280 - 81 (1987)	Test Methods for Hygroscopic Moisture (and Other Matter Volatile Under the Test Conditions) in Pigments	06.02
§D 281 - 84 (1989)	Test Method for Oil Adsorption of Pigments by Spatula Rub-Out	06.02
§D 283 - 84 (1990) ^{e1}	Test Methods for Chemical Analysis of Cuprous Oxide and Copper Pigments	06.02
D 284 - 88	Test Methods for Chemical Analysis of Mercuric Oxide Pigment	06.02
D 301 - 89	Test Methods for Soluble Cellulose Nitrate	06.02
D 302 - 85	Specification for Ethyl Acetate (85 to 88 % Grade) (Discontinued 1987†—Replaced by Specification D 4614)	06.03
D 303 - 85	Specification of <i>n</i> -Butyl Acetate (90 to 92 % Grade) (Discontinued 1987†—Replaced by Specification D 4615)	06.03
§D 304 - 90	Specification for <i>n</i> -Butyl Alcohol (Butanol)	06.03
D 305 - 84 (1990) ^{e1}	Test Method for Solvent-Extractable Material in Black Pigments	06.02
D 319 - 90	Specification for Amyl Alcohol (Synthetic)	06.03
§D 329 - 90	Specification for Acetone	06.03
D 330 - 89	Specification for 2-Butoxyethanol	06.03
D 331 - 90	Specification for 2-Ethoxyethanol	06.03
§D 332 - 87 (1991) ^{e1}	Test Method for Relative Tinting Strength of White Pigments by Visual Observation	06.02
D 333 - 87	Test Methods for Clear and Pigmented Lacquers	06.01
D 344 - 89	Test Method for Relative Hiding Power of Paints by the Visual Evaluation of Brushouts	06.01
§D 358 - 83 (1988)	Specification for Wood to Be Used as Panels in Weathering Tests of Coatings	06.01
D 360 - 89	Specification for Shellac Varnishes	06.02
D 362 - 84	Specification for Industrial Grade Toluene (See Section on Aromatic Hydrocarbons)	06.03
D 363 - 90	Specification for Tricresyl Phosphate	06.03
D 365 - 84 (1989) ^{e1}	Methods of Testing Soluble Nitrocellulose Base Solutions	06.02
§D 387 - 86	Test Method for Color and Strength of Color Pigments with a Mechanical Muller	06.02
D 411 - 83 (1987)	Methods of Testing Shellac Used for Electrical Insulation	06.02
§D 444 - 88	Test Methods for Chemical Analysis of Zinc Yellow Pigment (Zinc Chromate Yellow)	06.02
D 464 - 91	Test Methods for Saponification Number of Naval Store Products Including Tall Oil and Other Related Products	06.03
D 465 - 82 (1987) ^{e1}	Test Methods for Acid Number of Rosin	06.03
D 475 - 67 (1989)	Specification for Pure Para Red Toner Pigments	06.02
§D 476 - 84 (1989)	Specification for Titanium Dioxide Pigments	06.02
D 477 - 78	Specification for Zinc Sulfide Pigments (Discontinued 1988†)	06.02
D 478 - 86 (1991) ^{e1}	Specification for Zinc Yellow (Zinc Chromate) Pigments	06.02
§D 480 - 88	Test Methods for Sampling and Testing of Flaked Aluminum Powders and Pastes	06.03
D 509 - 70 (1987)	Test Methods of Sampling and Grading Rosin	06.03
D 520 - 84 (1989)	Specification for Zinc Dust Pigment	06.02
D 521 - 90	Methods for Chemical Analysis of Zinc Dust (metallic Zinc Powder)	06.02
§D 522 - 88 ^{e1}	Test Methods for Mandrel Bend Test of Attached Organic Coatings	06.01
§D 523 - 89	Test Method for Specular Gloss	06.01
§D 555 - 84 (1988) ^{e1}	Guide for Testing Drying Oils	06.03
D 561 - 82 (1989)	Specification for Carbon Black Pigment for Paint	06.02
§D 562 - 81 (1990) ^{e1}	Test Method for Consistency of Paints Using the Stormer Viscometer	06.01
§D 563 - 88	Test Method for Phthalic Anhydride Content of Alkyd Resins and Resin Solutions	06.02
§D 564 - 87 (1991) ^{e1}	Test Method for Liquid Paint Driers	06.03
D 600 - 90	Specification for Liquid Paint Driers	06.03
D 601 - 87 (1991) ^{e1}	Specification for Oiticica Oil (Permanently Liquid)	06.03
D 602 - 81 (1991) ^{e1}	Specification for Barium Sulfate Pigments	06.02
D 603 - 66 (1989)	Specification for Aluminum Silicate Pigments (Hydrous)	06.02
D 604 - 81 (1989)	Specification for Diatomaceous Silica Pigment	06.02
§D 605 - 82 (1989)	Specification for Magnesium Silicate Pigment (Talc)	06.02
§D 607 - 82 (1987) ^{e1}	Specification for Wet Ground Mica Pigments	06.02
D 608 - 90	Specification for Dibutyl Phthalate	06.03
D 609 - 90	Methods for Preparation of Steel Panels for Testing Paint, Varnish, Lacquer and Related Products	06.01
§D 610 - 85 (1989) ^{e1}	Test Methods for Evaluating Degree of Rusting on Painted Steel Surfaces	06.01
D 611 - 82 (1987) ^{e2}	Test Methods for Aniline Point and Mixed Aniline Point of Petroleum Products and Hydrocarbon Solvents	06.03
§D 656 - 87	Specification for Pure Toluidine Red Toner	06.02
D 658 - 91	Test Method for Abrasion Resistance of Organic Coatings by Air Blast Abrasive	06.01
§D 659 - 86 ^{e1}	Method of Evaluating Degree of Chalking of Exterior Paints (Discontinued 1990†—Replaced by Test Methods D 4214)	06.01
§D 660 - 87	Test Method for Evaluating Degree of Checking of Exterior Paints	06.01

CONTENTS, VOLUMES 06.01, 06.02, AND 06.03

SD 661 - 86 ^{el}	Test Method for Evaluating Degree of Cracking of Exterior Paints	06.01
SD 662 - 86 ^{el}	Test Method for Evaluating Degree of Erosion of Exterior Paints	06.01

D 713 - 90	Practice for Conducting Road Service Tests on Fluid Traffic Marking Materials	06.01
SD 714 - 87	Test Method for Evaluating Degree of Blistering of Paints	06.01
D 715 - 86 (1991) ^{el}	Test Methods for Analysis of Barium Sulfate Pigment	06.02
D 716 - 86 (1991) ^{el}	Test Methods for Evaluating Mica Pigment	06.02
SD 717 - 86 (1991) ^{el}	Test Methods for Analysis of Magnesium Silicate Pigment	06.02
D 718 - 86 (1991) ^{el}	Test Methods for Analysis of Aluminum Silicate Pigment	06.02
D 719 - 91	Test Methods for Analysis of Diatomaceous Silica Pigment	06.02
D 740 - 89	Specification for Methyl Ethyl Ketone	06.03
D 763 - 81 (1988) ^{el}	Specification for Raw and Burnt Umber Pigments	06.02
D 765 - 87 (1991) ^{el}	Specification for Raw and Burnt Sienna Pigments	06.02
SD 768 - 81 (1987) ^{el}	Specification for Yellow Iron Oxide Hydrated	06.02
D 769 - 87 (1991) ^{el}	Specification for Black Synthetic Iron Oxide	06.02
D 770 - 90	Specification for Isopropyl Alcohol	06.03
SD 772 - 86 ^{el}	Test Method for Evaluating Degree of Flaking (Scaling) of Exterior Paints	06.01
D 784 - 83 (1987)	Specification for Orange Shellac and Other Indian Lacs for Electrical Insulation	06.02
D 801 - 57 (1987)	Test Methods for Sampling and Testing Dipentene	06.03
D 802 - 82 (1987)	Test Methods for Sampling and Testing Pine Oil	06.03
D 803 - 82 (1987)	Test Methods for Testing Tall Oil	06.03
D 804 - 79 (1987)	Definitions of Terms Relating to Naval Stores and Related Products	06.03
D 817 - 91	Methods of Testing Cellulose Acetate Propionate and Cellulose Acetate Butyrate	06.02
SD 822 - 89	Practice for Conducting Tests on Paint and Related Coatings and Materials Using Filtered Open-Flame Carbon-Arc Light and Water Exposure Apparatus	06.01
SD 823 - 91	Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels	06.01
D 856 - 49 (1987)	Test Methods for Sampling and Testing Pine Tars and Pine-Tar Oils (Intent to Withdraw)	06.03
D 867 - 81 (1986) ^{el}	Specification for Pumice Pigment	06.02
D 868 - 85 (1989) ^{el}	Test Method for Evaluating Degree of Bleeding of Traffic Paint	06.01
SD 869 - 85 (1989) ^{el}	Test Method for Evaluating Degree of Settling of Paint	06.01
D 870 - 87	Practice for Testing Water Resistance of Coatings Using Water Immersion	06.01
D 871 - 91	Methods of Testing Cellulose Acetate	06.02
D 889 - 58 (1987)	Test Method for Volatile Oil in Rosin	06.03
D 890 - 58 (1987)	Test Method for Water in Liquid Naval Stores	06.03
D 911 - 87	Specification for Mercuric Oxide for Use in Antifouling Paints	06.02
SD 912 - 81 (1986)	Specification for Cuprous Oxide for Use in Antifouling Paints	06.02
D 913 - 88	Test Method for Evaluating Degree of Resistance to Wear of Traffic Paint	06.01
SD 914 - 72 (1989) ^{el}	Test Methods for Ethylcellulose	06.02
D 960 - 79 (1988)	Specification for Raw Castor Oil	06.03
D 961 - 86	Specification for Dehydrated Castor Oil	06.03
D 962 - 81 (1986) ^{el}	Specification for Aluminum Powder and Paste Pigments for Paints	06.02
D 963 - 81 (1986) ^{el}	Specification for Copper Phthalocyanine Blue Pigment	06.02
D 964 - 65 (1989)	Specification for Copper Powder for Use in Antifouling Paints	06.02
SD 968 - 81 (1991) ^{el}	Test Methods for Abrasion Resistance of Organic Coatings by Falling Abrasive	06.01
D 969 - 85 (1989) ^{el}	Test Method for Laboratory Determination of Degree of Bleeding of Traffic Paint	06.01
SD 970 - 86 (1991) ^{el}	Test Methods for Para Red and Toluidine Red Pigments	06.02
SD 1005 - 84 (1990) ^{el}	Test Methods for Measurement of Dry-Film Thickness of Organic Coatings Using Micrometers	06.01
SD 1006 - 73 (1986) ^{el}	Practice for Conducting Exterior Exposure Tests of Paints on Wood	06.01
D 1007 - 90	Specification for <i>sec</i> -Butyl Alcohol	06.03
SD 1013 - 88	Test Method for Determining Total Nitrogen in Resins and Plastics	06.02
SD 1014 - 83 (1988) ^{el}	Test Method for Conducting Exterior Exposure Tests of Paints on Steel	06.01
D 1063 - 51 (1987)	Test Method for Ash in Rosin	06.03
SD 1064 - 58 (1981)	Test Method for Iron in Rosin	06.03
D 1065 - 82	Test Methods for Unsaponifiable Matter in Rosin	06.03
SD 1078 - 86	Test Method for Distillation Range of Volatile Organic Liquids	06.03
D 1131 - 53 (1981) ^{el}	Methods of Testing Rosin Oils	06.03
SD 1133 - 90	Test Method for Kauri-Butanol Value of Hydrocarbon Solvents	06.03
SD 1135 - 86 (1991) ^{el}	Test Methods for Chemical Analysis of Blue Pigments	06.02
D 1150 - 55 (1987) ^{el}	Single- and Multi-Panel Forms for Recording Results of Exposure Tests of Paints	06.01
D 1152 - 89	Specification for Methanol (Methyl Alcohol)	06.03
SD 1153 - 90	Specification for Methyl Isobutyl Ketone	06.03
D 1155 - 89	Test Method for Roundness of Glass Spheres	06.02
SD 1186 - 87	Test Methods for Nondestructive Measurement of Dry Film Thickness of Nonmagnetic Coatings Applied to a Ferrous Base	06.01
D 1193 - 91	Specification for Reagent Water	06.03
D 1198 - 88	Test Method for Solvent Tolerance of Amine Resins	06.02
D 1199 - 86 (1991) ^{el}	Specification for Calcium Carbonate Pigments	06.02
SD 1200 - 88	Test Method for Viscosity by Ford Viscosity Cup	06.01
SD 1208 - 84 (1989) ^{el}	Test Methods for Common Properties of Certain Pigments	06.02
SD 1209 - 84 (1988) ^{el}	Test Method for Color of Clear Liquids (Platinum-Cobalt Scale)	06.01, 06.03

CONTENTS, VOLUMES 06.01, 06.02, AND 06.03

§D 1210 - 79 (1988) ⁶¹	Test Method for Fineness of Dispersion of Pigment-Vehicle Systems	06.01
D 1211 - 87	Test Method for Temperature-Change Resistance of Clear Nitrocellulose Lacquer Films Applied to Wood	06.01
D 1212 - 91	Methods for Measurement of Wet Film Thickness of Organic Coatings	06.01
D 1214 - 89	Test Method for Sieve Analysis of Glass Spheres	06.02
D 1240 - 82	Test Method for Rosin Acids in Fatty Acids	06.03
D 1257 - 90	Specification for High-Gravity Glycerin	06.03
D 1258 - 90	Test Methods for Testing High-Gravity Glycerin	06.03
§D 1259 - 85 (1990) ⁶¹	Test Methods for Nonvolatile Content of Resin Solutions	06.02
§D 1296 - 84 (1988) ⁶¹	Test Method for Odor of Volatile Solvents and Diluents	06.03
§D 1301 - 91	Test Methods for Chemical Analysis of White Lead Pigments	06.02
§D 1306 - 88	Test Method for Phthalic Anhydride Content of Alkyd Resins and Esters Containing Other Dibasic Acids (Gravimetric)	06.02
§D 1308 - 87	Test Method for Effect of Household Chemicals on Clear and Pigmented Organic Finishes	06.01
D 1309 - 88	Test Method for Settling Properties of Traffic Paints During Storage	06.01
D 1310 - 86 (1990) ⁶¹	Test Method for Flash Point and Fire Points of Liquids by Tag Open-Cup Apparatus	06.03
D 1312 - 56 (1987) ⁶¹	Test Methods for Apparent Free Phenols in Synthetic Phenolic Resins or Solutions Used for Coating Purposes	06.02
D 1316 - 87	Test Method for Fineness of Grind of Printing Inks by the NPIRI Grindometer	06.01
§D 1343 - 91	Test Method for Viscosity of Cellulose Derivatives by Ball-Drop Method	06.02
D 1347 - 72 (1989) ⁶¹	Test Methods for Methylcellulose	06.02
D 1348 - 89	Test Methods for Moisture in Cellulose	06.02
§D 1353 - 90	Test Method for Nonvolatile Matter in Volatile Solvents for Use in Paint, Varnish, Lacquer, and Related Products	06.03
D 1358 - 86	Test Method for Spectrophotometric Diene Value of Dehydrated Castor Oil and Its Derivatives	06.03
D 1360 - 90a	Test Method for Fire Retardancy of Paints (Cabinet Method)	06.01
§D 1363 - 88	Test Method for Permanganate Time of Acetone and Methanol	06.03
§D 1364 - 90	Test Method for Water in Volatile Solvents (Fischer Reagent Titration Method)	06.03
D 1366 - 86 (1991) ⁶¹	Practice for Reporting Particle Size Characteristics of Pigments	06.02
D 1392 - 87	Specification for Safflower Oil	06.03
§D 1394 - 76 (1991) ⁶¹	Test Methods for Chemical Analysis of White Titanium Pigments	06.02
D 1395 - 58 (1974)	Test Method for Abrasion Resistance of Clear Floor Coatings (Discontinued 1989†)	06.01
D 1396 - 73 (1987) ⁶¹	Test Methods for Chemical Analysis of Poly(Vinyl Butyral)	06.02
§D 1397 - 88	Test Method for Unsaponifiable Matter in Alkyd Resins and Resin Solutions	06.02
§D 1398 - 84	Test Method for Fatty Acid Content of Alkyd Resins and Alkyd Resin Solutions	06.02
D 1399 - 90	Test Method for Unsaponifiable Content of Tricresyl Phosphate	06.03
D 1400 - 87	Test Method for Nondestructive Measurement of Dry Film Thickness of Nonconductive Coatings Applied to a Nonferrous Metal Base	06.01
D 1439 - 83a (1989) ⁶¹	Test Methods for Sodium Carboxymethylcellulose	06.02
D 1462 - 87	Specification for Refined Soybean Oil	06.03
D 1466 - 86	Test Method for Sampling Liquid Oils and Fatty Acids Commonly Used in Paints, Varnishes, and Related Materials	06.03
D 1467 - 89	Guide for Testing Fatty Acids Used in Protective Coatings	06.03
§D 1468 - 84 (1988) ⁶¹	Test Method for Volatile Matter in Tricresyl Phosphate	06.03
D 1469 - 73 (1988) ⁶¹	Test Method for Total Rosin Acids Content of Coating Vehicles	06.02
§D 1474 - 85 (1991) ⁶¹	Test Methods for Indentation Hardness of Organic Coatings	06.01
§D 1475 - 90	Test Method for Density of Paint, Varnish, Lacquer, and Related Products	06.01
§D 1476 - 88	Test Method for Heptane Miscibility of Lacquer Solvents	06.03
D 1483 - 84 (1989) ⁶¹	Test Method for Oil Absorption of Pigments by Gardner-Coleman Method	06.02
D 1537 - 60 (1988) ⁶¹	Specification for Distilled Soybean Fatty Acids	06.03
D 1538 - 60 (1988) ⁶¹	Specification for Distilled Linseed Fatty Acids	06.03
D 1539 - 60 (1988)	Specification for Dehydrated Castor Acids	06.03
D 1540 - 82 (1987) ⁶¹	Practice for Effect of Chemical Agents on Organic Finishes Used in the Transportation Industry	06.01
D 1541 - 86	Test Method for Total Iodine Value of Drying Oils and Their Derivatives	06.03
§D 1542 - 60 (1988) ⁶¹	Test Method for Qualitative Detection of Rosin in Varnishes	06.01, 06.02
D 1543 - 86	Test Method for Color Permanence of White Architectural Enamels (Discontinued 1992†)	06.02
§D 1544 - 80 (1989) ⁶¹	Test Method for Color of Transparent Liquids (Gardner Color Scale)	06.01, 06.02, 06.03
§D 1545 - 89	Test Method for Viscosity of Transparent Liquids by Bubble Time Method	06.01, 06.02, 06.03
D 1546 - 62 (1987)	Method for Performance Tests of Clear Floor Sealers	06.01
D 1585 - 82	Test Methods for Fatty Acids Content of Tall Oil Rosin	06.03
D 1612 - 90	Test Method for Acetone in Methanol (Methyl Alcohol)	06.03
§D 1613 - 91	Test Method for Acidity in Volatile Solvents and Chemical Intermediates Used in Paint, Varnish, Lacquer, and Related Products	06.03
D 1614 - 91	Test Method for Alkalinity in Acetone	06.03
D 1615 - 60 (1987)	Test Methods for Glycerol, Ethylene Glycol, and Pentaerythritol in Alkyd Resins	06.02
§D 1617 - 90	Test Method for Ester Value of Solvents and Thinners	06.03
§D 1638 - 74 ⁶¹	Methods of Testing Urethane Foam Isocyanate Raw Materials (Discontinued 1991†)	06.03
§D 1639 - 90	Test Method for Acid Value of Organic Coating Materials	06.01
§D 1640 - 83 (1989) ⁶¹	Test Methods for Drying, Curing or Film Formation of Organic Coatings at Room Temperature	06.01
D 1641 - 59 (1987)	Test Method for Exterior Durability of Varnishes	06.01
§D 1642 - 70 (1987)	Test Methods for Elasticity or Toughness of Varnishes	06.01

CONTENTS, VOLUMES 06.01, 06.02, AND 06.03

CONTENTS, VOLUMES 06.01, 06.02, AND 06.03

6.01	D 2072 - 66 (1987) ⁶¹	Test Method for Water in Fatty Nitrogen Compounds	06.03
6.01	D 2073 - 66 (1987) ⁶¹	Test Methods for Total, Primary, Secondary, and Tertiary Amine Values of Fatty Amines, Amidoamines, and Diamines by Referee Potentiometric Method	06.03
6.01		Test Methods for Total, Primary, Secondary, and Tertiary Amine Values of Fatty Amines by Alternative Indicator Method	06.03
6.02	D 2074 - 66 (1987) ⁶¹	Test Method for Iodine Value of Fatty Amines, Amidoamines, and Diamines	06.03
6.02	D 2075 - 89	Test Methods for Acid Value and Amine Value of Fatty Quaternary Ammonium Chlorides	06.03
6.02	D 2076 - 64 (1987) ⁶¹	Test Method for Ash in Fatty Quaternary Ammonium Chlorides	06.03
6.01	D 2077 - 64 (1987)	Test Method for Iodine Value of Fatty Quaternary Ammonium Chlorides	06.03
6.01	D 2078 - 86 (1990)	Test Method for Nonvolatile Matter (Solids) in Fatty Quaternary Ammonium Chlorides	06.03
6.02	D 2079 - 82 (1987)	Test Method for Average Molecular Weight of Fatty Quaternary Ammonium Chlorides	06.03
6.02	D 2080 - 64 (1987)	Test Method for pH of Fatty Quaternary Ammonium Chlorides	06.03
6.02	D 2081 - 64 (1987)	Test Method for Percent of Non-Amines in Fatty Nitrogen Compounds	06.03
6.03	D 2082 - 82 (1987)	Test Method for Calculation of Percent of Primary, Secondary, and Tertiary Amines in Fatty Amines	06.03
6.03	D 2083 - 66 (1987)	Test Method for Acidity in Vinyl Acetate and Acetaldehyde	06.03
6.03	D 2086 - 89	Test Method for Iron in Formaldehyde Solutions	06.03
6.03	D 2087 - 89	Test Method for Clarity and Cleanness of Paint and Ink Liquids	06.02, 06.03
6.02	D 2090 - 88	Test Method for Print Resistance of Lacquers	06.01
6.02	§D 2091 - 88	Practice for Preparation of Zinc-Coated (Galvanized) Steel Surfaces for Painting	06.01
6.03	§D 2092 - 86	Test Method for Softening of Organic Coatings by Plastic Compositions (Discontinued 1990†)	06.01
6.01	D 2134 - 66 (1980) ⁶¹	Specification for Vinyl Acetate	06.03
6.01	D 2190 - 89	Test Method for Acetaldehyde Content of Vinyl Acetate	06.03
6.01	D 2191 - 89	Test Method for Purity of Aldehydes and Ketones	06.03
6.01	D 2192 - 89	Test Method for Hydroquinone in Vinyl Acetate	06.03
6.01	D 2193 - 89	Test Method for Concentration of Formaldehyde Solutions	06.03
6.01	D 2194 - 89	Test Methods for Pentaerythritol	06.03
6.01	§D 2195 - 89	Test Methods for Rheological Properties of Non-Newtonian Materials by Rotational (Brookfield) Viscometer	06.01
6.02	§D 2196 - 86 (1991) ⁶¹	Test Method for Adhesion of Organic Coatings by Scrape Adhesion	06.01
6.02	§D 2197 - 86 (1991) ⁶¹	Test Method for Stain Removal from Multicolor Lacquers	06.01
6.02	D 2198 - 84 (1989) ⁶¹	Method for Measurement of Plasticizer Migration from Vinyl Fabrics to Lacquers	06.01
6.03	D 2199 - 82 (1987)	Pictorial Surface Preparation Standards for Painting Steel Surfaces	06.01
6.03	D 2200 - 91	Test Method for Preparation of Hot-Dipped Nonpassivated Galvanized Steel Panels for Testing Paint, Varnish, Lacquer, and Related Products	06.01
6.03	D 2201 - 65 (1987) ⁶¹	Guide for Selection of Tests for Traffic Paints	06.01
6.02	D 2205 - 85 (1990) ⁶¹	Specification for Molybdate Orange Pigments	06.02
6.02	§D 2218 - 67 (1989) ⁶¹	Test Method for Freeze-Thaw Resistance of Water-Borne Coatings	06.01
6.02	§D 2243 - 90	Test Method for Calculation of Color Differences from Instrumentally Measured Color Coordinates	06.01
6.01	§D 2244 - 89	Test Method for Identification of Oils and Oil Acids in Solvent-Reducible Paints	06.03
6.01	§D 2245 - 90	Test Method for Finishes on Primed Metallic Substrates for Humidity-Thermal Cycle Cracking	06.01
6.02	D 2246 - 87	Practice for Testing Water Resistance of Coatings in 100 % Relative Humidity	06.01
6.02	§D 2247 - 87	Practice for Detergent Resistance of Organic Finishes	06.01
6.03	D 2248 - 89	Practice for Specifying Properties from Liquid Through Cured State for Coatings Factory Applied to Wood Products	06.01
6.03	D 2336 - 87 (1991) ⁶¹	Test Method for Freeze-Thaw Stability of Multicolor Lacquers	06.01
6.03	D 2337 - 84 (1989)	Test Method for Determining Particle Size of Multicolor Lacquers	06.01
6.03	D 2338 - 84 (1989) ⁶¹	Test Method for Arsenic in Paint	06.01
6.03	D 2348 - 91	Test Method for Qualitative Determination of Nature of Thinner in Solvent-Reducible Paints	06.01
6.03	D 2349 - 90	Test Method for Antimony Oxide in White Pigment Separated from Solvent-Reducible Paints	06.02
6.03	§D 2350 - 90	Test Method for Sulfide in White Pigment Separated from Solvent-Reducible Paints	06.02
6.03	D 2351 - 90	Test Method for Sulfur Dioxide in White Pigment Separated from Solvent-Reducible Paints	06.02
6.03	D 2352 - 85 (1990) ⁶¹	Test Method for Flow Ratings of Organic Coatings Using the Shell Flow Comparator (Discontinued 1992†)	06.01
6.03	D 2353 - 83	Test Method for Minimum Film Formation Temperature (MFT) of Emulsion Vehicles	06.02
6.03	D 2354 - 91	Test Methods for Hydroxypropyl Methycellulose	06.02
6.03	D 2363 - 79 (1989) ⁶¹	Test Methods for Hydroxyethylcellulose	06.02
6.03	D 2364 - 89	Test Method for Accelerated Testing of Moisture Blister Resistance of Exterior House Paints on Wood (Discontinued 1989†)	06.01
6.03	D 2366 - 68 (1980) ⁶¹	Test Method for Volatile Content of Coatings	06.01
6.01	§D 2369 - 90	Test Method for Tensile Properties of Organic Coatings	06.01
6.02	§D 2370 - 82 (1987) ⁶²	Test Method for Pigment Content of Solvent-Reducible Paints	06.01
6.03	D 2371 - 85 (1990) ⁶¹	Practice of Separation of Vehicle from Solvent-Reducible Paints	06.01
6.03	D 2372 - 85 (1990) ⁶¹	Test Method for Determination of Cobalt in Paint Driers by EDTA Method	06.03
6.03	D 2373 - 85 (1990) ⁶¹	Test Method for Lead in Paint Driers by EDTA Method	06.03
6.03	D 2374 - 85 (1990) ⁶¹	Test Method for Manganese in Paint Driers by EDTA Method	06.03
6.03	D 2375 - 85 (1990) ⁶¹	Test Method for Slump of Face Glazing and Bedding Compounds on Metal Sash	06.01
6.01	D 2376 - 84 (1989)	Specification for Formaldehyde 50 % Grade Uninhibited and 37 % Grade Inhibited and Uninhibited	06.03
6.01	D 2378 - 84 (1987)	Test Method for Acidity of Formaldehyde Solutions	06.03
6.01	D 2379 - 84 (1987)	Test Method for Methanol Content of Formaldehyde Solutions	06.03
6.01	D 2380 - 84 (1987)	Test Method for Silica in Cellulose	06.02
6.03	D 2438 - 89

CONTENTS, VOLUMES 06.01, 06.02, AND 06.03

D 3127 - 83	Specification for <i>n</i> -Ethyl Acetate (99 % Grade) (Discontinued 1987†—Replaced by Specification D 4614)	06.03
D 3128 - 89	Specification for 2-Methoxyethanol	06.03
D 3129 - 91	Guide for Testing Exterior Latex House Paints	06.01
D 3130 - 86	Specification for <i>n</i> -Propyl Acetate (96 % Grade)	06.03
D 3131 - 88	Specification for Isopropyl Acetate (99 % Grade)	06.03
D 3132 - 84 (1990) ^{ei}	Test Method for the Solubility Range of Resins and Polymers	06.02
D 3133 - 72 (1989) ^{ei}	Test Method for Quantitative Determination of Cellulose Nitrate in Alkyd Lacquers by Infrared Spectrophotometry	06.01
D 3168 - 85 (1990) ^{ei}	Practice for the Qualitative Identification of Polymers in Emulsion Paints	06.01
D 3169 - 89	Specification for Refined Sunflower Oil	06.03
§D 3170 - 87 (1991) ^{ei}	Test Method for Chipping Resistance of Coatings	06.01
D 3256 - 86 (1991) ^{ei}	Test Methods for Chemical Analysis of Phthalocyanine Blue and Green Pigments	06.02
§D 3257 - 88	Test Method for Aromatics in Mineral Spirits by Gas Chromatography	06.03
D 3258 - 80 (1987) ^{ei}	Test Method for Porosity of Paint Films	06.01
D 3259 - 84 (1990) ^{ei}	Practice for Infrared Determination of the Temperature of Applied Coatings on Wood Products During the Curing Cycle	06.01
D 3260 - 82 (1991)	Test Method for Acid and Mortar Resistance of Factory-Applied Clear Coatings on Extruded Aluminum Products	06.01
D 3271 - 87	Practice for Direct Injection of Solvent-Reducible Paints into a Gas Chromatograph for Solvent Analysis	06.01
§D 3272 - 76 (1988) ^{ei}	Practice for Vacuum Distillation of Solvents from Solvent-Reducible Paints for Analysis	06.01
§D 3273 - 86 (1991) ^{ei}	Test Method for Resistance to Growth of Mold on the Surface of Interior Coatings in an Environmental Chamber	06.01
§D 3274 - 82 (1988) ^{ei}	Test Method for Evaluating Degree of Surface Disfigurement of Paint Films by Microbial (Fungal or Algal) Growth or Soil and Dirt Accumulation	06.01
D 3276 - 86	Guide for Painting Inspectors (Metal Substrates)	06.01
§D 3278 - 89	Test Methods for Flash Point of Liquids by Setaflash Closed-Cup Apparatus	06.03
§D 3280 - 85 (1990) ^{ei}	Test Methods for Analysis of White Zinc Pigments	06.02
D 3281 - 84 (1989)	Test Method for Formability of Attached Organic Coatings with Impact-Wedge Bend Apparatus	06.01
D 3322 - 82 (1991)	Practice for Testing Primers and Primer Surfacers Over Preformed Metal	06.01
§D 3323 - 80 (1988) ^{ei}	Guide for Testing Interior Solvent-Reducible Flat Wall Paints	06.01
§D 3329 - 89	Test Method for Purity of Methyl Isobutyl Ketone by Gas Chromatography	06.03
§D 3335 - 85a ^{ei} (1991) ^{ei}	Test Method for Low Concentrations of Lead, Cadmium, and Cobalt in Paint by Atomic Absorption Spectroscopy	06.01
§D 3358 - 88	Guide for Testing Water-Borne Floor Paints	06.01
§D 3359 - 90	Test Methods for Measuring Adhesion by Tape Test	06.01
D 3360 - 80 (1989)	Test Method for Particle Size Distribution By Hydrometer of the Common White Extender Pigments	06.02
D 3361 - 87	Practice for Operating Light- and Water-Exposure Apparatus (Unfiltered Open-Flame Carbon-Arc Type) for Testing Paint, Varnish, Lacquer, and Related Products Using the Dew Cycle	06.01
D 3362 - 84 (1987)	Test Method for Purity of Acrylate Esters by Gas Chromatography	06.03
D 3363 - 74 (1989) ^{ei}	Test Method for Film Hardness by Pencil Test	06.01
D 3383 - 79a (1988) ^{ei}	Guide for Testing Solvent-Reducible Floor Paints	06.01
D 3424 - 75	Method of Evaluating the Lightfastness of Printed Matter	06.01
D 3425 - 80 (1988) ^{ei}	Guide for Testing Solvent-Reducible Interior Semigloss Wall and Trim Enamels	06.01
§D 3432 - 89	Test Method for Unreacted Toluene Diisocyanates in Urethane Prepolymers and Coating Solutions by Gas Chromatography	06.02
D 3450 - 90	Test Method for Washability Properties of Interior Architectural Coatings	06.01
D 3451 - 76 (1987) ^{ei}	Practices for Testing Polymeric Powders and Powder Coatings	06.01
D 3456 - 86 (1991) ^{ei}	Practice for Determining by Exterior Exposure Tests the Susceptibility of Paint Films to Microbiological Attack	06.01
D 3457 - 87 (1991) ^{ei}	Test Method for Preparation of Methyl Esters from Fatty Acids for Determination of Fatty Acid Composition by Gas-Liquid Chromatography	06.03
D 3459 - 87	Test Method for Humid-Dry Cycling for Coatings on Wood and Wood Products	06.01
D 3516 - 89	Test Method for Ashing Cellulose	06.02
§D 3539 - 87	Test Methods for Evaporation Rates of Volatile Liquids by Shell Thin-Film Evaporometer	06.01
D 3540 - 86	Specification for Primary Amyl Acetate, Synthetic (98 % Grade)	06.03
D 3541 - 91	Specification for 2-Ethylhexyl Acrylate	06.03
§D 3545 - 90	Test Method for Alcohol Content and Purity of Acetate Esters by Gas Chromatography	06.03
D 3546 - 90	Test Method for Formic Acid in Glacial Acetic Acid	06.03
D 3547 - 91	Specification for <i>n</i> -Butyl Acrylate	06.03
D 3548 - 86	Specification for Ethyl Acrylate	06.03
D 3618 - 85a (1991) ^{ei}	Test Method for Detection of Lead in Paint and Dried Paint Films	06.01
D 3619 - 77 (1989)	Specification for Aluminum Silicate Pigments (Anhydrous)	06.02
D 3620 - 90	Specification for Glacial Acetic Acid	06.03
D 3621 - 84	Practice for Determination of Water in Acetate Esters (Discontinued 1988†—Replaced by Test Method D 1364)	06.03
D 3622 - 90	Specification for <i>n</i> -Propyl Alcohol (1-Propanol)	06.03
D 3623 - 78a (1987)	Method for Testing Antifouling Panels in Shallow Submergence	06.01
D 3624 - 85a (1991) ^{ei}	Test Method for Low Concentrations of Mercury in Paint by Atomic Absorption Spectroscopy	06.01

CONTENTS, VOLUMES 06.01, 06.02, AND 06.03

D 3630 - 89	Guide for Determining Constituents Classified as Hazardous Contained in Protective Coatings	06.01
D 3680 - 89	Test Method for Residual Vinyl Chloride Monomer Content of Poly(Vinyl Chloride) Resins, Compounds, and Copolymers by Solution Injection Technique	06.02
D 3717 - 85a (1991) ^{ei}	Test Method for Low Concentrations of Antimony in Paint by Atomic Absorption Spectroscopy	06.01
D 3718 - 85a (1991) ^{ei}	Test Method for Low Concentrations of Chromium in Paint by Atomic Absorption Spectroscopy	06.01
D 3719 - 87	Test Method for Quantifying Dirt Collection on Coated Exterior Panels	06.01
D 3720 - 90	Test Method for Ratio of Anatase to Rutile in Titanium Dioxide Pigments by X-Ray Diffraction	06.02
D 3721 - 83 (1991) ^{ei}	Specification for Synthetic Red Iron Oxide Pigment	06.02
D 3722 - 82 (1991) ^{ei}	Specification for Natural Red and Brown Iron Oxide Pigments	06.02
D 3723 - 84 (1990) ^{ei}	Test Method for Pigment Content of Water-Emulsion Paints by Low-Temperature Ashing	06.01
D 3724 - 82 (1987) ^{ei}	Specification for Synthetic Brown Iron Oxide Pigment	06.02
§D 3725 - 78 (1988) ^{ei}	Test Method for Semiquantitative Determination of Fish Oil in Drying Oils and Drying Oil Fatty Acids by Gas-Liquid Chromatography	06.03
D 3726 - 84	Specification for <i>n</i> -Butyl Acetate (99.5 % Grade) (Discontinued 1987†—Replaced by Specification D 4615)	06.03
D 3727 - 84	Specification for Ethyl Acetate (99.5 % Grade) (Discontinued 1987†—Replaced by Specification D 4614)	06.03
D 3728 - 88	Specification for 2-Ethoxyethyl Acetate (99 % Grade)	06.03
D 3729 - 84	Specification for Methyl Ethyl Ketone (99.5 % Grade) (Discontinued 1989†—Replaced by Specification D 740)	06.03
D 3730 - 78 (1988) ^{ei}	Guide for Testing High-Performance Interior Architectural Wall Coatings	06.01
D 3732 - 82 (1989) ^{ei}	Practice for Reporting Cure Times of Ultraviolet-Cured Coatings	06.01
D 3733 - 78 (1984) ^{ei}	Test Method for Silicon Content of Silicone Polymers and Silicone-Modified Alkyds by Atomic Absorption	06.02
D 3734 - 91	Specification for High-Flash Aromatic Naphthas	06.03
D 3735 - 87	Specification for VM&P Naphthas	06.03
D 3792 - 91	Test Method for Water Content of Water-Reducible Paints by Direct Injection Into a Gas Chromatograph	06.01
D 3793 - 89	Test Method for Low-Temperature Coalescence of Latex Paint Films	06.01
D 3794 - 79 ^{ei}	Practice for Testing Coil Coatings	06.01
D 3804 - 86 (1991) ^{ei}	Test Method for Iron in Paint Driers by EDTA Method	06.03
D 3806 - 90a	Test Method for Small-Scale Evaluation of Fire-Retardant Paints (2-Foot Tunnel Method)	06.01
D 3842 - 86 (1991)	Guide for Selection of Test Methods for Coatings for Use in Light-Water Nuclear Power Plants	06.01
D 3843 - 89	Practice for Quality Assurance for Protective Coatings Applied to Nuclear Facilities	06.01
D 3845 - 89	Specification for Glacial Methacrylic Acid	06.03
D 3872 - 86 (1991) ^{ei}	Test Method for Ferrous Iron in Iron Oxides	06.02
D 3876 - 79 (1989) ^{ei}	Test Method for Methoxyl and Hydroxypropyl Substitution in Cellulose Ether Products by Gas Chromatography	06.02
D 3891 - 90	Practice for Preparation of Glass Panels for Testing Paint, Varnish, Lacquer, and Related Products	06.01

2	D 4538 - 90a	Terminology Relating to Protective Coating and Lining Work for Power Generation Facilities	06.01
1	D 4540 - 91	Guide for Testing Interior Latex Semigloss and Gloss Paints	06.01
1	D 4541 - 85 (1989) ^{e1}	Test Method for Pull-Off Strength of Coatings Using Portable Adhesion Testers	06.01
1	D 4563 - 86 (1991) ^{e1}	Test Method for Determination by Atomic Absorption Spectroscopy of Titanium Dioxide Content of Pigments Recovered from Whole Paint	06.01
2	D 4584 - 86 (1991) ^{e1}	Test Method for Measuring Apparent pH of Electrocoat Baths	06.01

CONTENTS, VOLUMES 06.01, 06.02, AND 06.03

D 4585 - 87 ^{ei}	Practice for Testing Water Resistance of Coatings Using Controlled Condensation	06.01
D 4587 - 91	Practice for Conducting Tests on Paint and Related Coatings and Materials Using a Fluorescent UV-Condensation Light- and Water-Exposure Apparatus	06.01
D 4610 - 86	Guide for Determining the Presence of and Removing Microbial (Fungal or Algal) Growth on Paint and Related Coatings	06.01
D 4613 - 86 (1990) ^{ei}	Test Method for Measuring Apparent pH of Water Insoluble Phenol-Formaldehyde Resins	06.02
D 4614 - 86	Specification for Ethyl Acetate (All Grades)	06.03
D 4615 - 86 ^{ei}	Specification for <i>n</i> -Butyl Acetate (All Grades)	06.03
D 4618 - 87	Specification for Design and Fabrication of Flue Gas Desulfurization System Components for Protective Lining Application	06.01
D 4619 - 91	Practice for Inspection of Linings in Operating Flue Gas Desulfurization Systems	06.01
D 4639 - 86 (1990) ^{ei}	Test Method for Volatile Content in Phenolic Resins	06.02
D 4640 - 86 (1990) ^{ei}	Test Method for Determining Stroke Cure Time of Thermosetting Phenol-Formaldehyde Resins	06.02
D 4706 - 87	Test Method for Determining Qualitatively Methylol Group in Phenolic Resins	06.02
D 4707 - 87	Test Method for Measuring Paint Spatter Resistance to Roller Application	06.01
D 4708 - 91	Practice for Preparation of Uniform Free Films of Organic Coatings	06.01
D 4709 - 87	Specification for Methyl Acrylate	06.03
D 4710 - 87	Specification for Acetaldehyde	06.03
D 4712 - 87a (1991)	Guide for Testing Industrial Water-Reducible Coatings	06.01
D 4713 - 87 ^{ei}	Test Methods for Nonvolatile Content of Printing Inks, Resin Solutions, and Vehicles	06.01
D 4747 - 87	Test Method for Determining Unreacted Monomer Content of Latexes Using Gas Chromatography	06.02
D 4752 - 87	Test Method for Measuring MEK Resistance of Ethyl Silicate (Inorganic) Zinc-Rich Primers by Solvent Rub	06.01
D 4758 - 87	Test Method for Nonvolatile Content of Latexes	06.02
D 4764 - 88	Test Method for Determination by X-ray Fluorescence Spectroscopy of Titanium Dioxide Content in Paint	06.01
D 4773 - 89	Test Method for Purity of Propylene Glycol Monomethyl Ether, Dipropylene Glycol Monomethyl Ether, and Propylene Glycol Monomethyl Ether Acetate	06.03
D 4787 - 88	Practice for Continuity Verification of Liquid or Sheet Linings Applied to Concrete Substrates	06.01
D 4794 - 88	Test Method for Determination of Ethoxyl Substitution in Cellulose Ether Products by Gas Chromatography	06.02
D 4795 - 88	Test Method for Nitrogen Content of Soluble Nitrocellulose—Alternative Method	06.02
D 4796 - 88	Test Method for Bond Strength of Thermoplastic Traffic Marking Materials	06.01
D 4797 - 88	Test Methods for Chemical and Gravimetric Analysis of White and Yellow Thermoplastic Marking Containing Lead Chromate and Titanium Dioxide	06.01
D 4827 - 88	Test Method for Determining the Unreacted Monomer Content of Latexes Using Capillary Column Gas Chromatography	06.02
D 4828 - 91	Test Method for Practical Washability of Organic Coatings	06.01
D 4834 - 88	Test Method for Detection of Lead in Paint by Direct Aspiration Atomic Absorption Spectroscopy	06.01
D 4835 - 89	Specification for Propylene Glycol Monomethyl Ether Acetate	06.03
D 4836 - 90	Specification for Dipropylene Glycol Monomethyl Ether	06.03
D 4837 - 89	Specification for Propylene Glycol Monomethyl Ether	06.03
D 4838 - 88	Test Method for Determining the Relative Tinting Strength of Chromatic Paints	06.01
D 4938 - 89	Test Method for Erosion Testing of Antifouling Paints Using High Velocity Water	06.01
D 4939 - 89	Test Method for Subjecting Marine Antifouling Coating to Biofouling and Fluid Shear Forces in Natural Seawater	06.01
D 4940 - 89	Test Method for Conductimetric Analysis of Water Soluble Ionic Contamination of Blasting Abrasives	06.01
D 4941 - 89	Practice for Preparing Drawdowns of Artists' Paste Paints	06.01
D 4942 - 89	Test Methods for Water Pickup of Lithographic Printing Inks and Vehicles in a Laboratory Mixer	06.01
D 4946 - 89 ^{ei}	Test Method for Blocking Resistance of Architectural Paints	06.01
D 4948 - 89	Test Method for Determination of the Upper Layer Separated from a Viscous Liquid	06.01
D 4958 - 91	Test Method for Comparison of the Brush Drag of Latex Paints	06.01
D 4960 - 89	Test Method for Evaluation of Color for Thermoplastic Traffic Marking Materials	06.01
D 5007 - 89	Test Method for Wet-to-Dry Hiding Change	06.01
D 5008 - 89	Test Method for Ethyl Methyl Pentanol Content and Purity Value of 2-Ethylhexanol by Gas Chromatography	06.03
D 5009 - 89	Test Method for Evaluating and Comparing Transfer Efficiency Under Laboratory Conditions	06.01
D 5010 - 91	Guide for Testing Printing Inks and Related Materials	06.01
D 5031 - 89	Practice for Conducting Tests on Paints and Related Coatings and Materials Using Enclosed Carbon-Arc Light and Water Exposure Apparatus	06.01
D 5043 - 90	Test Methods for Field Identification of Coatings	06.01
D 5062 - 90 ^{ei}	Test Method for Resin Solution Dilutability	06.01
D 5063 - 90	Guide for Use of Certification of Coating Conformance Form	06.01
D 5064 - 90	Practice for Conducting a Patch Test to Assess Coating Compatibility	06.01
D 5065 - 90	Guide for Assessing the Condition of Aged Coatings on Steel Surfaces	06.01
D 5066 - 91	Test Method for Determination of the Transfer Efficiency Under Production Conditions for Spray Application of Automotive Paints—Weight Basis	06.01
D 5067 - 90 ^{ei}	Specification for Artists' Watercolor Paints	06.01
D 5068 - 90	Practice for Preparation of Paint Brushes for Evaluation	06.01
D 5069 - 90	Practice for Preparation of Paint Roller Covers for Evaluation	06.01

CONTENTS, VOLUMES 06.01, 06.02, AND 06.03

D 5087 - 91	Test Method for Determining Amount of Volatile Organic Compound (VOC) Released from Automotive Coatings and Available for Abatement	06.01
D 5095 - 90	Test Method for Determination of the Nonvolatile Content in Silanes, Siloxanes, and Silane-Siloxane Blends Used in Masonry Water Repellent Treatments	06.01
D 5097 - 90	Test Method for Filter-Retained Solids Content of Polymer Latexes	06.02
D 5098 - 90	Specification for Artists' Acrylic Emulsion Paints	06.01
D 5107 - 90	Practice for Preparatory Surface Cleaning of Architectural Sandstone	06.01
D 5108 - 90	Test Method for Organotin Release Rates of Antifouling Coating Systems in Sea Water	06.01
D 5125 - 91	Test Method for Viscosity of Paints and Related Materials by ISO Flow Cups	06.03
D 5137 - 90	Specification for Hexyl Acetate	06.03
D 5139 - 90	Specification for Sample Preparation for Qualification Testing of Coatings to be Used in Nuclear Power Plants	06.01
D 5144 - 91	Guide for the Use of Protective Coating Standards in Nuclear Power Plants	06.01

D 2747-81	Test Method for Trace Quantities of Total Sulfur in Volatile Organic Liquids (Oxy-Hydrogen Combustion Methods) (Discontinued 1987†)	06.03	
D 2748-82	Test Method for Pyridine Bases in Tar Acids (Discontinued 1987†—Replaced by Test Method D 4471)	06.03	
D 2827-88 ^{e1}	Specification for Styrene Monomer 996	06.03	
D 2870-86	Test Method for Gel Time of Tar Acids	06.03	
D 2930-80 (1989) ^{e1}	Test Method for Maleic Acid in Maleic Anhydride by Potentiometric Titration	06.03	
D 2935-91	Test Method for Apparent Density of Industrial Aromatic Hydrocarbons	06.03	
D 3054-81 (1985)	Test Method for Purity and Benzene Content of Cyclohexane by Gas Chromatography	06.03	
D 3055-90	Specification for Cyclohexane 995	06.03	
D 3160-91	Test Method for Phenol Content of Isopropylbenzene (Cumene)	06.03	
D 3193-91	Specification for Ethylbenzene	06.03	
D 3264-86	Specification for Industrial Grade Aniline	06.03	
D 3366-90	Test Method for Color of Maleic Anhydride and Phthalic Anhydride in the Molten State and After Heating (Platinum-Cobalt Scale)	06.03	
D 3436-91	Practice for Sampling and Handling Aniline	06.03	
D 3437-89	Practice for Sampling and Handling Liquid Cyclic Products	06.03	
D 3438-89	Practice for Sampling and Handling Naphthalene, Maleic Anhydride, and Phthalic Anhydride	06.03	
D 3439-89	Test Methods for Assay of Alkaline Cresylate Solutions from Petroleum Sources	06.03	
D 3504-91	Specification for Maleic Anhydride	06.03	
D 3505-91	Test Method for Density or Relative Density of Pure Liquid Chemicals	06.03	
D 3626-85 (1990) ^{e1}	Test Method for Tar Acid Composition by Gas-Liquid Chromatography	06.03	
D 3627-91	Test Method for Color of Cresylic Acids ("C" Series Standards)	06.03	
D 3760-79 (1984)	Method for Analysis of Isopropylbenzene (Cumene) by Gas Chromatography	06.03	
D 3797-88	Test Method for Analysis of <i>o</i> -Xylene by Gas Chromatography	06.03	
D 3798-89	Test Method for Analysis of <i>p</i> -Xylene by Gas Chromatography	06.03	
D 3799-89	Test Method for Purity of Styrene by Freezing Point Method	06.03	
D 3852-90	Practice for Sampling and Handling Phenol and Cresylic Acid	06.03	
D 3961-89	Test Method for Trace Quantities of Sulfur in Liquid Aromatic Hydrocarbons by Oxidative Microcoulometry	06.03	
D 3962-80 (1989) ^{e1}	Test Method for Analysis of Styrene by Gas Chromatography	06.03	
D 4076-86 (1990)	Specification for <i>o</i> -Xylene 950	06.03	
D 4077-91	Specification for Isopropylbenzene (Cumene)	06.03	
D 4297-89	Practice for Sampling and Handling 4,4'-Isopropylidenediphenol (Bisphenol A)	06.03	
D 4471-85 (1989) ^{e1}	Test Method for Pyridine Bases in Cresylic Acid by Direct Titration	06.03	
D 4492-85 (1989) ^{e1}	Test Method for Analysis of Benzene by Gas Chromatography	06.03	
D 4493-89	Test Method for Solidification Point of 4,4'-Isopropylidenediphenol (Bisphenol A)	06.03	
D 4534-89	Test Method for Benzene Content of Cyclic Products by Gas Chromatography	06.03	
D 4588-87	Guide for Analysis of <i>p</i> -Xylene (Discontinued 1992†—Replaced by Specification D 5136)	06.03	
D 4589-91	Test Method for Nitrobenzene in Aniline	06.03	
D 4590-86	Test Method for Colorimetric Determination of <i>p</i> -tert-Butylcatechol in Styrene Monomer by Addition of Alcoholic NaOH	06.03	
D 4734-90	Specification for Refined Benzene-545	06.03	
D 4735-87 (1991) ^{e1}	Test Method for Determination of Trace Thiophene in Refined Benzene by Gas Chromatography	06.03	
D 4789-88	Test Method for Solution Color of 4,4'-Isopropylidenediphenol (Bisphenol A)	06.03

CONTENTS, VOLUMES 06.01, 06.02, AND 06.03

D 4790 - 89a	Terminology of Aromatic Hydrocarbons and Related Chemicals	06.03
D 4961 - 89	Test Methods for Gas Chromatographic Analysis of Major Organic Impurities in Phenol Produced by the Cumene Process	06.03
D 5060 - 90	Test Method for Determining Impurities in High-Purity Ethylbenzene by Gas Chromatography	06.03
D 5135 - 90	Test Methods for Analysis of Styrene by Capillary Gas Chromatography	06.03
D 5136 - 90	Specification for Purity p-Xylene	06.03
D 5194 - 91	Test Method for Trace Chloride in Liquid Aromatic Hydrocarbons	06.03
D 5211 - 91	Specification for Xylene for p-Xylene Feedstock	06.03
E 299 - 90	Test Method for Trace Amounts of Peroxides in Organic Solvents	06.03
E 300 - 86	Practice for Sampling Industrial Chemicals	06.03
E 691 - 87	Practice for Conducting an Interlaboratory Study to Determine the Precision of a Test Method	06.03

PENDING STANDARDS ACTION

The following standards action was on Society ballot when this edition went to press. If approved, the action will be noted in *Standardization News* and the document will be available soon thereafter as a separate reprint.

Revision of Standards:

- D 1492 - 91
- D 3359 - 91
- D 4417 - 91

New Standards:

- D 5165 - 91
- D 5180 - 91

Practice for the Laboratory Preparation of Gelled Vehicles Using a Resin Kettle	06.02
Test Method for Quantitative Test for Turbidity in Clear Liquids	06.02

List by Subjects

1992 ANNUAL BOOK OF ASTM STANDARDS, VOLUME 06.01

PAINT—TESTS FOR FORMULATED PRODUCTS AND APPLIED COATINGS

Since the standards in this book are arranged in alphanumerical sequence, no page numbers are given in this list. The standards listed in italics are related documents included for information only and do not appear in this volume.

For List by Subjects of Volume 06.02 and 06.03, see pp. 1095 and 1100
A complete Subject Index begins on p. 1133

PAINT AND RELATED COATINGS—AS LIQUIDS

Specifications for:

- | | |
|---------------------------|---|
| D 5098 – 90 | Artists' Acrylic Emulsion Paints |
| D 4302 – 90 | Artists' Paints: Oil, Resin-Oil, and Alkyd Paints |
| D 5067 – 90 ^{ei} | Artists' Watercolor Paints |

Physical Tests

General Test Methods

Test Methods for:

- | | |
|-----------------------------------|--|
| D 969 – 85 (1989) ^{ei} | Bleeding of Traffic Paint, Determination of Degree of |
| D 4399 – 90 | Electrical Conductivity of Electrocoat Baths, Measuring |
| §D 1210 – 79 (1988) ^{ei} | Fineness of Dispersion of Pigment-Vehicle Systems |
| D 1316 – 87 | Fineness of Grind of Printing Inks by the NPRI Grindometer |
| §D 2243 – 90 | Freeze-Thaw Resistance of Water-Borne Coatings |
| D 2337 – 84 | Freeze-Thaw Stability of Multicolor Lacquers |
| D 3793 – 89 | Low-Temperature Coalescence of Latex Paint Films |
| D 2574 – 86 | Microorganisms, Resistance of Emulsion Paints to Attack in the Container |
| §D 185 – 84 (1989) ^{ei} | Particles, Coarse, in Pigments, Pastes, and Paints |
| D 5062 – 90 ^{ei} | Resin Solution, Dilutability |
| §D 869 – 85 (1989) ^{ei} | Settling of Paint, Evaluating Degree of |
| D 1309 – 88 | Settling Properties of Traffic Paints During Storage |
| D 4144 – 82 (1987) | Stability, Package, of Coatings for Ultraviolet Curing, Estimating |
| §D 1849 – 80 (1987) ^{ei} | Stability, Package, of Paint |
| D 4948 – 89 | Upper Layer Separated from a Viscous Liquid, Determination of |

Practice for:

- | | |
|-------------|---|
| D 3925 – 91 | Sampling Liquid Paints and Related Pigmented Coatings |
|-------------|---|

Application Properties

Test Methods for:

- | | |
|----------------------------------|---|
| D 4958 – 91 | Brush Drag of Latex Paints, Comparison of |
| D 2353 – 83 | Flow Ratings of Organic Coatings Using the Shell Flow Comparator (Discontinued 1992†) |
| D 2801 – 69 (1981) ^{ei} | Leveling Characteristics of Paints by Draw-Down Method (Discontinued 1990†) |
| D 4062 – 88 | Leveling of Paints by Draw-Down Method |
| D 4400 – 89a | Sag Resistance of Paints Using a Multinotch Applicator |
| D 2376 – 84 (1989) | Slump of Face Glazing and Bedding Compounds on Metal Sash |
| D 4707 – 87 | Spatter Resistance to Roller Application, Measuring |

Practice for:

- | | |
|-------------|--|
| D 4941 – 89 | Preparing Drawdowns of Artists' Paste Paints |
|-------------|--|

§ Approved for use by agencies of the Department of Defense and, if indicated on the standard, replaces corresponding Federal or Military document. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.
† Although this standard has been officially withdrawn from Society approval, a brief description is included for information only.

LIST BY SUBJECTS, VOLUME 06.01

Color and Clarity of Liquids

Test Methods for:

- | | |
|-----------------------------------|--|
| §D 1209 - 84 (1988) ⁶¹ | Color of Clear Liquids (Platinum-Cobalt Scale) |
| §D 1544 - 80 (1989) ⁶¹ | Color of Transparent Liquids (Gardner Color Scale) |
| D 4838 - 88 | Tinting Strength, Relative, of Chromatic Paints, Determining |
| D 2090 - 88 | Clarity and Cleanliness of Paint and Ink Liquids (see Vols 06.02, 06.03) |

Density, Specific Gravity, and Weight per Gallon

Test Method for:

- | | |
|--------------|--|
| §D 1475 - 90 | Density of Paint, Varnish, Lacquer, and Related Products |
|--------------|--|

Consistency and Viscosity

Test Methods for:

- | | |
|-----------------------------------|---|
| §D 562 - 81 (1990) ⁶¹ | Consistency of Paints Using the Stormer Viscometer |
| D 4359 - 90 | Determining Whether a Material is a Liquid or a Solid |
| §D 2196 - 86 (1991) ⁶¹ | Rheological Properties of Non-Newtonian Materials by Rotational (Brookfield) Viscometer |
| D 4212 - 88 | Viscosity by Dip-Type Cups |
| D 4287 - 88 | Viscosity, High-Shear, Using ICI Cone/Plate Viscometer |
| §D 1200 - 88 | Viscosity by Ford Viscosity Cup |
| D 4040 - 91 | Viscosity of Printing Inks and Vehicles by the Falling-Rod Viscometer |
| §D 1545 - 89 | Viscosity of Transparent Liquids by Bubble Time Method |

Analytical Tests

Nonvolatile Content

Test Methods for:

- | | |
|---------------------------|--|
| §D 2697 - 86 | Clear or Pigmented Coatings, Volume Nonvolatile |
| D 5145 - 90 | Nonvolatile and Pigment Content of Electrocoat Baths |
| D 5095 - 90 | Nonvolatile Content in Silanes, Siloxanes, and Silane-Siloxane Blends Used in Masonry Water Repellant Treatments, Determination of |
| D 4713 - 87 ⁶¹ | Printing Inks, Resins Solutions, and Vehicles |
| §D 1644 - 88 | Varnishes |

Guide for:

- | | |
|----------------------------------|----------------------------|
| D 2832 - 83 (1991) ⁶¹ | Paint and Related Coatings |
|----------------------------------|----------------------------|

Pigment Content

Test Methods for:

- | | |
|----------------------------------|--|
| D 4451 - 85 (1991) ⁶¹ | Paints by Low-Temperature Ashing |
| D 2371 - 85 (1990) ⁶¹ | Solvent-Reducible Paints |
| §D 2698 - 90 | Solvent-Reducible Paints Using High-Speed Centrifuge |
| D 3723 - 84 (1990) ⁶¹ | Water-Reducible Paints by Low-Temperature Ashing |

Volatile Content

Test Methods for:

- | | |
|--------------|--|
| §D 2369 - 90 | Coatings |
| D 5200 - 91 | Volatile Organic Compounds of Solvent Reducible Paints in Aerosol Cans |
| D 5087 - 91 | Volatile Organic Compound (VOC) Released from Automotive Coatings and Available for Abatement, Determining Amount of |

Practice for:

- | | |
|-------------|---|
| D 3960 - 91 | Paints and Related Coatings, Volatile Organic Content (VOC) |
|-------------|---|

Water Content

Test Methods for:

- | | |
|-------------|---|
| D 3792 - 91 | Water-Reducible Paints by Direct Injection Into a Gas Chromatograph |
| D 4017 - 90 | Paints and Paint Materials by Karl Fischer Method |
| D 4942 - 89 | Water Pickup of Lithographic Printing Inks and Vehicles in a Laboratory Mixer |

Acid Value and Reactivity

Test Methods for:

- | | |
|--------------|---|
| §D 1639 - 90 | Acid Value of Organic Coating Materials |
|--------------|---|

LIST BY SUBJECTS, VOLUME 06.01

Miscellaneous Methods of Analysis

Test Methods for:

- D 4370 - 84 (1990)^{e1} Acid and Base Milliequivalent Content of Electrocoat Bath
- D 2348 - 91 Arsenic in Paint
- D 3133 - 72 (1989)^{e1} Cellulose Nitrate in Alkyd Lacquers by Infrared Spectrophotometry, Quantitative Determination of
- D 3718 - 85a Chromium in Paint by Atomic Absorption Spectroscopy, Low Concentrations of
- D 4457 - 85 (1991)^{e1} Dichloromethane and 1,1,1-Trichloroethane, Analysis for by Direct Injection into a Gas Chromatograph
- D 2621 - 87 Infrared Identification of Vehicle Solids from Solvent-Reducible Paints
- §D 3335 - 85a (1991)^{e1} Lead, Cadmium, and Cobalt in Paint by Atomic Absorption Spectroscopy, Low Concentrations of
- D 3618 - 85a (1991)^{e1} Lead in Paint and Dried Paint Films, Detection of
- D 4834 - 88 Lead in Paint by Direct Aspiration Atomic Absorption Spectroscopy, Detection of
- D 3624 - 85a (1991)^{e1} Mercury in Paint, Low Concentrations of, by Atomic Absorption Spectroscopy
- D 4584 - 86 (1991)^{e1} pH, Measuring Apparent, of Electrocoat Baths
- §D 1542 - 60 (1988)^{e1} Rosin in Varnishes, Qualitative Detection of
- D 2349 - 90 Thinner in Solvent-Reducible Paints, Qualitative Determination of Nature
- D 4764 - 88 Titanium Dioxide Content in Paint by X-ray Fluorescence Spectroscopy, Determination of
- D 4563 - 86 (1991)^{e1} Titanium Dioxide Content of Pigments Recovered from Whole Paint, by Atomic Absorption Spectroscopy
- D 2921 - 88 Water Repellents and Preservatives in Wood Products, Qualitative Tests for the Presence of
- §D 3432 - 89 Free Toluene Diisocyanates in Urethane Prepolymers and Coating Solutions by Gas Chromatography (see Vol 06.02)

Practices for:

- D 3271 - 87 Direct Injection of Solvent-Reducible Paints into a Gas Chromatograph
- D 3168 - 85 (1990)^{e1} Polymers in Emulsion Paints, Qualitative Identification of
- D 2372 - 85 (1990)^{e1} Separation of Vehicle from Solvent-Reducible Paints
- D 2743 - 68 (1987) Uniformity of Traffic Paint Vehicle Solids by Spectroscopy and Gas Chromatography
- §D 3272 - 76 (1988)^{e1} Vacuum Distillation of Solvents from Solvent-Reducible Paints for Analysis

Guide for:

- D 1978 - 91 Analysis of Electrocoat Bath Samples

Systematic Analysis

Test Methods for:

- D 215 - 91 White Linseed Oil Paints, Chemical Analysis of
- Panel Specifications and Preparation of Surfaces for Painting

Specification for:

- §D 358 - 83 (1988) Wood Panels for Weathering Tests of Coatings

Test Methods for:

- D 4940 - 89 Blasting Abrasives, Analysis of Water Soluble Ionic Contamination, Conductimetric Analysis of
- §D 1734 - 63 (1980)^{e1} Concrete and Masonry Panels, Preparation for Paint Testing
- D 4262 - 83 (1988) Concrete Surfaces, pH of Chemically Cleaned or Etched
- D 2201 - 65 (1987)^{e1} Galvanized Steel Panels, Hot-Dipped Nonpassivated, Preparation for Paint Testing
- D 4417 - 84 Steel, Blast Cleaned, Field Measurement of Surface Profile
- D 609 - 90 Steel Panels, Preparation for Paint Testing
- D 2200 - 91 Steel Surfaces, Pictorial Surface Preparation Standards for Painting

Practices for:

- D 1730 - 67 (1984)^{e1} Aluminum and Aluminum-Alloy Surfaces, Preparation for Painting
- D 1731 - 67 (1984)^{e1} Aluminum Surfaces, Hot-Dip, Preparation for Painting
- D 5107 - 90 Architectural Sandstone, Preparatory Surface Cleaning of
- D 4259 - 88 Concrete, Abrading
- D 4260 - 88 Concrete, Acid Etching
- D 4258 - 83 (1988) Concrete, Surface Cleaning for Coating
- D 4261 - 83 (1988) Concrete Unit Masonry, Surface Cleaning for Coating
- D 3891 - 90 Glass Panels, Preparation for Testing Paint and Related Products
- §D 1732 - 67 (1984) Magnesium Alloy Surfaces, Preparation for Painting
- §D 2092 - 86 Zinc-Coated (Galvanized) Steel Surfaces, Preparation for Painting

Guide for:

- D 4610 - 86 Microbial (Fungal or Algal) Growth, Determining Presence

Film Preparation

Test Methods for:

- §D 823 - 91 Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels, Producing
- D 1212 - 91 Thickness, Wet Film, Measurement, of Organic Coatings

LIST BY SUBJECTS, VOLUME 06.01

Practices for:

- D 4147 - 82 (1987)
- D 4414 - 84 (1990)⁶¹
- D 4708 - 91

Applying Coil Coatings Using the Wire-Wound Drawdown Bar
Thickness, Wet Film, Measurement by Notch Gages
Uniform Free Films of Organic Coatings

Drying and Curing

Test Methods for:

- §D 1640 - 83 (1989)⁶¹
- D 1643 - 60 (1988)
- D 3793 - 89
- D 711 - 89
- D 4752 - 87

Drying Times of Organic Coatings at Room Temperature
Gas Checking and Draft Resistance of Varnish Films
Low-Temperature Coalescence of Latex Paint Films
No-Pick-Up Time of Traffic Paint
Zinc-Rich Ethyl-Silicate Primers, Resistance to Rubbing with MEK Solvent

Practices for:

- D 3732 - 82 (1989)⁶¹
- D 3259 - 84 (1990)⁶¹
- D 2454 - 91

Cure Times of Ultraviolet-Cured Coatings, Reporting
Infrared Determination of the Temperature of Applied Coatings on Wood Products During the Curing Cycle
Overbaking, Determining Effect on Organic Coatings

DRY FILM PROPERTIES

Thickness

Test Methods for:

- D 4138 - 88
- §D 1186 - 87
- D 1400 - 87
- §D 1005 - 84 (1990)⁶¹
- D 2691 - 88
- G 12 - 83 (1988)

Destructive Measurement of Dry Film Thickness of Protective Coating Systems
Measurement of Dry Film Thickness on Ferrous Base
Measurement of Dry Film Thickness on Nonferrous Metal Base
Micrometer Measurement of Dry-Film Thickness of Organic Coatings
Microscopical Measurement of Dry Film Thickness of Coatings on Wood Products
Nondestructive Measurement of Film Thickness of Pipeline Coatings on Steel

Porosity and Permeability

Test Methods for:

- D 2065 - 91
- D 3258 - 80 (1987)⁶¹
- §D 1653 - 91a
- E 96 - 90

Determination of Edge Performance of Composite Wood Products Under Surfactant Accelerated Moisture Stress
Porosity of Paint Films
Water Vapor Permeability of Organic Coating Films
Water Vapor Transmission of Materials in Sheet Form (see Vols 04.06, 08.03, and 15.09)

Practice for:

- D 5162 - 91

Discontinuity (Holiday) Testing of Nonconductive Protective Coating on Metallic Substrates

Appearance Properties

Gloss, Reflectance, and Hiding Power

Test Methods for:

- E 97 - 82 (1987)
- D 3928 - 89
- D 4449 - 90
- E 430 - 91
- §D 523 - 89
- D 5150 - 91
- D 2805 - 88
- D 344 - 89
- D 2064 - 91
- D 4039 - 87
- D 5007 - 89
- E 306 - 71 (1976)⁶¹

45-deg 0-deg, Directional Reflectance Factor of Opaque Specimens by Broad-Band Filter Reflectometry
Gloss or Sheen Uniformity, Evaluation of
Gloss Differences Between Surfaces of Similar Appearance, Visual Evaluation of
Gloss of High-Gloss Surfaces Using Abridged Goniophotometry
Gloss, Specular
Hiding Power of Architectural Paints Applied by Roller
Hiding Power of Paints by Reflectometry
Hiding Power, Relative, of Paints by the Visual Evaluation of Brushouts
Print Resistance of Architectural Paints
Reflection Haze of High-Gloss Surfaces
Wet-to-Dry Hiding Change
Absolute Calibration of Reflectance Standards (see Vol 14.02)

Practices for:

- E 259 - 91
- D 3964 - 80 (1989)

Preparation of Reference White Reflectance Standards
Selecting Coating Specimens for Appearance Measurements

Color

Test Methods for:

- D 969 - 85 (1989)⁶¹
- §D 2244 - 89
- D 1543 - 86

Bleeding, Degree of Traffic Paint, Laboratory Determination of
Color Differences, Calculation from Instrumentally Measured Color Coordinates
Color Permanence of White Architectural Enamels (Discontinued 1992†)

LIST BY SUBJECTS, VOLUME 06.01

Test Methods for:

D 4960 - 89

Color for Thermoplastic Traffic Marking Materials, Evaluation of

Practice for:

D 3964 - 80 (1989)

Selecting of Coating Specimens for Appearance Measurements

Physical Strengths and Resistances (Nonchemical)

Test Methods for:

- D 658 - 91 Abrasion Resistance of Organic Coatings by Air-Blast Abrasive
- §D 968 - 81 (1991)^{e2} Abrasion Resistance of Organic Coatings by Falling Abrasive
- D 4060 - 90 Abrasion Resistance of Organic Coatings by the Taber Abrasive
- D 5181 - 91 Abrasion Resistance of Printed Matter by the GA-CAT Comprehensive Abrasion
- D 4213 - 87 Abrasion Resistance, Wet, of Interior Paints
- §D 3359 - 90 Adhesion by Tape Test, Measuring
- §D 2197 - 86 (1991)^{e1} Adhesion of Organic Coatings by Scrape Adhesion
- D 5179 - 91 Adhesion of Organic Coatings to Plastic Substrates by Direct Tensile Testing
- D 4541 - 85 (1989)^{e1} Adhesion Pull-Off Strength of Coatings Using Portable Testers
- G 10 - 83 (1988) Bendability of Pipeline Coatings
- D 2793 - 69 (1987) Block Resistance of Organic Coatings on Wood Substrates
- D 4946 - 89^{e1} Blocking Resistance of Architectural Paints
- D 4796 - 88 Bond Strength Test for Thermoplastic Traffic Marking Materials
- §D 3170 - 87 (1991)^{e1} Chipping Resistance of Coatings
- §D 1642 - 70 (1987) Elasticity or Toughness of Varnishes
- §D 522 - 88^{e1} Mandrel Bend Test of Coatings
- D 5178 - 91 Mar Resistance of Organic Coatings
- D 4145 - 83 Flexibility, Coating, of Prepainted Sheet
- D 3281 - 84 (1989) Formability of Attached Organic Coatings with Impact-Wedge Bend Apparatus
- D 4146 - 83 (1989)^{e1} Formability of Zinc Rich Primer/Chromate Complex Coatings on Steel
- D 3363 - 74 (1989)^{e1} Hardness, Film, by Pencil Test
- §D 1474 - 85 (1991)^{e1} Hardness, Indentation, of Organic Coatings
- D 4366 - 91 Hardness Testing of Organic Coatings by Pendulum Damping
- G 14 - 88 Impact Resistance of Pipeline Coatings (Falling Weight Test)
- G 13 - 89 Impact Resistance of Pipeline Coatings (Limestone Drop Test)
- G 17 - 88 Penetration Resistance of Pipeline Coatings (Blunt Rod Test)
- D 3003 - 71 (1987) Pressure Motting and Blocking Resistance of Organic Coatings on Metal Substrates
- §D 2091 - 88 Print Resistance of Lacquers

Standard Test Method of Salt Spray (Fog) Testing¹

This standard is issued under the fixed designation B 117; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense to replace Method 811.1 of Federal Test Method Standard No. 151b. Consult the DoD Index of Specifications and Standards for the specific year of issue that has been adopted by the Department of Defense.

1. Scope

1.1 This test method sets forth the conditions required in salt spray (fog) testing for specification purposes. Suitable apparatus which may be used to obtain these conditions is described in Appendix X1. The method does *not* prescribe the type of test specimen or exposure periods to be used for a specific product, nor the interpretation to be given to the results. It should be noted that there is seldom a direct relation between salt spray (fog) resistance and resistance to corrosion in other media, because the chemistry of the reactions, including the formation of films and their protective value, frequently varies greatly with the precise conditions encountered. Comments on the use of the test in research will be found in Appendix X2. For evaluation of corrosive conditions, see Appendix X3.

NOTE 1—This method is applicable to salt spray (fog) testing of ferrous and nonferrous metals, and is also used to test inorganic and organic coatings, etc., especially where such tests are the basis for material or product specifications.

1.2 The values stated in SI units are to be regarded as standard. The inch-pound units in parentheses are provided for information.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

- B 287 Method of Acetic Acid-Salt Spray (Fog) Testing²
- B 368 Method for Copper-Accelerated Acetic Acid-Salt Spray (Fog) Testing (CASS Test)³

¹ This test method is under the jurisdiction of ASTM Committee G-1 on Corrosion of Metals, and is the direct responsibility of Subcommittee G01.05 on Laboratory Corrosion Tests.

Current edition approved March 30, 1990. Published May 1990. Originally published as B 117 - 39 T. Last previous edition B 117 - 85 ϵ 1.

² Discontinued—See 1987 *Annual Book of ASTM Standards*, Vols 02.05 and 03.02.

³ *Annual Book of ASTM Standards*, Vol 02.05.

- D 609 Methods for Preparation of Steel Panels for Testing Paint, Varnish, Lacquer, and Related Products⁴
- D 1193 Specification for Reagent Water⁵
- D 1654 Method for Evaluation of Painted or Coated Specimens Subjected to Corrosive Environments⁴
- E 70 Test Method for pH of Aqueous Solutions with the Glass Electrode⁶

3. Apparatus

3.1 The apparatus required for salt spray (fog) testing consists of a fog chamber, a salt solution reservoir, a supply of suitably conditioned compressed air, one or more atomizing nozzles, specimen supports, provision for heating the chamber, and necessary means of control. The size and detailed construction of the apparatus are optional, provided the conditions obtained meet the requirements of this method.

3.2 Drops of solution which accumulate on the ceiling or cover of the chamber shall not be permitted to fall on the specimens being tested.

3.3 Drops of solution which fall from the specimens shall not be returned to the solution reservoir for respraying.

3.4 Material of construction shall be such that it will not affect the corrosiveness of the fog.

4. Test Specimens

4.1 The type and number of test specimens to be used, as well as the criteria for the evaluation of the test results, shall be defined in the specifications covering the material or product being tested or shall be mutually agreed upon by the purchaser and the seller.

5. Preparation of Test Specimens

5.1 Metallic and metallic-coated specimens shall be suitably cleaned. The cleaning method shall be optional depending on the nature of the surface and the contaminants, except that it shall not include the use of abrasives other than a paste of pure magnesium oxide nor of solvents which are corrosive or will deposit either corrosive or protective films. The use of a nitric acid solution for the chemical cleaning, or passivation, of stainless steel specimens is permissible when agreed upon by the purchaser and the seller. Care shall be taken that specimens are not recontaminated after cleaning by excessive or careless handling.

⁴ *Annual Book of ASTM Standards*, Vol 06.01.

⁵ *Annual Book of ASTM Standards*, Vol 11.01.

⁶ *Annual Book of ASTM Standards*, Vol 15.05.

5.2 Specimens for evaluation of paints and other organic coatings shall be prepared in accordance with applicable specification(s) for the material(s) being tested, or as agreed upon by the purchaser and supplier. Otherwise, the test specimens shall consist of steel meeting the requirements of Methods D 609 and shall be cleaned and prepared for coating in accordance with applicable procedure of Methods D 609.

5.3 Specimens coated with paints or nonmetallic coatings shall not be cleaned or handled excessively prior to test.

5.4 Whenever it is desired to determine the development of corrosion from an abraded area in the paint or organic coating, a scratch or scribed line shall be made through the coating with a sharp instrument so as to expose the underlying metal before testing. The conditions of making the scratch shall be as defined in Method D 1654, unless otherwise agreed upon between the purchaser and seller.

5.5 Unless otherwise specified, the cut edges of plated, coated, or duplex materials and areas containing identification marks or in contact with the racks or supports shall be protected with a suitable coating stable under the conditions of the test, such as ceresin wax.

NOTE 2—Should it be desirable to cut test specimens from parts or from preplated, painted, or otherwise coated steel sheet, the cut edges shall be protected by coating them with paint, wax, tape, or other effective media so that the development of a galvanic effect between such edges and the adjacent plated or otherwise coated metal surfaces, is prevented.

6. Position of Specimens During Test

6.1 The position of the specimens in the salt spray chamber during the test shall be such that the following conditions are met:

6.1.1 Unless otherwise specified, the specimens shall be supported or suspended between 15 and 30° from the vertical and preferably parallel to the principal direction of horizontal flow of fog through the chamber, based upon the dominant surface being tested.

6.1.2 The specimens shall not contact each other or any metallic material or any material capable of acting as a wick.

6.1.3 Each specimen shall be so placed as to permit free settling of fog on all specimens.

6.1.4 Salt solution from one specimen shall not drip on any other specimen.

NOTE 3—Suitable materials for the construction or coating of racks and supports are glass, rubber, plastic, or suitably coated wood. Bare metal shall not be used. Specimens shall preferably be supported from the bottom or the side. Slotted wooden strips are suitable for the support of flat panels. Suspension from glass hooks or waxed string may be used as long as the specified position of the specimens is obtained, if necessary by means of secondary support at the bottom of the specimens.

7. Salt Solution

7.1 The salt solution shall be prepared by dissolving 5 ± 1 parts by weight of sodium chloride in 95 parts of water conforming to Type IV water in Specification D 1193. The salt used shall be sodium chloride substantially free of nickel and copper and containing on the dry basis not more than 0.1 % of sodium iodide and not more than 0.3 % of total

impurities. Some salts contain additives that may act as corrosion inhibitors; careful attention should be given to the chemical content of the salt. Upon agreement between purchaser and seller, analysis may be required and limits established for elements or compounds not specified in the chemical composition given above.

7.2 The pH of the salt solution shall be such that when atomized at 35°C (95°F) the collected solution will be in the pH range of 6.5 to 7.2 (Note 4). Before the solution is atomized it shall be free of suspended solids (Note 5). The pH measurement shall be made electrometrically at 25°C (77°F) using a glass electrode with a saturated potassium chloride bridge in accordance with Method E 70, or colorimetrically using bromothymol blue as indicator, or short range pH paper which reads in 0.2 or 0.3 of a pH unit (Note 6).

NOTE 4—Temperature affects the pH of a salt solution prepared from water saturated with carbon dioxide at room temperature and pH adjustment may be made by the following three methods:

(1) When the pH of a salt solution is adjusted at room temperature, and atomized at 35°C (95°F), the pH of the collected solution will be higher than the original solution due to the loss of carbon dioxide at the higher temperature. When the pH of the salt solution is adjusted at room temperature, it is therefore necessary to adjust it below 6.5 so the collected solution after atomizing at 35°C (95°F) will meet the pH limits of 6.5 to 7.2. Take about a 50-mL sample of the salt solution as prepared at room temperature, boil gently for 30 s, cool, and determine the pH. When the pH of the salt solution is adjusted to 6.5 to 7.2 by this procedure, the pH of the atomized and collected solution at 35°C (95°F) will come within this range.

(2) Heating the salt solution to boiling and cooling to 95°F for maintaining it at 95°F for approximately 48 h before adjusting the pH produces a solution the pH of which does not materially change when atomized at 35°C (95°F).

(3) Heating the water from which the salt solution is prepared to 35°C (95°F) or above, to expel carbon dioxide, and adjusting the pH of the salt solution within the limits of 6.5 to 7.2 produces a solution the pH of which does not materially change when atomized at 35°C (95°F).

NOTE 5—The freshly prepared salt solution may be filtered or decanted before it is placed in the reservoir, or the end of the tube leading from the solution to the atomizer may be covered with a double layer of cheesecloth to prevent plugging of the nozzle.

NOTE 6—The pH can be adjusted by additions of dilute cp hydrochloric acid or cp sodium hydroxide solutions.

8. Air Supply

8.1 The compressed air supply to the nozzle or nozzles for atomizing the salt solution shall be free of oil and dirt (Note 7) and maintained between 69 and 172 kN/m² (10 and 25 psi) (Note 8).

NOTE 7—The air supply may be freed from oil and dirt by passing it through a water scrubber or at least 610 mm (2 ft) of suitable cleaning material such as sheep's wool, excelsior, slag wool, or activated alumina.

NOTE 8—Atomizing nozzles may have a "critical pressure" at which an abnormal increase in the corrosiveness of the salt fog occurs. If the "critical pressure" of a nozzle has not been established with certainty, control of fluctuation in the air pressure within plus or minus 0.7 kN/m² (0.1 psi), by installation of a suitable pressure regulator valve⁹ mini-

⁷ Registered U. S. Patent Office.

⁸ The Nullmatic pressure regulator (or equivalent) manufactured by Moore Products Co., H and Lycoming Sts., Philadelphia, PA 19124, is suitable for this purpose.

mizes the possibility that the nozzle will be operated at its "critical pressure."⁹

9. Conditions in the Salt Spray Chamber

9.1 Temperature—The exposure zone of the salt spray chamber shall be maintained at $35 \pm 1.1 - 1.7^\circ\text{C}$ ($95 \pm 2 - 3^\circ\text{F}$). The temperature within the exposure zone of the closed cabinet shall be recorded at least twice a day at least 7 h apart (except on Saturdays, Sundays, and holidays when the salt spray test is not interrupted for exposing, rearranging, or removing test specimens or to check and replenish the solution in the reservoir).

NOTE 9—A suitable method to record the temperature is by a continuous recording device or by a thermometer which can be read from outside the closed cabinet. The recorded temperature must be obtained with the salt spray chamber to avoid a false low reading because of wet-bulb effect when the chamber is open.

9.2 Atomization and Quantity of Fog—At least two clean fog collectors shall be so placed within the exposure zone that no drops of solution from the test specimens or any other source shall be collected. The collectors shall be placed in the proximity of the test specimens, one nearest to any nozzle and the other farthest from all nozzles. The fog shall be such that for each 80 cm^2 of horizontal collecting area there will be collected in each collector from 1.0 to 2.0 mL of solution per hour based on an average run of at least 16 h (Note 10). The sodium chloride concentration of the collected solution shall be 5 ± 1 weight % (Note 11). The pH of the collected solution shall be 6.5 to 7.2. The pH measurement shall be made electrometrically or colorimetrically using bromothymol blue as the indicator.

NOTE 10—Suitable collecting devices are glass funnels with the stems inserted through stoppers into graduated cylinders, or crystallizing dishes. Funnels and dishes with a diameter of 10 cm have an area of about 80 cm^2 .

NOTE 11—A solution having a specific gravity of 1.0255 to 1.0400 at 25°C (77°F) will meet the concentration requirement. The concentration may also be determined as follows: Dilute 5 mL of the collected solution to 100 mL with distilled water and mix thoroughly; pipet a 10-mL aliquot into an evaporating dish or casserole; add 40 mL of distilled water and 1 mL of 1 % potassium chromate solution (chloride-free) and titrate with 0.1 N silver nitrate solution to the first appearance of a permanent red coloration. A solution that requires between 3.4 and 5.1 mL of 0.1 N silver nitrate solution will meet the concentration requirements.

9.3 The nozzle or nozzles shall be so directed or baffled that none of the spray can impinge directly on the test specimens.

10. Continuity of Test

10.1 Unless otherwise specified in the specifications covering the material or product being tested, the test shall be continuous for the duration of the entire test period. Continuous operation implies that the chamber be closed and the spray operating continuously except for the short daily

interruptions necessary to inspect, rearrange, or remove test specimens, to check and replenish the solution in the reservoir, and to make necessary recordings as described in Section 9. Operations shall be so scheduled that these interruptions are held to a minimum.

11. Period of Test

11.1 The period of test shall be as designated by the specifications covering the material or product being tested or as mutually agreed upon between the purchaser and the seller.

NOTE 12—Recommended exposure periods are to be as agreed upon by the purchaser and seller, but exposure periods of multiples of 24 h are suggested.

12. Cleaning of Tested Specimens

12.1 Unless otherwise specified in the specifications covering the material or product being tested, specimens shall be treated as follows at the end of the test:

12.1.1 The specimens shall be carefully removed.

12.2 Specimens may be gently washed or dipped in clean running water not warmer than 38°C (100°F) to remove salt deposits from their surface, and then immediately dried. Drying shall be accomplished with a stream of clean, compressed air.

13. Evaluation of Results

13.1 A careful and immediate examination shall be made for the extent of corrosion of the dry test specimens or for other failure as required by the specifications covering the material or product being tested or by agreement between the purchaser and the seller.

14. Records and Reports

14.1 The following information shall be recorded, unless otherwise prescribed in the specifications covering the material or product being tested:

14.1.1 Type of salt and water used in preparing the salt solution,

14.1.2 All readings of temperature within the exposure zone of the chamber,

14.1.3 Daily records of data obtained from each fog-collecting device including the following:

14.1.3.1 Volume of salt solution collected in millimetres per hour per 80 cm^2 ,

14.1.3.2 Concentration or specific gravity at 35°C (95°F) of solution collected, and

14.1.3.3 pH of collected solution.

14.4 Type of specimen and its dimensions, or number or description of part,

14.5 Method of cleaning specimens before and after testing,

14.6 Method of supporting or suspending article in the salt spray chamber,

14.7 Description of protection used as required in 5.5,

14.8 Exposure period,

14.9 Interruptions in test, cause and length of time, and

14.10 Results of all inspections.

NOTE 13—If any of the atomized salt solution which has not contacted the test specimens is returned to the reservoir, it is advisable to record the concentration or specific gravity of this solution also.

⁹ It has been observed that periodic fluctuations in air pressure of $\pm 3.4\text{ kN/m}^2$ (0.5 psi) resulted in about a twofold increase in the corrosivity of the fog from a nozzle which was being operated at an average pressure of 110 kN/m^2 (16 psi). Controlling the fluctuations within $\pm 0.7\text{ kN/m}^2$ (0.1 psi), however, avoided any increase in the corrosivity of the salt fog. See Darsey, V. M. and Cavanagh, W. R., "Apparatus and Factors in Salt Fog Testing," *Proceedings, ASTM*, Vol 48, 1948, p. 153.

15. Precision and Bias¹⁰

15.1 The reproducibility of results in the salt spray test is highly dependent on the type of specimens tested and the evaluation criteria selected as well as the control of the operating variables. In any testing program, sufficient replicates should be included to establish the variability of the results. Substantial variability is often observed when similar specimens are tested in different fog chambers even though

¹⁰ Supporting data are available on loan from ASTM Headquarters. Request RR: G01-1003.

the testing conditions are nominally similar and within the ranges specified in this method.

15.2 The salt spray (fog) test is intended to reproduce the corrosion that occurs in atmospheres containing salt spray or splash. It has been widely observed, however, that rankings of different alloys or coating systems, or both, do not necessarily fall in the same order as atmospheric tests in marine or road salt splash environments. This test has been more useful in rating the relative resistance of a specific type of protective coating, for example, hot-dip zinc coatings on steel. Interpretation of the results of this method beyond this purpose must be verified by actual exposure tests.

APPENDIXES

(Nonmandatory Information)

X1. CONSTRUCTION OF APPARATUS

X1.1 Cabinets

X1.1.1 Standard salt spray cabinets are available from several suppliers, but certain pertinent accessories are required before they will function according to this method and provide consistent control for duplication of results.

X1.1.2 The salt spray cabinet consists of the basic chamber, an air-saturator tower, a salt solution reservoir, atomizing nozzles, specimen supports, provisions for heating the chamber, and suitable controls for maintaining the desired temperature.

X1.1.3 Accessories such as a suitable adjustable baffle or central fog tower, automatic level control for the salt reservoir, and automatic level control for the air-saturator tower are pertinent parts of the apparatus.

X1.1.4 The cabinet should be of sufficient size to test adequately the desired number of parts without overcrowding. Small cabinets have been found difficult to control

and those of less than 0.43-m³ (15-ft³) capacity should be avoided.

X1.1.5 The chamber may be made of inert materials such as plastic, glass, or stone, but most preferably is constructed of metal and lined with impervious plastics, rubber, or epoxy-type materials or equivalent.

X1.2 Temperature Control

X1.2.1 The maintenance of temperature within the salt chamber can be accomplished by several methods. It is generally desirable to control the temperature of the surroundings of the salt spray chamber and to maintain it as stable as possible. This may be accomplished by placing the apparatus in a constant-temperature room, but may also be achieved by surrounding the basic chamber of a jacket containing water or air at a controlled temperature.

X1.2.2 The use of immersion heaters in an internal salt solution reservoir or of heaters within the chamber is detrimental where heat losses are appreciable, because of solution evaporation and radiant heat on the specimens.

X1.2.3 All piping which contacts the salt solution or spray should be of inert materials such as plastic. Vent piping should be of sufficient size so that a minimum of back pressure exists and should be installed so that no solution is trapped. The exposed end of the vent pipe should be shielded from extreme air currents that may cause fluctuation of pressure or vacuum in the cabinet.

X1.3 Spray Nozzles

X1.3.1 Satisfactory nozzles may be made of hard rubber, plastic, or other inert materials. The most commonly used type is made of plastic. Nozzles calibrated for air consumption and solution-atomized are available. The operating characteristics of a typical nozzle are given in Table X1.1.

X1.3.2 It can readily be seen that air consumption is relatively stable at the pressures normally used, but a marked reduction in solution sprayed occurs if the level of the solution is allowed to drop appreciably during the test. Thus,

TABLE X1.1 Operating Characteristics of Typical Spray Nozzle

Siphon Height, in.	Air Flow, L/min				Solution Consumption, mL/h			
	Air Pressure, psi				Air Pressure, psi

FIG. X1.1 Typical Salt Spray Cabinet

the level of the solution in the salt reservoir must be maintained automatically to ensure uniform fog delivery during the test.¹¹

X1.3.3 If the nozzle selected does not atomize the salt solution into uniform droplets, it will be necessary to direct the spray at a baffle or wall to pick up the larger drops and prevent them from impinging on the test specimens. Pending a complete understanding of air-pressure effects, etc., it is important that the nozzle selected shall produce the desired condition when operated at the air pressure selected. Nozzles are not necessarily located at one end, but may be placed in the center and can also be directed vertically up through a suitable tower.

X1.4 Air for Atomization

X1.4.1 The air used for atomization must be free of grease, oil, and dirt before use by passing through well-maintained filters. Room air may be compressed, heated, humidified, and washed in a water-sealed rotary pump, if the temperature of the water is suitably controlled. Otherwise

cleaned air may be introduced into the bottom of a tower filled with water, through a porous stone or multiple nozzles. The level of the water must be maintained automatically to ensure adequate humidification. A chamber operated according to this method and Appendix will have a relative humidity between 95 and 98 %. Since salt solutions from 2 to 6 % will give the same results (though for uniformity the limits are set at 4 to 6 %), it is preferable to saturate the air at temperatures well above the chamber temperature as insurance of a wet fog. Table X1.2 shows the temperatures, at different pressures, that are required to offset the cooling effect of expansion to atmospheric pressure.

X1.4.2 Experience has shown that most uniform spray chamber atmospheres are obtained by increasing the atom-

TABLE X1.2 Temperature and Pressure Requirements for Operation of Test at 95°F

	Air Pressure, psi			
	12	14	16	18

	Air Pressure, kPa			
	83	96	110	124
Temperature, °C	46	47	48	49

¹¹ A suitable device for maintaining the level of liquid in either the saturator tower or reservoir of test solution may be designed by a local engineering group, or may be purchased from manufacturers of test cabinets as an accessory.

NOTE—The controls are the same, in general as for the laboratory cabinet (Fig. X1.1), but are sized to care for the larger cube. The chamber has the following features:

- (1) Heavy insulation,
- (2) Refrigeration door with drip rail, or pressure door with drip rail, inward-sloping sill,
- (3) Low-temperature auxiliary heater, and
- (4) Duck boards on floor, with floor sloped to combination drain and air exhaust.

FIG. X1.2 Walk-in Chamber, 1.5 by 2.4 m (5 by 8 ft) and Upward in Overall Size

izing air temperature sufficiently to offset heat losses, except those that can be replaced otherwise at very low-temperature gradients.

X1.5 Types of Construction

X1.5.1 A modern laboratory cabinet is shown in Fig.

FIG. X1.3 Typical Spray Nozzle

X1.1. Walk-in chambers are not usually constructed with a sloping ceiling due to their size and location. Suitably located and directed spray nozzles avoid ceiling accumulation and drip. Nozzles may be located at the ceiling, or 0.91 m (3 ft) from the floor directed upward at 30 to 60° over a passageway. The number of nozzles depends on type and capacity and is related to the area of the test space. An 11- to 19-dm³ (3- to 5-gal) reservoir is required within the chamber, with the level controlled. The major features of a walk-in type cabinet, which differs significantly from the laboratory type, are illustrated in Fig. X1.2. Construction of a plastic nozzle, such as is furnished by several suppliers, is shown in Fig. X1.3.

X2. USE OF THE SALT SPRAY (FOG) TEST IN RESEARCH

X2.1 The detailed requirements of this method are primarily for quality acceptance and should not be construed as the optimum conditions for research studies. The test has been used to a considerable extent for the purpose of comparing different materials or finishes with an acceptable standard. The recent elimination of many cabinet variables and the improvement in controls have made the three ASTM Salt Spray Tests: Method B 117, B 287, and B 368, into useful tools for many industrial and military production and qualification programs.

X2.2 The test has been used to a considerable extent for the purpose of comparing different materials or finishes. It should be noted that there is seldom a direct relation between salt spray (fog) resistance and resistance to corrosion in other media, because the chemistry of the reactions, including the formation of films and their protective value, frequently varies greatly with the precise conditions encountered. Informed personnel are aware of the erratic composition of basic alloys, the possibility of wide variations in quality and thickness of plated items produced on the same racks at the same time, and the consequent need for a mathematical determination of the number of specimens required to constitute an adequate sample for test purposes. In this connection it is well to point out that Method B 117 is not applicable to the study or testing of decorative chromium

plate (nickel-chromium or copper-nickel-chromium) on steel or on zinc-base die castings or of cadmium plate on steel. For this purpose Methods B 287 and B 368 are available, which are also considered by some to be superior for comparison of chemically-treated aluminum (chromated, phosphated, or anodized), although final conclusions regarding the validity of test results related to service experience have not been reached. Method B 117 is considered to be most useful in estimating the relative behavior of closely related materials in marine atmospheres, since it simulates the basic conditions with some acceleration due to either wetness or temperature or both.

X2.3 When a test is used for research, it may prove advantageous to operate with a different solution composition or concentration or at a different temperature. In all cases, however, it is desirable to control the temperature and humidity in the manner specified, and to make certain that the composition of the settled fog and that of the solution in the reservoir are substantially the same. Where differences develop, it is necessary to control conditions so that the characteristics of the settled fog meet the specified requirements for the atmosphere.

X2.4 Material specifications should always be written in terms of the standard requirements of the appropriate salt spray method, thereby making it possible to test a variety of materials from different sources in the same equipment.

X3. EVALUATION OF CORROSIVE CONDITIONS

X3.1 General—This appendix covers test panels and procedures for evaluating the corrosive conditions within a salt spray cabinet. The procedure involves the exposure of steel test panels and the determination of their mass losses in a specified period of time. This may be done monthly or more frequently to insure consistent operation over time. It is also useful for correlating the corrosive conditions among different cabinets.

X3.2 Test Panels—The required test panels, 76 mm by 127 mm by 0.8 mm, are made from SAE 1010 commercial grade cold-rolled carbon steel (UNS G10080).

X3.3 Preparation of Panels Before Testing—Clean panels before testing by degreasing only, so that the surfaces are free of dirt, oil, or other foreign matter that could influence the test results. After cleaning, weigh each panel on an analytical balance to the nearest 1.0 mg and record the mass.

X3.4 Positioning of Test Panels—Place a minimum of two weighed panels in the cabinet, with the 127-mm length supported 30° from vertical. Place the panels in the prox-

imity of the condensate collectors. (See Section 6.)

X3.5 Duration of Test—Expose panels to the salt fog for 48 to 168 h.

X3.6 Cleaning of Test Panels After Exposure—After removal of the panels from the cabinet, rinse each panel immediately with running tap water to remove salt, and rinse in reagent grade water (see Specification D 1193, Type IV). Chemically clean each panel for 10 min at 20–25°C in a fresh solution prepared as follows:

Mix 1000 mL of hydrochloric acid (Sp. Gr. 1.19) with 1000 mL reagent grade water (D 1193, Type IV) and add 10 grams of hexamethylene tetramine. After cleaning, rinse each panel with reagent grade water (Type IV) and dry (see 12.2).

X3.7 Determining Mass Loss—Immediately after drying, determine the mass loss by reweighing and subtracting panel mass after exposure from its original mass. The mass should not vary 20 % from test to test.

X3.7.1 Data generated in the Interlaboratory Study using this method are available from ASTM as Research Report.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Last ASTM Designation: B 287 - 74 (1980)^{e1}

Standard Method of Acetic Acid-Salt Spray (Fog) Testing

This method sets forth the conditions required in acetic acid-salt spray (fog) testing for specification purposes. Formerly under the jurisdiction of Committee G-1 on Corrosion of Metals, this method was discontinued in 1988 and replaced by G 85.

Standard Terminology Relating to Paint, Varnish, Lacquer, and Related Products¹

88 and

This standard is issued under the fixed designation D 16; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

abrasion resistance (coatings)—the ability of a coating to resist being worn away and to maintain its original appearance and structure when subjected to rubbing, scraping, or wear.

acid number (coatings)—the number of milligrams of potassium hydroxide (KOH) required to neutralize the free acids in 1 g of an oil, resin, varnish, or other substance; generally reported on the nonvolatile content.

acid value (coatings)—see **acid number**.

acrylic resin—under **resin, synthetic**, see **acrylic resin**.

adhesion promoters—materials built into the binder or added to the paint to form primary bonds to either the substrate or the previously applied coating with the specific aim of improving the dry or wet adhesion, or both.

alkyd resin—under **resin, synthetic**, see **alkyd resin**.

architectural coatings—coatings intended for on-site application to interior or exterior surfaces of residential, commercial, institutional or industrial buildings.

asbestos—see **industrial talc and industrial talc, nonasbestos type**.

associative thickener—water soluble polymers containing hydrophobic groups that are capable of nonspecific hydrophobic association similar to surfactants that elevate viscosity presumably by association between thickener particles or thickener and dispersed particles that may be present in the aqueous system such as latex particles rather than through high molecular weight or chain stiffness of the thickener molecules themselves.

autodeposition—a single-step immersion metal finishing process in which an organic coating is applied by means of unique surface chemical reactions carried out in an aqueous latex dispersion, also referred to as chemiphoresis. Components within the bath give rise to chemical reactions that slightly solubilize the metallic surface and lead to destabilization, deposition, and coalescence of the dispersed latex particles at that surface.

DISCUSSION—The deposition rate of the latex is controlled by the rate of surface solubilization. The process does not require any pretreatments such as phosphating, needs no external energy input, and gives rise to deposition wherever the solution wets the substrate. Irregularly shaped parts can be uniformly coated.

baking finish—a paint or varnish that requires baking at temperatures above 150°F (65°C) for the development of desired properties.

baking temperature—a temperature above 150°F (65°C).

batch—the total quantity of a material produced in a single final mixing operation after all production processes are complete, or just prior to filling.

bituminous varnish—under **varnish**, see **bituminous varnish**.

bleeding—the diffusion of coloring matter through a coating from the substrate; also, the discoloration arising from such diffusion. In the case of printing ink, the spreading or running of a pigment color by the action of a solvent such as water or alcohol.

blistering resistance (coatings)—the ability of a coating to resist the formation in the film of dome-shaped, liquid- or gas-filled projections resulting from local loss of adhesion and lifting of the film from the previously applied coating or the substrate.

bulking value—solid volume of a unit weight of material, usually expressed as gallons per pound. For practical purposes this is 0.120 divided by the specific gravity.

caulking compound—a soft, plastic material, consisting of pigment and vehicle, used for sealing joints in buildings and other structures where normal structural movement may occur. Caulking compound retains its plasticity for an extended period after application. It is available in forms suitable for application by gun and knife and in extruded preformed shapes.

cellulose lacquer—see **lacquer**.

chalking resistance (coatings)—the ability of a pigmented coating to resist the formation of a friable powder on its surface caused by the disintegration of the binding medium by degradative weather factors.

checking resistance (coatings)—the ability of a coating to resist slight breaks in the film that do not penetrate to the previously applied coating or to the substrate. The breaks should be called cracks if penetration extends to the previously applied coating or to the substrate. See **cracking resistance**.

chipping resistance (coatings)—the ability of a coating or layers of coatings to resist removal, usually in small pieces, resulting from impact by hard objects or from wear during service.

coating—a liquid, liquefiable or mastic composition that is converted to a solid protective, decorative, or functional adherent film after application as a thin layer.

color of an object—the aspect of the appearance of an object dependent upon the spectral composition of the incident light, the spectral reflectance or transmittance of the

¹ These definitions are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.16 on Definitions.

Current edition approved Oct. 15, 1991. Published December 1991. Originally published as D 16 - 11. Last previous edition D 16 - 90a.

object, and the spectral response of the observer.

hue—the attribute by which a perceived color is distinguished as red, yellow, green, blue, purple, or a combination of these. (White, gray, and black colors possess no hue.)

lightness—the attribute by which a perceived color is judged to be equivalent to a member of the continuous series of grays ranging from black to white.

saturation—the attribute by which a perceived color is judged to depart from gray of equal lightness toward a pure hue.

contrast ratio—ratio of the reflectance of a dry paint film over a black substrate of 5 % or less reflectance, to the reflectance of the same paint, equivalently applied and dried, over a substrate of 80 % reflectance.

coverage, coverage rate, covering power—ambiguous terms that are used in some instances to refer to hiding power and in others to mean spreading rate. The precise terms **hiding power** and **spreading rate** are preferred.

cracking resistance (coatings)—the ability of a coating to resist breaks of the film where the breaks extend through to the surface painted and the previously applied coating or the substrate is visible. The use of a minimum magnification of 10 diameters is recommended in cases where it is difficult to differentiate between cracking and checking. See **checking resistance**.

dirt (coatings)—see **soil**.

dirt resistance (coatings)—the ability of a coating to resist soiling by foreign material, other than microorganisms, deposited on or embedded in the dried coating.

distinctness-of-image gloss—the sharpness with which image outlines are reflected by the surface of an object.

dope—a composition, usually a cellulosic lacquer, for application on textiles and leathers.

drier—a composition that accelerates the drying of oil, paint, printing ink, or varnish. Driers are usually metallic compositions and are available in both solid and liquid forms.

drying oil—an oil that possesses to a marked degree the property of readily taking up oxygen from the air and changing to a relatively hard, tough, elastic substance when exposed in a thin film to the air.

durability—a relative term indicating degree of permanency. It may be applied to individual protective, decorative, or functional properties, for example, "the durability of gloss," but if used in a general way, for example, "the excellent durability of a paint," implies the ability of the described coating to retain, to the indicated degree, all the properties required for the continued service of the coating.

edge-tracking (coatings)—a residual, discernible pattern in a roller-applied coating characterized by trails from either or both ends of the roller.

emulsion paint—under **paint**, see **emulsion paint**.

enamel—a paint that is characterized by an ability to form an especially smooth film.

erosion resistance (coatings)—the ability of a coating to withstand being worn away by chalking or by the abrasive action of water or windborne particles of grit. The degree of resistance is measured by the amount of the coating retained. See **abrasion resistance**.

ester gum—under **resin**, synthetic, see **ester gum**.

extended pigments—organic pigments diluted with an extender (for example, alumina trihydrate, blanc fixe, or calcium carbonate).

filler—a pigmented composition for filling the pores or irregularities in a surface preparatory to application of other finishes.

fire-retardant—a descriptive term which implies that the described product, under accepted methods of test, will significantly: (a) reduce the rate of flame spread on the surface of a material to which it has been applied, or (b) resist ignition when exposed to high temperatures, or (c) insulate a substrate to which it has been applied and prolong the time required to reach its ignition, melting, or structural-weakening temperature.

filiform corrosion resistance (coatings)—the ability of a coating to resist that type of corrosion of metal substrates characterized by a definite thread-like structure and directional growth that occurs under coatings.

fire-retardant coating—a coating that will do one or more of the following: (1) reduce the flame spread on the substrate over which the coating is applied, sometimes at the sacrifice of the coating (see **intumescent coating**); (2) resist ignition of the substrate when exposed to high temperature; or (3) insulate the substrate to which the coating is applied and thereby prolong the time required to reach its ignition, melting or structural-weakening temperature.

flaking resistance (coatings)—the ability of a coating to resist the actual detachment of film fragments either from the previously applied coating or the substrate. Flaking is generally preceded by cracking, checking, or blistering and is the result of loss of adhesion. Also known as **scaling resistance**.

flattening agent—a material added to paints, varnishes, and other coating materials to reduce the gloss of the dried film.

forced drying temperature—a temperature between room temperature and 150°F (65°C).

fossil resin—under **resin**, natural, see **fossil resin**.

gallon, U. S.—a volume equal to 231 in.³ For paint, varnish, lacquer, and related products this is measured at 77°F (25°C).

glaze—a very thin coating of a paint product usually a semi-transparent coating tinted with Van Dyke brown, burnt sienna, or a similar pigment, applied on a previously painted surface to produce a decorative effect.

glazing compound—a dough-like material consisting of pigment and vehicle, used for sealing window glass in frames. It differs from putty in that it retains its plasticity for an extended period.

grinding japan—see **japan**, grinding.

grit—the coarse foreign particles in paint materials and coatings, often of irregular shape, that are hard, abrasive, and resistant to disintegration.

hiding power—the ability of a paint, or paint material as used, to hide or obscure a surface to which it has been uniformly applied. When expressed numerically, it is generally in terms of the number of square feet over which a gallon of paint, or pound of pigment, as used, can be uniformly spread to produce a specified contrast ratio (see

ratio (see

contrast ratio). The term covering power has no specific relationship to hiding power, and actually has no precise meaning.

hue—under color of an object, see *hue*.

hydroxyl number—the number of milligrams of potassium hydroxide (KOH) equivalent to the hydroxyl content of 1 g of sample.

industrial talc—a mineral product varying in composition from that approaching the theoretical formula of talc, $Mg_3Si_4O_{10}(OH)_2$, to mixtures of talc and other naturally associated minerals, some of which may be fibrous as defined in ASTM Definitions D 2946, Terms Relating to Asbestos. These fibrous minerals may or may not be asbestos.

industrial talc, nonasbestos type—industrial talc of which less than 2 particles per 100 particles (by light microscopy) are asbestos fibers, where "asbestos fiber" is defined as being both a fiber by Definitions D 2946 and one of the asbestiform varieties of serpentine, riebeckite, cummingtonite (which are chrysotile, crocidolite and amosite, respectively), anthophyllite, tremolite, or actinolite. The nonasbestiform varieties of these same minerals are not asbestos.

intumescent coating—a fire-retardant coating (which see) that when heated forms a foam produced by nonflammable gases, such as carbon dioxide and ammonia. This results in a thick, highly insulating layer of carbon (about fifty times as thick as the original coating) that serves to protect the coated substrate from fire.

japan—a varnish yielding a hard, glossy, dark-colored film. Japans are usually dried by baking at relatively high temperatures.

japan, a vehicle for japan colors; frequently contains shellac.
japan color—a paste containing pigment and a grinding japan vehicle used for lettering and decoration.

japan drier—a resinate-base liquid drier.

lacquer—a coating composition that is based on synthetic thermoplastic film-forming material dissolved in organic solvent that dries primarily by solvent evaporation. Typical lacquers include those based on nitrocellulose, other cellulose derivatives, vinyl resins, acrylic resins, etc.

lake—a special type of pigment consisting essentially of an organic soluble coloring matter combined more or less definitely with an inorganic base or carrier. It is characterized generally by a bright color and a more or less pronounced translucency when made into an oil paint.

Under this term are included two (and perhaps three) types of pigment: (a) the older original type composed of hydrate of alumina dyed with a solution of the natural organic color, (b) the more modern and far more extensive type made by precipitating from solution various coal-tar colors by means of a metallic salt, tannin, or other suitable reagent, upon a base or carrier either previously prepared or coincidentally formed, and (c) a number combining both types in varying degree might be regarded as a third class.

lap (coatings)—the region where one area of a coated surface merges into an adjacent freshly-coated area during application of a single coat to the entire surface.

DISCUSSION—The objective of the painter is to avoid showing the lap.

latex paint—under paint, see *latex paint*.

lightness—under color of an object, see *lightness*.

maleic resin—under resin, synthetic, see *maleic resin*.

liquid—(flammability regulations) a substance that has a definite volume but no definite form, except such given by its container. It has a viscosity of 1×10^{-3} to 1×10^3 St (1×10^{-7} to 1×10^{-1} $m^2 s^{-1}$) at 104°F (40°C) or an equivalent viscosity at agreed upon temperature. (This does not include powders and granular materials.) Liquids are divided into two classes:

Class A, low viscosity—a liquid having a viscosity of 1×10^{-3} to 25.00 St (1×10^{-7} to 25.00×10^{-4} $m^2 s^{-1}$) at 104°F (40°C) or an equivalent viscosity at an agreed upon temperature.

Class B, high viscosity—a liquid having a viscosity of 25.01 to 1×10^3 St (25.01×10^{-4} to 1×10^{-1} $m^2 s^{-1}$) at 104°F (40°C) or an equivalent viscosity at an agreed upon temperature.

mass color—the color, when viewed by reflected light, of a pigment-vehicle mixture of such thickness as to obscure completely the background. Sometimes called over-tone or mass-tone.

mass-tone—see *mass color*.

melamine resin—under resin, synthetic see *melamine resin*.

metal marking resistance—the ability of a coating to withstand streaking or marking when a metal object is rubbed against or dragged across the surface of the coating.

mildew (fungus) resistance (coatings)—the ability of a coating to resist fungus growth that can cause discoloration and ultimate decomposition of a coating's binding medium.

mildewstat—a chemical agent that inhibits the growth of mildew.

mohair paint roller cover—a cover in which the paint applying material is woven of short pile velour that contains wool or angora goathair.

natural resin—see *resin, natural*.

nondrying oil—an oil that does not of itself possess to a perceptible degree the power to take up oxygen from the air and lose its liquid characteristics.

nonvolatile content—the portion of a coating that does not evaporate during drying or curing under specified conditions, comprising the binder and, if present, the pigment. (The percent volatile content is obtained by subtracting the nonvolatile content from 100.)

nonvolatile vehicle—the liquid portion of a paint excepting its volatile thinner and water.

oil color—an oil paint containing a high concentration of colored pigment, commonly used for tinting paint.

oil paint—under paint, see *oil paint*.

oil varnish—under varnish, see *oil varnish*.

opacity—the degree of obstruction to the transmission of visible light.

In this sense "opacity" is a relative term, it being considered that given a film sufficiently thin, in paint technology at least, there is no absolutely opaque substance.

over-tone—see *mass color*.

paint vb—to apply a thin layer of a coating to a substrate by brush, spray, roller, immersion, or any other suitable means.

paint n, general—a pigmented coating. See *coating*.

paint n, specific—a classification sometimes employed to distinguish pigmented drying oil coatings ("paints") from synthetic enamels and lacquers.

emulsion paint—a paint, the vehicle of which is an emulsion of binder in water. The binder may be oil, oleoresinous varnish, resin, or other emulsifiable binder.

latex paint—a paint containing a stable aqueous dispersion of synthetic resin, produced by emulsion polymerization, as the principal constituent of the binder. Modifying resins may also be present.

oil paint—a paint that contains drying oil or oil varnish as the basic vehicle ingredient.

paste paint—a paint in which the pigment is sufficiently concentrated to permit a substantial reduction with vehicle before use.

water paint—a paint, the vehicle of which is a water emulsion, water dispersion, or ingredients that react chemically with water.

paint brush—a paint application tool consisting of a flexible brushing part composed of long filamentary material (brushing material) bound to a handle.

DISCUSSION—Typical types include designs for varnish, enamel, sash and wall painting. They are manufactured in a range of shapes and sizes.

paint brush bristle—hair of the swine (for example: pig, hog, boar), used in brushing material.

paint brush ferrule—outer band that joins the brushing material to the handle.

paint brush filament—a synthetic polymer extrusion used in brushing material.

paint brush head—brush without the handle.

paint brush length clear—also called "length out", the exposed length of the brushing material from the ferrule to the tip end.

paint brush thickness—measurement of the brushing material across the narrow opening of the ferrule.

paint pad—a paint application tool consisting of short filamentary material usually bonded to a flat, resilient backing connected to a handle designed to apply paint by a wiping action.

paint roller—a complete paint application tool consisting of a roller frame and a roller cover designed to apply paint by a rolling action.

paint roller core—a structural tube that forms the base of the roller cover to which paint applying material is attached.

paint roller cover—a tubular sleeve consisting of a paint applying material secured to a core.

paint roller cover pile height—also called "nap length"; the length of the roller cover paint applying material from pile backing to pile face.

paint roller frame—a frame and handle assembly designed to hold a roller cover.

paste paint—under *paint*, see *paste paint*.

penta resin—under *resin*, synthetic, see *penta resin*.

phenolic resin—under *resin*, synthetic, see *phenolic resin*.

picking—a rolling up in the lap (see *lap*) when the previously applied paint film is in a semisolid (gel-like) state of

drying, causing a tacky resistance to the brush or roller and resulting in an unsightly nonuniform appearance in the final dried film.

pigment—the fine solid particles used in the preparation of paint or printing ink and substantially insoluble in the vehicle. Asphaltic materials are not pigments except when they contain substances substantially insoluble in the vehicle in which they are used.

pigment volume—the percent by volume of pigment in the nonvolatile portion of a paint or printing ink, as calculated from bulking value and composition data. The letters PV are commonly used as an abbreviation.

pinholes—small pore-like flaws in a coating that extend entirely through the applied film and have the general appearance of pin pricks when viewed by reflected light.

plasticizer—a substance added to paint, varnish, or lacquer to impart flexibility.

primer—the first of two or more coats of a paint, varnish, or lacquer system.

printing ink—a colored or pigmented liquid or paste composition that dries to a solid film after application as a thin layer by printing machinery.

print resistance (coatings)—the ability of a coating to resist taking on the imprint due to the pressure of another surface placed against it.

putty—a dough-like material consisting of pigment and vehicle, used for sealing glass in frames, and for filling imperfections in wood or metal surfaces. See *glazing compound*.

resin, natural—a solid organic substance, originating in the secretion of certain plants or insects, which is thermoplastic, flammable, nonconductive of electricity; breaks with a conchoidal fracture (when hard); and dissolves in certain specific organic solvents but not water.

fossil resin—a natural resin of ancient origin usually found in the earth.

resin, synthetic—a synthetic substance physically similar to natural resin.

acrylic resin—a synthetic resin made from derivatives of acrylic acid.

alkyd resin—a synthetic resin made from polyhydric alcohols and polybasic acids; generally modified with resins, fatty oils or fatty acids.

ester gum—a resin made from rosin or rosin acids and a polyhydric alcohol, such as glycerine or pentaerythritol.

maleic resin—a resin made from a natural resin and maleic anhydride or maleic acid.

melamine resin—a synthetic resin made from melamine and aldehyde.

penta resin—ester gum made from rosin and pentaerythritol.

phenolic resin—a synthetic resin made from phenols and aldehydes.

styrene resin—a synthetic resin made from vinyl benzene.

urea resin—a synthetic resin made from urea and an aldehyde.

vinyl resin—a synthetic resin made from vinyl compounds.

rust (coatings)—the reddish material, primarily hydrated iron oxide, formed on iron or its alloys resulting from

exposure to humid atmosphere or chemical attack. See white rust.

rust resistance (coatings)—the ability of a coating to protect the substrate of iron or its alloys from rusting.

saturation—under color of an object, see saturation.

scaling resistance (coatings)—See flaking resistance.

sealer—a liquid composition to prevent excessive absorption of finish coats into porous surfaces; also a composition to prevent bleeding (see size).

semidrying oil—an oil that possesses the characteristics of a drying oil but to a lesser degree. There is no definite line of demarcation between drying and semidrying oils.

shade—a term descriptive of a lightness difference between surface colors, the other attributes of color being essentially constant. A lighter shade of a color is one that has higher lightness but approximately the same hue and saturation; and a darker shade is one that has a lower lightness.

Primarily, the term "shade" is derived from shadow and designates a change in appearance analogous to that produced by a local reduction in illumination. It should, therefore, when strictly used, express only the change toward a darker color. Shade of a color has been defined by several authorities as the mixture of black with that color, thus establishing its opposite character to "tint," but by extension of its relative sense it has been frequently and widely used to include lighter shades by use of the adjective "lighter" or "paler." Although such expressions apparently involve a contradiction, it is clear that while we may have a shade of a color or darker color of the same sort, it is easy to conceive of another shade not quite so dark and therefore lighter.

sheepskin paint roller cover—a cover in which the paint applying material is wool fleece still attached to its tanned natural skin.

size—usually a liquid composition to prevent excessive absorption of all paints into plaster, old wall paint, and similar porous surfaces; also a liquid composition used as a first coat on metal to improve adhesion of succeeding coats (latter usage is limited to the metal decorating industry).

The terms **sealer** and **size** are almost synonymous, but usage has established certain differences. A sealer is ordinarily a thin varnish or clear lacquer and is usually applied on wood and metal surfaces. Ordinary painter's **size** is a thin solution of glue, starch or other water-soluble substance and is usually applied on plaster surfaces, but **size** used in metal decorating is a thin varnish.

spar varnish—under varnish, see *spar varnish*.

spirit varnish—under varnish, see *spirit varnish*.

soil (coatings)—disfiguring foreign materials such as dirt, soot, or stain, other than microorganisms, deposited on or embedded in a dried film of applied coating material; also called *dirt*.

solid—(flammability regulations) a substance that has a viscosity greater than 1×10^3 St (1×10^{-1} m² s⁻¹) at 104°F (40°C) or an equivalent viscosity at an agreed upon temperature. (This includes powders and granular materials.)

spreading rate—the area covered by a unit volume of coating material frequently expressed as square feet per gallon.

stain—a discoloration, arising from foreign materials, that penetrates into the coating.

stain—a penetrating composition that changes the color of a surface, usually transparent and leaving practically no surface film.

styrene resin—under resin, synthetic, see *styrene resin*.

surfacers—a pigmented composition for filling minor irregularities to obtain a smooth uniform surface preparatory to applying finish coats; usually applied over a primer and sandpapered for smoothness.

synthetic paint roller cover—a cover in which the paint applying material is man-made material.

synthetic resin—see resin, synthetic.

talc—see industrial talc and industrial talc, nonasbestos type.

temporary coating—a coating designed to protect or decorate a substrate for a limited time that can be readily removed either by mechanical or chemical means.

thinner—the portion of a paint, varnish, lacquer, or printing ink, or related product that volatilizes during the drying process.

tint—a color produced by the mixture of white pigment or paint in predominating amount with a colored pigment or paint, not white. The tint of a color is, therefore, much lighter and much less saturated than the color itself.

tinting strength—the power of coloring a standard paint or pigment.

toner—an organic pigment that does not contain inorganic pigment or inorganic carrying base.

undertone—the color of a thin layer of pigment-vehicle mixture applied on a white background.

urea resin—under resin, synthetic, see *urea resin*.

urethane coatings—coatings based upon vehicles containing a minimum of 10 percent by weight (nonvolatile vehicle basis) of a polyisocyanate monomer reacted in such a manner as to yield polymers containing any ratio, proportion or combination of urethane linkages, active isocyanate groups, or polyisocyanate monomer. The reaction products may contain excess isocyanate groups available for further reaction at time of application or may contain essentially no free isocyanate as supplied.

Type I, one-package prereacted—urethane coatings characterized by the absence of any significant quantity of free isocyanate groups. They are usually the reaction product of a polyisocyanate and a polyhydric alcohol ester of vegetable oil acids and are hardened with the aid of metallic soap driers.

Type II, one-package moisture cured—urethane coatings characterized by the presence of free isocyanate groups and capable of conversion to useful films by the reaction of these isocyanate groups with ambient moisture.

Type III, one-package heat cured—urethane coatings that dry on cure by thermal release of blocking agents and regeneration of active isocyanate groups that subsequently react with substances containing active hydrogen groups.

Type IV, two-package catalyst—urethane coatings that comprise systems wherein one package contains a prepolymer or adduct having free isocyanate groups capable of forming useful films by combining with a relatively small quantity of catalyst, accelerator, or crosslinking agent such as a monomeric polyol or polyamine contained in a

second package. This type has limited pot-life after the two components are mixed.

Type V, two-package polyol—urethane coatings that comprise systems wherein one package contains a prepolymer or adduct or other polyisocyanate capable of forming useful films by combining with a substantial quantity of a second package containing a resin having active hydrogen groups with or without the benefit of catalyst. This type has limited pot-life after the two components are mixed.

Type VI, one-package nonreactive lacquer—urethane solution coatings characterized by the absence of any significant quantity of free isocyanate or other functional groups. Such coatings convert to solid films primarily by solvent evaporation.

varnish—a liquid composition that is converted to a transparent or translucent solid film after application as a thin layer.

bituminous varnish—a dark-colored varnish containing bituminous ingredients. The varnish may be either of the oil or spirit type.

oil varnish—a varnish that contains resin and drying oil as the basic film-forming ingredients and is converted to a solid film primarily by chemical reaction.

spar varnish—a varnish for exterior surfaces. The name originated from its use on spars of ships.

spirit varnish—a varnish that is converted to a solid film primarily by solvent evaporation.

vehicle—the liquid portion of a paint or printing ink. Anything that is dissolved in the liquid portion of a paint or printing ink is a part of the vehicle.

vernonia oil—a low-viscosity epoxidized drying oil from the seed of an African plant, *Vernonia galamensis*, containing three reactive epoxy groups and three carbon—carbon double bonds per triglyceride molecule and is characterized by its very low viscosity and melting point.

DISCUSSION—It flows easily even at temperatures below 0°C and thus needs only a fraction of the volatile solvents usually used for other drying oils. Thus, it can be used as a reactive diluent for high solids alkyds and epoxy coating formulations.

vinyl resin—under resin, synthetic, see vinyl resin.

volatile thinner—see thinner.

volume percent solids—the portion of a coating that remains as part of the dry film expressed as percent by volume.

DISCUSSION—This contrasts to another convention of expressing solids content by weight percent. Often a percent is given without specifying whether it is volume or weight. This is confusing and leads to errors in coating calculations.

water paint—under paint, see water paint.

wet adhesion—the ability of a coating film to adhere tightly to the substrate directly beneath it under wet conditions such as rain, dew, washing, etc.

wet storage stain (coatings)—See white rust.

white rust—white corrosion products (zinc hydroxide and zinc oxide) on zinc-coated articles. They form when the parts are stored so close together that condensed moisture is entrapped between them and the air circulation is inadequate to assist drying. Also called wet storage stain. See rust.

zinc-rich primer—a primer for ferrous metals, incorporating zinc dust at a concentration sufficient to make the dried film electrically conductive thus providing cathodic protection to the ferrous substrate.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

AASHTO No. T55

Standard Test Method for Water in Petroleum Products and Bituminous Materials by Distillation¹

This standard is issued under the fixed designation D 95; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This test method has been approved by the sponsoring committees and accepted by the cooperating organizations in accordance with established procedures.

This test method has been approved for use by agencies of the Department of Defense and for listing in the DoD Index of Specifications and Standards.

^{ε1} NOTE—Paragraphs 1.3 and 11.2 were added editorially in May 1990.

1. Scope

1.1 This test method covers the determination of water in petroleum products, tars, and other bituminous materials by the distillation method. The specific products considered during the development of this test method are listed in Table 1. For bituminous emulsions refer to Test Method D 244. This test method, along with ASTM Test Method D 4006 (API Chapter 10.2 and IP 358), supersedes the previous edition of ASTM Test Method D 95 (API Standard 2560, IP 74).

NOTE 1—With some types of oil, satisfactory results may be obtained from ASTM Test Method D 4007 (API Chapter 10.3, IP 358, and ASTM Method D 1796 API Chapter 10.6).

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For specific hazard statements, see 5.1.1.2 and 5.1.1.3.*

1.3 The values stated in SI units are to be regarded as the standard. The values in parentheses are for information only.

TABLE 1 Type of Solvent-Carrier Liquid Versus Material to be Tested

Type of Solvent-Carrier Liquid	Material to be Tested
Aromatic	asphalt, tar, coal tar, water gas tar, road tar, cutback bitumin, liquid asphalt, tar acid
Petroleum distillate	road oil, fuel oil, lubricating oil, petroleum sulfonates
Volatile spirits	lubricating grease

water-immiscible solvent, which co-distills with the water in the sample. Condensed solvent and water are continuously separated in a trap, the water settling in the graduated section of the trap and the solvent returning to the still.

4. Significance and Use

4.1 A knowledge of the water content of petroleum products is important in the refining, purchase, sale, and transfer of products.

4.2 The amount of water as determined by this method (to the nearest 0.05 volume %) shall be used to correct the volume involved in the custody transfer of oil.

5. Solvent-Carrier Liquid

5.1 A solvent-carrier liquid appropriate to the material being tested (see Table 1) shall be used.

5.1.1 *Aromatic Solvent*—The following aromatic solvents are acceptable:

5.1.1.1 *Industrial Grade Xylene.*

5.1.1.2 A blend of 20 volume % industrial grade toluene and 80 volume % industrial grade xylene (Warning—Flammable. Vapor harmful. See Annex A1.1.)

5.1.1.3 *Petroleum or Coal Tar Naphtha* (Warning—Extremely flammable. Harmful if inhaled. Vapors may cause fire. See Annex), free of water, yielding not more than 5% distillates at 125°C (257°F) and not less than 20% at 160°C (320°F) when tested by Method D 86 and with a relative density (specific gravity) not lower than 0.8545 at 15.56/15.56°C (60/60°F).

5.1.2 *Petroleum Distillate Solvent*—A petroleum distillate

FIG. 1 Typical Assembly with Glass Still (Dean and Stark)

FIG. 2 Two-millilitre Receiver Showing Alternative Connections to Glass Still

solvent, 5% boiling between 90° and 100°C (194° and 212°F) and 90% distilling below 210°C (410°F), shall be used.

5.1.3 *Volatile Spirits Solvent*—The following volatile spirits solvents are acceptable:

5.1.3.1 *Petroleum Spirit*, with a boiling range of 100° to 120°C (212° to 248°F).

5.1.3.2 *Isooctane*, of 95% purity or better.

6. Apparatus

6.1 *General*—The apparatus comprises a glass or metal still, a heater, a reflux condenser, and a graduated glass trap. The still, trap, and condenser may be connected by any suitable method that produces a leakproof joint. Preferred connections are ground joints for glass and O-rings for metal to glass. Typical assemblies are illustrated in Figs. 1, 2, and 3. The stills and traps should be chosen to cover the range of materials and water contents expected.

6.2 *Still*—A glass or metal vessel with a short neck and suitable joint for accommodating the reflux tube of the trap shall be used. Vessels of 500, 1000, and 2000-mL nominal capacity have proved satisfactory.

6.3 *Heater*—A suitable gas burner or electric heater may be used with the glass still. A gas ring burner with ports on the inside circumference shall be used with the metal still. The gas ring burner shall be of such dimensions that it may be moved up and down the vessel when testing materials that are likely to form or solidify in the still.

6.4 *Glassware*—Dimensions and descriptions of typical glassware for use in this method are provided in Specification E 123 and British Standard 756. A straight water-cooled condenser with a length of 400 mL is recommended in place of the length of 300 mL specified in British Standard 756.

NOTE 2—Instead of standardizing on a particular apparatus specification with respect to dimensions and style, a given apparatus will be deemed satisfactory when accurate results are obtained by the standard addition technique described in Section 7.

7. Standardization

7.1 A given assembly of apparatus will be considered

Note—Trap shall be 15 to 16 mm in inside diameter

FIG. 3 Typical Assemblies with Metal Still

satisfactory when accurate readings are obtained from the addition of known amounts of water from a calibrated buret or pipet to a clear hydrocarbon oil and tested in accordance with Section 9.

7.2 The readings shall be judged accurate if the permis-

sible limits given in Table 2 for the various sized graduated traps are not exceeded.

7.3 A reading outside the permissible limits suggests a malfunction resulting from vapor leaks, too rapid boiling, inaccuracies in calibration of the trap, or ingress of extraneous moisture. Eliminate these factors before repeating the standardization.

TABLE 2 Permissible Limits in Millilitres

Capacity of Receiver at 20°C	Volume of Water Added to Flask at 20°C	Permissible Limits for Recovered Water at 20°C
2	1	1 ± 0.05
10	1	1 ± 0.1
10	5	5 ± 0.2
25	12	12 ± 0.2

8. Sampling

8.1 Sampling is defined as all steps required to obtain an aliquot of the contents of any pipe, tank, or other system and to place the sample into the laboratory test container. Only representative samples obtained as specified in Practice D 4057 (API Chapter 8.1) and Method D 4177 (API Chapter

8.2) shall be used for this test method.

8.2 The size of the test portion should be based on the expected water content of the sample, such that the water yield does not exceed the capacity of the trap (unless a trap with a stopcock is used since excess water can be withdrawn into a graduated cylinder).

9. Procedure

9.1 Measure a suitable amount of sample to an accuracy of $\pm 1\%$ and transfer it to the still.

9.2 Measure ordinary liquid samples in a graduated cylinder of an appropriate size. Rinse the material adhering to the cylinder with one 50-mL and two 25-mL portions of the solvent-carrier liquid (see Section 5 and Table 1). Drain the cylinder thoroughly after the sample transfer and each rinsing.

9.3 Weigh solid or viscous materials directly into the still and add 100 mL of the selected solvent-carrier liquid. In cases of material with a low-water content when large samples must be used, a solvent-carrier liquid volume in excess of 100 mL may be necessary.

9.4 Glass beads or other boiling aids may be added, if necessary, to reduce bumping.

9.5 Assemble the components of the apparatus as illustrated in Figs. 1, 2, and 3 choosing the trap in accordance with the expected water content of the sample and making all connections vapor and liquid tight. If a metal still with a removable cover is used, insert a gasket of heavy paper, moistened with solvent, between the still body and the cover. The condenser tube and trap must be chemically clean to assure free drainage of water into the bottom of the trap. Insert a loose cotton plug in the top of the condenser to prevent condensation of atmospheric moisture inside it. Circulate cold water through the jacket of the condenser.

9.6 Apply heat to the still, adjusting the rate of boiling so that condensed distillate discharges from the condenser at the rate of 2 to 5 drops per second. If the metal still is used, start heating with the ring burner about 76 mL (3 in.) above

the bottom of the still and gradually lower the burner as the distillation proceeds. Continue distillation until no water is visible in any part of the apparatus except in the trap, and the volume of water in the trap remains constant for 5 min. If there is a persistent ring of water in the condenser tube, carefully increase the rate of distillation or cut off the condenser water for a few minutes.

9.7 When the evolution of water is complete, allow the trap and contents to cool to room temperature. Dislodge any drops of water adhering to the sides of the trap with a glass rod or other suitable means and transfer them to the water layer. Read the volume of the water in the trap to the nearest scale division.

10. Calculation

10.1 Calculate the water in the sample, as weight or volume percent, in accordance with the basis on which the sample was taken, as follows:

$$\text{Water, \%} = V/W \times 100$$

where:

V = volume of water in trap and

W = weight (or volume of sample).

Volatile water-soluble material, if present, may be measured as water.

10.2 Report the results as the water content to the nearest 0.05% if the 2-mL receiver has been used and to the nearest 0.1% if the 10-mL or 25-mL receiver has been used with a 100-mL or 100-g sample.

11. Precision and Bias

11.1 *Precision*—The criteria described in Section 11.1.1 and 11.1.2 should be used to judge the acceptability of results (95% probability) when using the 10-mL or 25-mL traps. The precision when using the 2-mL trap has not been established.

11.1.1 *Repeatability*—The difference between successive test results, obtained by the same operator with the same apparatus under constant operating conditions on identical test material, would, in the long run, in the normal and correct operation of the test method, exceed the values in Table 3 in only one case in twenty.

11.1.2 *Reproducibility*—The difference between two single and independent test results obtained by different operators working in different laboratories on identical test material, would, in the long run, in the normal and correct operation of the test method, exceed the values in Table 3 in only one case in twenty.

11.2 *Bias*—A bias statement is under development.

TABLE 3 Precision

Type	Water Collected, mL	Difference, mL
Repeatability	0.0-1.0	0.1
	1.1-25	0.1 or 2 % of the mean, whichever is greater
Reproducibility	0.0-1.0	0.2
	1.1-25	0.2 or 10 % of the mean, whichever is greater

ANNEX

(Mandatory Information)

A1. PRECAUTIONARY STATEMENTS

A1.1 Xylene/Toluene

Warning—Flammable. Vapor harmful.
Keep away from heat, sparks, and open flame.
Keep container closed.
Use with adequate ventilation.
Avoid breathing of vapor or spray mist.
Avoid prolonged or repeated contact with skin.

Vapors may cause flash fire.
Keep away from heat, sparks, and open flame.
Keep container closed.
Use with adequate ventilation.
Avoid a build-up of vapors and eliminate all sources of ignition, especially nonexplosion proof electrical apparatus and heaters.
Avoid prolonged breathing of vapors or spray mist.
Avoid prolonged or repeated skin contact.

A1.2 Naphtha

Warning—Extremely flammable.
Harmful if inhaled.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Guide for Testing Varnishes¹

This standard is issued under the fixed designation D 154; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

¹ NOTE—Editorial changes made throughout in October 1989.

1. Scope

1.1 This guide covers the selection and use of procedures for testing varnishes. Some test methods are included but most sections refer to specific ASTM test methods.

1.2 Varnishes may be applied under such diverse conditions to so many different surfaces, and their dried films may be subjected to so many kinds of wear and exposure, that it is not possible to assure desired performance from a single selection of test methods and numerical results. Those skilled in varnish technology may find partial assurance of obtaining desired qualities in various types of varnishes through careful selection of the methods covered and intelligent interpretation of results.

1.3 *This standard may involve hazardous materials, operations and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

LIQUID VARNISH PROPERTIES

3. Appearance

3.1 Appearance of the liquid varnish is important both for aesthetic reasons and because it indicates whether the dried film is likely to have a satisfactory appearance. Examine the liquid varnish for foreign matter, sediment or skins in accordance with Test Method D 2090.

4. Color

4.1 Most varnishes are predominantly yellow but the color of the liquid varnish is only a preliminary indication of the color of the dried varnish film. The initial color may bleach or may darken depending upon the conditions of exposure. Determine approximately and quickly the liquid color of small specimens in Gardner-Holdt tubes by comparison with the Gardner Color Standards in accordance with Test Method D 1544.

4.2 Measure the color of extremely pale varnishes by using larger specimens in 100-mL cylinders, 300 mm deep, in accordance with Test Method D 1209.

4.3 A more precise measure of color, in terms of tristimulus values, may be made on small specimens in 10-mm cells with parallel walls in accordance with Method E 308.

5. Viscosity

5.1 The viscosity of a varnish or clear vehicle is a property important in ease of application; varnishes for brush application are typically 1 to 2 St whereas varnishes with viscosities as high as 100 St may sometimes be added to lithography coatings or used as mixing vehicles for producing enamels. Viscosity is commonly measured at 77°F (25°C).

5.2 For the rapid, approximate measurement of the viscosity of transparent varnishes, determine the bubble time by Test Method D 1545. Report the viscosity either in stokes or in Gardner-Holdt letter designations as described in Table 1 of Test Method D 1545.

5.3 For a rapid, approximate measurement of the viscosity of translucent varnishes, determine the Ford cup efflux time in accordance with Test Method D 1200.

5.4 For the precise measurement of viscosity, use capillary viscometers as described in Test Method D 445.

6. Specific Gravity

6.1 Specific gravity of a varnish is the ratio of the weight of a given volume of the varnish at a given temperature to the weight of an equal volume of distilled water at the same temperature. Determine specific gravity or density at 77°F (25°C) or other agreed temperature in accordance with Test Method D 1475 which allows use of either a pycnometer or a weight per gallon cup.

7. Volatile Content

7.1 Volatile matter determination is an indication of the amount of material in the coating that will be given off to the atmosphere in the area where the coating is applied. Depending upon the method of application, the time required to vaporize the volatile and the conditions of the atmosphere surrounding the application, it is recommended that Test

	20.2	D 1729
Clear floor sealers	21	D 1546

Method D 2369 be used to determine the volatile content of a varnish.

8. Nonvolatile Matter

8.1 Nonvolatile content is an indication of the amount of permanent film-forming material contained in a varnish. The normal drying of a varnish film may involve varying amounts of absorption of oxygen from the air, loss of volatile solvents, and continuing decomposition of the dried film. The net result of this process may differ somewhat from a nonvolatile determination at a temperature higher than the normal drying conditions.

8.2 With due regard to the composition of the varnish, determine the nonvolatile matter in accordance with either Method A (3 h at 220°F (105°C)) or Method B (10 min at 300°F (149°C)) of Test Methods D 1644.

8.3 As noted in Test Method D 2369, nonvolatile matter can also be calculated by subtracting the volatile content from 100.

9. Flash Point

9.1 Determine the flash point of varnishes having a

viscosity of less than 9.5 cSt at 77°F (25°C) (45 SUS at 100°F) by Test Method D 56, and of varnishes having a viscosity of more than 9.5 cSt at 77°F by Test Methods D 93. Alternatively, use Test Methods D 3278, which gives comparable results to Test Methods D 56 and D 93, and Test Method D 1310.

NOTE—Due to various U.S. Government and State regulations, it is now necessary to check with appropriate departments to determine which ASTM Test Method is applicable.

10. Skinning

10.1 Varnishes, which dry by oxidation, may form a skin in a partially filled can or in a filled can that is stored for a long time. Since skins are insoluble in the varnish, they must be removed before use if a satisfactory film is to be obtained. Use the following test to determine if a varnish has an objectionable tendency to early skin formation:

10.1.1 *Container*—A wide-mouth jar with a capacity of 8-fluid oz (235 mL) and dimensions of 4½ in. (115 mm) in height and 2 in. (50 mm) in diameter.

10.1.2 *Procedure*—Measure a 6-fluid oz (180-mL) specimen of the varnish into the glass container. Screw the cover on tightly, invert the jar, and leave in an inverted position, at rest, and in the dark (placing under a box or in a drawer is satisfactory). Examine the varnish for skinning at specified time intervals.

11. Acid Value

11.1 The acid value of a varnish is an indication of reactivity with basic pigments and, within any one type of composition, may indicate conformity to a standard method of preparation. It is not a general criterion of excellence in a protective coating.

11.2 Determine the acid value in accordance with Test Method D 1639.

12. Reactivity of Paint Liquids

12.1 Reactivity of a varnish with zinc oxide is a partial indication of the stability of the consistency of enamels made from it and various basic pigments.

12.2 Determine the reactivity in accordance with Test Method D 479.

13. Rosin Content

13.1 Improper use of rosin and its derivatives is sometimes associated with inferior performance of varnishes containing them. Qualitative tests for rosin may be employed to detect the use of a significant amount in varnishes. Quantitative determination of rosin may be used to control rosin content within limits agreeable to the purchaser and the seller.

13.2 Determine the rosin content quantitatively in accordance with Test Method D 1469 and qualitatively with Test Method D 1542.

DRYING AND CURING PROPERTIES

14. Drying Time

14.1 Small variations in film thickness, air temperature and humidity, and exposure to light and other radiation may affect drying times by ±5 %.

14.2 Determine the drying stages appropriate to the varnish under test in accordance with the applicable sections of Test Methods D 1640.

15. Print-Free Time

15.1 Varnishes intended for floors, furniture, etc., are expected to bear heavy objects for long periods without marring of the surface or adhering to the object.

15.2 Determine the print-free time in accordance with that section of Test Methods D 1640.

DRY VARNISH PROPERTIES

16. Gloss

16.1 Because varnishes are transparent or translucent, gloss must be measured on films applied to a nonreflecting substrate. The usual material is plane, black glass as described in Test Method D 2805 and similar to the gloss standards used in Test Method D 523. Gloss measurements of varnishes on wood substrates are generally not valid because the reflectance of the substrate can affect the result, but comparative tests in one laboratory of different varnishes on the same substrate may be helpful.

16.2 Gloss is usually measured in accordance with Test Method D 523 using 60° geometry. For greater sensitivity in evaluating high gloss varnishes, the 20° geometry may be used or Test Method D 4039 which uses both 20° and 60° geometries.

16.3 Prepare specimens in accordance with Practice D 3964, applying the varnish to black glass panels with a film applicator that has a clearance of 3 mils (75 µm) for varnishes with a nonvolatile content of 35 % or more and 6 mils (150 µm) for those with a nonvolatile content less than 35 %.

16.4 Allow the films to dry under the conditions specified in Test Methods D 1640 for at least 24 h. For a rapid control test the films may be force dried at 120°F (50°C) for 1 h, providing it has been established that heat acceleration does not affect the gloss of the varnish.

16.5 Measure the gloss in accordance with Test Methods D 523 or D 4039 and report.

17. Resistance of Dried Films to Water and Alkali

17.1 Performance of varnish films is indicated in part by measurement of resistances of their dried films to water, alkali, and other reagents.

17.2 Determine the resistance to water and alkali in accordance with Test Method D 1647.

18. Abrasion Resistance

18.1 The durability and general performance of varnish films on floors is influenced by many factors such as mechanical properties, film thickness, and exposure to light, cleaning materials, various types of soil, and foot or vehicular traffic, so that no one set of tests are adequate to ensure universally satisfactory service.

18.2 An indication of the resistance to abrasion in service may be determined by Test Methods D 658, D 968, or D 4060. All these test methods are suitable for interlaboratory use only when results are compared by ranking instead of numerical values.

19. Exterior Durability

19.1 Durability of varnish films varies so widely with exposure to varying conditions of atmosphere and light or other radiation, that any one set of conditions is only a preliminary indication of general durability.

19.2 Determine the exterior durability in accordance with Test Method D 1641.

20. Color of Dried Film

20.1 The color of the dry film is usually more significant than that of the liquid varnish in establishing whether the color of a varnished object will be acceptable. This can be evaluated by determining, in accordance with Test Method D 2244, the color difference of white structural glass before and after application and drying of a varnish film.

20.2 If a varnish with a dry color known to be satisfactory is available, a standard panel can be prepared and used for visual color comparison in accordance with Practice D 1729.

21. Clear Floor Sealers

21.1 Clear floor sealers are varnishes of relatively low viscosity for application to wooden or other porous surfaces and are variously used as either the sole coating or for making the substrate more uniform for application of wax, varnish, or other coatings.

21.2 Evaluate clear floor sealers in accordance with Test Method D 1546.

22. Precision

22.1 No specific precision statement is made for this guide since this information is included in the referenced methods, if available.

Standard Test Methods for Coarse Particles in Pigments, Pastes, and Paints¹

This standard is issued under the fixed designation D 185; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^e) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense to replace Methods 4091, 4101 of Federal Test Method Standard No. 141. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

^{e1} NOTE—Editorial changes were made throughout in March 1989.

1. Scope

1.1 These test methods cover the determination of the amount of coarse particles in dry pigments and of coarse particles and skins in mixtures of pigments and vehicles.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 ASTM Standard:

E11 Specification for Wire-Cloth Sieves for Testing Purposes²

3. Significance and Use

3.1 In production of paints, smoothness of the paint film is of paramount importance. Agglomerates or coarse particles larger than 45 μm are difficult to disperse and may prevent obtaining a smooth film. These test methods are a valuable quality control test for grading raw materials.

4. Apparatus

4.1 The apparatus shall consist of a 3-in. (75-mm) 45- μm (No. 325) sieve conforming to Specification E 11. A 3-in. 45- μm sieve for comparison purposes should be retained in the laboratory as a reference standard. Whenever a new sieve is secured, a practical test of its accuracy should be made by running on it and on the reference standard sieve a comparison test, using a pigment that has a considerable amount of coarse particles. A reserve stock of such a pigment should be kept for this purpose.

5. Procedure for Insoluble Dry Pigments, Except Metallic Aluminum and Bronze Powders

5.1 Dry the sieve in an oven at $105 \pm 2^\circ\text{C}$, cool, and then

weigh on an analytical balance, recording the weight to 1 mg.

5.2 Weigh a specimen (25 g for basic carbonate and basic sulfate white leads, 25 g for red lead and mercuric oxide, 2 g for black pigments of low specific gravity, 3 g for Prussian blues and graphite, and 10 g for all other pigments) of the pigment to be tested on an analytical balance to 1 mg. Wet the sieve on both sides with alcohol and transfer the specimen of pigment to the sieve and wet with alcohol.

5.3 Hold the sieve under a tap delivering about 300 to 500 mL of the wash liquid (water) per minute. By slightly shaking the sieve, the pigment will be rapidly carried through. A soft camel's-hair brush may be used in aiding the operation. If the sieve is held at a slight angle so that the pigment gradually collects at one edge during the washing process, and then rotated, the pigment may be brushed out rapidly, with no risk of clogging the sieve.

5.4 After most of the finely divided portion of the pigment has passed through the sieve (from 2 min to 1 h, according to the kind of pigment), place the sieve in an 8-in. (200-mm) porcelain dish containing 250 mL of the wash liquid so that the sieve is covered to a depth of about $\frac{1}{2}$ in. Brush the pigment remaining on the sieve with a soft 1-in. (25-mm) camel's-hair brush at the rate of two strokes per second during two periods of 10 s each. Raise the sieve from the dish after each 10-s period to let the liquid on the sieve run through. Change the liquid in the dish after every two brushing periods. Continue this operation until the wash liquid passing over the residue and through the sieve is clear and free from solid particles. When the washing appears to be complete, collect about 200 mL of the wash liquid, after passing over the residue and through the sieve, in a clean 400-mL beaker. Stir the liquid vigorously, and set the beaker on a black surface in the case of white pigments and on a white surface in the case of colored pigments. The washing is not considered complete until such a test fails to show any particles collected about the middle of the bottom of the beaker.

NOTE 1—Occasionally, pigments will be found that foam when water is used as the wash liquid. In such instances, during the last washing in the porcelain dish the use of a liquid that breaks down the foaming and is readily miscible with water, such as alcohol, will usually overcome this difficulty.

5.5 When the washing is complete wash the pigment particles adhering to the brush back onto the sieve and wipe off the water below the sieve. Add a few drops of alcohol and then of ether to expedite drying. Dry the sieve for 1 h at

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.31 on Pigment Specifications.

8.1

105°C, cool, and weigh as described in 5.1. Calculate the percent of coarse particles.

6. Procedure for Metallic Aluminum and Bronze Powders

6.1 In the case of metallic aluminum and bronze powders follow the procedure described in Section 5 except use 5 g of the material as the specimen and denatured alcohol, instead of water, as the wash liquid.

7. Procedure for Carbon Black in Pellet Form

7.1 Dry, cool, and weigh the sieve as described in 5.1.

7.2 Prepare a stock solution of dispersing agent³ in water; using as high a concentration of dispersing agent as possible without losing fluidity. When solution has been obtained, filter through coarse filter paper. A quart of this solution will be sufficient for several tests.

7.3 Crush the pellets between two glass plates approximately 12-in. (305-mm) square, using a gentle rotating motion. If 10 g of carbon black are taken, crush about 2 g at a time. Weigh into a 600-mL beaker 10 g of the crushed particles. Add enough of the dispersing solution to make a heavy paste and mix well to incorporate thoroughly the carbon black. Dilute with water to about 300 mL; then pour into the clean 45- μ m (No. 325) sieve. First pass the tap water through a 45- μ m sieve.

7.4 Using a small camel's-hair brush, gently brush the mix through the sieve, running tap water slowly through at the same time. When it appears that all the dispersed black has gone through, stop the tap water and continue brushing until most of the water remaining on the sieve has gone through. Add a few millilitres of the stock solution of the dispersing agent, thoroughly mix with the brush, then turn on the tap water again and wash through as before. Repeat this operation until no dispersed black comes through the sieve. When about 0.5 g of sand-like material is left on the sieve, the end point is being approached. At this point, adding the dispersing solution and gently rubbing it into the residue with the finger still produces a colloidal dispersion of black which easily passes through the sieve. From this point on, before each addition of dispersing agent, work the residue into the center of the sieve with the tap water. Many washings and many additions of dispersing solution are required in order to reach the end point. Take care to make certain that all the black has been washed through the sieve.

7.5 Dry the sieve in an oven at 105°C for 1 h, cool, and weigh the residue. Calculate the percent of coarse particles. If the value thus obtained is greater than that specified, proceed as follows to remove any adhered carbon that will pass through the 45- μ m (No. 325) sieve: Transfer the particles on the sieve to a piece of white bond paper and gently rub the carbon onto the paper with the finger. When no further real blackening of the paper occurs, carefully transfer the residue to the balance pan, weigh, and recalculate the percent of coarse particles.

8. Procedure for Water-Soluble Pigments, Pastes in Oil, Pastes in Japan, and Mixed Paints

8.1 Dry, cool, and weigh the sieve as described in 5.1.

8.2 For water-soluble pigments use 10 ± 1 g as the specimen. For pastes in oil, pastes in Japan, and mixed paints use 25 ± 1 g as the specimen. For white leads and red lead use 50 ± 1 g as the specimen.

8.3 Weigh the specimen to 1 mg and transfer to a 250-mL beaker. Slowly add 100 mL of kerosine to the contents of the beaker, mixing thoroughly by use of a stirring rod with flattened end. Break up all lumps but do not grind the material.

8.4 Wet the sieve on both sides with kerosine; then transfer the contents of the beaker to the sieve using a wash bottle filled with kerosine.

8.5 Remove small particles retained on the stirring rod or beaker walls with a camel's-hair brush. Rinse the brush with kerosine.

8.6 When the washing is complete, wash the pigment particles adhering to the brush back onto the sieve and wipe off kerosine below the sieve. Dry the sieve for 1 h at 105°C, cool, and weigh as described in 5.1. Calculate the percent of particles.

9. Procedure for Ship-Bottom Paints Containing Resins and Alcohol

9.1 In the case of ship-bottom paints containing resins and alcohol follow the procedure described in Section 8, with specimen weight of 25 ± 1 g, but use denatured alcohol, instead of kerosine, as the wetting medium, for mixing with paint, and as the wash liquid.

10. Procedure for Cellulose Ester Lacquers

10.1 In the case of cellulose ester lacquers follow the procedure described in Section 8, with specimen weight of 25 ± 1 g of the material but use a mixture of equal parts of ethyl acetate, toluene, and denatured alcohol, instead of kerosine, as the wetting medium, for mixing with the lacquer, and as the wash liquid.

11. Procedure for Latex and Emulsion Paints

11.1 *Apparatus*—As described in Section 4 except that sieves used shall be as follows:

11.1.1 *Flat Paints*, a 3-in. (75-mm) 90- μ m (No. 170) sieve.

11.1.2 *Gloss and Semi-Gloss Paints*, a 3-in. (75-mm) 75- μ m (No. 200) sieve.

11.2 Dry, cool, and weigh the sieve as described in 5.1.

11.3 Weigh 25 g of paint to ± 1 g into a tared 250-mL beaker. Without delay, start adding 100 mL of water to the paint in the beaker, slowly and with hand stirring sufficient to thoroughly mix the paint with the water. Wet the sieve on both sides with water and transfer the contents of the beaker gradually to the sieve, using a wash bottle containing water. Small particles retained on the stirrer or beaker walls may be removed with a camel's-hair brush. Instead of tap water, use reagent water for diluting the paint sample, in the wash bottle, and for washing the paint through the sieve. The water may be delivered from a reservoir for the last step.

11.4 Follow the procedure described in 5.3. In using the camel's-hair brush, take care not to crush agglomerates that would not be broken down in normal application of the paint. Rinse the brush into the sieve at end of use.

11.5 Finally, dry, cool, and weigh the sieve for 1 h, as

³ Any dispersing agent specific for carbon black may be used, such as Darvan No. 1 available from R.T. Vanderbilt, 30 Winfield St., Norwalk, CT 06855.

described in 5.1. Then calculate the percent of coarse particles and skins.

12. Precision

12.1 Precision data are not available at this time. When available the appropriate precision statements will be added.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for the Chemical Analysis of White Linseed Oil Paints¹

This standard is issued under the fixed designation D 215; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers the chemical analysis of the usual white linseed oil paints. The methods included are listed in Table 1.

1.2 *This standard does not purport to address the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Purity of Reagents

3.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁶ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

3.2 Unless otherwise indicated, references to water shall be understood to mean Type II reagent grade water conforming to Specification D 1193.

4. Hazards

4.1 *Ammonium Hydroxide* causes severe burns and may be fatal if swallowed. Read the appropriate Material Safety Data Sheets (MSDS) before using.

4.2 *Hydrochloric and Sulfuric Acids* cause severe burns and may be fatal if swallowed. Read the appropriate MSDS before using.

4.3 *Acetic Acid* causes severe burns and may be fatal if swallowed. Read the appropriate MSDS before using.

4.4 *Nitric Acid* causes burns and may be fatal if swallowed. Vapor is extremely hazardous and may cause nitrogen oxide poisoning. Read the appropriate MSDS before using.

4.5 *Toluene* is flammable. Vapors are harmful. Use with adequate ventilation. Read the appropriate MSDS before using.

4.6 *Hydrogen Sulfide* is both an irritant and an asphyxiant. Read the appropriate MSDS before using.

4.7 *Ammonium Sulfide* evolves hydrogen sulfide on contact with acid or acid fumes. See 4.6. Read the appropriate MSDS before using.

4.8 *Barium Chloride*—Soluble barium salts are poisonous when taken by mouth. Read the appropriate MSDS before using.

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paint and Paint Materials.

Carbon Dioxide	27	D 1301
Total Soluble Sulfur Compounds	28	D 34
Soluble Sulfate	29	D 50
Sulfide Sulfur	30	D 2351
Sulfur Dioxide	31	D 2352
Matter Soluble in Water	32	D 1208

5. Preparation of Sample

5.1 On receipt of a sample, make a record of the label noting especially the brand, the name of the manufacturer, and any statement as to the composition of the paint and the net contents. Weigh the unbroken package, open, note odor and condition of the contents, pour into a clean container, and mix thoroughly by pouring from one container to the other, finally leaving the well-mixed sample in the second container which shall be tightly closed. The well-mixed sample shall be used at once for the analysis. The original can and cover may be cleaned with a suitable solvent, wiped dry, and then weighed. This weight subtracted from the original weight will give the net weight of the contents. If desired, the specific gravity of the paint may be determined, the weight per gallon calculated, and the volume of paint and the capacity of the container may be measured.

ANALYSIS OF PAINT

6. Water

6.1 Determine water in accordance with Test Methods D 1208.

7. Volatile Thinner

7.1 Determine the volatile matter in accordance with Test Method D 2369. Calculate the loss in weight as the percentage of water and volatile thinner. Subtract from this the percentage of water as determined in accordance with Section 6. Report the remainder as percent volatile thinner.

8. Nature of Thinner

8.1 Determine the nature of the thinner in accordance with Method D 2349.

9. Percentage of Pigment

9.1 Determine the percentage of pigment in accordance with Test Method D 2371. Preserve the pigment as prepared in a stoppered bottle for use in Sections 16 and 17.

10. Percentage of Nonvolatile Vehicle

10.1 Add together the percentages of water, volatile thinner, and pigment, and subtract the sum from 100. Report the remainder as nonvolatile vehicle.

TESTING NONVOLATILE VEHICLE

11. Separation of Vehicle

11.1 Separate the vehicle from the pigment in accordance with Method D 2372. Retain the vehicle so obtained for use in the unsaponifiable matter (see 12.1) and fatty acids (see 13.1) determinations.

12. Unsaponifiable Matter

12.1 Determine the unsaponifiable content of the vehicle in accordance with Test Method D 1398.

13. Fatty Acids

13.1 Determine the fatty acids in accordance with Method D 1398.

14. Iodine Number of Fatty Acids

14.1 Determine the iodine number of fatty acids (see 13.1) in accordance with Test Method D 1959.

NOTE 1—If appreciable amounts of rosin or of unsaponifiable matter are found to be absent in the vehicle of a paint, the iodine number of the fatty acids gives the best indication (though not proof) of the presence of linseed oil. An iodine number of less than 175 (Wijs) for the fatty acid is an indication that the nonvolatile vehicle was not pure linseed oil.

15. Rosin

15.1 Determine the presence of rosin in the fatty acids (see 13.1) in accordance with Test Method D 1542.

15.2 If desired, determine the amount of rosin quantitatively in accordance with Method D 1469.

ANALYSIS OF PIGMENT

Qualitative Analysis, Total Pigments—Single, Mixed, or Composite

16. Qualitative Analysis

16.1 Reagents:

16.1.1 *Acetic Acid.* (Precaution—See 4.3)

16.1.2 *Acid Ammonium Acetate Solution*—Mix 150 ml of acetic acid (8+2) 100 ml of water, and 95 ml of NH_4OH (sp gr 0.90).

16.1.3 *Ammonium Hydroxide* (sp gr 0.90)—Concentrated ammonium hydroxide (NH_4OH). (Precaution—See 4.1)

16.1.4 *Ammonium Polysulfide*—Pass H_2S gas into 200 ml of NH_4OH (sp gr 0.90) in a bottle immersed in running water or in iced water until the gas is no longer absorbed; then add 200 mL of NH_4OH (sp gr 0.90) and dilute with water to 1 litre. Digest this solution with 25 g of flowers of sulfur for several hours and filter.

16.1.5 *Ammonium Sulfate* ($(\text{NH}_4)_2\text{SO}_4$).

16.1.6 *Barium Chloride* ($\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$). (Precaution—See 4.8)

well, and

16.1.7 *Hydrochloric Acid (1+1)*—Mix equal volumes of concentrated hydrochloric acid (HCl, sp gr 1.19) (Precaution—See 4.2) and water.

16.1.8 *Hydrogen Peroxide (H₂O₂), 3%*.

16.1.9 *Hydrogen Sulfide (H₂S)*. (Precaution—See 4.6)

16.1.10 *Potassium Dichromate (K₂Cr₂O₇)*.

16.1.11 *Potassium Ferrocyanide, Standard Solution*—Dissolve 22 g of pure potassium ferrocyanide (K₄Fe(CN)₆·3H₂O) in water and dilute to 1 L. To standardize, transfer about 0.2 g (accurately weighed) of pure metallic zinc or freshly ignited pure zinc oxide to a 400-mL beaker. Dissolve in 10 mL of HCl (sp gr 1.19) and 20 mL of water. Drop in a small piece of litmus paper, add NH₄OH until slightly alkaline, add HCl until just acid, and then 3 mL of HCl (sp gr 1.19). Dilute to about 250 mL with hot water and heat nearly to boiling. Run in the K₄Fe(CN)₆ solution slowly from a buret, while stirring constantly, until a drop tested on a white porcelain plate with a drop of the uranyl indicator shows a brown tinge after standing 1 min. A blank should be run with the same amounts of reagents and water as in the standardization. The amount of K₄Fe(CN)₆ solution required for the blank should be subtracted from the amounts used in standardization and in titration of the sample. The standardization must be made under the same conditions of temperature, volume, and acidity as obtained when the sample is titrated.

16.1.12 *Potassium Iodide (KI)*.

16.1.13 *Sulfuric Acid (sp gr 1.84)*—Concentrated sulfuric acid (H₂SO₄). (Precaution—See 4.2)

16.1.14 *Sulfuric Acid (1+19)*—Carefully mix 1 volume of concentrated H₂SO₄ (sp gr 1.84) (Precaution—See 4.2) with 19 volumes of water.

16.2 *Procedure*:

16.2.1 The following qualitative analysis should be made and the quantitative scheme modified as required. Add acetic acid slowly to the pigment until all carbonate is decomposed (noting whether any H₂S is evolved), then add a large excess of acid ammonium acetate solution. Boil, filter, and test the filtrate for metals other than lead and zinc (especially calcium and barium). The absence of calcium in this filtrate indicates that the extending pigments contain no calcium carbonate (CaCO₃) or calcium sulfate (CaSO₄); the absence of barium indicates that the extending pigments contain no barium carbonate (BaCO₃).

NOTE 2—If the original sample contained BaCO₃, and lead sulfate (PbSO₄), CaSO₄, or other soluble sulfate, the soluble barium will form with the soluble sulfate a precipitate of BaSO₄ which will be determined as "insoluble matter." If the sample contained strontium sulfate (SrSO₄) or strontium carbonate (SrCO₃), some SrSO₄ may be counted as BaSO₄, some strontium will count as soluble barium, and some may be counted as calcium oxide (CaO). Strontium is not separated, as it probably will not be encountered, or will be present as an impurity in the barium and calcium compounds.

16.2.2 Wash the matter insoluble in acid ammonium acetate solution with another portion of this solution, and finally with hot water. This insoluble matter shall be dried, ignited, and tested for siliceous matter, BaSO₄, and titanium compounds. To test for the latter, place a small amount of the insoluble matter, or of the original sample (about 0.5 g) in a 250-mL resistant glass beaker; add 20 mL of concentrated H₂SO₄ (sp gr 1.84) and 7 to 8 g of (NH₄)₂SO₄. Mix well, and boil for a few minutes. A residue denotes the

presence of silica or siliceous matter. Cool the solution, dilute with 100 mL of water, heat to boiling, settle, filter, and wash with hot H₂SO₄ (1+19) until free from titanium. The residue may be tested for lead, barium, and silica.

16.2.3 Add H₂O₂ to a small portion of the filtrate; a clear yellow-orange color indicates the presence of titanium. Boil another portion of the filtrate with metallic tin or zinc; a pale blue to violet coloration indicates titanium.

16.2.4 Treat another portion (about 1 g) of the pigment with 20 mL of HCl (1+1) and note whether any H₂S is evolved; boil the solution for about 5 min, add about 25 mL of hot water, filter, and wash with hot water. Render a small portion of the filtrate alkaline with NH₄OH, acidify with HCl, and add a little BaCl₂ solution; a white precipitate (BaSO₄) indicates the presence of a soluble sulfate. To another portion of the filtrate add a little H₂SO₄; a white precipitate indicates the presence of lead, soluble barium, or both (some CaSO₄ may also separate). Filter, wash to remove free acid, and treat the precipitate with a few drops of KI solution; the formation of yellow lead iodide (PbI₂) indicates the presence of lead. The white precipitate may also be treated with H₂S water; the formation of black lead sulfide (PbS) indicates the presence of lead.

16.2.5 To another portion of the original filtrate (see 16.2.1) add NH₄OH until alkaline, render slightly acid with acetic acid, heat to boiling, and add a little K₂Cr₂O₇ solution; a yellow or orange-yellow precipitate indicates the presence of lead, soluble barium, or both. To another portion of the original filtrate add a few drops of K₄Fe(CN)₆ solution; a white precipitate with a bluish tinge indicates the presence of zinc. Pass into the remaining portion of the original filtrate a current of H₂S for 5 to 10 min, add an equal volume of water, and pass H₂S into the solution for about 5 min. Filter and wash with H₂S water. Digest the precipitate with ammonium polysulfide, filter, acidify the filtrate with HCl, and warm; the presence of antimony is indicated by the separation of an orange-colored precipitate. The filtrate from the H₂S precipitate may be tested for barium, calcium, and magnesium in the usual manner.

Quantitative Analysis, Single Pigment

17. Quantitative Analysis

17.1 If the sample is a single pigment, proceed in accordance with Practice D 34, for the particular pigment to be tested.

Quantitative Analysis, Mixed or Composite Pigments

18. Moisture and Other Volatile Matter

NOTE 3—On an extracted and dried pigment, this determination is of little value. If the original paint contained gypsum, a part of the combined water of the latter will be driven off in the drying of the extracted pigment and in the "moisture" determination.

18.1 Determine the moisture and other volatile matter in accordance with Test Methods D 280.

19. Loss on Ignition

NOTE 4—This determination may serve as a rough or approximate check in many cases on the carbon dioxide, water, etc.

19.1 Determine loss on ignition in accordance with Test Methods D 1208.

20. Insoluble Matter

20.1 Reagents:

20.1.1 Alcohol.

20.1.2 *Hydrochloric Acid* (sp gr 1.19)—Concentrated hydrochloric acid (HCl). (Precaution—See 4.2)

20.1.3 *Hydrochloric Acid* (1+1)—Mix equal volumes of concentrated HCl (sp gr 1.19) (Precaution—See 4.2) and water.

20.1.4 *Sodium Carbonate* (Na_2CO_3), anhydrous.

20.1.5 *Sodium Carbonate* (10 g/L)—Mix 10 g of Na_2CO_3 with water and dilute to 1 L.

20.1.6 *Sulfuric Acid* (1+4)—Carefully mix 1 volume of concentrated sulfuric acid (H_2SO_4 , sp gr 1.84) (Precaution—See 4.2) with 4 volumes of water.

20.2 Procedure:

20.2.1 Moisten 1 g of the pigment with a few drops of alcohol, cover, add 40 ml of HCl (1+1) and boil gently for 5 to 10 min. Wash the cover, evaporate to dryness, and heat at about 150°C for 30 min to 1 h to dehydrate the residue. Moisten the residue with 4 ml of concentrated HCl (sp gr 1.19), allow to stand a few minutes, dilute with 100 ml of hot water, boil a few minutes, filter hot through paper, and wash with hot water (until washings give no test for lead and chlorine).

20.2.2 Ignite the paper and residue in a platinum or porcelain crucible, cool, and weigh the total insoluble matter (Note 2). (The insoluble matter may be filtered off on a Gooch crucible, washed with hot water, dried at 105°C, cooled, and weighed; it shall then be ignited, cooled, and weighed, when it is desired to get the loss on ignition (combined water, organic matter, etc.) of the same, or if the insoluble matter is not to be further examined.) If the sample contains titanium pigment, practically all of the titanium dioxide (TiO_2) will be found in the insoluble matter along with barium sulfate (BaSO_4) and siliceous matter. Should an examination of the insoluble matter be necessary, it is advisable to remove the TiO_2 before proceeding further. The TiO_2 may be removed (or determined on a separate portion) in accordance with Test Methods D 1394.

20.2.3 After removing the TiO_2 , the residue containing siliceous matter and BaSO_4 may be ignited to remove the filter. To determine BaSO_4 , mix the ignited insoluble matter with about ten times its weight of anhydrous Na_2CO_3 (grinding the mixture in an agate mortar if necessary) and fuse in a covered platinum crucible, heating about 1 h. Let cool, place the crucible and the cover in a 200-mL glazed porcelain casserole (Note 5), add about 100 mL of water, and heat until the mass is disintegrated. Filter on paper into a 300-mL glazed porcelain casserole (leaving the crucible and the cover in the original casserole) and wash the casserole and filter thoroughly with a hot solution of Na_2CO_3 (10 g/L). Place the casserole containing the crucible and cover under the funnel, pierce the filter with a glass rod, and wash the residue into the original casserole by means of a jet of hot water. Wash the paper with hot HCl (1+1) and then with hot water. Remove the crucible and the cover. Evaporate the HCl solution to dryness, and heat at about 150°C for 30 min to 1 h. Moisten the residue with about 10 mL of concentrated HCl (sp gr 1.19), dilute with 100 mL of hot water, boil a few minutes, filter hot through paper, and wash thoroughly with hot water. Dilute the filtrate to a volume of 300 mL,

bring to boiling, and add, dropwise, 5 mL of H_2SO_4 (1+4). Allow to stand in a warm place for 1 h or so, filter on a weighed Gooch crucible, wash with hot water, ignite, cool, and weigh as BaSO_4 . Subtract the sum of the percentages of BaSO_4 and TiO_2 from the percentage of total insoluble matter and report the result as the percentage of insoluble siliceous matter (Note 6).

NOTE 5—A casserole is preferable to a beaker, as silica is dissolved from glass when in long contact with a strong sodium carbonate solution.

NOTE 6—Any soluble aluminum oxide (Al_2O_3) (or iron oxide (Fe_2O_3)) and in most cases magnesium oxide (MgO), and sometimes some calcium oxide (CaO), come from the siliceous pigment used. Magnesium oxide generally denotes the presence of asbestos.

20.2.4 To determine silica, acidify the filtrate from the barium carbonate (BaCO_3) filtration (20.2.3) with HCl, boil to expel the CO_2 , evaporate to dryness, bake to dehydrate the silica, moisten with HCl, dilute with 100 mL of hot water, and boil and filter through the same paper as was used to recover silica from the BaCO_3 portion. Wash thoroughly with hot water and proceed in accordance with Test Methods D 717.

20.2.5 If it is desired to look for magnesium, combine the filtrate obtained in accordance with 20.2.4 with the filtrate from the final BaSO_4 separation (20.2.3) and test for Al_2O_3 and MgO in the usual way. To recover MgO that may have dissolved in the procedure for the elimination of the TiO_2 , make the filtrate containing the TiO_2 just alkaline with NH_4OH , bring to boiling, filter, and wash. The filtrate may be tested for MgO . Any Al_2O_3 present will be precipitated along with the TiO_2 . To recover this, ignite and weigh as TiO_2 and Al_2O_3 . Deduct for TiO_2 present in the sample; the difference is Al_2O_3 .

21. Total Lead

21.1 Reagents:

21.1.1 *Acetic Acid*: Precaution—See 4.3.

21.1.2 *Ammonium Hydroxide* (sp gr 0.90)—Concentrated ammonium hydroxide (NH_4OH). Precaution—See 4.1.

21.1.3 *Ammonium Polysulfide*—See 16.1.4.

21.1.4 *Ammonium Sulfide* ($(\text{NH}_4)_2\text{S}$). Precaution—See 4.7.

21.1.5 *Ether*.

21.1.6 *Ethyl Alcohol* (95%).

21.1.7 *Hydrochloric Acid* (sp gr 1.19)—Concentrated hydrochloric acid (HCl) Precaution—See 4.2.

21.1.8 *Hydrogen Sulfide* (H_2S). Precaution—See 4.6.

21.1.9 "*Lead Acid*"—Mix 300 ml of concentrated H_2SO_4 (sp gr 1.84) and 1800 ml of water. Dissolve 1 g of lead acetate in 300 mL of water and add this to the hot solution while stirring. Let stand at least 24 h and siphon through a thick asbestos filter.

21.1.10 *Nitric Acid* (1+1)—Mix equal volumes of concentrated nitric acid (HNO_3 , sp gr 1.19) (Precaution—See 4.4) and water.

21.1.11 *Nitric Acid* (1+3)—Mix 1 volume of concentrated HNO_3 (sp gr 1.19) (Precaution—See 4.4) with 3 volumes of water.

21.1.12 *Potassium Dichromate Solution* (100 g/L)—Dissolve 100 g of potassium dichromate ($\text{K}_2\text{Cr}_2\text{O}_7$) in water and dilute to 1 L.

21.1.13 *Sodium Sulfide Solution (20 to 30 g/L)*—Dissolve 20 to 30 g of sodium sulfide (Na_2S) in water and dilute to 1 L.

21.1.14 *Sulfuric Acid (sp gr 1.84)*—Concentrated sulfuric acid (H_2SO_4). **Precaution**—See 4.2.

21.1.15 *Sulfuric Acid (1+1)*—Carefully mix 1 volume of concentrated H_2SO_4 (sp gr 1.84) (Precaution—See 4.2) with 1 volume of water.

21.2 Procedure:

21.2.1 Unite the filtrate and washings (total volume 150 to 200 mL) from the total insoluble matter (see Section 20), pass H_2S into the solution until it is saturated, add an equal volume of water, and again saturate with H_2S . Filter, wash with water containing a little H_2S , dissolve in hot HNO_3 (1+3), washing the paper with hot water. Add 10 to 20 mL of H_2SO_4 (1+1), evaporate until copious fumes of H_2SO_4 are evolved. Cool, add about 75 mL of water and then about 75 mL of ethyl alcohol (95%). Stir, let settle, filter on a Gooch crucible, wash with diluted alcohol, and dry in an oven at 105 to 110°C; or, ignite gently in a radiator⁷ or muffle, cool, and weigh as lead sulfate (PbSO_4). Calculate to lead oxide (PbO).

NOTE 7—It is not possible to determine the amount of basic lead carbonate and lead sulfate when carbonates or soluble sulfates of other metals, such as calcium, are present. Also, neither basic lead carbonate nor basic lead sulfate are definite compounds.

21.2.2 If the pigment contains antimony, filter and wash the sulfide precipitate as described in 21.2.1. Wash the precipitate with a fine jet of water from the paper into a porcelain dish or casserole, add 25 mL of ammonium polysulfide, cover the vessel, and warm the mixture at 40 to 60°C for 10 to 15 min while stirring frequently. Wash the cover, filter through the same paper, and wash with Na_2S (20 to 30 g/L) or $(\text{NH}_4)_2\text{S}$ solution. Discard the filtrate. Dissolve the residue in hot HNO_3 (1+3), and determine the lead as lead sulfate (PbSO_4) as described in 20.2.1; or, the original sulfide precipitate may be discarded and the lead determined on a separate portion of the pigment as follows: to 1 g of the sample in a covered beaker, add 40 mL of HCl (1+1) and boil gently for 5 to 10 min. Wash off the cover and evaporate to dryness. To the residue add sufficient HCl (sp gr 1.19) to dissolve the PbSO_4 (with pigments containing considerable amounts of PbSO_4 , it may be necessary to add 15 to 20 mL of HCl (sp gr 1.19)), add about 50 mL of hot water, boil a few minutes, filter hot through paper, and wash with hot water until the washings give no test for lead. (If the sample contains no insoluble matter, omit the filtration.)

21.2.3 To the filtrate add 20 mL of H_2SO_4 (sp gr 1.84) and evaporate until dense white fumes of sulfur trioxide (SO_3) are copiously evolved. Allow to cool, but not below 60°C, and then add slowly 50 mL of water while agitating the solution. Heat to boiling for several minutes in order to ensure complete solution of antimony sulfate. Allow the PbSO_4 to settle out until the supernatant liquid is clear, not letting the temperature fall below 60°C. If the liquid does not clear quickly it must be heated longer. When clear, pour the solution through a weighed porcelain Gooch crucible with asbestos mat, decanting the solution as completely as pos-

sible without allowing more than a very small amount of PbSO_4 to go over into the crucible. Add 10 mL more of concentrated H_2SO_4 (sp gr 1.84) to the PbSO_4 in the original beaker and boil for several minutes. Cool, add slowly 30 mL of water, and again heat to boiling for a few minutes. Allow the solution to cool to about 60°C and completely transfer the PbSO_4 to the Gooch crucible. Wash with "lead acid" (see 21.1.9) to remove soluble sulfates and finally wash free of acid with diluted alcohol (equal parts of ethyl alcohol or denatured alcohol and water). Dry in an oven at 105 to 110°C, or ignite gently in a radiator or muffle. Calculate to PbO , or determine as lead chromate (PbCrO_4) as described in 21.2.6.

21.2.4 If soluble compounds of barium or calcium are present, barium sulfate (BaSO_4) and calcium sulfate (CaSO_4) will be included with the PbSO_4 . If soluble silica (SiO_2) is present, it will also be included with the PbSO_4 . In such cases, the PbSO_4 precipitate after washing with diluted alcohol may be dissolved in acid ammonium acetate and the lead determined as PbCrO_4 as described in 21.2.6. For ordinary work, the amount of BaSO_4 dissolved by the acetate treatment may be disregarded.

21.2.5 If the pigment contains no soluble antimony, barium, or calcium compounds, the lead may be determined directly on the original pigment as follows: to 1 g of the sample in a covered beaker, add 25 mL of HNO_3 (1+1) and boil gently a few minutes. Wash off the cover, evaporate to dryness on a steam bath, moisten with HNO_3 , add hot water, and heat a few minutes. Filter and wash with hot water until washings are lead-free. Add 10 to 20 mL of H_2SO_4 (1+1) to the clear solution, evaporate, and determine lead as PbSO_4 as described in 21.2.1.

21.2.6 In the absence of soluble compounds of antimony, iron, aluminum, and barium, the following procedure may be used: treat 1 g of the original pigment with 25 mL of HNO_3 (1+1) and proceed as described in 20.2.1. To the clear solution, diluted to 200 mL, add NH_4OH in slight excess, acidify with acetic acid, and add 4 to 6 mL more of acetic acid. Heat to boiling and add 10 to 15 mL of a solution of $\text{K}_2\text{Cr}_2\text{O}_7$ (100 g/L). Heat until the yellow precipitate assumes an orange color, let settle, and filter on a weighed Gooch crucible. Wash by decantation until the washings are colorless, finally transferring all of the precipitate. Wash with ethyl alcohol (95 %) and then with ether. Dry to constant weight at 110°C, cool, and weigh as PbCrO_4 . Calculate to PbO .

22. Antimony Oxide

22.1 Determine antimony oxide in accordance with Test Method D 2350.

23. Soluble Barium

23.1 Boil the combined filtrate and washings, reduced to volume by evaporation if need be, from the lead sulfate (PbS) precipitate (see 21.2) to expel hydrogen sulfide (H_2S). Add a slight excess of H_2SO_4 (1+4) over the amount required to precipitate the barium, heat to boiling, let stand on a steam bath about 1 h, filter on a weighed Gooch crucible, wash with hot water, dry, ignite, cool, and weigh as barium sulfate (BaSO_4) (Notes 2 and 8). Calculate to barium oxide (BaO).

NOTE 8—The precipitate will include any BaSO_4 that may have been dissolved as such. The weighed precipitate should be tested for CaSO_4 .

⁷ U. S. Geological Survey, *Bulletin* 700 (1919), p. 33.

and if present, it should be removed by treating with hot HCl (1+3), filtering, washing, igniting, and again weighing.

24. Aluminum Oxide (Fe_2O_3 , TiO_2 , P_2O_5)

24.1 Reagents:

24.1.1 *Ammonium Chloride Solution* (25 g/L)—Dissolve at least 25 g of ammonium chloride (NH_4Cl) in water and dilute to 1 L.

24.1.2 *Ammonium Hydroxide* (1+5)—Mix 1 volume of concentrated ammonium hydroxide (NH_4OH , sp gr 0.90) (Precaution—See 4.1) with 1 volume of water.

24.1.3 *Hydrochloric Acid* (sp gr 1.19)—Concentrated hydrochloric acid (HCl). Precaution—See 4.2.

24.1.4 *Methyl Red Indicator, Alcoholic Solution* (2 g/L)—Dissolve 0.2 g of methyl red in alcohol and dilute to 100 mL.

24.1.5 *Nitric Acid* (sp gr 1.42)—Concentrated nitric acid (HNO_3). Precaution—See 4.4.

24.2 Procedure:

24.2.1 Boil the filtrate from the lead sulfide (PbS) precipitate (see 21.2) to expel hydrogen sulfide (H_2S), add a few drops of HNO_3 , and continue the boiling a few minutes to oxidize any iron that may be present. In case soluble barium was present, use the filtrate from 23.1. To the solution containing at least 25 g of NH_4Cl /L of solution, or an equivalent amount of HCl, add a few drops of methyl red indicator, alcoholic solution and heat just to boiling. Carefully add NH_4OH (1+5) dropwise until the color of the solution changes to a distinct yellow. Boil the solution for 1 to 2 min and filter at once. Wash the precipitate thoroughly with hot NH_4Cl solution (Note 9). Ignite the precipitate, cool, and weigh as aluminum oxide (Al_2O_3) (Note 10).

NOTE 9—For very accurate work, or when the precipitate is large, the precipitate should be dissolved in HCl (1+1) and the precipitation repeated.

NOTE 10—This precipitate may also contain ferric oxide (Fe_2O_3), titanium dioxide (TiO_2), and phosphorus pentoxide (P_2O_5).

25. Total Zinc

25.1 Reagents:

25.1.1 *Acetic Acid* (1+49)—Mix 1 volume of concentrated acetic acid (sp gr 1.05) (Precaution—see 4.3) with 49 volumes of water.

25.1.2 *Ammonium Acetate*.

25.1.3 *Ammonium Chloride* (NH_4Cl).

25.1.4 *Ammonium Hydroxide* (sp gr 0.90)—Concentrated ammonium hydroxide (NH_4OH). Precaution—See 4.1.

25.1.5 *Hydrochloric Acid* (sp gr 1.19)—Concentrated hydrochloric acid (HCl). Precaution—See 4.2.

25.1.6 *Hydrochloric Acid* (1+2)—Mix 1 volume of concentrated HCl (sp gr 1.19) (Precaution—See 4.2) with 2 volumes of water.

25.1.7 *Hydrogen Sulfide* (H_2S). Precaution—See 4.6.

25.1.8 *Potassium Ferrocyanide, Standard Solution*—See 16.1.11.

25.1.9 *Uranyl Indicator*—Dissolve 5 g of uranyl nitrate in water and dilute to 100 mL, or dissolve 5 g of uranyl acetate in water made slightly acid with acetic acid and dilute to 100 mL.

25.2 Procedure:

25.2.1 To the combined filtrate and washings from the alumina determination (see 24.2.1), add sufficient NH_4Cl to

give 5 g/100 mL of solution, and then add 1 g of ammonium acetate.⁸ Make slightly acid with acetic acid and pass in a current of H_2S to saturation. Allow the precipitate to settle completely, filter on paper, and wash with a solution of acetic acid (1+49) saturated with H_2S . Transfer the precipitate and filter to the vessel in which the precipitation was effected, add 30 mL of water and 10 mL of concentrated HCl (sp gr 1.19), heat until all zinc is in solution, add 200 mL of water and a small piece of litmus paper; add NH_4OH (sp gr 0.90) until slightly alkaline, make just acid with HCl, then add 3 mL of concentrated HCl (sp gr 1.19), heat nearly to boiling, and titrate with standard $\text{K}_4\text{Fe}(\text{CN})_6$ solution as described in 16.1.11 using uranyl indicator solution.

25.2.2 Zinc may be determined directly on the original sample as follows (Note 11): weigh accurately about 1 g (or an amount that will give a buret reading approximately equal to that obtained in the standardization) of the pigment, transfer to a 400-mL beaker, add 30 mL of HCl (1+2), boil a few minutes, add 200 mL of water, and a small piece of litmus paper; add concentrated NH_4OH until slightly alkaline, render just acid with HCl, then add 3 mL of HCl (sp gr 1.19), heat nearly to boiling, and titrate with standard $\text{K}_4\text{Fe}(\text{CN})_6$ solution as described in 16.1.11 using uranyl indicator solution.

NOTE 11—If the sample contains antimony, it should be precipitated by H_2S in the hot acid solution, filtered off, washed, and the filtrate neutralized, etc., for zinc. The H_2S precipitate may also contain lead sulfide (PbS). If no sulfide separation is made, any cadmium present will be counted as zinc.

25.2.3 When iron is present, total zinc may be determined directly on the original sample as follows (Note 11). Weigh accurately about 1 g (or an amount that will give a buret reading approximately equal to that obtained in the standardization) of the pigment, transfer to a 250-mL beaker, moisten with alcohol, add 30 mL of HCl (1+2), boil for 2 or 3 min, and add about 100 mL of water. Add about 2 g of NH_4Cl make slightly alkaline with NH_4OH , heat to boiling, let settle on a steam bath, filter into a 400-mL beaker, and wash the residue once with hot water. Remove the 400-mL beaker and pour HCl (1+2) on the residue, catching the filtrate therefrom in the 250-mL beaker; wash a few times with hot water. Add to this filtrate 1 g of NH_4Cl and make slightly alkaline with NH_4OH , boil, let settle, filter on paper used for first filtration, and wash thoroughly with hot water, catching the filtrate and washings in the 400-mL beaker containing the first filtrate. Add a small piece of litmus paper, acidify with HCl, add 3 mL of HCl (sp gr 1.19), heat nearly to boiling, and titrate with standard $\text{K}_4\text{Fe}(\text{CN})_6$ solution as described in 16.1.11.

25.2.4 With pigments containing zinc oxide (ZnO) and zinc sulfide (ZnS), the ZnO may be determined as follows: weigh accurately 1 g of the pigment, transfer to a 250-mL beaker, moisten with alcohol, add about 100 mL of acetic acid (1+49), stir vigorously but do not heat, cover and let stand for 18 h, stirring once every 5 min for the first 30 min. Filter, wash with acetic acid (1+49) followed by water until the washings give no test for zinc with $\text{K}_4\text{Fe}(\text{CN})_6$ solution.

water will

Dilute the clear filtrate to about 200 mL with water, add 30 mL of HCl (1+2), and a small piece of litmus paper; add NH_4OH (sp gr 0.90) until slightly alkaline, render just acid with HCl, then add 3 mL of concentrated HCl (sp gr 1.19), heat nearly to boiling, and titrate with $\text{K}_4\text{Fe}(\text{CN})_6$ solution as described in 25.2.4. Calculate this result to zinc, subtract from total zinc, and calculate the difference to zinc sulfide (ZnS). (Any zinc carbonate (ZnCO_3) or zinc sulfate (ZnSO_4) is included in the ZnO.)

26. Soluble Calcium

26.1 Reagents:

26.1.1 *Ammonium Hydroxide* (sp gr 0.90)—Concentrated ammonium hydroxide (NH_4OH). **Precaution**—See 4.1.

26.1.2 *Ammonium Oxalate, Saturated Solution* (NH_4)₂· C_2O_4 .

26.1.3 *Potassium Permanganate, Standard Solution* (0.1 N)—Dissolve 3.2 g of pure potassium permanganate (KMnO_4) in water and dilute to 1 L. Let stand 8 to 14 days, siphon off the clear solution (or filter through an asbestos filter), and standardize against NIST's standard sample 40c of sodium oxalate as follows: in a 400-mL beaker, dissolve 0.25 to 0.30 g (accurately weighed) of sodium oxalate in 250 mL of hot water (80 to 90°C) and add 15 mL of sulfuric acid (H_2SO_4 , 1+1). Titrate at once with the KMnO_4 solution, stirring the liquid vigorously and continuously. The KMnO_4 must not be added more rapidly than 10 to 15 mL/min, and the last 0.5 to 1 mL must be added dropwise with particular care to allow each drop to be fully decolorized before the next is introduced. The temperature of the solution should not be below 60°C by the time the end point is reached. (Too rapid cooling may be prevented by allowing the beaker to stand on a small asbestos-covered hot plate during the titration. The use of a small thermometer as a stirring rod is most convenient.) The weight of sodium oxalate used multiplied by 0.833 gives its iron equivalent. The KMnO_4 solution should be kept in a glass-stoppered bottle painted black to keep out light.

26.1.4 *Sulfuric Acid* (1+4)—Carefully mix 1 volume of concentrated sulfuric acid (H_2SO_4 , sp gr 1.84) (**Precaution**—See 4.2) with 4 volumes of water.

26.2 Procedure:

26.2.1 Heat to boiling the united filtrate and washings, reduced in volume if need be, from the ZnS determination (see 25.2.2), add 1 mL of NH_4OH and an excess of a hot saturated (NH_4)₂· C_2O_4 solution. Continue the boiling until the precipitate becomes granular; let stand about 1 h, filter, and wash with hot water. Ignite, cool, and weigh as calcium oxide (CaO) (Notes 2, 12, and 13). Alternatively, place the beaker in which the precipitation was made under the funnel, pierce the apex of the filter with a stirring rod, and wash the precipitate into the beaker with hot water. Pour warm H_2SO_4 (1+4) through the paper and wash a few times. Add about 30 mL of H_2SO_4 (1+4), dilute to about 250 mL, heat to 90°C, and titrate at once with 0.1 N KMnO_4 solution (the temperature of the solution should not be below 60°C when the end point is reached, see 25.1.3). Calculate to CaO (Notes 2, 12, and 13). (The iron equivalent of $\text{KMnO}_4 \times 0.502 = \text{CaO}$ value.)

NOTE 12—Care must be exercised in this washing, as 1 L of boiling water will dissolve over 0.01 g of calcium oxalate (CaC_2O_4).

NOTE 13—For more accurate work, the CaC_2O_4 precipitate should be ignited, cooled, cautiously moistened with water, redissolved in HCl, and the solution diluted to 100 mL. Add NH_4OH in slight excess, boil the liquid, and filter and wash if a precipitate appears. Reprecipitate the calcium with NH_4OH and (NH_4)₂· C_2O_4 , as described in 25.2.1, filter, wash, ignite, cool, and weigh; or, titrate as described.

27. Soluble Magnesium

27.1 Reagents:

27.1.1 *Ammonium Hydroxide* (sp gr 0.90)—Concentrated ammonium hydroxide (NH_4OH). **Precaution**—See 4.1.

27.1.2 *Hydrochloric Acid* (sp gr 1.19)—Concentrated hydrochloric acid (HCl). **Precaution**—See 4.2.

27.1.3 *Hydrochloric Acid* (1+3)—Mix 1 volume of concentrated HCl (sp gr 1.19) (**Precaution**—See 4.2) with 3 volumes of water.

27.1.4 *Sodium Ammonium Phosphate, Saturated Solution* ($\text{NaNH}_4\text{HPO}_4$).

27.2 Procedure:

27.2.1 Acidify the filtrate from the calcium determination (see 26.2.1) with HCl, add 10 mL of a saturated solution of $\text{Na}(\text{NH}_4)\text{HPO}_4$ and NH_4OH dropwise, with constant stirring. When the crystalline magnesium ammonium phosphate ($\text{Mg}(\text{NH}_4)\text{PO}_4$) has formed, add 5 mL excess of NH_4OH . Allow the solution to stand in a cool place for not less than 4 h, preferably overnight (Note 14). Filter and wash with water containing 2.5 % ammonia. Dissolve the precipitate in a small quantity of hot HCl (1+3), dilute the solution to about 100 mL with water, add 1 mL of a saturated solution of $\text{Na}(\text{NH}_4)\text{HPO}_4$ and NH_4OH dropwise, with constant stirring, until the precipitate is again formed, and then add 5 mL excess of NH_4OH . Let the precipitate stand in a cool place for not less than 2 h, filter on a Gooch crucible, wash with water containing 2.5 % of ammonia, ignite, cool, and weigh as magnesium pyrophosphate (MgP_2O_7) (Note 15). Calculate to magnesium oxide (MgO).

NOTE 14—The smaller the amount of magnesium present, the longer the precipitate must be allowed to settle.

NOTE 15—If the sample contained manganese, it will be caught in large part with the $\text{Mg}_2\text{P}_2\text{O}_7$. If desired, manganese may be determined by dissolving the $\text{Mg}_2\text{P}_2\text{O}_7$. If desired, manganese may be determined by dissolving the $\text{Mg}_2\text{P}_2\text{O}_7$ in nitric acid (**Precaution**—See 4.4) and applying the bismuthate method.

28. Carbon Dioxide

28.1 Determine carbon dioxide in accordance with Test Methods D 1301.

29. Total Soluble Sulfur Compounds (Note 2)

29.1 Determine total soluble sulfur in accordance with Methods D 34. This determination includes soluble sulfates, sulfur trioxide (SO_3) formed from sulfur dioxide, (SO_2), and the SO_3 that is formed from sulfide sulfur.

30. Soluble Sulfate (Note 2)

30.1 Determine soluble sulfates in accordance with Methods D 50.

31. Sulfide Sulfur

31.1 Determine sulfide sulfur in accordance with Test Method D 2351.

32. Sulfur Dioxide

32.1 Determine sulfur dioxide in accordance with Test Method D 2352.

33. Matter Soluble in Water

33.1 Determine matter soluble in water in accordance with Test Methods D 1208.

NOTE 16—The nature of the water-soluble matter may be determined by further examination, as the percentages of sulfur trioxide (SO_3) and calcium oxide (CaO) may be indicative.

NOTE 17—The water-soluble content of composite pigmentation, as determined in accordance with this method, is frequently higher than the sum of the water-soluble matter in the individual pigments. Possibly this is due to reaction in water between the individual pigments.

34. Calculation

34.1 The calculation of the component pigments of a mixed or combination pigment may be a somewhat difficult matter. Certain assumptions must be made, depending upon the complexity of the mixed pigment, as to the composition or formulas of component pigments and as to the manner in which the acidic and basic radicals are combined. Add any $\text{Al}_2\text{O}_3(\text{Fe}_2\text{O}_3)$ found in the soluble portion to the siliceous matter and report the sum as "insoluble siliceous matter" unless the soluble aluminum is high; in this case, an aluminate is probably present, and the Al_2O_3 should be reported as Al_2O_3 . If a small amount of soluble magnesium is found, it should also be added to the siliceous matter. If the soluble magnesium is high, the presence of MgCO_3 is indicated, and the MgO is calculated to MgCO_3 as described in 34.3. The insoluble siliceous matter reported should be based on the weight obtained on drying the total insoluble matter at 105°C if the combined water contained therein is to be considered.

34.2 Report TiO_2 as TiO_2 , ZnS as ZnS , and BaSO_4 as BaSO_4 . If CaCO_3 , CaSO_4 , BaCO_3 , and MgCO_3 are absent, calculate CO_2 to basic carbonate white lead ($\text{Pb}(\text{CO}_3)_2 \cdot \text{Pb}(\text{OH})_2$), and soluble SO_3 to PbSO_4 . Calculate any excess of lead to PbO , add it to the PbSO_4 , and report the sum as basic lead sulfate. Alternatively, multiply the sum of $\text{PbSO}_4 + \text{PbO}$ by 0.058 to obtain the ZnO ; add this result to the $\text{PbSO}_4 + \text{PbO}$ and report as basic sulfate white lead. (The ZnO factor is based on the assumption that the average composition of commercial basic sulfate white lead is 78.5 % PbSO_4 , 16.0 % PbO , and 5.5 % ZnO .) Lead oxide (PbO) should not be reported except in the presence of PbSO_4 unless the entire analysis is reported in the elementary or oxide form.

34.3 If the sample contains CO_2 but not soluble SO_3 , calculate total lead to basic carbonate white lead ($\text{Pb}(\text{CO}_3)_2 \cdot \text{Pb}(\text{OH})_2$); calculate residual CO_2 to CaCO_3 , then to BaCO_3 and MgCO_3 , if soluble barium and magnesium should be present in sufficient amounts to indicate the presence of these carbonates. The CO_2 result will be an index of this. A small amount of residual CaO is probably from the siliceous matter and should be added to the insoluble siliceous matter.

34.4 A small amount of soluble barium may be from the CaCO_3 used or may be due to the solubility of BaSO_4 , if this compound is present in the original pigment. This barium may be calculated to BaSO_4 and added to the BaSO_4 found in the insoluble matter.

34.5 If the sample contains soluble SO_3 but no CO_2 , calculate CaO to CaSO_4 or $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$; residual SO_3 to PbSO_4 ; add residual PbO to PbSO_4 and report the sum as basic lead sulfate. Alternatively, multiply $\text{PbSO}_4 + \text{PbO}$ by 0.058 and add the result to the $\text{PbSO}_4 + \text{PbO}$, and report the total as basic sulfate white lead.

34.6 If the sample contains CaCO_3 (MgCO_3 , BaCO_3) and also basic sulfate white lead, or CaSO_4 and basic carbonate white lead, or a mixture of these, it is not possible to determine or calculate the amount of PbCO_3 or PbSO_4 with any degree of certainty (see Notes 2 and 3). The presence of appreciable amounts of CaO and SO_3 in the water-soluble matter indicates the probable presence of CaSO_4 in the original pigment. The following arbitrary calculations may be made: calculate water-soluble SO_3 to CaSO_4 or $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$, subtract this SO_3 from total soluble SO_3 , and calculate the remainder to PbSO_4 ; calculate residual CaO to CaCO_3 , and then residual CO_2 to (PbCO_3)₂· $\text{Pb}(\text{OH})_2$. If there is an excess of CO_2 , calculate to MgCO_3 or BaCO_3 , if the amounts of soluble magnesium and barium indicate the probable presence of these carbonates. Add residual PbO to PbSO_4 and calculate as described in 34.5 to basic sulfate white lead.

34.7 Report total antimony as Sb_2O_3 .

34.8. Calculate sulfide sulfur to ZnS , subtract the zinc equivalent to the sulfur from the total zinc, then subtract the zinc required for the basic sulfate white lead, and report the remainder as ZnO .

34.9 Report directly the following: moisture and other volatile matter, loss on ignition, SO_2 and matter soluble in water.

35. Keywords

35.1 analysis of paint, white oil; analysis of pigment, white oil; lead analysis; white linseed oil paints, chemical analysis

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Methods for Clear and Pigmented Lacquers¹

This standard is issued under the fixed designation D 333; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

[†] NOTE—Keywords were added editorially in April 1991.

1. Scope

1.1 These test methods cover procedures for testing lacquers and lacquer coatings. The test methods included are listed in Table 1.

NOTE 1—In accordance with Definitions D 16, a lacquer is defined as a coating composition that is based on synthetic thermoplastic film-forming material dissolved in organic solvent(s) and that dries primarily by solvent evaporation. Typical lacquers include those based on nitrocellulose, other cellulose derivatives, vinyl resins, acrylic resins, etc.

NOTE 2—Lacquers may be applied under such diverse conditions, to so many different surfaces, and their dried films may be subjected to so many kinds of wear and exposure that it is not possible to assure desired performance from a single selection of test methods and numerical results therefrom. Those skilled in lacquer technology may find partial assurance of obtaining desired qualities in various types of lacquers through careful selection of the methods covered herein and intelligent interpretation of results therefrom.

NOTE 3—It is intended ultimately to remove all experimental procedures from Test Methods D 333 and to establish them as a guide to the selection of test methods for lacquer and perhaps to interpretation of results therefrom. Temporarily there remain in Test Methods D 333 a few tests that are too short or otherwise presently unsuitable for establishment under separate ASTM designations.

1.2 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Significance and Use

3.1 These test methods are intended to compile as well as provide screening tests in evaluating clear and pigmented lacquers as used in different coating operations.

3.2 Each coating system may contain from a simple one coat operation to a multicoat finishing system.

3.3 The substrates may be varied, ferrous and non ferrous, plastic or wood which can affect the performance of a given coating system.

3.4 Substrate cleaning, chemically or physically, is an

¹⁴ Annual Book of ASTM Standards, Vol 06.03.

4. General Requirements

4.1 All tests shall be made in diffused light (not in direct sunlight), and at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity, unless otherwise specified.

5. Preparation of Sample

5.1 Many clear lacquers and all pigmented lacquers contain suspended solids that have a tendency to settle to the bottom of the container. Stir any settled portion with a paddle or spatula and then shake vigorously for 10 min on a mechanical agitator. Since many lacquer solvents are extremely volatile, care should be taken during sampling and testing to avoid loss of significant amounts of volatile matter.

6. Weight Per Gallon

6.1 Determine the density as described in Test Method D 1475. This method is particularly adaptable for high-viscosity fluids or where a component is too volatile for a specific gravity balance determination. If a weight per gallon cup of 83.2-mL capacity is used, calculation of weight per gallon is simplified.

7. Nonvolatile Matter

7.1 Nonvolatile matter determination is an indication of the amount of permanent film-forming material contained in a lacquer. At ambient temperatures, drying of a lacquer film may involve gradual loss of slowly volatile solvents, hence solids determinations may differ from those resulting from a nonvolatile determination accelerated by a higher temperature.

7.2 Determine the nonvolatile content of lacquers as described in Test Methods D 1644. As an additional requirement, the specimen shall be reheated and reweighed until the weight is constant to within 1 mg. Test Method A of Test Methods D 1644 is preferred since Method B is potentially dangerous when used with lacquers.

8. Homogeneity

8.1 Good quality lacquers and their ingredients should be uniformly constituted and free from particles of foreign matter.

8.2 Determine the presence or absence of foreign matter in nonpigmented liquids for use in paints and lacquers or lacquers themselves as described in Test Method D 2090.

8.3 Determine the degree of dispersion (commonly referred to as "fineness of grind") of pigment, semiquantitatively, in pigmented coating systems in accordance with Test Method D 1210.

9. Color

9.1 The color of a clear lacquer is only a preliminary indication of the color of a dried film of lacquer. The initial color may bleach and another color may appear under certain conditions of exposure.

9.2 Determine the color of clear lacquers as described in Test Method D 1544. This method gives a comparison of the color of the sample with that of a color reference standard.

9.3 Determine the color of essentially water-white lacquers in accordance with Test Method D 1209. This method shall be used where the color-producing bodies in the lacquer have very nearly the same light-absorption characteristics as

those of the platinum-cobalt standards.

10. Viscosity

10.1 The viscosity of a lacquer is a property that can be used as a guide in determining the ease with which a given lacquer may be applied. For example, lacquers designed for spray application may be low in viscosity whereas they are high for doctor blade or roller application.

10.2 Determine the viscosity of clear and pigmented finishes designed for spray application as described in Test Method D 1200. This method is not recommended for lacquers with viscosities requiring more than 100 s efflux time.

10.3 For precise viscosity determinations in the range from 0.4 to 16 000 cSt proceed in accordance with Test Method D 445.

NOTE 4—Caution should be observed in that it is recognized that changes in viscosity may occur in lacquers upon aging.

11. Flash Point

11.1 The organic solvents used in lacquers have characteristic flash points. The flash point of a liquid is defined as the lowest temperature, corrected to 101.3 kPa (760 mmHg) of pressure, of the sample at which application of an ignition source causes the vapor of the sample to ignite under specified conditions of test.

11.2 Determine the flash point by Test Method D 56 or Test Methods D 93 for liquid storage regulations of Occupational Safety and Health Administration (OSHA) of U. S. Department of Labor and for classification of hazardous liquids for shipments under the regulations of U. S. Department of Transportation and bulk shipments by water.

11.2.1 Determine the flash point of lacquer or lacquer materials having a viscosity less than 9.5 cSt at 77°F (25°C) or 45 SUS at 100°F (37.8°C) (Method D 88) by Test Method D 56 and of lacquers having a viscosity of more than 9.5 cSt at 77°F (25°C) or 45 SUS at 100°F (37.8°C) by Method A of Test Methods D 93. Use Method B of Test Methods D 93 whenever there is a question that the heat transfer within a viscous lacquer is not sufficient to assure an accurate flash point. In addition, use Method B when testing pigmented lacquers or suspensions of solids and liquids which tend to skin under test conditions.

11.3 Test Methods D 3278, which give comparable results to Test Method D 56 and Test Methods D 93 while requiring a smaller specimen and less time to run, may be used as an alternative method.

12. Panel Preparation

12.1 In the evaluation of coated panels a uniform dry film thickness of lacquer is essential in order to eliminate any effect due to film thickness. Unless otherwise specified, the dry film thicknesses shall be as follows:

	Mils	Micrometres
Lacquer primer	0.3 to 0.6	8 to 15
Lacquer primer surfacer	1.0 to 2.0	25 to 50
Clear lacquer	1.0 to 1.2	25 to 31
Gloss pigmented lacquer	1.0 to 1.2	25 to 31
Lacquer putties	4.0 to 6.0	100 to 150

12.2 Panels may be prepared by either manual or automatic application of lacquers. First reduce lacquers with the

types of

specified thinner (if reduction is required) to the required dilution solids or viscosity. If no viscosity is specified, spray with standard-type guns at a viscosity of 17 to 25 s in a No. 4 Ford Cup at 25°C determined as described in Test Method D 1200.

12.3 Cold Spray—In manual application by cold spray, keep the air pressure constant and provide the air line with a moisture trap. Adjust the flow, gun distance from test panel, and spray pattern that the deposited film is kept smooth, level, and wet. Apply the number of coats or thickness, or both, specified in the product specification.

12.4 Hot Spray—The packaged material shall be applied with hot spray equipment approved by the Underwriter's Laboratory. When dilution is necessary, the material shall be reduced with the specified thinner to the viscosity required for hot spray application. The conditions of operation with respect to temperature of the heating unit, type of spray gun, atomization pressure and pressure on feed tank type, adjustment of air cap and fluid tip, distance of gun from work, and rate of flow of material at the spray nozzle shall be as agreed upon between purchaser and seller.

12.5 Automatic Application—Four methods of applying films of uniform thickness automatically are described in Test Methods D 823. The methods are as follows:

Test Method A—Automatic Spraying Machine,
Test Method B—Automatic Dip-Coater,
Test Method C—Automatic Blade Film Applicator, and
Test Method D—Motor-Driven Blade Film Applicator.

13. Film Thickness

13.1 Many properties of lacquer films vary with the thickness of the dry film. The measurement of dry film thickness may be accomplished with various apparatus depending upon the substrate to which the film is applied. Three nondestructive methods of thickness determination are given for films that are not easily removable from their substrate and thus do not lend themselves to simple measurement with a constant-pressure micrometer. Two destructive methods are given. The methods are as follows:

13.2 Nondestructive Methods:

13.2.1 Test Method D 1186. This method is also recommended for thin films, less than 0.5 mil (0.005 in.) (0.013 mm) in thickness.

13.2.2 Test Method D 1400, Method A. By the use of plastic shims of known thickness, the film thickness can be estimated to approximately $\pm 10\%$.

13.2.3 Test Methods D 1400, Method C.

13.3 Destructive Methods:

13.3.1 Test Methods D 1005.

13.3.2 Test Methods D 1400, Method B.

14. Gloss

14.1 This property relates to that aspect of the reflecting properties of a coating as determined by the brightness and configuration of reflected images.

14.2 Determine gloss of nonmetallic finishes in accordance with Test Method D 523. This method covers the measurement of the amount of light reflected specularly from a film's surface. While this property is a function of film gloss, correlation with visual observations is not always obtained.

15. Color-Pigmented Coatings

15.1 The colors of opaque objects such as painted surfaces may be specified using visual or instrumental means.

15.2 By visual means the colors of painted surfaces in terms of the Munsell Color System may be determined in accordance with Test Method D 1535. This method provides a simple alternative to the more precise and more complicated method of color specification based on spectrophotometry.

15.3 By spectrophotometer, either visual or photoelectric types, the colors of light-reflecting coatings and spectral characteristics may be determined using Method E 308.

16. Color Difference-Pigmented Coatings

16.1 The small daylight color differences between two similarly homogeneously colored, opaque objects such as painted surfaces may be determined using visual evaluating techniques or by instrumental means.

16.2 Determine by visual evaluation color differences of opaque materials using Practice D 1729. This practice specifies characteristics of light sources, illuminating and viewing conditions, size of specimens, and general procedures.

16.3 Determine small daylight color differences between opaque paint specimens in accordance with Method D 2244. This test method correlates reasonably well with visual judgments of character and perceptibility of color differences provided specimens are illuminated and viewed under conditions substantially the same as used in the instrument. For nonfluorescent opaque paint specimens or materials that do not contain metallic pigments ("bronze" powders and aluminum powders) or "pearly" pigments or other materials that produce optical phenomena that contribute to the visual effect, test in accordance with Test Method D 2244.

17. Elongation

17.1 An elongation test may be used as an indication of the flexibility of an attached organic coating. It can also show whether there is any change during aging.

17.2 Determine the elongation of attached organic coatings when applied to flat sheet metal of uniform surface texture in accordance with Test Method D 522 or Test Method D 1737.

18. Hardness

18.1 Determine film hardness of lacquers applied to plane rigid surfaces in accordance with Test Method D 1474. In this method the resistance of a coating to penetration by an indenter is measured and converted to a hardness value.

19. Abrasion Resistance

19.1 Determine the abrasion resistance as described in either Test Method D 658 or Test Method D 968. Both methods cover measurement of the resistance to abrasion of coatings applied to metal panels.

20. Print Test

20.1 A print test can be used to determine two characteristics of a film. If a film is thoroughly dry, the test will give a measure to the susceptibility of the film itself to pressure marring. However, as the test is used in a production situation, it can be used to determine the degree to which

film has released solvents and hence whether the product can be safely packed.

20.2 Determine imprinting of dried films as described in Test Method D 2091.

21. Household Chemical Resistance

21.1 Household chemicals may alter the surface of organic coatings, for example through discoloration, change in gloss, blistering, swelling, and loss of adhesion.

21.2 Determine, qualitatively, the effects of household chemicals in accordance with Test Method D 1308.

22. Outdoor Exposure

22.1 It is important to determine the resistance to outdoor exposure of lacquers destined for exterior use prior to their application to surfaces which may be difficult or costly to refinish, or both. Systems of primer and lacquer should be tested as a whole rather than as separate components. Experience indicates that the type of substrate employed has a marked bearing on weathering results. It is the purpose of several ASTM methods to minimize the influence of substrate variation by providing uniform panel selection and uniform procedures for conducting exposure tests and for evaluating and recording results.

22.2 *Preparation of Panels*—Depending on the substrate anticipated to be coated, panels for outdoor exposure testing should be prepared and tested in accordance with the following methods:

22.2.1 Test Method D 1733.

22.2.2 Methods D 609.

22.2.3 Method D 1014.

22.3 *Test Procedures*—Many properties of organic coatings should be evaluated periodically throughout the outdoor exposure period. These properties may be evaluated as follows:

22.3.1 *Blistering*—Test Method D 714.

22.3.2 *Chalking*—Method D 659.

22.3.3 *Checking*—Test Method D 660.

22.3.4 *Cracking*—Test Method D 661.

22.3.5 *Rusting*—Method D 610.

22.3.6 *Erosion*—Test Method D 662.

22.3.7 *Flaking*—Test Method D 772.

23. Temperature-Change Resistance

23.1 A test for resistance to temperature change, or a cold cracking test (as it is sometimes called), is designed to give an indication of the resistance of a coating system to fracturing or checking, caused both by changes in temperature and humidity and by age. The degree of correlation between test results and long-term room temperature aging varies with the type of lacquer. The industry uses the test widely and feels that systems showing good cold crack resistance usually will give satisfactory performance in service. Some factors that can affect results are the type of substrate, its thickness, the rate at which the individual panels are cooled, the film thickness, and the nature of any priming or sealer coats.

23.2 Determine the temperature-change resistance in accordance with Test Method D 1211. This method specifies that the test panels be aged 10 days. If the panels are much older than this, the resistance to checking is expected to be

less and sometimes considerably so depending on the nature of the film.

24. Salt Fog

24.1 Salt spray (fog) testing of lacquers applied to metal substrates is helpful in determining their resistance to failure in service under atmospheric conditions that might prevail in sea coast areas.

24.2 Under accelerated conditions of laboratory testing, only the temperature, the pH, or concentration of the salt solution, and other physical properties can be controlled, the selection of the substrate, the coating technique, the manner in which the coating is scribed (parallel or X's), the location or position of the panels within the cabinet, the length of the test, the inspection of the panels, and the method of reporting results must generally be as agreed upon between purchaser and seller. Systems of primer and lacquer should be tested as a whole rather than as separate components.

24.3 Determine the salt spray resistance as described in Method B 117.

25. Water Fog Testing

25.1 Water fog testing of lacquers is helpful in determining their resistance to failure in service under conditions of high humidity. Failure is usually evidenced by blushing, dulling, blistering, or excessive softening that does not disappear upon evaporation of the absorbed water. Systems of primer and top-coat lacquer should be tested as a whole rather than as separate components. The use of unrealistically short drying times or excessively low temperature bakes will give erratic and misleading results.

25.2 Determine resistance to failure under conditions of high humidity in accordance with Test Method D 1735.

26. Water Immersion Testing

26.1 Water immersion testing is best suited for testing lacquers or systems that will actually be soaked in water during service. Materials that will be subjected to humid atmospheres only should be subjected to water fog testing. Failure is usually evidenced by blushing, dulling, blistering, or excessive softening that does not disappear upon evaporation of the absorbed water.

26.2 Determine, in an accelerated manner, the resistance to failure of a coating immersed in water in accordance with Practice D 870.

27. Hiding Power

27.1 Hiding power of chromatic and non-chromatic coatings can be determined using Test Method D 2805.

28. Perspiration Resistance

28.1 The effects of human perspiration on the surface of organic coatings are varied. The coating may undergo an objectionable alteration in surface appearance such as discoloration, loss of gloss, blistering, wrinkling, or roughening. The coating may lose adhesion, soften, become embrittled, or any combination of these changes may take place.

28.2 Determine the effects of perspiration on organic coatings in accordance with Test Method D 2204. This method covers an accelerated procedure for determining the resistance to failure of organic coatings on metallic panels

when exposed to human perspiration.

29. Plasticizer Migration

29.1 Plasticizers used in vinyl fabrics may migrate into lacquer films that come in contact with the fabric and cause objectionable marring and softening of the lacquer film.

29.2 Determine the tendency for plasticizer to migrate in accordance with Test Method D 2199.

30. Chip Resistance

30.1 Chip resistance testing is useful for determining the ability of the coating or coating system, or both, to withstand

flying stones or other objects. Systems of primer and topcoat should be tested as a system rather than as separate components.

31. Light Stability of Clear Coatings

31.1 The ability of clear coatings not to change color upon exposure to sunlight is an important characteristic, especially over white or light-colored substrates. Coatings for indoor use may be tested in accordance with Test Method D 2620.

32. Keywords

32.1 clear lacquers; pigmented lacquers

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

1. Scope

1.1 This standard covers the test method for determining the resistance of clear and pigmented lacquer coatings to chipping by impact.

Standard Test Method for Relative Hiding Power of Paints by the Visual Evaluation of Brushouts¹

This standard is issued under the fixed designation D 344; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method provides for the qualitative and quantitative visual determination of the hiding power of a test paint relative to that of a comparison paint.

1.2 This test method describes only a brushout application procedure in specific detail, but its concepts are valid for other methods of application as well.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

- D 16 Terminology Relating to Paint, Varnish, Lacquer, and Related Products²
- D 1475 Test Method for Density of Paint, Varnish, Lacquer, and Related Products³
- D 1729 Practice for Visual Evaluation of Color Differences of Opaque Materials⁴
- D 2805 Test Method for Hiding Power of Paints by Reflectometry³
- E 97 Test Method for Directional Reflectance Factor, 45-deg 0-deg, of Opaque Specimens by Broad-Band Filter Reflectometry⁵

3. Terminology

3.1 Definitions:

3.1.1 For definitions of terms used in this test method, refer to Definitions D 16 and the *Paint/Coatings Dictionary*.⁶

3.2 Descriptions of Terms Specific to This Standard:

3.2.1 *relative hiding power, qualitative*—the characterization of a test paint as being better, equal, or poorer in hiding power than a comparison paint.

3.2.2 *relative hiding power, quantitative*—the spreading rate of a paint expressed as a percent of the spreading rate of

a comparison paint at equal hiding.

4. Summary of Test Method

4.1 *Qualitative*—The test and comparison paints are brushed out uniformly at the same spreading rate on black and white hiding power charts. After drying the brushouts are compared visually to see which paint has been most effective in reducing the substrate contrast.

4.2 *Quantitative*—Additional brushouts are made with the comparison paint, if and as necessary, to determine the spreading rate at which it matches the hiding of the test paint brushout.

5. Significance and Use

5.1 This test method evaluates the hiding power of a test paint relative to a comparison paint. The results have significance only within that relationship. It may be used for production control or quality comparisons.

5.2 When a paint is applied by brush or any other practical method, the opacity of the film is affected by variations in film thickness related to the application procedure and to the application characteristics of the paint. Two paints that hide equally well by this method might therefore differ considerably when applied with a doctor blade, since the latter method gives essentially perfect leveling. Different brushes or surface application conditions can likewise give different results.

NOTE 1—Test Method D 2805 describes an instrumental method for quantitatively determining hiding power without reference to a material paint standard. The paint film is applied at a uniform thickness (for example, with a doctor blade), the film thickness is measured rigorously, and the opacity is evaluated photometrically. Hiding power is thereby determined with a high degree of precision.

5.3 Test Method D 344 is less precise than Test Method D 2805, but is more practical because it is responsive to the application characteristics of paints and is simpler in concept and execution.

6. Apparatus

6.1 *Balance*, top-loading laboratory balance having a capacity of 100 g and sensitivity of 0.1 g.

6.2 *Syringe*, 10-mL capacity.

6.3 *Paint Brush*, ferrule 2 in. (50 mm) wide and $\frac{1}{16}$ in. (14 mm) thick, tapered polyester filaments $2\frac{3}{4}$ in. (70 mm) long with flagged chisel trim tip.⁷

⁷ Describes the Leneta-EZ Painter Certified Standard Paint Brush used by the round-robin participants, available from Leneta Company, P. O. Box 86, Ho-Ho-Kus, NJ 07423. Equivalent brushes may be used.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.26 on Optical Properties.

Current edition approved May 26, 1989. Published August 1989. Originally published as D 344 - 32. Last previous edition D 344 - 84.

³ *Annual Book of ASTM Standards*, Vol 06.01.

⁴ *Annual Book of ASTM Standards*, Vol 14.02.

⁵ *Annual Book of ASTM Standards*, Vols 06.01 and 14.02.

⁶ Published by the Federation of Societies for Coatings Technology, 492 Norristown Rd., Blue Bell, PA 19422.

6.4 *Container*, ½-pint can or 250-mL beaker.

6.5 *Test Surface*, a smooth-surfaced paper chart having adjacent black and white areas and coated with a suitable varnish or lacquer so as to render the surface impervious to paint liquids. The black and white areas of the chart shall have luminous reflectance factors of 1 % maximum and 75 % minimum, respectively, when tested in accordance with Test Method E 97. The white areas of the charts used in any one testing program shall not differ in their reflectance factors by more than 1 %. Any suitable regular design of contrasting areas may be used. The chart⁸ shall have a defined test area of 0.1 m². Larger test areas may be used if available, with appropriate modification of the indicated calculations.

6.6 *Illumination*, a light source providing diffuse light of reasonable intensity, preferably northern sky light or an approximation of same. (See Practice D 1729).

7. Preparation of Brushouts

7.1 Select a convenient and suitable spreading rate, mutually agreeable to all parties involved in the testing program, and preferably in the range from 400 to 800 ft²/gal (9.8 to 19.6 m²/L). In any case, the spreading rate shall not be so low that the substrate contrast is difficult to see nor so high that it is difficult to apply the paint at a reasonably uniform film thickness.

NOTE 2—The gallon unit referred to here and throughout this test method is the U.S. gallon (3785.4 mL).

7.2 Determine the density *D* in grams per millilitre of the comparisons and test paints, in accordance with Test Method D 1475.

7.3 Calculate to three significant figures the volume *V* in millilitres to apply for the selected spreading rate *SR* as follows:

$$V(\text{mL}) = \frac{100}{SR(\text{m}^2/\text{L})} = \frac{4074.6}{SR(\text{ft}^2/\text{gal})}$$

7.4 Calculate to three significant figures, the weight *W* in grams corresponding to the volume *V*(mL) as follows:

$$W(\text{g}) = V(\text{mL}) \times D(\text{g/mL})$$

7.5 To prepare a brushout, first stir the paint well. Then precondition the brush by dipping it into the paint and working it out on a smooth, nonporous surface. Take up the desired volume of paint in the syringe and weigh it with the brush in the empty container. Place the test chart on a level bench top, distribute the paint from the syringe all around onto the test area of the chart, then brush the paint out uniformly within the test area. Set the brushout aside to dry in a horizontal position, protected adequately from dust and under normal room conditions of ventilation and temperature. Reweigh the empty syringe with the brush and container. The loss of weight represents the actual weight of paint applied to the test surface as opposed to the intended weight calculated from 7.3 and 7.4. If there is a discrepancy do not attempt to correct it by removing or applying paint

since this would disturb the leveling of the brushout. Instead, calculate the actual spreading rate as follows:

$$SR_A = \frac{B}{A} \times SR_B$$

where:

SR_A = actual spreading rate,

B = intended weight,

A = actual weight, and

SR_B = intended spreading rate.

8. Evaluation Procedure

8.1 *Viewing conditions*—When the test and comparison paint brushouts are thoroughly dry, place them vertically side by side against a flat surface and view them from a distance of 5 to 10 ft (1.5 to 3 m) under illumination conditions as described in 6.6.

8.2 Qualitative Evaluation:

8.2.1 If the contrast between the black and white areas of the test paint brushout is adjudged less than, equal to, or more than that of the comparison paint brushout, then the hiding power of the test paint is considered as better than, equal to, or poorer than that of the comparison paint.

8.2.2 If the actual spreading rate of the lower contrast paint-out is lower than that of the other paint-out by more than 3 %, prepare a second brushout with either paint so as to eliminate the difference, then compare again to confirm or revise the previous estimation of relative hiding power.

8.3 Quantitative Evaluation:

8.3.1 If the hiding of the test paint brushout does not match that of the comparison paint at the same spreading rate, make a series of additional comparison paint brushouts at several other spreading rates, differing in steps of approximately 15 % and providing contrasts above and below that of the test paint brushout. Refer to these and to the original comparison paint brushout as standards. If the standards are prepared correctly each increase in spreading rate will correspond to a perceptible increase in contrast. Compare the standards under the viewing conditions described in 8.1 to assure that this is the case.

8.3.2 Compare the brushout of the test paint with the standards under the specified viewing conditions to determine which standard it matches in contrast or, if none, to which pair of successive standards it is intermediate. In the latter case view the test paint brushout with the two standards on either side and rate the contrast of the test paint brushout by estimating the contrast difference between it and the lower spreading rate (lower contrast) standard, as a fraction of the contrast difference between the two standards to the nearest fourth. Keeping the test paint brushout in the middle, reverse the position of the two standards and rate the test paint brushout again in the same way. The final rating is the mean of the two to the nearest eighth.

8.3.3 Calculate the spreading rate (*SR_C*) of the comparison paint at which it is estimated to match the hiding of the test paint brushout as follows:

$$SR_C = SR_1 + X(SR_2 - SR_1)$$

where:

SR₁ = spreading rate of the lower spreading rate (lower contrast) standard,

SR₂ =

X =

nstead,

SR_2 = spreading rate of the higher spreading rate (higher contrast) standard, and

X = fractional contrast rating of the test paint brushout.

8.3.4 Calculate the relative hiding power of the test paint in accordance with the definition in 3.2.2 as follows:

$$HP_t = \frac{SR_t}{SR_c} \times 100$$

where:

HP_t = relative hiding power of the test paint,

SR_t = spreading rate of the test paint, and

SR_c = spreading rate of the comparison paint at equal hiding, as determined by an actual match with one of the standards or by estimation between two standards as described in 8.3.2.

9. Report

9.1 *Qualitative* (see 8.2)—Report the relative hiding power of the test paint as better than, equal to, or poorer than the comparison paint. The report may be amplified by such terms as exactly, slightly, moderately, considerably, etc., as may seem appropriate.

9.2 *Quantitative* (see 8.3)—Report the relative hiding power of the test coating to the nearest whole number. This is a purely numerical value. Physical units such as square feet per gallon or square metres per litre are not applicable.

10. Precision

10.1 *Qualitative*—Four test paints were rated versus a comparison paint by three laboratories, twice each by one laboratory and once each by the other two, for a total of 16 trials. There was only one discrepancy, which occurred with a paint that was apparently very similar in hiding power to the comparison paint. These results indicate that the method is effective, but more results would be required to develop an appropriate precision statement. Table 1 gives the results of these tests.

10.2 *Quantitative*—In an interlaboratory study of this

TABLE 1 Round Robin Results of Relative Hiding Power of Four White Paints versus a Comparison White Paint

^a Indicates that the test paint hides better than the comparison paint.

^b Comparison paint, relative hiding power equals 100.

^c Indicates that the test paint hides poorer than the comparison paint.

method four coatings were evaluated for hiding power against a fifth coating taken as the standard. In one laboratory each material was tested twice, but only once in the other two laboratories. Statistical analysis of the results revealed that the two results for each coating from the one laboratory were as variable as those from the other two. Consequently, the two results were treated as being individual results and the between-laboratory standard deviation was found to be 10 % with 12 df. Based on this standard deviation, the following criterion should be used for judging the acceptability of results at the 95 % confidence level:

10.2.1 *Reproducibility*—Two single results obtained by operators in different laboratories should be considered suspect if they differ in relative hiding power by more than 32 %.

10.2.2 *Repeatability*—A reasonable estimate of within-laboratory precision could not be obtained because only one laboratory repeated the test. However, the repeatability should be similar to the reproducibility.

11. Keywords

11.1 hiding power; relative hiding; opacity

Standard Specification for Wood to Be Used as Panels in Weathering Tests of Coatings¹

This standard is issued under the fixed designation D 358; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense to replace Method 2031 of Federal Test Standard No. 141. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

1. Scope

1.1 This specification designates woods for weathering tests of exterior solvent-borne or water-borne paints and other materials of similar purpose. Such tests may include either outdoor exposure tests or accelerated laboratory tests. It is the purpose of this specification to minimize the influence of variation of wood of a given species on test results.

2. General Considerations

2.1 A variety of different species should be used for testing finishes because of the wide variations in the anatomy and the density between wood species. The factors have tremendous influences on finish performance. Latewood band width and density are especially important to finish performance, and these parameters vary significantly between wood species. Cedar and redwood have relatively low proportions of hard summerwood distributed in narrow bands and contain extractives that discolor some paint films. Southern pine has a large proportion of hard summerwood in wide bands.

2.2 The angle between the growth rings and the surface of the specimen is very critical to finish performance. Commercial practice utilizes the following classification system. Boards in which growth form an angle of less than 30° with the wide surface of the piece are said to be flat-sawn or flat-grained; those with the rings intersecting at angles between 30° and 60° are termed bastard-sawn; and those with angles greater than 60° are termed quarter-sawn, edge grain, or vertical grain.

WESTERN RED CEDAR

3. Species

3.1 The material for test panels shall be western red cedar (*Thuja plicata*).

4. Weight per Volume

4.1 When the wood is in equilibrium with air at 60 to 65 % relative humidity and 70 ± 1°F (21 ± 0.5°C) it shall weigh 22 to 23 lb/ft³ (350 to 370 kg/m³) or at 50 ± 5 % relative humidity and 73.5 ± 3.5°F (23 ± 2°C), which are

¹ This specification is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility D01.52 on Factory-Coated Wood Products.

Current edition approved Oct. 28, 1983. Published December 1983. Originally published as D 358 - 33. Last previous edition D 358 - 77.

specified in Specification D 3924 as standard conditions for testing paint and related coatings, it shall weigh 21.4 to 22.4 lb/ft³ (343 to 359 kg/m³).

NOTE 1—The density requirement is to eliminate wood specimens that vary greatly from the average for that species. Either set of conditions may be used to establish the density. At 60 to 65 % relative humidity wood has a moisture content of approximately 12 % while at 45 to 55 % relative humidity it contains 9 to 10 %. The former is closer to the moisture content of wood exposed to most exterior climatic conditions.

5. Character of Wood

5.1 The wood shall be heartwood having edge grain and shall be free of knots and other defects. The color of the wood shall be uniform across each panel with no streaks that are excessively light or dark. The number of annual growth rings per inch along the radius of the log from which the wood was obtained shall not be less than ten. The surfaces shall be smoothly planed and sanded thoroughly with 150 grit sandpaper within two weeks of testing.

6. Thickness of Panels

6.1 The minimum thicknesses (Note 2) in proportion to width (across the grain) shall be as follows:

Panel Width, in. (mm)	Minimum Thickness, in. (mm)
Less than 3 (less than 75)	3/8 (10)
3 to 6 (75 to 150)	7/16 (11)
Over 6 (over 150)	1/4 (19)

NOTE 2—Minimum thicknesses in proportion to width (across the grain) do not apply to panels made of clapboard or siding of commercial types, which shall be used as regularly marketed.

WHITE PINE AND PONDEROSA PINE

7. Species

7.1 White pine wood shall be northern white pine (*Pinus strobus*). Western white pine (*Pinus monticola*), or sugar pine (*Pinus lambertiana*). Western white pine is sometimes called Idaho white pine. Ponderosa pine wood shall be *Pinus ponderosa*.

8. Weight per Volume

8.1 When the wood is in equilibrium with air at 60 to 65 % relative humidity and 70 ± 1°F (21 ± 0.5°C) it shall weigh 23 to 27 lb/ft³ (370 to 430 kg/m³) or at 50 ± 5 % relative humidity and 73.5 ± 3.5°F (23 ± 2°C) it shall weigh 22.4 to 26.4 lb/ft³ (359 to 423 kg/m³). (See Note 1.)

9. Character of Wood

9.1 The wood shall be free of knots, pitch pockets, and other defects. The color of the wood shall be uniform across each panel with no streaks that are excessively light or dark. The number of annual growth rings per inch along the radius of the log from which the wood was obtained shall be not less than 15. The surfaces shall be smoothly planed and sanded thoroughly with 150 grit sandpaper within two weeks of testing.

9.2 The wood shall be selected as edge grain or flat grain as desired. The test surface of flat grain wood shall be on the bark side.

10. Thickness of Panels

10.1 The minimum thicknesses (see Note 3) in proportion to width (across the grain) shall be as follows:

Panel Width, in. (mm)	Minimum Thickness, in. (mm)
Less than 3 (less than 75)	$\frac{7}{16}$ (11)
3 to 6 (75 to 150)	$\frac{7}{16}$ (11)
Over 6 (over 150)	$\frac{3}{4}$ (19)

SOUTHERN PINE

11. Species

11.1 The material for test panels shall be southern pine (*Pinus sp.*), suitable for siding purposes. It is not to be limited to a single species, but shall conform to the requirements prescribed in Sections 12 and 13.

12. Weight per Volume

12.1 When the wood is in equilibrium with air at 60 to 65 % relative humidity and $70 \pm 1^\circ\text{F}$ ($21 \pm 0.5^\circ\text{C}$) it shall weigh 32 to 38 lb/ft³ (510 to 610 kg/m³) or at 50 $\pm$ 5 % relative humidity and $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) it shall weigh 31 to 37 lb/ft³ (500 $\pm$ 590 kg/m³). (See Note 2.)

13. Character of Wood

13.1 The wood shall be free of knots, pitch pockets, and other defects. The color of the wood shall be uniform across each panel with no streaks that are excessively light or dark. The number of annual growth rings per inch along the radius of the log from which the wood was obtained shall be not less than 4 nor more than 12. The surfaces shall be smoothly planed and sanded thoroughly with 150 grit sandpaper within two weeks of testing.

13.2 The wood shall be sapwood having flat grain.

14. Thickness of Panels

14.1 The minimum thicknesses (see Note 3) in proportion to width (across the grain) shall be as follows:

Panel Width, in. (mm)	Minimum Thickness, in. (mm)
Less than 3 (less than 75)	$\frac{7}{16}$ (11)
3 to 6 (75 to 150)	$\frac{7}{16}$ (11)
Over 6 (over 150)	$\frac{3}{4}$ (19)

REDWOOD

15. Species

15.1 The material for test panels shall be redwood (*Sequoia sempervirens*).

16. Weight per Volume

16.1 When the wood is in equilibrium with air at 60 to 65 % relative humidity and $70 \pm 1^\circ\text{F}$ ($21 \pm 0.5^\circ\text{C}$) it shall weigh 28 to 29 lb/ft³ (450 to 460 kg/m³) or at 50 $\pm$ 5 % relative humidity and $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) it shall weigh 27.2 to 28.2 lb/ft³ (436 to 452 kg/m³). (See Note 1.)

17. Character of Wood

17.1 The material shall be heartwood, as nearly edge grain as possible. The number of annual growth rings per inch along the radius of the log from which the wood was obtained shall be not less than 18. The wood shall be free of knots, oil streaks, and other defects such as wavy burl grain. The color of the wood shall be uniform across each panel with no streaks that are excessively light or dark. The surfaces shall be smoothly planed and sanded thoroughly with 150 grit sandpaper within two weeks of testing.

18. Thickness of Panels

18.1 The minimum thicknesses (see Note 2) in proportion to width (across the grain) shall be as follows:

Panel Width, in. (mm)	Minimum Thickness, in. (mm)
Less than 3 (less than 75)	$\frac{3}{8}$ (10)
3 to 6 (75 to 150)	$\frac{7}{16}$ (11)
Over 6 (over 150)	$\frac{3}{4}$ (19)

DOUGLAS FIR

19. Species

19.1 The material for test panels shall be Douglas fir (*Pseudotsuga menziesii*).

20. Weight per Volume

20.1 When the wood is in equilibrium with air at 60 to 65 % relative humidity and $70 \pm 1^\circ\text{F}$ ($21 \pm 0.5^\circ\text{C}$) it shall weigh 30 $\pm$ 36 lb/ft³ (480 to 580 kg/m³) or at 50 $\pm$ 5 % relative humidity and $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) it shall weigh 29 to 35 lb/ft³ (460 to 560 kg/m³). (See Note 1.)

21. Character of Wood

21.1 The wood shall be free of knots, pitch pockets, and other defects. The color of the wood shall be uniform across each panel with no streaks that are excessively light or dark. The number of annual growth rings per inch along the radius of the log from which the wood was obtained shall be not less than ten. The surfaces shall be smoothly planed and sanded thoroughly with 150 grit sandpaper within two weeks of testing.

21.2 The wood shall be heartwood and selected as edge grain or flat grain as desired. The test surface of flat grain wood shall be on the bark side.

22. Thickness of Panels

22.1 The minimum thicknesses (see Note 2) in proportion to width (across the grain) shall be as follows:

Panel Width, in. (mm)	Minimum Thickness, in. (mm)
Less than 3 (less than 75)	$\frac{7}{16}$ (11)
3 to 6 (75 to 150)	$\frac{7}{16}$ (11)
Over 6 (over 150)	$\frac{3}{4}$ (19)

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Methods for Mandrel Bend Test of Attached Organic Coatings¹

This standard is issued under the fixed designation D 522; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense to replace Method 6222 of Federal Test Method Standard No. 141. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

^{ε1} NOTE—Table 2 was editorially corrected in May 1989.

1. Scope

1.1 These test methods cover the determination of the resistance to cracking (flexibility) of attached organic coatings on substrates of sheet metal or rubber-type materials.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

- D 823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels²
- D 1005 Test Methods for Measurement of Dry-Film Thickness of Organic Coatings Using Micrometers²
- D 1186 Test Methods for Nondestructive Measurement of Dry Film Thickness of Nonmagnetic Coatings Applied to a Ferrous Base²
- D 1400 Test Method for Nondestructive Measurement of Dry Film Thickness of Nonconductive Coatings Applied to a Nonferrous Metal Base²

3. Summary of Test Methods

3.1 The coating materials under test are applied at uniform thickness to panels of sheet metal or rubber-type materials. After drying or curing the coated panels are bent over a mandrel and the resistance to cracking of the coating is determined. In Test Method A the coated panels are bent over a conical mandrel. In Test Method B the coated panels are bent over cylindrical mandrels of various diameters.

4. Significance and Use

4.1 Coatings attached to substrates are elongated when the substrates are bent during the manufacture of articles or when the articles are abused in service. These test methods

have been useful in rating attached coatings for their ability to resist cracking when elongated. They have been useful in evaluating the flexibility of coatings on flexible substrates.

5. Test Specimens

5.1 Substrates:

5.1.1 If the purpose of the test is to determine the percent of elongation of the coating material, the substrate shall be cold-rolled steel strip 1/32 in. (0.8 mm) (22 gage) thick.

5.1.2 If the purpose of the test is to rate the coated material for resistance to cracking, the substrate may be any type of sheet metal or rubber-type material (for example, steel, aluminum, tinplate, or synthetic rubber). The thickness of the sheet metal may be less than 1/32 in. (0.8 mm) and the thickness of the rubber-type materials may be as great as 1/2 in. (13 mm).

5.1.3 The recommended panel size is 4 in. (100 mm) in width and 6 in. (150 mm) in length. The maximum size that the conical mandrel can accommodate is 4 1/2 in. (115 mm) wide and 7 1/2 in. (190 mm) long.

5.1.4 The surface preparation of the substrate shall be agreed upon between the purchaser and the seller. Prior to the application of the coating, round slightly the edges of metal panels to remove burrs in order to eliminate anomalous edge effects.

NOTE 1—If elongations are to be determined for coatings applied to substrates other than 1/32 in. (0.8 mm) thick cold-rolled steel, they must be measured with a special mandrel jig as described in Appendix X1.2 and shown in Fig. X1.1. The procedure for using the jig is described in Appendix X1.3.

5.2 Coated Panels:

5.2.1 Apply uniform coatings of the materials under test to the substrates in accordance with Test Methods D 823 and air dry or bake under conditions mutually agreeable to the purchaser and the seller. If percent elongation is to be measured, a minimum thickness of 1.0 mil is required on 1/32 in. (0.8 mm) thick cold-rolled steel. Perform a minimum of three determinations of coating thickness on each of the specimens in accordance with Test Methods D 1005, D 1186, or D 1400.

6. Conditioning and Number of Tests

6.1 Condition the test specimens for at least 24 h at 73.5 ± 3.5°F (23 ± 2°C) and 50 ± 5 % relative humidity, and test in the same environment or immediately on removal therefrom

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.23 on Physical Properties of Applied Paint Films. Current edition approved May 27, 1988. Published November 1988. Originally published as D 522 - 39. Last previous edition D 522 - 85.

² Annual Book of ASTM Standards, Vol 06.01.

unless otherwise specified by the purchaser and seller.

6.2 Test at least three replicate specimens in Test Method A and at least two replicate specimens in Test Method B at each mandrel diameter of interest.

TEST METHOD A—CONICAL MANDREL TEST

7. Apparatus

7.1 *Conical Mandrel Tester*, consisting of a metal cone, a rotating panel-bending arm, and panel clamps, all mounted on a metal base as illustrated in Fig. 1.

7.1.1 *Cone*, smooth steel, 8 in. (203 mm) in length, with a diameter of 1/8 in. (3 mm) at one end and a diameter of 1 1/2 in. (38 mm) at the other end.

8. Procedure

8.1 With the operating lever of the apparatus in a horizontal position, slip the test specimen between the mandrel and the drawbar with the finish side towards the drawbar. Rigidly clamp the specimen in a vertical position adjacent to the mandrel by placing the long edge behind the clamping bar in such a manner that the panel is always set up to the narrow end of the mandrel. Slip two sheets of No. 1 brown kraft wrapping paper, substrate 30, thoroughly lubricated on each side with talc, between the specimen and the drawbar and hold in position only by the pressure of the drawbar against the paper.

8.2 Move the lever through about 180° at uniform velocity to bend the specimen approximately 135°. If the purpose of the test is to measure percent elongation, the bend time should be about 15 s. To determine crack resistance under more simulated use conditions, the bend time should be some value between 1.5 s and 5 s to be agreed upon between the purchaser and the seller.

8.3 Examine the bent surface of the specimen immediately with the unaided eye for cracking. Having determined and suitably marked the end of the crack farthest from the small end of the mandrel, which shall be considered as the end point, bring the drawbar to the starting position and remove the panel from the mandrel. Measure the distance from the farthest end of the crack to the small end of the mandrel. This distance is used to compute the elongation.

FIG. 1 Conical Mandrel Test Apparatus

The mandrel diameter at which cracking ceased is taken as the resistance to cracking value.

NOTE 2—In some cases, the measured distance is used as a measure of crack resistance.

9. Calculation

9.1 Determine the elongation of the finish from the plotted curve in Fig. 2. This curve represents the relationship between the percent elongation and the diameter of the conical mandrel for a 1.0 mil coating thickness. The relation between the distance along the conical mandrel and the corresponding diameter has also been plotted on this curve.

9.2 Adjust the percent elongation value obtained from Fig. 2 for coating thickness by adding the correction obtained from Fig. 3.

NOTE 3—*Example*—Suppose a visual examination of the finish on the bent cold-rolled steel specimens 1/32 in. (0.8 mm) in thickness shows that the end of the first crack in the coating is at a distance of 3 in. (75 mm) from the small end of the cone. From Fig. 2 determine the percent elongation of the film from the measured crack distance, in this example 5.2 %. To correct for coating thickness add the value obtained in Fig. 3. At a crack distance of 3 in. the correction per mil (25 μm) of coating thickness is 0.3 %. If the film thickness in the example is 2 mils (50 μm), the actual percent elongation is $5.2 + (2 \times 0.3) = 5.8 \%$.

10. Report

10.1 Report the following information:

- 10.1.1 Mean and range of coating elongation or resistance to cracking values for each specimen,
- 10.1.2 Mean and range of coating film thickness for each specimen,
- 10.1.3 Specimen preparation procedures used,
- 10.1.4 Test conditions, and
- 10.1.5 Mean and range of elongation or resistance to cracking, and film thickness for the replicate specimens.

11. Precision

11.1 Results are not available to determine the precision of this test method. This test method has been in use for many years and is considered acceptable for evaluating the resistance to cracking of attached coatings.

FIG. 2 Distance Along Cone and Corresponding Mandrel Size versus Percent Elongation for Specimens on Cold-Rolled Steel 1/32 in. (0.8 mm) in Thickness

FIG. 3 Correction for Thickness of Film

TEST METHOD B—CYLINDRICAL MANDREL TEST

12. Apparatus

12.1 *Elongation Test Equipment*, consisting of rods or surfaces, including cylindrical steel diameters of 1 in. (25 mm), 3/4 in. (19 mm), 1/2 in. (12.7 mm), 3/8 in. (9.5 mm), 1/4 in. (6.4 mm), and 1/8 in. (3.2 mm), mounted on a metal base. An example of an acceptable form of this device is illustrated in Fig. 4.

13. Procedure

13.1 Place the test panel over a mandrel with the uncoated side in contact and with at least 2 in. (50 mm) overhang on either side. Using a steady pressure of the fingers, bend the panel approximately 180° around the mandrel at a uniform velocity in a time of 1.5 to 5 s, the time being that agreed upon between the purchaser and the seller. Remove and examine the panel immediately for cracking visible to the unaided eye. If cracking has not occurred, repeat the procedure using successively smaller diameter

mandrels on previously untested areas of a specimen until failure occurs or until the smallest diameter mandrel has been used.

13.1.1 This procedure can be applied as a "pass/fail" test by determining whether cracking is produced by a specified mandrel size.

13.1.2 The resistance to cracking value for a coating is taken as the mandrel diameter at which cracking ceases.

14. Calculation

14.1 Determine the elongation range of the material from Table 1 in which the elongation of a 1 mil (25 μm) thick coating on 1/32 in. (0.8 mm) cold-rolled steel is given for each mandrel diameter.

14.2 If the coating thickness exceeds 1 mil (25 μm), correct the determined elongation for film thickness using the factors for each mandrel diameter given in Table 2. Calculate the total elongation of the coating as follows:

$$E = e_1 + tc_1$$

where:

E = total elongation, %

e_1 = elongation from Table 1, %

t = thickness, mils, and

c_1 = correction factor from Table 2.

15. Report

15.1 Report the following information:

15.1.5 Mean and range of elongation, resistance to cracking, and film thickness for the replicate specimens.

16. Precision and Bias

16.1 Results are not available to determine the precision

of these test methods. These test methods have been in use for many years and are considered acceptable for evaluating the crack resistance of attached coatings.

INDEX TERMS

17. Index Terms

17.1 These test methods are indexed under the following terms: cracking; flexibility; resistance—cracking.

APPENDIX

(Nonmandatory Information)

XI. RELATIONSHIP BETWEEN ELONGATION AND MANDREL SIZE

X1.1 In the mandrel test, the specimens are elongated considerably past their elastic limit. Therefore, the elongations obtained are considerably higher than elongation values calculated from a theoretical equation that is based on the assumption that the elastic limits of the specimens are not exceeded.

X1.2 The elongation values corresponding to mandrel diameters in Figs. 2 and 3 of these test methods were obtained by direct measurements with a special mandrel jig.

X1.3 This jig shown in Fig. X1.1 consists of two forks for holding the mandrel and specimen in position and a roller with which the specimen is tightly wrapped around and held against the mandrel.

X1.4 *Measuring Elongation With Jig*—Make two parallel

gage scratches with a sharp stylus on the edge of the specimen so located that when it is wrapped around the mandrel the included angle between the scratches will be approximately 180°. In locating the scratches, it is necessary to make sure that they will be within the section of the specimen that, after bending, is tightly wrapped against the mandrel. Having located the scratches, measure the linear distance between them to within 2 μm. Clamp the specimen in the jig and bring the roller down tight against it. Draw the roller around causing the specimen to be tightly wrapped and secured against the surface of the mandrel. In order to hold the jig in this position hold the forks together with a C-clamp. Then rigidly mount the clamped jig on the table of the measuring machine.³ Each of the gage scratches shall be made to coincide with the vertical cross-hair of the measuring eyepiece while the horizontal cross-hair is tangent to the curvature of the upper surface of the specimen. Take the angle reading at each of these points. The difference between the two angle readings is a measure of the included angle formed by the two gage scratches, and the radii drawn coincident with the scratches. Read the angle readings in minutes and seconds to a precision of 5 s. Also determine the total diameter of the mandrel and the bent specimen. From these data calculate the percent elongation E at the surface of the specimen as follows:

$$L = \alpha\pi/180r$$

$$E = [(L - d)/d] \times 100$$

where:

α = angle, °

L = arc length,

r = radius of curvature for system (mandrel radius + panel thickness + coating thickness), and

d = original distance between scratches.

FIG. X1.1 Jig for Determining Elongation of Bent Metal Specimens

³ A star comparator has been found suitable for this purpose.

Standard Test Method for Specular Gloss¹

This standard is issued under the fixed designation D 523; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This test method has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

1. Scope

1.1 This test method covers the measurement of the specular gloss of nonmetallic specimens for glossmeter geometries of 60°, 20°, and 85° (1-7).²

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

E 97 Test Method for Directional Reflectance Factor, 45-deg 0-deg, of Opaque Specimens by Broad-Band Filter Reflectometry⁵

E 430 Method for Measurement of Gloss of High-Gloss Surfaces by Goniophotometry⁵

3. Terminology

3.1 Definitions:

3.1.1 *relative luminous reflectance factor*—the ratio of the luminous flux reflected from a specimen to the luminous flux reflected from a standard surface under the same geometric conditions. For the purpose of measuring specular gloss, the standard surface is polished glass.

3.1.2 *specular gloss*—the relative luminous reflectance factor of a specimen in the mirror direction.

4. Summary of Test Method

4.1 Measurements are made with 60°, 20°, or 85° geometry

(8, 9). The geometry of angles and apertures is chosen so that these procedures may be used as follows:

4.1.1 The 60° geometry is used for intercomparing most specimens and for determining when the 20° geometry may be more applicable.

4.1.2 The 20° geometry is advantageous for comparing specimens having 60° gloss values higher than 70.

4.1.3 The 85° geometry is used for comparing specimens for sheen or near-grazing shininess. It is most frequently applied when specimens have 60° gloss values lower than 10.

5. Significance and Use

5.1 Gloss is associated with the capacity of a surface to reflect more light in some directions than in others. The directions associated with mirror (or specular) reflection normally have the highest reflectances. Measurements by this test method correlate with visual observations of surface shininess made at roughly the corresponding angles.

5.1.1 Measured gloss ratings by this test method are obtained by comparing the specular reflectance from the specimen to that from a black glass standard. Since specular reflectance depends also on the surface refractive index of the specimen, the measured gloss ratings change as the surface refractive index changes. In obtaining the visual gloss ratings, however, it is customary to compare the specular reflectances of two specimens having similar surface refractive indices. Since the instrumental ratings are affected more than the visual ratings by changes in surface refractive index, non-agreement between visual and instrumental gloss ratings can occur when high gloss specimen surfaces differing in refractive index are compared.

5.2 Other visual aspects of surface appearance, such as distinctness of reflected images, reflection haze, and texture, are frequently involved in the assessment of gloss (1), (6), (7). Method E 430 includes techniques for the measurement of both distinctness-of-image gloss and reflection haze. Test Method D 4039 provides an alternative procedure for measuring reflection haze.

5.3 Little information about the relation of numerical-to-perceptual intervals of specular gloss has been published. However, in many applications the gloss scales of this test method have provided discriminations between coated specimens that have agreed well with visual discriminations of gloss (10).

5.4 When specimens differing widely in perceived gloss of color, or both, are compared, nonlinearity may be encountered in the relationship between visual gloss difference ratings and instrumental gloss reading differences.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.26 on Optical Properties.

Current edition approved March 31, 1989. Published May 1989. Originally published as D 523 - 39 T. Last previous edition D 523 - 85¹.

6. Apparatus⁶

6.1 Instrumental Components—The apparatus shall consist of an incandescent light source furnishing an incident beam, means for locating the surface of the specimen, and a receptor located to receive the required pyramid of rays reflected by the specimen. The receptor shall be a photosensitive device responding to visible radiation.

6.2 Geometric Conditions—The axis of the incident beam shall be at one of the specified angles from the perpendicular to the specimen surface. The axis of the receptor shall be at the mirror reflection of the axis of the incident beam. The axis of the incident beam and the axis of the receptor shall be within 0.1° of the nominal value indicated by the geometry. With a flat piece of polished black glass or other front-surface mirror in the specimen position, an image of the source shall be formed at the center of the receptor field stop (receptor window). The length of the illuminated area of the specimen shall be not more than one third of the distance from the center of this area to the receptor field stop. The dimensions and tolerance of the source and receptor shall be as indicated in Table 1. The angular dimensions of the receptor field stop are measured from the receptor lens in a collimated-beam-type instrument, as illustrated in Fig. 1, and from the

⁶ A list of manufacturers of glossmeters can be obtained from ASTM Headquarters.

test surface in a converging-beam-type instrument, as illustrated in Fig. 2. See Figs. 1 and 2 for a generalized illustration of the dimensions. The tolerances are chosen so that errors in the source and receptor apertures do not produce an error of more than one gloss unit at any point on the scale (5).

6.2.1 The important geometric dimensions of any specular-gloss measurement are:

6.2.1.1 Beam axis angle(s), usually 60° , 20° , or 85° .

6.2.1.2 Accepted angular divergences from principal rays (degree of spreading or diffusion of the reflected beam).

NOTE 1—The parallel-beam glossmeters possess the better uniformity of principle-ray angle of reflection, but the converging-beam glossmeters possess the better uniformity in extent of angular divergence accepted for measurement.

NOTE 2—*Polarization*—An evaluation of the impact of polarization on gloss measurement has been reported (11). The magnitude of the polarization error depends on the difference between the refractive indices of specimen and standard, the angle of incidence, and the degree of polarization. Because the specimen and standard are generally quite similar optically, measured gloss values are little affected by polarization.

6.3 Vignetting—There shall be no vignetting of rays that lie within the field angles specified in Table 1.

6.4 Spectral Conditions—Results should not differ significantly from those obtained with a source-filter photocell combination that is spectrally corrected to yield CIE luminous efficiency with CIE source C. Since specular reflection is, in general, spectrally nonselective, spectral corrections need to be applied only to highly chromatic, low-gloss specimens upon agreement of users of this test method.

6.5 Measurement Mechanism—The receptor-measurement mechanism shall give a numerical indication that is proportional to the light flux passing the receptor field stop with $\pm 1\%$ of full-scale reading.

7. Reference Standards

7.1 Primary Standards—Highly polished, plane, black glass of refractive index of 1.567 for the sodium D line shall be assigned a specular gloss value of 100 for each geometry. The gloss value for glass of any other refractive index shall be computed from the Fresnel equation (5). For small differences in refractive index, however, the gloss value is a linear function of index, but the rate of change of gloss

FIG. 1 Diagram of Parallel-Beam Glossmeter Showing Angular and Source Mirror-Image Position

FIG. 2 Diagram of Converging-Beam Glossmeter Showing Apertures and Source Mirror-Image Position

with index is different for each geometry. Each 0.001 increment in refractive index produces a change of 0.27, 0.16, and 0.016 in the gloss value assigned to a polished standard for the 20, 60, and 85° geometries, respectively. For example, glass of index 1.527 would be assigned values of 89.2, 93.6, and 99.4, in order of increasing geometry.

NOTE 3—Polished black glass has been reported to change in refractive index with time largely due to chemical contamination (10). The original values can be restored by optical polishing with cerium oxide. A wedge of high-purity quartz provides a more stable reference standard than glass.

7.2 *Working Standards*⁷—Ceramic tile, depolished ground opaque glass, emery paper, and other semigloss materials having hard and uniform surfaces are suitable when calibrated against a primary standard on a glossmeter known to meet the requirements of this test method. Such standards should be checked periodically for constancy by comparing with primary standards.

7.3 *Store standards* in a closed container when not in use. Keep them clean and away from any dirt that might scratch or mar their surfaces. *Never* place standards face down on a surface that may be dirty or abrasive. Always hold standards at the side edges to avoid getting oil from the skin on the standard surface. Clean the standards in warm water and a mild detergent solution brushing gently with a soft nylon brush. (Do not use soap solutions to clean standards, because they can leave a film.) Rinse standards in hot running water (temperature near 150°F (65°C)) to remove detergent solution, followed by a final rinse in distilled water. *Do not wipe standards.* The polished black glass high-gloss standard may be dabbed gently with a lint-free paper towel or other lint-free absorbent material. Place the rinsed standards in a warm oven to dry.

8. Preparation and Selection of Test Specimens

8.1 This test method does not cover preparation techniques. Whenever a test for gloss requires the preparation of test specimens, use the procedures given in Test Methods D 823.

⁷ Gloss standards are available from Byk/Gardner, 2435 Linden Lane, Silver Spring, MD 20910 and Hunter Associates Laboratory, Inc., 11495 Sunset Hills Road, Reston, VA 22090.

NOTE 4—To determine the maximum gloss obtainable from a test material, such as a paint or varnish, use Methods B or C of Test Methods D 423.

8.2 Select specimens in accordance with Practice D 3964.

9. Instrument Calibration

9.1 Operate the glossmeter in accordance with the manufacturer's instructions.

9.2 Verify the instrument zero by placing a black cavity in the specified position. If the reading is not within ± 0.1 of zero, adjust it algebraically from subsequent readings or adjust the instrument to read zero.

9.3 Calibrate the instrument at the start and completion of every period of glossmeter operation, and during the operation at sufficiently frequent intervals to assure that the instrument response is practically constant. To calibrate, adjust the instrument to read correctly the gloss of a highly polished standard, properly positioned and oriented, and then read the gloss of a working standard in the mid-gloss range. If the instrument reading for the second standard does not agree within one unit of its assigned values, check cleanliness and repeat. If the instrument reading for the second standard still does not agree within one unit of its assigned value, repeat with another mid-range standard. If the discrepancy is still more than one unit, do not use the instrument without readjustment, preferably by the manufacturer.

10. Procedure

10.1 Position each specimen in turn beneath (or on) the glossmeter. If specimens have brush marks or similar texture marks, place them in such a way that the directions of the marks are parallel to the plane of the axes of the incident and reflected beams.

10.2 Obtain at least three readings on a 3 by 6-in. (75 by 150-mm) area of the test specimen. If the range is greater than 10 gloss units, take additional readings and calculate the average, discarding divergent results as in the section on Outliers of Practice D 3980. For larger specimens, take a proportionately greater number of readings.

11. Corrections

11.1 Apply diffuse corrections only upon agreement between the producer and the user. To apply the correction

subtract it from the glossmeter reading. To measure the correction, illuminate the specimen perpendicularly and view at the incident angle with the receiver aperture specified in 6.2 for the corresponding geometry. To compute the correction, multiply the 45°, 0° directional reflectance of the specimen, determined in accordance with Test Method E 97, by the effective fraction of the luminous flux reflected by the perfect diffuse reflector and accepted by the receiver aperture. The luminous flux entering the receiver aperture from the perfect white diffusor would give the following gloss indications for each of the geometries:

Geometry, °	Gloss of Perfect White Diffuser
60	2.5
20	1.2
85	0.03

12. Report

12.1 Report the information following:

12.1.1 Mean specular gloss readings and the geometry used.

12.1.2 If uniformity of surface is of interest, the presence of any specimen that exhibits gloss readings varying by more than 5 % from their mean.

12.1.3 Where preparation of the test specimen has been necessary, a description or identification of the method of preparation.

12.1.4 Manufacturer's name and model designation of the glossmeter.

12.1.5 Working standard or standards of gloss used.

13. Precision

13.1 On the basis of studies of this test method by several laboratories in which single determinations were made on different days on several ceramic tiles and painted panels differing in visually perceived gloss, the pooled within-laboratory and between-laboratories standard deviations were found to be those shown in Table 2. Based on these standard deviations, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

13.1.1 **Repeatability**—Two results, each of which are single determinations obtained on the same specimen by the

TABLE 2 Standard Deviation of Gloss Determinations

Type of Gloss ^a	No. of Specimens	Degrees of Freedom		Standard Deviations	
		Within-Laboratory	Between-Laboratories	Within-Laboratory ^a	Between-Laboratories ^b
20°	4	40	34	0.4	1.2
60°	4	40	34	0.3	1.2
85°	2	16	6	0.2	0.6

Type of Gloss ^a	No. of Painted Panels	Degrees of Freedom		Standard Deviations	
		Within-Laboratory	Between-Laboratories	Within-Laboratory ^a	Between-Laboratories ^b
20°	8	80	72	0.6	2.2
60°	22	220	136	0.3	1.2
85°	5	48	18	0.3	2.4

^a Single determinations.

^b For means of three determinations.

TABLE 3 Maximum Acceptable Differences for Two Results

Type of Gloss ^a	Repeatability (Within Laboratories) ^a		Reproducibility (Between Laboratories) ^b	
	Ceramic Tiles	Painted Panels	Ceramic Tiles	Painted Panels
20°	1.1	1.7	3.5	6.4
60°	0.9	0.9	3.4	3.5
85°	0.6	0.8	2.0	7.2

^a Single determinations.

^b For means of three determinations.

same specimen should be considered suspect if they differ by more than the maximum acceptable differences given in Table 3.

13.1.2 **Reproducibility**—Two results, each the mean of three determinations, obtained on the same specimen by different laboratories should be considered suspect if they differ by more than the maximum acceptable differences given in Table 3. This does not include variability due to preparation of panels in different laboratories.

Non-ferrous metal types of paint, particularly semi-gloss, the measurement is affected by method of film preparation and drying conditions. The reproducibility of results from such materials may be poorer than the values given in Table 3.

The American Society for Testing and Materials takes no position respecting the validity of the patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee. It shall be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration of the responsible technical committee, which you may attend. If you feel that your comments have been ignored, please write to the managing editor, who should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Consistency of Paints Using the Stormer Viscometer¹

This standard is issued under the fixed designation D 562; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This method has been approved for use by agencies of the Department of Defense pursuant to the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

^{e1} NOTE—Editorial changes were made throughout in May 1990.

1. Scope

1.1 This test method covers the determination of the consistency of paints and related coatings using the Stormer viscometer.

1.2 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

- 2.1 *ASTM Standard:*
E 1 Specification for ASTM Thermometers²

3. Terminology

3.1 Descriptions of Terms Specific to This Standard:

3.1.1 *consistency*—load in grams to produce a rotational frequency of 200 r/min.

3.1.2 *Krebs units (KU)*—values of a scale commonly used to express the consistency of paints generally applied by brush or roller. This scale is a log function of the “load to produce 200-r/min” scale.

4. Summary of Test Method

4.1 The load required to produce a rotational frequency of 200 r/min for an offset paddle rotor immersed in a paint is determined.

5. Significance and Use

5.1 This test method provides values that are useful in specifying and controlling the consistency of paints, such as consumer or trade sales products.

6. Apparatus

6.1 *Viscometer*,³ Stormer, with the paddle-type rotor as illustrated in Figs. 1 and 2. The stroboscopic timer attachment in Fig. 1 can be removed and the instrument used without it but with a sacrifice of speed and accuracy. The

stroboscopic timer gives the 200 r/min reading directly.

6.2 *Container*—1-pt (500-mL), 3 3/8 in. (85 mm) in diameter.

6.3 *Thermometer*—An ASTM Stormer Viscosity thermometer with a range from 20 to 70°C and conforming to the requirements of Thermometer 49C, as prescribed in Specification E 1.

6.4 *Stopwatch*—A suitable timer measuring to 0.2 s.

6.5 *Test Oils*—A set covering the range from 5 to 1000 g.

7. Test Procedure

7.1 *Test Oils*—Standard oils, calibrated in absolute viscosity (poises), that fall within the viscosity range of the coatings to be measured. These oils should differ in viscosity by at least 5 P.

NOTE 1—The pertinent range of the Stormer is covered by oils having viscosities of 4 P (40 KU), 10 P (85 KU), and 14 P (95 KU).

7.1.1 *Test Oils*—Standards are silicone, hydrocarbon, linseed, and castor oils. Silicone and hydrocarbon oils calibrated in poises are commercially available.⁴ Uncalibrated linseed and castor oils may be calibrated with any apparatus that reports measurements of absolute viscosity.⁵

7.1.2 *Conversion*—The load to produce 200 r/min to each oil bearing the viscosity value in poises to load in grams by the following equation:⁶

$$L = (610\eta + 906.6\rho)/30$$

where

η = viscosity of oil in poises and

ρ = density of oil in g/cm³.

8. Test Results

8.1 *Procedure*—Remove rotor and weight carrier from the viscometer. Wind the string is wound evenly on the drum and the rotor is set up itself.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.24 on Physical Properties of Liquid Paints and Paint Materials.

Current edition approved Oct. 30, 1981. Published December 1981. Originally published as D 562 - 47 T. Last previous edition D 562 - 55 (1976).

FIG. 1 Stormer Viscometer with Paddle-Type Rotor and Stroboscopic Timer

8.2 Attach a 5-g weight onto the string and then release the brake. If the viscometer starts to run from this dead start and continues to run through several revolutions of the string drum, it is satisfactory for use. If it does not start unaided when the 5-g weight is applied, the instrument should be reconditioned.

8.3 Check the dimensions of the paddle-type rotor. They should be within ± 0.004 in. (0.1 mm) of the dimensions shown in Fig. 2.

8.4 Select two standard oils having assigned values of load to produce 200 r/min within the range of the values expected for the coatings to be measured (see 7.1).

8.5 Adjust the temperature of the standard oils to $25 \pm 0.2^\circ\text{C}$. The temperature of the Stormer apparatus should be the same. If the specified temperature cannot be obtained, record the temperature of the oil at the beginning and end of test to 0.2°C .

8.6 Determine the load in grams to produce 200 r/min with each of the two oils, using either Procedure A described in Section 9 or Procedure B described in Section 10.

8.6.1 If the oil temperature was not at $25 \pm 0.2^\circ\text{C}$ during the test, correct the measured load in grams for the deviation from that temperature.

NOTE 2—Load corrections for deviations of oil temperature from the specified temperature can be made by means of a previously established plot of load versus oil temperature (see Appendix X1).

8.7 If the measured load (corrected for any temperature deviation from standard) is within $\pm 15\%$ of the assigned load values for the oils, the Stormer apparatus can be considered to be in satisfactory calibration.

9. Procedure A (Without Stroboscopic Attachment)

9.1 Thoroughly mix the sample and strain it into a 1-pt (500-mL) container to within $\frac{1}{4}$ in. (20 mm) of the top.

9.2 Bring the temperature of the specimen to $25 \pm 0.2^\circ\text{C}$ and maintain it at that temperature during the test. The

All dimensions shall be to a tolerance of ± 0.004 in. (0.1 mm).

FIG. 2 Paddle-Type Rotor for Use With Stormer Viscometer

temperature of the specimen and apparatus should be the same.

9.2.1 If the specified temperature cannot be obtained, record the temperature of the specimen at the beginning and end of test to 0.2°C .

9.3 When the temperature of the specimen has reached equilibrium, start the test by placing the specimen on the platform of the viscometer immediately on the paddle-type rotor is immersed in the specimen to the mark on the shaft of the rotor.

9.4 Place a weight on the spindle of the viscometer and determine a load that will produce 100 revolutions in the range of 25 to 35 s.

9.5 Using the load determined in 9.4, select two loads that will produce 100 revolutions (time to give 100 revolutions) within the range of 27 to 33 s. Make these measurements at the beginning and end of the test, that is, permit the rotor to make an additional 100 revolutions before starting the timing for 100 revolutions.

9.6 Repeat the test as described in 9.5 until two readings for each load are obtained that differ within 0.5 s.

10. Procedure B (With Stroboscopic Timer)

10.1 Follow the steps in Section 9 (to 9.3) for the preparation of the specimen.

10.2 Connect the stroboscopic attachment of the viscometer to a stroboscopic timer.

10.3 Place a weight on the spindle of the viscometer and determine a load that will produce 100 revolutions in the range from 25 to 35 s.

10.4 Using the load determined in 10.3, select a weight (to the nearest 0.1 g) that will produce the 200-r/min pattern

(Fig. 3) on the stroboscopic timer, that is, where the lines appear to be stationary.

10.4.1 Lines moving in the direction of paddle rotation indicate a speed greater than 200 r/min and therefore, weight should be removed from the hanger. Conversely, lines moving opposite to direction of paddle rotation indicate a speed less than 200 r/min and weight should be added.

NOTE 3—There are other patterns that appear at speeds other than 200 r/min (See Fig. 4). The pattern for 200 r/min should be determined before running any tests.

10.5 Repeat the determination in 10.4 until a consistent value of load is obtained (that is, to within 5 g).

11. Calculation

11.1 Procedure A:

11.1.1 Calculate the load to within 5 g, to produce 100 revolutions in 30 s by interpolating between the load weights recorded for the readings made between 27 and 33 s for 100 revolutions.

11.1.2 Correct the load determined for any deviation of the specimen temperature from the specified temperature (see Appendix X1).

11.1.3 If desired, determine from Table 1 the KU corresponding to the load to produce 100 revolutions in 30 s.

NOTE 4—Table 1 has been constructed so that it is not necessary to interpolate between loads to obtain the KU corresponding to the load to produce 100 revolutions in 30 s. The table provides KU values computed for a range of 27 to 33 s for 100 revolutions.

11.2 Procedure B:

11.2.1 If desired, determine from Table 2 the KU value corresponding to the load to produce 200 r/min.

FIG. 3 Stroboscopic Lines Opening When Timer is Adjusted to Exactly 200 r/min

FIG. 4 Stroboscopic Lines Appearing as Multiples that May be Reached at 200 r/min Reached

12. Report

12.1 Report the following information:

12.1.1 The load in grams to produce 200 r/min (100 revolutions in 30 s).

12.1.2 The specimen temperature.

12.1.3 The specimen temperature of the specimen during the test and whether the specimen was corrected for any deviation from 25°C.

12.1.4 The KU value if Procedure A or Procedure B was used.

13. Precision

13.1 On the basis of the study in which determinations were made on three solvent-reducible, two water-reducible, and two non-reducible materials at each of six laboratories on each of two different days, the within-laboratory coefficient of variation was found to be 1 % in load grams or 1.5 % in KU, and the between-laboratory coefficient of variation was found to be 1 % in load grams or 4 % in KU.

13.2 On the basis of the above coefficients, the following criteria should be used to determine the acceptability of results at the 95 % confidence level.

13.2.1 If two results are obtained on the same material, the difference between the two test times should be considered unacceptable if it is more than 9 % in load grams or 12 % in KU.

13.2.2 If four or more results, each the mean of four individual results, are obtained on the same material, the difference between the mean of four individual results should be considered suspicious if it is more than 3 % in load grams or 12 % in KU.

APPENDIX

(Nonmandatory Test Method)

X1. EFFECT OF SPECIMEN TEMPERATURE ON STORMER CONSISTENCY

X1.1 For maximum accuracy in determining the effect of specimen temperature on Stormer consistency, measurements should be performed at three different specimen temperatures covering the range of interest. The change in load or KU per 1°C change can be determined from these results.

X1.2 It has been observed that the consistency of an oil is considerably more sensitive to temperature than is the consistency of a paint.

X1.3 Some typical effects of temperatures on the consistency of oil and paint are given below:

temperatures are given below:

	Mean Value at 25°C		Change per 1°C Change	
	Load, g	KU value	Load, g	KU value
High consistency oil	149	72	14	2.5
Medium consistency oil	217	85	18	2.0
Low consistency oil	286	93	11	1.5
High consistency paint	195	81	8	1.0
Medium consistency paint	440	108	40	2.0
Low consistency paint	300	95	4	0.5
Very low consistency paint	425	105	4	0.5

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expected to determine the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own.

This standard is subject to revision at any time by the responsible technical committee. It may be withdrawn at any time and if not revised, either reapproved or withdrawn. Your comments are invited and should be addressed to ASTM Headquarters. Your comments will appear on the technical committee, which you may attend. If you feel that your comments should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Preparation of Cold-Rolled Steel Panels for Painting with Varnish, Conversion Coatings, and Related Coating Products¹

This standard is issued under the fixed designation D 609; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of subsequent superscript, epsilon (ε) indicates an editorial change since the last revision or approval.

1. Scope

1.1 This practice covers various types of cold rolled steel panels and the procedures to be followed in their preparation for testing paint, varnish, lacquer, conversion coatings, and related products.

1.2 The procedures are as follows:

Procedure A—Conversion coatings (phosphates, chromates, etc.)

Procedure B—Vapor degreasing

Procedure C—Solvent brushing

Procedure D—Solvent wiping

Procedure E—Alkaline cleaning

1.3 This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Referenced Documents

2.1 ASTM Standards:

A 109 Specification for Steel, Carbon, Cold-Rolled Strip²

A 366/A 366M Specification for Steel, Carbon, Cold-Rolled Sheet, Commercial Quality²

**D 235 Specification for Mineral Spirits (Petroleum Spirits)
(Hydrocarbon Drycleaning Solvents)³**

3. Summary of Practice

3.1 Several procedures for preparation and cleaning of steel test panels are described as shown in Table 1.

4. Significance and Use

4.1 The procedures described in this practice are designed to provide steel panels with a uniform and reproducible surface for testing of paint, varnish, lacquer, conversion coatings, and related products.

5. Test Panels

5.1 Prepare the test panels from rust and stain-free cold-rolled steel as described in 5.2, 5.3, 5.4, and Table 1. The panels shall be made to a size and thickness as agreed upon between the purchaser and seller. Edges shall be

smooth and uniform. The steel may have been coated with a suitable rust preventive compound for protection during transport and storage. However, long-term storage of the steel on the surface may cause an oil/solvent stain or a rusted stain. Since such stains inhibit chemical treatments, the steel selected for panels shall be free of oil stains and shall be free of processing variation caused by pickling.

5.2.2.2. *Steel mill finish*—The metallic finish produced by steel mill rolls has a grainy, crystalline texture. This finish is typical of cold-rolled steel and is often painted surfaces on automobiles, appliances, and other products. It can be partially characterized by measuring the average peak-to-valley distance and the number of peaks per inch. However, conversion coating and treatment of these surfaces may vary because of differences in grain size, grain boundaries, and surface condition.

also be polished (or "ground") after the last pass of the mill. Flat polishing is accomplished by rubbing the surface with a fine, flat, polished surface and provide a smooth surface for testing. Flat polishing is a derivative of the surface on which the specimen is polished significantly improves the performance of certain types of surface stress measurement. The nature of the steel surface must be free of any level of surface contamination that is completely removed as described in the following section. In any case, a minimum of 0.001 in. of surface must be removed. Care must be taken to ensure that the polishing apparatus and after cleaning the specimen is complete removal of grit and debris from the polished surface.

smooth finish produced by the sanding process. This smooth finish has the properties such as low surface roughness, which is desirable to prevent corrosion.

When the film is removed from the panel, it should be washed in running water for 10 minutes by immersing a 10" x 10" piece of film in a jar of distilled water. The film should be dried by hanging it over the edge of a sink and allowing it to dry in the open air. Do not use heat, blower, or desiccants or other drying agents.

1. **Identify the conversion cost.** The conversion cost is the cost of converting raw materials into finished goods. It is the cost of the process that transforms the raw materials into the final product.

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct-responsibility of Subcommittee D01.27 on Accelerated Testing.

Current edition approved Aug. 24, 1990. Published November 1990. Originally published as D 609 - 41. Last previous edition D 609 - 73 (1980)

³ *Annual Book of ASTM Standards*, Vols 05.01 and 06.03.

TABLE 1

NOTE— μ in. = microinches; nm = nanometer.

Type No.	Description	Thickness, in. (mm)	Mean	ASTM Specification
1	Cold-rolled steel, as rolled (matte)	0.02 to 0.038 (0.6 to 1.0)	100–150	A 109, A 366
2	Cold-rolled steel, flat-polished one side	0.024 to 0.038 (0.6 to 1.0)	100–150	A 109, A 366
3	Cold-rolled steel, as rolled (smooth)	0.010 to 0.024 (0.25 to 0.6)	100–150	A 109, A 366

manufacturer's directions as to the application of the conversion coating. Preparation of test panels may consist of one or more steps of cleaning, rinsing, or conditioning prior to the application of the conversion coating. Additional rinsing with water will usually be required after the conversion coating is applied. To prevent rust, force dry immediately after rinsing.

6.3 Procedure B: Vapor Degreasing—Suspend the panels in a vapor-phase type degreaser containing stabilized 1,1,1-trichloroethane and allow them to remain above the boiling solvent. When the panels attain vapor temperature, condensation of vapor onto the panels no longer occurs. Prewiping with a clean lintless cloth saturated with mineral spirits may be necessary, since vapor degreasing generally does not remove solid particulate matter such as dirt, etc. (see Note).

NOTE—Other organic solvents or combinations of solvents that will produce a water-break free surface may be used if agreed upon between the purchaser and the supplier.

6.4 Procedure C: Solvent Brushing—Power-brush scrub the panel with mineral spirits (Specification D 235). When all soluble and loosely adhering soil has been washed off, flush with clean mineral spirits. Dry at a temperature of 125

°F (50°C) for one hour (see Note).

6.5 Procedure D: Solvent Wiping—Using clean lintless cloth, wipe the panel with mineral spirits, thoroughly rub the panel with a clean lintless cloth, ensuring soil has been removed. Store at a temperature of 125°F (50°C) for one hour (see Note).

6.6 Procedure E: Aqueous Alkaline Cleaning—Use aqueous alkaline cleaning solutions as appropriate. Clean the panels with an aqueous alkaline solution or immersion. Follow the recommendations of the manufacturer of the rinsing with water. Rinse the panels with clean water. Dry the panels at 125°F (50°C) for one hour (see Note).

Do not use panels that are not to be used for testing. Do not use panels impregnated with oil or grease. Do not use panels impregnated with volatile organic compounds. Do not use panels impregnated with waterproof bag or other material. Do not use panels impregnated with fingerprints, do not use panels impregnated with fingerprints. Handle the panels with clean hands and clean gloves.

The American Society for Testing and Materials takes no position regarding the validity of claims for patents or for the right to make or use any process, product, or apparatus mentioned in this standard. Users of this standard are advised that the validity of such claims is not the responsibility of the Society, and the risk of infringement of such rights, are entirely those of the user.

This standard is subject to revision at any time by the responsible technical committee. If not revised, either reapproved or withdrawn. Your comments are invited. Comments should be addressed to ASTM Headquarters. Your comments will be considered by the technical committee, which you may attend. If you feel that your comments are not fully represented in the views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Evaluating Degree of Rusting on Paint

This standard is issued under the fixed designation D 610; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of supersession. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reissuance.

This method has been approved for use by agencies of the Department of Defense under Standard No. 141A. Consult the DoD Index of Specifications and Standards for the location of this standard within the Index and for any subsequent revision. Approved by the Department of Defense.

⁶¹ NOTE—Editorial changes were made throughout, including the title, in October.

1. Scope

1.1 This test method covers the evaluation of the degree of rusting on painted steel surfaces using visual standards. These visual standards² were developed in cooperation with the Steel Structures Painting Council (SSPC) to further standardization of methods.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 Adjunct:

D610 Degree of rust (four photos)²

3. Significance and Use

3.1 The amount of rusting beneath or through a paint film is a significant factor in determining whether a coating system should be repaired or replaced. This test method provides a standardized means for quantifying the amount of rust present.

4. Interferences

4.1 The colored photographic reference standards and the associated rust-grade scale cover only rusting not accompanied by blistering and evidenced by visible rust.

4.1.1 Rust blistering beneath paint may be graded using the same scale by assuming the rust was completely visible and noting that the rusting was rust blistering.

4.2 The use of reference standards²

4.2.1.1. The following must not be used:

4.2.1. The user may make accurate fault.

4. Iron is not needed for iron or not should

4.2.4 *Area and perimeter of a rectangle* The area of a rectangle is the product of its length and width. The perimeter of a rectangle is the sum of its four sides.

[illegible]

5. Procedure

5.3.1 The following information must be included in the geographic reference section of the report:

- (a) A detailed description of the area covered by the verbal description;

Note: The area under the curve of the exponential function $y = 2^x$ from $x = 0$ to $x = 10$ and the area under the curve of the exponential function $y = 2^x$ from $x = 0$ to $x = 100$ have the same value. The area under the curve of the exponential function $y = 2^x$ from $x = 0$ to $x = 100$ is the same as the area under the curve of the exponential function $y = 2^x$ from $x = 0$ to $x = 10$. The area under the curve of the exponential function $y = 2^x$ from $x = 0$ to $x = 10$ is the same as the area under the curve of the exponential function $y = 2^x$ from $x = 0$ to $x = 100$.

Not only do the $\mathbb{Z}^3$ show

5. The area required for the processing of the waste shall be based upon the quantity of waste to be processed and the type of processing equipment to be used.

5. The blistering was as if it were

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.46 on Industrial Protective Painting.

This test method has been jointly approved by ASTM and the Steel Structures Painting Council.

Current edition approved Oct. 25, 1985. Published December 1985. Originally published as D 610 - 41. Last previous edition D 610 - 68 (1981).

² The colored photographic reference standards are available at a nominal cost from ASTM Headquarters (request Adjunct No. 12-406100-00), and from the Steel Structures Painting Council, 4400 5th Ave., Pittsburgh, PA 15213.

Standard Test Method for Abrasion Resistance of Organic Coatings¹ Abrasive¹

This standard is issued under the fixed designation D 658; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A superscript epsilon (ϵ) indicates an editorial change since the last revision or approval. A

1. Scope

1.1 This test method covers the determination of the resistance of organic coatings to abrasion produced by an air blast of abrasive on coatings applied to a plane, rigid surface, such as a metal or glass panel.

1.2 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

- D 823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels²
- D 968 Test Method for Abrasion Resistance of Organic Coatings by Falling Abrasive²
- D 1005 Test Methods for Measurement of Dry Film Thickness of Organic Coatings Using Micrometers²
- D 1186 Test Methods for Nondestructive Measurement of Dry Film Thickness of Nonmagnetic Coatings Applied to a Ferrous Base²
- D 1400 Test Method for Nondestructive Measurement of Dry Film Thickness of Nonconductive Coatings Applied to a Nonferrous Metal Base²
- E 11 Specification for Wire-Cloth Sieves For Testing Purposes³

3. Terminology

3.1 Description of Term Specific to This Standard:

3.1.1 *abrasion resistance*—the weight of abrasive required to wear through a unit film thickness of the coating.

4. Summary of Test Method

4.1 An abrasive under the action of a controlled air stream is allowed to impinge on a coated panel until the substrate becomes visible. The amount of abrasive used per unit film thickness is reported as the abrasion resistance of the coating.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.23 on Physical Properties of Applied Paint Films.

Current edition approved Feb. 22, 1991. Published April 1991. Originally published as D 658 - 42 T. Last previous edition D 658 - 81(1986)¹.

Fig. 1. Test apparatus (continued)

5. The test method described in Fig. 1 and Fig. 2 are two similar methods for determining the abrasion resistance of organic coatings. The test method described in Fig. 3 is a modification of the test method described in Fig. 1 and Fig. 2. The test method described in Fig. 3 is useful in the testing of coatings.

6. The test method described in Figs. 1 and 2 is a modification of the test method described in Fig. 3. The test method described in Fig. 3 is useful in the testing of coatings.

7. The test method described in Fig. 3 is a modification of the test method described in Fig. 1 and Fig. 2. The test method described in Fig. 3 is useful in the testing of coatings.

8. The test method described in Fig. 3 is a modification of the test method described in Fig. 1 and Fig. 2. The test method described in Fig. 3 is useful in the testing of coatings.

FIG. 2 Abrasion Test Apparatus (Open)

the holder. Insect screen (approximately 270 openings per square inch) is suitable for this purpose.

6.2 Air Supply, oil-free, under pressure, capable of maintaining a selected pressure within ± 200 Pa.

6.3 *Standard Abrasive*⁵—Silicon carbide grain passing a No. 170 (90- μ m) sieve and retained on a No. 200 (75- μ m) sieve.

NOTE 2—To obtain maximum accuracy and precision of results, the abrasive should be sieved for a minimum of ½ h with vigorous agitation, and only that portion which passes through a No. 170 (90-µm) sieve and is retained on a No. 200 (75-µm) sieve should be used in the test. The retained portion of the abrasive is considered satisfactory if a minimum of 85 % by weight meets the grain size requirements of 90 to 75 µm. Use the sieves described in Specification E 11.

7. Specimens

7.1 Apply uniform coatings of the material to be tested to a plane, rigid panel, such as metal or glass. Prepare a minimum of two coated panels for the material.

7.2 Cure the coated panels under conditions of humidity and temperature as agreed upon by the purchaser and seller.

NOTE 3—The coatings should be applied in accordance with Test Methods D 823, or as agreed upon between the purchaser and the seller.

NOTE 4—The thickness of the dry coatings should be measured in accordance with Test Methods D 1005, D 1400, or D 1186.

NOTE 5—For the apparatus shown in Figs. 1 and 2, the coated panels should not be larger than 5 by 4 by ¼ in. (125 by 100 by 6.3 mm) thick.

⁵ Suitable silicon carbide grain is Carborundum grain #180GG obtainable from the Carborundum Co., P. O. Box 423, Electro Minerals Div., Niagara Falls, NY 14302, or 180-mesh silicon carbide obtainable from City Chemical Corp., 132 W. 22nd St., New York, NY 10011. Other grades of abrasive may be used when mutually agreed upon between the purchaser and the seller.

8. Summary

8.1.4.1. The inner tube of the oil-free air supply shall be

10. Procedure

10.1 Place one test panel on the specimen stage. Pour a quantity of abrasive into the abrasive holder (funnel) of the apparatus. Lower the nozzle to touch the surface of the test specimen and close the door of the tester. Turn on the air supply and adjust it to the pressure reading established in the standardization of the apparatus.

10.2 Release the stream of abrasive by removing the pinchcock attached to the tubing, and allow to flow until the coating is worn through to the base metal. Consider the end point as having been reached when a small spot approximately 2 mm in diameter is worn through in the center of the wear pattern. When this point is reached, immediately shut off the abrasive stream and determine the weight of abrasive used.

NOTE 7—The amount of abrasive used can be determined either by (1) weighing the abrasive in the funnel before and after a run, or by (2) opening the bottom of the abrasion tester, collecting the abrasive used in a container, and weighing the abrasive.

10.3 Repeat 10.1 and 10.2 for two additional locations on the test specimen.

10.4 Measure the thickness of the coating adjacent to each wear pattern.

NOTE 8—The silicon carbide grain from previous tests may be reused, provided it is sieved through a No. 100 (150- μ m) sieve before it is returned to the holder in order to eliminate all of the large particles of the coating that chipped off during the abrasion test. The silicon carbide grain shall be replaced after it has been used five times.

10.5 Repeat 10.1 to 10.4 on at least one additional panel coated with the material under test.

11. Calculation

11.1 For each abrasion determination on a coated panel, calculate the abrasion resistance, A , in grams per mil as follows:

$$A = W/T$$

where:

W = weight of abrasive used, g (to one decimal place) and
 T = thickness of coating, mils (to one decimal place).

11.2 Calculate the mean of the abrasion resistance values

The American Society for Testing and Materials takes no position with any item mentioned in this standard. Users of this standard should be aware that some of the items may be the subject of patent rights, and the risk of infringement of such rights, are entirely their own.

This standard is subject to revision at any time by the responsible technical committee. It may be revised, amended, or withdrawn. Your comments are invited and should be addressed to ASTM Headquarters. Your comments will be considered for inclusion in a possible future revision of this standard. If you feel that your comments are not being given the proper consideration, please contact the responsible technical committee, which you may attend. If you feel that your views are not being given the proper consideration, please contact the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Method of Evaluating Degree of Chalking of Exterior Paints

This method covers the evaluation of the degree of chalking on white and light-colored exterior paints. It describes the procedure used to transfer to a test fabric the chalk which is then compared to a set of standard chalking test panels. Formerly under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings, this method was discontinued in 1990 and replaced by ASTM Test Methods D 4214, for Chalking of Exterior Paints on Films.¹

¹ Annual Book of ASTM Standards, Vol 06.01.

1. Scope

1.1 The test method checks the degree of chalking on exterior paint films intended for use on exterior surfaces.

Standard Test Method for Evaluating Degree of Checking of Exterior Paints¹

This standard is issued under the fixed designation D 660; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A second number in parentheses indicates the year of last superscript epsilon (e) indicates an editorial change since the last revision.

This test method has been approved for use by agencies of the Department of Defense in accordance with the Federal Test Method Standard No. 141A and for listing in the DoD Index of Specifications and Standards.

1. Scope

1.1 The illustrated reference standards included in this test method are representative of degrees and types of checking of exterior paint films. These standards are primarily intended for comparative evaluation.

2. Referenced Documents

2.1 ASTM Standards:

- D 661 Test Method for Evaluating Degree of Cracking of Exterior Paints²
- D 1150 Single and Multi-Panel Forms for Recording Results of Exposure Tests of Paints²

3. Definition

3.1 *checking*—that phenomenon manifested in paint films by slight breaks in the film that do not penetrate through the last applied coating. Where precision is necessary in evaluating a paint film, checking may be described as *visible* (as seen with the naked eye) or as *microscopic* (as observed under a magnification up to ten diameters).

4. Significance and Use

4.1 Since checking is not easily recognizable, this test method is intended to provide, through definition and illustrations, a means of evaluating the degree of this film failure.

5. Types of Checking

5.1 Many types of checking are recognized, of which some are:

5.1.1 *Irregular Pattern Type*—Checking in which the breaks develop in the surface of the film in no definite pattern.

5.1.2 *Line and Short Parallel Type*—Checking in which the breaks in the surface of the film are generally arranged in parallel lines.

5.1.3 *Switch Type*—Checking in which the breaks in the surface of the film form short and long irregular lines

or irregular patterns, resembling a cracked pattern.

5.1.4 *Three-Pronged Type*—Checking in which the breaks in the surface of the film form a definite three-pronged pattern, resembling a three-pronged fork or a three-pronged star.

5.1.5 *Geometric Pattern Type*—Checking in which the breaks in the surface of the film form definite geometric patterns, such as squares, rectangles, or circles.

5.1.6 *Short Break Type*—Checking in which the breaks in the surface of the film form individual short breaks, which may be arranged in a definite pattern.

5.1.7 *Long Break Type*—Checking in which breaks in the surface of the film form long, narrow patterns. These patterns may be arranged in a definite pattern.

5.1.8 *Oval Type*—Checking in which the breaks in the surface of the film form oval shapes.

5.1.9 *Irregular Pattern Type*—Checking in which the breaks in the surface of the film form an irregular pattern.

5.1.10 *Three-Pronged Type*—Checking in which the breaks in the surface of the film form a definite three-pronged pattern, resembling a three-pronged fork or a three-pronged star.

5.1.11 *Geometric Pattern Type*—Checking in which the breaks in the surface of the film form definite geometric patterns, such as squares, rectangles, or circles.

5.1.12 *Short Break Type*—Checking in which the breaks in the surface of the film form individual short breaks, which may be arranged in a definite pattern.

5.1.13 *Long Break Type*—Checking in which breaks in the surface of the film form long, narrow patterns. These patterns may be arranged in a definite pattern.

5.1.14 *Oval Type*—Checking in which the breaks in the surface of the film form oval shapes.

5.1.15 *Irregular Pattern Type*—Checking in which the breaks in the surface of the film form an irregular pattern.

5.1.16 *Three-Pronged Type*—Checking in which the breaks in the surface of the film form a definite three-pronged pattern, resembling a three-pronged fork or a three-pronged star.

5.1.17 *Geometric Pattern Type*—Checking in which the breaks in the surface of the film form definite geometric patterns, such as squares, rectangles, or circles.

5.1.18 *Short Break Type*—Checking in which the breaks in the surface of the film form individual short breaks, which may be arranged in a definite pattern.

5.1.19 *Long Break Type*—Checking in which breaks in the surface of the film form long, narrow patterns. These patterns may be arranged in a definite pattern.

5.1.20 *Oval Type*—Checking in which the breaks in the surface of the film form oval shapes.

5.1.21 *Irregular Pattern Type*—Checking in which the breaks in the surface of the film form an irregular pattern.

5.1.22 *Three-Pronged Type*—Checking in which the breaks in the surface of the film form a definite three-pronged pattern, resembling a three-pronged fork or a three-pronged star.

5.1.23 *Geometric Pattern Type*—Checking in which the breaks in the surface of the film form definite geometric patterns, such as squares, rectangles, or circles.

5.1.24 *Short Break Type*—Checking in which the breaks in the surface of the film form individual short breaks, which may be arranged in a definite pattern.

5.1.25 *Long Break Type*—Checking in which breaks in the surface of the film form long, narrow patterns. These patterns may be arranged in a definite pattern.

5.1.26 *Oval Type*—Checking in which the breaks in the surface of the film form oval shapes.

5.1.27 *Irregular Pattern Type*—Checking in which the breaks in the surface of the film form an irregular pattern.

Standard Test Method for Evaluating Degree of Cracking of Exterior Paints¹

This standard is issued under the fixed designation D 661; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^ε) indicates an editorial change since the last revision or reapproval.

This test method has been approved for use by agencies of the Department of Defense to replace Method 6471 of Federal Test Method Standard No. 141A and for listing in the DoD Index of Specifications and Standards.

^{ε1} NOTE—Footnote 3 was editorially changed in December 1988.

1. Scope

1.1 This test method covers the evaluation of the degree of cracking of exterior paints by comparison with photographic standards.

2. Referenced Documents

2.1 ASTM Standards:

D 660 Test Method for Evaluating Degree of Checking of Exterior Paints²

D 1150 Single- and Multi-Panel Forms for Recording Results of Exposure Tests of Paints²

2.2 Other Standards:

Pictorial Standards of Coating Defects Handbook³

3. Definition

3.1 *cracking*—that phenomenon manifested in paint films by a break extending through to the surface painted. Where this is difficult to determine, the break should be called a crack only if the underlying surface is visible. The use of a magnification of 10 diameters is recommended in cases where it is difficult to differentiate between cracking and checking (see Test Method D 660).

4. Significance and Use

4.1 Cracking failure of paint films can occur in use. This test method provides a means of evaluating the degree of the failure by comparing the pictorial standards.

5. Types of Cracking

5.1 Three types of cracking are recognized:

5.1.1 *Irregular Pattern Type*—Cracking in which the breaks in the film are in no definite pattern.

5.1.2 *Line Type*—Cracking in which the breaks in the film are generally arranged in parallel lines, usually either horizontally or vertically, over the surface of the film. These breaks often follow the line of brush marks.

5.1.3 *Sigmoid Type*—Cracking in which the breaks in the film form a pattern consisting of curves meeting and intersecting, usually on a relatively large scale.

6. Use of Photographic Reference Standards

6.1 The photographic reference standards that are part of this test method and are provided in the *Pictorial Standards of Coating Defects Handbook* are representative of the degree of cracking of exterior paint films. Figures 1 and 2 are for illustration purposes only and should not be used for evaluation.

6.2 The use of the photographic reference standards³ illustrated in Fig. 1 requires the following precautions:

6.2.1 The accompanying photographic reference standards show line-type cracking only. Irregular and sigmoid-type cracking may also be interpreted from these photographs.

6.2.2 Care must be taken not to confuse various types of failure that may be present on the same surface. This is particularly true in observing cracking and checking. Cracking may very often be an advanced stage of checking and is very often in evidence along with checking and other failures.

6.2.3 It must be realized that the degree of failure will vary over any given area. Therefore, an average portion of the film should be used for comparison. On larger surfaces it is recommended that ratings be made at several locations and the mean and range reported.

6.2.4 Paint films may collect excessive quantities of dirt, which may mask the type and degree of failure. If necessary, dirt should be removed by careful and gentle brushing with a moderately soft brush.

6.2.5 In examining wood panels for cracking failure, the possibility of wood failure should be recognized. This takes the form of a cracking or splitting of the wood itself with a resultant rupture of the paint film. Also, some panels will develop "resin spewing" which will cause early failure by cracking. These points should be taken into consideration in any evaluations.

6.3 For convenience in recording the data obtained, the

Standard Test Method for Evaluating Degree of Erosion of Exterior Paints¹

This standard is issued under the fixed designation D 662; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^e) indicates an editorial change since the last revision or reapproval.

This test method has been approved for use by agencies of the Department of Defense to replace Method 6431 of Federal Test Method Standard No. 141A and for listing in the DoD Index of Specifications and Standards.

^{e1} NOTE—Footnote 4 was editorially changed in December 1988.

1. Scope

1.1 This test method covers the evaluation of the degree of erosion of exterior paints by comparison with photographic standards.

2. Referenced Documents

2.1 ASTM Standards:

D 659 Method of Evaluating Degree of Chalking of Exterior Paints²

D 1150 Single- and Multi-Panel Forms for Recording Results of Exposure Tests of Paints²

2.2 Other Standards:

*Pictorial Standards of Coating Defects Handbook*³

3. Definition

3.1 *erosion*—that phenomenon manifested in paint films by the wearing away of the finish to expose the substrate or undercoat. The degree of failure is dependent on the amount of substrate or undercoat visible. Erosion occurs as the result of chalking. (See Method D 659 for evaluation of chalking.)

4. Significance and Use

4.1 Erosion failure of paint films can occur in use. This test method provides a mean of evaluating the degree of failure by comparing to pictorial standards.

5. Types of Erosion

5.1 Only one type of erosion is recognized, as defined in Section 3.

6. Use of Photographic Reference Standards

6.1 The photographic reference standards that are part of this test method and are provided in the *Pictorial Standards of Coating Defects Handbook* are representative of the degree of erosion of exterior paint films. Figure 1 is for illustration purposes only and should not be used for evaluation.

6.2 The use of the photographic reference standards³ illustrated in Fig. 1 requires the following precautions:

6.2.1 Care must be taken not to confuse various types of failure that may be present on the same surface.

6.2.2 It must be realized that the degree of failure will vary over any given area. Therefore, an average portion of the film should be used for comparison. On larger surfaces it is recommended that ratings be made at several locations and the mean and range reported.

6.2.3 The photographic standards used represent various degrees of erosion of a white brushing type paint over a dark primer. This system was necessary to provide sufficient contrast for photographic purposes. The erosion of a film to its normal substrate is, however, readily visible to the naked eye so it may easily be compared to the standards and given a numerical rating.

6.2.4 In doubtful cases, erosion is sometimes more visible in a damp film than in a dry film. Also, with severe erosion, it is often easier to rate the degree of erosion in a damp film than in a dry film.

6.2.5 While erosion of a sprayed film is more regular in its wearing away, a numerical rating can be given to it by interpreting the amount of erosion in terms of these standards.

6.3 For convenience in recording the data obtained, the records may be kept on forms such as Standard D 1150.⁴

7. Precision and Bias

7.1 No precision or bias statement has been established for this test method.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.27 on Accelerated Testing.

Standard Test Method for No-Pick-Up Time of Traffic Paint¹

This standard is issued under the fixed designation D 711; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

1. Scope

1.1 This test method covers a laboratory test for determining the no-pick-up time of a traffic paint by a rubber wheel.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 *ASTM Standard:*
D2000 Classification System for Rubber Products in Automotive Applications²

3. Significance and Use

3.1 This test method serves as a control test and should be used only as such. There is no direct correlation between the results of this test and field applications.

4. Apparatus

4.1 The apparatus³ as shown in Fig. 1 shall consist of a steel cylinder of the shape and dimensions as indicated, fitted with two replaceable O-rings and a ramp of shape and dimensions as shown.

4.2 The detailed dimensional requirements of the steel cylinder are given in Fig. 1. The total weight of the assembly complete with O-rings shall be 11 lb 14 oz $\pm$ 1 oz (5386 $\pm$ 28 g).

4.3 The detailed dimensional requirements of the ramp are shown in Fig. 1.

4.4 The replaceable O-rings shall be made of synthetic rubber or rubber-like material meeting the requirements of HK 715 of Specification D 2000.

4.5 The dimensional requirements of the O-ring are as

follows:

Outside diameter	4 1/2 in. (104 mm)
Inside diameter	3 3/8 in. (85 mm)
Cross section	3/8 in. (9.5 mm)

5. Procedure

5.1 Prepare a test stripe at least 3 in. (75 mm) in width of the paint to be tested by a mechanical spreader, or other suitable means on a clean plate glass panel at a wet film thickness of 15 ± 0.5 mils. (Use a plate glass panel approximately 4 by 8 by 1/8 in. (100 by 200 by 3 mm).)

5.1.1 Record the time of application. Allow the panel to dry in a horizontal position under the laboratory conditions specified (73.5 $\pm$ 3.5°F (23 $\pm$ 2°C) and 50 $\pm$ 5 % relative humidity).

5.1.2 Test the paints used with drop-in beads without beads unless otherwise specified or agreed upon between the purchaser and the seller.

5.2 Butt the glass plate against the ramp. At regular intervals remove the wheel from its rest, hold against the rest as a starting point, then free roll the weighted wheel down the inclined ramp and over the paint film with each roll of the wheel over a new wheel path. Position the wheel properly so that a clean surface of the wheel will come into contact with the paint film. As many as three passes of the wheel can be made before the wheel needs to be cleaned. This can be done with a rag saturated with acetone. It is best to set aside the wheel after washing until all the solvent has evaporated.

5.3 Note the end point for no-pick-up time when no paint adheres to the rubber rings of the test wheel when it is rolled over the paint film. As the end point is approached, roll the weighted wheel over the paint film every 30 s.

6. Report

6.1 Report the time elapsed between application of the paint and the end point as the drying time for no-pick-up of the traffic paint.

7. Precision and Bias

7.1 *Precision*—Because of the poor precision of this test method, if it is used in a specification, the maximum deviation from the maximum no-pick-up time specified should be agreed upon between the purchaser and the seller.

7.2 *Bias*—Bias cannot be determined.

8. Keywords

8.1 auto no-track time; drying time; traffic paint

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.44 on Traffic Paints.

Standard Practice for Conducting Road Service Tests on Fluid Traffic Marking Materials¹

This standard is issued under the fixed designation D 713; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

NOTE—Paragraphs 9.4 and 9.5 were inadvertently deleted and were reinstated in February 1990.

1. Scope

1.1 This practice covers the determination of the relative service life of fluid traffic marking materials such as paint, thermoplastic, epoxy, and polyester products under actual road conditions using transverse test lines. Materials under test are applied under prescribed conditions and periodic observations are made using prescribed performance criteria.

1.2 *This practice may involve hazardous materials, operations and equipment. This practice does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this practice to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*

D 711 Test Method for No-Pick-Up Time of Traffic Paint²

D 913 Test Method for Evaluating Degree of Resistance to Wear of Traffic Paint²

3. Significance and Use

3.1 This practice is an accelerated evaluation of bead retention and wear characteristics of fluid traffic marking materials. It is used to determine the useful life of such markings in the field. The same procedures are applicable to evaluating longitudinal lines to determine service life.

4. Type and Location of Pavement for Tests

4.1 Select sections where traffic is moderate and free-rolling with no grades, curves, intersections, or access points near enough to cause excessive braking or turning movements, where wear is uniform with full exposure to the sun throughout daylight hours, and there is good drainage. Select surfaces that are representative of the pavements upon which the fluid traffic marking material will be used in practice. Such surfaces include portland cement concrete, sheet asphalt, bituminous concrete, rock asphalt, and bituminous surface treatment.

5. Conditions at Time of Application

5.1 Clean the test area thoroughly of all foreign material. Do not apply traffic paint when the pavement surface is damp or wet nor when the pavement temperature is below 50°F (10°C). Application between 10 a.m. and 3 p.m. is recommended. During application record air and pavement temperature hourly.

6. Measurement of Wet Film Thickness

6.1 To aid in obtaining the correct film thickness, a length of roofing paper placed by the side of the road can be used. Place a rigid metal test panel on the roofing paper and in the path of the test line. A 12 by 12-in. (300 by 300-mm) metal panel $\frac{1}{16}$ in. (1.5 mm) in thickness is satisfactory. Immediately after the test line is applied by the motorized striper, read the wet film thickness. If the wet film thickness is not satisfactory, adjust the spray pressure and repeat until the target wet film thickness is attained. It is important that no glass beads or other interfering materials be present that would give a false wet film reading. When the wet film thickness is correct, apply a test line across a tared metal panel and weigh immediately. A balance must be immediately available and be thoroughly shielded from wind as well as be of 1500-g capacity with 0.1 g or better sensitivity. As a basis for determination of glass bead application (7.1) the weight of a paint line 4 by 12 in. (without consideration for solvent loss) can be calculated as follows:

$$W = 0.0943 \times t \times g$$

where:

W = weight of paint line, g,

t = mil thickness, and

g = weight per gallon, lb.

7. Measurement of Glass Beads

7.1 After the completion of 6.1, apply another test line to a tared panel with the motorized striper, this time also adding the glass beads, and weigh immediately. The weight difference between this measurement and that in 6.1 gives the amount of glass beads on the panel. The process can be repeated if an adjustment in the bead application rate is needed. The weight of applied glass beads can be calculated as follows:

$$W = 1.418 \times B$$

where:

W = weight of glass beads, g, and

B = glass beads per gallon of paint, lb.

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.44 on Traffic Coatings.

Current edition approved February 15, 1990. Published April 1990. Originally published as D 713 - 43 T. Last previous edition D 713 - 87.

² *Annual Book of ASTM Standards*, Vol 06.01.

8. Application Procedure

8.1 Apply the test stripes 4 in. (100 mm) in width and transversely on the road. At the option of the purchaser, the test stripes may be applied to the pavement at an angle of 45° to the direction of the traffic, or longitudinally in each wheel path, in order to increase the area of contact with traffic.

8.2 Apply test stripes (trained personnel under the supervision of the purchaser) by using a pavement-marking machine similar to the production pavement marking equipment. Apply the test stripes to at least two sections of each road surface selected to ensure against undetected road surface problems. When more than one specimen is tested at more than one location, change the sequence of placement to minimize the effect of time of day and time period before the test deck is opened to traffic.

8.3 Apply at least two lines of each specimen in each section for better statistical reliability. A tared panel as used in the measurement of glass beads (see 7.1) should be placed between the wheel track of one line's application as a double check for material and glass bead application rates. Weights between this reading and that found in 7.1 should agree within 0.5 g. The purchaser may wish to place another smaller panel between the wheel tracks to retain for future reference.

8.4 The road surface test lines have a wet film thickness within ± 0.5 mil of that required by the purchaser.

NOTE 1—If no wet film thickness is specified, 15.0 mil is recommended.

8.5 A fluid marking material with which the purchaser has had considerable production experience is included in the test series as a control.

8.6 Glass beads are placed in the paint film within ± 0.5 lb/gal of that required by the purchaser. All glass beads are supplied by the purchaser.

NOTE 2—If no bead application rate is specified, 6.0 lb/gal of paint is recommended.

9. Performance Criteria

9.1 *Auto-No-Track Time*—The auto no-track time is determined by passing over the freshly applied line in a simulated passing maneuver with a standard size passenger car with regular treads (no snow treads). A line showing no visual pick-up and redeposition of the materials onto the pavement surface when viewed from a distance of 50 ft in the highway direction is considered as showing no pick-up and conforming to the drying time requirements.

9.1.1 The test line is applied at the same temperature, the same wet film thickness, and the same rate of glass beads as will be specified by the purchaser in production application.

9.1.2 The no-track maximum time is measured when the pavement temperature is from 60 to 120°F (15 to 50°C) and under local humidity conditions, providing that the pavement is dry.

NOTE 3—A laboratory no-track test is described in Test Method D 711. This test is a laboratory control test and has little or no correlation with field results. Some paints have a tendency to skin over rapidly allowing the specimen to meet the maximum specified time for the laboratory test, but would be unsatisfactory at that time on a road surface.

9.2 *Appearance*—The impression of the observer of the

general condition of the test lines when viewed without any detailed inspection, from a distance of at least 10 ft. It is a measure of satisfactory or unsatisfactory appeal to the observer. It includes a comparison of the color of the surface under consideration with the original color, taking into account changes due to yellowing, bleeding, darkening, fading, dirt collection, mold growth, etc. This determination is made in each wheel track in an area extending 9 in. (229 mm) each side of the point of greatest wear. The appearance is rated either acceptable or unacceptable.

9.3 *Durability*—The durability is equal to one tenth of the percentages of material remaining on the pavement (when examined by the unaided eye). This determination is made in each wheel track in an area extending 9 in. (229 mm) each side of the point of greatest wear. The percent of paint remaining on the pavement is considered as the percent of the prescribed area of test stripe in which the substrate is not exposed. Make the evaluations in accordance with Test Method D 913.

NOTE 4—In the absence of a specification by the purchaser, failure shall be a rating less than 4 (less than 40 % material remaining on the pavement).

9.4 *Night Visibility*—Night visibility designates the apparent brightness when examined at night under tungsten illumination from the side of the road, with eye and light source separated by 1½ in. (40 mm) that corresponds to an observation angle of approximately ½°. Night visibility determinations are made in the wheel track areas used for rating durability, and are based on a factor of 10 for an unexposed standard panel placed next to the test stripe and 0 for no apparent brightness.

NOTE 5—In the absence of a specification by the purchaser, failure shall be a rating less than 4.

NOTE 6—A new test method for night visibility using a retro-reflectometer is being developed which is expected to have much greater precision.

9.5 *Length of Useful Life*—The length of useful life is determined by the number of days of duration between the date the sample was applied to the road surface and the date any one of the designated measurements falls below the specified minimum rating.

10. Evaluation Procedure

10.1 Make periodic inspections of the test sections in accordance with 9.2, 9.3, and 9.4. Record at each inspection the general daytime appearance (including color), film condition, and night visibility (retro-reflectance).

10.2 Inspect the test lines at regular monthly intervals. As the test lines approach failure, they should be evaluated every 2 weeks (weather permitting). The test lines must be evaluated until failure. Different types of traffic paint and markings do not wear out in a linear manner. Hence, it is not possible to extrapolate to failure some intermediate data. The winter season is also a must when evaluating test lines.

11. Calculation

11.1 Make cost calculations as follows:

$$C = M/L \times F$$

where:

C = cost per foot per day of useful life,

M = c
L = le
F = fe

NOTE
calculati
performa
other flu
character
available
When te

M = cost of paint per gallon,
 L = length of useful life in days as previously observed, and
 F = feet per gallon actually applied.

NOTE 7—The cost of the glass beads is usually not included in the calculation because it will be a constant when comparing the relative performance of a specified class of paint. Various types of paints and other fluid marking materials, however, can have different bead wetting characteristics, and beads with different wetting characteristics also are available, either of which could influence the useful life of the line. When testing more than one type of material or one type of bead, the

optimum cost/performance may be at a different bead application rate than that recommended in 8.6.

11.2 To determine the relative performance of the different fluid traffic marking materials during the course of the test, the following weighted rating, R , can be used:

$$R = 0.30A + 0.30D + 0.40N$$

where:

A = appearance as defined in 9.2 and determined using a rating from 0 to 10,

D = durability as defined in 9.3, and

N = night visibility as defined in 9.4.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Evaluating Degree of Blistering of Paints¹

This standard is issued under the fixed designation D 714; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This test method has been approved for use by agencies of the Department of Defense to replace Method 6461 of Federal Test Method Standard No. 141 A and for listing in the DoD Index of Specifications and Standards.

1. Scope

1.1 This test method employs photographic reference standards to evaluate the degree of blistering that may develop when paint systems are subjected to conditions which will cause blistering. While primarily intended for use on metal and other nonporous surfaces, this test method may be used to evaluate blisters on porous surfaces, such as wood, if the size of blisters falls within the scope of these reference standards. When the reference standards are used as a specification of performance, the permissible degree of blistering of the paint system shall be agreed upon by the purchaser and the seller.

2. Significance and Use

2.1 A phenomenon peculiar to painted surfaces is the formation of blisters relative to some system weakness. This test method provides a standard procedure of describing the size and density of the blisters so that comparisons of severity can be made.

3. Reference Standards

3.1 The photographic reference standards are glossy prints.² Figures 1 to 4 are reproductions of these standards and are included to illustrate two characteristics of blistering: size and frequency.

3.2 *Size*—Reference standards have been selected for four steps as to size on a numerical scale from 10 to 0, in which

No. 10 represents no blistering. Blistering standard No. 8 represents the smallest size blister easily seen by the unaided eye. Blistering standards Nos. 6, 4, and 2 represent progressively larger sizes.

3.3 *Frequency*—Reference standards have been selected for four steps in frequency at each step in size, designated as follows:

Dense, *D*,
Medium dense, *MD*,
Medium, *M*, and
Few, *F*.

NOTE 1—A quantitative physical description of blistering would include the following characteristics determined by actual count:

Size distribution in terms of mensuration units,
Frequency of occurrence per unit area,
Pattern of distribution over the surface, and
Shape of blister

For the usual tests, an actual count is more elaborate than is necessary.

4. Procedure

4.1 Subject the paint film to the test conditions agreed upon by the purchaser and the seller. Then evaluate the paint film for the degree of blistering by comparison with the photographic reference standards in Figs. 1 to 4.

5. Reporting

5.1 Report blistering as a number (Note 2) designating the size of the blisters and a qualitative term or symbol indicating the frequency.

5.2 Intermediate steps in size or frequency of blisters may be judged by interpolation.

5.3 When the distribution of blisters over the area has a nonuniform pattern, use an additional phrase to describe the distribution, such as "small clusters," or "large patches."

NOTE 2—The number refers to the largest size blister that is numerous enough to be representative of the specimen. For example, photographic standard No. 4, "Dense," has blisters ranging in size from about No. 7 to No. 4, inclusive.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.27 on Accelerated Testing.

Current edition approved May 29, 1987. Published July 1987. Originally published as D 714 - 43 T. Last previous edition D 714 - 56 (1981).

² Glossy prints of the photographic reference standards showing types of blistering are available at a nominal charge from ASTM Headquarters, 1916 Race St., Philadelphia, PA 19103. Request Adjunct No. 12-407140-00.

Standard Test Method for Evaluating Degree of Flaking (Scaling) of Exterior Paints¹

This standard is issued under the fixed designation D 772; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This test method has been approved for use by agencies of the Department of Defense to replace Method 6441 of Federal Test Method Standard No. 141A and for listing in the DoD Index of Specifications and Standards.

1. Scope

1.1 This test method covers the evaluation of the degree of flaking (scaling) of exterior paints by comparison with photographic standards.

2. Referenced Documents

2.1 ASTM Standard:

D 1150 Single and Multi-Panel Forms for Recording Results of Exposure Tests of Paints²

2.2 Other Standards:

*Pictorial Standards of Coating Defects Handbook*³

3. Definition

3.1 *flaking (scaling)*—that phenomenon manifested in paint films by the actual detachment of pieces of the film itself either from its substrate or from paint previously applied. Flaking (scaling) is generally preceded by cracking or blistering, and is the result of loss of adhesion, usually due to stress-strain factors coming into play.

4. Significance and Use

4.1 Flaking (scaling) failure of paint films can occur in use. This test method provides a means of evaluating the degree of failure by comparing to pictorial standards.

5. Type of Flaking (Scaling)

5.1 Only one type of flaking (scaling) is recognized, as defined in Section 3.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.27 on Accelerated Testing.

Current edition approved Aug. 29, 1986. Published October 1986. Originally published as D 772 - 44 T. Last previous edition D 772 - 47 (1981)^{ε1}.

² *Annual Book of ASTM Standards*, Vol 06.01.

³ Copies of the pictorial photographic reference standards are contained in the publication *Pictorial Standards of Coating Defects* and may be obtained from the Federation of Societies for Coatings Technology, 492 Norristown Rd., Blue Bell, PA 19422. The silver halide-gelatin photographs are intended to be the only primary reference standards for this method. The reproductions of them in this test method are for the purpose of illustration only.

6. Use of Photographic Reference Standards

6.1 The photographic reference standards that are part of this test method and are provided in the *Pictorial Standards of Coating Defects Handbook* are representative of the degree of cracking of exterior paint films. Figure 1 is for illustration purposes only and should not be used for evaluation.

6.2 The use of the photographic reference standards² illustrated in Fig. 1 requires the following precautions:

6.2.1 Care must be taken not to confuse various types of failure that may be present on the same surface.

6.2.2 It must be realized that degree of failure will vary over any given area. Therefore, an average portion of the film should be used for comparison. On larger surfaces it is recommended that ratings be made at several locations and the mean and range reported.

6.2.3 In technical literature, a distinction is sometimes made between flaking and scaling. In most cases, however, flaking and scaling refer to the same phenomenon. In some instances, the term flaking is used to describe the detachment of pieces of film less than 1/4 in. (6.4 mm) in size, and scaling, the detachment of pieces over 1/4 in. in size. In other instances, the term flaking is used to describe the detachment of pieces of film from the immediate undercoat (intercoat failure) and scaling the detachment of pieces from the base (complete failure). It should be kept in mind that the flakes may vary widely in size and shape from those illustrated by the reference standards in Fig. 1, varying from a fraction of an inch to several inches in size.

6.2.4 Peeling is frequently due to a moisture condition and when this is evident it should be taken into consideration in any evaluation.

6.2.5 For convenience in recording the data obtained, the records may be kept on forms such as Standard D 1150.⁴

7. Precision and Bias

7.1 No precision or bias statement has been established for this test method.

⁴ These record sheets may be obtained from ASTM Headquarters (order Adjunct No. 12-41150-11 and 12-41150-21) and from the Federation of Societies for Coatings Technology.

FIG. 1 Degrees of Flaking (Scaling) (Concluded)

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Conducting Tests on Paint and Related Coatings and Materials using Filtered Open-Flame Carbon-Arc Light and Water Exposure Apparatus¹

This standard is issued under the fixed designation D 822; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

1. Scope

1.1 This practice covers accelerated exposure testing of paint, varnish, lacquer, and related products using filtered open-flame carbon-arc devices as described in Practice G 23. Two basic apparatus types are available for coating evaluation since open-flame carbon-arc devices can be manufactured with or without automatic humidity control. These are Types E and EH as described in Practice G 23.² Each type of device can be operated with different types of glass filters that filter various amounts of ultraviolet (UV) radiation. *All references to use of this practice must include a description of the filter used.* Table 1 describes commonly used test conditions. Interlaboratory comparisons *must* be made only with devices using the same filter type and test conditions.

1.2 Previous versions of this practice described exposures using either open-flame carbon arcs or enclosed carbon arcs.

NOTE 1—A new practice using enclosed carbon-arc exposure apparatus is under development. Another procedure for exposing these products is covered by Practice D 3361 in which the specimens are subjected to radiation from an unfiltered open-flame carbon arc that produces much higher levels of short wavelength radiation than filtered open flame or enclosed carbon arcs. Only automatic humidity controlled open-flame carbon-arc apparatus (Type EH) is applicable to Practice D 3361.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For specific hazard statements, see Section 4.*

TABLE 1 Test Cycles Commonly Used for Carbon-Arc Exposure Testing of Paints, Varnishes, Lacquers and Related Coatings

Cycle Description	Black Panel Temp, ^a °F (°C)	Typical Uses
102 min light	145 ± 5	general coatings
18 min light and water spray	(63 ± 2.5)	
18 h using:		general coatings
102 min light	145 ± 5	
18 min light and water spray	(63 ± 2.5)	
6 h at 95 ± 4 % relative humidity with no water spray	75 ± 3 (24 ± 1.5)	
48 min light	145 ± 5	original equipment manufactured coatings
12 min light and water spray	(63 ± 2.5)	
4 h light	145 ± 5	exterior pigmented paints
4 h water spray	(63 ± 2.5)	
12 h light	145 ± 5	exterior wood stains and clears
12 h water spray	(63 ± 2.5)	
8 h light	145 ± 5	marine enamels
10 h light and water spray	(63 ± 2.5)	
6 h water spray		

^a Unless otherwise indicated, black panel temperature during light only portion of the cycle.

^b Historical convention has established this as a very commonly used test cycle.

sure of Nonmetallic Materials⁴

3. Significance and Use

3.1 This practice is intended to evaluate coating films for their stability in apparatus that expose ultraviolet (UV) light and moisture. If the spectral power distribution of the light source used for exposure tests does not adequately simulate that of terrestrial solar radiation, it may produce a different type of degradation and distort the ranking of materials obtained in outdoor exposures. Figures 1 and 2 compare representative spectral power distributions of the open-flame carbon arc (with two different types of glass filters) with that of terrestrial sunlight. Soda borosilicate glasses remove more short wavelength UV radiation than potash lithia glasses⁷ and their use can provide carbon-arc exposures that are a better approximation of terrestrial solar UV. Exposures using soda borosilicate glass filters will typically take longer to produce photochemical degradation.

3.2 No single operating procedure for light-exposure apparatus with or without water can be specified as a direct simulation of natural exposure. This practice does not express, or imply, a specific correlation with outdoor exposure.

3.3 Since natural environments vary with respect to climate, geography, and topography, it may be expected that the effects of natural exposures will vary accordingly. Furthermore, all materials are not affected equally by the same environment. Therefore, results obtained by use of this practice should not be represented as equivalent to those of any natural weathering test until the degree of correlation has been empirically established for the material in question.

3.4 Variations in results are possible between instruments of the same type operating within the accepted limits of this practice. It is recommended that results obtained using this practice be compared with those of a control or reference

⁷ Pyrex No. 7740 and Correx No. 7058 Glass Filters, manufactured by Corning Glass Works, Corning, NY 14831, or equivalent, have been found satisfactory for this purpose.

NOTE—Sunlight was measured in Phoenix, AZ, at the summer solstice with clear sky at solar noon using a double grating monochromator (1-nm bandpass) with a quartz cosine receptor on an equatorial follow-the-sun mount. The carbon arc irradiance was measured at the sample plane centered within the allowed sample area. Because of momentary fluctuations in intensity due to flickering of the carbon arc flame, the spectral power distributions shown in this figure are representative and are not meant to be used to calculate or estimate total radiant exposure for tests in carbon-arc devices.

FIG. 1 Representative Spectral Power Distributions (250 to 400 nm) for Terrestrial Sunlight and Open Flame Carbon Arc Using Two Types of Glass Filters

NOTE—Measurements made as described in Fig. 1. Because of momentary fluctuations in intensity due to flickering of the carbon arc flame, the spectral power distributions shown in this figure are representative and are not meant to be used to calculate or estimate total radiant exposure for tests in carbon-arc devices.

FIG. 2 Representative Spectral Power Distributions (250 to 300 nm) for Terrestrial Sunlight and Open Flame Carbon Arc Using Two Types of Glass Filters

material that is mutually agreed upon between the interested parties.

3.5 All references to exposures in accordance with this practice must include a complete description of the filter glass and test cycle used.

4. Hazards

4.1 Precaution—In addition to other precautions, never look directly at the carbon arc because UV radiation can damage the eye. Most carbon-arc machines are equipped

with door safety switches, but users of old equipment must be certain to turn the OPERATE switch to OFF before opening the test-chamber door.

4.2 The burning carbon rods used in these devices become very hot during use. Make sure to allow at least 15 min for the arcs to cool after the device is turned off before attempting to change the carbon rods. Avoid inhaling ash dust when changing carbon rods.

5. Test Specimens

5.1 Apply the coating to flat (plane) panels with the substrate, method of preparation, method of application, coating system, film thickness, and method of drying consistent with the anticipated end use, or as mutually agreed upon between the producer and user.

5.2 Panel specifications and methods of preparation include but are not limited to Methods D 609, Specification D 358, or Practice D 1730. Select panel sizes suitable for use with the exposure apparatus.

5.3 Coat test panels in accordance with Test Methods D 823 and measure the film thickness in accordance with an appropriate procedure selected from Test Methods D 1005, D 1186, or D 1400. Nondestructive methods are preferred because panels so measured need not be repaired.

5.4 Prior to exposing coated panels in the apparatus, condition them at $73 \pm 3^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity for one of the following periods in accordance with the type of coating:

Baked coatings	24 h
Radiation-cured coatings	24 h
All other coatings	7 days

NOTE 2—The procedures and specifications described in 5.2 through 5.4 are recommended but others may be used if agreed upon between all interested parties.

6. Procedure

6.1 Mount the test specimens vertically both above and below the horizontal center line of the source of radiation. Rotate the specimens from the upper to lower portion of the revolving sample rack to provide more uniform exposure conditions over their surface. Samples may also be inverted during rotation. When the exposure interval does not exceed 24 h, locate each specimen equidistant from the horizontal axis of the arc. For exposure intervals not exceeding 100 h, rotate the specimens daily. For longer exposures, expose specimens for approximately as many hours in the top portion of the specimen rack as in the bottom portion. Other methods of achieving uniform total irradiation may be employed if mutually agreed upon between the concerned parties.

6.2 Table 1 lists test-cycle conditions commonly used for evaluation of paints, varnishes, lacquers, and related coatings. As discussed in 3.1, each of the test cycles can be run using different types of glass filters. The filter glass used must

be agreed upon between all interested parties.

6.3 It is recommended that the temperature of the water used for specimen spray be $60 \pm 9^\circ\text{F}$ ($16 \pm 5^\circ\text{C}$). Water used for specimen spray must meet the purity levels specified in Practice G 23 in order to avoid unrealistic water spotting.

6.4 When mutually agreed upon, cycles other than those listed in Table 1 may be used. The term "cycle" is defined as the set of exposure conditions (light, light plus water spray, dark periods) that are repeated.

7. Periods of Exposure

7.1 Use one of the following methods to determine the duration of the exposure under this practice:

7.1.1 A mutually agreed upon specified number of total hours.

7.1.2 The number of total hours of exposure required to produce a mutually agreed upon amount of change in either the test specimen or an agreed upon control or reference material.

8. Evaluation of Specimens After Exposure

8.1 Determine the changes in exposed test specimens in accordance with ASTM Test Methods D 523, D 610, D 659, D 660, D 661, D 662, D 714, D 772, D 2244, D 2616, D 4214, E 97 and Practice D 1729. Consider product use requirements when selecting appropriate methods.

8.2 Evaluate test specimens by ranking their performance relative to a control or reference material exposed at the same time.

8.3 Plot properties of test specimens and controls as a function of exposure time and compare rate of change with that of the control or reference material. When this method of evaluation is used, the control or reference material must be exposed at the same time and in the same device as the test specimen.

8.4 Other methods for evaluating test specimens may be used if mutually agreed upon between all interested parties.

9. Report

9.1 Report the following information:

9.1.1 Complete description of exposure procedure used including the following:

9.1.1.1 Light/light plus water/dark cycle used,

9.1.1.2 Operating black-panel temperature during all portions of the exposure cycle,

9.1.1.3 Operating relative humidity,

9.1.1.4 Type and thickness of filter glass used, and

9.1.1.5 Temperature of water used for water spray.

9.1.2 Total hours of test.

9.1.3 Test specimen preparation.

9.1.4 Identification of controls used.

9.1.5 Results of evaluation test or tests performed on specimens and control or standard samples.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels¹

This standard is issued under the fixed designation D 823; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

These test methods have been approved for use by agencies of the Department of Defense to replace Method 2121 of Federal Test Method Standard No. 141A. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

1. Scope

1.1 Five test methods are given for preparing films of uniform thickness of coatings on test panels. These test methods are:

- Test Method A—Automatic Spray Machine Application
- Test Method B—Motor-Driven Dip Coater Application
- Test Method C—Motor-Driven Blade Film Application
- Test Method D—Hand-Held Spray Gun Application
- Test Method E—Hand-Held Blade Film Application

1.2 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

TEST METHOD A—AUTOMATIC SPRAY MACHINE APPLICATION

3. Summary of Test Method

3.1 A liquid material is applied to a test panel by means of an automatic spray machine consisting of a mounted spray gun and a panel holder. This machine can (1) move the

panel holder, with test panel, at a uniform speed through the atomized spray produced by a fixed spray gun, or (2) it can move the gun, with atomized spray, at a uniform speed past the test panel mounted on a fixed panel holder. A machine equipped with a programmable system can index the spray gun vertically for multiple passes and for multiple coats with selective time delay.

3.2 The thickness of coating applied is controlled by the traverse speed of the panel or gun, the fluid delivery rate of the gun, the viscosity of the material, and the amount of nonvolatile matter in the material.

4. Significance and Use

4.1 This test method should be used for those coatings that are designed for spray applications of objects in the factory or in the field. It is particularly important that it be used in the evaluation of metallic coatings for appearance properties, such as gloss and color.

4.2 Coatings applied by this test method may exhibit a slight orange-peel or spray wave.

5. Apparatus

5.1 *Test Panels*, of any smooth, planar material of a size that can be accommodated by the panel holder of the automatic spray machine.

5.1.1 When steel panels are used, they should be prepared in accordance with the appropriate method in Methods D 609.

5.2 *Automatic Spray Machine*,³ equipped with a panel holder and a mounting for a spray gun. The machine shall be designed to move the panel holder at a uniform speed past the fixed gun mount, or designed to move the gun mount at a uniform speed past the fixed panel holder. The panel holder or the gun mount traverse speed shall be adjustable from 25 to 100 ft (7.5 to 30 m)/min. Typical machines are shown in Fig. 1.

NOTE 1—Some automatic spray machines provide additional features that can improve the uniformity of film preparation. Some examples are: a z-bar panel holder; indexing of the panel holder at right angles to the gun to provide uniform lapping; and automatic control of number of passes, time between passes, and lapping distance.

5.3 *Spray Gun*, any that will provide a uniform fan-type

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.23 on Physical Properties of Applied Paint Films.

Current edition approved Sept. 15, 1991. Published November 1991. Originally published as D 823 - 45 T. Last previous edition D 823 - 87.

² *Annual Book of ASTM Standards*, Vol 06.01.

³ Machines suitable for this purpose are manufactured by Eclipse Systems, Inc., 12 Cork Hill Rd., Franklin, NJ 07416; Spraymation, Inc., 5320 N.W. 35th Ave., Ft. Lauderdale, FL 33309-6314.

spray pattern at least 6 in. (150 mm) in width is satisfactory. The gun may be triggered manually or automatically.

5.4 *Pressure Gage*, covering the range of 0 to 100 psi (0 to 690 kPa).

5.5 *Air Pressure Regulator*.

5.6 *Air Supply*, oil-free, under pressure.

6. Preparation of Apparatus

6.1 Mount the spray gun on the automatic spray machine. Connect the air line hose from the regulator to the air pressure gage which in turn is connected to the air inlet of the spray gun.

6.2 Set the gun so that its tip is at the desired distance from the test panel surface, usually in the range from 8 to 12 in. (200 to 300 mm).

6.3 With the gun trigger fully open, adjust the air regulator to provide the desired reading on the air pressure gage.

NOTE 2—A suitable air pressure is usually from 40 to 75 psi (275 to 520 kPa).

6.4 Set the automatic spray machine controls to provide the desired traverse speed of the panel holder or the gun mount, whichever is pertinent to the type of machine being used.

NOTE 3—Suitable traverse speeds for automotive coatings usually range from 700 to 900 in./min (17.5 to 22.5 m/min).

7. Procedure

7.1 Strain the material to be sprayed into the container to be used with the spray gun. Reduce the material to a viscosity suitable for spraying.

7.2 Connect the container to the gun and test the spray gun operation while stationary, for correct spray pattern and uniformity by allowing a momentary spray to be deposited on a piece of paper placed in the panel position. Adjust the air pressure material flow, and spray fan width controls until the desired pattern and uniformity are obtained. Further refinements may be made in the spray pattern by modifying

FIG. 2 Dip-Coater

the air pressure, the type of thinning agent, and the consistency of the material.

NOTE 4—The width of the spray pattern should be considerably wider than the width of the test panel to assure spray uniformity on the test panel.

7.3 Place a test panel on the panel holder and start the machine. Operate the spray gun so that it will begin spraying a few seconds before the test panel enters the spray pattern and continue spraying a few seconds after the test panel leaves the spray pattern.

7.4 Remove the coated panel and bake, force-dry, or air-dry it, in accordance with its type, in a vertical position in a dust-free atmosphere, as described in Specification D 3924.

7.5 Determine the thickness of the coating in accordance with Test Methods D 1005, D 1186, D 1212, or D 1400, whichever is appropriate.

8. Report

8.1 Report the following information:

8.1.1 Type of coating material,

8.1.2 Viscosity and percent of nonvolatile coating material,

8.1.3 Distance of test panel from gun tip,

8.1.4 Air pressure,

8.1.5 Number of spray passes,

8.1.6 Traverse speed,

8.1.7 Temperature and relative humidity at time of application, and

8.1.8 Film thickness values obtained for applied coating.

9. Precision

9.1 The precision of preparing coated panels by this test method depends on the type of coating applied and its thickness.

9.2 For most types of coatings, individual thickness readings taken over the surface of the applied coating can be expected to deviate from the mean by no more than $\pm 5\%$.

METHOD B—MOTOR-DRIVEN DIP COATER APPLICATION

10. Summary of Test Method

10.1 A motor-driven device is employed to withdraw the test panel from a container of the coating material at a desired uniform rate.

10.2 The thickness of coating applied is controlled by the speed of panel withdrawal, the viscosity of the material, and the percent of solids in the material.

11. Significance and Use

11.1 This test method is limited to those materials that flow out to smooth films when test panels are dipped into the material and withdrawn.

12. Apparatus

12.1 *Dip Coater*,⁴ consisting of a mechanism that will withdraw a panel from a container of the coating material at a predetermined rate. Suitable apparatus, is shown in Fig. 2(a) and 2(b):

12.1.1 The apparatus shown in Fig. 2(a) uses a cord wound around a step-cone pulley on the shaft of a motor to provide panel withdrawal rate of 2, 3, and 4-in. (50, 75, and 100-mm)/min. Prior to withdrawal, the panel, attached to the cord, is lowered by hand into the container holding the material.

12.1.2 The apparatus shown in Fig. 2(b) uses a cord driven by a variable-speed device that can provide panel immersion and withdrawal rates that are continuously variable from 2.5 to 20 in. (65 to 510 mm)/min.

NOTE 5—Rectangular containers (F-style can with lid cut off) are useful because the smaller exposed surfaces of the liquid coating reduces volatile loss.

12.2 *Test Panels*, of any clean, smooth, rigid substrate of a size that can be accommodated by the dip coater and the container.

12.2.1 When steel panels are used they shall be prepared in accordance with the appropriate method in Methods D 609.

NOTE 6—The test panels should not exceed 12 in. (300 mm) in length, but the width may be varied up to 12 in. if a suitable counterweight is used and a dip tank of adequate size is provided. Use of a multiple hook will permit dipping several panels at one time.

13. Procedure

13.1 Adjust the coating material to the proper percentage of solids and viscosity. Measure the temperature of the material in the container at the time of application.

NOTE 7—The operating conditions (viscosity, percent of nonvolatile matter, and rate of withdrawal) are specific for a given coating material and film thickness and need to be determined by trial. Subsequent reproduction of the same operating conditions should give the same film thickness. Data are available⁵ on a variety of materials and film thickness to indicate the range required. The viscosity range for normal film thickness of 0.5 to 2.0 mil (13 to 50 mm) has been shown to be 1 to 2.5 P.

13.2 Place the prepared test panel on the hook attached to the cord and lower it into the container holding the coating material. Wind the cord once completely around the pulley of the correct size to give the desired rate of withdrawal.

13.2.1 For the stepped-cone pulley apparatus, wind the cord once completely around the pulley of the correct size to give the desired weight of withdrawal.

13.2.2 For the continuously variable speed apparatus set the desired panel immersion and withdrawal rates on the control panel.

13.3 Start the motor and withdraw the panel at the desired rate, with a smooth movement entirely free of

vibration. Bake, force-dry, or air-dry the coated panel, in accordance with its type, in a vertical position in a dust-free atmosphere in accordance with Specification D 3924.

13.4 Determine the thickness of the coating in accordance with Test Methods D 1005, D 1186, or D 1400, whichever is appropriate.

13.5 If the coating thickness is too low, coat another panel using a slower rate of panel withdrawal. If the coating thickness is too high, coat another panel using a faster rate of panel withdraw.

13.6 Continue in this manner until a test panel having the desired film thickness is produced. Measure thickness on at least three different areas of the test panel to determine coating uniformity.

NOTE 8—With the dip coater, non-uniform thickness on a panel is frequently obtained. Hence, if the film thickness is greater at the bottom than the top, the viscosity should be increased or the panel withdrawal speed should be reduced, or both.

14. Report

14.1 Report the following information:

14.1.1 Type of coating material,

14.1.2 Viscosity, temperature, and percent nonvolatile of coating material,

14.1.3 Rate of withdrawal,

14.1.4 Air temperature and relative humidity at time of application, and

14.1.5 Mean and range of dry film thickness values obtained.

15. Precision

15.1 The precision of preparing coated panels by this test method depends on the type of coating applied and its thickness.

15.2 For most types of coatings, individual thickness readings taken over the surface of the applied coating can be expected to deviate from the mean by no more than $\pm 5\%$.

METHOD C—MOTOR-DRIVEN BLADE FILM APPLICATION

16. Summary of Test Method

16.1 A uniform film is produced by an applicator blade that is pushed across the test panel at a uniform speed by a motor-driven device.

16.2 The thickness of coating applied is controlled by the clearance of the applicator blade and the viscosity and percentage of solids of the material.

17. Significance and Use

17.1 This test method is applicable to substrates consisting of smooth rigid materials, such as metal or glass, and of non-rigid materials, such as paper charts. It is more reliable for producing uniform films than is the use of hand-held draw-down applicators.

18. Apparatus

18.1 *Motor-Driven Blade Film Applicator*,⁶ consisting of a

⁶ Suitable apparatus may be obtained from several suppliers of paint testing equipment.

⁴ Suitable dip coaters are the Garard Dip Coater obtainable from Paul N. Gardner Co., Inc., 316 N.E. First St., P.O. Box 10688, Pompano Beach, FL 33061-6688 and the Dipcoater obtainable from Technical Equipment Co., P.O. Box 208, Willoughby, OH 44094.

⁵ Information covering viscosity, percent of solids, rates of withdrawal and film thickness for a variety of finishing materials is given in the paper by Payne, H. F., "The Dip Coater, An Instrument For Making Uniform Films by the Dip Method," *Industrial and Engineering Chemistry, Analytical Edition*, Vol 15, 1943, p. 48.

FIG. 3 Blade Film Applicator, Motor-Driven, Method C

base plate, a bar for holding an applicator blade, and a driving mechanism. The base plate shall hold paper charts flat by means of a vacuum. The blade holder shall be designed to accommodate common types of applicator blades and to accept weights for loading the applicator blade. A mechanism shall be provided to stop the blade movement automatically at the end of the draw-down. A suitable apparatus is shown in Fig. 3.

18.2 *Vacuum Source*, a vacuum pump or a water aspirator.

18.3 *Applicator Blade*, any common type, either with adjustable or fixed clearances.

18.4 *Test Panels*, any clean, smooth, rigid substrate or may be paper charts or similar materials.

NOTE 9—Rigid panels shall be cleaned in an approved manner. Steel panels shall be prepared in accordance with the appropriate method in Test Method D 609.

19. Procedure

19.1 Clean the base plate and place the test panel on it.

19.2 If a vacuum is needed to hold the test panel flat, connect the vacuum source to the base plate and turn it on.

NOTE 10—When films are being applied to paper charts or tin foil, a sheet of paper should first be placed on the vacuum plate to prevent formation of dimples at the plate perforations.

19.3 Select an applicator blade having a clearance that should provide a wet film thickness that will give the desired dry film thickness; or, if specified, the required wet film thickness. Insert the blade in the blade holder and load the holder with weights if needed.

19.4 Place a suitable amount of the coating material on the test panel in front of the blade. Start the motor-drive and coat the test panel.

19.5 Remove the coated panel and bake, force-dry, or air-dry the coating, in accordance with its type, in a horizontal position in a dust-free atmosphere in accordance with Specification D 3924.

NOTE 11—Paper charts should be taped down to prevent curling of the edges that causes the wet film to flow towards the center.

19.6 Clean the applicator blade.

19.7 Determine the thickness of the applied coating in accordance with Test Method D 1005, D 1186, or D 1400 whichever is appropriate.

19.8 If the coating thickness is too low, coat another panel using a larger blade clearance. If the coating thickness is too high, coat another panel using a smaller blade clearance.

19.9 Continue in this manner until a test panel having the desired dry film thickness is produced. Measure thickness on at least three different areas of the test panel to determine coating uniformity.

20. Report

20.1 Report the following information:

20.1.1 Type of coating material,

20.1.2 Viscosity and percentage of solids of coating material;

20.1.3 Clearance of applicator blade used,

20.1.4 Air temperature and relative humidity at time of application, and

20.1.5 Mean and range of the film thickness values obtained.

21. Precision

21.1 The precision of preparing coated panels by this test method depends on the type of coating applied and its thickness.

21.2 For most types of coatings, individual thickness readings taken over the surface of the applied coating can be expected to deviate no more than $\pm 5\%$ from the mean.

METHOD D—HAND-HELD SPRAY GUN APPLICATION

22. Summary of Test Method

22.1 A uniform film of a coating material is produced on

a test panel by the means of a spray gun hand-held by a person skilled in its use.

22.2 The thickness of coating applied is controlled by the traverse speed of the gun, the number of passes of the gun, the fluid delivery rate of the gun, the viscosity of the material, and the amount of nonvolatile matter in the material.

23. Significance and Use

23.1 This test method is applicable to the coating of substrates consisting of smooth, rigid materials, such as metal or glass. It is usually less reliable for producing uniform films than is the automatic spray method. However, films sufficiently uniform for most physical property tests of materials can be produced by a hand-held spray gun operated by a person skilled in its use.

24. Apparatus

24.1 *Spray Gun*, any that will provide a uniform fan-type spray pattern at least 6 in. (150 mm) in width is satisfactory.

24.2 *Air Pressure Gage*, covering the range from 0 to 100 psi (0 to 690 kPa).

24.3 *Air Pressure Regulator*.

24.4 *Air Supply*, oil-free and under pressure.

24.5 *Panel Holder*.

25. Preparation of Apparatus

25.1 Connect the air line hose from the regulator to the air pressure gage which in turn is connected to the air inlet of the spray gun.

25.2 With the trigger fully open, adjust the air regulator to provide the desired reading on the air pressure gage.

NOTE 12—A suitable air pressure is usually from 40 to 75 psi (275 to 520 kPa).

26. Procedure

26.1 Strain the material to be sprayed into the container to be used with the spray gun. Reduce the material to a viscosity suitable for spraying.

26.2 Connect the container to the gun and test the spray gun operation for correct spray pattern and uniformity by allowing a momentary spray to be deposited on a piece of paper placed in the panel position. Adjust the air pressure, material flow, and spray width controls until the desired pattern and uniformity are obtained. Further refinements may be made in the spray pattern by modifying the air pressure, the type of thinning agent, and the consistency of the material.

NOTE 13—The width of the spray pattern should be considerably wider than the width of the test panel to assure spray uniformity on the test panel.

26.3 Place a test panel on the panel holder. Hold the spray gun tip 10 to 12 in. (250 to 300 mm) from the test panel surface and trigger the spray gun. Begin by aiming the gun at right angles to the panel so that the spray pattern is just beyond the edge of the panel. Gradually make the spray pattern move across the panel at a traverse speed of 10 to 15 in. (250 to 400 mm)/s.

26.4 Reverse the traverse direction of the spray gun and make the spray pattern move across the panel again.

26.5 Remove the panel from its holder and bake or

air-dry the coating, in accordance with its type, in a horizontal position in a dust-free atmosphere in accordance with Specification D 3924.

26.6 Clean the spray gun with solvent.

26.7 Measure the film thickness of the dry applied coating in accordance with Test Methods D 1005, D 1186, or D 1400 whichever is appropriate.

26.8 If the coating thickness is too low, coat another panel using more passes of the spray pattern. If the coating thickness is too high, coat another panel with fewer passes of the spray pattern or, if this is not feasible, reduce the material further with thinner.

27. Report

27.1 Report the following information:

27.1.1 Type of coating material,

27.1.2 Viscosity and percent nonvolatile of coating material,

27.1.3 Temperature and relative humidity at time of application, and

27.1.4 Mean and range of dry film thickness values obtained.

28. Precision

28.1 The precision of preparing coated panels by this test method depends on the type of coating applied, and its thickness and the skill of the operator.

28.2 For most types of coatings, individual thickness readings taken over the surface of the applied coating can be expected to deviate from the mean by no more than $\pm 10\%$ if the coating has been applied by a skilled operator.

METHOD E—HAND-HELD BLADE FILM APPLICATION

29. Summary of Test Method

29.1 A uniform film of a coating material is produced on a test panel by the means of a hand-held applicator blade.

29.2 The thickness of coating applied is controlled by the rate at which the applicator blade is drawn across the test panel, the viscosity of the material, the amount of nonvolatile matter in the material, and the clearance of the blade.

30. Significance and Use

30.1 This test method is applicable to the coating of substrates consisting of smooth, rigid materials such as metal or glass. It is applicable to the coating of smooth cardboard and paper charts if some means is used to assure that these substrates are held flat.

30.2 This test method is usually less reliable for producing uniform films than is the motor-driven applicator blade method. However, films sufficiently uniform for most physical property tests of materials can be produced by a hand-held applicator blade operated by a person skilled in its use.

31. Apparatus

31.1 *Film Applicator Blade*, any common type, either with adjustable or fixed clearances.

31.2 *Auxiliary Flattening Bar*, precision ground.

31.3 *Test Panels*, any clean, smooth, rigid substrates or may be paper charts or other similar materials.

FIG. 4 Use of Auxiliary Flattening Bar

32. Procedure

32.1 Select an applicator blade that has a clearance that will provide a wet film thickness that should result in the desired film thickness.

32.2 For coating rigid substrates:

32.2.1 Position the applicator blade near the edge of the panel and place a pool of the liquid material in front of it.

32.2.2 Grasp the sides of the applicator with the fingers and pull it across the panel at a speed of about 10 to 12 in. (250 to 300 mm)/s.

32.3 For coating non-rigid substrates:

32.3.1 Position the applicator blade near the edge of the panel and place a pool of the liquid material in front of it. Place the auxiliary bar in front of the pool of material (see Fig. 4).

32.3.2 Grasp the sides of the applicator with the fingers and pull it across the panel at a speed of about 10 to 20 in. (250 to 500 mm)/s. As the auxiliary bar is pushed by the applicator, it should press the substrate flat adjacent to the advancing edge of the applicator.

32.4 Bake or air-dry the applied coating, in accordance with its type in a horizontal position in a dust free atmosphere in accordance with Specification D 3924.

32.5 Clean the applicator bar with solvent.

32.6 Measure the film thickness of the dry-applied coating in accordance with Test Methods D 1005, D 1186, or D 1400 whichever is appropriate.

32.7 If the coating thickness is too low, select an applicator blade with a greater clearance and coat another panel. If the coating thickness is too high, select an applicator blade with a smaller clearance and coat another panel.

33. Report

33.1 Report the following information:

33.1.1 Type of coating material,

33.1.2 Viscosity and percent nonvolatile of coating material,

33.1.3 Clearance of applicator blade used,

33.1.4 Air temperature and relative humidity at time of application, and

33.1.5 Mean and range of the film thickness values obtained.

34. Precision

34.1 The precision of preparing coated panels by this test method depends on the type of coating applied, its thickness and the skill of the operator.

34.2 For most types of coatings, individual thickness readings taken over the surface of the applied coating can be expected to deviate from the mean by no more than $\pm 10\%$ if the coating has been applied by a skilled operator.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Evaluating Degree of Bleeding of Traffic Paint¹

This standard is issued under the fixed designation D 868; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Editorial changes were made throughout, including the title, in October 1989.

1. Scope

1.1 The photographic reference standards that are part of this test method² are representative of the degrees of bleeding of traffic or pavement marking paints. The standards are intended primarily for comparative evaluation in the laboratory.

1.2 Bleeding as defined is the only type of discoloration in this test method.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standard:

D 969 Test Method for Laboratory Determination of Degree of Bleeding of Traffic Paint³

2.2 Adjunct:

D 868 Bleeding resistance of paint (one photo)²

3. Terminology

3.1 Description of Term Specific to This Standard:

3.1.1 *bleeding characteristic*—that condition of discoloration manifested in traffic paint when applied to tar or asphaltic-type substrates. The number assigned to evaluate the degree of bleeding failure represents in these reference standards a measure of the contrast between the color of the

dry film on a nonbleeding surface and the color of the dry film on the test surface.

4. Significance and Use

4.1 Solvents in a traffic paint may cause bleeding of pavement constituents into the traffic marking, thereby rendering the traffic marking less effective as a lane or directional indicator. This test method in conjunction with the method for panel preparation in Test Method D 969 is used to evaluate such bleeding properties. The evaluation is very subjective and raises questions as to the usefulness of the results for specification compliance.

5. Use of Photographic Reference Standards

5.1 The photographic reference standards that are part of this test method² are representative of the degrees of bleeding of traffic or pavement marking paints. The photograph in Fig. 1 is for illustration purposes only and should not be used for evaluation.

5.2 The use of the photographic reference standards shown in Fig. 1 should be as follows:

5.3 In preparing films to compare with the reference standards for evaluating the extent of bleeding, the paint shall be applied to:

5.3.1 A nonbleeding reference surface, and

5.3.2 The test surface.

5.4 The paint under test shall be applied at a film thickness sufficient to ensure complete hiding.

5.5 The contrast in color between the films over the nonbleeding reference surface and the test surface shall be compared with the reference standards in Fig. 1 for a numerical rating.

NOTE—The degree of bleeding must necessarily be a function of both the bleeding surface agreed upon and the initial color of the paint. For instance, a yellow paint in general would be expected to show less bleeding than a white paint since its initial color is darker and as a consequence the discoloration effect of the bleeding surface upon this darker color will be minimized.

6. Precision and Bias

6.1 *Precision*—Due to the poor precision of this test method, if it is used in a specification, the permissible deviation from the maximum specified value should be agreed upon between the purchaser and the seller.

6.2 *Bias*—Bias cannot be determined.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.44 on Traffic Coatings.

Current edition approved Nov. 29, 1985. Published January 1986. Originally published as D 868 - 46 T. Last previous edition D 868 - 48 (1981)^{e1}.

TRAFFIC PAINT COLOR BLEEDING STANDARDS

FIG. 1 Degrees of Bleeding

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Evaluating Degree of Settling of Paint¹

This standard is issued under the fixed designation D 869; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^e) indicates an editorial change since the last revision or reapproval.

This method has been approved for use by agencies of the Department of Defense to replace Method 4208 of Federal Test Method Standard No. 141A. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

^{e1} NOTE—Editorial changes were made throughout, including the title, in October 1989.

1. Scope

1.1 This test method covers the determination of the degree of pigment suspension and ease of remixing a shelf-aged sample of paint to a homogeneous condition suitable for the intended use.

1.2 *This standard may involve hazardous materials, operations and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

- 2.1 *ASTM Standard:*
D1309 Test Method for Settling Properties of Traffic Paints During Storage²

3. Significance and Use

3.1 Paints, if not formulated or processed properly may settle excessively. Paint that settles excessively is difficult to reincorporate into the paint system causing time delays or valuable pigment being left in the drum. This test method is an attempt to evaluate the degree of settling caused by the accelerated Test Method D 1309. This very subjective method of evaluation in conjunction with the variables of Test Method D 1309 raises questions as to the usefulness of the results for specification compliance.

4. Apparatus

4.1 *Container*, standard 1-pt (500-mL) friction-top can paint container, $3\frac{3}{8} \pm \frac{1}{16}$ in. (85.5 $\pm$ 1.5 mm) in diameter, and $3\frac{7}{8} \pm \frac{1}{16}$ in. (98.5 $\pm$ 1.5 mm) in height.

4.2 *Spatula*, weighing 45 ± 1 g with square-end blade $4\frac{3}{4}$ in. (125 mm) in length and approximately $1\frac{3}{16}$ in. (20 mm) in width, shall be used to examine the paint for pigment settling and reincorporation characteristics.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.44 on Traffic Coatings.

Current edition approved Sept. 27, 1985. Published November 1985. Originally published as D 869 - 46 T. Last previous edition D 869 - 78.

² *Annual Book of ASTM Standards*, Vol 06.01.

5. Procedure

5.1 Place the specimen to be tested for pigment suspension in a 1-pt (500-mL) container, filling the can to within $\frac{1}{2}$ in. (13 mm) of the top. Close the can tightly and hold undisturbed for shelf aging for 6 months or for such other periods of time agreed upon between the purchaser and the seller.

5.2 Open the can holding the shelf-aged sample without shaking or agitation, and examine the sample without removal of supernatant vehicle. Use the spatula to determine the extent and character of portions of the paint that may have separated during storage. Prepare a suitable spatula for this purpose by cutting the tip from an ordinary 5-in. (127-mm) flexible steel laboratory spatula to the specified length. Hold the spatula perpendicular to and in the center area of the paint at a height whereby the bottom edge of the spatula is level with the top of the can. Drop the spatula from that position. Rate the condition of the sample in accordance with 5.4.

5.3 After examination of the entire specimen as described in 5.2, if a portion of the pigment has separated out to form a firm cake at the bottom of the container pour the supernatant portion of the liquid off into a clean container and hold for subsequent use. Reincorporate the separate cake by hand stirring with the spatula, adding back the liquid in small amounts until the pigment has been reincorporated to form a homogeneous paint suitable for the intended use or until it is determined that the pigment cake cannot be reincorporated by hand stirring. Rate the condition of the specimen in accordance with 5.4.

5.4 Rate the sample for degree of settling on a scale from 10 to 0 in accordance with the following. Give intermediate conditions the appropriate odd number.

Rating	Description of Paint Condition
10	Perfect suspension. No change from the original condition of the paint.
8	A definite feel of settling and a slight deposit brought up on spatula. No significant resistance to sidewise movement of spatula.
6	Definite cake of settled pigment. Spatula drops through cake to bottom of container under its own weight. Definite resistance to sidewise motion of spatula. Coherent portions of cake may be removed on spatula.
4	Spatula does not fall to bottom of container under its own weight. Difficult to move spatula through cake sidewise and slight edgewise resistance. Paint can be remixed readily to a homogeneous state.
2	When spatula has been forced through the settled layer it is very difficult to move spatula sidewise. Definite edgewise resistance to movement of spatula. Paint can be remixed to a homogeneous state.

Rating	Description of Paint Condition
0	Very firm cake that cannot be reincorporated with the liquid to form a smooth paint by stirring manually.

method, if it is used in a specification, the maximum deviation from the settling limits specified should be agreed upon between the purchaser and the seller.

6.2 *Bias*—Bias cannot be determined.

6. Precision and Bias

6.1 *Precision*—Due to the poor precision of this test

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Standard Practice for Testing Water Resistance of Coatings Using Water Immersion¹

This standard is issued under the fixed designation D 870; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers the basic principles and operating procedures for testing water resistance of coatings by the partial or complete immersion of coated specimens in distilled or de-mineralized water at ambient or elevated temperatures. Although the apparatus and procedure could be employed in immersion tests using solutions of various materials in water, this practice is limited to tests in water alone.

1.2 This practice is limited to the methods of obtaining, measuring, and controlling the conditions and procedures of water immersion tests. It does not specify specimen preparation, specific test conditions, or evaluation of results.

NOTE 1—Alternative practices for testing the water resistance of coatings include Practices D 1735, D 2247, and D 4585.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

D 3359 Test Methods for Measuring Adhesion by Tape Test²

D 3363 Test Method for Film Hardness by Pencil Test²

D 4585 Practice for Testing Water Resistance of Coatings Using Controlled Condensation²

3. Summary of Practice

3.1 Coated specimens are partially or wholly immersed in water in a container that is resistant to corrosion. The exposure conditions are varied by selecting: (a) the temperature of the water, and (b) the duration of the test. Water permeates the coating at rates that are dependent upon the characteristics of the coating and upon the temperature of the water. Any effects such as color change, blistering, loss of adhesion, softening, or embrittlement are observed and reported.

4. Significance and Use

4.1 Immersion in water can cause the degradation of coatings. Knowledge on how a coating resists water immersion is helpful in predicting its service life. Failure in a water immersion test may be caused by a number of factors including a deficiency in the coating itself, contamination of the substrate, or inadequate surface preparation. The test is therefore useful for evaluating coatings alone or complete coating systems.

4.2 Water immersion tests are used for research and development of coatings and substrate treatments, specification acceptance, and quality control in manufacturing. These tests typically result in a pass or fail determination, but the degree of failure may also be measured. A coating system is considered to pass if there is no evidence of water-related failure after a specified period of time.

4.3 Results obtained from water immersion tests in accordance with this practice should not be represented as being equivalent to a period of exposure to water in the natural environment, until the degree of quantitative correlation has been established for the coating or coating system.

4.4 Corrosion tests of a scribed coating on a ferrous substrate are impractical in water immersion tests as the corrosion products tend to contaminate the water bath. Continuous overflow of the test tank is sometimes required to maintain consistent water quality.

4.5 The apparatus for the test is relatively inexpensive and can be as simple as a glass beaker with a stirrer. It is also

⁵ Annual Book of ASTM Standards, Vol 14.02.

possible to use very large tanks for testing coated pipe or other large coated products.

5. Apparatus

5.1 *Tank*, constructed of corrosion-resistant materials. Heating units, if required, should preferably be located outside the tank.

5.2 *System*, for circulation of the water with pressurized air, a stirrer, or a pump.

5.3 *Supports for the Test Specimens*, constructed of non-conductive materials to hold the specimens 30 mm apart and 30 mm from the bottom and sidewalls of the tank.

NOTE 2—The circulating system is for the purpose of exposing all the water in the tank to room air so the water does not become stratified and oxygen-depleted at the lower levels.

6. Test Specimens

6.1 This practice does not cover the preparation of test specimens. The substrate composition and surface preparation, specimen preparation, and the number of specimens should be agreed upon prior to testing.

NOTE 3—Applicable methods for the preparation of test panels and substrates are given in Method D 609 and Practice D 1730. Test Methods D 823 covers application techniques for the production of uniform films.

7. Procedure

7.1 Fill the tank with water to a depth where the test specimens are immersed for approximately three-quarters of their length. Reagent water conforming to Type IV of Specification D 1193 is suitable for use.

7.2 Heat the water to the desired temperature with the circulating system in operation. If no temperature is specified, heat the water to $100 \pm 2^\circ\text{F}$ ($38 \pm 1^\circ\text{C}$). Maintain the temperature throughout the test.

7.3 Place the test specimens in the tank so that the plane of the specimens is parallel to the flow of water in the tank. Protect the edges and backs of the specimens from corrosion

if these surfaces are not to be tested.

7.4 Replace the water if it becomes cloudy or colored. Continuous replacement of the water is permitted.

7.5 Conclude the test after a specified period of time or after effects from water immersion have been observed.

7.6 Wipe the test specimens dry. Rate specimens for changes in color, blistering, etc. Evaluate specimens no less than 5 min and no more than 10 min after removal from test, as the effects from water exposure can change within a short time. Remove only as many specimens as can be rated within the specified time.

NOTE 4—The 0 to 10 scale described in ASTM STP 500⁶ is preferred for rating. Relevant procedures for evaluating water effects are described in Test Methods D 610, D 714, D 2616, D 3359, and D 3363.

7.6.1 If possible, rate the specimens again after they have been removed from the test for a recovery period long enough that moisture absorbed within the specimens dries out and the specimens reach moisture equilibrium with room air. A recovery period from 12 to 24 h is generally sufficient. The post-recovery rating allows evaluation of the permanent effects of the exposure as distinct from the transient effects, and is especially important for evaluation of color and gloss.

8. Report

8.1 Report the following information:

8.1.1 Sample identification.

8.1.2 Results of the evaluation(s).

8.1.3 Reference to Practice D 870.

8.1.4 Hours of test duration.

8.1.5 Test temperature.

8.1.6 Brief description of water quality and water replacement procedure.

8.1.7 Special conditions of test or any deviations in test procedure.

Standard Test Method for Evaluating Degree of Resistance to Wear of Traffic Paint¹

This standard is issued under the fixed designation D 913; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the evaluation of degree of resistance to wear that may occur with traffic paints in road tests (see Practice D 713) or in actual service, using photographic standards for comparative evaluation.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 ASTM Standard:

D 713 Practice for Conducting Road Service Tests on Fluid Traffic Marking Materials²

3. Description of Term Specific to This Standard

3.1 *failure, described by these reference standards*—that condition manifested in traffic paint by actual detachment of entire sections of the film from its substrate or from paint previously applied. The degree of resistance to failure is judged by the amount of substrate that is covered.

4. Significance and Use

4.1 This test method is designed to evaluate the resistance to wear of a traffic paint. It must be remembered that a high degree of performance of paint applied to a bare road surface may not guarantee similar results when the same paint is applied over old paint lines.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.44 on Traffic Coatings.

Current edition approved March 25, 1988. Published May 1988. Originally published as D 913 - 47 T. Last previous edition D 913 - 83.

² *Annual Book of ASTM Standards*, Vol 06.01.

5. Type of Failure

5.1 The failure as described in Section 3 does not presume any specific mechanism, and all areas where the substrate is visible shall be considered a failure.

6. Use of Photographic Reference Standards

6.1 The photographic reference standards³ that are part of this test method are representative of the degrees of resistance to wear of stripes of traffic paint. The examples shown in Fig. 1 are for illustration purposes only and should not be used for evaluation.

6.1.1 The degree of resistance to wear is likely to vary over any given area. It is therefore necessary to use one of the following grading methods:

6.1.1.1 Select an area as representative and base the rating of the stripe on this area or

6.1.1.2 Grade segments of the stripe and average these gradings.

6.1.2 The photographic reference standards (Note) represent four degrees (97 %, 92 %, 77 %, 60 %) of resistance to wear. Substrate revealed by failure is readily discernible with the naked eye.

NOTE—The reference standards are representative of stripes of traffic paints. The percentage of surface covered is shown on each reference standard.

7. Procedure

7.1 Compare the representative areas of the traffic paint stripes with the photographic reference standards and estimate the percent of intact film.

8. Report

8.1 Report the mean and range of the substrate coverage estimations, if appropriate.

³ Full-size (8 by 10-in. (203 by 254-mm)) glossy prints of the photographic reference standards showing degrees of chipping are available from ASTM Headquarters. Order PCN 12-409130-00.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. Standard Test Methods for Abrasion Resistance of Organic Coatings by Falling Abrasive¹

This standard is issued under the fixed designation D 968; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

These test methods have been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue that has been adopted by the Department of Defense.

¹ NOTE—Keywords were added editorially in January 1991.

1. Scope

1.1 These test methods cover the determination of the resistance of organic coatings to abrasion produced by abrasive falling onto coatings applied to a plane rigid surface, such as a metal or glass panel.

1.2 Two test methods based on different abrasives are covered as follows:

	Sections
Method A—Falling Sand Abrasion Test	1-12
Method B—Falling Silicon Carbide Abrasion Test	13-19

1.3 These methods should be restricted to testing in only one laboratory when numerical values are used because of the poor reproducibility of the methods (see 13.1.2 and 21.1.2). Interlaboratory agreement is improved significantly when ranking is used in place of numerical values.

1.4 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

² Annual Book of ASTM Standards, Vol 06.01.

³ Annual Book of ASTM Standards, Vol 14.02.

3. Terminology

3.1 Description of Term Specific to This Standard:

3.1.1 *abrasion resistance*—the amount of abrasive required to wear through a unit film thickness of the coating.

4. Summary of Test Methods

4.1 Abrasive is allowed to fall from a specified height through a guide tube onto a coated panel until the substrate becomes visible. The amount of abrasive per unit film thickness is reported as the abrasion resistance of the coating on the panel. Silica sand or silicon carbide may be used, as specified.

5. Significance and Use

5.1 Silica sand produces a slower rate of abrasion for organic coatings than provided by silicon carbide but, for some types of coatings, it provides greater discrimination.

5.2 The abrasion resistance scales produced by the two methods differ, but the methods provide approximately the same rankings of coatings for abrasion resistance.

5.3 Each of the methods has been found useful for rating the abrasion resistance of specific types of coatings. For example Method A (falling sand) has been used for rating floor coatings while Method B (falling silicon carbide) has been used for rating coatings for ship decks.

METHOD A—FALLING SAND ABRASION TEST⁴

6. Apparatus and Materials

6.1 *Abrasion Tester*, as illustrated in Figs. 1 and 2.⁵ A gate for starting the flow of abrasive is located near the top of the guide tube. It consists of a metal disk inserted into a slit in the side of the guide tube with a collar covering the slit. The guide tube shall be firmly supported in a vertical position over a suitable receptacle, which shall contain a support for holding the coated panel at an angle of 45° to the vertical, so that the opening of the tube is directly above the area to be abraded and the distance from the tube to the coated surface face at the nearest point is 1 in. (25 mm) when measured in the vertical direction. The base of the apparatus shall be fitted with adjusting screws for properly aligning the equipment.

⁴ Hipkins, C. C., and Phain, R. J., "The Falling Sand Abrasion Tester," *ASTM Bulletin*, No. 143, December 1946, pp. 18-22.

⁵ A suitable abrasion tester may be obtained from Gardner/BYK-Gardner, Inc., Gardner Laboratory, 2435 Linden Lane, Silver Spring, MD 20910.

accordance with Test Methods D 1005, D 1400 or D 1186.

8. Standardization

8.1 Pour a quantity of standard sand into the funnel. Examine the sand stream falling from the lower end of the guide tube and align the apparatus by means of the adjusting screws in the base until the inner concentrated core of the sand stream falls in the center of the flow when viewed at two positions at 90° to each other. Introduce a measured volume of sand (2000 ± 10 mL is a convenient amount) and determine the time of efflux. The rate of flow shall be 2 L of sand in 21 to 23.5 s.

8.2 Secure a trial panel in the testing position, as described in 6.1, and introduce the sand in increments until a spot $\frac{5}{32}$ in. (4 mm) in diameter is worn through to the base material. The overall abraded area shall be elliptical in shape, about 1 in. (25 mm) in width and $1\frac{1}{4}$ in. (30 mm) in length. The center of the area of maximum abrasion shall be on the center line through the longer axis of the abraded pattern and within $\frac{9}{16}$ to $1\frac{1}{16}$ in. (14 to 17 mm) of the top edge. Slight final adjustment of the instrument may be required to center the abrasion spot in the pattern. A final check on alignment is made by determining the amount of sand that passes through a $\frac{5}{32}$ -in. (4-mm) hole in a metal panel placed directly under the tube. Place a container under the hole in the panel and allow a weighed amount of sand to pass through the tube onto the panel. Weigh the amount of sand that passed through the hole into the container. The apparatus can be considered to be in calibration if the amount of sand that passed through the hole is 90 to 93 % of the

FIG. 1 Apparatus for Falling Sand Abrasion Test

6.2 *Standard Abrasive*—Natural silica sand from the St. Peters or Jordan sandstone deposits (located in the central United States) shall be considered standard when not more than 15 % of the grains in a sample are retained on a No. 20 (850 μ m) sieve and not more than 5% of the grains pass a No. 30 (600 μ m) sieve after 5 min of continuous sieving. The sand is characterized by its roundness of grains and its exceptionally high silicon dioxide content. Use the sieves described in Specification E 11.

NOTE 1—The abrading qualities of sand obtained from different sources may differ slightly, even though the sand meets the sieve requirements. Therefore, for maximum precision of test results, purchaser and seller should use sand from the same source.⁶

7. Test Specimens

7.1 Apply uniform coatings of the material to be tested to a plane, rigid surface such as a metal or glass panel. Prepare a minimum of two coated panels for the material.

7.2 Cure the coated panels under the conditions of humidity and temperature agreed upon between the purchaser and seller.

NOTE 2—The coatings should be applied in accordance with Test Methods D 823, or as agreed upon between the purchaser and the seller.

NOTE 3—The thickness of the dry coatings should be measured in

⁶Sources of acceptable sand are the Ottawa Silica Co., P.O. Box 577, Ottawa, IL 61350; the Quackenbush Co., 3 West College Dr., Arlington Heights, IL 60004; and the Unimin Corp., 50 Locust Ave., New Canaan, CT. 06840.

NOTE—All dimensions are given in inches. 1 in. = 25.4 mm.

amount of sand that impinged on the panel.

9. Conditioning

9.1 Unless otherwise agreed upon between purchaser and seller, condition the coated test panels for at least 24 h at $23 \pm 2^\circ\text{C}$ and $50 \pm 5\%$ relative humidity. Conduct the test in the same environment or immediately on removal.

10. Procedure

10.1 Mark off on each coated panel three circular areas, each approximately 1 in. (25 mm) in diameter, and so arranged that each can be properly positioned in the panel support of the abrasion tester. Measure the thickness of the coating by Test Methods D 1005, D 1186, or D 1400 in at least three locations in each area. Record the mean of each set of measurements as the thickness of the coating over the respective area.

10.2 After conditioning, secure the coated panel in the tester as described in 6.1. Adjust the panel so that one of the marked areas will be centered under the guide tube. Pour standard sand, measured volumetrically, into the funnel. Withdraw the gate and allow the sand to flow through the guide tube and impinge on the coated panel. Collect the sand in a container located at the bottom of the tester. Repeat this operation until a $\frac{5}{32}$ -in. (4-mm) diameter area of the coating has worn through to the substrate. A convenient increment of sand to employ during the test is 2000 ± 10 mL. As the end-point is approached, increments of 200 ± 2 mL may be introduced into the funnel.

NOTE 4—When the gate is withdrawn from the guide tube, make certain that a collar covers the slit opening in the tube.

10.3 Abrade each of the remaining marked-off areas of the coated panel as outlined in 9.2.

NOTE 5—Check the alignment of the guide tube at frequent intervals to ensure that the concentrated inner core of the sand stream is falling in the center of the flow.

NOTE 6—After 25 passes through the apparatus, resieve the sand with a No. 30 sieve to remove fines. Replace the sand after 50 passes.

10.4 Repeat 10.1 to 10.3 on at least one additional panel coated with the material under test.

11. Calculation

11.1 For each area of the coated panel tested, calculate the abrasion resistance, A , in litres per mil from the following equation:

$$A = V/T$$

where:

V = volume of abrasive used, L (to one decimal place) and
 T = thickness of coating, mils (to one decimal place).

11.2 Calculate the mean of the abrasion resistance values obtained for different areas of the coated panel and the mean value of the replicate panels.

12. Report

12.1 Report the following information for each coated panel tested:

12.1.1 Temperature and humidity during curing and at the time of testing,

12.1.2 Type and source of abrasive,

12.1.3 Litres of abrasive used for each area tested,

12.1.4 Coating thickness in mils for each area tested,

12.1.5 Abrasion resistance values for each area tested,

12.1.6 Mean abrasion resistance for each coated panel tested, and

12.1.7 Mean abrasion resistance and range of the replicate coated panels.

13. Precision⁷

13.1 On the basis of an interlaboratory test of this test method in which three laboratories tested four types of coatings differing in their abrasion resistance, the within-laboratory coefficient of variation was found to be 9 % with 22 degrees of freedom and the between-laboratories coefficient of variation 35 % with 7 degrees of freedom. Based on these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level.

13.1.1 *Repeatability*—Two results, each the mean of three runs, obtained by the same operator should be considered suspect if they differ by more than 25 % of their mean value.

13.1.2 *Reproducibility*—Two results, each the mean of three runs, obtained by operators in different laboratories should be considered suspect if they differ by more than 118 % of their mean value.

NOTE 7—The reproducibility of this test is improved substantially when rankings of the coatings by magnitude of abrasion resistance are used. In the interlaboratory test for evaluating precision, all laboratories ranked the coatings in the same order.

METHOD B—FALLING SILICON CARBIDE TEST

14. Apparatus and Materials

14.1 *Abrasion Tester*, as described in 6.1, with two exceptions:

14.1.1 A metal washer with an opening of 8.5 ± 0.1 mm is centered in the bottom opening of the funnel to restrict the flow of the abrasive.

14.1.2 The disk gate installed in a slit at the top of the guide tube may be replaced by a gate in the bottom of the funnel. This gate consists of a solid metal disk attached to a long vertical screw and mounted above the washer.

14.2 *Standard Abrasive*⁸—Silicon carbide grain shall be considered standard when graded as follows after a suitable period of continuous sieving:

Less than 1 % retained on a No. 10 (2.00 mm) sieve
Maximum of 20 % retained on a No. 14 (1.40 mm) sieve
0 % pass a No. 20 (0.85 μm) sieve

14.2.1 Use the sieves described in Specification E 11.

15. Test Specimens

15.1 Prepare the coated panels as outlined in 7.1 and 7.2.

16. Standardization

16.1 Standardize the abrasion tester by the procedures

⁷ Supporting data are available from ASTM Headquarters. Request RR-D01-1037.

⁸ An acceptable silicon carbide grain is #16 grade Carborundum, obtainable from the Carborundum Co., P.O. Box 423, Electro Minerals Div., Niagara Falls, NY 14302. A suitable equivalent may be used.

the procedures

rs. Request RR:D01-

orandum, obtainable is Div., Niagara Falls

given in 8.1 and 8.2, with the following exceptions:

- 16.1.1 Use silicon carbide where sand is specified.
- 16.1.2 Weigh the volume of silicon carbide to be introduced into the tester. Determine the efflux time for this volume. The rate of flow shall be 10 ± 1 g/s.

17. Conditioning

17.1 Unless otherwise agreed upon between purchaser and seller, condition the coated panels for at least 24 h at $23 \pm 2^\circ\text{C}$ and 50 ± 5 % relative humidity. Conduct the test in the same environment or immediately on removal therefrom.

18. Procedure

18.1 Measure the thickness of the coating by the procedures given in 10.1.

18.2 Abrade the coated panel by the procedures given in 10.2 and 10.3 using silicon carbide as the abrasive. Determine the volume or weight, or both, of abrasive used to reach the end point.

18.3 Repeat 18.1 and 18.2 on at least one additional coated panel of the material under test.

19. Calculation

19.1 For each area of the coated panel tested, calculate the abrasion resistance in litres per mil from the equation given in 10.1 or, calculate the abrasion resistance, A , in kilograms per mil from the equation:

$$A = W/T$$

where:

W = weight of abrasive used, kg (to one decimal place) and T = thickness of coating, mils (to one decimal place).

19.2 Calculate the mean of the abrasion resistance values

obtained at different locations on the test specimen and the mean values of the replicate panels.

20. Report

20.1 Report the information specified in Section 12. Abrasion resistance may be reported as litres per mil or as kilograms per mil.

21. Precision⁷

21.1 On the basis of an interlaboratory test of this test method in which operators in three laboratories tested four coatings having a broad range of abrasion resistance, the within-laboratory coefficient of variation was found to be 19 % with 16 degrees of freedom and the between-laboratories coefficient of variation 45 % with 8 degrees of freedom. Based upon these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

21.1.1 *Repeatability*—Two results, each the mean of three runs, obtained by the same operator should be considered suspect if they differ by more than 56 % of their mean value.

21.1.2 *Reproducibility*—Two results, each the mean of three runs, obtained by operators in different laboratories should be considered suspect if they differ by more than 147 % of their mean value.

NOTE 8—The reproducibility of this test is improved substantially when rankings of the coatings by magnitude of abrasion resistance are used. In the interlaboratory test for evaluating precision, all laboratories ranked the coatings in the same order.

22. Keywords

22.1 abrasion (of paints/related coatings); falling abrasive tester; falling sand abrasion test; falling silicon carbide abrasion test; resistance, abrasion

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Laboratory Determination of Degree of Bleeding of Traffic Paint¹

This standard is issued under the fixed designation D 969; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{ε1} NOTE—Editorial changes were made throughout, including the title, in October 1989.

1. Scope

1.1 This test method covers a laboratory test procedure for determining the degree of bleeding of traffic or pavement marking paints.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 476 Specification for Titanium Dioxide Pigments²

D 867 Specification for Pumice Pigment²

D 868 Test Method for Evaluating Degree of Bleeding of Traffic Paint³

D 1199 Specification for Calcium Carbonate Pigments²

2.2 Adjunct:

D 868 Bleeding resistance of paint (one photo)⁴

3. Significance and Use

3.1 Solvents in a traffic paint may cause bleeding of pavement constituents into the traffic marking, thereby rendering the traffic marking less effective as a lane or directional indicator. This test method describes how to prepare a panel for evaluation. The very subjective method of evaluating the degree of bleeding raises questions as to the usefulness of the result for specification compliance.

4. Apparatus

4.1 Film Applicator—A conventional type drawdown

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.44 on Traffic Coatings.

Current edition approved Nov. 29, 1985. Published January 1986. Originally published as D 969 - 48 T. Last previous edition D 969 - 54 (1981)^{ε1}.

Standard Test Method for Measurement of Dry-Film Thickness of Organic Coatings Using Micrometers¹

This standard is issued under the fixed designation D 1005; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

⁶¹ NOTE—Figure 1 which was inadvertently deleted was editorially included in May 1990.

1. Scope

1.1 This test method covers the measurement of film thickness of dried films of paint, varnish, lacquer, and related products using micrometers. Procedures A and B utilize stationary micrometers and Procedures C and D, hand-held micrometers. Procedures A and C are not recommended for films less than 0.5 mils (12.5 μm) in thickness. The minimum thickness required for Procedures B and D is a function of that required to enable removal of the sample as a free film.

1.2 The procedures appear as follows:

1.2.1 *Procedure A*—Stationary micrometer for measuring coatings applied to plane rigid surfaces.

1.2.2 *Procedure B*—Stationary micrometer for measuring free films.

1.2.3 *Procedure C*—Hand-held micrometer for measuring coatings applied to plane rigid surfaces.

1.2.4 *Procedure D*—Hand-held micrometer for measuring free films.

1.3 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D609 Methods for Preparation of Steel Panels for Testing Paint, Varnish, Lacquer, and Related Products²

D823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels²

D2370 Test Method for Tensile Properties of Organic Coatings²

3. Significance and Use

3.1 This test method is particularly applicable to the measurement of free films and is also satisfactory for the

measurement of films on laboratory test panels.

3.2 The accuracy and precision of the thickness measurements may be influenced by the deformability of the coating. This test method is not applicable to coatings that are readily deformable under the load of the measuring instrument.

3.3 The accuracy and precision of the thickness measurements are also influenced by the uniformity of the substrate when the coatings are applied to laboratory test panels.

4. Apparatus

4.1 Procedures A and B:

4.1.1 The apparatus shall consist of a dial comparator, dial indicator, or micrometer. A rigid base is required for mounting the dial comparator or dial indicator gages. The presser foot of the micrometer or dial indicator shall be circular, from $\frac{1}{16}$ to $\frac{1}{8}$ in. (1.5 to 3.0 mm) in diameter, and shall be flat on the bottom. The presser foot shall be fixed to an indicator that reads to 0.1 mil (2.5 μm). The load on the presser foot shall be between 20 and 40 psi (140 and 275 kPa). For Procedure B, a smooth uncoated test plate is also required.

4.1.2 Verify the accuracy of instrument calibration by setting to zero with the anvils closed followed by measuring shims of known thicknesses or standards specifically designed for this purpose. Record the standard thickness gage measurement and the micrometer reading. Use these results to construct a calibration curve.

4.2 *Procedures C and D*—The apparatus shall consist of a hand-held micrometer. The anvils of the micrometer shall be circular, from $\frac{1}{16}$ to $\frac{1}{8}$ in. (1.5 to 3.0 mm) in diameter, with flat bottoms. Verify the accuracy of instrument calibration by setting to zero with the anvils closed followed by measuring shims of known thicknesses or standards specifically designed for this purpose. Record the standard thickness gage measurement and the micrometer reading. Use these results to construct a calibration curve.

5. Test Specimens

5.1 *Procedures A and C*—Apply test films to a suitable plane, rigid base material from which the dried film may be satisfactorily removed. The panels shall be of sufficient size to permit film thickness measurements to be made 1 in. (25 mm) from any edge.

5.1.1 Coatings should be applied in accordance with Test

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.23 on Physical Properties of Applied Paint Films.

Current edition approved Aug. 31, 1984. Published December 1984. Originally published 1949. Last previous edition D 1005 - 51(1979).

² Annual Book of ASTM Standards, Vol 06.01.

Methods D 823 or as agreed upon between the purchaser and the seller.

5.2 *Procedures B and D*—Free films of the test material are required. Alternatively, the test materials can be applied to an appropriate substrate in order that they can be removed as free films without deformation. If the method of specimen preparation affects the film forming properties of the test material or requires cutting or scraping to remove the free film, use Procedures A or C instead.

5.2.1 Free films may be prepared in accordance with Test Method D 2370.

6. Procedure

6.1 Procedure A:

6.1.1 Mount the test panel rigidly on a suitable base. Clamp or hold it to the base in such a way that there will be no movement or spring of the panel during the film thickness measurement.

6.1.2 Close the gage slowly until contact is made, but without visible distortion of the film. Read the gage, estimating to 0.1 mil (2.5 μm), and record the reading.

6.1.3 Open the gage and remove the film carefully from the area where the measurement was taken. Any suitable means, chemical or mechanical, may be used to remove the film, taking care not to distort the panel. Close the gage, slowly on the area from which the film was removed, and take a reading, estimating to 0.1 mil (2.5 μm).

6.1.4 The difference in the gage readings before and after the removal of the film is the thickness of the film. Record to 0.1 mil (2.5 μm).

6.1.5 As an alternative to the above, the panels may be measured in distinct locations prior to the application of the coating, and again in the identical locations after the coating has cured. The difference represents the coating thickness.

6.1.6 Take a sufficient number of readings to characterize the panel. A recommended minimum is three determinations for a 3 by 6-in. (75 by 150-mm) panel and more in proportion to size.

6.2 Procedure B:

6.2.1 Mount a smooth uncoated test panel rigidly on a suitable base. Clamp or hold it to the base in such a way that there will be no movement or spring of the panel during the film thickness measurement. Figure 1 illustrates one satisfactory way of rigidly mounting the panel for measurement.

6.2.2 Close the gage slowly until contact is made. Read the gage, estimating to 0.1 mil (2.5 μm), and record the reading.

6.2.3 Open the gage and lay a free film of the test material on the panel in the same area where the measurement was taken. Close the gage slowly with care not to distort the film and take a reading, estimating to 0.1 mil (2.5 μm).

6.2.4 The difference in the gage readings is the thickness of the film. Record to 0.1 mil (2.5 μm).

6.2.5 When conditions permit, perform a minimum of three determinations adjacent to one another on each film.

6.3 Procedure C:

6.3.1 Hold the hand-held micrometer in such a manner that the micrometer can be steadied against a film surface. Separate the micrometer anvils to a distance at least twice that of the film thickness to be measured.

6.3.2 Place the coated base material between anvil con-

FIG. 1

tacts. Be sure to align the panel so that it is perpendicular to the contact points. Carefully bring the micrometer anvil into contact with the film by releasing the spring tension or rotating the adjustment barrel. Do not compress the film.

6.3.3 Record the film thickness to 0.1 mil (2.5 μm). For spring-loaded micrometers, record the value directly from the dial indicator. For barrel micrometers, record the value using the instrument in the friction mode. The friction mode allows the thimble sleeve to slip without further turning the measuring screw. The friction mode provides for a consistent measuring pressure from panel to panel.

6.3.4 Open the gage and remove the film carefully from the area where the measurement was taken. Any suitable means, chemical or mechanical, may be used to remove the film, taking care not to distort the panel. Close the gage, slowly on the area from which the film was removed, and take a reading, estimating to 0.1 mil (2.5 μm).

6.3.5 The difference in the gage readings before and after the removal of the film is the thickness of the film. Record to 0.1 mil (2.5 μm).

6.3.6 As an alternative to the procedures in 6.3.2 through 6.3.5, the panels may be measured in distinct locations prior to the application of the coating, and again in the identical locations after the coating has cured. The difference represents the coating thickness.

6.3.7 Take a sufficient number of readings to characterize the panel. A recommended minimum is three determinations for a 3 by 6-in. (75 by 150-mm) panel and more in proportion to size.

6.4 Procedure D:

6.4.1 Hold the hand-held micrometer in such a manner that the micrometer can be steadied against a film surface. Separate the micrometer anvils to a distance at least twice that of the film thickness to be measured.

6.4.2 Place the free film to be measured between anvil contacts. Be sure to align the film so that it is perpendicular to the contact points. Carefully bring the micrometer anvil into contact with the film by releasing the spring tension or rotating the adjustment barrel. Do not compress the film.

6.4.3 Record the film thickness to 0.1 mil (2.5 μm). For spring-loaded micrometers, record the value directly from

the dial indicator. For barrel micrometers, record the value using the instrument in the friction mode. The friction mode allows the thimble sleeve to slip without further turning the measuring screw. The friction mode provides for a consistent measuring pressure from film to film.

6.4.4 When conditions permit, perform a minimum of three determinations adjacent to one another on each film.

7. Report

7.1 Report the results as the mean thickness of a number of determinations, accompanied by a statement of the number of observations and the standard deviation of the determinations.

8. Precision and Bias

8.1 *Precision*—On the basis of an interlaboratory study of Procedure C in which operators in two laboratories on two or three days made four replicate measurements on each of three coated panels differing in film thickness, the within-laboratory standard deviations were found to be 0.17 mil at the 1-mil thickness level, 0.32 mils at the 4-mil thickness level, and 0.28 mil at the 8-mil thickness level. On the basis of the same interlaboratory study of Procedure C in which operators in seven laboratories made four replicate measure-

ments on each of three coated panels differing in film thickness, the between-laboratories standard deviations were found to be 0.09 mil at the 1-mil thickness level, 0.29 mil at the 4-mil thickness level, and 0.33 mil at the 8-mil thickness level. Based on these standard deviations, the following criteria should be used to judge the precision of results at the 95 % confidence level:

8.1.1 *Repeatability*—Two measurements, each the mean of four replicates, obtained by the same operator should be considered suspect if they differ by more than 0.7 mil at the 1-mil thickness level and by more than 1.2 mils at the 4 to 8-mil thickness level.

8.1.2 *Reproducibility*—Two measurements, each the mean of four replicates, obtained by operators in different laboratories should be considered suspect if they differ by more than 0.3 mils at the 1-mil thickness level and by more than 1.1 mils at the 4 to 8-mil thickness level,

8.2 *Bias*—Bias has not been determined.

9. Keywords

9.1 dial comparator; dial indicator; dial indicator gage; film—dry film thickness; measurement of organic coatings; micrometer

Standard Practice for Conducting Exterior Exposure Tests of Paints on Wood¹

This standard is issued under the fixed designation D 1006; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This practice has been approved for use by agencies of the Department of Defense to replace Method 6161.1 of Federal Test Method Standard No. 141A and for listing in the DoD Index of Specifications and Standards.

^{e1} NOTE—Editorial changes were made throughout in April 1986.

1. Scope

1.1 This practice deals only with the testing of house paints and trim paints on new, previously unpainted wood.

1.2 This practice describes a test procedure that embodies the principles considered necessary for reliable results. Variations necessitated by circumstances may be introduced by agreement provided they do not violate these principles. One procedure embodying the principles is described in the Annex for use by those who find it convenient.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 358 Specification for Wood to Be Used As Panels in Weathering Tests of Coatings²

D 1150 Single and Multi-Panel Forms for Recording Results of Exposure Tests of Paints²

2.2 U.S. Federal Standard:

TT-W-571b Federal Specification for Wood-Preservative, Recommended Treating Practice³

3. Significance and Use

3.1 The procedure described in this practice is intended to aid in evaluating the performance of house and trim paints applied to new, previously unpainted wood.

3.2 Since natural environment varies with respect to season, geography, and topography, test results can vary in accordance with location and may not correlate to actual in-service performance (5.1).

4. Extent of Test Program

4.1 The extent of the exterior exposure test program must be governed by the breadth of the conclusions desired. The

types of paints to be tested, the range in climatic conditions to be met, also the types of woods and structures on which the paints are to be used are important factors to be considered in establishing the exposure program.

5. Location of Test Stations

5.1 The climatic conditions of the test sites should be representative of those of the area in which the paints are to be used. The type and rate of failure of a paint film will vary when exposed to different combinations of climatic and atmospheric conditions. For reliable results, exposure sites should be selected that are representative geographically, climatically, and in atmospheric contaminations with those of the locality in which the paint will be used. To obtain conclusions that are valid for paints with national distribution requires exposure at several sites, selected to cover a wide range in climatic conditions.⁴

6. Exposure Positions

6.1 Panels for testing house paints and trim paints should be exposed on vertical test fences facing both south and north. In comparisons where dirt collection and mildew resistance are not pertinent, north vertical exposures may be omitted. There should be no obstructions close enough to shade test panels from the sun more than 2 h after sunrise, or 2 h before sunset.

6.2 In the case where it is desirable to expose coated panels in a sheltered area, such as under eaves, a suitable test fence with a sheltered or eave arrangement can be used (see Annex).

7. Construction of Test Fences

7.1 Test fences should be durable and rigid enough to remain upright under the action of prevailing winds and frost throughout the contemplated period of testing.⁵

7.2 Lower edges of test panels, when mounted on test fences, should be at least 18 in. (460 mm) above ground level to avoid dampness and mud splash. Backs of painted boards or plywood should be protected against direct exposure to the weather by methods such as, (1) having panels on both

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.27 on Accelerated Testing.

Current edition approved Oct. 29, 1973. Published December 1973. Originally published as D 1006 - 51 T. Last previous edition D 1006 - 56 (1970).

⁴ Suggested sites include the Great Lakes region, Florida, extreme southern Louisiana, the southwest region, and northeast region.

⁵ Fences, such as presented by W. A. Southard in the May 1959 issue of the *Official Digest*, are acceptable.

sides of the fence, (2) mounting the panels on sheathing, and (3) closing the opposite side of the fence.

7.3 Fences should have watertight caps to keep water from getting behind test panels.

8. Selection of Woods for Test Panels

8.1 Paint need be tested only on woods on which it is likely to be used in practice. Conclusions drawn from tests made on a limited variety of woods, however, should not be generalized for woods of other kinds.

NOTE—See Specification D 358.

8.2 Prior to use, test lumber and panels should be stored under such conditions that the moisture content of the wood will be maintained within the normal range for exterior woodwork in the region in which the tests are made.

9. Construction of Test Panels

9.1 For house paints, unless the pattern of the siding requires some other choice, test panels should be made of one or the other of two patterns of siding, namely, $\frac{1}{2}$ or $\frac{3}{4}$ by 6-in. (13 or 20 by 150-mm) bevel siding or 1 by 6-in. (25 by 150-mm) drop siding.

9.2 If the panels in the house paint test are not subdivided, one 3-ft (900-mm) length of 6-in. (150-mm) siding will be acceptable. If the panels are subdivided, two 18-in. (460-mm) lengths are sufficient. Exposures on wood panels should preferably be carried out on three panels to allow for variations in the wood.

9.3 For trim paints, the test panel should carry 1 by 4-in. (25 by 100-mm) pieces of trim lumber at each end.

9.4 A test panel of 1.5 ft² (1400 cm²) or more in area, as provided in 9.2, may be subdivided into two or more test areas each not less than 10 in. (250 mm) long and 0.75 ft² (700 cm²) in area. Each test area is for painting with a different paint. Paints placed on the test areas of one panel furnish a comparison as to behavior.

9.5 When it will not interfere with the properties to be tested, all panels should be coated on the back to prevent warping.

10. Control or Comparison Paint for Extending the Comparisons

10.1 When several paints are to be compared, one paint should be selected as a standard of comparison or "control." The control paint should then be applied on one test area of each test panel. Variations caused by wood differences are revealed in the behavior of the control paint, and can be used to adjust the ratings of the other paints to a common basis.

For best results there should be two controls—one known to perform well and one known to perform poorly.

11. Application of Paints

11.1 All tests that are to be compared closely with one another should be placed on exposure as nearly simultaneously as possible. When a group of tests is too extensive for completion within a month, use a control paint or duplicate of at least 5 % of the test areas at successive exposure periods.

11.2 It is best in theory and practice to do the painting out-of-doors in proper weather for painting; however, indoor painting is permissible provided no more than 1 week⁶ elapses between successive coats and between applying the last coat and exposing on the test fence; and provided, further, that all painting is done under essentially the same drying conditions. It is necessary to allow each coat to cure sufficiently before top coating.

11.3 Preferred procedure is to apply paints with the test panel in a vertical position and kept vertical until the paint has set. If paint is spread on horizontal panels, the panels should be placed vertically immediately thereafter.

11.4 Records should be kept of the spreading rates at which paints are applied. When the purpose of the tests is to compare commercial paints, it may be appropriate to let the painter apply them at what seems to be their natural spreading rates. When the purpose is to study variation in paint composition, application should usually be at suitable predetermined spreading rates which can be controlled by applying a given weight or volume of coating to a measured area.

12. Inspections and Records

12.1 After panels have been exposed to the weather, inspections should be made after not more than 1 month, at 3 months, and at intervals of 3 months during the first 2 years, and every 6 months thereafter. Midwinter inspections, however, may be omitted in northern latitudes.⁷ Inspections may be made more frequently if desired. Usually the exposures should be continued for a considerable length of time after deterioration has reached the point at which best practice calls for repainting.

12.2 Records should be kept on forms such as Standard D 1150.⁸

⁶ Seventy-two hours is the preferred maximum.

⁷ Inspection should be made to assure that exposed panels are not covered by accumulated snow banks.

⁸ These record sheets may be obtained from ASTM Headquarters (order, Adjunct No. 12-411500-11 and 12-411500-21) and from the Federation of Societies for Coatings Technology, 492 Norristown Rd., Blue Bell, PA 19422.

ANNEX

(Mandatory Information)

A1. CONSTRUCTION OF TEST FENCE AND TEST PANELS

A1.1 The plan for test fence and panels described in this Annex conforms to the principles set forth in this practice. It represents only one of numerous possible embodiments of the principles recommended.

A1.2 Construction of Test Fence:

A1.2.1 The test fence, or test rack, runs east and west, and is constructed to hold test panels on both sides so that there are panels facing both north and south. There are two rows of panels, one above the other, on each side of the fence. A 90° cap is placed along the top of the fence, and projects approximately 1 in. (25 mm) beyond the face of the mounted panels. The fence must be sufficiently sturdy in construction to withstand strong winds. It is mounted on wood posts that are impregnated with creosote under pressure, in accordance with Fed. Spec. TT-W-571b.

A1.2.2 Figure A1.1 shows one span or unit. The fence can be extended to as many units as the site permits or as are needed for the number of exposure tests to be made. Additional fences may be built parallel to one another, but they should be spaced far enough apart to keep each fence from casting shadows on the adjacent fences during all but the first 2 h after sunrise and the last 2 h before sunset at the time of the winter solstice.

A1.2.3 When cleated panels of drop siding, which do not have backing, are used, there shall always be a pair of panels, one facing north and one facing south, to give the backs mutual protection from the weather. If for any reason there are panels on one side only of the fence, the other side shall be covered with roofing paper or other covering to protect the backs of the panels.

A1.3 Construction of Test Panels:

A1.3.1 House Paints—The boards of siding are assembled in a manner similar to house construction. Five pieces of ½ by 6-in. (13 by 150-mm) bevel siding are nailed securely on a backing of ¼-in. (6-mm) plywood exterior grade, as shown in Fig. A1.2. The top board is a blank connecting board, cut to narrower width and painted as hereinafter described. The other four boards are test boards: they may be all of one species or two each of two different species. The overlap between boards should be not less than 1 in. (25 mm). Cadmium- or zinc-coated nails, 1½ in. (28 mm) long, should be used and should be spaced as indicated, and clinched on the back. The lower edge of the bottom board is shimmed out from the plywood with a wood shim and the bottom board projects ¼ in. beyond the shim in order to permit insertion of a panel underneath. The top of the panel, which

NOTE—1 in. = 25.4 mm; 1 ft = 0.3048 m.

FIG. A1.1 ASTM Panel Rack for Exterior Exposure of Paints

is a blank board precoated with chalk-resisting exterior paint such as aluminum paint, is cut to a width of $4\frac{1}{2}$ in. (115 mm); the cutting makes a suitable shim for use under the bottom board. The plywood projects $\frac{1}{2}$ in. beyond the boards at the ends and 1 in. (25 mm) at the bottom; at the top the plywood projects 2 in. (50 mm) beyond the top of the second board and is overlapped by about $2\frac{1}{2}$ in. (65 mm) by the top blank board. Holes are bored through the top blank board as indicated to permit positioning of the panel on the fence by means of small pegs. Holes are bored through the projecting ends of the plywood to permit secure fastening of the panels to the fence by means of wood clamps held in position by bolts with wing nuts as indicated (see also Fig. A1.1).

A1.3.1.1 Panels made of 6-in (150-mm) drop siding should consist of four test boards 37 in. (940 mm) long, and a narrow blank connecting board 3 in. (75 mm) wide, fitted snugly together and held by three cleats, $\frac{3}{8}$ by 2 in. (16 by 50 mm) wide, nailed firmly on the backs. By adjusting the width

of the blank connecting board the dropsiding panels can be made to fit on fences designed as shown in Fig. A1.1, although it may be impracticable to mount both types of panel together on the same fence.

A1.3.2 *Trim Paints*—An example of a panel for testing trim paint is shown in Fig. A1.3. It is a modification of the panel shown in Fig. A1.2. The modification consists in shortening the pieces of siding to 27 in. (685 mm) to make room for two pieces of trim lumber, 1 by 4 in. (25 to 100 mm), at each end; and in narrowing the exposed width of the siding to 4 in. to make room for another piece of trim lumber, 1 by 6 in. (25 by 150 mm), across the top. This piece is undercut, as shown in the sketch, so as to fit over the siding. The cap may be made of galvanized iron, aluminum, or painted iron. No blank connecting boards between two panels are needed. The panel may be fastened to the fence in the same way as the body paint panel. A much less elaborate panel, satisfactory in many cases, is merely a plain board, approximately 1 by 6 by 36 in. (25 by 150 by 915 mm).

NOTE—1 in. = 25.4 mm.

FIG. A1.3 ASTM Test Panel for Exterior Exposure of Trim Paints

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Conducting Exterior Exposure Tests of Paints on Steel¹

This standard is issued under the fixed designation D 1014; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This test method has been approved for use by agencies of the Department of Defense to replace Method 6160 of Fed. Test Method Std. No. 141 A and for listing in the DoD Index of Specifications and Standards.

¹ NOTE—Editorial changes were made throughout in March 1988.

1. Scope

1.1 This test method covers the determination of the relative service of exterior paints and other materials of similar purpose when applied on steel surfaces exposed out-of-doors.

1.2 Experience indicates that the steel used as a test surface has a marked bearing upon the weathering results. It is the purpose of this test method to minimize the influence of variation in steel surfaces on any series of tests by providing for uniformity in the selection of the steel surface, particularly in cooperative work. This test method also outlines uniform procedures for conducting the exposure tests and for evaluating and recording results.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

G 7 Practice for Atmospheric Environmental Exposure Testing of Nonmetallic Materials⁴

3. Significance and Use

3.1 The procedures described in this test method are intended to aid in evaluating performance of coatings on either new or previously rusted steel.

3.2 Since the natural environment varies with respect to season and geographic location, test results may not correlate with in-service performance.

4. Base Materials for Test Specimens

4.1 A minimum of two and preferably four test specimens shall be used to evaluate the performance of any paint system.

4.2 The surface preparation for the test panels should be that expected to be done in the field or in-service. The surface preparation shall be the same for all test panels in the test program unless surface preparation is one of the variables to be evaluated. Surface preparation must be essentially identical for all test panels, as the thoroughness of preparation may directly determine the performance life of the applied coating system.

4.3 The test panels should be fabricated from the same material over which the coating is expected to perform in-service. Any of the following surfaces may be used:

4.3.1 *Abrasive Blasted Steel Plate*—The steel plate shall conform to Specification A 36 or Specification A 283. The minimum thickness shall be $\frac{1}{16}$ in. (1.6 mm). The minimum size shall be 4 by 6 in. (100 by 150 mm). Burrs and sharp projections shall be removed from the edges by filing. The test panels shall be freed of oil by suitable grease-removing solvents in accordance with Methods B, C, or D of Methods D 609. The surface shall be blasted to meet the requirements

of Standard D 2200, $Sa\ 2\frac{1}{2}$, if another degree of surface preparation has not been agreed upon.

4.3.2 Rusted Surfaces—Hot rolled steel angle or plate, or both, are useful for determining the performance of paints applied to structures that cannot be thoroughly cleaned of rust and corrosion products. The steel angle and plate shall conform to Specification A 283. The steel angles shall be at least 4 by 4 by $\frac{1}{8}$ in. (100 by 100 by 3.2 mm) in cross section and 12 in. (305 mm) in length. The minimum size of the steel plate shall be 4 by 6 in. (100 by 150 mm) with a minimum thickness of $\frac{1}{16}$ in. (1.6 mm). Burrs and sharp projections shall be removed from the edges by filing. The test pieces shall be freed from oil by the use of suitable grease-removing solvents in accordance with Methods B, C, or D of Methods D 609. Those persons desiring to test coatings over rusty or slightly rusted surfaces (Note 1) should refer to Standard D 2200, select the degree of rusting desired from the rust grades given, and utilize the degree of surface preparation that can be accomplished in the field or on the job.

NOTE 1—When testing over rusty surfaces, the test specimens should preferably be pre-corroded (weathered) in the same environment in which they ultimately will be exposed. The environment in which the steel is rusted prior to painting has considerable influence on the performance of paint applied to such steel. Artificial rusting, however, is permitted but conditions must be stated in the test report.

4.3.3 Cold-Rolled Steel Strip—Cold-rolled steel strip has a slightly roughened surface free from mill scale and rust, and is useful for checking the relative performance of paints on a clean, uniform surface. The steel strip shall conform to one of the types described in Methods D 609. The panels shall be not less than 4 by 6 in. (102 by 152 mm) in size and all edges shall be smooth and uniformly rounded. The metal panels shall be prepared by the agreed upon method (A, B, C, or D) in Methods D 609.

4.4 After surface preparation, the panels shall be prime coated as soon as possible to prevent flash rusting or deposit of any foreign contaminant on the cleaned surface. After surface preparation, if the panels are stored prior to coating, precautions must be taken to preserve the clean surface.

5. Painting Test Specimens

5.1 Apply all coatings in strict accordance with the coating manufacturer's written recommendations. The method of application expected for the production work on the job should also be used for test panel application.

5.2 If the method of application is unknown select one of the following (Note 2):

- Method A—Automatic Spray Machine
- Method B—Automatic Dip Coater
- Method C—Manual Spray Application
- Method D—Motor Driven Blade Applicator
- Method E—Brush Application
- Method F—Roller Coating
- Method G—Curtain Coating

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

NOTE 2—Details for the application of paint by Methods A, B, or D are given in Test Methods D 823.

5.3 Measure and record the film thickness of each coat in accordance with the methods recommended in Test Methods D 1186. If the test panel is covered by rust and mill scale, these methods will be less accurate, as they are influenced by the surface characteristics of this base metal. In such cases, approximations can be made by wet film thickness measurements in accordance with Methods D 1212, or the amount of paint applied to a known area can be weighed and the average dry film thickness computed. It should be noted that even though dry film thickness measurements in accordance with Test Methods D 1186 are less accurate on surfaces with rust and mill scale than on smooth steel surfaces, they are still more accurate than those obtained by Methods D 1212 or weighing.

5.4 Allow the proper drying time between coats for multiple paint systems and before exposure as required by the coatings manufacturer and include in the test record.

5.5 Paint the back and edges of all test specimens with the same systems as that being tested on the front of each panel. This painting provides considerable information on the behavior of the paint system on the reverse side.

5.6 The test specimens may be scribed to base metal prior to exposure. Rate any corrosion from this point of damage in accordance with Methods D 610.

6. Exposure

6.1 The type of exposure and the position of the painted specimens may be selected from the following:

- 5°, facing south
- 45°, facing south
- 45°, facing north
- Vertical, facing south
- Vertical, facing north

Insulated (backed or black box) in accordance with Practice G 7.

6.2 Mount the specimens so they do not cast shadows on each other, or contact each other or any metallic material, or any material capable of acting as a wick. Also, mount the specimens so that the products of weathering and rain water drippings do not flow from one to another.

NOTE 3—A suitable material for the construction of racks and supports is painted wood. Metal, such as aluminum, is also suitable if the test specimens are properly insulated as by the use of porcelain or suitably selected plastic.

7. Test Period and Rating of Paints

7.1 The test period shall be sufficient to evaluate the characteristics of the system under consideration.

7.2 Inspect at regular intervals.

7.3 Evaluate (resistance to or) degree of rusting, chalking, checking, cracking, and blistering using the following ASTM photographic reference standards: Test Methods D 610, D 659, D 660, D 661, and D 714.

Standard Single- and Multi-Panel Forms for Recording Results of Exposure Tests of Paints¹

This standard is issued under the fixed designation D 1150; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^e) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Editorial changes were made throughout in May 1987.

1. Single-Panel Paint Record Form

1.1 The single-panel form² provides on one sheet the complete exposure record of a paint test panel. It provides a record for a period of 60 months for 15 or more different types of failure. On the front side there are eight graphs upon which the record for practically every type of failure may be plotted. The type of failure is specified on six of the graphs as indicated and there are two additional graphs for special types of failure that may be required. In order to record three types of failure on a single graph the symbols X, O, and (dot) are used. The numerical system of grading is used. Ten indicates perfection or absence of failure while zero represents complete failure. Ratings are plotted along the vertical axis in steps of 2. Intermediate ratings in steps of 1 may be plotted between the lines. Time is plotted along the horizontal axis. To illustrate the use of the single-panel record form, Fig. 1 shows a section of one graph with gloss, chalking, and erosion ratings recorded.

1.2 On the reverse side of the single-panel form are columns for recording the composition, the reduction procedure, and miscellaneous information for a paint system for as many as four coats. Ample space is provided for additional remarks.

D 772 Test Method for Evaluating Degree of Flaking (Scaling) of Exterior Paints³

2.2 Other Documents:

*Exposure Standards Manual*⁴

3. Multi-Panel Paint Inspection Sheet

3.1 Although the single-panel form may be used in the field to record results directly, it is recommended that observation in the field be recorded on the multi-panel paint inspection sheet² and later be transcribed to the single form. Provision is made on the multi-panel form for recording twenty different observations of twenty different panels. The type of failure is to be written in the spaces under the heading "Properties." The back of the sheet may be used for remarks or any additional data that need be recorded.

4. Photographic Reference Standards

4.1 The following ASTM test methods refer to photographic reference standards for use in evaluating exposure tests of paints:

4.2 *Chalking*—Method D 659.

4.3 *Checking*—Test Method D 660.

4.4 *Cracking*—Test Method D 661.

4.5 *Erosion*—Test Method D 662.

4.6 *Flaking*—Test Method D 772.

4.7 *Rusting*—Method D 610.

4.8 *Blistering*—Test Method D 714.¹

4.9 The *Exposure Standards Manual* also contains pictorial standards for evaluating paint failures.

Standard Test Methods for Nondestructive Measurement of Dry Film Thickness of Nonmagnetic Coatings Applied to a Ferrous Base¹

This standard is issued under the fixed designation D 1186; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

These test methods have been approved for use by agencies of the Department of Defense to replace Method 6181 of Federal Test Standard No. 141A and for listing in the DoD Index of Specifications and Standards.

1. Scope

1.1 These test methods cover the nondestructive measurement of the dry film thickness of nonmagnetic coatings applied over a ferrous base material using commercially available test instruments. The test methods cover the use of instruments based on magnetic measuring principles only. Test Method A provides for the measurement of films using magnetic pull-off gages and Test Method B provides for the measurement of films using magnetic flux gages.

1.2 These test methods are not applicable to coatings that will be readily deformable under the load of the measuring instrument.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

D823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels²

2.2 Steel Structures Painting Council Standard:

SSPC-PA2 Measurement of Dry Paint Thickness with Magnetic Gages³

TEST METHOD A—MAGNETIC PULL-OFF GAGES

3. Summary of Test Method

3.1 Instruments complying with this test method measure thickness by using a spring calibrated to determine the force required to pull a permanent magnet from a ferrous base coated with a nonmagnetic film. The instrument must be placed directly on the coating surface to take a reading.

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.23 on Physical Properties of Applied Paint Films.

Current edition approved May 29, 1987. Published July 1987. Originally published as D 1186 - 51. Last previous edition D 1186 - 81.

² *Annual Book of ASTM Standards*, Vol 06.01.

³ Available from Steel Structures Painting Council, 4400 Fifth Ave., Pittsburgh, PA 15213.

4. Significance and Use

4.1 The attractive force of the magnet to the substrate varies inversely with the thickness of the applied film. The spring tension required to overcome the attraction of the magnet to the substrate is shown on the instrument scale as the distance (in mils or micrometres) between the magnet and the substrate.

4.2 The accuracy of the measurements may be influenced when made closer than 1 in. (25 mm) to an edge.

5. Apparatus

5.1 *Permanent Magnet*, small, either attached directly to a coil spring ("pencil" gage)⁴ or to a horizontal lever arm which is attached to a helical spring ("banana" gage).⁵ Increasing force is applied to the magnet by extending the coil spring in the first case or turning a graduated dial that coils the helical spring in the second. The readings obtained are shown directly on the instrument scale or converted by reference to a calibration curve.

6. Test Specimens

6.1 When this test method is used in the field, the specimen is the coated structure or article on which the thickness is to be evaluated.

6.2 For laboratory use, apply the materials to be tested to panels of the composition and surface conditions on which it is desired to determine the thickness.

NOTE 1—Applicable test panel description and surface preparation methods are given in Methods D 609.

NOTE 2—Coatings should be applied in accordance with Test Methods D 823 or as agreed upon between the purchaser and the seller.

7. Calibration of Apparatus

7.1 Calibrate the instrument in an area free of stray magnetic fields, such as power lines, generators, or welding equipment. There shall be no vibration apparent on the test piece when the instrument is being calibrated.

7.2 Use a bare section of the substrate after the specified surface preparation method has been accomplished. If an uncoated section of the substrate is not available, uncoated test panels of a similar steel type on which the specified surface preparation has been performed, may be used.

⁴ Apparatus of the "pencil" type found to be suitable for this purpose includes Tinsley Gage, Elcometer Pencil Pull-Off Gage.

⁵ Apparatus of the "banana" type found to be suitable for this purpose includes Magne Gage, Mikrotest, Elcometer Inspector Thickness Gage.

7.3 Use nonmagnetic thickness shims for calibration. Most shims are non-precision and, therefore, thickness must be verified with a micrometer.

NOTE 3—Other thickness standards such as National Bureau of Standards certified thickness calibration standards may be used for the calibration of the magnetic pull-off gages. The use of these thickness standards requires a different calibration method as described in SSPC-PA2.

7.4 Select calibration shims in the expected thickness range to be measured. For example, if a coating is approximately 3 mils (75 μ m) in thickness, calibrate the instrument at 3 mils. Then check the calibration, using shims of both a lesser and greater thickness, to determine the thickness range over which the instrument will register accurately.

7.5 Lay a calibration shim on the bare, uncoated substrate and bring the instrument magnet in direct contact with the shim. Remove the magnet from the shim by slowly rotating the dial scale ring clockwise (for helical spring-type instruments) or lifting the entire instrument housing (for coil spring-type instruments). Hold the shim so that it will not flex during calibration, causing the magnet to lift prematurely. Observe the thickness shown on the instrument scale at the moment when the magnet breaks contact with the surface.

7.6 If the instrument scale reading does not agree with the shim thickness, calibration is required. This can be accomplished by physical calibration or by drafting a calibration curve. A calibration curve involves plotting a graph with the actual gage reading on one axis and the shim reading on the other. For physical calibration, consult the manufacturer's instructions.

NOTE 4—Instruments based on the scale dial ring/helical spring can be calibrated and used in any position, while those based on the coil spring must be calibrated and used in the vertical position only.

8. Procedure

8.1 Use the instrument only after it has been calibrated in accordance with Section 7.

8.2 Assure that the coating is dry prior to use of the instrument.

8.3 Inspect the magnet tip and surface to be measured to assure that they are clean. Adherent magnetic filings or other surface contaminants will affect gage readings.

8.4 Take readings in areas free of vibration, electrical, or magnetic fields.

8.5 If thickness readings are encountered outside the range of accuracy determined during calibration in 7.4, repeat the calibration procedure in that range. Check the calibration frequently during use to assure that the instrument continues to read properly.

8.6 Take a sufficient number of readings to characterize the sample.

8.6.1 For laboratory measurements, a recommended minimum is three for a 3 by 6-in. (75 by 150-mm) panel and more in proportion to size.

8.6.2 For field measurements, a recommended minimum is five determinations at random for every 100 ft² (10 m²) of surface area. Each of the five determinations should be the mean of three separate gage readings within the area of a 1/2-in. (12-mm) diameter circle.

8.7 Make measurements at least 1 in. (25 mm) away from any edge or corner of the specimen. If it is necessary to measure closer than 1 in., recheck the calibration in the specific area to determine the extent of the effect (if any) the edge has on the measurement.

8.8 Report the instrument used, serial number, range, and mean of the thickness readings found.

9. Precision

9.1 An interlaboratory test was conducted to determine the within-laboratory and between-laboratory precision of several types of instruments in measuring a wide range of coating thickness by this method. On the basis of this interlaboratory test, the within-laboratory coefficients of variation and between-laboratory coefficients of variation were found to be those shown in Table 1 for the instruments evaluated. Based upon these coefficients of variation, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

9.1.1 *Repeatability*—Two results by the same operator with the same instrument should be considered suspect if they differ by more than the maximum allowable difference values shown in Table 1.

9.1.2 *Reproducibility*—Two results, each the mean of four measurements, obtained by operators in different laboratories should be suspect if they differ by more than the maximum allowable difference values shown in Table 1.

TEST METHOD B—MAGNETIC FLUX GAGES

10. Summary of Test Method

10.1 This test method covers instruments that measure coating thickness by changes in the magnetic flux within the instrument probe or the instrument itself. The instrument probe must remain in direct contact with the coating at all times during measurement.

11. Significance and Use

11.1 The magnitude of flux changes is an inverse (nonlinear) function of the distance between the probe and the ferrous substrate.

11.2 The accuracy of the measurements may be influenced when made closer than 1 in. (25 mm) to an edge or 3 in. (75 mm) to another mass of steel. The edge or mass of steel may cause flux leakage from the instrument, thus distorting the readings.

12. Apparatus

12.1 The testing apparatus shall be mechanically or electrically operated. The mechanically operated instruments house an integral horseshoe magnet, the contacts of which are placed directly on the coated substrate.⁶ The electrically operated instruments utilize a separate instrument probe that houses the magnet and must be placed directly on the surface.⁷ In both types, the coating thickness is shown on the instrument scale or meter.

⁶ Apparatus of the mechanical type found to be suitable for this purpose includes Elcometer 101.

⁷ Apparatus of the probe type found to be suitable for this purpose includes the Minitest, Minitecor, Verimeter, GE Gage, Ferascope, and Accuderm.

^A Insufficient results for reliable estimate.

^B No interlaboratory results provided.

^C Between-laboratories precision usually larger than within-laboratory precision.

13. Test Specimens

13.1 The test specimens described in Section 6 are suitable for the instruments of Test Method B.

14. Calibration of Apparatus

14.1 Follow the steps outlined in 7.1 through 7.4.

14.2 Hold the instrument contact or probe handle firmly on the surface and perpendicular to the measuring plane during calibration and use. Follow the manufacturer's instructions for the specific adjustment of the instrument.

NOTE 5—The probe-type instruments can be calibrated and used in any position, but the integral-magnet type must be recalibrated or calibration verified for each position of use.

15. Procedure

15.1 Follow the steps outlined in 8.1 through 8.7.

15.2 Take measurements no closer than 1 in. (25 mm) to an edge or 3 in. (75 mm) to another mass of steel. If such measurements are necessary, recheck the calibration in the specific area to determine the effect the edge or mass of steel has on the instrument reading.

15.3 Report the instrument used, serial number, range, and mean of the thickness readings found.

16. Precision

16.1 *Precision*—On the basis of an interlaboratory study of this test method in which several types of instruments

Standard Test Method for Viscosity by Ford Viscosity Cup¹

This standard is issued under the fixed designation D 1200; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

This standard has been approved for use by agencies of the Department of Defense to replace Method 4282 of Federal Test Method Standard No. 141. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

1. Scope

1.1 This test method covers the determination of the viscosity of Newtonian or near-Newtonian paints, varnishes, lacquers, and related liquid materials with the Ford-type efflux viscosity cup. If the material is non-Newtonian, that is, shear-thinning or thixotropic, Test Method D 2196 should be used.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 2196 Test Methods for Rheological Properties of Non-Newtonian Materials by Rotational (Brookfield) Viscometer²

E 1 Specification for ASTM Thermometers³

3. Terminology

3.1 Definitions:

3.1.1 *Newtonian liquid*—a liquid in which the viscosity is independent of the shear stress or shear rate. If the ratio of shear stress to shear rate is not constant, the liquid is non-Newtonian.

3.1.2 *Near-Newtonian liquid*—a liquid in which the variation of viscosity with shear rate is small and the effect on viscosity of mechanical disturbances such as stirring is negligible.

4. Summary of Test Method

4.1 The Ford viscosity cup is filled level full with the liquid under test, and the time for the material to flow through one of the standard orifices is measured.

5. Significance and Use

5.1 This test method is useful for the determination of package and application viscosities of a number of paints

and other coatings and in the thinning of these materials, but is limited to Newtonian or near-Newtonian liquids.

5.2 There are other types of apparatus for measuring viscosity in the laboratory that produce more accurate results.

6. Apparatus

6.1 *Ford Viscosity Cups*—Nos. 1, 2, 3, 4, and 5 Ford viscosity cups made of corrosion- and solvent-resistant materials assembled as complete units (Note 1), and conforming to the dimensional requirements shown in Fig. 1. The orifice dimensions are considered as a guide only as the combination of cup and orifice dimensions must permit conformance to the flow formula for each cup as listed in the Appendix.

NOTE 1—If the orifice is removed from the cup for any reason the cup should be recalibrated before use as described in the Appendix.

6.2 *Thermometer*—Saybolt Viscosity Thermometer conforming to the requirements for Thermometer 17C (19 to 27°C) or 17F (66 to 80°F) as prescribed in Specification E 1.

6.3 *Timing Device*—Any timing device may be used providing that the readings can be taken with a discrimination of 0.2 s or better.

7. Test Specimen

7.1 The specimen of the material to be tested shall be visibly homogeneous and free of any foreign material or air bubbles.

8. Temperature of Testing

8.1 All measurements with the Ford viscosity cups shall be made at 77°F (25°C) or a temperature agreed upon between producer and user. Temperature drift during the test should be kept to a minimum and should not exceed $\pm 0.4^\circ\text{F}$ ($\pm 0.2^\circ\text{C}$).

NOTE 2—It is impossible to predict the effect of temperature change on each material with which the apparatus may be used. This factor may be less than 1 % per degree Celsius for some liquids whereas others may be as high as 8 to 10 % per degree Celsius.

9. Calibration

9.1 Cups should be calibrated in accordance with the procedure described in the Appendix. The frequency of this calibration check depends upon the amount of use and the care that the individual cup receives. If the cup varies more

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paints and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.24 on Physical Properties of Liquid Paints and Paint Materials.

Current edition approved Oct. 31, 1988. Published December 1988. Originally published as D 1200 - 52 T. Last previous edition D 1200 - 82.

² *Annual Book of ASTM Standards*, Vol 06.01.

³ *Annual Book of ASTM Standards*, Vol 14.03.

than 10 % from standard, it should not be used.

10. Conditioning

10.1 Bring the material to a temperature a few degrees below that desired and then agitate vigorously for 10 min on a reciprocating shaker in a pint can two-thirds full. Allow to stand undisturbed for 10 min while adjusting further to the desired temperature. Make the viscosity determination at the end of the 10-min period.

11. Procedure

11.1 Make viscosity determinations in a room free of drafts and rapid changes in temperature. For the highest degree of precision the room temperature should be between 72 and 82°F (22 and 28°C). Determinations should be made at a temperature above the dew point of the atmosphere surrounding the apparatus.

FIG. 1 Ford Viscosity Cup and Orifices

11.2 Choose the proper cup so that the time of efflux will be between 20 and 100 s (preferably between 30 and 100 s) for cup Nos. 3, 4, and 5; between 55 and 100 s for cup No. 1; and between 40 and 100 s for cup No. 2 (Fig. 2).

11.3 Level the instrument so that a cup may be filled level full without a meniscus or overflow at one side.

11.4 Determine the time in seconds of efflux as follows: Close the orifice, for example, by holding a rubber stopper against it. Fill the cup with the prepared specimen. The preferred method is to overfill the cup and scrape off the excess with a straightedge. Pull the stopper away and simultaneously start the timing device. Measure the time until the first break in the stream.

11.5 Measure the temperature of the fluid in the efflux stream.

11.6 If the cup has been established to be nonstandard when calibrated as described in the Appendix, apply the percent difference to the measured seconds to get the corrected viscosity in Ford-cup seconds.

12. Care of Cup

12.1 Following each determination, clean the cup by the use of a suitable solvent and a soft brush. Under no conditions should metal cleaning tools be brought into contact with the instrument. Particular care must be exercised in cleaning the orifice to avoid any film deposit or nicks on the inside walls.

13. Report

13.1 Report the following information:

13.1.1 The efflux time to the nearest 0.2 s for the cup orifice combination (for example, viscosity 33.2 s with No. 4 Ford-cup), the temperature of the test specimen (as in the efflux stream), and the immediate history of agitation and rest prior to the measurement.

14. Precision and Bias

14.1 On the basis of an interlaboratory test of this test method in which eight cooperators from four different laboratories made measurements on five different paints, the within-laboratory coefficient of variation was found to be 2.8 % with 35 df and the between-laboratory coefficient of variation was found to be 6.9% with 30 df. Based on these coefficients, the following criteria should be used for judging

FIG. 2 Approximate Viscosity Curves for Ford Cups

the acceptability of results at the 95 % confidence level:

14.1.1 *Repeatability*—Two results obtained by the same operator on different days should be considered suspect if they differ by more than 8 %.

14.1.2 *Reproducibility*—Two results obtained by operators in different laboratories should be considered suspect if

they differ by more than 20 %.

15. Index Terms

15.1 This test method is indexed under the following terms: flow cup; viscometers—Ford; Ford cup.

APPENDIX

X1. Calibration Procedure for Ford Cups

X1.1 The orifice of the Ford cup is commonly made of brass or some other corrosion-resistant material which is subject to wear with use and cleaning. A small change in diameter of the orifice becomes significant in the results obtained with the use of this type of viscosity-measuring apparatus.

X1.2 The viscosity standards⁴ are available only as 1-pt. samples.

X1.3 Select the appropriate liquid viscosity standard for the cup to be calibrated (see Table X1.1). Bring this cup and the liquid viscosity standard to a constant temperature as close as possible to 77.0°F (25.0°C) or to the operating temperature of the cup. Determine the time of efflux to the nearest 0.2 s using the procedure detailed in Section 11. Keep the temperature drift to within $\pm 0.4^\circ\text{F}$ ($\pm 0.2^\circ\text{C}$). If the temperature is not 77°F, the actual temperature must be noted and the viscosity of the standard oil corrected to this temperature.

X1.4 The following formulas are used to convert the time of flow in seconds, t , to kinematic viscosity V :

$$V_1 = 0.49 (t - 35.0)$$

$$V_2 = 1.44 (t - 18.0)$$

$$V_3 = 2.31 (t - 6.58)$$

$$V_4 = 3.85 (t - 4.49)$$

$$V_5 = 12.1 (t - 2.00)$$

where V_1 , V_2 , V_3 , V_4 , and V_5 = kinematic viscosity using orifice No. 1, 2, 3, 4, and 5, respectively, cSt.

TABLE X1.1 Viscosity Standards Recommended for Calibrating Ford Viscosity Cups

Cup Number	Approximate Cup Viscosity Range, cSt	Standard Oil Designation	Approximate Designated Viscosity at 77°F (25°C), cSt ⁴
1	10 to 35	S-10	20
2	25 to 120	S-20	35
3	49 to 220	S-60	120
4	70 to 370	S-60	120
5	200 to 1200	S-200	460

⁴ Exact viscosities are supplied with the oil samples.

X1.5 The difference between the certified viscosity and the determined viscosity, multiplied by 100 and divided by the certified viscosity, will give the percent variation of the cup from standard. A percent correction can be applied to the seconds flow when the cup is in normal use. If the cup varies more than 10 % from standard, it is recommended that the orifice be replaced and that the cup be recalibrated.

⁴ Certified kinematic viscosity standards are available from the Cannon Instrument Co., P.O. Box 16, State College, Pa. 16801. For particular oils applicable for use with the Ford Cups refer to Table X1.1. Oils available from other sources, having known kinematic viscosities, may also be used.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. Standard Test Method for Color of Clear Liquids (Platinum-Cobalt Scale)¹

This standard is issued under the fixed designation D 1209; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense to replace Method 4243.1 of Federal Test Method Standard No. 141. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

^{e1} NOTE—Paragraph 1.3 and Footnotes 6, 7, and 10 were added editorially and subsequent footnotes renumbered in March 1988.

1. Scope

1.1 This test method describes a procedure for the visual measurement of the color of essentially light colored liquids (Note 1). It is applicable only to materials in which the color-producing bodies present have light absorption characteristics nearly identical with those of the platinum-cobalt color standards used.

NOTE 1—A procedure for estimating color of darker liquids, described for soluble nitrocellulose base solutions, is given in Methods D 365.

1.2 This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For specific hazard statements see Section 6.

1.3 For hazard information and guidance, see the supplier's Material Safety Data Sheet.

3. Significance and Use

3.1 The property of color of a solvent varies in importance with the application for which it is intended, the amount of color that can be tolerated being dependent on the color characteristics of the material in which it is used. The paint, varnish, and lacquer solvents, or diluents commercially available on today's market normally have little or no color. The presence or absence of color in such material is an indication of the degree of refinement to which the solvent has been subjected or of the cleanliness of the shipping or storage container in which it is handled, or both.

3.2 For a number of years the term "water-white" was considered sufficient as a measurement of solvent color. Several expressions for defining "water-white" gradually appeared and it became evident that a more precise color standard was needed. This was accomplished in 1952 with the adoption of Test Method D 1209 using the platinum-cobalt scale. This test method is similar to the description given in *Standard Methods for the Examination of Water and Waste Water*⁷ and is referred to by many as "APHA Color." The preparation of these platinum-cobalt color standards was originally described by A. Hazen in the *American Chemical Journal*⁸ in which he assigned the number 5 (parts per ten thousand) to his platinum-cobalt stock solution. Subsequently, in their first edition (1905) of *Standard Methods for the Examination of Water*, the American Public Health Association, using exactly the same concentration of reagents, assigned the color designation 500 (parts per million) which is the same ratio. The parts per million nomenclature is not used since color is not referred directly to a weight relationship. It is therefore recommended that the incorrect term "Hazen Color" should not be used. Also, because it refers primarily to water, the term "APHA Color" is undesirable. The recommended nomenclature for referring to the color of organic liquids is "Platinum-Cobalt Color, Test Method D 1209."

3.3 The petroleum industry uses the Saybolt colorimeter Test Method D 156 for measuring and defining the color of hydrocarbon solvents; however, this system of color measurement is not commonly employed outside of the petro-

TABLE 1 Absorbance Tolerance Limits For No. 500 Platinum-Cobalt Stock Solution

Wavelength, nm	Absorbance
430	0.110 to 0.120
455	0.130 to 0.145
480	0.105 to 0.120
510	0.055 to 0.065

leum industry. It has been reported by various sources that a Saybolt color of +25 is equivalent to 25 in the platinum-cobalt system or to colors produced by masses of potassium dichromate ranging between 4.8 and 5.6 mg dissolved in 1 L of distilled water. Because of the differences in the spectral characteristics of the several color systems being compared and the subjective manner in which the measurements are made, exact equivalencies are difficult to obtain.

4. Apparatus

4.1 *Spectrophotometer*, equipped for liquid samples and for measurements in the visible region.⁹

NOTE 2—The spectrophotometer used must be clean and in first-class operating condition. The instrument should be calibrated in accordance with the instructions given in the Standards for Checking the Calibration of Spectrophotometers (200 to 1000 nm).¹⁰

4.2 *Spectrophotometer Cells*, matched having a 10-mm light path.

4.3 *Color Comparison Tubes*—Matched 100-mL, tall-form Nessler tubes, provided with ground-on, optically clear, glass caps. Tubes should be selected so that the height of the 100-mL graduation mark is 275 to 295 mm above the bottom of the tube.

4.4 *Color Comparator*—A color comparator constructed to permit visual comparison of light transmitted through tall-form, 100-mL Nessler tubes in the direction of their longitudinal axes. The comparator should be constructed so that white light is passed through or reflected off a white glass plate and directed with equal intensity through the tubes, and should be shielded so that no light enters the tubes from the side.¹¹

5. Reagents

5.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.¹² Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water

⁹The Beckman Model B and its equivalents have been found satisfactory for this purpose.

¹⁰See National Bureau of Standards Letter Circular LC-1017.

¹¹A unit available from Scientific Glass and Instruments, Inc., P.O. Box 6, Houston, TX 77001, has been found suitable for this purpose.

35	7	350	70
40	8	400	80
50	10	450	90
60	12	500	100 ^A

^A This is platinum-cobalt color No. 10 in Methods D 365.

conforming to Type IV of Specification D 1193.

5.3 *Cobalt Chloride* ($\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$).

5.4 *Hydrochloric Acid* (sp gr 1.19)—Concentrated hydrochloric acid (HCl).

5.5 *Potassium Chloroplatinate* (K_2PtCl_6).

6. Hazards

6.1 Concentrated hydrochloric acid is a corrosive chemical.

7. Platinum-Cobalt Reference Standards

7.1 *Platinum-Cobalt Stock Solution*—Dissolve 1.245 g of potassium chloroplatinate (K_2PtCl_6) and 1.00 g of cobalt chloride ($\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$) in water. Carefully add 100 mL of hydrochloric acid (HCl, sp gr 1.19) and dilute to 1 L with water. The absorbance of the 500 platinum-cobalt stock solution in a cell having a 10-mm light path, with reagent water in a matched cell as the reference solution,¹³ must fall within the limits given in Table 1.

7.2 *Platinum-Cobalt Standards*—From the stock solution, prepare color standards in accordance with Table 2 by diluting the required volumes to 100 mL with water in the Nessler tubes. Cap the tubes and seal the caps with shellac or a waterproof cement. When properly sealed and stored, these standards are stable for at least 1 year and do not degrade markedly for 2 years.¹⁴

7.2.1 For a more precise measurement of light colors below 15 platinum-cobalt, prepare color standards from the stock solution in accordance with Table 3 by diluting the required volumes to 100 mL with water in the Nessler tubes. Use a semi-microburet for measuring the required amount of stock solution.

8. Procedure

8.1 Introduce 100 mL of specimen into a Nessler tube, passing the specimen through a filter if it has any visible turbidity. Cap the tube, place in the comparator, and compare with the standards.

9. Report

9.1 Report as the color the number of the standard that

¹³See the manufacturer's instruction manual for complete details for operating the spectrophotometer.

TABLE 3 Platinum-Cobalt Color Standards for Very Light Colors

Color Standard Number	Stock Solution, mL	Color Standard Number	Stock Solution, mL
1	0.20	9	1.80
2	0.40	10	2.00
3	0.60	11	2.20
4	0.80	12	2.40
5	1.00	13	2.60
6	1.20	14	2.80
7	1.40	15	3.00
8	1.60		

most nearly matches the specimen. In the event that the color lies midway between two standards, report the darker of the two.

9.2 If, owing to differences in hue between the specimen and the standards, a definite match cannot be obtained, report the range over which an apparent match is obtained, and report the material as "off-hue."

10. Precision¹⁵

10.1 Color Standards:

10.1.1 These precision statements are based upon an interlaboratory study in which five platinum-cobalt standards having values of 25, 75, 170, 385, and 475 were prepared in accordance with the instructions given in Section 7 of this test method and were given coded labels. These solutions were tested by one analyst in each of ten different laboratories making a single observation on one day and then repeating the observation on a second day. The analysts were requested to estimate the color to the nearest one unit for solutions below 40 platinum-cobalt, to the nearest five units for solutions between 40 and 100 platinum-cobalt and to the nearest ten units for solutions above 100 platinum-

cobalt. In this interlaboratory study, the within-laboratory coefficient of variation was found to be 1.8 % with 60 degrees of freedom, and the between-laboratories coefficient of variation was found to be 5.3 % with 54 degrees of freedom. Based on these results, the following criteria, calculated in accordance with Practice E 180, should be used for judging the acceptability of results at the 95 % confidence level when the results are obtained under optimum conditions where the hue of the sample matches exactly the hue of the standards. Poorer precision will be obtained in varying degrees as the hue of the sample departs from that of the standards.

10.1.1.1 *Repeatability*—Two results, obtained by the same analyst on different days, should be considered suspect if they differ by more than 5.1 %.

10.1.1.2 *Reproducibility*—Two results, obtained by analysts in different laboratories, should be considered suspect if they differ by more than 15 %.

10.2 Specimen:¹⁶

10.2.1 In an interlaboratory study of this test method in which the standards described in Table 3 were used, the within-laboratory standard deviation was found to be one platinum-cobalt unit at 56 degrees of freedom and the between-laboratory standard deviation was found to be 2 platinum-cobalt units at 25 degrees of freedom. Based on these standard deviations, the following criteria should be used for judging, at the 95 % confidence level, the acceptability of results obtained on light colored samples.

10.2.1.1 *Repeatability*—Two results, each the mean of duplicates, obtained by the same operator on different days should be considered suspect if they differ by more than two platinum-cobalt units.

10.2.1.2 *Reproducibility*—Two results, each the mean of duplicates, obtained by operators in different laboratories should be considered suspect if they differ by more than seven platinum-cobalt units.

¹⁶ These precision statements are based on interlaboratory studies conducted by Committee E-15 on Industrial Chemicals on samples of ethylene glycol and methanol as reported in Method E 202, Method E 346, and research report RR: E15-28.

¹⁵ Supporting data are available from ASTM Headquarters. Request RR: D01-1024.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. Standard Test Method for Fineness of Dispersion of Pigment-Vehicle Systems¹

This standard is issued under the fixed designation D 1210; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This test method has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

^{e1} NOTE—Editorial changes were made throughout in June 1988.

1. Scope

1.1 This test method covers measurement of the degree of dispersion (commonly referred to as "fineness of grind") of the pigment in a pigment-vehicle system such as liquid coatings and their intermediates. It may also be used to assess the inclusion of particulates by a cleanliness rating.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Summary of Test Method

2.1 The product is spread by means of a scraper in a calibrated tapered path. At some point in this path, particles or agglomerates, or both, will become visible. A direct reading from the calibrated scale is then made at the point where the particles form a definite pattern. When the single path gage is used it is also possible to rate "cleanliness" (see 6.2).

3. Significance and Use

3.1 In making pigmented products, the pigment is usually dispersed in a portion of the vehicle in some sort of mill. At this stage, it is necessary to be able to judge if the pigment agglomerates have been sufficiently broken up so as not to interfere with the smoothness of the finished coating film. This test method describes a way of making this judgment.

4. Apparatus

4.1 **Gage**—A hardened steel, stainless steel, or chrome-plated steel block (Fig. 1) approximately 6.7 in. (170 mm) in length, and 0.6 in. (15 mm) in thickness. The top surface of the block shall be ground smooth and planar and shall contain one or two paths 5 in. (127 mm) in calibrated length. The path shall be tapered uniformly in depth lengthwise from 100 μ m (about 4 mils) at 10 mm from one end to zero depth at the other with intermediate calibrations in accordance with the depth at those points. Preferred calibrations are

Hegman units and micrometres (Note 1). Two path widths are covered by this test method:

4.1.1 Two parallel paths each 0.5 in. wide (12.5 mm) and spaced 0.5 in. apart centered in a block 2.5 in. (65 mm) wide.

4.1.2 One path 2 in. (50 mm) in width centered in a block 3.5 in. (90 mm) wide.

NOTE 1—Several arbitrary scales and modifications of the gage are used by industry. In order that readings obtained with these arbitrary scales and modifications can be reported in the preferred units, the approximate relationship of these scales to gage depth is shown in the following example:

Hegman Scale ^A	Depth, μ m ^B	Depth, mils ^B	PC or FSPT Scale ^C	NPIRI Scale ^D
0	100	4	0	40
1	90	3.5	1/4	35
2	75	3	2/4	30
3	65	2.5	3/4	25
4	50	2	5	20
5	40	1.5	6/4	15
6	25	1	7/4	10
7	15	0.5	8/4	5
8	0	0	10	0

^A Sometimes referred to in error as the North Standard scale.

^B Rounded to nearest 5 μ m or 0.5 mil.

^C Federation of Societies for Paint Technology scale.

^D National Printing Ink Research Institute scale, 0 to 10 on the NPIRI Production Grindometer, but extended on many gages to 20 or 30.

4.2 **Scraper**—A double-edged hardened steel, stainless steel, or chrome-plated steel blade (Fig. 2) 3.75 in. (95 mm) long, 1.5 in. (38 mm) wide, and 0.25 in. (6.4 mm) thick. The two edges on the 3.75-in. sides shall be rounded to a radius of 0.015 in. (0.38 mm).

5. Care of Gage

5.1 Clean the gage immediately after each use. Use a solvent and a soft cloth. Keep the gage covered or encased at all times when not in use. Protect gages that lie idle for extended periods of time from rust with an oil coating or oil-soaked wrap.

5.2 Do not allow any hard materials to come in contact with the gage surface or scraper in any manner that might result in scarring or nicking. Avoid tapping or scratching with other metal.

5.3 The scraper may be rendered unsatisfactory for use by wear or nicks of the contact edge or warpage (Note 2). Replace or recondition unsatisfactory blades.

NOTE 2—Wear or warpage of the scraper may be noted by facing the edge of the scraper down on the smooth level face of the gage, then

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials, and is the direct responsibility of Subcommittee D01.24 on Physical Properties of Liquid Paint and Paint Materials.

Current edition approved Nov. 30, 1979. Published January 1980. Originally published as D 1210 - 52. Last previous edition D 1210 - 78.

FIG. 1 Fineness Gages

inspecting the contact edge by means of a strong light, placed behind the gage. Rocking the scraper forward or back will reveal poor contact due to wear or warpage. Any light coming through between scraper and gage face shows that the scraper has been damaged and is not satisfactory for use.

6. Visual Standards

6.1 The diagrams in Fig. 3 are reproductions of six typical fineness gage patterns with the double-path gage in 4.1.1, and they should be viewed with the purpose of standardizing the relationship of particle distribution to fineness designation. The arrow in each drawing represents the end point (reading) for that distribution. These patterns are to be used for notation of frequency of particles and should not be interpreted according to the size of the dots. Although called "standards," they are really examples of fineness readings to be used as a guide, since no two particle distributions will be exactly the same.

6.2 Similarly, Fig. 4 exhibits typical fineness gage patterns for the 2-in. (51-mm) gage in 4.1.2. These diagrams are to be used like those for the double-path gage except that a "cleanliness" rating is also shown. "Cleanliness" is descrip-

NOTE—1 in. = 25.4 mm
FIG. 2 Scraper

tive of the number of particles that appear in the path above the fineness designation. Three ratings are indicated: A (0 to 8 specks), B (9 to 15 specks), and C (16 or more specks).

FIG. 3a Typical Fineness Gage Patterns

7. Procedure

7.1 Place the gage on a horizontal flat, nonslippery surface and wipe clean immediately before the test. Be sure the gage surface is free of lint.

7.2 Hand stir the specimen (Note 3) vigorously for 2 min, taking care that air bubbles are not whipped into the paint. To be sure of an accurate grind reading, specimens must be free of air bubbles.

NOTE 3—For this test method to function properly, the pigment particles in the specimens to be tested should be free to settle to the bottom of the gage channel after the drawdown. Therefore, before testing, high-viscosity intermediate specimens that have little ability to flow should be reduced with a compatible liquid. Reduction should be in approximately the same proportion as the intermediate will be reduced in practice.

7.3 Immediately place the material to be tested in the deep end of the path, or paths, so that it overflows the path

slightly. When using the double-path gage, place material in both paths.

7.4 Holding the scraper in both hands, nearly vertical but inclined slightly toward the operator, draw the material down the length of the path toward the shallow end of the gage with a uniform, brisk motion in approximately 1 to 2 s. Exert upon the scraper only sufficient pressure to clean excess material from the face of the gage. Within 10 s of placing the specimen on the gage, make a reading as follows:

7.4.1 View the gage from the side, perpendicular to the length of the path. Keeping the gage between the operator and the light source, make the angle between the face of the gage and the line of vision between 20 and 30°.

NOTE 4—Clear finishes may have to be viewed at a lower angle or they may have to be opacified with a finely ground colorant or dye in order to see better the particles of flattening pigment.

7.4.2 definite and 4).

he operator
e face of the

lower angle or
rant or dye in

7.4.2 Observe the point where the material first shows a definite speckled pattern, not just isolated specks (see Figs. 3 and 4). This is the fineness reading. When using the two-path gage, average the values in the two paths to the nearest 1/4 Hegman unit. This average is considered one reading.

7.5 After the first drawdown and reading, which are preliminary for establishing proper test conditions and locating the position of the fineness reading, repeat the procedure twice, beginning with 7.3, to obtain two test readings. This process allows the two test readings to be made with limited time lapses between completion of drawdown and reading. (Do not consider any reading for the reported fineness when the time lapse exceeds 10 s.) Average the two readings to the nearest 1/4 Hegman units (5 μ m).

7.6 Interpretation of Dispersion Pattern:

7.6.1 Inspect the initial drawdown for pattern and the

approximate fineness. Determine the point in the particle distribution that approximates a similar end point pattern to that of the pictorial standards.

7.6.2 Judge cleanliness on the one-path gage either by comparison to the typical fineness patterns (shown only at a 6 Hegman level but applicable by analogy to any fineness level) or by counting nibs coarser than the selected fineness level (see 6.2 for cleanliness ranges).

8: Report

8.1 Report the following information:

8.1.1 Whether the two-path gage in 4.1.1 or the one-path gage in 4.1.2 was used.

8.1.2 The average of two readings conforming to the conditions of 7.6. Report micrometre readings to the nearest

FIG. 3c Typical Finesse Gage Patterns

multiple of 5 μm and Hegman readings to the nearest $\frac{1}{4}$ unit.

8.1.3 Cleanliness may be reported also when using the two-path gage.

9. Precision and Bias²

9.1 On the basis of an interlaboratory test of this test method in which 23 operators in 7 laboratories tested 6 samples of paints covering a broad range of compositions and finenesses, the single-operator standard deviation was found to be 0.27 Hegman units (3.4 μm), the within-laboratory standard deviation was found to be 0.70 Hegman units (8.8 μm) and the between-laboratories standard deviation was found to be 0.74 Hegman units (9.3 μm). Based on

these standard deviations and the requirement that readings are to be reported to the nearest $\frac{1}{4}$ Hegman unit or multiple of 5 μm , the following criteria should be used for judging the precision of results at a 95% confidence level:

9.1.1 *Repeatability*—Two results obtained by a single operator should be considered suspect if they differ by more than $\frac{1}{4}$ Hegman unit (10 μm).

9.1.2 *Reproducibility*—Two results, each the mean of two readings, obtained by different operators in the same or different laboratories should be considered suspect if they differ by more than $2\frac{1}{4}$ Hegman units (25 μm).

10. Index Terms

10.1 This test method is indexed under the following terms: pigment dispersion (paint); fineness of grind (dispersion); Hegman scale.

Standard Test Method for Temperature-Change Resistance of Clear Nitrocellulose Lacquer Films Applied to Wood¹

This standard is issued under the fixed designation D 1211; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers determination of the resistance to checking and cracking of clear nitrocellulose lacquer films applied to wood or plywood substrates when subjected to sudden changes from high to low temperatures.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D805 Testing Veneer, Plywood, and Other Glued Veneer Constructions²

D2571 Guide for Testing Wood Furniture Lacquers³

3. Description of Terms Specific to This Standard

3.1 True cold-checks on solid wood show as one or more straight cracks on the applied film. Cold-checks manifest themselves in either of two ways:

3.1.1 Long continuous wavy lines with the grain or at various directions at angles that can be perpendicular to the direction of the grain.

3.1.2 Innumerable fine lines erratic in direction and length forming a network over a portion or all of the panel. This effect may be likened to crazing of the lacquer film.

3.1.3 On plywood the direction of the cracks will often vary because of the stresses set up by other than the top stratum. Therefore, all checks may be considered as failures, and appropriate notations on the character of the cracks must be made to assist in the interpretation. While it is recognized that cracks in the substrate may occur (veneer checking), failures observed in the lacquer coating may be due to action of moisture (humidity) or of cold, or both. Checking caused by moisture appears along the grain and is characterized by short cracks (usually not more than $\frac{1}{2}$ in. (13 mm) in length) occurring either singly or in clusters. These lines or clusters may progress along the grain in a discontinuous fashion. Should either veneer checking or

moisture checking be observed, the test should be discontinued, and rerun.

3.2 The checks may be perceptible only by visual observation of the panels at an angle, under a strong light, or the cracks may be wide enough to be readily discernible in direct daylight.

4. Summary of Test Method

4.1 Lacquer-coated wood panels are subjected first to a high temperature, followed by an exposure to low temperature, and then a return to room temperature for given periods of time, which constitutes one cycle. The method does not define the number of cycles which a lacquer must withstand, this condition being a requirement which must be agreed upon by the purchaser and the seller.

5. Significance and Use

5.1 A common type of failure of clear films applied to wood is cracking or checking that may occur over a period of time either with the grain or at an angle. This cold check test is designed to accelerate the appearance of checks or cracks by cycling the temperature.

NOTE 1—Except when elaborate precautions are taken to control the moisture content of the wood before and after finishing and during the test, failures may quite often occur as a result of dimensional changes in the wood due to moisture change rather than temperature change.

6. Apparatus

6.1 *Refrigerator (Dry Ice)*—The refrigerator should be a well-insulated box, cooled by air which has been circulated over solid carbon dioxide (dry ice). The air must strike the panels indirectly after passing over the solid carbon dioxide. The unit shall have a capacity and temperature control sufficient to cool the test panels in accordance with the requirements prescribed in Section 9.

6.2 *Mechanical Refrigerator*—As a less desirable alternative, a well-insulated mechanical refrigerator may be used having sufficient capacity to cool the test panels in accordance with the requirements prescribed in Section 9. The refrigerator should have some means for providing air circulation. It should be understood that results obtained with a mechanical refrigerator may not correspond to results obtained with a "dry ice" refrigerator. Consequently the type of unit employed shall be stated in the report.

6.3 *Oven*—The oven shall be electrically heated and of any standard type capable of being automatically controlled and of sufficient capacity to heat the panels under test to $120 \pm 5^\circ\text{F}$ ($49 \pm 3^\circ\text{C}$) within 1 h. A circulating fan shall be installed in the oven.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.55 on Factory-Applied Coatings on Preformed Products.

7. Test Panels

7.1 Unless otherwise agreed, the test panel shall be cut from synthetic resin-bonded, five-ply plywood with faces and backs made with straight-grain walnut veneer having no sizing or other surface pretreatment. The dimensions of the test panel shall be 6 by 12 in. (152 by 305 mm), and approximately $\frac{3}{16}$ in. (8 mm) thick.

7.2 Solid wood, heavier or lighter veneers, or other species of wood may be agreed upon by the purchaser and the seller. Type of wood and panel size should be clearly defined in the report.

7.3 The wood selected shall have a moisture content of not less than 6.0 % and not more than 8.0 % at the time of testing. The moisture content of the wood may be determined by an electric moisture gage or in accordance with Methods D 805.

7.4 Panels may be conditioned to a moisture content of 7 to 8 % under any of the following conditions:⁴

Temperature, °F	Relative Humidity, %
65 to 75	35 to 40
90 to 100	40 to 45
120 to 125	45 to 50

8. Preparation of Panels

8.1 *Five-Ply Plywood* (With faces and backs made with straight-grain, closed face walnut veneer having no sizing or other surface pretreatment) shall be prepared as follows:

8.1.1 Sand panels until smooth with No. 240 sandpaper, or equivalent.

8.1.2 Fill with representative walnut wood paste filler and allow to dry for 24 h at not less than 70 nor more than 80°F.

8.1.3 Spray a sufficient number of coats of about equal thickness of the test lacquer on the panel within an 8-h period to give a total dry film thickness of 3 ± 0.5 mil (75 ± 13 μ m). Allow a minimum period of 2 h between coats. Do not edge or back the panel with any protective coating.

8.1.4 To minimize the effects of variations in the wood, apply a control lacquer of known performance to a portion of each panel in the same manner as the test lacquer. After aging, the panels may be cut (Note 2) into sections finished only with one lacquer, but each section should conform to the description given in Section 6.

NOTE 2—Cutting of panel is optional and may be contingent upon the size and capacity of the test equipment.

8.1.5 The thickness of films applied to panels may be determined with reasonable accuracy by placing a metal panel adjacent to the wood panel being prepared and measuring the film thickness on the metal panel with a magnetic thickness gage. The plywood panel must be sanded and rubbed before testing and the use of waxes or oils should be closely regulated since these can make a difference in the results obtained. For sanding and rubbing procedure, see Practice D 2571.

8.2 *Panels of Five-Ply Plywood with Walnut Veneer for Complete Lacquer System*—Proceed as agreed upon by the purchaser and the seller.

8.3 *Panels of Solid Wood, Lighter or Heavier Veneers, or Other Species of Wood*—Proceed as agreed upon by the purchaser and the seller.

8.4 *General Treatment*—Except where specific agreements exist between the purchaser and the seller, all panels shall be subjected to the following treatment:

8.4.1 Prepare at least three panels for each lacquer or lacquer system and each other variable, such as type of panel, that may be under test.

8.4.2 Air-dry overnight.

8.4.3 Age finished test panels for ten days under conditions that will maintain a moisture content of 6 to 8 %.

9. Procedure

9.1 Place a predetermined number of panels, depending on the capacity of the oven and refrigerator, vertically in racks so that air can pass between all panels. The lacquered sides of the panels shall not face the walls of the heating or cooling units. Place the racks for 1 h in an oven at $120 \pm 5^\circ\text{F}$ ($48.9 \pm 3^\circ\text{C}$) in such a manner as to avoid localized overheating. At the expiration of this period, transfer the panels within 1 min to a refrigerating unit maintained at $-5 \pm 2^\circ\text{F}$ ($-21 \pm 1^\circ\text{C}$) (unless special conditions indicate some other agreement between the purchaser and the seller). The number of panels shall be such that the time required to reach this temperature is not less than 30 min and not more than 45 min. The temperature can be measured by a thermocouple imbedded in the panel just underneath the film.

9.2 Remove the panels from the refrigerator after 1 h exposure. After allowing 15 min relaxation period, inspect the panels under a strong light. Best results will be obtained if the light source is directed from behind and over the shoulder of the observer. Circle checks with crayon, since they will often heal or at least appear to heal and become relatively invisible. Once the capacity of any given oven-refrigerator combination (number of panels that will permit specified rates of heating and cooling) has been determined, make all subsequent tests with this number of panels using dummy panels where necessary. If this precaution is not followed, rates of cooling and heating will differ each time the test is run, and reproducibility will suffer.

9.3 The period of 1 h at 120°F (49°C) followed by 1 h at -5°F (-21°C) and 30 min at room temperature (15 min relaxation period, 15 min to allow for inspection), constitutes one cycle. Repeat this cycle until failure occurs or until a prescribed minimum number of cycles has been obtained.

9.4 The failure end point is defined as the cycles on which innumerable fine lines appear as described in Section 3 or on which a total of four checks (1 to 2 in. (25 to 50 mm) in length) or two checks (more than 2 in. (50 mm) in length) appear in the film. Exclude the outer $\frac{1}{2}$ -in. (13 mm) perimeter of panel when examining for failure (cracks).

9.5 Unless a laboratory operates on three shifts there will be a relaxation period every night and over week ends. The report should show when these rest periods occurred.

10. Report

10.1 Report the following information:

10.1.1 Type of construction, variety, and size of wood panels used, for example, 5-ply, $\frac{3}{16}$ -in. (8-mm) walnut

⁴These conditions were taken from the curve on p. 191 of the *Wood Handbook*, Forest Products Laboratory, Madison, WI.

veneer, 6 by 12 in. (152 by 305 mm),

10.1.2 Type of refrigerator, that is, "dry ice" or mechanical,

10.1.3 Finishing system and schedule of application, and

10.1.4 Number of cycles passed without failure and note of all wood failures, specifying the cycle on which such failures occurred.

11. Precision

11.1 Results on all three panels should fall within ± 2 cycles of the mean of all three panels. If this does not occur, additional panels shall be run until there are at least three panels which fall within this range. All panels that have been run are to be taken into consideration. This requirement also applies to panels finished with the control lacquer. Precision as stated here applies only to the test panels described in Section 7.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Methods for Measurement of Wet Film Thickness of Organic Coatings¹

This standard is issued under the fixed designation D 1212; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 These test methods cover the determination of wet film thickness of organic coatings such as paint, varnish, and lacquer. Two methods are described as follows:

1.1.1 In *Test Method A*, the Wet Film Thickness Gage (English or Metric graduation (see 5.1)) is used to measure wet film thicknesses up to 60 mils on the English scale series, and up to 700 μm on the metric scale series (Sections 5 through 8).

1.1.2 In *Test Method B*, the Pfund Gage is used to measure wet film thicknesses up to 14.2 mils (360 μm) (Sections 9 through 13).

1.2 *This standard does not purport to address if any, the safety problems associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 ASTM Standard:

D 823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels²

3. Summary of Test Methods

3.1 The material is applied in the laboratory to plane, rigid test panels or in the field to the surface being coated. The wet film thickness is determined as quickly as possible to reduce shrinkage due to solvent loss.

3.2 In *Test Method A*, a gage with one eccentric and two concentric wheels is rolled over the surface and the point where the eccentric wheel first touches the wet film is determined.

3.3 In *Test Method B*, a gage with a convex lower surface is pushed into the wet film until the center touches the substrate. The diameter of the spot of wet coating left on the convex surface is measured and the film thickness calculated from the diameter of the spot and the radius of curvature.

4. Significance and Use

4.1 Wet film thickness measurements aid in the prediction of dry film thickness. In instances where dry film thickness cannot be measured nondestructively, wet film thickness is frequently specified. Also, the ability to deter-

mine wet film thickness during application can provide the opportunity to correct the application procedures.

TEST METHOD A

5. Apparatus

5.1 *Wet Film Thickness Gage*³—Two versions of the gage are now in use⁴: The original design as shown in Fig. 1 and a later design as shown in Fig. 2. Both designs consists of an eccentric center wheel supported by two concentric wheels so as to provide two scales that are bilaterally symmetrical. As the gage is rolled on the film, there is a change in clearance between the wet film and the eccentric wheel. The point at which the film first touches the center wheel measures the thickness of the film.

5.2 The later design shown in Fig. 2, moves the eccentric wheel from between the concentric wheels, as shown in Fig. 1, to the outside of the gage and closer to one of the concentric wheels. Gage reading errors of parallax across the gage are eliminated as the two scales are placed directly on the eccentric wheel and errors when measuring on uneven support surfaces are reduced by placing the eccentric wheel closer to one of the supporting concentric wheels.

5.3 Best precision is obtained when using the near linear central portion of each scale, constituting about 80 % of its total range as shown in the diagram in Figs. 1 and 2. Therefore, the range of the particular gage selected for use should be such that the measured film thickness falls within, and preferably toward the center of the middle 80 % of each scale. Gages are available covering the following ranges in mils and microns:

Range, mils	Smallest Graduation, mils
0 to 2	0.1
0 to 4	0.2
2 to 12	0.5
10 to 30	1.0
20 to 60	2.0
Range, μm	Smallest Graduation, μm
0 to 40	2.0
0 to 100	5.00
50 to 250	10.00
200 to 700	25.00

³ Available from BYK-Gardner, Inc., Gardner Laboratory, 2435 Linden Ln., Silver Spring, MD 20910 and from the Paul N. Gardner Company, Inc., 316 N.E. First Street, Pompano, FL 33060.

⁴ Both versions of this gage (Interchemical (INMOT) and Model "C"), available from BYK-Gardner, Inc., are covered by U.S. Patents 2 507 592 and 3 128 558, and are held by Maynard R. Euverard, 113 Angell Town Ln., Williamsburg, VA 23185. Interested parties are invited to submit information regarding the identification of acceptable alternatives to this patented item to the Committee on Standards, ASTM Headquarters, 1916 Race St., Philadelphia, 19103. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend.

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.23 on Physical Properties of Applied Paint Films.

Current edition approved May 15, 1991. Published July 1991. Originally published as D 1212 - 52 T. Last previous edition D 1212 - 85.

FIG. 1. Interchemical Wet Film Thickness Gages

FIG. 2. Model "C" Wet Film Thickness Gages

6. Procedure

6.1 Apply the material in accordance with Test Methods D 823 to suitable plane rigid panels of area sufficiently large to permit film thickness measurements at least 1 in. (25 mm) from any edge. Determine the film thickness immediately after application.

6.2 Support the test panels on a suitable level base in such a way that there will be no movement or spring of the panels during the film thickness measurements. Place the gage on the wet film so that the minimum marking is at the top and the greatest clearance between the eccentric wheel and the film is directly over the wet film. Roll the gage over the film one-half revolution in one direction toward the minimum marking on the gage and repeat in the opposite direction. Read the points at which the coating first makes contact with the eccentric wheel and determine the mean which is considered as one reading.

6.3 If the coating contains a solvent that evaporates rapidly or if the solids content is low, make at least a second separate reading on a freshly applied film and calculate the mean of the separate readings.

7. Report

7.1 Report the mean of the separate readings and the range and smallest graduation of the gage used.

8. Precision⁵

8.1 In an interlaboratory study of this test method, in which two operators in at least six laboratories made measurements with the 0- to 2- and 0- to 4-mil gages on three materials, applied at two film thicknesses, the pooled within-laboratory standard deviation was found to be 0.12 mils with 34 df and the between-laboratories standard deviation 0.18 for two determinations and 0.17 for four determinations with 25 df. Based on these standard deviations, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

8.1.1 *Repeatability*—Results, each the mean of opposite rolls of the 0- to 2- or 0- to 4-mil gage, obtained by the same operator should be considered suspect if they differ by more than 0.4 mil for two determinations and 0.5 mil for four determinations.

8.1.2 *Reproducibility*—Two results, each the mean of two separate determinations, obtained by operators in different laboratories, should be considered suspect if they differ by more than 0.55 mil.

⁵ Supporting data are available from ASTM Headquarters. Request D01-1023.

9.2 Steel millimetres.

10. Procedure

10.1 App

⁶ Keinrath, C Technology Cir

FIG. 3 Pfund Gage

8.2 The precision of higher range gages is expected to be proportional to film thickness.

TEST METHOD B

9. Apparatus

9.1 *Pfund Gage*⁶—The gage⁶ shown in Fig. 3 consists of a convex lens *L* with lower surface having a radius of curvature of 250 mm mounted in a short tube *T*₁, that slides freely in an outer tube *T*₂. The compression springs *S* keep the convex surface out of contact with the wet film until pressure is applied to the top of *T*₁, forcing the lens *L* down through the film. The displaced material forms an oversized circular spot of diameter *D*, on the convex lens (larger than the diameter *D* corresponding to the thickness *T* of the film) because of the meniscus effect due to wetting and surface tension effects on the glass lens.

9.2 *Steel Scale* (furnished with Pfund Gage), calibrated in millimetres.

10. Procedure

10.1 Apply the material to suitable plane, rigid panels of

area sufficiently large to permit film thickness measurements at least 1 in. (25 mm) from any edge. Determine the film thickness immediately after application.

10.2 Support the test panels on a suitable flat level base in such a way that there will be no movement or spring of the panels during the film thickness measurements. As shown in the second diagram in Fig. 3, place the gage on the coated surface and slowly force the inner tube down as far as it will go (point *F* on surface *AB* of the base) allowing displaced material to escape through the notches in the outer tube but preventing lateral motion of the gage. Upon releasing the pressure, an oversized circular spot is retained on the lens. Its diameter *D* is the length of the line *EG* and corresponds to the sum of two thicknesses: *AK* = *BC* = thickness of underlying undisturbed coating; and *KE* = *CG* = thickness of overlying displaced coating.

10.3 Remove the gage from the surface, measure to the nearest 0.5 mm in two directions at approximate right angles the diameter of the oversize spot on the lens using the steel scale, and determine the mean of the two measurements that is considered as one reading. Make at least two separate tests to obtain the grand mean film thickness.

10.4 Although this procedure refers to measurements on flat test panels, the same technique may be used in the field or shop on commercial articles, provided the substrate is not distorted at the point of contact to an extent that would affect the measurements.

10.5 If coarse particles in the wet film prevent the lens from making contact with the base at the point *F*, the results will not be valid.

11. Calculation

11.1 The relations between the diameter of the oversized spot on the lens in millimetres, the approximate thickness of the undisturbed wet film, and the coverage in square feet per gallon are given in a printed table supplied with the Pfund gage. It has been found that empirical equations give approximate values for the wet film thickness, *t*, as follows:

$$t \text{ (in mils)} = (D^2 \times 1000) / 16R \times 25.4 = 0.0943 D^2$$

$$t \text{ (in micrometres)} = (D^2 \times 1000) / 16R = 0.25 D^2$$

where:

D = diameter of spot, mm, and

R = radius of curvature of convex lens (250 mm).

based on the fundamental assumption that *t* is exactly one half of the total thickness of the film at the diameter *D*, as shown in the second diagram in Fig. 3.

11.2 The Pfund gage cannot be calibrated by the manufacturer prior to delivery. For the best results, a correction factor must be established for each type and thickness of material, based on freshly prepared films of known wet film thickness, as measured by Test Method A (Interchemical Wet Film Thickness Gage).

12. Report

12.1 Report the mean of at least two separate readings as the wet film thickness.

13. Precision

13.1 In an interlaboratory study of this method, in which two operators in five laboratories made measurements on three materials applied at two film thicknesses, the pooled

within-laboratory standard deviation was found to be 0.21 mil with 30 df and the between-laboratories standard deviation with 24 df 0.285 mil for two measurements and 0.265 mil for four measurements. Based on these standard deviations, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

13.1.1 *Repeatability*—Results, which are the mean of the two measurements at right angles, obtained by the same operator should be considered suspect if they differ by more

than 0.6 mil for two determinations and 0.8 mil for four determinations.

13.1.2 *Reproducibility*—Two results, each the mean of two separate determinations, obtained by operators in different laboratories, should be considered suspect if they differ by more than 0.85 mil.

Standard Test Method for Effect of Household Chemicals on Clear and Pigmented Organic Finishes¹

This standard is issued under the fixed designation D 1308; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This test method has been approved for use by agencies of the Department of Defense to replace Method 6011, 6081 of Federal Test Method Standard No. 141A and for listing in the DoD Index of Specifications and Standards.

1. Scope

1.1 This test method covers determination of the effect of household chemicals on clear and pigmented organic finishes, resulting in any objectionable alteration in the surface, such as discoloration, change in gloss, blistering, softening, swelling, loss of adhesion, or special phenomena.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 *ASTM Standard:*
D 609 Methods for Preparation of Steel Panels for Testing Paint Varnish, Lacquer, and Related Products²

3. Summary of Test Method

3.1 Three test methods, each of which is particularly applicable to individual reagents under study, are described as follows:

3.1.1 *Spot Test, Covered*—The reagent is placed on the test surface and immediately covered with a watch glass.

3.1.2 *Spot Test, Open*—The test surface is subjected directly to the effect of substance, such as citrus fruit, oils, greases, beverages, etc.

3.1.3 *Immersion Test*—A suitably prepared panel is immersed in the test reagent.

4. Significance and Use

4.1 Resistance to various liquids used in the home is an important characteristic of organic finishes. These test methods provide the means by which the relative performance of coating systems may be evaluated. It should be recognized that continuous films are necessary for reliable results.

5. Test Panels

5.1 *Steel Panels*—See Method D 609.

5.2 *Other Metal Panels*, as agreed upon by the purchaser and the seller of the finish being tested.

6. Reagents

6.1 The choice of reagent shall be governed by ultimate coating use and by agreement between the purchaser and the seller of the finish being tested. The following reagents are suggested:

6.1.1 *Distilled Water*, cold.

6.1.2 *Distilled Water*, hot.

6.1.3 *Ethyl Alcohol* (50 % volume).

6.1.4 *Vinegar* (3 % acetic acid).

6.1.5 *Alkali Solution*.

6.1.6 *Acid Solution*.

6.1.7 *Soap Solution*.

6.1.8 *Detergent Solution*.

6.1.9 *Lighter Fluid and Other Volatile Reagents*.

6.1.10 *Fruit*—Piece of cut fruit, with cut portion placed face down on panel for time agreed upon between the purchaser and the seller.

6.1.11 *Oils and Fats*—Butter, margarine, lard, shortening, vegetable oils, etc.

6.1.12 *Condiments*—Mustard, catsup.

6.1.13 *Beverages*—Coffee, tea, cocoa.

6.1.14 *Lubricating Oils and Greases*.

6.1.15 *Other Reagents*, as agreed upon between the purchaser and the seller.

7. Procedure

7.1 *Panel Preparation*—Spot and direct application tests may be carried out on the fabricated article coated with the finishing system under evaluation, if sufficient plane surface is available. For immersion tests and tests where the finished article is not available, select panels in accordance with Methods D 609, or prepare special metal panels according to agreement between the purchaser and the seller of the finish. Apply the finish according to the method and the schedule prescribed by the user of the lacquer. This schedule includes number of coats, film thickness, and other features. Allow the finished panels to age 1 week at normal room conditions, about 77°F (25°C) and 50 % relative humidity, before testing.

7.2 *Spot Test, Covered*—Conduct the test at 73.5 $\pm$ 3.5°F (23 $\pm$ 2°C) and 50 $\pm$ 5 % relative humidity, or as agreed upon between the purchaser and the seller. Using a 5-mL pipet graduated in 0.1 mL, pipet onto the horizontal panel 1 mL of the reagents listed in Section 6 and immediately cover with a watch glass. After an interval agreed upon by the

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.55 on Factory-Applied Coatings on Preformed Products.

Current edition approved May 29, 1987. Published July 1987. Originally published as D 1308 - 54 T. Last previous edition D 1308 - 79 (1981) ^{ϵ} .

² *Annual Book of ASTM Standards*, Vol 06.01.

purchaser and the seller, wipe the spot clean and examine immediately for effects as listed in Section 1. Frequently used intervals are 15 min, 1 h, and 16 h, or by agreement between the producer and the user. If desired, allow the panel to recover for a specified period, and examine for return of original properties.

7.3 Spot Test, Open—Conduct the test at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity, or as agreed upon between the purchaser and the seller. Place a small portion of the reagent on a horizontal panel or surface, with the exception of fruit juices, as mentioned in 5.1.10. After a time interval, as agreed upon between the purchaser and the seller, wipe the spot clean and examine immediately for effects as listed in Section 1. Frequently used intervals are 15 min, 1 h, and 16 h, or by agreement between the producer and the user. If desired, allow the panel to recover for a specified period and examine for return of original properties.

7.4 Immersion—Immerse panels to a depth of 50 % in the specified reagents (6.1.1, 6.1.2, 6.1.5, 6.1.6, 6.1.7, and 6.1.8) contained in beakers, at a temperature and length of time agreed upon between the purchaser and the seller. Withdraw the panels, wash with distilled water, and examine immedi-

ately for any of the effects listed in Section 1. If desired, allow the panels to recover for a specified period and examine for return of the original properties. In general, it will not be necessary to seal the edges of the applied film. If the reagent effect is noted only around the panel edges, the test should be repeated using a suitable edge sealer. When sealing of edges is required, the selection of the sealer should be a matter of agreement between the purchaser and the seller.

8. Report

8.1 Report the following information:

8.1.1 System and the testing method employed. The test conditions are an important factor in the results obtained and, therefore, should be defined in the report.

8.1.2 The type of the effect, if any (see Section 1).

9. Precision and Bias

9.1 This test is designed to provide a working procedure for examination of the effect of household chemicals on clear and pigmented organic finishes. The effects will be in terms of appearance, and numerical values are assigned if a rating scale is used. Precision numbered values are not usually obtained for this type of qualitative test.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Settling Properties of Traffic Paints During Storage¹

This standard is issued under the fixed designation D 1309; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers a laboratory procedure for simulating in 2 weeks the settling that might occur in traffic paint during approximately 12 months' normal storage.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* For a specific hazard statement, see Note in 5.2.

2. Referenced Document

2.1 ASTM Standard:

D 869 Test Method for Evaluating Degree of Settling of Paint²

3. Significance and Use

3.1 Paints, if not formulated or processed properly, or both, may settle excessively. This test method is an attempt to simulate the conditions that would accelerate settling of the pigment in order to evaluate settling properties within 2 weeks. The variables of this test method in conjunction with the very subjective method of evaluating the degree of settling (Method D 869) raise questions as to the usefulness of the results for specification compliance.

4. Apparatus

4.1 *Container*—Standard 1-pt (500-mL), friction top can paint container $3\frac{3}{8} \pm \frac{1}{16}$ in. (85.5 $\pm$ 1.5 mm) in diameter and $3\frac{1}{2} \pm \frac{1}{16}$ in. (98.5 $\pm$ 1.5 mm) in height.

4.2 *Spatula*, weighing 45 ± 1 g with square-end blade $4\frac{3}{4}$ in. (125 mm) in length and approximately $1\frac{3}{16}$ in. (20 mm) in width. A suitable spatula may be prepared by cutting the tip from an ordinary 5-in. (125-mm) flexible steel laboratory

spatula to the specified length.

4.3 *Freezer*, maintained at from -5 to -10°F (-21 to -23.3°C).

4.4 *Oven*, maintained at $160 \pm 2^{\circ}\text{F}$ ($71 \pm 1^{\circ}\text{C}$).

4.5 *Lid Clips*.

5. Procedure

5.1 Thoroughly mix the paint to be evaluated to a homogeneous consistency. Transfer enough of the paint to a 1-pt (500-mL) paint can to fill it to within $\frac{1}{2}$ in. (13 mm) of the top. Close the can tightly, securing the lid with four clips, and subject it to the following exposure cycle.

5.1.1 Monday through Friday:

5.1.1.1 Place in freezer at 8:00 a.m.

5.1.1.2 Transfer to oven at 10:00 a.m.

5.1.1.3 Transfer to freezer at 2:00 p.m.

5.1.1.4 Transfer to oven at 4:00 p.m.

5.1.2 *From 4:00 p.m. Friday until 8:00 a.m. Monday:*

5.1.2.1 Place in the oven at 4:00 p.m. Friday.

5.1.2.2 At 8:00 a.m. Monday morning, after the can has been in the oven over a weekend, place it in the freezer and continue the cycles described above for another 7 days. Each time the can of paint is removed from the oven give it one sharp "spank" on the table top. The spank consists of a short rapid jar of the bottom of the can of paint against the top of the table. The violence of the jar is such that if the bottom of the can of paint were spanked against the platform of a scale instead of a table top the scale would register approximately 5 lb (2.27 kg) weight.

5.2 At the completion of the exposure, allow the paint to cool at room temperature for 4 h and determine the degree of settling in accordance with Method D 869.

NOTE: Warning—Open cans slowly and carefully to allow release of residual vapor pressure.

6. Report

6.1 Report the "accelerated settling rating" in accordance with the degree of settling scale given in the Procedure section of Method D 869.

7. Precision and Bias

7.1 A round robin has been completed and precision and bias statements are being generated.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.44 on Traffic Coatings.

Current edition approved March 25, 1988. Published May 1988. Originally published as D 1309 - 54 T. Last previous edition D 1309 - 83 ϵ 1.

² Annual Book of ASTM Standards, Vol 06.01.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Fineness of Grind of Printing Inks By the NPIRI Grindometer¹

This standard is issued under the fixed designation D 1316; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method describes the procedure for determining the fineness of grind of printing inks using a NPIRI grindometer. It evaluates the size of the largest particles in a finished dispersion but not average particle size or concentration of sizes.

1.2 This test method is applicable to any dispersion that is fine enough to fall within the 0–25 μm range of the specified grind gage. With a minor variation in procedure, it is applicable to both paste (nonvolatile) and liquid (volatile) inks.

NOTE 1—The 0–25 μm gage specified in this test method is similar in principle to the 0–100 μm Hegman gage described in Test Method D 1210. Sieve analysis for concentration of particles above 45 μm is covered in Test Method D 185.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 185 Test Method for Coarse Particles in Pigments, Pastes, and Paints²

D 1210 Test Method for Fineness of Dispersion of Pigment-Vehicle Systems³

E 691 Practice for Conducting an Interlaboratory Test Study to Determine the Precision of Test Methods⁴

3. Descriptions of Terms Specific to This Standard

3.1 *fineness of grind*—a measure of the size and prevalence of oversize particles in a printing ink dispersion.

3.2 *scratch*—a depression at least 10 mm in length in the surface of a grind gage drawdown. A scratch develops when a particle (or agglomerate) is trapped between the blade and the bottom of the path and is drawn along by the blade.

3.3 *speckle*—protuberance of particles above the surface of a grind gage drawdown. Speckles occur at gage depths greater than those at which scratches occur and are caused by

oversize particles that are not hard enough or of the proper size to produce scratches.

4. Summary of Test Method

4.1 This test method utilizes a grind gage having two precision machined grooves each 1 in. (25.4 mm) wide and with a 0–1 mil (0–25 μm) taper. The test specimen is drawn down the paths slowly if a nonvolatile (paste) ink, briskly if a volatile (liquid) ink. The drawdowns are examined for the scale readings at which four and ten scratches appear and at which a preponderance of speckles disappear. The mean of readings from four paths constitutes a single determination.

5. Significance and Use

5.1 Oversize particles in a printing ink may damage a printing plate and adversely affect the appearance of printed ink films. Fineness of grind measurements are useful for deciding when to stop the dispersion process and for determining if the test material meets specifications as agreed upon between the supplier and the customer.

5.2 Speckle endpoints identify the size of the largest particles in a finished printing ink. They provide a better measure of overall dispersion quality than do scratch endpoints but, while their single-operator precision is better, their between-laboratory precision is far poorer.

5.3 Scratch endpoints indicate the size and relative number of the coarsest hard particles in a finished printing ink. They provide a measure of grittiness; the higher the 4-scratch endpoint, the grittier the ink; the smaller the difference between the 4- and 10-scratch endpoints, the larger the number of gritty particles in this range. Scratch endpoints may, however, miss gritty particles that ride in the bank ahead of the scraper; for this reason, they are not recommended for premixes or other dispersions containing a preponderance of gritty particles.

6. Apparatus

6.1 *NPIRI Grindometer*,⁵ consisting of a block of hardened steel⁵ 1 in. (25 mm) in thickness,⁶ 3½ in. (89 mm) in width and 9½ in. (240 mm) in length. The top surface of the block is precision machined so as to contain two paths, each 1 in. in width, 6½ in. (165 mm) in length, and tapered uniformly in depth lengthwise from 1 mil (25 μm) to zero depth. Depth markings are inscribed on the shoulders at each 0.1 mil (2.5 μm) change in taper. Scale inscriptions and the

35	3.5	88	100	1
40	4.0	100		0

^A Numbers above dashed lines are inscribed on the side or on the left shoulder of all standard NPIRI Grindometers. Numbers below dashed lines represent extended scales available on special gages.

^B Nominal depth, not necessarily thickness of material deposited in paths of grind gages. Path fillage is about 80 % for a high viscosity (sheet-fed, offset) ink; 60 % for a low viscosity (letterpress news) ink. Path fillage is also decreased by fast drawdowns.

^C Numbers above dashed lines are inscribed at every fifth calibration line on the right shoulder of newer NPIRI Grindometers.

^D Paint Scale in Test Method D 1210.

relationship among various scales are given in Table 1.

6.2 *Scraper*,⁷ a double edged blade conforming to Test Method D 1210.

6.3 *Ink Knife*, small.

7. Materials

7.1 *Rags or Tissues*, lint- and metal-free.

7.2 *Solvent*, naphtha or other as appropriate for the ink under test.

8. Care of Gage and Blade

8.1 *Cleanliness*—The scraper and the block must be perfectly clean prior to a drawdown. Any dirt or lint present may produce a scratch and give a false reading.

8.2 *Misuse*—The grindometer is a precision instrument and must be treated as such. Do not let any hard materials contact the gage surface or scraper in any manner that might result in scarring or nicking. Avoid tapping or scratching with other metal. Use only soft metal-free cloths for cleanup.

8.3 *Normal Wear*—Under steady usage over an extended period of time, both scraper and block will wear but localized scraper wear is much more rapid than block wear. Periodically check the blade as follows:

8.3.1 *Method 1*—Place a small quantity of an ink across one end of a flat glass plate and make a drawdown. A uniform drawdown indicates that the particular scraper edge is in good condition. A streak of ink or a heavier film of ink at the places corresponding to the shoulders of the

⁷ A second scraper should be procured for use while the first scraper is being reconditioned or is otherwise out of commission.

grindometer is evidence of blade damage or excessive wear. Repeat the drawdown with the other edge of the blade.

8.3.2 *Method 2* (from Test Method D 1210)—Face one edge of the scraper down across the bottom of the top surface of the grindometer or other smooth level surface. Place a strong light behind the scraper and examine the contact edge; any light coming through shows that the blade edge has been damaged and is not satisfactory for use. Wear and warpage can also be detected by rocking the blade back and forth. Repeat the procedure on the other edge of the blade.

8.4 *Rusting*—The grindometer is made of carbon steel and is subject to rusting. Apply a coating of grease or other rust-preventative and keep covered or encased when not in use.

NOTE 2: Caution—Do not use a gage or blade that exhibits damage or wear (see 8.2 to 8.4). Replace or return to the manufacturer for reconditioning.

9. Sampling

9.1 Approximately 2 to 3 mL of ink sample is sufficient to fill four paths of the grindometer. When taking samples either from a container or from a disperser, push aside the top layer and take the sample from below. This technique prevents skin or surface dust from being transferred to the gage.

9.2 If the sample is a liquid ink, hand stir the sample vigorously for 2 min, taking care that air bubbles are not whipped in.

10. Procedure

10.1 Place the gage on a flat, non-slippery surface so that the deep end of the grooves is farthest from the operator. Wipe clean immediately before the test. Be sure the gage surface is dry and free of lint and wipe marks.

10.2 Using the ink knife, transfer a small quantity of ink across the deep end of both grooves about 1/2 in. (12.5 mm) from the end of the block. Alternatively, different inks may be placed in the two respective paths.

10.3 Grasp the scraper in both hands and, holding in a vertical position, place it behind the ink of the gage. Apply adequate pressure to ensure positive contact of the blade with the surface of the gage and draw the ink down the length of the path. Ink remaining on the shoulders is evidence of insufficient pressure.

10.3.1 *Paste Inks*—Make the drawdown with a smooth steady stroke that takes 7 to 10 s to complete.

10.3.2 *Liquid Inks*—Make the drawdown with a brisk stroke that takes 1 to 2 s to complete. When testing fluid inks, it is essential to work quickly, as partial drying of the ink specimen or the ink film can influence test results.

10.4 Set the blade on a sheet of scrap paper, and immediately pick up the gage to read the endpoints. Rotate the gage in a light until the patterns, when viewed from the side, are clearly visible. Record endpoints (see Section 11) within 10 s of completing the drawdown.

10.5 Immediately clean the gage and repeat the procedure in 10.2 through 10.4 until readings have been made on 10 paths per sample. If a reference standard was used in one path, alternate its position on the repeat tests.

TABLE 2 Precision of Grindometer Endpoints for Roll-Milled Dispersions

Endpoints	Standard Deviation, gu	Degrees of Freedom	Maximum Allowable Difference, gu(μm)
A. Repeatability (single operator)			
4-scratch	0.31	36	0.87 (2.2)
10-scratch	0.27	36	0.76 (1.9)
Speckles	0.15	30	0.43 (1.1) ^a
B. Reproducibility (between laboratories)			
4-scratch	0.72	30	2.1 (5.0)
10-scratch	0.70	30	2.0 (5.0)
Speckles	1.97	24	5.6 (14.2) ^a

^a Comparable figures from the precision statement of Test Method D 1210 are 10 μm for repeatability and 25 μm for reproducibility.

11. Reading of Endpoints and Report

11.1 Read the following endpoints to $\frac{1}{2}$ gu (see NPIRI scale in Table 1) or to 1 μm or both.

11.1.1 The first point from the deep end at which four scratches, each at least 10 mm long, occur simultaneously. The scratches need not reach the bottom of the plate groove.

11.1.2 As in 11.1 for ten scratches.

11.1.3 The place at which speckles disappear.

11.2 Record the three types of endpoints on a total of four paths and compute the respective means.

11.3 When reporting endpoints, mean figures may be rounded to $\frac{1}{2}$ gu, or to 1 μm , or both.

12. Precision and Bias^a

12.1 Precision:

12.1.1 An interlaboratory study of this test method was conducted in which one operator in each of seven laboratories made two determinations, each the mean of readings on four drawdowns, on two different days on six carbon black dispersions. The samples represented two different levels of premixing, each followed by one, two, or four passes on a roll mill. The results were analyzed statistically in accordance with Practice E 691. On the basis of the standard deviations shown in Table 2, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

12.1.1.1 *Repeatability*—Two results, each the mean of readings on four drawdowns, obtained by the same operator should be considered suspect if they differ by more than the scale readings given in the last two columns of Table 2, Section A.

12.1.1.2 *Reproducibility*—Two results, each the mean of readings on four drawdowns, obtained by operators in different laboratories should be considered suspect if they differ by more than the scale readings given in the last two columns of Table 2, Section B.

12.2 *Bias*—Bias cannot be determined as there is no standard material. In the interlaboratory study described in 12.1.1, speckle endpoints were more sensitive to expected differences in degree of dispersion than were scratch endpoints.

^a Supporting data are available from ASTM Headquarters. Request RR: D01-1054.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Standard Test Method for Fire Retardancy of Paints (Cabinet Method)¹

This standard is issued under the fixed designation D 1360; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method determines quantitatively the fire retardant properties of a coating or coating system on a wood surface and the leaching effect of water on the fire retardancy of the coating or coating system. Specifically, this test method determines the weight loss and char index of coated panels subjected to a flame and the effect of leaching of the coating on these parameters.

1.2 This test method should be used solely to measure and describe the properties of materials, products, or systems in response to heat and flame under controlled laboratory conditions and should not be considered or used for the description, appraisal, or regulation of the fire hazard of materials, products, or systems under actual fire conditions.

1.3 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 Federal Standard:²

Fed. Spec. TT-V-119—Varnish, Spar, Phenolic Resin

2.2 Military Standard:²

Mil. Spec. MIL-A-22397—Adhesive, Phenol, and Resorcinol Resin Base for Marine Use

3. Terminology

3.1 Description of Terms Specific to This Standard:

3.1.1 *fire retardancy, n*—in paint, the ability of a paint to retard the spread of a flame over coated substrate usually at the sacrifice of the paint film.

4. Summary of Test Method

4.1 *Fire Retardancy*—Panels are conditioned before and after coating with the material under test. They are subjected to a flame from a small amount of burning alcohol or other solvent and the weight loss and char index are determined.

4.2 *Leaching*—Similarly prepared panels are immersed in water for a specified time and then subjected to the fire-retardancy test. The weight loss, char index, and difference in weight loss and char index between leached and unleached panels are determined.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.22 on Health and Safety.

Current edition approved Oct 26, 1990. Published December 1990. Originally published as D 1360 - 55 T. Last previous edition D 1360 - 90.

² Available from Standardization Documents Order Desk, Bldg. 4 Section D, 700 Robbins Ave., Philadelphia, PA 19111-5094, ATTN: NPODS.

5. Significance and Use

5.1 This test method determines the relative fire-retardant properties of coatings and the water leaching of the fire-retardant material from the applied coating. Leaching simulates the effect of high humidity, weathering, and washing on the fire retardancy of a coating, and is specified in various regulations and specifications for fire-retardant paints.

6. Apparatus

6.1 *Cabinet*³—A glass and metal box as shown in Fig. 1.

6.2 *Assembly*,³ consisting of supports for the test panels and solvent cup. The assembly is shown within the cabinet in Fig. 1.

6.3 *Cylindrical Cup*, to hold solvent, made of brass to the following dimensions:

Outside diameter, in. (mm)	1 5/16 (24)
Outside height, in. (mm)	1 1/16 (17)
Wall thickness, in. (mm)	1/32 (1)
Volume, mL	6.0
Operating capacity, mL	5.0

6.4 *Balance*, weighing to 0.1 g.

6.5 *Buret or Pipet*, calibrated in millilitres.

6.6 *Container or Water Bath*, 12.5 by 6.5 by 6.5 in. (320 by 165 by 165 mm), galvanized steel with cover to accommodate 15 panels, or other sizes to accommodate 5 to 10 panels.

6.7 *Oven* capable of maintaining a temperature of $120 \pm 3^\circ\text{F}$ ($50 \pm 2^\circ\text{C}$).

6.8 *Constant Temperature and Humidity Cabinet or Room*, maintained at $50 \pm 5\%$ relative humidity and $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$).

7. Test Materials

7.1 *Ignition Fuel*, absolute ethyl alcohol (ethanol) or comparable solvent blend.

NOTE 1—A mixture of 71.4 % reagent grade isopropanol and 28.6 % reagent grade methanol having the same heat of combustion as pure absolute ethanol may be used as the source of ignition.

7.2 Test Panels:

7.2.1 Unless otherwise specified or agreed, yellow poplar heartwood panels 1/4 by 6 by 12 in. (6 by 150 by 305 mm), close-grain, and as nearly edge grain as possible, free from knots and other imperfections, with surfaces planed and sanded. Panels shall be of solid wood or edge glued sections to obtain the width, provided that no strip is less than 1 1/2 in.

³ A suitable cabinet and assembly may be obtained from Custom Scientific Instruments, Inc., 13 Wing Drive, Cedar Knolls, NJ, 07927. Drawings of cabinet, assembly, etc., may be obtained from ASTM Headquarters. Order PCN 12-413-600-14.

(38 mm) wide and that no more than two glue lines occur in any one panel. The adhesive used in glueing these panels shall conform to Mil. Spec. MIL-A-22397. Test panels shall be kiln dried so as to contain no more than 10.0 weight % moisture and after conditioning as specified in 8.1 shall weigh from 27 to 30 lb/ft³ (125 to 140 g/panel).

7.2.2 Douglas fir or other woods shown in Table 1 may be used where required. Table 1 shows the densities and weight per panel for each wood after conditioning.

NOTE 2—Asbestos board (or inorganic reinforced cement board), steel, or concrete may be used upon agreement between the purchaser and the seller.

8. Preparation of Test Panels

8.1 Condition panels for 14 days in a controlled atmosphere of 50 ± 5 % relative humidity and 73.5 ± 3.5°F (23 ± 2°C) prior to coating. Seal the ends of the panels with two coats of varnish conforming to Fed. Spec. TT-V-119 after the conditioning. Allow each coat of varnish to air dry 18 to 24 h.

8.2 Brush apply the material under test in one coat at 250 ft²/gal (6 m²/L) (wet film thickness of 6.4 mils) or in two coats at 500 ft²/gal (12 m²/L) (3.2 mils per coat) to each face

of each panel, obtaining as uniform coverage as possible. Application can be by other conventional means and in as many coats to obtain the necessary weight of coating or desired wet or dry film thickness. Also coat the edges and sides of the panels with the same material. When applied in more than one coat, dry 24 h between coats under standard conditions (see 6.8) and, after the final coat, dry 14 days under the controlled conditions. Prior to subjecting the specimens to the burning test, place them in the oven at 120 ± 3°F (50 ± 2°C) for a period of 40 h.

8.3 Calculate the weight of the coating to be applied using the following equation:

$$W = \frac{(6 \times 12)}{144S} D \times 454$$

where:

W = weight of applied wet coating, g,
 D = coating density, lb/gal, and
 S = spreading rate in ft²/gal.

8.3.1 Use the following equation when metric units are employed:

$$W = (46.4D)/S$$

where:

TABLE 1 Densities and Panel Weights of Various Woods

NOTE—Conditioned at relative humidity $50 \pm 5\%$ and $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) for 14 days.

Type of Wood	Density (9 to 10 weight % Moisture), lb/ft ³ (kg/m ³)	Weight of 6 by 12 by 1/4 in. (152 by 305 by 6 mm) Panel, g
Red cedar	21.4–22.4 (345–360)	101–106
Douglas fir	29–35 (465–560)	137–165
White pine–ponderosa pine	22.4–26.4 (360–420)	106–125
Southern yellow pine	31–37 (495–590)	147–175
Redwood	27.2–28.2 (435–450)	129–133

W = weight of applied wet coating, g.
 D = coating density, g/mL, and
 S = spreading rate, m²/L.

9. Procedure—Fire Retardancy

9.1 Assemble the apparatus as shown in Fig. 1, including the stack extension and downdraft hood, in an area where facilities are available for the removal or escape of combustion products (standard laboratory hood without forced ventilation). Weigh the panel to be tested to the nearest 0.1 g and record the weight. Center the panel, face down, on the angular supports with the lower edge 2 in. (50 mm) from the angle formed by the floor and the side wall of the cabinet. Place the fuel cup, at room temperature, on the pedestal so that the vertical distance from the cup lip nearest to the face of the specimen is exactly 1.0 in. (25 mm). Using a buret or pipet, add 5.0 mL of pure absolute ethanol or any mixture with the same heat of combustion (Note 1) to the cup and ignite without delay by means of a flame approximately 1/2 in. (13 mm) in length. Close the door and adjust the draft to assure complete burning of the alcohol. Allow the test to continue until all flames self-extinguish. Repeat this procedure with at least five replicate panels.

9.2 **Weight Loss**—Cool each panel to room temperature and weigh to the nearest 0.1 g. Determine the weight loss in grams of each of the five specimens by subtracting from its original weight (see 9.1). Calculate the mean and standard deviation for the weight loss. If the standard deviation of the five replicates is greater than 10% of the mean, test five additional panels and calculate the mean weight loss of the ten panels.

9.3 **Char Index**—Cut the panels by means of a fine-toothed saw along the lines of maximum length and width of attack. Measure in centimetres the maximum width of charring of the wood panel below the paint film on the lateral cut. Likewise, measure the maximum length of charring found on the longitudinal cut. Measure the maximum depth to which charring has penetrated the wood as evidenced on the longitudinal or lateral cuts. Determine the

char index by multiplying the maximum char length, width, and depth figures. Calculate the mean and standard deviation for the char index. If the standard deviation of the five replicates is greater than 10% of the mean, test five additional panels and calculate the mean char index on the basis of the ten panels.

10. Procedure—Leaching Test

10.1 Prepare, coat, and condition 15 panels of each material under test as described in Section 8.

10.2 At the end of 14 days at 50 % humidity and 73.5°F (23°C), immerse the 15 panels in 2250 ± 30 mL of water (150 mL/panel) (Note 3) for 40 h at $120 \pm 3^\circ\text{F}$ ($50 \pm 2^\circ\text{C}$).

NOTE 3—The water bath is made to contain 15 panels and 2250 mL of water to cover the specimens. If less than 15 coated panels are immersed, add blank panels to make up the 15. Place panels so that their faces do not touch. Cover the bath to prevent excessive evaporation.

10.3 Subject each of the 15 panels to the fire retardant test in accordance with 9.1 and calculate the differences in mean weight loss and mean char index between the leached and the unleached set of specimens as follows:

Δ wt. loss = mean wt. loss of leached specimens – mean wt. loss of unleached specimens.
 Δ char index = mean char index of leached specimens – mean char index of unleached specimens.

11. Report

11.1 Report the following information:

11.1.1 The number of coats and the coverage in ft²/gal (m²/L) of the total numbers of coats for each set of each material under test,

11.1.2 The mean weight loss and the mean char index of the set exposed only to the fire retardancy test, the number of specimens used in calculating the means, and the final standard deviation, and

11.1.3 The difference in mean weight loss and mean char index between the sets of unleached and leached specimens as determined in 10.3.

12. Precision and Bias

12.1 The precision of this test is to be determined.

12.2 **Bias**—The bias of this test method cannot be determined as the value of fire retardancy can be defined only in terms of a test method.

13. Keywords

13.1 cabinet method; char index; fire retardancy; government specification; paint

Standard Test Method for Nondestructive Measurement of Dry Film Thickness of Nonconductive Coatings Applied to a Nonferrous Metal Base¹

This standard is issued under the fixed designation D 1400; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

1. Scope

1.1 This test method covers the nondestructive measurement of the dry film thickness of electrically nonconductive coatings applied over a nonferrous metal base using commercially available eddy current instruments.

1.2 This test method is not applicable to coatings that will be readily deformable under the load of the measuring instrument.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels²

D 1730 Practices for Preparation of Aluminum and Aluminum-Alloy Surfaces for Painting³

3. Summary of Test Method

3.1 Instruments covered by this test method measure coating thickness by the use of eddy currents. The instrument probe must be placed directly on the coating surface to take a reading.

4. Significance and Use

4.1 The instrument probe coil is energized by alternating current which induces eddy currents in the metal substrate. The eddy currents in turn create opposing alternating magnetic fields in the substrate that modify the electrical characteristics of the probe coil. The extent of such changes is dependent upon the distance between the probe and the metal, the distance being shown on the instrument meter as the thickness (mils or micrometers) of the intervening coating.

4.2 The accuracy of the measurements may be influenced when made closer than 1 in. (25 mm) to an edge or 3 in. (75 mm) to another mass of metal.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.23 on Physical Properties of Paint Films.

Current edition approved May 29, 1987. Published July 1987. Originally published as D 1400 - 56. Last previous edition D 1400 - 81.

² Annual Book of ASTM Standards, Vol 06.01.

³ Annual Book of ASTM Standards, Vols 02.05 and 06.01.

5. Apparatus

5.1 *Eddy Current Thickness Gages*, commercially available, suitable to measure coating thickness accurately.⁴

6. Test Specimens

6.1 When this test method is used in the field, the specimen is the coated structure or article on which the thickness is to be evaluated.

6.2 For laboratory use apply the materials to be tested to panels of the composition and surface conditions on which it is desired to determine the thickness.

NOTE 1—Applicable test panel description and surface preparation methods are given in Practices D 1730.

NOTE 2—Coatings should be applied in accordance with Test Methods D 823, or as agreed upon between the purchaser and the seller.

7. Calibration of Apparatus

7.1¹ Calibrate the instrument in an area free of stray magnetic fields, such as power lines, generators, or welding equipment. There shall be no vibration apparent on the test piece when the instrument is being calibrated.

7.2 Use a bare section of the substrate after the specified surface preparation method has been accomplished. If an uncoated section of the substrate is not available, uncoated test panels of a similar metal type over which the specified preparation has been performed may be used.

7.3 Use nonmagnetic thickness shims for calibration. Most shims are non-precision and therefore, thickness must be verified with a micrometer.

7.4 Select calibration shims in the expected thickness range to be measured. If a coating is expected to be 3 mils (75 μ m) in thickness, calibrate the instrument at 3 mils. Then check the calibration using shims of both a lesser and greater thickness to determine the thickness range over which the instrument will register accurately.

7.5 Follow the manufacturer's instructions for the specific adjustment of the instrument.

8. Procedure

8.1 Use the instrument only after it has been calibrated in accordance with Section 7.

8.2 Assure that the coating is dry prior to use of the instrument.

⁴ Apparatus found to be suitable include the Permascope, Dermatron, Minitest, and Minitecor. Sources for the instruments are available from ASTM, 1916 Race St., Philadelphia, PA 19103.

8.3 Inspect the probe tip and surface to be measured to assure that they are clean, otherwise erroneous readings can result.

8.4 Take readings in areas free of vibration, electrical, or magnetic fields.

8.5 If thickness readings are found outside the range of accuracy determined in 7.4, repeat the calibration procedure in that range. Check the calibration frequently during use to assure that the instrument continues to read properly.

8.6 Take a sufficient number of readings to characterize the sample.

8.6.1 For laboratory measurements a recommended minimum is three for a 3 by 6 in. (75 by 150 mm) panel and more in proportion to size.

8.6.2 For field measurements a recommended minimum is five determinations at random for every 100 ft² (10 m²) of the surface area. Each of the five determinations should be the mean of three separate gage readings within the area of a 1/2 in. (12 mm) diameter circle.

8.7 Take measurements no closer than 1 in. (25 mm) to an edge or 3 in. (75 mm) to another mass of metal. If such measurements are necessary, recheck the calibration in the specific area to determine the effect the edge or mass of metal has on the instrument reading.

8.8 Report the instrument used, serial number, range, and mean of thickness readings found.

9. Precision

9.1 *Precision*—On the basis of an interlaboratory study of this test method in which eddy-current instruments from four manufacturers were used in several laboratories to measure a moderate range of dry-film thickness on the same set of panels, the within-laboratory and between-laboratories coefficients of variation were found to be as shown in Table 1. Based upon these coefficients the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

9.1.1 *Repeatability*—Two results obtained by the same operator using instruments from the same category should be considered suspect if they differ by more than the maximum allowable difference values given in Table 1 for the appropriate film thickness.

9.1.2 *Reproducibility*—Two results, each the mean of four measurements, obtained by operators in different laboratories using instruments from the same category should be considered suspect if they differ by more than the maximum allowable difference values given in Table 1 for the appropriate film thickness.

TABLE 1 Precision of Film Thickness Measurements

	Within Laboratory:					
	Coating Thickness					
	0.5 to 1.5 mils			3 to 3.5 mils		
	Degrees of Freedom (DF)	Coefficient of Variation (v_w), %	Maximum Allowable Difference (MAD), %	Degrees of Freedom (DF)	Coefficient of Variation (v_w), %	Maximum Allowable Difference (MAD), %

Standard Test Methods for Indentation Hardness of Organic Coatings¹

This standard is issued under the fixed designation D 1474; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

These test methods have been approved for use by agencies of the Department of Defense to replace Method 6212 of Federal Test Method Standard No. 141A. Consult the DoD Index of Specifications and Standards for the specific year of issue that has been adopted by the Department of Defense.

^{ε1} NOTE—Keywords were added editorially in January 1991.

1. Scope

1.1 These test methods cover the determination of the indentation hardness of organic materials such as dried paint, varnish, and lacquer coatings, when applied to an acceptable plane rigid surface, for example, metal or glass.

1.2 Two methods are covered as follows:

	Sections
Method A—Knoop Indentation Hardness	6 to 12
Method B—Pfund Indentation Hardness	13 to 19

1.3 Method A, which has the greater precision, provides hardness values in terms of Knoop Hardness Number (KHN). Method B provides hardness in terms of Pfund Hardness Number (PHN). Although the hardness value scales of these methods differ, the methods agree in the ranking of coating hardness.

1.4 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

- D 823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels²
- D 1005 Test Methods for Measurement of Dry-Film Thickness of Organic Coatings Using Micrometers²
- D 1186 Test Methods for Nondestructive Measurement of Dry Film Thickness of Nonmagnetic Coatings Applied to a Ferrous Base²
- D 1400 Test Method for Nondestructive Measurement of Dry-Film Thickness of Nonconductive Coatings Applied to a Nonferrous Metal Base²

3. Terminology

3.1 Definitions:

3.1.1 *indentation hardness*—the resistance to penetration by an indenter.

3.1.2 *Knoop indenter*—a pyramidal diamond of prescribed dimensions.

3.1.3 *Pfund indenter*—hemispherical quartz or sapphire indenter of prescribed dimensions.

3.1.4 *Knoop hardness number, KHN*—the indentation hardness determined with a Knoop indenter, and calculated as follows:

$$KHN = L/A_p = L/l^2 C_p$$

where:

L = load applied to the indenter, kg,

l = measured length of long diagonal of the indentation, mm,

C_p = indenter constant relating l^2 to A_p , and

A_p = projected area of indentation, mm².

3.1.5 *Pfund hardness number, PHN*—the indentation hardness determined with a Pfund indenter, and calculated as follows:

$$PHN = L/A = 4L/\pi d^2 = 1.27 (L/d^2)$$

where:

L = load/kg applied to the indenter, kg,

A = area of projected indentation, mm², and

d = diameter of projected indentation, mm.

4. Significance and Use

4.1 Indentation hardness measurements have proven to be useful in rating coatings on rigid substrates for their resistance to mechanical abuse, such as that produced by blows, gouging, and scratching. These measurements do not necessarily characterize the resistance to mechanical abuse of coatings that are required to remain intact when deformed.

5. Test Specimens

5.1 The substrate for the coating shall be an acceptable plane rigid surface such as glass or metal.

5.2 The coating thickness on any one panel shall be uniform within 0.1 mil (3 μm). Coatings to be compared shall be of equal thickness within 0.2 mil (5 μm). For maximum accuracy, the minimum permissible coating thickness shall be such that the depth of indentation does not exceed three fourths of the coating thickness, to minimize the effect of the substrate.

5.3 At least three replicate specimens shall be tested for each coating to be evaluated.

5.4 Coatings should be applied in accordance with Test Methods D 823 and their dry film thickness should be

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.23 on Physical Properties of Applied Paint Films.

Current edition approved Sept. 27, 1985. Published November 1985. Originally published as D 1474 - 57 T. Last previous edition D 1474 - 68 (1979)^{ε1}.

² Annual Book of ASTM Standards, Vol 06.01.

measured in accordance with Test Methods D 1005, D 1186, or D 1400.

METHOD A—KNOOP INDENTATION HARDNESS

6. Summary of Method

6.1 This method consists of applying a load to the surface of a coating by means of a pyramidal shaped diamond having specified face angles, and converting the measurements of the resultant permanent impression to a hardness number.

7. Apparatus

7.1 *Hardness Tester*,³ consisting of a load applicator, a Knoop indenter, and a microscope fitted with a movable micrometer stage. The apparatus shall mechanically bring the indenter into contact with the test surface with negligible impact, apply the selected full load, maintain it for 18 ± 0.5 s, and withdraw the indenter.

7.2 *Knoop Indenter*—The Knoop indenter is a pyramidal diamond with included longitudinal angles of $172^\circ 30'$ and included transverse angle of $130^\circ 0'$.

NOTE 1—The ratio of the long to the short diagonal of the impression is approximately 7:1; the ratio of the long diagonal to the depth of penetration is approximately 30:1.

7.3 *Microscope*—The microscope shall have a filar micrometer eyepiece and sufficient objectives to permit the measurement of the length of impression to within $\pm 1\%$. The specimen shall be firmly supported on a movable micrometer stage attached to the microscope.

8. Calibration

8.1 Adjust the illumination in the microscope to give maximum contrast when viewing an indentation.

8.2 By means of a calibrated scale, determine the factor for each microscope objective that will convert the filar scale units of the eyepiece to millimetres.

8.3 With a 25-g load on the indenter, determine the KHN of a calibrated standard (Note 2) whose assigned value is not greater than 50 KHN. If the obtained value is within $\pm 5\%$ of the assigned value, the instrument is considered to be in calibration.

NOTE 2—A suitable source of calibrated standards in this hardness range is not available. Therefore, by agreement of the parties concerned, a stable specimen (such as an aged coating of a baked enamel applied to a flat substrate) should be used to calibrate the participating hardness testers.

9. Procedure

9.1 Unless otherwise specified, make the hardness determinations at $73.5 \pm 3.50^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity after equilibrating the specimens under these conditions for at least 24 h.

9.2 Rigidly attach the specimen to the movable stage so that the surface to be measured is normal to the direction of indentation.

³ Among the hardness testers meeting the apparatus requirements for this method are the Tukon Micro-hardness Tester and the Riehle Kentron Micro-hardness Tester, available from the Page-Wilson Measurement System Div., 929 Connecticut Ave., Box 9021, Bridgeport, CT 06602.

NOTE 3—The panel should be so mounted that it cannot move with respect to the stage in any direction during the course of the test.

9.3 Use the microscope to select an area of the test specimen that is free of surface irregularities and imperfections. Place this area under the indenter by means of the movable micrometer stage.

NOTE 4—If good impressions cannot be obtained because of the roughness of the surface of the specimen, gently polish the surface with No. 400 carborundum and finish off with jewelers rouge before making the impression.

9.4 Preset the apparatus to apply a 25-g load and perform the test according to the manufacturer's instructions. Maintain the time the indenter is in contact with the specimen for 18 ± 0.5 s.

NOTE 5—For maximum accuracy, care must be taken that the indenter does not penetrate the coating to a depth beyond three fourths of the coating thickness. This is necessary to eliminate any major substrate effect on the hardness measurement.

9.5 Immediately after the completion of the cycle, adjust the movable stage so that the indentation is in the field of the microscope. Focus the microscope on the indentation so that both extremities of the long diagonal (that is, where the upper edges of the indentation just converge) are as sharp as possible. Measure the length of the long diagonal of the impression with the filar micrometer eyepiece.

NOTE 6—Select a microscope objective that will cause the length of impression to be between 200 and 800 filar units to assure maximum accuracy in measurement.

9.6 From the measurements obtained in 9.5, the information given in Note 1, and the measured film thickness at the place of indentation, calculate the depth of indenter penetration. If the depth of penetration exceeds three-fourths of the coating thickness, the results may be influenced by substrate proximity. Therefore, for maximum accuracy it is desirable to prepare thicker specimens and repeat the test. Instead of this procedure, at the option of purchaser and seller, an indenter load of less than 25 g may be used.

9.7 Repeat the procedure described in 9.3, 9.4, and 9.5 until at least five impressions have been made at widely spaced locations on the specimen.

10. Calculation

10.1 Calculate the mean indentation length in filar units.

10.2 Convert this mean indentation length to KHN by means of the appropriate tables supplied with the instrument.

NOTE 7—If a conversion table is not available, the KHN may be calculated as follows:

$$\text{KHN} = 0.025/l^2 C_p$$

where:

0.025 = load applied, kg, to the indenter,

l = length of long diagonal of indentation, mm, and

C_p = indenter constant = 7.028×10^{-2} .

11. Report

11.1 Report the following information:

11.1.1 Mean and range of KHN values obtained for each specimen, stating the number of indentations made and the indenter load used;

- 11.1.2 Mean film thickness of each specimen, based on the measurements made at the points of indentation,
- 11.1.3 Specimen preparation and conditioning techniques used, and
- 11.1.4 Mean and range of KHN values of the replicate panels.

12. Precision

12.1 On the basis of an interlaboratory test of this method in which operators in six laboratories tested seven coated panels having a broad range of hardness, the within-laboratory coefficient of variation was found to be 3 % with 21 degrees of freedom and the between-laboratories coefficient of variation 8 % with 30 degrees of freedom. Based upon these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

12.1.1 *Repeatability*—Two results, each the mean of three determinations on a specimen, obtained by the same operator should be considered suspect if they differ by more than 9 % of their mean value.

12.1.2 *Reproducibility*—Two results, each the mean of three determinations on a specimen, obtained by operators in different laboratories should be considered suspect if they differ by more than 24 % of their mean value.

METHOD B—PFUND INDENTATION HARDNESS

13. Summary of Method

13.1 This method consists of applying a load to the surface of a coating, by means of a transparent colorless quartz or synthetic sapphire hemisphere having a specified diameter, and converting the measurement of the resultant observed impression under load to a hardness number.

FIG. 1 A Pfund Hardness Tester (Shown Before Application of Weight)

14. Apparatus

- 16.3 W the inden the full lo
- 16.4 A measure t eyepiece c the diam the inden controlled

⁴ A hardness Pfund Indent: 1415 Park Av

14. Apparatus

14.1 *Hardness Testers*—The hardness testers used in this method shall consist of a load applicator, a Pfund quartz or sapphire indenter, and a microscope fitted with a stage. The apparatus shall be constructed so as to permit the indenter to be brought manually into contact with the specimen surface with negligible impact.

14.2 *Pfund Indenter*^{*}—The Pfund indenter (Fig. 1) is a transparent colorless quartz or synthetic sapphire hemisphere with a spherical radius of 0.125 in. (3.18 mm) and a maximum spherical eccentricity of 0.002 in. (0.05 mm).

14.3 *Microscope*—The microscope shall have a filar micrometer eyepiece and sufficient objectives to permit the measurement of the diameter of impression to within $\pm 1\%$. The specimen shall be rigidly supported on the microscope stage.

14.4 *Timer*, capable of measuring a time interval of 60 ± 0.5 s.

15. Standardization

15.1 Adjust the illumination in the microscope to give maximum contrast when viewing an indentation.

15.2 By means of a calibrated scale, determine the factor for each microscope objective that will convert the filar scale units of the eyepiece to millimetres.

15.3 With a 1.0-kg load on the indenter, determine the PHN of a calibrated standard (Note 2) with an assigned value not greater than 40 PHN. If the value obtained is within $\pm 5\%$ of the assigned value, the instrument shall be considered to be in calibration.

16. Procedure

16.1 Unless otherwise specified, make the hardness determination at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity, after holding the specimens under these conditions for not less than 24 h.

16.2 Rigidly attach the specimens to the instrument stage such that the surface to be measured is normal to the direction of indentation (Note 3).

16.3 With a 1.0-kg load on the indenter, carefully bring the indenter into contact with the specimen surface, apply the full load, and start the timer.

16.4 At the end of 60 s, while still under full load, rapidly measure the diameter of the circular impression with the filar eyepiece of the microscope (Note 6). It is very important that the diameter measurements be made rapidly so that the time the indenter is in contact with the specimen is closely controlled.

^{*}A hardness tester meeting the apparatus requirements of this method is the Pfund Indentation Hardness Tester, available from the United States Testing Co., 1415 Park Ave., Hoboken, NJ 07030.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

16.5 From the measurements obtained in 16.4, the information given in 14.2, and the measured film thickness at the place of indentation, calculate the depth of indenter penetration. If the depth of penetration exceeds three fourths of the coating thickness, the results may be influenced by substrate proximity. Therefore, for maximum accuracy it may be desirable to prepare thicker specimens and repeat the test.

16.6 Repeat the procedure in 16.3 and 16.4 until a total of at least five impressions have been made at widely spaced locations on the specimen.

17. Calculation

17.1 Calculate the mean indentation diameter in filar units.

17.2 Convert this mean indentation diameter to millimetres using the appropriate factor determined in 15.2.

17.3 Calculate the PHN as follows:

$$\text{PHN} = 1.27/d^2$$

where:

d = mean indentation diameter, mm.

18. Report

18.1 Report the following information:

18.1.1 Mean and range of PHN values obtained for each specimen, stating the number of indentations made,

18.1.2 Mean film thickness of the specimen, based on measurements made near the points of indentation,

18.1.3 Specimen preparation and conditioning techniques used, and

18.1.4 Mean and range of PHN values of the replicate panels.

19. Precision

19.1 On the basis of an interlaboratory test of this method in which operators in four laboratories tested seven coated panels having a broad range of hardness, the within-laboratory coefficient of variation was found to be 6 % with 28 degrees of freedom and the between-laboratories coefficient 12 % with 18 degrees of freedom. Based upon these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

19.1.1 *Repeatability*—Two results, each the mean of three determinations on a specimen, obtained by the same operator should be considered suspect if they differ by more than 18 % of their mean value.

19.1.2 *Reproducibility*—Two results, each the mean of three determinations on a specimen, obtained by operators in different laboratories should be considered suspect if they differ by more than 36 % of their mean value.

20. Keywords

20.1 hardness (indentation); hardness (Pfund); Knoop hardness tester; Pfund hardness tester

Standard Test Method For Density of Paint, Varnish, Lacquer, and Related Products¹

This standard is issued under the fixed designation D 1475; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This method has been approved for use by agencies of the Department of Defense to replace Method 4184.1 of Federal Test Method Standard No. 141A and for listing in the DoD Index of Specifications and Standards.

1. Scope

1.1 This test method covers the measurement of density of paints, varnishes, lacquers, and components thereof, other than pigments, when in fluid form.

1.2 For higher precision when working with nonpigmented materials (drying oils, varnishes, resins and related materials), Test Method D 1963 can be used to determine specific gravity and, thence, density.

1.3 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 ASTM Standard:

- D 1963 Test Method for Specific Gravity of Drying Oils, Varnishes, Resins and Related Materials at 25/25°C²
- D 4052 Test Method for Density and Relative Density of Liquids by Digital Density Meter³
- E 380 Practice for Use of the International System of Units (SI) (the Modernized Metric System)⁴

3. Terminology

3.1 Definitions:

3.1.1 *density*—the mass (weight in vacuum) of a unit volume of the liquid at any given temperature. In this method, it is expressed as the weight in grams per millilitre, or as the weight in pounds avoirdupois of one U. S. gallon, of the liquid at the specified temperature; in the absence of other temperature specification, 25°C is assumed.

3.1.2 *specific gravity*—the ratio of the mass of a unit volume of a material at a stated temperature to the mass of the same volume of distilled water at the same temperature.

4. Summary of Test Method

4.1 The accurately known absolute density of distilled water at various temperatures (Table 1) is used to calibrate the volume of a container. The weight of the paint liquid contents of the same container at the standard temperature

(25°C) or at an agreed-upon temperature is then determined and density of the contents calculated in terms of grams per millilitre, or pounds per gallon at the specified temperature.

5. Significance and Use

5.1 Density is weight per unit volume. It is a key property in the identification, characterization, and quality control of a wide range of materials. Density measurements in terms of weight per-gallon are commonly used to check paint quality. If the density is not within specification, there is a good chance that there was a mischarge or other serious problem.

5.2 This test method is suitable for the determination of density of paint and related products and components when in liquid form. It is particularly applicable when the fluid has too high a viscosity or when a component is too volatile for a density balance determination.

5.3 This test method provides for the maximum accuracy required for hiding power determinations. It is equally suitable for work in which less accuracy is required, by ignoring the directions for recalibration and consideration of temperature differentials, and using the container as a "weight-per-gallon" cup.

5.4 Automatic equipment for measuring density is available (see Test Method D 4052) from several manufacturers. Such apparatus has been used for resins and latices as well as for oils and solvents. Before such equipment is used for a given product, results must be checked very carefully. Particularly with paints and resins, there are possibilities of gumming, fouling, and other interferences with operation.

6. Interferences

6.1 Highly viscous materials may entrap air and give erroneous low density values.

6.2 Paint liquids may be trapped in the ground glass of metal joints of the pieces of apparatus and give erroneous high density values.

7. Apparatus

7.1 *Pycnometer*—Any type, or weight-per-gallon cup having a capacity of from 20 to 100 mL may be used, provided that it may be filled readily with a viscous liquid, adjusted to exact volume, and covered to exclude loss of volatile matter.

7.2 *Thermometers*, graduated in 0.1°C, such as are supplied with glass pycnometers.

7.3 *Constant-Temperature Bath*, held at $25 \pm 0.1^\circ\text{C}$ is desirable.

7.4 *Laboratory Analytical Balance*.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.24 on Physical Properties of Liquid Paints and Paint Materials.

NOTE 1—The usual weight-per-gallon cup and similar specialized pycnometers may have filled weights that exceed the capacity of the usual laboratory analytical balance. In such cases, use of a hanging pan, triple-beam balance, with scales graduated to 0.01 g has been found to provide results the mean of which was consistent with the overall precision and accuracy of the method.

7.5 Desiccator and Desiccated Balance, or a room of reasonably constant temperature and humidity are desirable.

8. Calibration of Pycnometer or Cup

8.1 Determine the volume of the container at the specified temperature by employing the following steps:

8.1.1 Clean and dry the container and bring it to constant weight. Chromic acid (see 8.1.1.1) or other effective glass cleaner and nonresidual solvents may be used with glass containers and solvents with metal containers. For maximum accuracy, continue rinsing, drying, and weighing until the difference between two successive weighings does not exceed 0.001 % of the weight of the container. Fingerprints on the container will change the weight and must be avoided. Record the weight, M , in grams.

8.1.1.1 Precaution—Chromic acid cleaning solution is corrosive to skin, eyes and mucous membranes and can cause severe burns. Avoid contact with eyes, skin or clothing. In making dilute solution, always add acid to water with care. In case of contact, flush skin with water, using a shower if exposure is severe. Flush eyes for 15 minutes with copious amounts of water. Immediately call a physician. Remove clothing immediately and wash before reuse. Chromic acid cleaning solution is a strong oxidizer. Avoid contact with organic or reducing substances as a fire could result. See supplier's Material Safety Data Sheet for further information. Other cleaners are much safer and may be equally effective.

8.1.2 Fill the container with freshly boiled distilled water at a temperature somewhat below that specified. Cap the container, leaving the overflow orifice open. Immediately remove excess overflowed water or water held in depressions by wiping dry with absorbent material. Avoid occluding air bubbles in the container.

8.1.3 Bring the container and contents to the specified temperature using the constant-temperature bath or room if

necessary. This will cause further slight flow of water from the overflow orifice due to the expansion of the water with the rise of the temperature.

8.1.4 Remove the excess overflow by wiping carefully with absorbent material, avoiding wicking of water out of orifice, and immediately cap the overflow tube where such has been provided. Dry the outside of the container, if necessary, by wiping with absorbent material. Do not remove overflow that occurs subsequent to the first wiping after attainment of the desired temperature (Note 2). Immediately weigh the filled container to the nearest 0.001 % of its weight (Note 3). Record this weight, N , in grams.

NOTE 2—Handling the container with bare hands will increase the temperature and cause more overflow from the overflow orifice, and will also leave fingerprints; hence, handling only with tongs and with hands protected by clean, dry, absorbent material is recommended.

NOTE 3—Immediate and rapid weighing of the filled container is recommended here to minimize loss of weight due to evaporation of the water through orifices, and from overflow subsequent to the first wiping after attainment of temperature where this overflow is not retained by a cap.

8.1.5 Calculate the container volume as follows:

$$V = (N - M) / \rho$$

where:

V = volume of container, mL,

N = weight of container and water, g (7.1.4),

M = weight of dry container, g (7.1.1), and

ρ = absolute density of water at specified temperature, g/mL (see Table 1).

8.1.6 Obtain the mean of at least three determinations.

9. Procedure

9.1 Repeat the steps in Section 8, substituting the sample for the distilled water and a suitable nonresidual solvent for the acetone or alcohol (see 8.1.2 and Note 4). Record the weight of the filled container, W , and the weight of the empty container, w , in grams.

NOTE 4—Trapping of paint liquids in ground glass or metal joints is likely to result in high values of density that appear to increase with the viscosity and density of the material; such errors should be minimized by firm seating of the joints.

NOTE 5—Trapping of air bubbles will result in low values for density. The tendency to trap air increases with increasing viscosity. Specimens should not be tested if they contain bubbles or foam. Slow stirring, standing, or the application of a vacuum may remove bubbles. If these do not work, a dilution may be necessary (see Appendix X1).

9.2 Calculate the density in grams per millilitre as follows:

$$D_m = (W - w) / V$$

where:

D_m = density, g/mL.

9.3 Calculate the density in pounds per gallon as follows:

$$D = (W - w) K / V$$

where:

D = density, lb/gal,

K = 8.3454 (Note 6), and

V = volume of container, mL (see 8.1.6).

NOTE 6—The factor K , 8.3454, is calculated from volume-weight relationship as follows:

$$8.345404 = [(2.54)^3 \times (231.00)] / (453.59237)^c$$

^a (2.54)³ is the conversion factor for millilitres to cubic inches.

^b 231.00 is the conversion factor for cubic inches to gallons.

^c 453.59237 is the conversion factor for grams to pounds.

10. Report

10.1 In reporting the density, state the test temperature to the nearest 0.1°C, the units, and the value calculated to the third place to the right of the decimal point (for example, $D = x.xxx$ lb/gal at 25°C); state the mean, the range, and the number of replicate determinations.

11. Precision and Bias

11.1 The precision estimates are based on an interlaboratory study in which one operator in each of six different laboratories analyzed in duplicate on two different days five samples of paint ranging in density from 8.5 to 12.5 lbs/gal.

The results were analyzed statistically in accordance with Practice E 180. The within-laboratory coefficient of variation was found to be 0.20 % relative with 25 degrees of freedom and the between-laboratory coefficient of variation was 0.61 % relative with 20 degrees of freedom. Based on these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

11.1.1 *Repeatability*—Two results, each the mean of duplicate determinations, obtained by the same operator on different days should be considered suspect if they differ by more than 0.6 % relative.

11.1.2 *Reproducibility*—Two results, each the mean of duplicate determinations, obtained by operators in different laboratories should be considered suspect if they differ by more than 1.8 % relative.

11.2 No data on bias has been generated for this test method.

12. Keywords

12.1 density; pycnometer; weight per gallon; weight per gallon cup

APPENDIX

(Nonmandatory Information)

X1. Diluting of a Material to Improve Air Release

X1.1 To reduce viscosity and improve air release, a known weight of a material that traps air may be diluted with a known weight of a solvent or another diluent of known density. After careful blending to achieve homogeneity and release air, the density of the diluted material is measured by the technique described in this test method. The following equation may be used to calculate the density of the original material:

$$D_o = \frac{W_o}{\frac{W_o + W_d}{D_{d1}} - \frac{W_d}{D_{d2}}}$$

where:

D_o = density of original material,

D_{d1} = density diluted measured in test,

D_{d2} = density diluent,

W_o = original weight, and

W_d = diluent weight.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Effect of Chemical Agents on Organic Finishes Used in the Transportation Industry¹

This standard is issued under the fixed designation D 1540; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{e1}NOTE—Paragraph 1.2 was changed editorially and footnote 4 added editorially in May 1987.

1. Scope

1.1 This practice covers determination of the effect of commonly encountered chemical agents on applied organic finishes used in the transportation industry.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. Specific hazard statements are given in Note 3.*

NOTE 1—This practice is a companion standard to Test Method D 1308.

2. Referenced Documents

2.1 ASTM Standards:

- D 609 Methods for Preparation of Steel Panels for Testing Paint, Varnish, Lacquer, and Related Products²
- D 925 Test Methods for Rubber Property—Staining of Surfaces (Contact, Migration, and Diffusion)³
- D 1308 Test Method for Effect of Household Chemicals on Clear and Pigmented Organic Finishes²

3. Summary of Test Method

3.1 The test surface is subjected to test by contact, as described in 7.2, 7.3, or 7.4, with an agent suspected of having a deleterious effect, under conditions appropriate to that agent.

4. Significance and Use

4.1 This practice is designed to provide a working procedure for the examination of the effect of chemical agents on applied transportation finishes. Any change in surface appearance or condition reflects an objectionable tendency of the finish to be affected by the agent used. The change is manifested by softening, swelling, discoloration, loss of gloss, blistering, loss of adhesion, or other special phenomena.

5. Test Panels

5.1 *Steel Panels*—Steel panels as described in Methods D 609.

5.2 Other test surfaces may be agreed upon between the purchaser and the seller of the finish being tested.

6. Chemical Agents

6.1 The choice of the agent shall be governed by ultimate coating use and by agreement between the purchaser and the seller of the finish being tested. The following staining agents are listed as being of general interest.

- 6.1.1 Glycol based antifreeze up to 100 volume, %.
- 6.1.2 Acid, alkali, and salt solutions,
- 6.1.3 Soap and synthetic detergent solutions,
- 6.1.4 Lubricating oils and greases,
- 6.1.5 Polish abrasives, creams, waxes,
- 6.1.6 Road oils and tars; seam sealers,
- 6.1.7 Rubber or other elastomers; plastics, tapes,
- 6.1.8 Gasolines,
- 6.1.9 Water,
- 6.1.10 Hydraulic fluids,
- 6.1.11 Alcohol windshield washing compounds, and
- 6.1.12 Others.

7. Procedure

7.1 *Panel Preparation*—Carry out spot and direct application tests on the fabricated article coated with the finishing system under evaluation, if sufficient plane surface is available. Otherwise, select panels in accordance with 5.1. Apply the finishing system in accordance with the method and schedule prescribed by the purchaser. Age the finished film to suit the exposure conditions, as agreed between the purchaser and the seller of the film-forming material.

7.2 *Spot Test for Liquid Agents*—Conduct the test at $73 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity. Place a small portion of the staining agent on a horizontal test surface, making several spots approximately 1 in. (25 mm) in diameter. After the time agreed upon has elapsed, such as 4, 8, 24, and 72 h, wipe off a spot, and examine it immediately for visual and physical evidence of the effects listed in Section 4. Polish the test surface lightly with any suitable liquid car cleaner, and evaluate the surface in accordance with agreement on the basis of removability. Expose the test surface to sunlight for at least 8 h, or to strong ultraviolet light (Note 2) at 150°F (65°C) or less as agreed upon, for 1 h. Evaluate the surface on the basis of either disappearance of defects or development of defects not previously visible.

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.27 on Accelerated Tests for Protective Coatings.

Current edition approved Sept. 1, 1982. Published November 1982. Originally published as D 1540 - 58 T. Last previous edition D 1540 - 61 (1973).

² Annual Book of ASTM Standards, Vol 06.01.

³ Annual Book of ASTM Standards, Vol 09.01.

Prepare surfaces for water spotting tests by exposing them to an RS ultraviolet lamp for 6 h, and then polishing. Then proceed as follows: apply water drops, heat in an oven at 150°F for 15 min, and then lightly polish. Any variations in the procedure shall be as agreed upon between the purchaser and the seller of the film-forming material.

NOTE 2—The RS sunlamp manufactured by the General Electric Co. is recommended for this test. Other ultraviolet light sources are acceptable if agreed upon by the purchaser and seller, and if the appropriate exposure equivalent is known and used.

7.3 *Contact Test for Solids*—The materials listed in 6.1.7 may produce a deterioration of the appearance in several of the ways listed in Section 4, but must be held in close contact with the surface. Frequently the agent may cause an effect only when heated, therefore, they should be heated for this test. Test finishes with rubber as a staining agent, in accordance with Test Methods D 925. Plastics may be held in contact with the finish, and tested as described in 7.2.

7.4 *Gasoline* (Caution: Note 3)—To determine the staining effect of gasoline, place some in a buret. Allow the gasoline to fall 4 in. (100 mm) onto the test surface placed below and at an angle of 20° from the horizontal. The dropping rate should be about 10 drops per minute. Place an

RS sunlamp (Note 2) 15 in. (380 mm) from the test surface so that its rays shine at 90° to the surface. Continue the test until 200 mL of gasoline have been dropped during 3½ h.

NOTE 3: Caution—This test should be run where there is adequate ventilation, and provision should be made for draining the drippings into a safety can. Other precautions against fire should be observed.

7.5 In evaluating the results, the 0 to 10 scale prescribed in ASTM STP 500⁴ should be used.

8. Report

8.1 Report the following information:

8.1.1 The system and the test method employed. Test conditions are an important factor in the results obtained, and therefore, should be defined in the report.

8.1.2 The type and appearance of the effect obtained, if any, (see Section 4). It is customary to record stain-free contact time as a basis of comparison. Where agreed, the effect of the agent may also be evaluated by the use of a color difference meter spectrophotometer, glossmeter, hardness instrument, or other applicable apparatus.

⁴ Paint Testing Manual, ASTM STP 500, ASTM, 1972.

Standard Test Method for Qualitative Detection of Rosin in Varnishes¹

This standard is issued under the fixed designation D 1542; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense to replace Method 5031, 5032 of Federal Test Standard No. 141. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

¹ NOTE—Editorial changes were made throughout, including the title, in May 1988.

1. Scope

1.1 This test method covers procedures for the qualitative detection of rosin in varnishes by the Lieberman-Storch Test, and the Halphen-Hicks Test. The rosin may be present as either free rosin (abietic acid), esterified rosin, or as metal salts.

1.2 This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Apparatus

- 2.1 Test Tubes, 2.5 by 15 cm.
- 2.2 Filter Funnel, 75 mm in diameter.
- 2.3 Porcelain Spot Plate.

3. Reagents

- 3.1 Acetic Anhydride.
- 3.2 Bromine Reagent—Dissolve 1 part by volume of bromine in 4 parts by volume of carbon tetrachloride (CCl_4).
- 3.3 Phenol Reagent—Dissolve 1 part by volume of phenol in 2 parts by volume of carbon tetrachloride (CCl_4).

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.33 on Varnish and Resins, Including Shellac.

Current edition approved Sept. 19, 1960. Published November 1960. Originally published as D 1542 - 58 T. Last previous edition D 1542 - 58.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

3.4 Sulfuric Acid Reagent—Add 35.7 mL of concentrated sulfuric acid (H_2SO_4 , sp gr 1.84) slowly to 34.7 mL of water, and cool to room temperature. Store in a glass-stoppered bottle.

4. Procedure

4.1 Lieberman-Storch Test—Place 0.1 to 0.2 g of the sample in a test tube, and add 15 mL of acetic anhydride. Heat gently until the specimen is dissolved or dispersed. Cool and filter with an ashless rapid filter paper, into a clean test tube. Place a few drops of the clear solution in a depression of the spot plate, and add one drop of sulfuric acid reagent, so that the acid will mix slowly with the filtrate. If rosin is present, a fugitive violet color develops immediately. A pink or brown coloration should be ignored. A control specimen containing rosin should be run simultaneously.

4.2 Halphen-Hicks Test—Dissolve a small quantity of the sample in 1 to 2 mL of the phenol reagent. Pour the solution into a cavity of the spot plate until it just fills the depression. A portion of the solution will spread out on the flat part of the plate a short distance beyond the rim of the cavity, unless too much of the carbon tetrachloride has been lost by evaporation, when a drop or two more should be added to produce the spreading effect referred to. Immediately in an adjacent cavity, place 1 mL or more of the bromine reagent, so that the bromine vapors evolved will contact the surface of the solution in the other cavity. Sometimes it is necessary to blow a gentle current of air in the proper direction to accomplish this satisfactorily, or both cavities may be covered by a watch glass of suitable size. The development of a fugitive violet coloration, best observed upon a flat portion of the test plate, indicates the presence of rosin.

Standard Test Method for Color Performance of White Architectural Enamels

This test method describes a laboratory procedure for evaluating the color permanence of white architectural enamels. Formerly under the jurisdiction of Committee D-1 on Paint and Related Coatings and Materials. This test method was discontinued in 1992.

Standard Test Method for Color of Transparent Liquids (Gardner Color Scale)¹

ncls.

This standard is issued under the fixed designation D 1544; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense to replace Method 4248 of Federal Test Method Standard No. 141. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

¹ NOTE—Editorial changes were made throughout in April 1989.

1. Scope

1.1 This test method covers the measurement of the color of transparent liquids by means of comparison with arbitrarily numbered glass standards. It applies to drying oils, varnishes, fatty acids, polymerized fatty acids, and resin solutions. Its application to other materials has not been tested.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

- D 1545 Test Method for Viscosity of Transparent Liquids by Bubble Time Method²
- E 308 Method for Computing the Colors of Objects by Using the CIE System³

3. Apparatus

3.1 *Glass Standards*, 18, numbered separately, and having the color characteristics given in Table 1. A suitable procedure for their calibration is contained in Appendix A1. The color shall be produced by the glass components only.

3.2 *Glass Tubes*, clear, 10.65 mm in inside diameter and about 114 mm in outside length. (Viscosity tubes, as described in Test Method D 1545, are satisfactory.)

3.3 Suitable apparatus for comparing sample and standard. The apparatus may be of any design, but should have the following characteristics:

3.3.1 *Illumination*—CIE Illuminant C.

3.3.2 *Surrounding Field*—The field should not differ significantly in brightness from the samples and standards and should be essentially achromatic.

3.3.3 *Field of View*—The specimen and one or more

TABLE 1 Color Specifications of Reference Standards

Gardner Color Standard Number	Chromaticity Coordinates ^A		Luminous Transmittance Y, %	Transmittance Tolerance, ±
	x	y		
1	0.3177	0.3303	80	7
2	0.3233	0.3352	79	7
3	0.3329	0.3452	76	6
4	0.3437	0.3644	75	5
5	0.3558	0.3840	74	4
6	0.3767	0.4061	71	4
7	0.4044	0.4352	67	4
8	0.4207	0.4498	64	4
9	0.4343	0.4640	61	4
10	0.4503	0.4760	57	4
11	0.4842	0.4818	45	4
12	0.5077	0.4638	36	5
13	0.5392	0.4458	30	6
14	0.5646	0.4270	22	6
15	0.5857	0.4089	16	2
16	0.6047	0.3921	11	1
17	0.6290	0.3701	6	1
18	0.6477	0.3521	4	1

^A A duplicate standard shall have chromaticity coordinates that differ from the reference standard by no more than one third of the difference in x or y between adjacent reference standards. In any one set, no two standards shall be closer together than two thirds of the difference in x or y between corresponding reference standards.

standards should subtend a visual angle of about 2 deg and be in the field of view simultaneously.

3.3.4 *Separation of Standard and Specimen*—There should be a perceptible separation between specimen and standard, but this should be as small as is mechanically possible.

4. Procedure

4.1 Fill a glass tube with the material under test. If the material is perceptibly cloudy, first filter it.

4.2 Compare with glass standards, determining which standard most closely matches the specimen in brightness and saturation. Ignore hue differences.

5. Report

5.1 Report the color as the number of the standard most closely matching the specimen. If more precise measurements are needed, report as either matching a standard or lighter or darker. Thus, between colors 5 and 6, the steps will be 5, 5+, 6-, and 6.

¹ This method is under the jurisdiction of Committee D-1 on Paint and Related Coatings and is the direct responsibility of Subcommittee D01.26 on Optical Properties.

Current edition approved March 10, 1980. Published May 1980. Originally published as D 1544 - 58 T. Last previous edition D 1544 - 68 (1974).

² Annual Book of ASTM Standards, Vols 06.01, 06.02, and 06.03.

³ Annual Book of ASTM Standards, Vol 14.02.

6. Precision and Bias

6.1 On the basis of a study in which one observer at each of 80 laboratories made duplicate determinations on four samples, the "between" and "within" standard deviations were found to be 0.5 and 0.1 color number, respectively. Based on these standard deviations, the following criteria should be used for judging the acceptability of results at the 95 % confidence level.

6.2 *Repeatability*—Two results obtained by a single operator should be considered suspect if they differ by more than two thirds of a color number.

6.3 *Reproducibility*—Two results, each of the mean of duplicate measurements, made by operators in different laboratories should be considered suspect if they differ by

more than four thirds of a color number.

NOTE 1—If desired, liquid standards matching the colors given in Table 1, in glass tubes similar to the sample tubes may be used. These may be filled with potassium chloroplatinate for the light colors and solutions of ferric chloride and cobalt chloride in hydrochloric acid for the darker colors. The specifications and approximate composition of these solutions are given in Test Method D 1544 - 58 T.⁴ Many Glass Standards in current use do not conform to the values of Table 1.

NOTE 2—The precision data were obtained using an instrument in which two standards are viewed simultaneously. There are other instruments available for color matching which would be expected to give similar results, but the statement above applies only to the instrument checked.

⁴ See 1961 Book of ASTM Standards, Part 8.

APPENDIX

(Nonmandatory Information)

X1. CALIBRATION OF GLASS REFERENCE STANDARDS

X1.1 Select a dual beam spectrophotometer with a sufficiently small light beam at the sample position so that all rays will pass through the standards to be calibrated. Alternatively equip the spectrophotometer with a condensing lens to accomplish this purpose.

X1.2 Place the standards in turn in the sample position of the spectrophotometer. If the comparator is provided with a separate green filter in front of the light source, place this

filter in the reference beam of the dual beam spectrophotometer during calibration of each standard.

X1.3 Obtain spectral transmittance data for each glass reference standard by following Method E 308.

X1.4 From the spectral transmittance data for each reference standard calculate the CIE tristimulus values, X , Y , Z , and the chromaticity coordinates, x , y , for CIE Illuminant C (see Method E 308).

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Viscosity of Transparent Liquids by Bubble Time Method¹

This standard is issued under the fixed designation D 1545; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense to replace Method 4271 of Federal Test Method Standard No. 141. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

1. Scope

1.1 This test method covers the determination of the viscosity in bubble seconds by timing. The bubble seconds are approximately equal to stokes for most liquids.

1.2 The test method is applicable to transparent liquids that are free from crystalline or gel particles.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Terminology

2.1 Definition:

2.1.1 *viscosity*—the resistance experienced by one portion of a liquid moving over another portion of the liquid. The absolute unit of viscosity in the cgs system is the poise which is expressed as dyne-seconds per square centimetre. Stokes are equal to poises divided by density. The absolute SI viscosity unit is the pascal-second.

3. Apparatus

3.1 *Constant-Temperature Bath*—Any suitable bath capable of maintaining temperature at $25 \pm 0.1^\circ\text{C}$ with water as the bath medium.

3.2 *Standard Viscosity Tubes*,² of clear glass and with flat bottoms, 10.65 ± 0.025 mm in inside diameter; 114 ± 1 mm in outside length. Plainly legible lines shall be located as follows (Note 1):

27 ± 0.5 mm
 100 ± 0.5 mm
 108 ± 0.5 mm

The distance between the first and second lines shall be 73 ± 0.5 mm.

NOTE 1—All distances shall be measured from the outside bottom of the tube.

3.3 *Reference Standards*—A series of standard viscosity

tubes (3.2) filled with transparent liquids having predetermined viscosities in stokes and bubble seconds and spaced in logarithmically even increments of about 26 % ($\log 1.260 = 0.100$), as listed in Table 1. The standards shall be marked alphabetically or numerically as shown in Table 1 without reference to stokes or bubble time (Note 2). Also listed in Table 1, for general and historical reference only, is the long established series of Gardner-Holdt letter standards, in tubes that do not have the three lines and are shorter than the standard viscosity tubes described in 3.2.

NOTE 2—For convenience, the reference standards can be divided in three series: light series, 15 tubes marked 0.22 to 8.0; heavy series, 14 tubes marked 10 to 200; and very heavy series, 7 tubes, marked 250 to 1000.

3.4 *Timing Device*—Stopwatch or electric stop clock capable of being read to a precision of 0.1 s.

3.5 *Tube Racks*, capable of inverting one or more viscosity tubes 180° to within 1° of a vertical position while rack and tubes are immersed in the constant temperature bath.

3.6 *Viscosity Tube Corks*, No. 2 short.

4. Procedure

4.1 Fill a standard viscosity tube with the material to be tested to approximately level with the 108-mm line.

4.2 Transfer the tube to a constant 25°C temperature bath with the cork loosely inserted. Hold at this temperature for 10 min.

NOTE 3—Adequate control of the temperature bath is essential. A variation of 0.1°C in the temperature of the bath will cause a 1 % variation in the timed bubble travel.

4.3 At the end of 10 min adjust the level of the liquid so that the bottom meniscus will be level with the 100-mm line. Insert the cork so that the bottom of the cork is on the level with the 108-mm line. This will ensure a bubble of suitable and uniform size.

4.4 Insert the tube in the rack and immerse in the 25°C water bath. Allow the tube(s) to stand with cork down in the bath a minimum of 20 min before determining the viscosity.

NOTE 4—For viscosities of liquids that have a timed bubble travel of 4 s or less, more precise results can be obtained by comparison against reference standards having a predetermined viscosity or timed bubble travel.

4.5 To read, invert the tube quickly and determine the time required for the bubble to rise in seconds. When determining the time in seconds start the timing device when the top of the bubble becomes tangent to the 27-mm line on

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.33 on Polymers and Resins.

Current edition approved Oct. 27, 1989. Published December 1989. Originally published as D 1545 - 58 T. Last previous edition D 1545 - 76(1989)¹.

² Empty standard viscosity tubes are available from the R. P. Cargille Laboratories, Inc., 33 Village Park Rd., Cedar Grove, NJ, or Byk-Gardner Inc., Gardner Laboratory, 2435 Linden Lane, Silver Spring, MD 20910.

^A Arranged to show relationship between stokes, bubble seconds, and Gardner-Holdt letters. Stokes are shown in logarithmic progression.

^B The bubble time, in seconds, of the numerical tubes under 4 s was determined by a technique employing a movie camera.

^C For reference purposes only. Numbered tubes are no longer commercially available.

^D Above 2.65 the bubble seconds as measured by the kinematic method are approximately equivalent for most products. Below 2.65 this relationship does not hold.

the tube. Stop the timing when the top of the bubble becomes tangent with the 100-mm line. This gives a 73-mm timed bubble travel. All timings shall be made with the tube in an exact vertical position.

NOTE 5—Positioning of the tube in a vertical position is mandatory. A tube one radius off the vertical will give an error of approximately 10 % in the time of bubble travel.

5. Report

5.1 Report the following information:

5.1.1 The viscosity obtained by the timing method expressed as "bubble seconds" or "approximate stokes."

NOTE 6—The time in seconds or "bubble seconds" is an approximate measurement of stokes when the bubble time method is applied to most raw materials and finished products encountered by the paint, varnish, and lacquer industries. This relationship does not hold for silicones or water dispersions of gums or similar materials. Viscosity results by this test method are influenced by non-Newtonian behavior and by surface tension. Other variations on bubble-tube viscometers are described in ASTM STP 500, Section 3.2.9.³

6. Precision and Bias

6.1 On the basis of an interlaboratory study⁴ of this test method in which ten laboratories tested liquids ranging in viscosity from 4.5 to 440 St, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

6.1.1 Two results obtained by the same operator should be considered suspect if they differ by more than 4.9 % relative.

6.1.2 Two results, each the mean of duplicates, obtained by operators in different laboratories should be considered suspect if they differ by more than 9.0 % relative.

Standard Method for Performance Tests of Clear Floor Sealers¹

This standard is issued under the fixed designation D 1546; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This method covers the testing of clear floor sealers for appearance of finish, treatment of worn areas, the application of finishing materials such as varnish, liquid or paste waxes either solvent or emulsion type, and resistance to ink staining.

NOTE 1—The resistance of the sealer to other reagents may be determined by this procedure when agreed upon by the purchaser and the seller.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

- 2.1 *U.S. Federal Specifications:*
 - P-W-155 Solvent Wax²
 - P-W-158 Emulsion Wax²
 - TT-I-563 Blue-Black Ink²
 - TT-V-71-f Varnish²

3. Apparatus

- 3.1 *Maple Panels*—First grade maple flooring 2½ by 12 in. (64 by 305 mm).
- 3.2 *Sandpaper*—No 0 and 00 garnet paper.
- 3.3 *Cheesecloth*.
- 3.4 *Blotting Paper*.

4. Materials

- 4.1 *Blue-Black Ink*, (Federal Specification TT-I-563).
- 4.2 *Varnish*, (Federal Specification TT-V-71-f).
- 4.3 *Solvent Wax*, (Federal Specification P-W-158).

¹ This method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D 01.33 on Varnish and Resins, Including Shellac.

Current edition approved Sept. 28, 1962. Published November 1962. Originally published as D 1546 - 58 T. Last previous edition D 1546 - 58.

² Available from Standardization Documents Order Desk, Bldg. 4, Section D, 700 Robbins Ave., Philadelphia, PA 19111-5094.

4.4 *Emulsion Wax*, (Federal Specification P-W-155).

5. Panel Preparation

5.1 Sand the five maple panels with No. 00 garnet paper until the surface is flat and smooth. Remove the excess sanding dust with a clean dry cloth.

5.2 Apply a liberal coat of sealer to the panels using a pad of clean cheesecloth. Note fluidity and ease of application. Allow the sealer to set 15 min for absorption into the wood. Wipe off the excess sealer using a pad of cheesecloth (note whether the excess sealer removed in this manner can be wiped readily and cleanly from the surface). The surface shall be free of all excess sealer. Allow the panels to dry 24 h at a temperature between 70 and 90°F (21.1 and 32.2°C).

5.3 Apply a second coat of sealer following the procedure described in 5.2.

NOTE 2—Other methods of application and panel preparation may be used when agreed upon by the purchaser and the seller.

6. Procedure

6.1 *Appearance of Finish*—Examine the panel, treated as described in Section 5, for the presence of surface film. Note whether the treated surface of the panel has a soft, even sheen and whether the grain of the wood is clouded or obscured.

6.2 *Resistance to Ink Stain*—Place several drops of blue-black ink on the surface of a treated panel at various places and allow to remain for 3 min. Take up the ink with blotting paper and wipe the spots lightly with a damp cloth. Examine the surface for any indication of the presence of ink.

6.3 *Treatment of Worn Spots*—Simulate on a treated panel worn areas by rubbing the surface with No. 0 steel wool. Over these panels apply a thin coat of sealer. Burnish the worn areas with No. 00 steel wool immediately after application of the sealer. When dry, examine the treated areas to determine whether they blend with the surface of the panel without showing any signs of lap marks.

6.4 *Application of Finishing Materials*—To a treated panel apply a finish coat of the varnish. To a second treated panel apply a coat of the solvent wax. To a third treated panel apply the emulsion wax. Note whether the properties of the finishing materials are adversely affected by the sealed surface or whether the finishing material adversely affects the sealed surface.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Acid Value of Organic Coating Materials¹

This standard is issued under the fixed designation D 1639; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense to replace Methods 5071, 5072, 5073 of Federal Test Method Standard No. 141. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

1. Scope

1.1 This test method covers the measurement of the free acidity present in the nonvolatile portion of varnishes, oils, certain resins, and paint vehicles, by the reaction with standard alkali solution.

1.2 If carboxylic anhydrides are present, only one half of the reactive groups will be titrated and indicated by this test method.

1.3 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 362 Specification for Industrial Grade Toluene²

D 770 Specification for Isopropyl Alcohol²

D 1259 Test Methods for Nonvolatile Content of Resin Solutions³

D 1644 Test Methods for Nonvolatile Content of Varnishes⁴

D 1960 Test Method for Loss on Heating of Drying Oils²

3. Terminology

3.1 Definition:

3.1.1 *acid value*—the number of milligrams of potassium hydroxide (KOH) required to neutralize the alkali-reactive groups in 1 g of material under the conditions of test (see 6.4).

4. Significance and Use

4.1 This test method is used to determine the free acidity present in the nonvolatile portion of varnishes, oils, certain resins, and paint vehicles by the reaction with a standard alkali solution. Use of this test method provides a means whereby the relative applicability of the varnish, oil, resin, or paint vehicle to the particular end use may be estimated by the buyer and the seller.

4.2 This test method also provides a convenient method of process control for the manufacture of certain resins and paint vehicles designed to meet particular requirements of the buyer and the seller.

5. Reagents and Solvents

5.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁵ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 *Phenolphthalein Indicator Solution* (10 g/L)—Dissolve 1 g of phenolphthalein in 100 mL of methanol, ethanol, or isopropanol.

5.3 *Potassium Hydroxide, Methyl Alcohol (Methanol) Solution* (1 mL = 5.6 mg KOH)—Dissolve 6.6 g of potassium hydroxide (KOH) in 1 L of methyl alcohol. Standardize against National Institute of Standards and Technology standard potassium hydrogen phthalate Standard Reference No. 84, using phenolphthalein as the indicator (5.2). Do not adjust the concentration of the solution, but calculate the milligrams of KOH per litre of solution, K. (See Note.)

NOTE 1—At the discretion of the purchaser and the seller, an aqueous solution of potassium hydroxide of 0.1 N or 0.5 N may be used.

NOTE 2—Potassium hydroxide, methyl alcohol (methanol) solution may be purchased from most major laboratory chemical supplier houses. This material should be standardized as just indicated.

5.4 *Neutral Solvent Mixture*—Mix equal parts by volume of isopropyl alcohol (isopropanol) (see Specification D 770) and industrial toluene (see Specification D 362). Neutralize the mixture using 0.1 N KOH solution (4.3) and phenolphthalein indicator solution (5.2) until the pink color persists for 1 min.

6. Procedure

6.1 Weigh or transfer into a 250-mL Erlenmeyer flask the specimen mass, S, prescribed in Table 1.

6.2 Add 100 mL of neutral solvent. Mix until all material is dissolved, warming if necessary. Cool to room tempera-

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.33 on Polymers and Resins.

TABLE 1 Specimen Size

Expected Acid Value	Approximate Specimen Mass, g	Accuracy of weighing, plus or minus, mg
0 to 5	20	50
Over 5 to 15	10	50
Over 15 to 30	5	50
Over 30 to 100	2.5	1
Over 100	1	1

ture, about 77°F (25°C), before titrating. Add 1 mL of phenolphthalein indicator solution and titrate with the 0.1 N KOH solution (5.3) to the end point, which is a pink color persisting for 30 s (V).

6.3 Repeat with a second specimen.

6.4 In the case of materials containing a solvent, determine the nonvolatile content in accordance with Test Methods D 1259, D 1644, D 1960 or other applicable method agreed upon between the purchaser and the seller.

7. Calculation

7.1 Calculate the acid value *A* as follows:

$$A = \frac{VK}{S \times N}$$

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

where:

V = volume of KOH solution required for titration of the specimen, mL,

K = weight of KOH per millilitre of KOH solution, g,

S = specimen weight, g, and

N = nonvolatile content of the material expressed as a decimal fraction.

7.2 Calculate the mean of the two runs.

8. Report

8.1 Report the acid value of the nonvolatile matter to the nearest decimal (0.1).

9. Precision

9.1 Because of the many types of material covered by this test method, the precision is not as good as might be expected of a quantitative analytical method. The following criteria should be used for judging the acceptability of results:

9.1.1 *Repeatability*—Duplicate results obtained by the same operator should be considered suspect if they differ by more than 10 % of the mean acid value.

9.1.2 *Reproducibility*—Two results obtained by operators in different laboratories should be considered suspect if they differ by more than 20 % of the mean acid value.

Standard Test Methods for Drying, Curing, or Film Formation of Organic Coatings at Room Temperature¹

This standard is issued under the fixed designation D 1640; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

^{e1} NOTE—Editorial changes were made throughout in April 1989.

1. Scope

1.1 These test methods cover the determination of the various stages and rates of film formation in the drying or curing of organic coatings normally used under conditions of ambient room temperature.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D202 Methods of Sampling and Testing Untreated Paper Used for Electrical Insulation²

D823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels³

D1005 Test Methods for Measurement of Dry-Film Thickness of Organic Coatings Using Micrometers³

D2091 Test Method for Print Resistance of Lacquers³

2.2 U.S. Government Standards:

Fed. Spec. No. CCC-C-440, Cheesecloth⁴

Fed. Spec. No. CCC-C-419b, Type III, Army Duck⁴

2.3 TAPPI Standards:⁵

T 402 Standard Conditioning and Testing Atmospheres for Paper, Board, Pulp Handsheets, and Related Products

3. Significance and Use

3.1 These test methods are used to determine the various stages and rates of drying, curing, and film formation of organic coatings for the purpose of comparing types of

coatings or ingredient changes, or both. This is significant in the development of organic coatings for various end uses and also for production quality control.

4. Coatings and Recommended Film Thicknesses

4.1 Whenever tests are to be performed on coatings not listed in Table 1, there should be a prior agreement between the purchaser and seller as to the substrate, film thickness, and application method for testing the specific coating involved.

5. Test Conditions

5.1 Conduct all drying tests in a well-ventilated room or chamber, free from direct drafts (Note 1), dust, products of combustion, laboratory fumes and under diffused light (see 5.4). Make all measurements at a temperature of $23 \pm 2^\circ\text{C}$ and $50 \pm 5\%$ relative humidity with the coated panels in a horizontal position while drying.

NOTE 1—A device to equalize air change conditions has been developed by F. Scofield.⁶ Relative humidity should be controlled for moisture-cured and two-package urethane coatings, since their cure is greatly affected by the existing moisture conditions.

5.2 Tests should be carried out at practical viscosities at which films can be applied to the proper film thickness with resultant good flow and leveling properties. In the absence of any specific material specification, instructions for preparation of the film should be determined and agreed upon between the purchaser and the seller.

5.3 Films to be tested should have practical thicknesses commensurate with performance characteristics expected under actual usage for the type under test. All testing should be done within an area, any point of which is not less than $\frac{1}{2}$ in. (15 mm) from the film edge.

5.4 *Light Conditions*—Illumination of the films during the entire drying test period should be about 25 ft-candles (270 lx) from normal laboratory or sky sources, never from direct sunlight or other sources high in nonvisible radiant energy.

6. Preparation of Test Specimens

6.1 Carry out all tests as described in 6.1.1, 6.1.2 and 6.1.3, unless otherwise noted.

⁶ Gardner and Sward, *Paint Testing Manual*, ASTM STP 500, ASTM, 13th edition, 1972, p. 269.

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.33 on Polymers and Resins.

^a This tal upon betw
^b See 6.1

6.1.1 All test specimens shall be prepared and tested by one operator properly skilled in the methods to be used. Apply the specimens in duplicate at a time arranged so that examination intervals will fall within the normal working hours of the operator.

6.1.2 Apply the materials to be tested on clean glass panels or other specific substrate of suitable dimensions agreed upon between the purchaser and the seller. Ground-glass plates are more suitable for certain types of coatings that tend to crawl, such as low-viscosity drying oils. Suitable plates can be prepared by roughening the surface of polished glass by grinding a paste of silicon carbide (grit 1-F) and water between two glass plates.

6.1.3 The test films preferably shall be cast with a doctor blade having a clearance sufficient to give the recommended dry film thickness indicated in Table 1. When a suitable doctor blade is not available, or it has been agreed upon to apply the film in some other manner, the various conventional and automatic methods of spray, dip, flow, and brush application may be used, provided dry film thicknesses conform to the requirements given in Table 1. See Test Methods D 823 for a description of the spray and dip methods of application.

6.1.4 Measure the dry film thickness of test films with the proper film thickness gage. This shall be a micrometer, dial comparator, or dial indicator as described in Test Methods D 1005. When plates of small area are used, measurement of dry film thickness can be made by weighing plates before and after coating and calculating from plate area and coating solids.

7. Procedure

7.1 When test methods or end points other than those listed in 7.2 to 7.9 are used, there shall be a prior agreement between the purchaser and the seller.

7.2 **Set-To-Touch Time**—To determine set-to-touch time, lightly touch the test film with the tip of a clean finger and immediately place the fingertip against a piece of clean, clear glass. Observe if any of the coating is transferred to the glass. For the purpose of this test, the pressure of the fingertip against the coating shall not be greater than that required to transfer a spot of the coating from $\frac{1}{8}$ to $\frac{3}{16}$ in. (3 to 5 mm) in cross section. The film is set-to-touch when it still shows a tacky condition, but none of it adheres to the finger.

7.3 Dust-Free Times:

7.3.1 **Cotton Fiber Test Method**—Separate a number of individual fibers from a mass of absorbent cotton with the

TABLE 1 Recommended Film Thickness of Materials to be Tested^a

Material	Dry Film Thickness
Drying oils	1.25 ± 0.25 mil (32 ± 6 μ m) ^b
Varnishes	1 ± 0.1 mil (25 ± 2 μ m) (See 7.3.2)
Laquers	0.5 ± 0.1 mil (12.5 ± 2 μ m) (See 7.4.2)
Resin solutions	0.5 ± 0.1 mil (12.5 ± 2 μ m)
Enamels	1.5 ± 0.25 mil (36.5 ± 6 μ m)
Oil paints	1.8 ± 0.2 mil (46 ± 2.5 μ m) (see 6.2)
Water paints	1 ± 0.1 mil (25 ± 2 μ m)

^a This table is a general guide to be used when nothing more specific is agreed upon between the purchaser and the seller.

^b See 6.2 and 7.4.1. Add driers a minimum of 24 h before test.

NOTE—1 in. = 25.4 mm.

FIG. 1 Typical Dust-Free Tester

aid of tweezers. At regular drying intervals, drop several of the cotton fibers from a height of 1 in. (25 mm) onto a marked section of the film. The film is considered to have dried dust free when the cotton fibers can be removed by blowing lightly over the surface of the film.

7.3.2 **Powder Test Method**—Deposit finely divided calcium carbonate (pigment grade) on the film at definite intervals during the drying period and, after the film has dried tack-free, remove by blowing with a gentle stream of air and wiping with a soft rag or camel-hair brush. The coating is considered dust-free at the time interval when the pigment can be removed completely.

7.3.2.1 Deposit the calcium carbonate from a box through a 160-mesh screen in a pattern $1\frac{1}{2}$ in. (40 mm) long and $\frac{3}{8}$ in. (10 mm) wide. Fasten a vibrator to the side of the container to facilitate the passage of the pigment through the screen in a uniform pattern. Support the apparatus so that there is a clearance of about $\frac{1}{8}$ in. (3 mm) between the screen and the test film. Figure 1 shows a typical dust-free tester⁷ and Fig. 2 shows the pattern obtained in testing a black enamel. The enamel shown is considered dust free at the 4½-h rating.

7.4 Tack-Free Times:

7.4.1 Paper Test Method:

7.4.1.1 **Test Paper**—The test paper shall be K-4 Power Cable Paper⁸ that when conditioned in accordance with the TAPPI Standard Method T 402, conforms to the following requirements:

⁷ The dust-free tester was designed and built by Technical Subcommittee 37 of the New York Paint and Varnish Production Club and is described in "Investigation of Methods of Measuring Drying Time," *Official Digest*, Federation of Paint and Varnish Production Clubs, No. 286, November 1948, pp. 836-843. This paper also includes a study of the Zapon tack tester.

⁸ Paper meeting these requirements may be obtained from Crocker Technical Papers, Inc., 431 Westminster St., Fitchburg, MA 01420, their Grade R 20-34.

FIG. 2 Example Pattern from Dust-Free Drying Time Test

Basis weight (24 by 36/500), lb	90 ± 5
Thickness, mils (μm)	6.65 (17)
Air resistance (s/100 cm ² /in. ²)	350
Coefficient of static friction ⁴	0.5
Friction angle, °	22
Tensile strength, machine direction/cross direction	119/32
Tear, machine direction/cross direction	180/250
Elongation, machine direction/cross direction, %	3.0/7.0
pH of water extract	7.4
Ash content, max, %	0.6

⁴ All tests except this one shall be run in accordance with Test Method D 202. All values for properties are typical values and not specification limits.

7.4.1.2 Lay a 2 by 3-in. (50 by 75-mm) piece of the special test paper on the film and place upon it a steel cylinder 2 in. in diameter, and of such weight 6.28 lb, (2.85 kg), as to produce a pressure of 2 psi (13.8 kPa). At the end of 5 s, remove the cylinder and invert the test panel. The film is considered free from after-tack when the paper drops off of the test film within 10 s.

7.4.2 A variation of the test method described in 7.4.1 using the same test paper can be used to test the tack-free time of insulating varnishes. In this method the piece of paper shall be 1½ in. (40 mm) in width and 6 in. (150 mm) in length. The varnish is considered tack-free when this strip of paper does not adhere to it when it is pressed on the surface of the varnish for 1 min by a cylindrical 1-lb (450-g) weight, 1 in. (25 mm) in diameter. In this test, apply the paper in the vicinity of the center of the specimen at right angles to the length of the coated specimen.

7.4.3 *Mechanical Test Method (Tack Tester)*⁹—The tack tester to be used in this method comprises essentially a base or surface-contacting portion 1-in. (25-mm) square and a counter-balancing portion 1 by 2 in. (25 by 50 mm) in area. Both portions are made up from a continuous metal strip

⁹ The standard tack tester is fully described in the U. S. Patent 2,406,989, Sept. 3, 1946.

0.016 to 0.018 in. (0.41 to 0.46 mm) in thickness. To prepare the apparatus for use (see 7.4.3.1), fit the base with several thicknesses of masking tape and paper strips to provide a means of attaching the aluminum foil and so adjust the angle of the 1 by 2-in. counter-balancing strip so that a weight of 5 g placed in the geometric center of the base portion is just sufficient to overcome the unbalanced force.

7.4.3.1 The tester is prepared for use by carrying out the following steps in sequence:

(1) Wrap the metal base with three thicknesses of masking tape, sticky side out,

(2) Cover the outer layer with a good grade of paper, except for two exposed strips, equally spaced, about ¼ by 1 in. (6.4 by 25 mm) in area on the top of the tester, and

(3) Cover the paper on the contact side of the base with one thickness of pressure-sensitive cellulose tape previously fixed to the metal base of the tester. The cellulose tape serves two purposes:

First, to pull the layers of masking tape firmly against the front of the metal base, and

Second, to provide a smooth surface for the foil. Attach the aluminum foil to the base of the tester by pressing gently but firmly a 1 by 2-in. (25 by 50-mm) piece of foil, 0.0005 in. (13 μm) in thickness against one of the ¼ by 1-in. (6.4 by 25-mm) exposed strips of masking tape on the top surface of the base. Wrap the foil tightly and smoothly around the base, exposing the shiny side, and finally press the outer end gently against the remaining exposed strip of masking tape. When it finally becomes necessary to replace wrinkled or soiled aluminum foil, the ends are easily removed from the masking tape by exerting a slow, even, upward pull sufficient to overcome the tack of the tape without tearing the foil.

7.4.3.2 A film is considered to have dried tack-free when the tack tester tips over immediately on removing a 300-g weight allowed to act for 5 s on the counter-weighted metal square base fitted with masking tape and aluminum foil.

7.5 Dry-To-Touch Time:

7.5.1 *Drying Oils*—Continue testing after the set-to-touch time has been observed. The film is considered dry when it no longer adheres to the finger and does not rub up appreciably when the finger is lightly rubbed across the surface.

7.5.2 *Lacquers (and Sealers)*—Touch the film lightly at varying intervals of time. The film is considered dry when no pronounced marks are left by the finger touching the film in the same area on each observation. Test sealers on wood or other porous substrates as agreed upon between the purchaser and the seller.

7.6 Dry-Hard Time:

7.6.1 With the end of the thumb resting on the test film and the forefinger supporting the test panel, exert a maximum downward pressure (without twisting) of the thumb on the film. Lightly polish the contacted area with a soft cloth. The film is considered dry-hard when any mark left by the thumb is completely removed by the polishing operation.

7.7 Dry-Through (or Dry-To-Handle) Time:

7.7.1 Place the test panel in a horizontal position at a height such that when the thumb is placed on the film, the arm of the operator is in a vertical line from the wrist to the shoulder. Bear down on the film with the thumb, exerting the maximum pressure of the arm, at the same time turning

the thumb. The film there is evidence

or agreed
method,
or multi

the thumb through an angle of 90° in the plane of the film. The film is considered dry-through or dry-to-handle when there is no loosening, detachment, wrinkling, or other evidence of distortion of the film.

7.8 Dry-To-Recoat:

7.8.1 A film is considered dry for recoating when a second coat or specified topcoat can be applied without the development of any film irregularities such as lifting or loss of adhesion of the first coat, and the dry time of the second coat does not exceed the maximum specified (if any) for the first coat.

7.9 Print-Free Time:

NOTE 2—This procedure is similar to Test Method D 2091, except that the time to reach the print-free condition is determined, while Test Method D 2091 is used to evaluate whether a film is print free at a specified time.

7.9.1 *Test Panels*—Apply the material under test to clean plane panels, at least 3 by 6 in. (75 by 150 mm) in size, made of wood, metal, glass, plastic or other material as agreed upon between the purchaser and the seller.

7.9.2 *Imprinting Fabric*—Eight-ounce Army duck conforming to Type III of U.S. Fed. Spec. No. CCC-C-419b or cheesecloth conforming to Fed. Spec. No. CCC-C-440.

7.9.2.1 A pad should be used with the cheesecloth only, made of nonwoven felt cloth at least 0.05 in. (1.3 mm) thick, weighing 7 oz/yd² (0.24 kg/m²) and larger than the plane end of the weight.

7.9.3 *Weights*—Consisting of metal cylinders not less than 2 in. (50 mm) in diameter with plane ends perpendicular to the axis and of a length to give a pressure of ½ or 1 lb/in.² (3.5 or 6.9 kPa).

7.9.4 Procedure:

7.9.4.1 Apply the test material to several of the specified or agreed-upon panels by a film applicator, or other specified method, as described in Test Methods D 823 in either single or multiple coats, as agreed upon between the purchaser and

the seller. In the absence of a specified dry film thickness, the values listed in Table 1 should be used.

7.9.4.2 Allow the coated panels to dry under the conditions specified in Section 5, unless otherwise agreed. At appropriate intervals, starting shortly before the coating is expected to be print-free, carry out the print-free test as described in Test Method D 2091, comparing the appearance with the photographic standards appearing therein, until the test shows the coating to be print-free.

8. Frequency of Testing

8.1 It is suggested that test intervals be set at periods of approximately 10 % of the total test time. If frequency varies considerably from the 10 % interval or such time interval is impractical, the intervals used shall be reported.

9. Report

9.1 Reports of tests shall include all applicable conditions that deviated from the standards as outlined or special conditions or tests used and the results of the test.

10. Precision

10.1 Because of the subjective nature of the drying time tests, the agreement to be expected between laboratories depends upon their understanding of the terms used, and is difficult to establish with certainty. Within any laboratory, the agreement depends upon the material being tested, some coatings being much sharper in their end point than others, but duplicate determinations should agree within 10 % of the time of drying.¹⁰

11. Keyword

11.1 drying time

¹⁰ See Prane, J. W., "A Latin Square Drying Time Study," *Paint Industry Magazine* (August 1961), for a study of precision of drying time measurements.

Standard Test Method for Exterior Durability of Varnishes¹

This standard is issued under the fixed designation D 1641; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the testing of the exterior durability of varnishes applied to a wooden base.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standard:

D962 Specification for Aluminum Powder and Paste Pigments for Paints²

2.2 Military Specification:

MIL-V-16399 Varnish, Moisture-Proof³

3. Apparatus

3.1 *Maple Panels*, of close-grained clear maple, 3 by 12 by 1/2 in. (76 by 305 by 13 mm), with all edges rounded to a 1/4-in. (6.4-mm) radius.

3.2 *Varnish Brushes*, 1-in. (25-mm) pure bristle.

3.3 *Sandpaper*, 180-grit.

3.4 *Balance*, capable of weighing to an accuracy of 0.1 g.

3.5 *Tung Oil Phenolic Aluminum Sealer*, 12 1/2 gal (47.3 L) "oil length" (12 1/2 gal of oil/100 lb (45.4 kg) of resin.

NOTE 1—This sealer is composed of a vehicle made in accordance with Military Specification MIL-V-16399 Type B, 27 June, 1951, plus aluminum paste meeting the requirements of Specification D 962, Type II, Class B, using: 1 gal MIL-V-16399 Type B varnish,³ and 2 lb aluminum paste.

4. Preparation of Test Panels

4.1 *Weight of Panel*—Weigh the test panel to the nearest 0.1 g, prior to varnishing.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.33 on Varnish and Resins, Including Shellac.

Current edition approved Sept. 10, 1959. Published November 1959. Replaces Sections 56-60 of D 154.

² *Annual Book of ASTM Standards*, Vol 06.02.

³ Available from Standardization Documents Order Desk, Bldg. 4 Section D, 700 Robbins Ave., Philadelphia, PA 19111-5094, Attn: NPODS.

4.2 *Application of First Coat*—For the first coat, thin a portion of the varnish in the proportion of 1 pt of mineral spirits thinner to 1 gal (500 ml in 4 L) of varnish. Coat both sides, ends, and all edges of the test panel, using a small brush and taking the precaution to brush the coat out well. Allow the varnish coat to dry 24 h at room temperature before applying the second coat.

4.3 *Application of Second Coat*—Before applying the second coat, lightly sand the panel with 180-grit sandpaper, and reweigh the panel. Record the final weight of the first coat. Do not touch the sides of the panel after sanding. Using the varnish as received, apply a second coat, covering both sides and all edges of the panel. Apply the second coat as evenly as possible. Allow it to dry for 24 h before applying the third coat.

4.4 *Application of Third Coat*—Before applying the third coat, lightly sand the panel with 180-grit sandpaper, taking care not to touch the sides of the panel after sanding. Weigh the panel, and record the weight of the second coat. Using the varnish as received, apply the third coat, covering both sides and all edges of the panel. Apply this coat with a full brush, laying the varnish on as evenly as possible. Allow it to dry for 24 h. Weigh the panel, and record the weight of the third and final coat.

4.5 *Application of Aluminum Sealer*—Using the aluminum sealer supplied with the varnish samples, coat one side and all the edges of the panel with a smooth, even coat. Great care should be taken to see that the ends and edges of the panel are completely covered. Allow the panel to dry a minimum of 24 h before exposure.

5. Exposure

5.1 Expose all panels outdoors in the early Spring, at 45° facing south. The weather conditions at the site of exposure should duplicate, if possible, the conditions under which varnish will be exposed in regular use.

6. Panel Examination

6.1 Inspect the panels at monthly intervals after the initiation of the exposure test. Sponge off the panels with a pad of cheesecloth under a gentle stream of cold water, and immediately dry thoroughly with a soft cloth or low-pressure stream of air. Examine each panel for the following failure characteristics, grading each type of failure from "1" to "10,"

"1" s
evident

Standard Test Methods For Elasticity or Toughness of Varnishes¹

This standard is issued under the fixed designation D 1642; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

These methods have been approved for use by agencies of the Department of Defense to replace Methods 4151, 4152 of Federal Test Method Standard No. 141 and for listing in the DoD Index of Specifications and Standards.

1. Scope

1.1 These methods cover the determination of elasticity or toughness of any varnish which is miscible with the diluents specified, under the conditions of the test.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Summary of Methods

2.1 Elasticity or toughness of the varnish may be determined by proportionately reducing its elasticity or toughness by the addition of a standard solution of a resin. The long-accepted use of run-kauri gum may now be less convenient due to a limited supply of this resin. Accordingly, an equally acceptable resin is prescribed in Method A (Sections 3 to 6). Method A is based on the preparation of a rosin-pentaerythritol ester, the properties of which in terms of acid value and melting point can be controlled, and on a solvent that is free of any inherent polymerization tendency. Where desired, run-kauri gum may be used as prescribed in Method B (Sections 7 to 9).

2.2 For varnishes that are less elastic or tougher than zero standard resin reduction, Method C (Sections 10 to 13), based on proportionately increasing the elasticity or toughness of the varnish by means of the addition of linseed oil, is provided.

METHOD A—STANDARD ROSIN PENTAERYTHRITOL ESTER RESIN REDUCTION

3. Preparation of the Rosin-Pentaerythritol Ester Solution

3.1 Apparatus:

3.1.1 *Flask*, 3-litre, 3-neck flask.

3.1.2 *Gas Burner* having a capacity of 12 000 Btu/h (3.5 kW).

3.1.3 *Agitator*—Motor-driven agitator with blade peripheral speed of 600 ft (182.9 m)/min. The agitator shall be of the three-blade type with a blade width of $\frac{3}{4}$ in. (19 mm) and a blade diameter of $1\frac{1}{4}$ in. (44.5 mm).

¹ These methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.33 on Varnish and Resins, Including Shellac.

Current edition effective Dec. 24, 1970. Originally issued 1959. Replaces D 1642 - 59. Replaces Sections 20-32 of D 54.

3.1.4 *Thermometer*—An ASTM Partial Immersion Thermometer having a range from 20 to 760 F, 16 in. (406 mm) in length, and conforming to the requirements for Thermometer 3F in ASTM Specification E 1, for ASTM Thermometers.²

3.1.5 Carbon Dioxide Supply.

3.2 Materials:

3.2.1 W. W. Gum Rosin:

Melting point	173 to 177 F (78 to 81 C)
Acid number	165 to 167

3.2.2 Pentaerythritol:

Hydroxyl content	49.5%
Ash content	less than 0.2%
Melting point	at least 250 C

3.2.3 Hi-Flash Naphtha:

Type	aromatic
Color	water-white
Distillation range	first drop not below 150 C
Dry point	not above 193 C
Acid wash color	not darker than No. 10
	color standard ³
Specific gravity 15.56/15.56 C	0.855 to 0.890
Flash point (Tag open cup)	105 F (40.66 C)

3.3 *Procedure*—Heat 3 lb (1361 g) of rosin in the flask fitted with the thermometer, a carbon dioxide inlet extending below the surface of the reacting liquid, and a loose cork stuffing box fitting the center neck of the flask through which is extended the agitator shaft. When the rosin reaches a temperature of 450 F (232 C), start the motor stirrer, adjust the CO₂ flow so that about two bubbles break to the surface per second, and add 0.33 lb (150 g) of pentaerythritol slowly through the center neck while keeping the agitator running. The size of the hole in the cork accommodating the agitator shaft should be large enough to allow the escape of CO₂ and water vapor from the flask and prevent any pressure build-up. After all of the pentaerythritol has been added, heat to 600 F (315 C) and hold for an acid number of 8. The softening point should be about 263 F (128 C) as determined by the Test Method for Softening Point by Ring and Ball Apparatus (ASTM Designation: E 28).⁴ The time required is about 6½ h at this temperature. When the resin reaches the correct acid number and melting point, turn off the heat. Allow the carbon dioxide to flow until the flask has cooled to 400 F (204 C), then pour the liquid resin into a tared receiver and carefully reduce to 33½ % nonvolatile matter content.

with hi-flash naphtha. Store the solution in tightly-closed amber glass bottles.

4. Test Panels

4.1 Test panels shall be No. 31 gage (0.227 mm) bright tin plate weighing not more than 0.51 nor less than 0.39 lb/ft² (25 or less than 19 g/dm²). It is important that the tin plate shall be within the limits prescribed. The panel shall be about 3 by 5 in. (76 by 120 mm) and shall be thoroughly cleaned with benzene immediately before using (cleaned but not buffed) and wiped dry with a clean cloth.

5. Procedure

5.1 *Reduction of the Varnish*—Carefully determine the nonvolatile matter content of the varnish under test, as described in ASTM Methods D 1644, Test for Nonvolatile Content of Varnishes.⁵ Then take at least 10 g of the varnish and add to it an amount of the standard resin solution equivalent to the specified percentage reduction by weight of the nonvolatile matter in the varnish. Mix the varnish and the solution thoroughly.

5.2 *Application of Reduced Varnish*—Flow a coat of the reduced varnish on one of the tin panels described in Section 4. Let stand in a nearly vertical position at room temperature 70 to 90 F (21 to 32 C) for 1 h. Place the panel in a horizontal position in a properly ventilated oven and bake for 5 h at 203 to 212 F (95 to 100 C). Remove the panel from the oven and allow to cool at 77 F (25 C) for 30 min.

5.3 *Bending of Test Panel*—Quickly bend the coated panel over a 1/8-in. (3-mm) rod held firmly by suitable supports. With the coated side of the panel uppermost, place it in position on the rod so that the rod is equidistant from the top and bottom edges of the panel. Bend the panel double in 1 s at a temperature of 77 ± 0.2 F (25 ± 0.1 C). Examine the film at the bend under a magnification of 5 diameters, using diffused light having a color temperature of 6500 K and intensity of about 165 ft-candles (1770 lx). (For those not equipped with a standard illuminant, viewing the panel at a north window illuminated by a fairly light overcast sky will approximate these conditions.) No cracks shall occur over the bent area between the points 1/4 in. (6.4 mm) from each side of the panel.

6. Report

6.1 Report varnishes that do not show cracks under this test as passing the percentage of standard resin reduction specified.

6.2 If a limiting percentage rather than a specified percentage is desired, successive changes of 10 % standard resin reduction, based on the nonvolatile matter content of the varnish, shall be made until a limiting percentage is found. For example, varnishes may be reported as passing 40 % standard resin reduction and breaking at 50 %.

METHOD B—RUN-KAURI REDUCTION

7. Preparation of Standard Run-Kauri Solution

7.1 Weigh into a side-tube type distillation flask of suitable size an amount of clear, hard, bright pieces of "No. 1

Grade" kauri gum, equivalent to approximately one third of the volumetric capacity of the flask. Attach the flask to a water-cooled condenser. Carefully melt and distill the gum, collecting the distillate in a tared receiver. Stop the distillation when 25 % by weight of the gum has been collected in the tared receiver. A thermometer so placed in the distilling flask that its bulb is level with the discharging end of the flask should read about 600 F (316 C) at this point. Pour the residue in the distillation flask into a clean pan, and when cool break it up into small pieces.

7.2 Place in a tared beaker a given weight of the small pieces of the run-kauri gum, which shall be free from all dust or powder, together with twice its weight of freshly distilled gum spirits of turpentine conforming to ASTM Specification D 13, for Spirits of Turpentine,⁴ using only that portion distilling between 307 and 338 F (153 and 170 C). Dissolve the gum in the turpentine by heating the contents of the beaker slowly to a temperature of 302 F (150 C). The contents of the beaker should be stirred occasionally to prevent the sootened gum from adhering to the bottom of the beaker, thus avoiding possible over-heating of the gum and facilitating its solution. Allow the solution to cool to between 167 and 212 F (75 and 100 C) and filter through a fluted filter paper into a previously weighed, clean, brown glass bottle equipped with a screw cap.

7.3 *Examination of Run-Kauri Solution for Solvent Compatibility*—To 5 ml of the run-kauri solution in a clean, clear glass tube add 5 ml of mineral spirits conforming to ASTM Specification D 235, for Petroleum Spirits (Mineral Spirits),⁴ and in addition having an aniline point of between 55 and 60 C determined in accordance with ASTM Method D 611, Test for Aniline Point and Mixed Aniline Point of Petroleum Products and Hydrocarbon Solvents.⁶ Mix thoroughly and allow to stand for 1 h at room temperature, between 70 and 90 F (21 and 32 C). At the end of 1 h the mixture shall be completely miscible and show no clouding, precipitation, or separation. If clouding, precipitation, or separation occurs, the run-kauri solution shall be considered unsatisfactory for use.

7.4 *Adjustment of Run-Kauri Solution to Proper Nonvolatile Matter Content*—Transfer 10 to 15 ml of the filtered run-kauri solution to a stoppered flask or weighing pipet and determine the percentage of nonvolatile matter as described in Methods D 1644, with the following modifications: Add approximately 2 g of raw castor oil, accurately weighed, to each 80-mm dish or lid before adding the run-kauri solution and heat for 3 h at 115 ± 2 C. At least three determinations shall be made, using samples of run-kauri solution weighing 1.2 ± 0.1 g, and at least two blanks shall be run on the castor oil alone under the same conditions to determine its loss in weight. Calculate the nonvolatile matter content of the run-kauri solution, making allowance for the loss in weight of the raw castor oil. From the average nonvolatile matter content thus determined and the weight of the run-kauri solution, calculate the amount of freshly distilled gum spirits of turpentine required to adjust the nonvolatile matter content of the run-kauri solution to 33.3 weight %. After the

⁶ Annual Book of ASTM Standards, Vol 05.01 and 06.03.

⁵ Annual Book of ASTM Standards, Vol 06.01.

addition of the required amount of the turpentine, repeat the nonvolatile matter determination and record the nonvolatile matter content, which shall be $33.3 \pm 0.1\%$.

8. Procedure

8.1 Using test panels prepared as in Section 4, and run-kauri solution as in Section 7, follow the procedure described in Section 5.

9. Report

9.1 Report as directed in Section 6, expressing the results in terms of run-kauri reduction instead of standard resin reduction.

METHOD C—ADDITION OF LINSEED OIL

10. Scope

10.1 This method is applicable to varnishes that are less elastic or tough than zero standard resin reduction. It is identical with that described in Method A, except that the $33\frac{1}{2}\%$ solution of standard resin in hi-flash naphtha is replaced by a $66\frac{2}{3}\%$ solution of heat-bodied linseed oil for proportionately increasing the elasticity of the varnish under test.

11. Preparation of Standard Bodied Oil Solution

11.1 Heat a high grade of alkali-refined linseed oil having an acid number less than 1.0 in an open kettle at a temperature of 300 ± 5 C until the viscosity of the oil after cooling is between 6 and 10 St (0.0006 and 0.0010 m²/s) at 77 F (25 C).

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

11.2 Standardize a quantity of the heat-bodied linseed oil by reducing it with one half its weight of pure redistilled turpentine conforming to Specification D 13,⁴ using only that portion of the turpentine distilling between 307 and 338 F (153 and 170 C).

12. Procedure

12.1 Prepare the test panels and perform the addition of the standard bodied oil solution to the varnish and the flowing on, baking, and bending of the test panel exactly as described in Section 5.

13. Report

13.1 Report the minimum percentage of the oil solution that must be added to the varnish, based on its nonvolatile matter content, so that the final mixture when flowed on a test panel and baked does not crack on the subsequent bending over a 3-mm rod.

14. Precision

14.1 The precision of this method is limited by the character of the testing ingredients and procedures and the interpretation and visual observation of the results. These results are not specifically numerically oriented and, therefore, comparison with standards of control materials known to have acceptable properties, determine the precision.

Standard Test Methods for Gas Checking and Draft Test of Varnish Films¹

This standard is issued under the fixed designation D 1643; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 These test methods cover the determination of the gas checking and draft test of varnish films.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 *ASTM Standard:*

D 1640 Test Methods for Drying, Curing, or Film Formation of Organic Coatings at Room Temperature²

GAS CHECKING

3. Scope

3.1 This test method³ covers two alternative procedures for detecting nonuniform appearance that may develop while a film of varnish dries in an atmosphere that has been fouled by products of combustion. The nonuniform appearance is generally related to wrinkling, which is sometimes microscopic and which is variously described as checking, crow's-footing, crystallization, or dulling. Appearance non-uniformities that develop on dried films and are described by such terms as orange-peel, haze, silking, flooding, etc., are not within the scope of this test method.

4. Summary of Test Method

4.1 The varnish film under test is exposed to foul gas for various periods before the film has been converted from liquid to substantially solid, since the foul gas is effective, within the scope of these test methods, only before the varnish film has become set-to-touch or dust-free.

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and the direct Responsibility of Subcommittee D 01.33 on Varnish and Resins, Including Shellac.

Current edition approved Sept. 19, 1960. Published November 1960. Originally published as D 1643 - 59 T. Last previous editions D 1643 - 59 T. Replaces Sections 2 to 14 of Method D 154.

² *Annual Book of ASTM Standards*, Vol 06.01.

³ See *Paint Testing Manual*, ASTM STP 500, ASTM, 1972.

PROCEDURE A—BELL JAR TEST

5. Apparatus

5.1 The form and arrangement of the apparatus shall be designed to provide an even distribution of the products of combustion over the test panels.

5.1.1 *Glass Bell Jar*, approximately 8 in. (203 mm) in diameter and 12 in. (300 mm) in height, inside dimensions, having a ground-glass rim.

5.1.2 *Ground-Glass Base Plate*, of suitable size.

5.1.3 *Metal Frame*, fitted inside the bell jar and provided with a suitable support for holding a tin-plate disk 6 in. (152 mm) in diameter in a horizontal position 2 in. (51 mm) above the wick of the lamp.

5.1.4 *Additional Horizontal Supports*, for holding the various varnished panels under test.

5.1.5 *Small Kerosine Glow Lamp*, without a chimney, or a small alcohol lamp filled with kerosine, using a round wick not over 1/4 in. (6.4 mm) in diameter and adjusted to give a flame of 1/2 in. (20 mm) in height.

5.1.6 *Tin-Plate Panels*, 3 by 5 in. (76 by 127 mm) or smaller, cut from commercial No. 31 gage (0.227 mm) bright tin plate, weighing 0.39 to 0.51 lb/ft² (1.9 to 2.5 kg/m²) and carefully cleaned with toluene and dried before use.

6. Procedure

6.1 Determine the normal set-to-touch or dust-free drying time of the varnish under test in accordance with Test Methods D 1640. Divide this time by five to arrive at the different drying periods at which the material is to be tested. Thus, if a material sets to touch in 1 h, test the specimens for resistance to gas at drying periods of 12, 24, 36, and 48 min, respectively.

6.2 Flow the varnish to be tested on the tin-plate panels at the determined intervals of time. Allow the panels to drain in a nearly vertical position at room temperature 65 to 75°F (18 to 24°C).

6.3 After the required interval of drying time has passed, place the panels in a horizontal position on the upper supports of the frame. Light the lamp and place it on or near the center of the ground-glass base plate. After the bell jar has been placed tightly over the frame and lamp, the flame should extinguish in about 4 min.

6.4 Remove the panels and examine for gas effects after they have remained in the jar for 30 min.

7. Report

7.1 Describe the presence or absence of gas effects on the test panel for each drying interval.

Diameter of Dish	Weight of Nonvolatile Residue	
	45 mm	100 mm
For a 2.5-mil varnish film	0.12 g	0.60 g
For a 5-mil varnish film	0.25 g	1.20 g

8.2 Place the dish on the hot plate at $150 \pm 3.5^\circ\text{C}$ for 10 min. Cool to room temperature in a desiccator, then reweigh.

9. Calculation

9.1 Calculate the nonvolatile matter as described in Section 5.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

10. Report

10.1 Report the nonvolatile matter of the sample to the nearest 0.1 %.

INDEX TERMS

11. Index Terms

11.1 These test methods are indexed under the following terms: nonvolatile matter content; varnishes.

1. Scope

1.1 Test methods for determining the nonvolatile matter content of all types of varnishes, including those used in the paint and coating industry.

1.2 These test methods are applicable to the determination of nonvolatile matter content of varnishes, including those used in the paint and coating industry.

2. Referenced Standards

2.1 ASTM D 609 - Standard Test Method for Determining the Nonvolatile Matter Content of Paints by Gravimetric Analysis
2.2 ASTM D 1193 - Standard Test Method for Determining the Nonvolatile Matter Content of Paints by Gravimetric Analysis
2.3 ASTM D 3924 - Standard Test Method for Determining the Nonvolatile Matter Content of Paints by Gravimetric Analysis

3. Summary of Test Method

3.1 The test method involves the weighing of a known amount of varnish onto a tin can, followed by immersion in a water bath at $150 \pm 3.5^\circ\text{C}$ for 10 minutes. The varnish is then removed from the water bath and allowed to cool to room temperature. The weight of the nonvolatile matter is determined by weighing the residue left in the tin can.

4. Significance and Use

4.1 This test method is used to determine the nonvolatile matter content of varnishes, which is a measure of the amount of solid material in the varnish. This information is used to compare the nonvolatile matter content of different varnishes and to determine the nonvolatile matter content of a varnish for use in a specific application.

5. Reagents and Materials

5.1 The test method requires the use of a tin can, a water bath, and a balance.

¹ These test methods are published in the Annual Book of ASTM Standards, Vol. 11.01, Paint and Related Coatings, published by the American Society for Testing and Materials, 1916 Race St., Philadelphia, PA 19103.
² Annual Book of ASTM Standards, Vol. 11.01, Paint and Related Coatings, published by the American Society for Testing and Materials, 1916 Race St., Philadelphia, PA 19103.

Standard Test Methods for Resistance of Dried Films of Varnishes to Water and Alkali¹

This standard is issued under the fixed designation D 1647; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 These test methods cover the determination of the resistance of dried varnish films to immersion in water and dilute alkali at room temperature.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 609 Methods for Preparation of Steel Panels for Testing Paint, Varnish, Lacquer, and Related Products²

D 1193 Specification for Reagent Water³

D 3924 Specification for Standard Environment for Conditioning and Testing Paint, Varnish, Lacquer, and Related Materials²

3. Summary of Test Methods

3.1 *Test Method A*—The material under test is flowed onto tinplate panels and dried for 48 h. The panels are then immersed to half their length in reagent water for 18 h, or other agreed upon time, removed, and examined visually.

3.2 *Test Method B*—The material under test is applied to glass test tubes by dipping and dried for 72 h. The tubes are then suspended in dilute sodium hydroxide for periods ranging from 1 to 24 h, removed, rinsed, and after drying for 30 min, examined visually.

4. Significance and Use

4.1 Dried Varnish Films are a source of primary protection for surfaces. Exposure to water and dilute alkali solutions are two factors which tend to break down this protective coating. This test method can be used as a comparison basis between manufacturer and consumer to determine the ability of the varnish to resist water and dilute alkali.

5. Reagents

5.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended

that all reagents conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁴

5.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water as defined by Type IV of Specification D 1193.

TEST METHOD A—WATER RESISTANCE OF DRIED FILMS

6. Apparatus and Materials

6.1 *Beaker*, glass, 600 mL or larger.

6.2 *Tinplate Panels*, 3 by 5 in. (75 by 125 mm) cut from commercial No. 31 gage (0.225-mm) bright tin plate, weighing 0.4 to 0.5 lb/ft² (1.90 to 2.50 kg/m²) and carefully cleaned and dried before use in accordance with Methods B or C of Methods D 609.

7. Procedure

7.1 Flow the varnish onto the tin panels, allow to drain in a nearly vertical position, and dry for 48 h in the standard atmosphere described in Specification D 3924.

7.2 Place the panels in a beaker containing about 2.5 in. (65 mm) of water at room temperature, immersing the ends that were uppermost during drying, and allow to remain in the water for 18 h, or other suitable period as agreed upon between the purchaser and the seller.

7.3 Remove the panels from the water, wipe carefully, and allow to dry at room temperature. Note the time required for whitening, if any, to disappear. Blooming, which sometimes occurs on immersion, is considered a type of whitening.

8. Report

8.1 Report the results of the water test as follows:

8.1.1 Not visibly affected,

8.1.2 Whitening disappears within 20 min,

8.1.3 Whitening does not disappear within 20 min, but disappears within 2 h,

8.1.4 Whitening does not disappear within 2 h, but disappears within 24 h, or

8.1.5 Whitening does not disappear within 24 h.

TEST METHOD B—DILUTE ALKALI RESISTANCE OF DRIED FILMS

9. Reagent

9.1 *Sodium Hydroxide Solution* (30 g/L)—Dissolve 30 g

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.33 on Polymers and Resins.

Current edition approved April 28, 1989. Published June 1989. Originally published as D 1647 - 59. Last previous edition D 1647 - 83.

⁴ "Reagent Chemicals, American Chemical Society Specifications," Am. Chemical Soc., Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY, and the "United States Pharmacopeia."

of sodium hydroxide (NaOH) in water and dilute to 1 L.

10. Procedure

10.1 Thoroughly clean and dry twenty 1 by 6-in. (25 by 150-mm) test tubes in toluene. Dip the tubes into the varnish under test, remove immediately, invert the tubes, and allow the varnish to dry for 72 ± 1 h in the standard atmosphere described in Specification D 3924. A suggested test schedule to fit into normal working hours is shown in Table 1.

10.2 Into each of ten 1000-mL, tall-form lipless, chemically resistant plastic or glass beakers, place 300 mL of the NaOH solution. Suspend a set of two varnish-coated tubes in each beaker so that the tubes do not touch the bottom or sides of the beaker and are immersed for a distance of approximately 2 in. (50 mm). As a suspending device (see Fig. 1), use a wooden cover plate and two dowels, and two one-hole cork stoppers, the dowels and the corks fitting into the tubes and the cover plate fitting the beaker as tightly as possible. Maintain the NaOH solution at a temperature of $23 \pm 2^\circ\text{C}$.

10.3 Remove a set of two varnish-coated tubes after immersion for each of the following time periods: 1, 2, 3, 4, 5, 6, 7, 8, 16, and 24 h. Rinse the tubes under a gentle stream of water, allow to air-dry for 30 min, and examine for film

NOTE—1 in. = 25.4 mm.

FIG. 1 Apparatus for Alkali Resistance Test

TABLE 1 Suggested Test Schedule

Day	Hour	Operation
Monday	8:30 a.m.	coat 16 tubes
	4:00 p.m.	coat 4 tubes
Thursday		dry tubes for 72 h
	8:30 a.m.	start alkali immersion on first 16 tubes
	9:30 a.m. and each hour thereafter to 4:30 p.m.	remove one set of tubes from alkali, rinse, and air-dry for 30 min
	10:00 a.m. and each hour thereafter to 5:00 p.m.	examine varnish film on set of tubes removed 1/2 h earlier
Friday	4:00 p.m.	start alkali immersion on last 4 tubes
	8:00 a.m.	remove one set of tubes from alkali, rinse, and air dry for 30 min
	8:30 a.m.	examine varnish film on set of tubes removed and rinsed 1/2 h earlier
	4:00 p.m.	remove last set of tubes, rinse, and air-dry for 30 min
	4:30 p.m.	examine varnish film on last set of tubes

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

whitening, blistering, or removal. The end point of the test is the number of hours immersion at which the first signs of film whitening, blistering, or removal are noted on the vertical sides of the tubes or on the spherical bottom portion of the tube. The results may be compared with those from materials known to give acceptable performance. For referee work, the test on materials known to be acceptable should be made simultaneously.

11. Report

11.1 Report the results of the alkali test as follows:

11.1.1 Type of varnish, and

11.1.2 End point of the test, h.

12. Precision

12.1 Precision has not been determined due to the multiplicity of ambient test conditions.

Standard Test Methods for Water Vapor Transmission of Organic Coating Films¹

This standard is issued under the fixed designation D 1653; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

These test methods have been approved for use by agencies of the Department of Defense to replace Method 6171 of Federal Test Method Standard No. 141A. Consult the DoD Index of Specifications and Standards for the specific year of issue that has been adopted by the Department of Defense.

1. Scope

1.1 These test methods cover the determination of the rate at which water vapor passes through films of paint, varnish, lacquer, and other organic coatings. The films may be free films or they may be applied to porous substrates.

1.2 Two test methods are covered as follows:

1.2.1 *Test Method A—Dry Cup Method*, and

1.2.2 *Test Method B—Wet Cup Method*.

1.2.3 Agreement should not be expected between results obtained by different methods. The method that most closely approaches the conditions of use should be selected.

1.3 The values stated in inch-pound units are to be designated as the standard. Metric-inch pound conversion factors are stated in 13.2.1.2 and 13.2.2.2.

1.4 *This standard does not purport to address the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

D 1005 Test Methods for Measurement of Dry-Film Thickness of Organic Coatings Using Micrometers²

D 1193 Specification for Reagent Water³

D 4708 Practice for Preparation of Free Films of Organic Coatings²

E 104 Practice for Maintaining Constant Relative Humidity by Means of Aqueous Solutions⁴

3. Terminology

3.1 Descriptions of Terms Specific to This Standard:

3.1.1 *water vapor transmission rate, WVT*—the steady water vapor flow in unit time through unit area of a body, between two specific parallel surfaces, under specific conditions of temperature and humidity at each surface. Accepted

inch-pound unit is grains per square foot per hour. Accepted SI unit is grams per square metre per 24 h.

3.1.2 *water vapor permeance, WVP*—the steady water vapor flow in unit time through unit area of a body (WVT) induced by unit vapor pressure difference (Δp) between the two surfaces of a coating. Therefore, $WVP = WVT/\Delta p$. Accepted inch-pound unit is grains per square foot per hour per inch of mercury (called a perm). Accepted SI unit is grams per square metre per 24 h per millimetre of mercury (called a metric perm).

4. Summary of Test Methods

4.1 In Test Method A (Dry Cup Method), the test specimen is sealed to the open mouth of a cup or dish containing desiccant, and the assembly placed in a test chamber with a controlled atmosphere. Two sets of exposure conditions are acceptable for this test method.

4.1.1 *Condition A*, consisting of 50 % relative humidity at 73°F (23°C), and

4.1.2 *Condition B*, consisting of 90 % relative humidity at 100°F (38°C).

4.2 In Test Method B (Wet Cup Method), the test specimen is sealed to the open mouth of a cup or dish containing water, and the assembly placed in a test chamber with a controlled atmosphere. Two sets of exposure conditions are acceptable for this test method:

4.2.1 *Condition A*, consisting of 50 % relative humidity at 73°F (23°C), and

4.2.2 *Condition C*, consisting of very low (near zero) relative humidity at 73°F (23°C).

4.3 In both methods, periodic weighings of the cup or dish are made to determine the rate of water vapor movement through the specimen.

5. Significance and Use

5.1 One of the factors affecting the performance provided by an organic coating is the degree of resistance to the passage of water vapor. Hence, the water vapor transmission characteristics of coatings are important in assessing their performance in practical use.

5.2 The purpose of these test methods is to obtain values of water vapor transfer through coatings that range in permeability from high to low. These values are for use in design, manufacture, and marketing.

5.3 The water vapor transmission is not a linear function of film thickness, temperature or relative humidity.

5.4 Values of water vapor transmission rate (WVT) and water vapor permeance (WVP) can be used in the relative

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.23 on Physical Properties of Applied Paint Films.

Current edition approved Sept. 15, 1991. Published November 1991. Originally published as D 1653 - 59 T. Last previous edition D 1653 - 91.

² Annual Book of ASTM Standards, Vol 06.01.

³ Annual Book of ASTM Standards, Vols 06.03 and 11.01.

⁴ Annual Book of ASTM Standards, Vol 11.03.

rating of coatings only if the coatings are tested under the same closely controlled conditions of temperature and relative humidity, and if their thicknesses are equal.

6. Apparatus

6.1 *Perm Cup⁵ or Dish*, consisting of a container made of a noncorroding material, impermeable to water or water vapor. If the cup or dish is made of aluminum, it must be anodized or given a protective clear coating to prevent corrosion.

6.1.1 One type of cup that is suitable has a flanged edge and is equipped with a separate corresponding flange, so that the test specimen can be held between them. The contacting faces of the flanges shall be ground to such flatness that when the film is in position, moisture transfer can occur only through the exposed film area. For hard films, or films having a very rough surface, a soft rubber gasket may be inserted between the film and the flange. The flanges shall then be held together with suitable clamps.

6.1.2 Another suitable cup is any open circular dish to which the test film can be sealed with wax or sealant.

6.2 *Test Chamber*, with a controlled temperature and relative humidity as specified in Section 4. Air shall be circulated throughout the chamber to maintain uniform conditions at all test locations. For low or high humidity conditions, a standard desiccator or other suitable cabinet may be used. For maintaining constant relative humidity by means of aqueous solutions, refer to procedures outlined in Practice E 104.

6.3 *Analytical Balance*, having an adequate capacity for the weight of the test cups and a sensitivity of 1 mg.

7. Reagents and Materials

7.1 *Purity of Water*—Unless otherwise indicated, reference to water shall be understood to mean reagent water conforming to Type IV of Specification D-1193.

7.2 *Desiccant*, consisting of either anhydrous calcium chloride (CaCl_2) or anhydrous magnesium perchlorate ($\text{Mg}(\text{ClO}_4)_2$). The calcium chloride should be dried at 400°F (200°C) before use. If calcium chloride will react with the test specimen, an adsorbing desiccant such as a silica gel may be used but the moisture gain by this desiccant during the test must be limited to 4 %. Use caution in handling magnesium perchlorate because of possible chemical reaction that may be produced if it comes in contact with some organic materials.

7.3 *Sealant*, such as wax for attaching the test specimen to the top of the perm cup or dish. It must be highly resistant to the passage of water vapor. It must not lose weight to, or gain weight from, the atmosphere in an amount, over the required period of time, that would affect the test results by more than 2 %. It must not affect the vapor pressure in a water-filled dish.

NOTE 1—Among acceptable sealants are (1) a 60:40 mixture of microcrystalline wax and refined crystalline paraffin wax, (2) tissue embedding wax, and (3) a 50:50 mixture of beeswax and rosin.

⁵ Perm Cups, 10 cm² and 25 cm² in area, available from Paul N. Gardner Co., Inc., 316 N.E. First Street, Pompano Beach, FL 33061, and BYK/Gardner, Inc., Gardner Laboratory, 2435 Linden Ln., Silver Spring, MD 20910 have been found satisfactory for this purpose.

7.4 *Release Paper*, prepare free films, whenever possible to eliminate the potential interference of substrates, on release paper⁶ or glass substrates following procedures outlined in Practice D 4708.

7.5 *Film Support*, for preparing films that are too brittle or otherwise unsatisfactory for handling as free films, support materials such as paper charts,⁷ filter paper, and glass cloth have been found satisfactory in some instances. Such support can have an effect on the test results.

8. Test Specimens

8.1 It is very important that the test specimens be smooth, and completely continuous films of uniform thickness throughout the test area. Apply air dry coatings to substrates using one of the methods described in Test Methods D 823 or Practice D 4708.

NOTE 2—Special test conditions may require that the coating be applied by brushing, roller coating or other special methods. The thickness of the coating applied shall be within normal range for the type of material under test, and shall not vary by more than 5 % of the total thickness in any test series.

NOTE 3—When applying bake finishes, bake for specified time and temperature in accordance with manufacturers' instructions. Permeance may vary with the baking schedule or the time of air drying.

8.2 Air dry the coated material in a horizontal position for 7 days in a room preferably maintained at 73.5 ± 3.5°F (23 ± 2°C) and 50 ± 5 % relative humidity. If the material to be used is a free film, remove it from the substrate and allow the previously unexposed surface to dry for an additional 7 days. The drying schedule may be modified as recommended by manufacturer.

NOTE 4—Examine test film for the presence of pinholes or other defects before commencing the test. It may be advisable to apply the test material in two coats, applying the second coat perpendicular to the first coat and allowing for an adequate dry period between coats to achieve the desired film thickness.

8.3 Measure the thickness of the test specimen in several places with a micrometer using procedures in Test Methods D 1005 to ensure a uniform thickness.

8.4 When coatings are applied to support materials, the coated side of the test specimen should be placed away from the desiccant or towards the water in the cup, depending upon use. Coatings should not be applied to both sides of a support. Glass cloth is preferred for coatings that are cured by baking.

TEST METHOD A—DRY CUP METHOD

9. Test Conditions

9.1 Unless other conditions are agreed upon between the purchaser and the seller, the tests shall be performed under one or more of the following conditions:

9.1.1 *Condition A*—Test chamber or cabinet maintained at 73° ± 1°F (23 ± 0.6°C) and 50 ± 2 % relative humidity.

9.1.2 *Condition B*—Test chamber or desiccator maintained at 100 ± 1°F (38 ± 0.6°C) and 90 ± 2 % relative humidity.

⁶ Release Paper, Form RP-1K, available from the Leneta Co., P.O. Box 110, Ho-Ho-Kus, NJ 07423, has been found satisfactory for this purpose.

⁷ Paper charts, Form NWK, available from the Leneta Co., have been found suitable for this purpose.

specimen c
and adjust

10. Procedure

10.1 Prepare at least three perm cups or dishes for each test material as follows:

10.1.1 Fill the cups with desiccant to within 1/4 in. (6 mm) of the top edge.

10.1.2 If the cups are equipped with flanges, place the test specimen between the flanges and adjust the clamps to hold it firmly in position.

10.1.3 If the cups are not equipped with flanges, seal the test specimen to the top edge of the cups with wax as follows:

10.1.3.1 First carefully place the test specimen, cut to the size of the cup, on a thin cardboard ring soaked in molten wax.

10.1.3.2 Then place the specimen-covered frame over the mouth of the cup. Thoroughly seal the frame to the edge of the cup at the temperature to be used in the test. If the coating is on a substrate or support, place the coated side away from the desiccant in the cup.

NOTE 5—Imperfections in the film that are not readily visible will produce inconsistent results; consequently make sure that the test is always run in triplicate.

10.4 Weigh the loaded cups to 1 mg and place them in the test cabinets or desiccators. Record time, temperature and relative humidity.

10.5 Remove the cups for periodic weighing to determine weight gain. Coatings expected to have high WVT ratings, over 10 perms, may require weighings more frequently than once a day.

10.6 In general, weigh the cups every 24 h for a period of 3 weeks, or until the weight change has become constant. Record the time that weighings are taken to the precision of approximately 1 % of the time span between weighings. Thus, if weighings are made every day, a time to the nearest 15 minutes would be allowed.

10.7 Shake cups containing desiccant everyday to prevent surface saturation of the material. If moisture absorbed by the desiccant exceeds 20 % of the desiccant weight, discontinue the test.

10.8 Return the cups to the test chamber immediately after weighing.

TEST METHOD B—WET CUP METHOD

11. Test Conditions

11.1 Unless other conditions are agreed upon between the purchaser and the seller, perform the test(s) under one or more of the following conditions:

11.1.1 *Condition A*—Test chamber or cabinet maintained at 73 ± 1°F (23 ± 0.6°C) and 50 ± 2 % relative humidity.

11.1.2 *Condition C*—Test chamber or desiccator maintained at 73 ± 1°F and very low (near zero) relative humidity.

12. Procedure

12.1 Prepare at least three cups for each test material as follows:

12.1.1 Fill the cups with water to within 1/4 in. (6 mm) of the top edge.

12.1.2 If the cups are equipped with flanges, place the test specimen over the opening of the cups between the flanges and adjust the clamps to hold them firmly in position. If the

coating is on a substrate or support, place the coated side towards the water in the cups.

12.1.3 If the cups are not equipped with flanges, seal the test specimens to the top edge of the cups with wax in accordance with procedures in 10.1.3.1 and 10.1.3.2.

12.2 Weigh the loaded cups to 1 mg and place them in the test chamber. Record time, temperature and relative humidity. Follow procedures outlined in 10.5 and 10.6.

12.3 Return the cups to the test chamber immediately after weighings.

13. Calculations

13.1 For each material tested, plot the weight change against elapsed time. When a straight line adequately fits the plot of at least four properly spaced points, a nominally steady state exists and the slope of the straight line is the rate of water vapor transmission.

13.2 Calculate one or more of the following, depending on the water vapor transmission characteristics to be determined:

13.2.1 Calculate the water vapor transmission rate, WVT:

13.2.1.1 In inch-pound units as follows:

$$WVT = (G/t)/A = \text{grains per ft}^2 \text{ per 1 h} \quad (1)$$

where:

G = weight change, grains (from the straight line),

t = time during which G occurred, h, and

A = test area, ft²,

1 g = 15.43 grains.

13.2.1.2 In metric units as follows:

$$WVT = (G/t)/A = \text{grams per m}^2 \text{ per 24 h} \quad (2)$$

where:

G = weight change, g (from the straight line),

t = time during which G occurred, h, and

A = test area, m².

13.2.2 Calculate the permeance, WVP:

13.2.2.1 In inch-pound units as follows:

$$WVP = WVT/\Delta p = \text{grains per ft}^2 \text{ per 1 h per in. of mercury (perms)} \quad (3)$$

where:

$\Delta p = S(R_1 - R_2)$,

S = in. Hg (saturation vapor pressure at test temperature),

(see Table 1),

R_1 = relative humidity at vapor source, and

R_2 = relative humidity at vapor sink.

13.2.2.2 In metric units as follows:

$$WVP = WVT/\Delta p = \text{grams per m}^2 \text{ per 24 h per millimetre of mercury, (metric perms)} \quad (4)$$

where:

$\Delta p = S(R_1 - R_2)$,

S = mm Hg (saturation vapor pressure at test temperature), (see Table 1),

R_1 = relative humidity at vapor source, and

R_2 = relative humidity at vapor sink.

14. Report

14.1 Report the following information:

14.1.1 Method of coating application and curing procedure used.

TABLE 1 Saturation Vapor Pressure

Temperature		Pressure	
°F	°C	in. Hg	mm Hg

101.5	38.6	2.021	51.323

14.1.2 Mean film thickness of the test specimens for each material.

14.1.3 Type of film support used, if any.

14.1.4 Method used (Test Method A (Dry Cup) or Test Method B (Wet Cup)).

14.1.5 Test temperature and relative humidity in the test chamber.

14.1.6 Computed rate of water vapor transmission (WVT), either in inch-pound or in metric units.

14.1.7 The computed permeance in terms of both perms and metric units.

15. Precision and Bias⁸

15.1 In an interlaboratory study of these test methods in which one operator in each of three laboratories determined in triplicate the permeance of three coatings covering the range of interest for vapor barrier coatings, the interlaboratory standard deviation for the dry-cup procedure was found to be 0.073 perms with 6 df and the interlaboratory wet-cup coefficient of variation 21.54 % relative with 6 df, with no results having been discarded. Based upon these values, the following criteria should be used for judging, at the 95 % confidence level, the acceptability of results:

15.1.1 Repeatability:

15.1.1.1 *Test Method A*—Two results, each the mean of triplicate runs, obtained by the same operator should be considered suspect if they differ by more than 0.25 perms at dry-cup permeance of less than 1.0 perms.

15.1.1.2 *Test Method B*—Two results, each the mean of triplicate runs, obtained by the same operator should be considered suspect if they differ by more than 74.2 % relative at wet-cup permeances of 5 to 30 perms.

15.1.2 *Reproducibility*—Intralaboratory precision is normally better than interlaboratory precision. However, one participant in this exchange has noted relatively large differences when the same coating was tested in quadruplicate with fairly long intervals between tests.

15.2 Bias is not applicable to these test methods.

16. Keywords

16.1 permeability; permeance; perms; water vapor permeance; water vapor transmission

Standard Method for Evaluation of Painted or Coated Specimens Subjected to Corrosive Environments¹

This standard is issued under the fixed designation D 1654; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^e) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

^{e1} NOTE—Editorial changes were made throughout in July 1984.

1. Scope

1.1 This method covers the treatment of previously painted or coated specimens for accelerated and atmospheric exposure tests and their subsequent evaluation in respect to corrosion, blistering associated with corrosion, loss of adhesion at a scribe mark, or other film failure.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

B 117 Method of Salt Spray (Fog) Testing²

B 287 Method of Acetic Acid-Salt Spray (Fog) Testing³

D 610 Test Method for Evaluating Degree of Rusting on Painted Steel Surfaces⁴

D 714 Test Method for Evaluating Degree of Blistering of Paints⁴

D 1014 Test Method for Conducting Exterior Exposure Tests of Paints on Steel⁴

D 2803 Test Method for Filiform Corrosion Resistance of Organic Coatings on Metal⁴

3. Significance and Use

3.1 This method provides a means of evaluating and comparing basic corrosion performance of the substrate, pretreatment, or coating system, or combination thereof, after exposure to corrosive environments.

4. Apparatus

4.1 **Scribing Tool**—A straight-shank tungsten carbide tip, lathe cutting tool (Brazed tool, Style E, with 1/64-in. nose radius) is recommended; however, other styles may be used

provided they are ground to a single point having an included angle of $60 \pm 15^\circ$. Any other type of scribing instrument such as a scalpel, razor blade, knife, or sharp pointed tool is unacceptable unless agreed upon between the producer and the user.

4.2 **Straightedge**—Any straightedge of sufficient length and rigidity to guide the scribing tool in a straight line.

4.3 **Air Compressor**—A source of compressed air capable of producing 80 psi (550 kPa) open line pressure.

4.4 **Air Gun**—An air dusting gun and nozzle combination⁵ to meet the following specification:

Air Consumption, ft ³ /min (m ³ /min)	Pressure, psi (kPa)	Nozzle Diameter, in. (mm)
8.4 (0.24)	80 (550)	0.12 (3.0)

4.4.1 A guard consisting of barriers, baffles, or screens is required to protect the operator and other individuals near the area where the air is being used. The guard must be placed between the air nozzle and the operator. A device such as a sand-blasting cabinet has been found to be acceptable.

NOTE 1—The use of an air gun without a guard is in violation of the U. S. Occupational Safety and Health Administration regulation.

4.5 **Scraping Tool**—A rigid metal spatula, dull knife, or similar instrument.

4.6 **Scale**—Any rule with 1-mm divisions.

4.7 **Grid**, plastic or wire with 1/2-in. (13-mm) squares necessary to permit measurements of the required accuracy.

5. Preliminary Treatment of Test Specimens

5.1 Scribed Specimens:

5.1.1 Where specified or agreed upon, prepare each specimen for testing by scribing it in such a manner that the scribe can be exposed lengthwise when positioned in the test cabinet. This position will allow solution droplets to run lengthwise along the scribe.

5.1.2 Scribe the specimen by holding the tool at approximately a 45° angle to the surface. Position the tool so that only the carbide tip is in contact with the surface. Pull the scribing tool to obtain a uniform V-cut through the coating that is being tested. The scribe should be of sufficient length to cover the significant test area but should not contact the

¹ This method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.27 on Accelerated Tests For Protective Coatings.

Current edition approved Nov. 26 and Dec. 3, 1979. Published January 1980. Originally published as D 1654 - 59. Last previous edition D 1654 - 74.

² Annual Book of ASTM Standards, Vols 03.02 and 06.01.

³ Discontinued; see 1988 Annual Book of ASTM Standards, Vol 06.01.

⁴ Annual Book of ASTM Standards, Vol 06.01.

⁵ Spray gun and nozzles, Model No. 22-L and 0010 have been found satisfactory and may be obtained from Spray Systems Co. Equivalents may be used.

edge of the specimen. The scribe must penetrate all coatings on the metal, leaving a uniformly bright line free of burrs. Quality of the scribe may be observed with the aid of low-power magnification. Note, mark, and describe defects, coding, and flaws that may affect results.

5.1.3 Scribe lines other than those of a single, straight nature may be used if agreed upon between the producer and the user.

5.1.4 Expose scribed specimens in accordance with 6.1 and rate in accordance with Section 7.

5.2 *Unscribed Specimens*—Specimens coated with paint undercoats, oils, or waxes may be evaluated without a scribe. Expose such specimens in accordance with Section 6 and rate for corrosion of the general surface in accordance with Section 8.

6. Exposure of Test Specimens

6.1 Expose test specimens in accordance with Methods B 117, B 287, D 1014, D 2803, or any other applicable test method, as agreed upon between the producer and the user. The length of test and evaluation intervals should be agreed upon prior to exposure of specimens.

7. Procedure A—Evaluation of Scribed Specimens

7.1 *Method 1 (Air Blow-Off)*—Rinse each specimen after completion of the exposure period, using a gentle stream of water at a temperature up to 110°F (45°C). Holding the nozzle at approximately a 45° angle, blow along the entire scribe line, disturbing the surface adjacent to the scribe mechanically by the air nozzle to ensure an opening for the air blast. Complete the air blasting within 15 min of specimen removal from the exposure cabinet. If the air blasting cannot be completed within the prescribed time, immerse the specimens in water at room temperature or store in a plastic bag to avoid any drying effect.

7.2 *Method 2 (Scraping)*—Rinse the specimen after completion of the exposure period, using a gentle stream of water at a temperature up to 110°F (45°C). Scrape the specimen vigorously with an instrument described in 4.5 while under the gentle stream of the rinse water. Hold the scraper with its face perpendicular to the specimen surface and parallel to the scribe, moving it back and forth across the scribe to remove the coating that has been undercut and has suffered loss of adhesion only, not to remove the coating that still has adhesion. Complete the scraping within 15 min of specimen removal from the exposure cabinet. If scraping cannot be completed within the prescribed time, immerse the speci-

mens in water at room temperature or store in a plastic bag to avoid any drying effect.

NOTE 2—Some specimens exposed to natural weathering do not require rinsing, air blasting, or scraping to evaluate corrosion. Alternative methods may be used if agreed upon between the producer and the user.

7.3 *Rating*—Rate the corrosion or loss of paint extending from a scribe mark as prescribed in Table 1. Record the representative mean, maximum, and minimum creepage from the scribe, and note whether or not the maximum is an isolated spot. Also, rate in accordance with Table 2 the prevalence of corrosion on areas removed from the scribe.

8. Procedure B—Evaluation of Unscribed Areas

8.1 Rinse the specimen after completion of the exposure period (Section 6), using a gentle stream of water at a temperature up to 100°F (40°C). Dry the surface of the specimen with paper towels or compressed air. Drying should be done in such a manner that the corrosion on the specimen surface is not disturbed.

8.2 Evaluate unscribed specimens for corrosion spots, blisters, and any other types of failure that may occur. Depending upon the contour of the specimen, the use of a grid, as described in 4.7, is recommended as an aid in evaluating this type failure (Fig. 1). The percent of surface failure, excluding rust staining or run down, can be estimated by counting the number of squares that have points of failure and relating this number to the total number of squares covering the test area. Discount corrosion within 1/2 in. (12.7 mm) of edges.

8.3 *Rating*—Convert percent failure to the rating number in accordance with Table 2. In some instances, the rating number may be used as a factor with the corresponding exposure time intervals to produce a performance index number.

NOTE 3—Formation of under-film corrosion may be evaluated and reported in accordance with Table 2 if the film is first carefully stripped with a neutral stripper. Exercise care to avoid alteration of the corrosion pattern or pretreatment.

NOTE 4—Where the character of the failure permits, the photographic blister standards given in Test Method D 714 may be used to describe the results of the exposure test, in respect to size of blisters or corroded areas, while Method D 610 may serve to describe the frequency and distribution, if desired.

9. Report

9.1 Report the ratings of the test specimens, the procedures, and, for scribed panels, the method followed. Also

NOTE—1 in. = 25.4 mm.

FIG. 1 Typical Grid with 1/2-in. (13-mm) Squares

report the exposure test to which the specimens were subjected.

10. Precision and Use

10.1 Since this is a method of evaluation based on measurements after various tests, the statement of precision

applicable to each specific method of exposure to corrosive atmospheres applies. The preferred methods of measurement, using ruled plastic sheets, are at least equal in precision to the various methods of exposing test specimens to corrosive environments.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practices for Preparation of Aluminum and Aluminum-Alloy Surfaces for Painting¹

This standard is issued under the fixed designation D 1730; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{ε1} NOTE—Section 2 was added and subsequent sections were renumbered editorially in September 1984.

1. Scope

1.1 These practices cover four types of treatment for preparation of aluminum and aluminum-alloy surfaces for painting, as follows:

1.1.1 Type A—Solvent Cleaning.

1.1.2 Type B—Chemical Treatments.

1.1.3 Type C—Anodic Treatments.

1.1.4 Type D—Mechanical Treatments. These four types cover a number of procedures, as described herein.

1.2 Variations in surface treatment produce end conditions which differ, and which do not necessarily yield identical results when paints are applied. Service conditions will dictate the type of surface preparation that should be selected, although the quality produced by any individual method may vary with different alloys.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 *ASTM Standard:*

D 609 Methods for Preparation of Steel Panels for Testing Paint, Varnish, Lacquer, and Related Products²

3. Type A—Solvent Cleaning

3.1 Solvent cleaning does not disturb the natural oxide film on the metal and may prove adequate for some applications, such as ambient indoor or very mild service conditions. Three methods may be employed, as follows:

3.1.1 *Method 1, Manual Swabbing or Dip-Washing*, with a solvent such as mineral spirits or high-flask solvent naphtha. With this method it is extremely difficult to prevent accumulation of contaminants on the swab or in the solvent. This method is only recommended when other treatments are impractical.

3.1.2 *Method 2, Solvent Spray Cleaning*, in accordance with Method A, Procedure 1 of Methods D 609.

3.1.3 *Method 3, Vapor Degreasing*, in special equipment employing trichloroethylene vapor, in accordance with Method A, Procedure 2 of Method D 609.

4. Type B—Chemical Treatments

NOTE 1—Materials and procedures employed in these methods of treatment are available from a number of sources as proprietary compounds or methods. Selection may be made from available sources.

4.1 *Method 1, Alkaline Cleaners*—Alkaline solutions, such as caustic soda, etch the metal, thus destroying the natural oxide film. They are followed by an acid treatment, preferably nitric acid or phosphoric acid. They shall not be used on assembled structures. Inhibited alkaline cleaners are sometimes employed as a pretreatment to remove grease and oil prior to an acid treatment. Inhibited alkaline cleaners do not etch the surface. They are not generally recommended unless followed by a conversion treatment, such as described in Methods 4, 5, 6, or 7.

4.2 *Method 2, Sulfuric Acid, Chromium Trioxide Etch*—This treatment provides a clean and uniform surface without undue etching, and is effective for removing oil and water stains and any film formed during heat-treatment. The etching solution is prepared by adding 1 gal (3.78 L) of concentrated sulfuric acid and 45 oz (1.28 kg) of chromium trioxide to 9 gal (34 L) of water. It is used at a temperature of 160 to 180°F (71 to 82°C) (depending on the alloy and the amount of film) for about 5 min and is followed by a water rinse. This treatment produces a passive surface suitable for painting under mild to intermediate exposure conditions and where clear finishes are to be applied.

4.3 *Method 3, Alcoholic Phosphoric Acid Cleaner*—This treatment involves the use of an aqueous solution of phosphoric acid (10 to 15 volume %) with alcohol or other organic solvents, together with wetting agents, emulsifying agents, etc. The solution may be applied by swabbing or dipping at room temperature (70 to 90°F (21 to 32°C)), and should be allowed to remain on the surface for several minutes, followed by thorough rinsing with clean water. A very thin phosphate film is formed which tends to protect the metal and promote paint adhesion under mild to intermediate exposure conditions.

NOTE 2—U.S. Military Specification MIL-M-10578B describes a treatment of this type.

4.4 *Method 4, Crystalline Phosphate Treatment*—This surface-coating method consists in reacting the aluminum surface in a zinc-acid-phosphate solution containing ox-

¹ These practices are under the jurisdiction of ASTM Committee B-8 on Metallic and Inorganic Coatings.

6)—Th

dizing agents and other salts for accelerating the coating action. The aluminum surface is converted to a finely crystalline, phosphate coating of the proper texture adapted to inhibit corrosion and increase the adherence and durability of any applied paint film. It is recommended for product finishes. The phosphate coating process may be carried out by immersion or spray application. The aluminum surface is converted to the phosphate coating by immersion in the processing solution for 30 s to 4 min at 125 to 140°F (51 to 60°C), or by spraying the solution for 10 s to 2 min at 125 to 160°F (51 to 71°C).

NOTE 3—Before applying the treatments according to Methods 4, 5, 6, and 7 of Type B, the aluminum surfaces should be freed of grease, oil, or other foreign material by means of the procedure described in Method 3 of Type A, Method 1 of Type B, or any other suitable method.

NOTE 4—This treatment complies with the requirements of U.S. Federal Specification TT-C-490.

4.5 Method 5, Amorphous Phosphate Treatment—This process comprises treatment of clean aluminum surfaces in a warm (95 to 130°F (35 to 54°C)) aqueous solution comprising phosphoric, and hydrofluoric acids, chromium trioxide or a solution thereof. The aluminum surface is converted to a thin, adherent, amorphous coating, iridescent green to gray-green in color, depending upon the aluminum alloy treated, which inhibits corrosion and increases the adherence and durability of applied paint films. This method is recommended for use under the more severe conditions of service, and for product finishes. The coating process may be carried out by immersion or spray application. The time of treatment will vary from 15 to 45 s for the spray process, and from 30 s to 3 min for the immersion application (see Notes 3 and 5).

NOTE 5—Most of the treatments conforming to Methods 5, 6, and 7 of Type B comply with the requirements of U. S. Military Specification MIL-C-5541.

4.6 Method 6, Carbonate Chromate Treatment—This process comprises treatment in a hot (180 to 190°F (82 to 88°C)) dilute solution of sodium carbonate and potassium chromate for periods from 2 to 20 min, followed by a water rinse. The surface is then given a final treatment in hot 5% potassium dichromate solution, followed by a final rinse. The treatment produces a thin, adherent, conversion coating on the surface, increasing the corrosion resistance of the metal and promoting paint adhesion. This method is recommended for use under the more severe conditions of service and for product finishes (see Notes 3 and 5).

4.7 Method 7, Amorphous Chromate Treatment—This process comprises treatment of clean aluminum surfaces in aqueous chromium trioxide solutions containing suitable accelerating agents such as fluoride-containing materials. The aluminum surface is converted to an adherent, amorphous, mixed metallic oxide coating, iridescent golden to light-brown in color, which increases the corrosion-resistance and the adherence and durability of any applied paint film. This method is recommended for use under the more severe conditions of service and for product finishes. The coating process may be carried out by immersion, spray, or brush application, at room temperature (70 to 90°F (21 to 32°C)), in from 15 s to 5-min contact time (see Notes 3 and 5).

4.8 Method 8, Acid-Bound Resinous Treatment (see Note 6)—This surface treatment involves the use of a suitably

applied acid-bound resinous film of approximately 0.3 to 0.5 mils (7.6 to 12.7 μ m) thickness. The treatment is based on three primary components: a hydroxyl-containing resin; a pigment capable of reacting with the resin and an acid; and an acid capable of insolubilizing the resin by reacting with the resin, the pigment, and the metal substrate. The aluminum surface should be prepared by Methods 1, 2, or 3 of Type A (see Section 3) or chemical treatments, Type B, 4.1 or 4.2 prior to the application of this treatment. The film may be applied by brush, spray, or dip. Under normal conditions it should dry sufficiently for recoating within 30 min; and within 8 h it should not be softened by organic solvents commonly used in paint coatings. The film has good adhesion to the metal substrate and promotes good adhesion of most subsequent organic coatings to itself. This method is recommended for severe service conditions, particularly on fabricated structures, either in the shop or in the field.

NOTE 6—Materials meeting the requirements of U.S. Military Specification MIL-P-15328b may be used to apply Method 8 of Type B.

5. Type C—Anodic Treatments (see Note 7)

5.1 Anodic treatment in either sulfuric acid or chromium trioxide electrolyte will provide a protective and inert oxide coating which increases the corrosion-resistance of the metal and promotes paint adhesion. It is recommended where maximum corrosion-resistance by the treatment itself is desired. Anodic treatments should not be used on assemblies of dissimilar metals. The two procedures are as follows:

NOTE 7—Treatments conforming to Methods 1 and 2 of Type C comply with the requirements of U.S. Military Specification MIL-A-8625.

5.2 Method 1, Sulfuric Acid Anodic—This treatment consists in making the part the anode in a 15% sulfuric acid electrolyte (by weight) and applying current at a potential of about 16 to 18 V and a current density of 12 A/ft² until desired thickness of coating is obtained. After rinsing in cold water, the coating is sealed for 10 min by treatment in a boiling solution of 5% potassium dichromate. This method is not recommended where danger of acid entrapment is encountered.

5.3 Method 2, Chromium Trioxide Anodic—This treatment consists in making the part the anode in a 10 weight % chromium trioxide electrolyte at a temperature of 100°F (38°C) and applying a potential of 40 V for a period of 30 to 60 min. After first rinsing in cold water, the coating is finally rinsed in water at 150°F (66°C) minimum, and dried; an optional final sealing treatment to obtain maximum protection is obtained by immersion in a solution containing 0.01 g chromium trioxide per litre of water (0.0013 or 1 gal) at a temperature of 208 to 212°F (98 to 100°C) for 5 min.

6. Type D—Mechanical Treatments

6.1 Method 1, Hand or Power Wire-Brushing, or other abrasive treatment. Wire-brushing, either by hand or power, roughens the surface of the metal and mechanically improves the anchorage for superimposed paint films. The disadvantages are that the natural oxide film on the metal is disrupted and oil or grease films and other foreign matter are not completely removed.

6.2 Method 2, Sandblasting, where employed on aluminum or its alloys, must be carried out at relatively low pressures and with a fine silica sand. It roughens the surface

and mechanically improves the anchorage for paint films, but destroys the natural oxide film on the metal. Where used, it should be followed by an inhibitive chemical treatment.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practices for Preparation of Hot-Dip Aluminum Surfaces for Painting¹

This standard is issued under the fixed designation D 1731; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

¹ NOTE—Section 2 was added and subsequent sections were renumbered editorially in September 1984.

1. Scope

1.1 These practices describe procedures for the preparation of hot-dip aluminum surfaces for painting.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 ASTM Standard:

D 609 Methods for Preparation of Steel Panels for Testing Paint, Varnish, Lacquer, and Related Products²

3. Types of Surface Preparations

3.1 Two types of surface preparations are covered as follows:

3.1.1 Solvent Cleaning, and

3.1.2 Chemical Treatments.

3.2 These two types cover several methods as described in Section 5. Variations in surface treatment produce end conditions which differ and which do not necessarily yield identical results when paints are applied. Service conditions will dictate the type of surface preparation that should be selected.

4. Solvent Cleaning

4.1 The surfaces may be prepared for painting by any of the methods for solvent cleaning described in 4.2 and 4.3.

4.2 *Method 1—Manual swabbing or dip washing with a solvent such as mineral spirits or high flask solvent naphtha. It is extremely difficult to produce a clean metal surface by this method. Accumulated contaminants in the solvent or on the swab are frequently redeposited on the surface being prepared.*

4.3 *Method 2—Solvent spray cleaning in accordance with Method A, Procedure 1 of Methods D 609.*

4.4 *Method 3—Vapor degreasing in special equipment in accordance with the latest revision of Method A, Procedure 2 of Method D 609, employing trichlorethylene or perchloro-*

ethylene vapor. Solvent cleaning does not disturb the natural oxide film on the metal and may prove adequate for some applications.

5. Chemical Treatment

5.1 The surfaces may be prepared for painting by any of the methods for chemical treatment (Note 1) described in 5.2 to 5.9:

NOTE 1—Materials and procedures employed in these methods of treatment are available from a number of sources as proprietary compounds or methods. Selection may be made from available sources.

5.2 *Method 1, Alkaline Cleaners—Etching alkaline solutions, such as caustic soda, should be avoided because of the possibility of dissolving away the aluminum coating thereby exposing the base metal. Since inhibited alkaline cleaners do not etch the surface, they can be used to remove grease, oil, and other organic solids from hot dip aluminum. After alkali cleaning, the surface should be thoroughly rinsed with clean water. Most often alkaline-cleaned surfaces are subsequently processed by one of the following methods, described in 5.3 to 5.9:*

5.3 *Method 2, Alcoholic Phosphoric Acid Cleaners—This treatment involves the use of an aqueous solution of phosphoric acid with alcohol or other organic solvents, together with wetting agents, emulsifying agents, etc. The solution may be applied by swabbing or dipping (preferably at a temperature of 70 to 90°F (21 to 32°C)). The solution should remain on the surface for several minutes, followed by thorough rinsing with clean water. A very thin phosphate film is formed which tends to protect the metal and promote paint adhesion.*

NOTE 2—Materials meeting the requirements of the latest revision of U.S. Military Specification MIL-M-10578B may be used.

5.4 *Method 3, Acid Fluoride Deoxidizer—This treatment includes the use of nitric or sulfuric acid with chromium trioxide and a fluoride. It provides a clean and uniform surface without undue roughening and is effective for removing inorganic soils and any film formed during the production of the hot dip aluminum. The deoxidizing solution is generally used at a temperature of 70 to 130°F (21 to 54°C) (depending on the alloy and the amount of film) and is followed by a water rinse.*

NOTE 3—Before applying the treatments according to Chemical Treatment Methods 3, 4, 5, 6 and 7, the aluminum surfaces should be freed of grease, oil or other foreign material by means of the procedure described in Solvent Cleaning Method 3, Chemical Treatment Method 1 or any other suitable method.

¹ These practices are under the jurisdiction of ASTM Committee B-8 on Metallic and Inorganic Coatings.

Current edition approved Sept. 8, 1967. Published November 1967. Originally published as D 1731-60. Last previous edition D 1731-66.

² Annual Book of ASTM Standards, Vol 06.01.

5.5 Method 4, Crystalline Phosphate Treatment—This surface-coating method consists in reacting the aluminum surface in a 130 to 145°F (54 to 63°C) (approximately) zinc acid-phosphate solution containing oxidizing agents and other salts for accelerating the coating action. The aluminum surface is converted to a crystalline, phosphate coating of the proper texture adapted to inhibit corrosion and increase the adherence and durability of any applied paint film. The phosphate coating process may be carried out by immersion or spray application. The aluminum surface is converted to the phosphate coating by immersion in the processing solution for 30 s to 4 min, or by spraying the solution for 10 s to 2 min (Note 3).

5.6 Method 5, Amorphous Phosphate Treatment (see Note 4)—This process comprises treatment of clean aluminum surfaces in a 90 to 125°F (32 to 51°C) aqueous solution comprising phosphoric, hydrofluoric acids and chromium trioxide. The aluminum surface is converted to a thin, adherent, amorphous coating, iridescent green to gray green in color, depending upon the aluminum alloy treated, which inhibits corrosion and increases the adherence and durability of applied paint films. The coating process may be carried out by immersion or spray application. The time of treatment will vary from 15 to 45 s for the spray process and 30 s to 3 min for the immersion application (Note 3).

5.7 Method 6, Carbonate Chromate Treatment (see Note 4)—This process comprises treatment in a 160 to 180°F (71 to 82°C) dilute solution of sodium carbonate and potassium chromate for periods from 2 to 20 min, followed by a water rinse. The surface is then given a final treatment in a 150 to 160°F (66 to 71°C), 5% potassium dichromate solution followed by a final rinse. The treatment produces a thin, adherent, conversion coating on the surface, increasing the corrosion resistance of the metal and promoting paint adhesion (Note 3).

5.8 Method 7, Amorphous Chromate Treatment (see Note 4)—This process comprises treatment of clean aluminum surfaces in aqueous chromium trioxide solutions containing suitable accelerating agents such as fluoride-containing materials. The aluminum surface is converted to an adherent, amorphous, mixed metallic oxide coating, iridescent golden to light brown in color, which increases the corrosion resistance and the adherence and durability of any applied paint film. The coating process may be carried out by immersion, spray or brush application, at 70 to 130°F (21 to 54°C), in from 15 s to 5 min contact time. It may be necessary to precede this treatment with a deoxidizer as described in Method 3 (see Note 3).

NOTE 4—Most of the treatments conforming to Chemical Treatment Methods 5, 6, and 7, comply with the requirements of the latest revision of U.S. Military Specification MIL-C-5541.

5.9 Method 8, Acid-Bound Resinous Treatment (see Note 5)—This surface treatment is based on the deposition of an acid-bound resinous film of approximately 0.3 to 0.5 mils (7.6 to 12.7 μ m) in thickness on the aluminum surface in such a manner as to enhance the adhesion of subsequently applied paint coatings. The treatment is based on three primary components: a hydroxyl-containing resin; a pigment capable of reacting with the resin and an acid; and an acid capable of insolubilizing the resin by reacting with the resin, the pigment and the metal substrate. The aluminum surface should be pretreated by Solvent Cleaning Methods 1, 2 or 3 or Chemical Treatment Methods 1 or 2 prior to the application of this treatment. The film may be applied by brush, spray, or dip. Under normal conditions it shall dry sufficiently for recoating within 30 min. The film has good adhesion to the metal substrate and promotes good adhesion of most subsequent organic coatings to itself.

NOTE 5—Materials meeting the requirements of the latest revision of U.S. Military Specification MIL-C-15328 may be used to apply to Chemical Treatment Method 8.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practices for Preparation of Magnesium Alloy Surfaces for Painting¹

This standard is issued under the fixed designation D 1732; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

These recommended practices have been approved for use by agencies of the Department of Defense and for listing in the DoD Index of Specifications and Standards.

1. Scope

1.1 These practices cover two classes of treatment for preparation of magnesium alloy surfaces for painting, as follows:

Class I—Chemical Treatments. Class II—Anodic Treatments.

In general, the latter treatments are the more protective of the two classes. Mechanical (abrasive) treatments, solvent cleaning, alkaline solution treatments, and acid pickles not resulting in protective conversion coatings are suitable preliminary treatments only for metal to be exposed under mildly corrosive (indoor) exposures. When a high degree of corrosion protection and paint adhesion are desired, as in many outdoor environments, surface preparation by one of the above conversion-coat classes is necessary.

NOTE 1—*Testing of Coatings*—Quality control tests of coatings are frequently desirable, and these generally consist of exposures, with or without paint, to salt spray, humidity, or natural environments, with suitable procedures for assessing the degree of breakdown suffered after fixed time intervals. It is recommended that quality control tests of coatings shall be made as far as possible with high-purity material (for example AZ31A alloy),² the inherent corrosion rate of which is relatively consistent from batch to batch) and that precautions shall be taken to remove surface contamination before coatings are applied. Such contamination shall be removed by acid pickling to a depth of at least 0.001 in. (25 μ m) per side.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. (See Note 11.)*

PRELIMINARY TREATMENT OF SURFACES

2. Procedure

2.1 Certain anodic treatments simultaneously produce conversion coatings on, and remove contamination from, magnesium alloy surfaces. In general, however, apply con-

version coatings only to surfaces previously freed from all contamination, including oxide, rolling-scale, corrosion product, burned-on drawing and forming lubricant, and the contamination introduced by blast cleaning and fabrication operations. Contamination in or under surface conversion coatings seriously reduces their protective values (Note 2). For the removal of tenacious surface contamination, such as rolling-scale or casting skin, an acid pickle to dissolve some of the actual surface is essential. When organic contamination, such as grease or oil, is also present, an initial degreasing operation in solvent or in an alkaline degreasing solution is usually necessary to allow the subsequent acid to wet the surface. These matters are discussed in more detail under the headings of the specific cleaners or treatments (Note 3), as follows:

2.2 *Alkaline Cleaners*—Oil, grease, and old (but not baked) chrome-pickle coatings are readily removed by most commercially available heavy-duty alkaline cleaners; but such cleaners are not suitable for removing oxide and the like, for which purpose use acid pickles, preceded by alkaline cleaners. Remove graphite lubricant and also baked chrome-pickle coatings by a solution conforming to the following composition:

Caustic soda (NaOH)	12 oz (90 g)
Wetting agent	0.1 oz (0.74 g)
Water (Note 4)	1 gal (1 litre)

Soak the parts in the above cleaner for 10 to 20 min at boiling-point, and a treatment shall follow either in the chromic acid-nitrate pickle described under 2.3.3 or, for parts machined to fine tolerances, in the chromium trioxide solution described under 2.3.1. After alkaline cleaning, rinse in water very thoroughly. Alkaline cleaners may be held in plain steel tanks.

2.3 *Acid Cleaners* (Note 1)—Acid picking removes mill-scale, oxide, corrosion product, and the like. Use as a preliminary treatment for surface conversion coatings when the highest degrees of surface uniformity and protective values are required. Acid cleaners are as follows:

2.3.1 For Sand and Permanent Mold Castings:

2.3.1.1 *Nitric-Sulfuric Acid Solution*—Use a solution of 8 volume % of concentrated nitric acid (HNO_3) plus 2 volume % of concentrated sulfuric acid (H_2SO_4) in water (see Note 1(a)) at 70 to 90°F (21 to 32°C) as a preliminary treatment for new sand castings and to remove the surface-contaminating effects of blast cleaning. Immerse for about 10 to 15 s, or until 0.002 in. (51 μ m) per surface is removed. The solution may be held in ceramic, rubber, synthetic rubber, or vinyl-lined tanks.

¹ These practices are under the jurisdiction of ASTM Committee B-8 on Metallic and Inorganic Coatings.

Current edition approved Sept. 8, 1967. Published November 1967. Originally published as D 1732-60. Last previous edition D 1732-66.

² For information concerning magnesium and aluminum alloys, see ASTM Specification B 80, B 90, B 91, B 93, B 107, and B 209 covering these alloys, in the section on Aluminum and Magnesium and Their Alloys, *Annual Book of ASTM Standards*, Vol 02.02. See also ASTM Practice B 275, for Codification of Certain Nonferrous Metals and Alloys, Cast and Wrought.

2.3.1.2 Chromic Acid Solution—Use a boiling 20 weight % solution of chromic anhydride (CrO_3) in water to remove old chemical and anodic treatments, corrosion product, and oxide layers, without significant dissolution of metal and hence without changing the dimensions of machined parts. Immersion time varies from 1 to 5 min, depending upon the condition of the surface. The solution may be held in lead-lined steel or ASTM alloy No. 990A or its Aluminum Association equivalent, alloy No. 1100 aluminum tanks.

2.3.2 For Die Castings:

2.3.2.1 Chromium Trioxide-Nitric-Hydrofluoric Acid Solution—This solution is used to produce a smut-free surface on die castings, without violent attack of the metal. The solution shall conform to the following composition:

Chromium trioxide (CrO_3)	37.5 oz (280 g)
Hydrofluoric acid (60% HF)	1 fl oz (8 ml)
Nitric acid (70% HNO_3)	3.25 fl oz (25 ml)
Water (Note 4)	to 1 gal (1 litre)

Immerse the parts in the above solution at 70 to 90°F (21 to 32°C) for 30 s to 2 min, or until a bright, clean surface is obtained. The solution may be held in tanks lined with synthetic rubber or vinyl-base materials.

2.3.3 For Wrought Products:

2.3.3.1 Acetic Acid-Nitrate Solution—This solution rapidly removes surface contamination to 0.001 in. (25.4 μm). Use for wrought parts subsequently to be finished for the maximum protective value. The solution shall conform to the following composition:

Glacial acetic acid	25.5 fl oz (199 ml)
Sodium (NaNO_3)	6.6 oz (49.5 g)
Water (Note 4)	to 1 gal (1 litre)

Immerse the parts in the above solution at 70 to 90°F (21 to 32°C) for 30 s upwards, or until a bright, clean surface is obtained. When heavy surface contamination, such as hot-rolled mill-scale is to be removed, immersion times shall be sufficient to remove at least 0.001 in. (25 μm) per surface. The solution may be held in No. 990A aluminum, ceramic, or rubber-lined tanks.

2.3.3.2 Chromium Trioxide-Nitrate Solution—Use this solution following the use of the method described in 2.2 for the removal of burned-on graphite lubricants from hot-formed parts. The solution shall conform to the following composition:

Chromium trioxide (CrO_3)	1.5 lb (180 g)
Sodium nitrate (NaNO_3)	2 oz (15 g)
Water (Note 4)	to 1 gal (1 litre)

Immerse the parts in the above solution at 70 to 90°F (21 to 32°C) for approximately 5 min, for the removal of graphite.

2.4 Abnormally slow reaction in the above solution indicates that it is depleted and that the pH has risen to 1.7 or higher. Revivify the solution by the addition of chromium trioxide to bring the pH back to 0.5 to 0.7. Attempt no more than four revivifications. The solution may be held in ceramic, No. 990A aluminum, 18-8 stainless steel, or synthetic rubber-lined tanks.

NOTE 2—Removal of Contamination by Welding Fluxes—When a part to be painted has been welded by an operation involving the use of flux, such flux shall be removed before the subsection of the part to any surface preparation process. Such removal shall be made immediately by immersing the part in hot water with scrubbing, and finally by immersing it for 1 h in a boiling 5% solution of sodium dichromate,

after which the part shall be well rinsed.

NOTE 3: Suspension of Articles for Treatment—The use of magnesium alloy suspension wires is preferred for use in acid pickles in order to avoid objectionable contamination of the solutions through dissolution of the wire materials. Heavy metal contamination, particularly of copper, may deposit on the magnesium surface and lead to seriously reduced corrosion resistance. Copper suspension wires in the hot dichromate solutions are not objectionable.

NOTE 4: Quality of Water—In the preparation and make-up of acid pickles, dichromate solutions, and hot-water rinses, precautions shall be taken against the use of water contaminated with heavy-metal impurities, or excessive chlorides or sulfates. No upper limits can be specified at this stage for soluble impurities in the water, but powdering of coatings and poor resistance to corrosion are known to result from the use of contaminated water. Thus, when a choice exists, water from steam condensate or ion-exchange-treated water shall be employed in preference to well water or hard tap water.

SURFACE PREPARATION PROCEDURES—CHEMICAL

3. Class I, Type I (Chrome Pickle)³

3.1 Scope—Class I, Type I treatment is applicable to all forms and alloys of magnesium except certain special alloys containing silver, but since it may remove as much as 0.0006 in. (15 μm) of metal per surface, it shall not be used on parts machined to fine tolerances. When properly applied, the process constitutes a good paint base, but rigid control is required at each step. The treatment is applicable to magnesium alloy containing inserts of, or attached to, other metals.

3.2 Procedure—For wrought parts the bath shall conform to the following composition:

Sodium dichromate ($\text{Na}_2\text{Cr}_2\text{O}_7 \cdot 2\text{H}_2\text{O}$)	1.5 lb (180 g)
Nitric acid (HNO_3) (sp gr 1.42)	1.5 pt (187 ml)
Water (Note 4)	to 1 gal (1 litre)

3.2.1 For die-, sand- and permanent-mold castings the solution shall conform to the following composition:

Sodium dichromate ($\text{Na}_2\text{Cr}_2\text{O}_7 \cdot 2\text{H}_2\text{O}$)	1.5 lb (180 g)
Nitric acid (HNO_3) (sp gr 1.42)	1.5 pt (187 ml)
Sodium potassium, or ammonium acid fluoride (NaHF_2 , KHF_2 , or NH_4HF_2)	2 oz (15 g)
Water (Note 4)	to 1 gal (1.0 litres)

For wrought products, sand, and permanent-mold castings the above solutions operate at 70 to 90°F (21 to 32°C). The immersion times shall be from 1 to 2 min, the necessary time increasing with use of the solution. For die-castings give the parts a 15 to 30 s dip in water at 160 to 180°F (71 to 82°C), followed immediately by a 10-s dip in the second of the above baths, operated at 120 to 140°F (49 to 60°C). Failure to preheat the castings results in no coating in 10 s.

3.2.2 Following immersion remove the parts, allow to drain for not less than 5 s nor more than 30 s, then wash thoroughly in cold running water, followed by a dip in hot water at 160 to 180°F (71 to 82°C) to facilitate drying. Do not allow the parts to drain following the chromate treatment for more than the specified 30 s; excessive drainage times result in powdery coatings of poor value as paint bases. Such coatings also result from the use of hot-water rinses, the temperatures of which are in excess of 180°F (82°C). Paint the parts preferably immediately after they are dry. The solution may be held in Type 316 stainless steel, or ceramic tanks or in steel tanks lined with synthetic rubber or

vinyl-base material. Aluminum minimum are pickle.

3.3 Revivify metal, associates that the plished by the the dichromate free nitric acid when the free 0.5 pt/gal (6 procedure) a ZK60A alloy if good paint solution or lustrous coat for the best Revivify in a

vinyl-base materials. Tanks of ASTM alloy No. 990 A, or its Aluminum Association equivalent, Alloy No. 1100 aluminum are satisfactory for the nonfluoride-containing pickle.

3.3 *Revivification of Solutions*—Sluggish reaction with the metal, associated with pale yellow, lustrous coatings, indicates that the solution is depleted. Revivification is accomplished by the addition of dichromate and nitric acid, to raise the dichromate again to 1.5 lb (180 g)/gal (1 litre) and the free nitric acid to levels indicated in the table below. Revivify when the free nitric acid content of the solution is depleted to 0.5 pt/gal (62.3 ml/litre) (see Section 11 for analytical procedure) and shall take place once only for M1 and ZK60A alloys,³ and not more than six times for other alloys if good paint-base properties are desired. Excessive use of the solution or too many revivifications result in smooth, lustrous coatings not possessing the degree of etch necessary for the best paint adhesion with conventional primers. Revivify in accordance with the following table:

Revivification Number	Adjust Concentration of HNO ₃ to:
1	1.3 pt/gal (162 ml/litre)
2	1.1 pt/gal (137 ml/litre)
3 to 6	0.9 pt/gal (113 ml/litre)

4. Class I, Type II (Sealed Chrome Pickle)⁴

4.1 *Scope*—Class I, Type II treatment is applicable to all types and forms of magnesium-base alloys, subject only to the limitations of the Class I, Type I treatment, since it is essentially the same process as the latter, followed by sealing. In protective qualities and as a paint base, this treatment is somewhat superior to that of Class I, Type I treatment under severe exposure conditions (Note 5).

4.2 *Procedure*—Following chrome pickling as specified under Section 3 and rinsing in cold water, transfer the parts immediately to a boiling solution conforming to the following composition:

Sodium dichromate (Na ₂ Cr ₂ O ₇ ·2H ₂ O)	1.5 lb (180 g)
Calcium or magnesium fluoride (CaF ₂ or MgF ₂)	½ oz (2.5 g)
Water (Note 4)	to 1 gal (1.0 litre)

Boil the parts in the above solution for 30 min, after which rinse them in cold running water, followed by a rinse in hot water at a temperature of not less than 160°F (71°C) nor more than 180°F (82°C) to facilitate drying. Preferably apply the paint coating immediately after the parts are dry. The solution may be held in a steel tank.

NOTE 5: *Causes of Defective Coatings*—The following information is intended to provide guidance on the causes of the most usual defects arising in the application of either Class I, Type I or Class I, Type II coatings:

(a) *Spotted Coatings* are caused by ineffective preliminary degreasing, or by the presence of excessive surface contamination not removed prior to or during the chrome pickling treatment, or both.

(b) *Nonadherent Powdery Coatings* are caused by:

- (1) Too long an interval between removal from the chrome pickle and rinsing,
- (2) Ratio of acid to sodium dichromate too high,
- (3) Temperature of the solution or of the hot-water rinse too high,
- (4) Metal improperly degreased, or
- (5) Solution revivified too many times.

⁴ Conforming to Class I, Type II treatments are the AMC "L" process, the Dow No. 10 process, and Type II treatment of Military Specification MIL-M-3171A.

5. Class I, Type III⁵

5.1 *Scope*—Class I, Type III treatment is applicable to all types and forms of magnesium-base alloys except M1 alloy² and certain rare-earth alloys similar to EK30A.² It produces in itself no appreciable dimensional change and is, therefore, applicable to parts machined to fine tolerances. The treatment is applicable to magnesium containing inserts of, or attached to, other metals, but in such cases the preliminary treatment (5.2) shall be in the bifuoride bath (Solution No. 2) described in 5.2.2.

NOTE 6: *Causes of Defective Coatings*—The following information is intended to provide guidance on the causes of the more usual defects arising in the application of coatings from the Class I, Type III treatment.

(a) *Nonadherent Powdery Coatings* are caused by:

- (1) Over-dilution of the hydrofluoric acid or acid fluoride solution,
- (2) Low pH (less than 4.0) of the dichromate solution,
- (3) Insufficient precleaning of the metal surface, and
- (4) Direct contact between the steel tank containing the dichromate solution and the article being treated.

(b) *Failure to Coat and Nonuniform Coatings* are caused by:

- (1) High pH of the dichromate solution,
- (2) Low concentration of the dichromate,
- (3) Insufficient precleaning of the metal surface,
- (4) Omission of fluoride treatment,
- (5) Use of an unsuitable alloy for the treatment, for instance, M1 alloy,
- (6) Excessive immersion time in the hydrofluoric acid solution or use of an H₂F₂ concentration in the dichromate solution in excess of 0.2%,
- (7) Insufficient rinsing after the hydrofluoric acid dip, and
- (8) Insufficient heating of the dichromate solution (minimum temperature should be 200°F (93°C)).

5.2 *Procedure*—Following cleaning as prescribed in Section 2, treat the parts first by immersion at 70 to 90°F (21 to 32°C) in one or other of the following solutions:

5.2.1 Solution No. 1:

Hydrofluoric acid (60% H ₂ F ₂)	24 fl oz (187 ml)
Water (Note 4)	to 1 gal (1 litre)

5.2.2 Solution No. 2:

Sodium, potassium, or ammonium acid fluoride (NaHF ₂ , KHF ₂ , or NH ₄ HF ₂)	6½ oz (50 g)
Water (Note 4)	to 1 gal (1 litre)

Solutions No. 1 and No. 2 may be held in tanks consisting of steel lined with lead or rubber. In solution No. 1, immerse AZ31A and AZ31B alloy parts³ for from 30 s to 1 min; immerse all other alloys for 5 min. In solution No. 2, immerse all the alloys for 5 min. Solution No. 2 is suitable for use with all forms of magnesium alloys except those castings which have not been acid-pickled after blasting; these castings shall be treated in the hydrofluoric acid solution (solution No. 1). Following one or other of the above treatments, the parts shall be rinsed thoroughly in cold running water and transferred to a solution conforming to the following composition:

Sodium dichromate (Na ₂ Cr ₂ O ₇ ·H ₂ O)	1 to 1.5 lb (120 to 180 g)
Calcium or magnesium fluoride (CaF ₂ or MgF ₂)	½ oz (2.5 g)
Water (Note 4)	to 1 gal (1 litre)

⁵ Conforming to Class I, Type III treatments are the AMC "G" process, the Dow No. 7 process, and the Type III treatment of Military Specification MIL-M-3171A.

Operate the above solution at boiling point and immerse the parts therein for 30 min, following which thoroughly rinse them in cold running water, followed by a hot-water dip to facilitate drying. Preferably, apply the paint coating as soon as possible thereafter. A mild steel tank is suitable for holding the above solution.

5.3 Maintenance of Solutions:

5.3.1 *Fluoride Solutions*—Keep the concentration of free hydrofluoric acid in the solutions of 5.2.1 and 5.2.2 constant by the addition, as required, of either hydrofluoric acid or acid fluoride, respectively. See Section 9 for the analytical procedure.

5.3.2 *Dichromate Solution*—Keep the pH of the dichromate solution within the limits 4.0 to 5.5, or 4.0 to 4.8 in the case of AZ31A or AZ31B alloy,² by addition of chromium trioxide as required. Maintain the level by the addition of water. Maintain the solution saturated with respect to either magnesium or calcium fluoride by continuous immersion of a cloth bag containing excess of one or other of these compounds.

SURFACE PREPARATION PROCEDURES—ANODIC

6. Class II, Type I (Galvanic Dichromate Treatment)⁶

6.1 *Scope*—This treatment produces black coatings of good protective and paint-base qualities, and is applicable to all alloys and forms of magnesium, including M1 alloy,² with or without attachments of other metals. No appreciable dimensional change results, and hence the treatment is also applicable to articles machined to fine tolerances.

6.2 *Procedure*—Following cleaning as prescribed in Section 2, treat the articles in fluoride solution No. 1 or No. 2 as prescribed in 5.2. Use the latter solution when other metals are attached to the magnesium. After rinsing, immerse the articles in a solution conforming to the following composition:

Ammonium sulfate ((NH ₄) ₂ SO ₄)	4 oz (30 g)
Sodium dichromate (Na ₂ Cr ₂ O ₇ · 2H ₂ O)	4 oz (30 g)
Ammonia (NH ₄ OH) (sp gr 0.880)	1/2 fl oz (2.6 ml)
Water (Note 4)	1 gal (1 litre)

Operate the above solution at 120 to 140°F (49 to 60°C). The articles shall be made the anodes in the solution, with the tank, if of mild steel, acting as cathode, or with separate steel cathodes if the tank is lined with nonmetallic materials. No separate generator is necessary, but the magnesium parts must be electrically connected with the tank, or with the separate cathode plates through an external connection, taking care that the parts do not make direct contact with the cathode material.

6.2.1 The time of treatment shall be such that a uniform black coating is obtained on the articles. This takes from 10 to 30 min, and the consumption of from 70 to 150 A·min/ft² (929 cm²). An anodic current density of not more than 10 A/ft² (929 cm²) is desirable.

6.2.2 Following the treatment, rinse the parts thoroughly in cold running water, followed by a hot-water dip to facilitate drying.

⁶ Conforming to Class II, Type I treatment are the AMC "K" process, the Dow No. 9 process, and Type IV treatment of Military Specification MIL-M-3171A.

6.3 Maintenance of Solutions:

6.3.1 *Fluoride Solutions*—Maintain the fluoride solutions as under 5.3.1. See Section 9 for the analytical procedure.

6.3.2 *Sulfate-Dichromate Solution*—Maintain the pH of this solution between 5.6 and 6.2 by periodic additions of a solution containing 5 weight % of both chromic anhydride (CrO₃) and concentrated sulfuric acid (H₂SO₄, sp gr 1.84).

7. Class II, Type II⁷

7.1 *Scope*—This treatment is applicable to all forms and alloys of magnesium. Many aluminum alloys will anodically polarize in the treatment solution, and hence magnesium parts with aluminum attachments or inserts can be anodized. With aluminum alloys containing copper, however, the coating of the magnesium will proceed only if the area of the aluminum alloy is small compared to that of the magnesium. Metals other than aluminum or its base alloys shall not be in contact with the magnesium.

7.2 *Coating Properties*—The anodic coating consists of two phases: the first-formed phase is greenish-tan in color and about 0.0002 in. (5 μm) thick; whereas the second phase, formed only at higher voltages following the production of the tan coating, is fused and vitreous in nature, dark-green in color, and of thickness about 0.0012 in. (30 μm), causing a dimensional increase of about 0.001 in. (25 μm) per surface. The corrosion-resistance and paint-base characteristics are similar, and excellent for both the above phases. The coating possesses high abrasion resistance, but spalls under compression deformation. The dark-green coating can be partially impregnated with low-viscosity, penetrating, organic coating materials, a procedure that considerably reduces its spalling tendency.

NOTE 7—The dark-green coating of Class II, Type II treatments is recommended in preference to the thin tan coating only when:

- (a) Preliminary removal of surface contamination is not convenient.
- (b) The highest degree of abrasion-resistance is required from the coating.
- (c) A dimensional increase (see above) can be tolerated.
- (d) The article will not be subjected in service to impact, deformation, or flexing likely to cause spalling of the coating.

7.3 *Procedure*—The thin tan coating is formed with a current consumption and in a time approximately one quarter of that required to form the dark-green coating. The latter forms only after the voltage across the solution has reached the spark potential. During the ensuing coating formation, surface contamination, including graphite, is concurrently removed. Thus, articles intended to receive the dark-green coating need not first be cleaned. On the other hand, the formation of the thinner tan coating does not concurrently remove surface contamination. Since such contamination can seriously reduce corrosion resistance, it is mandatory that a preliminary cleaning, including acid pickling (2.2) shall be given to articles intended to receive the lower-voltage tan coating.

7.3.1 Rack and clean parts as appropriate (see above), and anodize either by direct or alternating current in an electrolyte conforming to one of the following compositions, respectively:

⁷ Conforming to Class II, Type II treatment is the Dow No. 17 process.

	Direct Current	Alternating Current
Ammonium acid fluoride (NH_4HF_2)	32 oz (240 g)	40 oz (300 g)
Sodium dichromate ($\text{Na}_2\text{Cr}_2\text{O}_7 \cdot 2\text{H}_2\text{O}$)	13.3 oz (99 g)	13.3 oz (99 g)
Phosphoric acid (85% H_3PO_4)	11.5 fl oz (90 ml) to 1 gal (1 litre)	11.5 fl oz (90 ml) to 1 gal (1 litre)
Water (Note 4)		

The temperature of the solution shall preferably be from 160°F to 180°F (71 to 82°C). It will not operate below 140°F (60°C), but temperatures higher than 180°F (82°C) do not deleteriously affect the results. After anodizing rinse the parts in running cold water, followed by a short immersion in hot water, or by treatment with hot air, to facilitate drying. Preferably, apply the paint coating immediately after the parts are dry.

7.4 Power Requirements—A current consumption of from 50 to 500 A·min/ft² (929 cm²) is necessary, according to both the composition of the alloy being treated and the type of coating desired. Thus, in the case of the dark-green coating on AZ31 alloy, for a 10-min treatment with alternating current, a current density of 30 A/ft² (929 cm²) is applied; but greater or lesser currents may be utilized by varying the time of treatment as, for example, application of 50 A/ft² (929 cm²) for 6 min. On the other hand, for the same alloy, the thin tan coating may be applied with alternating current, with a current consumption of 75 A·min/ft² (929 cm²), equivalent to a treatment time of only 1½ min at 50 A/ft² (929 cm²). As the coating forms, the resistance of the circuit increases, and consequently the voltage must be increased to maintain a constant current density. Normally the voltage across the bath will reach from 75 to 95 for the dark-green coating (according to alloy composition) and from 60 to 75 for the thin tan coating. In carrying out the treatment, a constant current control is a considerable advantage, inasmuch as the total treatment time can be preset and manual control of the voltage and current then become unnecessary.

7.4.1 As guides to the current consumptions with various alloys, some data are presented in Table 1. It will be appreciated that rigid current consumptions in the formation of the thin tan coating cannot be specified, since this coating can be varied in thickness considerably between say 0.0001 in. (2.5 µm) and 0.0005 in. (12.7 µm), and still be formed below the critical spark potential at which the dark-green vitreous coating begins to develop.

7.5 Solution Control—With depletion of the bath upon use, the final voltage required to impress the above currents on the article will slowly rise, but even for the full green coating at least 20 ft² (50 dm²) of surface can be treated per

gallon (1.0 litre) of solution before any change in the final voltage is experienced; and up to 40 ft² (98 dm²)/gal (1 litre) can be treated before revivification of the solution becomes necessary.

7.5.1 Prior to revivification, analyze for dichromate and phosphoric acid (see Sections 10 and 12), and make up differences from the original composition by additions of sodium dichromate and phosphoric acid.

7.5.2 A simple method for the determination of fluoride in the solution is not yet available. The fluoride concentration, is not critical, provided it always exceeds minimum concentration, below which pitting of the articles may ensue during their treatment. When revivifications are made by additions of sodium dichromate and phosphoric acid, make a concurrent addition of ammonium acid fluoride, equal to three times the weight of sodium dichromate added. Secondly, if pitting of the articles should occur under treatment, it is an indication that the fluoride content of the solution is too low, and about 5 oz (38 g)/gal (1 litre) of ammonium acid fluoride shall then be added in order to relieve the trouble.

7.6 Tank and Rack Materials—Mild steel is suitable for tanks and heating coils. Other metals, such as copper, aluminum, lead, zinc, Monel, and stainless steels are attacked by the electrolyte. When direct current is used the tank itself can be the cathode, but, when alternating current is used, at least two magnesium parts are necessary, of area ratios not more than 3 to 1, each one serving as electrode. The articles shall not contact the tank, otherwise pitting will ensue.

7.6.1 Racks shall be normally made of magnesium alloy, but aluminum alloys containing magnesium, such as ASTM alloy No. GR20A, or its Aluminum Association equivalent, alloy No. 5052, can be used if desired, provided they are not allowed to be in the solution on open circuit. Use a spring clip with magnesium ends for providing contact with thin sheet material, the liquid level not being allowed to extend beyond the limit of the magnesium ends of the clip. No solution-line attack is experienced on magnesium. Magnesium racks may be stripped by immersion for 2 min in hot 20% chromium trioxide solution or by immersion at room temperature for about 8 min in the chromium trioxide-nitrate solution bath described in Section 2.2.3.

8. Class II, Type III^a

8.1 Scope—This treatment is applicable to all forms and alloys of magnesium, free from attachments or inserts of other metals.

8.2 Coating Properties—The anodic coating consists of two phases: The first-formed subcoating phase is a light tan in color, and causes a dimensional increase of about 0.0002 in. (5 µm) per side; the second and thicker phase, formed at higher voltages, is dark brown and causes a dimensional increase of from 0.001 in. to 0.0012 in. (25 µm to 30 µm) per surface. The paint-base characteristics are similar, and excellent for both the above phases.

8.2.1 The dark-brown coating is hard and highly abrasion-resistant, but it spalls under compression deformation and its

TABLE 1 Current Consumption with Various Alloys

Alloy	Alternating Current				Direct Current			
	Voltage		A·min/ft ² (929 cm ²)		Voltage		A·min/ft ² (929 cm ²)

^a Conforming to Class II, Type III treatment is the HAE process.

formation can cause a loss of fatigue strength of the metal. Such loss is negligible with metal of thickness 0.1 in. (2.5 mm) or over, rising to 3% and 9% for thicknesses of 0.094 in. (2.4 mm) and 0.040 in. (1 mm), respectively, all under reversed bending and corrected for coating thickness. No loss of fatigue strength arises from application of the thin tan coating, and neither is this coating subject to spalling.

8.3 Procedure—Rack and clean with hot alkaline cleaner (2.1) or chromium trioxide (2.2.1), or both, as appropriate, and anodize with alternating current in an electrolyte conforming to the following composition:

Potassium hydroxide (KOH)	18 to 20 oz (135 to 150 g)
Aluminum hydroxide (Al(OH) ₃) soluble in hot KOH solution (Note 8)	4 oz (30 g)
Potassium fluoride (K ₂ F ₂)	4.5 oz (34 g)
Trisodium phosphate (Na ₃ PO ₄)	4.5 oz (34 g)
Potassium manganate (K ₂ MnO ₄) (Note 9)	2.5 oz (19 g)
Water (Note 4)	to 1 gal (1 litre)

Dissolve the constituents of the electrolyte in the above order. Maintain the temperature of the electrolyte between 77 and 100°F (25 to 38°C).

NOTE 8—If an exceptionally hard, abrasion-resistant dark-brown coating is desired, the aluminum hydroxide in the above electrolyte shall be increased to 6 to 7 oz (45 to 52 g)/gal (1 litre).

NOTE 9—Potassium manganate (K₂MnO₄) in the above electrolyte may be replaced with an equal weight of potassium permanganate (KMnO₄), but in such case the permanganate shall be completely dissolved in water before it is added to the solution and an additional 1½ oz (11 g) of potassium hydroxide shall also be added. During operation of the bath, the permanganate is slowly reduced to manganate, complete conversion taking place after a metal area of approximately 2 ft² (18.6 dm²)/gal (1 litre) of electrolyte has been treated.

8.4 Post-Treatment—After the electrolytic treatment, rinse the parts well in water and immerse for 1 min at room temperature in a solution consisting of 2.7 oz (20 g) of sodium dichromate (Na₂Cr₂O₇·2H₂O) and 13.3 oz (99 g) of ammonium bifluoride (NH₄HF₂)/gal (1 litre) of solution. Following the immersion, remove the parts and dry without rinsing. Paint at any convenient time after the parts have dried.

8.5 Power Requirements—The practical range from current density is from 15 to 20 A/ft² (9.3 dm²) with voltages rising to from 70 to 86 (depending on alloy) for the hard brown coating and to 58 V for the thin tan coating. In this current density range, the terminating voltage is reached in from 45 to 60 min for the hard brown coating and in 10 min or less for the thin tan coating. Raise the voltage quickly from zero to 40 or more, and adjust the current and retain at the density desired. Normally the voltage will rise to 55 or more within 1 min, but as the coating forms, the resistance of the circuit increases and the voltage must be raised continuously to maintain the desired current density.

NOTE 10—If, at low initial voltages, the current remains high and coating formation does not proceed, a "surge" current shall be imposed by rapidly raising the voltage to 40, followed by immediately lowering it to zero. The voltage shall then be adjusted in the normal manner to maintain the desired current density.

8.6 Solution Control—The operating life of the electrolyte is extremely long, and under normal conditions of use it need never be discarded. Manganate and aluminate deplete slowly with use, whereas the depletion of fluoride and phosphate is extremely slow.

8.6.1 In the case of the dark-brown coating, a lightening of the normal color indicates a depletion of manganate in the solution, and additions shall then be made of 1 oz (7.5 g) of potassium manganate plus 1½ oz (11 g) of aluminum hydroxide for each gal (1 litre) of solution. Add the aluminum hydroxide after first dissolving it in a solution containing a weight of potassium hydroxide equal to that of the aluminum hydroxide to be added.

8.6.2 A rough coating indicates either a low, or an excessively-high, alkalinity in the electrolyte. The alkalinity shall be maintained between 10 and 12% free KOH, as determined by the method described in Section 13.

8.7 Tank and Rack Materials—Plain black iron is suitable for tanks and cooling coils. Suspend the parts by magnesium-base alloy clips or the like and protect them at the solution level by electroplaters' vinyl tape. Magnesium racks may be stripped of coating when necessary by immersion in hot 20% chromium trioxide solution (Note 11).

8.7.1 Divide parts to be treated into two batches each of approximately the same surface area. Rack each of the batches and connect electrically to one or other of the inlet terminals of the power supply so that the magnesium parts constitute both electrodes of the electrolysis bath (Note 12).

NOTE 11: Safety Precautions—Consideration should be given to the health hazards associated with the procedures covered by this specification. Precautions must be taken to avoid skin contact with any of the solutions involved, and to avoid inhalation of vapors, fumes, or spray arising therefrom. Baths containing dichromate or fluoride shall be fitted with exhausts to remove all spray arising therefrom.

NOTE 12: Repair Treatments—Pretreatment films that have been damaged shall be repaired before painting. Repair shall be effected by one of the treatments below. The phosphate touch-up solution of 8.2 below necessitates special preparation, whereas a chrome pickle solution is often already available. Nevertheless, for brush-on treatment, the phosphate solution possesses the advantages of being nontoxic and nonirritant.

(a) **Chrome Pickle Repair Treatment**—The chrome pickle solution for Class I, Type I treatments (for wrought parts) shall be copiously and continuously applied to the damaged area by brush for at least 1 min. The treated surface shall then be thoroughly flushed with water and, when dry, rubbed vigorously with a clean dry rag to remove loose powdery matter which, if allowed to remain, would deleteriously affect the adhesion of superimposed paint.

(b) **Phosphate Repair Treatment**—A solution shall be used conforming to the following composition:

Monoammonium phosphate (NH ₄ H ₂ PO ₄)	16 oz (84 g)
Ammonium sulfite ((NH ₄) ₂ SO ₃ ·H ₂ O)	4 oz (30 g)
Ethylene glycol monobutyl ether	13 to 20 fl oz (101 to 156 ml)
Water (see Note 4)	1 gal (1 litre)

The above solution shall be applied copiously to the damaged area by brush in sufficient quantity to keep the surface wet for at least 1 min, or until a medium to dark-gray continuous coating is formed. The treated metal surface shall then be well flushed with water and allowed to dry before the paint is applied.

ANALYTICAL PROCEDURES

9. Fluoride Solutions

9.1 This method is applicable to the relevant baths of Class I, Type III (Section 5) and Class II, Type I (Section 6) treatments. The concentrations of both hydrofluoric acid (HF) and bifluoride shall be determined by titration with 1 N sodium hydroxide (NaOH) with 1 N sodium hydroxide (NaOH) solution, using phenolphthalein as indicator.

9.2 Maintain the hydrofluoric acid solution described in 5.2 by additions of fresh acid to give a titration of between 10 and 20 ml of 1 N NaOH solution per 2 ml of sample. Maintain the bifluoride solution described in 5.2 so that 10 ml thereof gives a titration of 4.5 to 5.5 ml of 1 N NaOH solution.

9.3 For the hydrofluoric acid the sample shall be drawn into a wax-lined pipet, discharged therefrom into at least 100 ml of distilled water, and titrated immediately. A rubber bulb, or a length of rubber tubing fitted to the suction end of the pipet, shall be used in drawing the sample into the pipet.

10. Dichromate Solutions

10.1 This method is applicable to solutions of the following treatments: Class I, Types I, II, and III; and Class II, Types I and II (Sections 3, 4, and 5; and Sections 6 and 7, respectively).

10.2 Add 1 ml of the dichromate solution concerned to 150 ml of distilled water, and mix therewith 5 ml of concentrated hydrochloric acid (HCl, sp gr 1.19) and 5 g of potassium iodide (KI). After at least 2 min, titrate the liberated iodine in the solution with 0.1 N sodium thiosulfate ($\text{Na}_2\text{S}_2\text{O}_3$) solution using starch as an internal indicator.

10.3 Calculation:

$$A \times 0.0415 = B$$

$$A \times 4.96 = C$$

where:

A = millilitres of 0.1 N $\text{Na}_2\text{S}_2\text{O}_3$ solution,
B = pounds per gallon of sodium dichromate ($\text{Na}_2\text{Cr}_2\text{O}_7 \cdot 2\text{H}_2\text{O}$), and
C = grams per litre of sodium dichromate.

11. Nitric Acid Solution

11.1 This method is applicable to Class I, Types I and II treatment solutions.

11.2 Mix 50 ml of distilled water with 1 ml of the solution in question, and titrate the mixture with 0.1 N sodium hydroxide (NaOH) solution to a pH of 4.0 to 4.05, using a pH meter with a glass electrode.

11.3 Calculation:

$$A \times 0.0505 = B$$

$$A \times 6.34 = C$$

where:

A = millilitres of 0.1 N NaOH solution, and
B = pints per gallon of nitric acid (HNO_3),
C = millilitres of 70% nitric acid per litre.

12. Phosphoric Acid Solution

12.1 This method is applicable to the Class II, Type II treatment solution. The phosphoric acid is precipitated as ammonium phosphomolybdate, which is dissolved in an

excess of sodium hydroxide, such excess being titrated with standard acid. Interference from fluoride is prevented by converting it to fluoborate, by addition of boric acid.

12.2 *Molybdate Reagent*—Prepare as follows: mix 118 g of 85% molybdic acid (H_2MoO_4) with 400 ml of distilled water, add 80 ml of ammonium hydroxide (NH_4OH) solution (sp gr 0.880) with stirring, and filter when solution is complete. Slowly pour the filtrate, with stirring, into a cold mixture of 400 ml of concentrated nitric acid (HNO_3 , sp gr 1.42) and 600 ml of water. Allow the solution to stand over night, and filter.

12.3 *Procedure*—Dilute a 14-ml weighed sample of the solution under examination to 500 ml, and then further dilute 50 ml of this diluted solution to 500 ml. Then again dilute 25 ml of the latter solution to 100 ml, and add 10 g of ammonium nitrate (NH_4NO_3), 1 g of boric acid (H_3BO_3), and 15 ml of concentrated nitric acid (HNO_3 , sp gr 1.42). Heat the mixture to 104°F (40°C) and slowly add 40 ml of molybdate reagent. Allow the resulting precipitate of ammonium phosphomolybdate to stand for 30 min, and then filter through a fine-texture, low-ash paper. Wash the precipitate free from acid by means of a 1% solution of potassium nitrate (KNO_3), and mix, together with the filter paper, with an excess of 0.1 N sodium hydroxide (NaOH) solution, using phenolphthalein as indicator. Titrate the excess of NaOH with 0.1 N hydrochloric acid (HCl).

12.4 Calculation:

$$\text{Phosphoric acid } (\text{H}_3\text{PO}_4), \% = [(A - B)/C] \times 0.426$$

where:

A = millilitres of 0.1 N NaOH solution,
B = millilitres of 0.1 N HCl, and
C = grams of sample in aliquot.

13. Free Alkali

13.1 This method is applicable to the Class II, Type III solution. Manganate, fluoride, and phosphate are precipitated by barium nitrate addition, and the filtrate therefrom is titrated with standard acid.

13.2 Pipet a 2-ml sample of the solution under examination into a 25-ml glass-stoppered graduated cylinder, followed by addition of 10 ml of 0.25 N sodium hydroxide (NaOH) solution and 0.5 g of barium nitrate ($\text{Ba}(\text{NO}_3)_2$) crystals. Shake this mixture vigorously for 1 min, filter through a medium-texture, low-ash paper, and wash the precipitate free from alkali, preserving all filtrate. Using a pH meter with a glass electrode, titrate the free alkali in this filtrate to pH 10.5, with 0.25 N hydrochloric acid (HCl).

13.3 Calculation:

$$\text{Potassium hydroxide}, \% = 2.805 \times [(A/4) - 2.5]$$

where:

A = millilitres of acid used.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend, if you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Method of Making and Preparing Concrete and Masonry Panels for Testing Paint Finishes¹

This standard is issued under the fixed designation D 1734; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This method has been approved for use by agencies of the Department of Defense and for listing in the DoD Index of Specifications and Standards.

^{e1} Note—Editorial changes were made in Sections 2.1 and 5.3 on October 1980.

1. Scope

1.1 This method describes the procedures and materials required in making concrete and masonry panels for use in testing paint finishes designed for either portland cement concrete or stucco surfaces.

2. Apparatus

2.1 *White Asbestos Cement Shingles*, 12 by 24 in. (305 by 610 mm) in size, or asbestos cement sheet, $\frac{1}{8}$ in. (3.12 mm) thick, of the required size.

2.2 *Forms*, wooden or rustproof metal, to make panels of the required size.

2.3 *Container*, of wood, stainless steel, or other rustproof metal of sufficient size to mix the mortars.

2.4 *Notched or Serrated Applicator*, similar to those used in applying cement for tile or linoleum flooring.

2.5 *Miscellaneous Equipment*—Wooden or cork trowel, wooden screed, steel trowel and 3-in. (76-mm) wide stiff-bristle paint brush.

NOTE 1—Wooden trowels, screeds or containers may be made of seasoned oak which may be rendered nonabsorptive by immersion for 15 min in paraffin at 220 C (392 F) in accordance with ASTM Method C 227, Test for Potential Alkali Reactivity of Cement-Aggregate Combinations (Mortar Bar Method).²

3. Materials

3.1 *Portland Cement*, conforming to the requirements of Type I of ASTM Specification C 150, for Portland Cement.²

3.2 *Masonry Cement*, conforming to the requirements of Type II of ASTM Specification C 91, for Masonry Cement.²

3.3 *Natural Sand*, conforming to the requirements of ASTM Specification C 144, for Aggregate for Masonry Mortar,³ modified as follows:

3.3.1 The standard sand may provide too coarse a texture on portland cement concrete panels. If smoother texture is desired, the requirement of the specification that not more than 35 % shall pass the No. 50 (300- μ m) sieve should be waived, and the sand should be required to contain from 50

to 60 % passing the No. 50 sieve, and from 5 to 20 % passing the No. 100 (150- μ m) sieve, with the other provisions of grading remaining unchanged.

3.3.2 The standard sand will provide aggregate too large for a satisfactory masonry cement (stucco) mortar mixture. Satisfactory sand may be obtained by requiring that 100 % pass the No. 16 (1.18-mm) sieve, from 45 to 80 % pass the No. 30 (600- μ m) sieve, from 65 to 75 % pass the No. 50 sieve, and from 10 to 30 % pass the No. 100 sieve.

3.4 *Water*, of sufficient purity as to be potable.

3.5 *Resin Emulsion*.⁴

4. Size of Test Panels

4.1 For use on outdoor testing racks, the panels shall be 8 by 12 by $\frac{3}{8}$ in. (203 by 305 by 9.5 mm) in size.

4.2 For machine exposure tests, the panels shall be of a size to fit the apparatus to be used for such tests. The panels shall be $\frac{1}{8}$ in. (9.5 mm) in thickness and should have a surface area of not less than 18 in.² (116 cm²).

5. Application of Bond Coat

5.1 Prepare forms of correct size for panels to be made and place upon a wooden platen or table. The forms should be oiled or waxed before use.

5.2 For ease in removing the finished test panel, make the forms easily demountable, or equip the table upon which panels are made with several plungers, operated by foot pressure, which may be used to force the completed panel up and out of forms easily.

5.3 Cut the asbestos-cement shingles or the asbestos-cement sheet in rectangles $\frac{1}{32}$ in. (0.8 mm) under the required panel size to provide a slip fit within the forms. (Caution—Use vacuum dust collector for removal of asbestos-cement particles during cutting.)

5.4 For each square foot of panel to be made, make up a bond coat consisting of 60 g of sand, 20 g of cement, 8 g of water, and 20 g of emulsion.

5.5 In the mixing box, thoroughly mix the sand and cement (dry), then add the water. After thoroughly mixing, add the emulsion and mix until homogeneous.

¹ This method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials.

NOTE 2—I mix may be weight of wat

6.2 Place side up, wit on top of mixture int top with a trowel to le Finally, bru

NOTE 3—I may be wette water-cement and sloppy m

5.6 Wet the smooth or back side of the shingle, or the surface of the sheet to which the bond coat will be applied, about 5 min before applying the bond coat.

5.7 Distribute the required amount of bond coat upon the previously wetted shingle or asbestos cement sheet, using either a brush, or a notched applicator or scraper, having notches approximately $\frac{1}{8}$ in. (3.2 mm) deep.

5.8 Clean the edges of the panel immediately after coating, so that the panel will fit in forms when ready to apply the concrete or masonry mix.

5.9 Allow the bond-coated panel to stand overnight (minimum).

6. Preparation of Concrete Panels

6.1 In the mixing box, prepare the concrete, from 1 part of portland cement and 3 parts of sand by volume. Thoroughly mix these dry ingredients. Add water and mix thoroughly. Use only enough water to make the mortar sufficiently plastic as to be easily worked into the corners of the form.

NOTE 2—Using dry ingredients, a good portland cement concrete mix may be obtained by using sufficient water to give a ratio between weight of water and weight of cement of approximately 0.6 (± 0.1) to 1.0.

6.2 Place the previously coated shingle or sheet, coated-side up, within the forms. Place the wet concrete in the forms on top of the coated base with the steel trowel, work the mixture into the corners and next to the form. Strike off the top with a wooden screed and use a wooden or cork float or trowel to level off the surface and work to the desired texture. Finally, brush the surface evenly with the dry paint brush.

NOTE 3—If deemed desirable, the surface of the bond-coated base may be wetted prior to placing the concrete mix. If this is done, the water-cement ratio should be reduced to compensate, otherwise a wet and sloppy mix may result.

6.3 During the first hour of the setting period, gas may form between the bond coat and the concrete coat, causing bubbles to form upon the surface of the panel. These should be broken carefully or punctured by a slender, sharp instrument to permit the gas to escape. Any holes thus made may be smoothed over, or filled up, about an hour later.

6.4 After the concrete has set up sufficiently to permit removal of the forms from the panel, or the panel from the forms, smooth the edges to desired texture, and cover with a wet cloth.

6.5 Keep the panel covered with the wet cloth until seasoned to desired age, wetting the cloth thoroughly twice daily. To provide freedom from crazing or cracking, a minimum seasoning period of seven days is recommended.

6.6 Before using, bevel off top exposed edges with a carborundum stone, sufficiently to prevent edge-breakage in use.

7. Preparation of Masonry Panels

7.1 In the mixing box, prepare the masonry or stucco mix from 1 part of portland cement, $1\frac{1}{2}$ parts of masonry cement, and 3 parts of sand, by volume. Thoroughly mix these dry ingredients. Add water and mix thoroughly. Use only enough water to make the mortar sufficiently plastic as to be easily worked into the corners of the form.

NOTE 4—The addition of masonry cement to the stucco mix makes a more workable mix than using only portland cement, and the water-cement ratio may be reduced to 0.5 (± 0.1) to 1.0.

7.2 Proceed as described in Section 6.2 to 6.6.

8. Identification

8.1 Identify the back of each panel (shingle or asbestos cement sheet side) as to type of mix (concrete or masonry) and data of manufacture.

NOTE 5—For optimum reproducibility, panels used in the same test should be of the same age, cure and seasoning.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Testing Water Resistance of Coatings Using Water Fog Apparatus¹

This standard is issued under the fixed designation D 1735; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers the basic principles and operating procedures for testing water resistance of coatings in an apparatus similar to that used for salt spray testing.

1.2 This practice is limited to the methods of obtaining, measuring, and controlling the conditions and procedures of water fog tests. It does not specify specimen preparation, specific test conditions, or evaluation of results.

NOTE 1—Alternative practices for testing the water resistance of coatings include Practices D 870, D 2247, and D 4585.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

D 4585 Practice for Testing Water Resistance of Coatings Using Controlled Condensation³

3. Summary of Practice

3.1 Coated specimens are placed in an enclosed chamber where a water fog is sprayed on them. The temperature of the chamber is usually maintained at 100°F (38°C). The exposure condition is varied by selecting the duration of the test. Water permeates the coating at rates that are dependent upon the characteristics of the coating. Any effects such as color change, blisters, loss of adhesion, softening, or embrittlement are observed and reported.

4. Significance and Use

4.1 Water can cause the degradation of coatings, so knowledge of how a coating resists water is helpful in predicting its service life. Failure in water fog tests may be caused by a number of factors including a deficiency in the coating itself, contamination of the substrate, or inadequate surface preparation. The test is therefore useful for evaluating coatings alone or complete coating systems.

4.2 Water fog tests are used for research and development of coatings and substrate treatments, specification acceptance, and quality control in manufacturing. These tests usually result in a pass or fail determination but the degree of failure may also be measured. A coating system is considered to pass if there is no evidence of water-related failure after a specified period of time.

4.3 Results obtained from the use of water fog tests in accordance with this practice should not be represented as being equivalent to a period of exposure to water in the natural environment, until the degree of quantitative correlation has been established for the coating or coating system.

4.4 The test apparatus is identical to that used in Method B 117, and the conversion of the apparatus to water fog testing is not difficult. Corrosion tests of a scribed coating on a ferrous substrate are possible as the water that drips off of the specimens is not recirculated.

5. Apparatus

5.1 *Test Chamber, Test Specimen Supports, and Fog Collecting Devices*, as specified in Method B 117.

6. Test Specimens

6.1 This practice does not cover the preparation of test specimens. The substrate composition and surface preparation, specimen preparation, and the number of specimens

should be agreed upon.

NOTE 2—All substrates are Methods D 82 uniform films.

7. Procedure

7.1 Fill the Type III of S

7.2 Maintain 2°F (38 ± temperature

7.3 Support from the vertical the direction for flat specimens. In other, any acting as a one specimen

7.4 Place fog for measurement nozzle with place them: Glass funnels or dish mended.

7.5 Adjust of water/h i mm.

NOTE 3—T mL/h for a cc

7.6 Oper closed until

should be agreed upon prior to testing.

NOTE 2—Applicable methods for the preparation of test panels and substrates are given in Methods D 609 and Practices D 1730. Test Methods D 823 cover application techniques of the production of uniform films.

1. Procedure

7.1 Fill the reservoir with reagent water conforming to Type III of Specification D 1193.

7.2 Maintain the test chamber at a temperature of $100 \pm 2^\circ\text{F}$ ($38 \pm 1^\circ\text{C}$). Other temperatures may be used if the temperature is reported in Section 8.

7.3 Support or suspend specimens approximately 15° from the vertical with the plane of the specimen parallel to the direction of fog flow. Slotted wood supports are suitable for flat specimens. Provide for free settling of fog on all specimens. Space specimens so that they do not touch each other, any metallic material, or any material capable of acting as a wick. Arrange the specimens so that water from one specimen does not drip on other specimens.

7.4 Place two containers within the chamber to collect the fog for measurement. Locate one container near the fog nozzle with the other as far as possible from the nozzle and place them so that they collect only the fog from the nozzle. Glass funnels with the stem extending into graduated cylinders or dishes having a diameter of 100 mm are recommended.

7.5 Adjust the atomizing air supply so that 1.5 to 3.0 mL of water/h is collected in a collector with a diameter of 100 mm.

NOTE 3—The fog rate specified in Method B 117 is only 1.0 to 2.0 mL/h for a collector with a diameter of 100 mm.

7.6 Operate the test continuously with the test chamber closed unless otherwise specified. Short interruptions to

inspect or remove specimens or to replenish the water supply are permitted.

7.7 Conclude the test after a specified period of time or after effects from exposure to water fog are observed.

7.8 Wipe the test specimens dry. Rate specimens for changes in color, blistering, etc. Evaluate specimens no less than 5 min and no more than 10 min after removal from test, as the effects from water exposure can change within a short time. Remove only as many specimens as can be rated within the specified time.

NOTE 4—The 0 to 10 scale described in the ASTM STP 500⁷ is preferred for rating. Relevant procedures for evaluating water effects are described in Test Methods D 610, D 714, D 2616, D 3359, and D 3363.

7.8.1 If possible, rate the specimens again after they have been removed from the test for a recovery period long enough that moisture absorbed within the specimens dries out and the specimens reach moisture equilibrium with room air. A recovery period of 12 from 24 h is generally sufficient. The post-recovery rating allows evaluation of the permanent effects of the exposure as distinct from the transient effects, and is especially important for evaluation of color and gloss.

8. Report

8.1 Report the following information:

8.1.1 Sample identification.

8.1.2 Results of the evaluation(s).

8.1.3 Reference to Practice D 1735.

8.1.4 Hours of test duration.

8.1.5 Test temperature.

8.1.6 Rate of fog collection and pH of water collected.

8.1.7 Special conditions of test or any deviations in test procedure.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Efflorescence of Interior Wall Paints¹

This standard is issued under the fixed designation D 1736; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the tendency of an interior wall paint to effloresce under normal environmental conditions. Historically this phenomenon has been exhibited primarily with latex, or other water-based paints, and the method has been used in testing aqueous products.

1.2 This test method is limited to the determination of the efflorescence resulting from migration of soluble salts from within the paint film. It does not deal with the efflorescence attributable to certain substrates.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

- 2.1 *ASTM Standard:*
D 1193 Specification for Reagent Water²

3. Terminology

3.1 Descriptions of Terms Specific to This Standard:

3.1.1 *efflorescence*—a condition that occurs when soluble salts in the dried paint film or in the substrate migrate to the film surface during exposure. It should not be confused with other causes of nonuniform appearance or whitening that may occur at the time of application. Efflorescence is seen as either a light, medium, or heavy deposits of crystals. It exists both in isolated patches and over wide areas. Another evidence of efflorescence is the development of a non-uniform appearance of flat or glossy areas during the cycling procedure of the test.

3.1.2 degrees of efflorescence:

3.1.2.1 *flattening and glossing*—A nonuniform decrease or increase in gloss noticeable when the surface is illuminated and viewed at near grazing angles. There is no apparent change in color when viewed perpendicularly to the surface.

3.1.2.2 *fine efflorescence*—A barely discernible whitening of the surface when viewed perpendicularly.

3.1.2.3 *medium efflorescence*—A readily noticeable whitening of the surface without a marked masking of the color.

3.1.2.4 *heavy efflorescence*—A white deposit sufficient to mask the color.

4. Summary of Test Method

4.1 Painted panels are exposed to controlled cycles of low temperature and high humidity, and to standard conditions of temperature and humidity, inducing a fine condensate on the surface. The test is run for a maximum of eight cycles.

5. Significance and Use

5.1 The test conditions are similar to conditions that produce efflorescence inside a home or building. The degree of efflorescence and the number of cycles required to produce it are a good indication of the paint's ability to resist efflorescence.

6. Apparatus

6.1 *Test Cabinet*—A cold-wall type of household refrigerator without exposed cooling coils. Additional humidity shall be introduced into the test area from a pan of water on the chamber floor, or by putting water in the butter conditioner and setting the conditioner at its highest temperature. Conditions in the test cabinet shall be maintained at $42 \pm 3^\circ\text{F}$ ($5.5 \pm 1.5^\circ\text{C}$) and at 75 to 80 % relative humidity. Any other type of cabinet used should be checked for reproducibility of test results by comparison with a recommended cabinet.

7. Reagents

7.1 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water as defined by Type IV of Specification D 1193.

8. Test Panels

8.1 A sealed substrate shall be used. One satisfactory surface is tempered hardboard sealed with one coat of shellac varnish (3 to 4-lb cut). The panel size shall be 6 by 18 in. (150 by 450 mm). If the panel does not fit the cabinet, the size may be changed, although the area should be kept approximately the same.

9. Preparation of Panels

9.1 Apply the shellac varnish to the test panel and allow to dry. Brush two coats of the test paint on both sides of the sealed panel. Apply the test paint at a temperature above 60°F (15.5°C) and allow approximately 1 h between coats or, if not a latex paint, allow an appropriate time for drying between coats. After applying the second coat, dry the panel for 1 h (or appropriate time) at the same temperature and observe for uniformity of appearance at all angles of viewing before placing in the test cabinet. If the panels are

nonuniform in panels. If the erred unaccept

² *Annual Book of ASTM Standards*, Vols 06.03 and 11.01.

nonuniform in gloss or color, reject them and prepare new panels. If the condition persists, the paint should be considered unacceptable for testing.

10. Procedure

10.1 Hang the panels vertically in the test cabinet with a spacing of 1 to 2 in. (25 to 50 mm) between them and chill for 23 h. Then place them in a room at approximately 77°F (25°C) and 50 % relative humidity until the surface is dry (approximately 30 min).

10.2 Inspect for efflorescence by observing the panels at an 85° angle of incidence to a light source so that any change in surface appearance can readily be noted.

10.3 Return the panels to the test cabinet at 42°F (5.5°C), 80 % relative humidity for ½ h to chill before receiving a steam treatment as follows:

10.3.1 Heat ½ in. (13 mm) deep reagent water in a flat-bottom pan to boiling. Remove or reduce the heat until there is no bubbling.

10.3.2 Remove the panel from the cabinet and hold it over the pan until a fine condensate forms on the surface. As soon as the fine condensate covers about 75 % of the panel area return the panel immediately to the test cabinet. It should take only a few seconds to develop the condensate, and the panel should be replaced in the test cabinet in less than 5 to 10 s.

NOTE 1—Place the steam apparatus as near as possible to the test cabinet. The panel temperature will rise quite rapidly and will interfere with the formation and retention of condensate if the panel is out of the test cabinet too long. Formation of too large a condensate droplet will

cause water spots or rundown streaks and interfere with the development and rating of efflorescence.

10.4 Subject the panels to eight cycles, unless heavy efflorescence is observed in fewer cycles. The 23 h in the test cabinet followed by conditioning at standard temperature and humidity and by observation of the panels constitute the first cycle; the steaming, 23-h chilling, conditioning, and observation constitute subsequent cycles, with exposure in the test cabinet over the weekend constituting one test cycle. Start the test on Monday or Tuesday so that only one weekend cycle is included in the test series. Other end points may be established by agreement between the purchaser and the manufacturer.

11. Report

11.1 Report any glossing, flattening, light, medium, or heavy efflorescence, and the percent of the surface covered. When heavy efflorescence occurs in fewer than eight cycles, report the number of cycles required to produce this condition.

12. Precision

12.1 This test method was developed to provide a reliable qualitative and semiquantitative measure of efflorescence. Available information on the method is not sufficient to establish its reproducibility on a quantitative basis, so that a statistical statement of precision is not possible. However, the need for other than a reliable qualitative or semiquantitative rating is not apparent at this time; further studies will be undertaken if the need arises.

13. Keywords

13.1 efflorescence

Standard Test Method for Elongation of Attached Organic Coatings With Cylindrical Mandrel Apparatus

This test method covers the determination by the cylindrical test apparatus of the elongation of attached organic coatings when applied to flat sheet metal of uniform surface texture.

Formerly under the jurisdiction of Committee D-1 on Paint and Related Coatings and Materials.

This test method was discontinued in 1988 and replaced by ASTM Test Methods D 522, for Mandrel Bend Test of Attached Organic Coatings.¹

¹ Annual Book of ASTM Standards, Vol 06.01.

1. Scope
1.1 This test method covers the determination of elongation of organic coatings that may be applied to flat sheet metal of uniform surface texture. Such procedures are described in this test method.

NOTE
failures
methods
linseed-o

2. Terminology
2.1 Definitions of terms relating to films and coatings are given in Terminology D 155.

¹ This test method was discontinued in 1988 and replaced by ASTM Test Methods D 522, for Mandrel Bend Test of Attached Organic Coatings. This test method was published by the American Society for Testing and Materials, 1916 Race St., Philadelphia, PA 19104.

Standard Classification for Reporting Paint Film Failures Characteristic of Exterior Latex Paints¹

This standard is issued under the fixed designation D 1848; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This classification covers descriptions of properties that may be observed in weathered latex paint films. These descriptions should be used in reporting the condition of such paint films.

NOTE 1—In inspecting weathered exterior latex paints, defects or failures in the films may be observed that are not described in ASTM methods for evaluating the deterioration of exterior paints of the linseed-oil type.

2. Types of Defects

2.1 The following types of defects of exposed latex paint films are recognized:

2.1.1 *Efflorescence*, characterized by a commonly white, nonuniform powdery incrustation not readily removed by wiping. Usually it cannot be removed with water only but can be removed with dilute mineral acid.

2.1.2 *Mottling (or Blotching)*—The presence of irregularly shaped and randomly distributed areas of nonuniform appearance in color, gloss, or sheen.

2.1.3 *Water Spotting*—Nonuniformities in color, gloss, or sheen in the shape of spots or streaks, caused by drops or rivulets of water.

2.1.4 *Crawling*—Defect in which the wet film recedes from small areas of the substrate (usually caused by insufficient wetting) leaving those areas uncoated.

2.1.5 *Pinholing*—The presence of a series of fine holes or voids in the film.

2.1.6 *Mud-Cracking*, characterized by an irregular broken network of cracks in the film.

3. Index Terms

3.1 This standard is indexed under the following terms: exterior paints/coatings; latex paints.

¹ This classification is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.42 on Architectural Finishes.

Current edition approved Oct. 31, 1988. Published December 1988. Originally published as D 1848 - 61 T. Last previous edition D 1848 - 63 (1984) ϵ 1.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Package Stability of Paint¹

This standard is issued under the fixed designation D 1849; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This test method has been approved for use by agencies of the Department of Defense to replace Method 3018 of Federal Test Method Standard No. 141A and for listing in the DoD Index of Specifications and Standards.

¹NOTE—Editorial changes were made throughout in May 1987.

1. Scope

1.1 This test method covers the change in consistency and certain other properties that may take place when packaged paint of either the solvent-reducible or water-reducible type is stored at a temperature above freezing.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 562 Test Method for Consistency of Paints Using the Stormer Viscometer²

D 869 Test Method for Evaluating Degree of Settling of Paint²

3. Apparatus

3.1 *Spatula*, weighing 45 ± 1 g with square-ended blade $4\frac{3}{4}$ in. (120 mm) in length and approximately $1\frac{3}{16}$ in. (20 mm) in width as described in Method D 869.

3.2 *Viscometer*—A Stormer viscometer with the paddle-type rotor as described in Test Method D 562.

3.3 *Paint Brush*, 1-in. (25-mm) nylon.

3.4 *Test Surface*—A smooth-surfaced paper chart coated with a suitable varnish or lacquer so as to render the surface impervious and resistant to paint liquids.

4. Procedure

4.1 Obtain duplicate samples of the paint in original, unopened containers (Note 1). Examine one of the samples received for the characteristics listed in 4.2, using the procedures therein described. Weigh the other unopened sample to the nearest 1 g, then hold it undisturbed for specified periods of time and ranges of temperature, as agreed between purchaser and seller (Note 2). After storage, reweigh the sample without shaking to determine loss of weight resulting from faulty closure.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.42 on Architectural Finishes.

Current edition approved Aug. 1, 1980. Published September 1980. Originally published as D 1849 - 61 T. Last previous edition D 1849 - 79.

² Annual Book of ASTM Standards, Vol 06.01.

NOTE 1—Containers should preferably be no larger than 1 qt (1 L).

NOTE 2—Storage for 1 month at $125 \pm 2^\circ\text{F}$ ($52 \pm 1^\circ\text{C}$) simulates some of the effects of storage for 6 months to 1 year at $73 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$). However, it should be recognized that storage at 125°F may not simply accelerate changes occurring at 73°F ; with latex paints, for example, at 125°F the growth of some putrefying bacteria is inhibited.

4.2 Bring the stored sample to $73 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$). Note evidence of pressure or vacuum in the unopened container. Open the container and note skinning, corrosion and odor of putrefaction, rancidity or souring. Disregard other odors. If the sample is in a 1-qt (1-L) or smaller container, measure the character of the lower or settled layer with the spatula as described in Method D 869. If the sample is larger than 1 qt, omit this step. Hand stir the paint 300 stirs in 2 min with a spatula appropriate to the container, stirring so as to ensure uniform distribution of any settled material (Note 3). Immediately after stirring, measure the consistency of the paint as prescribed in Test Method D 562: without allowing the paint to reset after stirring.

4.3 Apply the stored paint to one test panel and the control paint to the other. After the brushed film has completely dried, examine it for grains $\frac{1}{32}$ in. (0.8 mm) in diameter, even larger gelatinous lumps, and streaks caused by such grains or lumps.

NOTE 3—Avoid the use of a mechanical shaker or syringe-type measuring device that may disperse these lumps.

5. Report

5.1 For the stored sample only, report the time of storage in days and the temperature of storage in degrees Fahrenheit or Celsius. Report the initial and final sample weight.

5.2 For both the sample tested as received and the stored sample, report the following:

5.2.1 Skinning, pressure, corrosion of the container, and odor of spoilage, each quality separately designated as follows:

- 10 = none
- 8 = very slight
- 6 = slight
- 4 = moderate
- 2 = considerable
- 0 = complete failure

5.2.2 Rigidity of the lower layer as determined in accordance with Method D 869, if performed;

5.2.3 Consistency as the weight in grams necessary to produce 200 r/pm on the Stormer viscometer;

5.2.4 (designate

10 =

Standard Guide for Analysis of Electrocoat Bath Samples¹

This standard is issued under the fixed designation D 1978; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide covers the selection of test methods for determination of the important parameters that affect the performance of electrocoating paints.

1.2 The test methods involved are D 4370, D 4399, D 4584, and D 5145.

2. Referenced Documents

2.1 ASTM Standards:

D 4370 Test Methods for Acid and Base Milliequivalent Content of Electrocoat Baths²

D 4399 Test Method for Measuring Electrical Conductivity of Electrocoat Baths²

D 4584 Test Method for Measuring Apparent pH of Electrocoat Baths²

D 5145 Test Method for Nonvolatile and Pigment Content of Electrocoat Baths²

3. Significance and Use

3.1 This guide indicates test procedures recommended for the maintenance of acceptable performance of the paint in an electrocoating bath. Several critical parameters must be

determined throughout the operation of the bath. These parameters must be adjusted when deviations from the norm occur.

3.2 The test methods for electrocoat baths are unique, as the aqueous samples have a nonvolatile content between 8 and 25 %. Constant agitation must be present when the samples are taken and during the measurement of some of the parameters.

4. Test Methods

4.1 *Acid and Base Content*—Test Methods D 4370 covers the determination of acid and base milliequivalent content of electrocoat baths.

4.2 *Electrical Conductivity*—Test Method D 4399 describes the determination of the electrical conductivity of electrocoat baths.

4.3 *pH Determination*—Test Method D 4584 describes the measurement of the apparent pH of paints and ultrafiltrates of electrocoat baths.

4.4 *Nonvolatile and Pigment Content*—Test Method D 5145 covers the determination of nonvolatile and inorganic pigment content of electrocoat baths.

5. Precision

5.1 The referenced test methods have precision limits listed. Reference to the individual standards for precision statements is recommended.

6. Keywords

6.1 electrical conductivity; nonvolatile content; electrocoat baths; pH; pigment content

Standard Test Method for Print Resistance of Architectural Paints¹

This standard is issued under the fixed designation D 2064; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers an accelerated procedure for evaluating the print resistance of architectural paints. It differs from print resistance Test Method D 2091 in that the latter is concerned with lacquer finishes under packaging, shipping, and warehousing conditions, whereas this test method is concerned with decorative coatings undergoing random on-site pressure contact.

NOTE 1—Printing should not be confused with blocking, which is measured in Test Method D 4946. The former relates to the indentation of a surface, and the latter, the sticking together of two surfaces.

2. Referenced Documents

2.1 ASTM Standards:

D 2091 Test Method for Print Resistance of Lacquers²
D 4946 Test Method for Blocking Resistance of Architectural Paints²

3. Terminology

3.1 Definitions:

3.1.1 *print resistance*—the ability of a paint film to resist forming a permanent impression in a semihardened film as a result of a pressure from an object placed on it.

3.2 For additional definitions of terms, refer to *Paints/Coatings Dictionary*.³

4. Summary of Test Method

4.1 A piece of cheesecloth is placed on the painted surface and topped with a No. 8 rubber stopper (position smaller diameter of stopper on the cheesecloth) and a 500-g weight to create a pressure of about 0.9 psi (6.2 kPa). This assembly is placed in a 140°F (60°C), or other agreed upon temperature, oven for 1 h. When cooled, the resulting paint surfaces are rated on the numerical scale of 0 to 10, which corresponds to a subjective rating of an impression resulting from their being in contact with the cheesecloth.

5. Significance and Use

5.1 The ability of a coating to resist printing is important because its appearance is adversely affected if the smoothness of the coating film is altered by contact with another surface, particularly one with a texture. Interior paint systems, particularly gloss and semigloss on window sills and other

horizontal surfaces, often have objects such as flower pots placed on them that may tend to leave a permanent impression. This tendency for a paint film to “print” is a function of the hardness of the coating, the pressure, temperature, humidity, and the duration of time that the object is in contact with the painted surface.

6. Apparatus

6.1 *Conditioning Room*, at 65 to 85°F (18 to 29.5°C) and 40 to 60 % relative humidity.

6.2 *Glass Slides*, approximately 3 by 6 in. (75 by 150 mm).

6.3 *Drawdown Applicator*, 3-in. (75-mm) wide with a clearance of 6 mils (150 μ m).

6.4 *Oven*, maintained at 140 $\pm$ 3.5°F (60 $\pm$ 2°C) or, other agreed upon temperature.

6.5 *Rubber Stoppers*, No. 8 (40-mm top diameter and 32-mm bottom diameter).

6.6 *Cheesecloth*, medium weave.⁴

6.7 *Scissors*.

6.8 *Weight*, 500-g.

7. Procedure

7.1 Cast the paints being tested on glass slides using a drawdown applicator with a clearance of 6 mils (150 μ m). Allow the coated glass slides to dry in the conditioned room for 7 days.

7.2 Cut out approximately 1½ by 1½-in. (40 by 40-mm) pieces of cheesecloth, one piece for each slide. Use cheesecloth that is usually supplied with 4 intact layers. Do not separate the layers.

7.3 Place the test slides on a horizontal tray, painted face upward, then place one piece of cheesecloth over each slide and top with the small diameter face of a No. 8 stopper and a 500-g weight, one weight and stopper for each specimen. (Weights and stoppers should be equilibrated in the oven prior to running the test.) It is recommended that control paints of known satisfactory and unsatisfactory performance be used in each test run and that the tests be run in duplicate.

7.4 Place the entire assembly in the oven and remove it after exactly 1 h. Immediately lift off the weights and stoppers without disturbing the cheesecloth and allow to cool.

7.5 After approximately ½ h, remove the cheesecloths and carefully examine the appearance of the films underneath. Note the depth and amount of cheesecloth pattern left in the paint film. If necessary examine the panel, for better

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and Devices and is the direct responsibility of Subcommittee D01.42 on Architectural Finishes.

⁴ Idealfold bleached cotton cheesecloth, Grade 20 B, Weave 24/20, 36-in. wide, 70 yd² available from Hermitage Industries, Inc., Camden, SC 29020, or an equivalent may be used.

perception of indentations, by viewing it at a low (grazing) angle of illumination.

8. Interpretation of Results

8.1 Rate print resistance is rated on a numerical scale of 0 to 10 corresponding to a subjective rating of the degree to which the paint film has been imprinted. Record the numerical value for print resistance in accordance with the following ASTM style rating or scoring system:

Numerical Rating	Qualitative Characterization (Resistance to Printing)	Quantitative Description (Amount of Printing)
10	perfect	none
8	very good	very slight
6	good	slight
4	fair	moderate
2	poor	considerable
0	very poor	very great

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

9. Report

9.1 Report the print resistance rating determined in accordance with 8.1. Specify temperature used.

10. Precision

10.1 Data are unavailable for a conventional intra- and interlaboratory precision statement. However, based on actual laboratory experience, with experienced operators, the repeatability is estimated to be plus or minus one unit. The employment of common control paints with mutually agreed ratings should make it possible for interlaboratory agreement (reproducibility) to approach intralaboratory agreement (repeatability). Although numerical ratings may differ with different operators or at different times, ranking should be about the same. As in many tests the precision improves with practice.

Standard Test Method for Determination of Edge Performance of Composite Wood Products Under Surfactant Accelerated Moisture Stress¹

This standard is issued under the fixed designation D 2065; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

1. Scope

1.1 This test method is intended to serve as a means for measurement of swelling and cracking of the coated or uncoated edge of a composite wood substrate that has been subjected to wetting by a test solution containing surface active agent.

1.2 *This standard does not purport to address the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 ASTM Standard:

D 661 Test Method for Evaluating Degree of Cracking of Exterior Paints²

3. Terminology

3.1 Description of Terms Specific to This Standard:

3.1.1 *crack rating*—a numerical value on a scale from 1 to 10, with 10 representing no evidence of cracking of the edge (see Test Method D 661).

3.1.2 *composite wood products*—boards or other structural or decorative materials manufactured from wood fibers, flakes or strands and various resin binders consolidated under heat, or pressure, or both.

4. Summary of Test Method

4.1 A surfactant solution is placed in a tray that contains a sponge. A preweighed and calipered panel with a coated edge is placed with the edge in contact with the surfactant saturated sponge for 2 h. The exposed panel is blotted dry, reweighed, recalipered, and inspected for edge cracking. Percentage weight and thickness changes are calculated and recorded. Edge cracking is rated in accordance with Test Method D 661 and recorded.

5. Significance and Use

5.1 This test method provides a measure of the dimensional stability and integrity of the coated edge of various composite wood products under accelerated moisture stress. It is widely used as an indicator or predictor of the anticipated performance of composite wood products during

exterior exposure. It may be used for developmental evaluation of coatings, substrates, or both. It may also be useful for quality control or monitoring of the production of coated or uncoated composite wood products.

6. Apparatus

6.1 *Wide Flat Tray or Pan*, suitable to contain the required number of sponges and test boards. The sides must be high enough to safely contain at least 1/4 in. (6 mm) of solution.

6.2 *Rack or Holder*, suitable to support the required number of test boards at the nominal 60° angle.

6.3 *Micrometer or Vernier Caliper*, of sufficient capacity for the board thickness to be measured and capable of 0.1 mm accuracy.

6.4 *Balance*, with sufficient capacity (typically 400 g) and 0.01 g accuracy.

6.5 *Suitable Saw*, for cutting of samples.

6.6 *Common Household Cellulose Sponges*, cut to suitable size.

7. Materials

7.1 A sufficient supply of test solution.

7.2 Appropriately identified test boards cut to proper size.

8. Hazards

8.1 When using saws, wear goggles, dust mask, and use proper machine safeguards to prevent injury.

9. Procedure

9.1 See Fig. 1.

9.2 Make the required test solution.³ Pour solution into the tray to saturate all sponges, and allow to reach room temperature. A 1/4-in. (6-mm) depth of solution in the tray works well.

9.3 Cut board specimens to a suitable size. A 4 (10.2) by 5-in. (12.7-cm) size has been found to be convenient. The 4-in. (10.2-cm) dimension should be the coated edge. Preparation of triplicate specimens is recommended.

9.4 Measure thickness of the samples along the edge to be tested. Three measurements at 1-in. (2.54-cm) intervals (Fig. 2) are recommended for a 4-in. (10.2-cm) specimen. Record results.

9.5 Weigh the samples to the nearest 0.01 g and record.

9.6 Place boards in the tray on sponges as noted in Fig. 1. If coated edges are to be tested, note that the sponges must be

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.52 on Factory-Coated Wood Building Products.

Current edition approved May 15, 1991. Published July 1991.

² *Annual Book of ASTM Standards*, Vol 06.01.

³ Common test solutions such as 1.0 % TRITON® X-100 available from Rohm and Haas Co., Independence Mall West, Philadelphia, PA 19105 or equivalent, is made using warm, (over 120°F (49°C)), distilled, or deionized water.

FIG. 1 Test Apparatus Side View

FIG. 2 Specimen Dimensions

narrower than the length (nominally 4 in. or 10.2 cm) of the contacting coated edges to prevent contact of the solution with the uncoated edges of the samples. Sponges 3.5-in. (9.0-cm) wide have been used successfully. For the same

reason, the coated face of the board must rest against the sponge at a 60° angle to prevent contact of the solution with the uncoated back of the board.

9.7 The test duration is 2 h. After 2 h, remove the boards and blot the edges dry with paper towels.

9.8 Observe and record changes as follows:

9.8.1 Visually inspect the edges for cracks and record the crack rating in accordance with Test Method D 661. Repeat the observation 48 h later.

9.8.2 Remeasure the thickness of the boards at the same spots measured in 4.4. Record the percent change at each spot.

9.8.3 Reweigh the boards and record the weight gain and percent weight gain, and

9.8.4 Calculate averages and standard deviations for the percent thickness change and percent weight gain.

10. Precision and Bias

10.1 The precision and bias of this test method have not been fully determined. Future round robins are planned.

11. Keywords

11.1 accelerated moisture stress; detergent test; wood or composite-wood

Standard Test Methods for Relative Tinting Strength of Printing Ink Dispersions¹

This standard is issued under the fixed designation D 2066; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

1. Scope

1.1 These test methods cover procedures for determining the relative tinting strength of printing ink dispersions by visual or instrumental evaluation.

1.2 These test methods are applicable to paste-type printing inks, flushed pigments, and other pigment dispersions that are essentially nonvolatile under ordinary room conditions and for which there is a wet reference standard of the same pigmentation and consistency. With proper choice of tinting base, they are applicable to dispersions of any color, including black and white.

NOTE 1—The instrumental procedures for tinting strength are similar in principle to those described in Test Methods D 387, D 2745, and D 4838.^{2,3}

1.3 *This standard does not purport to address the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

PH 2.17 Geometric Conditions for Reflection Density⁶

PH 2.18 Spectral Conditions for the Measurement of Optical Density⁶

PH 2.30 Viewing Conditions for Graphic Arts and Photography—Color Prints, Transparencies and Photomechanical Reproductions⁶

3. Terminology

3.1 Definitions relating to color attributes and color differences are covered in Terminology D 16 and E 284.

3.2 Descriptions of Terms Specific to This Standard:

3.2.1 *tinting strength*—the ability of a material to impart its color to a standard base; the reciprocal of the relative concentration required to match the reference material in a standard base.

3.2.2 *masstone (or masscolor)*—the color of a material that is thick enough to mask any background.

3.2.3 *undertone (or undercolor)*—the color of a thin film of a material.

4. Summary of Test Methods

4.1 Thin and thick films of the standard and unknown dispersions are drawn down in juxtaposition on bond and on coated paper. Visual evaluation of the relative undertone and masstone provides a check on color equivalency.

4.2 The standard and unknown dispersions are each reduced to the same concentration in a suitable tinting base. Thick wet drawdowns of the two tints are evaluated for tinting strength by Test Methods A or B.

4.2.1 *Test Method A—Visual Evaluation*: If the strength of the tints is judged unequal, aliquots of the stronger tint are further reduced until equivalence is obtained. The tinting strength of the unknown dispersion is calculated from the weight of extra tinting base added per unit weight of the stronger tint.

4.2.2 *Test Method B—Instrumental Evaluation*: Reflectance measurements are made on thick wet films of the original tints. The tinting strength of the unknown dispersion is calculated according to the Kubelka-Munk equation.

4.3 Preparation of a confirming tint is recommended as an unbiased method of verification. The preferred approach is to prepare a new tint of the unknown at a concentration calculated to match the standard tint.

5. Significance and Use

5.1 Tinting strength is an essential property of printing ink dispersions. Although test results on wet drawdowns and

tints do not guarantee equivalency of dry printed ink films, they provide useful parameters for quality assurance of established formulations, gaging relative degree of dispersion, and estimating the color value of colorants from different batches, sources, or grades.

6. Apparatus

6.1 *Laboratory Balance*, sensitive to at least 1.0 mg, preferably 0.1 mg.

6.2 *Spatulas*, (2) with flexible blades 80 to 120 mm in length (for weighing and mixing).

6.3 *Mixing Surface*, such as a glass or similar slab fixed to a work bench.

6.4 *Putty Knife*, with an 80–120 mm wide blade having a smooth straight edge (for use as a drawdown blade).

6.5 *Standard Daylight*, preferably a D50 light source conforming to ANSI Standard PH 2.30.

6.6 *Reflectance Measuring Instrument*, (for instrumental evaluation). Unless otherwise agreed upon, the instrument shall be a spectrophotometer with hemispherical (integrating-sphere) geometry conforming to Test Method E 1331, a spectrophotometer with bidirectional (45/0 or 0/45) geometry conforming to Test Method E 1349, or a tristimulus (filter) colorimeter with either geometry conforming to Test Method E 1347. Alternatively, a reflection densitometer conforming to ANSI Standard PH 2.17 and having a set of Status T or Status E filters⁷ (see 12.3.2), conforming to ANSI Standard 2.18 may be used for certain colors.

NOTE 2—The filter systems in typical densitometers are suitable only for use with black, white, and the three process colors (yellow, magenta and cyan). Instrumental evaluation of other colors requires a spectrophotometer or a colorimeter.

7. Materials

7.1 *Reference (Standard) Dispersion*, having the same pigmentation and consistency as the test (unknown) dispersion.

7.2 *Tinting Base*, as agreed upon between the producer and user, consisting of a suitable pigment well dispersed in a vehicle that is compatible with the vehicle in the test dispersion. The consistency of the base should not be appreciably lower than that of the test dispersion. Driers are not generally used because they may affect the color of the base and corresponding tints.

7.2.1 *White Base*,⁸ for testing colored and black dispersions. A suitable white base may contain by weight 60 % of either zinc oxide or titanium dioxide and 40 % vehicle.

7.2.2 *Black Base*, for testing white dispersions. A suitable black base may contain by weight 4 % black pigment (preferably non-flocculating), 43 % precipitated calcium carbonate, and 53 % vehicle. Alternatively, a neutral black nondrying printing ink such as a news ink.

7.2.3 *Dark Blue Base* (optional), for visual testing of white dispersions. A suitable dark blue base may contain by weight

42 % ultramarine blue, 18 % precipitated calcium carbonate, and 40 % vehicle.

7.2.4 *Light Blue Base* (optional), for visual testing of yellow dispersions. A suitable light blue base may contain by weight 1 % phthalocyanine blue dispersion and 99 % white base.

NOTE 3—Mixtures of a light blue base with yellow samples produce green tints, differences between which are more easily detected by eye than are mixtures of white and yellow. However, false results may be obtained. The use of a blue base is not recommended for visual tests on greenish-yellow colorants and is not permitted for instrumental evaluation of any yellow colorant.

7.3 *Weighing Substrate*, nonabsorbent, such as skin paper⁹ or small glass plates ca 75 to 100 mm square.

7.4 *Drawdown Substrates*, one consisting of white bond paper at least 50-mm wide and 150-mm long with a black bar at least 20-mm wide imprinted across the short dimension about half way down the length of the sheet, and a second one consisting of white coated paper.¹⁰

7.5 *Microscope Cover Glasses*¹¹ (optional, for instrumental measurements), made of finest optical glass, 50 by 45 mm, 0.13- to 0.17-mm thick.

7.6 *Standard Spacer* (optional, for instrumental measurements), such as cardstock the same size as the cover glass described in 7.5, about 1-mm thick, with a 35-mm diameter hole.

8. Sampling

8.1 These test methods do not include a method for preparation of dispersions. If colorants from different batches or sources are being evaluated, it is important that the standard and unknown samples be dispersed either in the identical manner or to the maximum degree, as agreed upon between the producer and the user.

8.2 Carefully select a dispersed sample that is free of skin and other contamination and representative of the lot being evaluated. Transfer to a clean container, protect with skin paper, close and seal.

9. Evaluation of Masstone and Undertone for Relative Color

9.1 Using the bond paper with the black bar, place small portions of the standard and unknown dispersions close together, but not touching, in the center at one end of the sheet in the long dimension.

9.2 Place the blade of the drawdown knife behind the pastes and, using heavy pressure, draw down a thin film of the pastes in juxtaposition. When the middle of the black bar is reached, raise the blade slightly and draw down the remaining pastes in a layer sufficiently thick that the black bar is not visible. Remove excess material.

9.3 Immediately examine the drawdowns under the standard D50 light or other agreed upon light source. Judge

⁹ Skin paper available from NAV Pack, 18 Monterey Lane, Englishtown, NJ 07726 or equivalent, has been found suitable for this purpose.

¹⁰ Bond paper with a black bar (Form 3NT-4) available from The Leneta Co., P.O. Box 86, Hahokus, NJ 07423 or equivalent, has been found suitable for this purpose.

¹¹ Microscope cover glasses available from Fisher Scientific Co. (catalogue no. 12-545H) or other scientific supply houses have been found suitable for this purpose.

⁷ Status T filters are available in the USA, Status E in other countries. The major difference is in the peak transmission of the blue filter.

⁸ A spectrophotometrically controlled universal white bleach, containing by weight 60 % zinc oxide (Florence White Seal) and 40 % Herculyn-D plasticizer, is available from National Printing Ink Research Institute (NPIRI), Lehigh University, Sinclair Laboratory 7, Bethlehem, PA 18015.

the hue, depth, cleanliness, transparency and other properties of the unknown dispersion relative to the standard dispersion. Record qualitative observations of the thin film over white paper as the relative undertone, the thin film over the black bar as the relative transparency, and the thick film as the relative masstone.

9.4 Repeat 9.1 and make a tight drawdown on a sheet of coated paper. Make an immediate visual judgment of the relative undertone. Include relative gloss and bronzing in the evaluation.

NOTE 4—When the consistencies of the standard and unknown dispersions are significantly different, the film thicknesses of the tight drawdowns may not be comparable. In such cases, judgments regarding relative hue should be reserved until the tints are examined (see Note 8 in 11.6).

NOTE 5—If the hue or cleanliness of the test dispersion is significantly different from the standard dispersion, tinting strength cannot be tested by the procedures covered in this test method. A numerical assessment of such systems may be obtained by making color measurements according to Test Methods E 1331, E 1347, or E 1349 and calculating color differences by the 1976 CIELAB equations in accordance with Test Method D 2244.

10. Preparation of Tints

10.1 Select a tinting base appropriate to the sample being tested (see 7.2). Examine the base for uniformity. If there are signs of separation or settling, stir thoroughly in container. If necessary, transfer the quantity required for testing to a slab and mix to ensure that the same composition of base will be used for both the standard and the unknown samples.

10.2 Tare or counterbalance a weighing substrate. Using guidelines suggested in Table 1, weigh out the desired amount of the standard dispersion. The quantity of specimen need not be exactly as listed in Table 1 but must be weighed to at least three significant figures. Divide the actual weight by the desired decimal concentration to obtain the total tint weight. The difference between the total weight and the specimen weight represents the weight of bleaching base to be added.

10.3 Gently mix the specimen and tinting base on the weighing substrate until the tint is uniform. Use a circular stirring motion, periodically scraping all material from the surface of the substrate. *Do not use so much energy that further dispersion will result.* If necessary, transfer all mate-

TABLE 1 Suggested Tint Concentrations for Strength Testing of Printing Ink Dispersions^a

Type of Dispersion	Dispersion Concentration in Tint	Ratio Dispersion	Content of Tint, g

with carbon black base	0.98	49:1	4.90	0.10 ^c	5.0

^a In NPIRI Universal Bleaching Base except where noted; Figures are given as a guide. It is recommended that standard batches be checked first to establish tint concentrations that give proper lightness levels.

^b Materials should be weighed to three significant figures. Increase weights by a factor contingent on the balance sensitivity.

^c Use double the quantity for instrumental tinting strength conducted by spectrophotometry and confirmed by aliquot reduction.

^d For white dispersions, weigh tinting base first.

rial to a glass slab and continue mixing with a gentle scraping and stirring motion until a uniform color *with no specks or streaks* is achieved. With a clean putty knife, push the tint to one side of the slab. Clean the putty knife and remainder of the slab.

NOTE 6—With flushes and other high viscosity dispersions, it is recommended that the tinting base be mixed into the specimen in small increments.

10.4 Repeat 10.2 and 10.3 with the unknown dispersion. Be sure the specimen concentration in the tint and the type of tinting base are identical to that used for the standard dispersion.

10.5 If there will be a delay in the evaluation process, transfer the tints to small clean containers and label appropriately. Always gently restir immediately before subsequent use in order to minimize problems of flooding or floating.

TEST METHOD A—TINTING STRENGTH BY VISUAL EVALUATION

11. Procedure

11.1 Using separate ink knives, gently stir the standard and the test tints. Place a small quantity of each tint close together, but not touching, at one end of a small glass plate or other drawdown substrate. Hold the drawdown knife at a low angle (5 to 15° from horizontal) and, using light pressure, draw down the tints in juxtaposition. The two films must be in contact with each other, smooth, and sufficiently thick so as to mask any background.

11.2 Immediately examine the drawdowns under the standard light. If the two tints appear equal, record the tinting strength of the unknown as 100 %. If the tints are unequal in strength, estimate the strength difference between the stronger and weaker color either from experience or from instrumental measurements (see Eq 4a or 4b in 13.2.2).

NOTE 7—With colored and black samples, the stronger tint will be darker. With white samples, the stronger tint will be lighter.

11.3 Weigh to three significant figures an aliquot of about 1 g (or a quantity representing about 10 to 20 %) of the stronger tint. Multiply the exact weight by the estimated strength difference in decimal units; add tinting base accordingly. For example, for an estimated 10 % difference, add 0.10 g base/g aliquot of the stronger tint.

11.4 Gently mix the adjusted tint until uniform. Gently remix the original tint of the weaker dispersion, make a thick drawdown versus the adjusted tint as in 11.1, and examine as in 11.2.

11.5 If the drawdowns are still unequal, *discard* the adjusted tint. Weigh out a new aliquot of the stronger tint and add more or less tinting base than in 11.3.

11.6 Repeat 11.3 and 11.4 until the drawdowns show that the adjusted tint equals the strength of the lighter tint. When equivalency is obtained, record whether the standard or unknown tint was stronger, the weight of the final aliquot, and the weight of added tinting base.

NOTE 8—If there is a difference in color between the unknown and standard dispersions, a situation will result wherein, as dilution progresses, the darker tint will revert to the lighter tint without obtaining a match. In such cases, this method cannot be used (see Note 5).

11.7 Compute the strength of the unknown dispersion (u)

as a percentage of a standard dispersion(s) as follows:

$$TS_u \% = \frac{1 + (b/a)_u}{1 + (b/a)_s} \times 100 \quad (1)$$

where:

TS_u = tinting strength of the unknown dispersion,
 b = weight of extra tinting base added to an aliquot of the stronger tint to obtain equivalence, g, and
 a = weight of the aliquot, g.

The term b/a represents the strength difference between the stronger and weaker colorant. For the weaker dispersion, $b/a = 0$ and drops out of Eq 1. When the unknown dispersion is stronger, Eq 1 reduces to:

$$TS_u \% = 1 + (b/a)_u \times 100 \quad (1a)$$

When the standard dispersion is stronger, Eq 1 reduces to:

$$TS_u \% = \frac{1}{1 + (b/a)_s} \times 100 \quad (1b)$$

NOTE 9—Tinting strength is always expressed as a decimal or a percentage of the unknown relative to the standard. The practice of expressing results as a strength difference may lead to erroneous calculations of the replacement concentration. See Eq 3 in 13.1.

11.8 Since replication of visual tinting strength tests inherently suffers from bias, prepare a confirming tint in accordance with the procedure given in 13.1.

TEST METHOD B—TINTING STRENGTH BY INSTRUMENTAL EVALUATION

12. Procedure

12.1 Set the instrument for the large area of view or illumination and standardize in accordance with Test Methods E 1331, E 1347, or E 1349, or, in the case of a densitometer, the manufacturer's instructions. If it is the intent to make measurements directly on wet tints, it may be useful to protect the instrument with a material such as plastic wrap with the porthole cut out.

12.2 Gently remix the standard tint prepared in Section 10. Place a sufficient quantity on a small glass plate or other rigid surface so that the material is at least 30 to 35 mm in diameter and thick enough to mask any background. Alternatively, use a standard spacer (see 7.6) to prepare a thick sandwich between two microscope cover glasses.

12.3 Measure the reflectance factor in one of the following manners:

12.3.1 *Spectrophotometer*: Following the procedure given in Test Method E 1331 or E 1349, quickly mount the tint on the porthole of the spectrophotometer and, within or at 45 s, measure the reflectance factor between 420 and 680 nm. If hemispherical geometry is used, the specular component may be either included or excluded, as long as the same condition is consistently used. Make a minimum of two measurements, moving or rotating the specimen between runs. Record the spectral reflectance factor in decimal units at the wavelength of maximum absorption (minimum reflectance) and compute the mean.

12.3.2 *Densitometer*: If the tint involves black, white or a process color, select the filter having the appropriate Status T or Status E response in accordance with ANSI Standard PH 2.18. The peak transmission of the visual response filter should be at 555 nm for blacks and whites; of the blue filter, at 460 nm (Status T) or 440 nm (Status E) for process

yellows; of the green filter, at 530 nm for magentas; of the red filter, at 600 nm for cyans. Make measurements as in 12.3.1 at two or three different locations. If the readout is density, convert to the reflectance factor as follows:

$$R = 10^{-D}$$

If the readout is percent reflectance, record in decimal units.

12.4 Alternatively, measure the CIE tristimulus values of the specimen on a spectrophotometer in accordance with Test Method E 1331 or Test Method E 1349 or on a tristimulus colorimeter in accordance with Test Method E 1347. Make the measurements as in 12.3.1. If hemispherical geometry is used, the specular component may be either included or excluded as long as the same condition is consistently used. The tristimulus values may be based on either the CIE 1964 (10°) supplementary standard observer and standard illuminant D₆₅ or the CIE 1931 (2°) standard observer and standard illuminant C, as long as the same basis is consistently used. Record in decimal units the lowest appropriate value, for example, X with blue colors, Y with reds, blacks, and whites, or Z with yellows.

12.5 Repeat 12.2 and 12.3 or 12.4 with the unknown tint.

12.6 Calculate the tinting strength of the unknown dispersion according to the Kubelka-Munk equation as follows:

$$TS_u \% = \frac{[(1 - R_{\infty})^2 / 2R_{\infty}]_u}{[(1 - R_{\infty})^2 / 2R_{\infty}]_s} \times 100 \quad (2)$$

where:

R_{∞} = spectral reflectance factor, expressed as a decimal fraction, of an infinitely thick layer of material (at the wavelength of maximum absorption), or, by mutual agreement, an appropriate tristimulus value.

NOTE 10—If the tint represents a white pigment, use Eq 2 in the inverted form.

NOTE 11—The term $[(1 - R_{\infty})^2 / 2R_{\infty}]$ represents K/S of the colorant, where K is the absorption coefficient and S is the scattering coefficient, both of which are specific to a colorant. Therefore, if the pigmentation in the unknown dispersion is different from that in the standard dispersion, that is, the dispersions are metameric, Eq 2 no longer applies. The equation is also reported to work best when the reflectance factor or tristimulus value of the tints used is about 0.40 and the tinting strength of the unknown is within 10 % of the standard.

12.7 If the tinting strength result for the unknown is not within 10 % of the standard, reduce an aliquot of the stronger tint by the procedure given in 13.2. Remeasure the adjusted tint and calculate a new tinting strength value (see 13.2.5).

12.8 Prepare a confirming tint (see 13.1) if the original tinting strength value was not within 10 % of the standard (see 13.1 or 13.2 if within 10 %).

13. Preparation of Confirming Tint

13.1 Replacement Concentration:

13.1.1 In this method of confirmation, a new tint of the unknown dispersion is prepared at a concentration calculated to match the standard tint.

13.1.2 Compute the replacement concentration, also called color value, as follows:

$$C_u = C_s / TS_u \quad (3)$$

where:

14. R

14.1

C_u = concentration of the unknown dispersion required to match the standard dispersion,
 C_s = concentration of the standard dispersion in the original tint prepared in 10.2, and
 TS_u = tinting strength result for the known dispersion in decimal units.

13.1.3 Weigh out a quantity of the unknown dispersion similar to that employed in 10.2. Divide the actual weight by C_u to obtain the total tint weight. The difference between the total and the specimen weight represents the weight of tinting base to be added. Mix as in 10.3.

13.1.4 Gently remix the original tint of the standard dispersion. Make a thick drawdown of both tints as in 11.1. If the two tints match, the tinting strength result computed for the unknown dispersion is correct.

13.1.5 Failure of the two tints to match suggests a weighing error or inadequate mixing of the tints. Clean up and start over from Section 10.

13.1.6 Use Eq 3 to compute the color/money/value of a colorant from different sources or grades (optional). Multiply C_u and C_s by their respective unit costs. Add to each the costs of other components in a formulation, represented by $(1 - C_u)$ and $(1 - C_s)$. The lower total cost figure is the better value.

13.2 Reduction of the Stronger Tint:

13.2.1 In this method of confirmation, the instrumental tinting strength result is used to calculate the strength difference between the stronger and weaker dispersion. An aliquot of the stronger tint is reduced accordingly.

13.2.2 Compute the strength difference, b/a by re-arrangement of Eq 1a or 1b. If the test dispersion is the stronger, that is, TS_u in decimal units is greater than 1.0 then:

$$(b/a)_u = TS_u - 1 \quad (4a)$$

If the standard dispersion is the stronger, that is, TS_u is less than 1.0 then:

$$(b/a)_s = (1/TS_u) - 1 \quad (4b)$$

13.2.3 Weigh out an aliquot of the stronger tint as in 11.3. Multiply the exact weight by b/a to obtain the weight of bleaching base to be added. Mix the adjusted tint until uniform.

13.2.4 Evaluate the adjusted tint by either of the following procedures:

13.2.4.1 *Visual Evaluation*—Draw down the adjusted tint versus the original tint of the weaker color as in 11.1.4. Failure to obtain equivalency on the first cut may suggest a weighing error or the inapplicability of the Kubelka-Munk equation (Eq 2), or both. If necessary, reduce a new aliquot until equivalency is obtained. Calculate the correct tinting strength according to Eq 1a or 1b.

13.2.4.2 *Instrumental Evaluation*—Prepare a thick film of the adjusted tint, remeasure the reflectance, and calculate the adjusted tinting strength by Eq 2. If 100 %, the original tinting strength value is correct. If not 100 %, compute the correct tinting strength by multiplying the original tinting strength percentage by the adjusted tinting strength in decimal units.

14. Report

14.1 Report the following information:

14.1.1 The type and identification of the test dispersion, the reference standard dispersion, and the nature of the tinting base,

14.1.2 The results of the visual evaluation of the relative color difference (masstone and undertone) of the drawdowns on bond and coated paper,

14.1.3 The relative tinting strength and the method by which it was determined (visual or instrumental). If the instrumental method was used, the manufacturer and type of instrument, the geometry (including for hemispherical geometry whether the specular component was included or excluded) and, if used, the basis for the calculation of tristimulus values,

14.1.4 The method, if any, by which the tinting strength result was confirmed, and

14.1.5 Any deviation, by agreement or otherwise, from the procedures given in these test methods.

15. Precision and Bias

15.1 Precision:

15.1.1 An interlaboratory study of these test methods was conducted in which 3 sets of process color printing inks ranging in tinting strength from 75 to 85 % were tested by operators in 6 different laboratories. The tests were conducted as blind duplicates on each of 2 days. In addition to visually evaluated tinting strength, the same reductions were measured spectrophotometrically or densitometrically, or both. The estimated standard deviations and the degrees of freedom are given in Table 2. Based on these standard deviations, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

15.1.1.1 *Repeatability*—Two results obtained by the same operator on different days should be considered suspect if they differ by more than the maximum allowable difference indicated in Table 2.

15.1.1.2 *Reproducibility*—Two results, each the mean of results obtained on different days by operators in different laboratories, should be considered suspect if they differ by more than the maximum allowable difference indicated in Table 2.

15.2 *Bias*—The tinting strength results obtained in the interlaboratory study of these test methods were higher than the formulated values by the amounts shown in Table 3.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Print Resistance of Lacquers¹

This standard is issued under the fixed designation D 2091; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense to replace Method 6211 of Federal Test Method Standard No. 141. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

1. Scope

1.1 This test method covers the resistance of dried lacquer films to imprinting.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels²

D 1005 Test Methods for Measurement of Dry-Film Thickness of Organic Coatings Using Micrometers²

D 1186 Test Methods for Nondestructive Measurement of Dry Film Thickness of Nonmagnetic Coatings Applied to a Ferrous Base²

D 1400 Test Method for Nondestructive Measurement of Dry Film Thickness of Nonconductive Coatings Applied to a Nonferrous Base²

2.2 U.S. Federal Specifications:

CCC-C-419(f) Cloth, Duck, Cotton, Unbleached, Plied³

CCC-C-440(e) Cloth, Cheesecloth, Bleached and Unbleached³

3. Summary of Test Method

3.1 A weight presses a piece of fabric against the test surface. The surface is then examined and changes in appearance of the test surface are reported.

4. Significance and Use

4.1 An unsatisfactory appearance can result from pressure deformation of a film inherently too soft or containing residual solvent. This test method is primarily used to evaluate the resistance of a lacquer finish to printing under

the conditions of packaging, shipping, and warehousing.

5. Apparatus and Materials

5.1 *Test Panels*—A plane surface consisting of wood, metal, paper supported on plate glass, plastic, or other surface with an area at least 100 % greater than the base of the weight. The planeness, smoothness, and composition should be agreed upon by the purchaser and the seller.

5.2 *Imprinting Fabric*, 8-oz Army duck, Type III, conforming to Fed. Spec. CCC-C-419(f) or cheesecloth, Type I, conforming to Federal Specification CCC-C-440(e).

NOTE—With the cheesecloth only, use a pad of nonwoven felt cloth at least 0.05 in. (1.3 mm) thick, weighing 7 oz/yd² (0.24 kg/m²) and larger than the plane end of the weight.

5.3 *Weights*, consisting of metal cylinders cut from standard stock 2 in. (51 mm) in diameter, with plane ends perpendicular to the axis, and of a length to give a pressure of 1/2 or 1 lb/in.² (3.5 or 7.0 kPa).

5.4 *Automatic Application Equipment, (Optional)*, as described in Test Methods D 823.

5.5 *Film Thickness Measuring Apparatus*, as described in Test Methods D 1005, D 1186, and D 1400.

6. Preparation of Test Specimen

6.1 *Single Coats*—Prepare a specimen for test by applying the test lacquer to a panel with a film applicator or other specified method, as described in Test Methods D 823, to give a specified film thickness to be stated in the result. In the absence of a specified dry film thickness, 1 ± 0.1 mil (25 ± 3 μ m) is recommended.

6.2 *Multiple Coats*—Use the finish system as agreed upon between the purchaser and the seller. In the absence of a specified dry film thickness, 3 ± 0.3 mils (75 ± 8 μ m) are recommended.

6.3 *Conditioning*—Allow to dry as agreed upon between the purchaser and the seller, but run the test within 48 h after coating. In the absence of a specified drying schedule, a period of 24 h at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and a relative humidity of 50 ± 5 % is recommended.

7. Procedure

7.1 Place over a uniform area of the specimen either a smooth piece of duck cloth or a piece of cheesecloth with a felt pad cushion. Place one or more weights, each on top of the other, on the duck or cheesecloth and pad and maintain the weight in compliance with one of the following test conditions:

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D 01.55 on Factory-Applied Coatings on Preformed Products.

Current edition approved March 25, 1988. Published September 1988. Originally published as D 2091 - 62 T. Last previous edition D 2091 - 87.

² *Annual Book of ASTM Standards*, Vol 06.01.

³ Available from Standardization Documents Order Desk, Bldg. 4, Section D, 700 Robbins Ave., Philadelphia, PA 19111-5094.

7.1.1 At $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity for an 18-h period,

7.1.2 At 120°F (50°C) for a 4-h period, or

7.1.3 At 140°F (60°C) for a 4-h period.

7.2 After the specified time, remove the weight, pad, and fabric. Remove lint and dust from the panel with a clean air stream. Examine the specimen immediately under bright, diffused illumination for impression of the fabric into the lacquered surface and compare to photographic standards (Fig. 1).

8. Report

8.1 Report the following information:

8.1.1 Surface involved,

8.1.2 Drying schedule,

8.1.3 Film thickness,

8.1.4 Weight used,

8.1.5 Test temperature used, time, and

8.1.6 Conditions of test other than those primarily specified in this test method.

9. Precision

9.1 Results varying by more than 1° of print should be suspect, either with the same or different operators.

(a) Heavy

(b) Medium

(c) Slight

FIG. 1 Print Resistance

Standard Practice for Preparation of Zinc-Coated (Galvanized) Steel Surfaces for Painting¹

This standard is issued under the fixed designation D 2092; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

1. Scope

1.1 This practice describes six methods of preparation for painting new zinc-coated (galvanized) surfaces produced by either the hot-dip method or by electroplating. This practice covers surfaces that have not been treated previously at the mill to provide temporary protection against staining by moisture other than by easily removed protective oils (see Appendix X1).

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 U.S. Federal Specification:

TT-P-641 Primer Coating, Zinc Dust Oxide (for Galvanized Surfaces)²

2.2 U.S. Military Specification:

DoD-P-15328 Primer (Wash) Pretreatment (Formula No. 117 for Metals)²

2.3 Canadian Standard:

CGSB, 1-GP-198 Primer, Cementitious for Galvanized Surfaces³

2.4 Steel Structures Painting Council Specification:

Paint No. 27 Basic Zinc Chromate-Vinyl Butyrol Wash Primer⁴

3. Summary of Practice

3.1 This practice describes methods of preparation that provide galvanized surfaces suitable for painting, specifically so that an applied coating system can develop the adhesion necessary for satisfactory service life.

3.2 Six methods of surface preparation (Note 1) are covered as follows:

3.2.1 Method A—Crystalline Zinc Phosphate Treatment.

3.2.2 Method B—Chromate Treatment.

3.2.3 Method C—Aqueous Chromic-Organic Treatment.

3.2.4 Method D—Acid-Bound Resinous Treatment.

3.2.5 Method E—Annealing Heat Treatments.

3.2.6 Method F—Amorphous Complex-Oxide Treatment.

NOTE 1—Materials employed in these methods of treatment are available from a number of sources as proprietary compounds or methods. Selection may be made from available sources.

3.3 Variations in surface preparation produce end conditions that differ and that do not necessarily yield identical results when paints are applied. Service conditions will dictate the type of surface preparation to be selected, although the quality produced by any individual method may vary with different zinc coatings.

3.4 Galvanized surfaces are treated by using various methods and apparatus; satisfactory application may be made at the following locations:

	Mill	Plant	Field
Method A	Y	Y	Y
Method B	Y	Y	...
Method C	Y	Y	...
Method D	Y	Y	Y
Method E	Y	...	...
Method F	Y	Y	...

3.5 This practice does not describe the cleaning necessary to provide a zinc-coated (galvanized) surface suitable for the application of the treatments. Many cleaning methods are applicable and should be agreed upon between the purchaser and the supplier.

NOTE 2—Most producers of zinc-coated (galvanized) steel sheets and coils have adopted the practice of applying an inhibitor to the zinc surface to give temporary protection against staining by moisture during shipping or storage. Some of these inhibitors will interfere with proper reaction of most of the treatments described in these methods, and an unsatisfactory surface for painting will result. It is strongly recommended that the purchaser consult the supplier of the chemical treatment to be used as to the suitability of the zinc surfaces for treatment by any of these methods (see Appendix X2).

4. Significance and Use

4.1 This practice describes procedures that can be used to prepare new zinc-coated surfaces for painting and improve the bond of paint to the zinc surface.

5. Processes

5.1 *Method A, Crystalline Zinc Phosphate Treatment*—This conversion-coating method consists of reacting the zinc surface in a zinc acid phosphate solution containing oxi-

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.46 on Industrial Protective Coatings.

Current edition approved Sept. 26, 1986. Published November 1986.

² Available from Standardization Documents Order Desk, Bldg. 4 Section D, 700 Robbins Ave., Philadelphia, PA 19111-5094, Attn: NPODS.

³ Available from Canadian Government Publishing Center, Supply and Services, Ottawa, Ontario K1A 0S9 Canada.

⁴ Available from Steel Structures Painting Council, 4400 Fifth Ave., Pittsburgh, PA 15213.

dizing agents and other salts for accelerating the coating action. The zinc surface is converted to a crystalline phosphate coating of the proper texture to inhibit corrosion and increase the adherence and durability of the paint film. Such treatments are recommended for product finishes and may be carried out by immersion, spray, or brush application.

5.2 Method B, Chromate Treatment—This treatment consists of a dip or spray with a dilute solution of a mixture of chromium trioxide and other acids, with the proper accelerator, for a period from 5 to 30 s at room temperature to 130°F (55°C) to provide a thin amorphous chromate coating that increases corrosion resistance and paint adhesion.

5.3 Method C, Aqueous Chromic-Organic Treatments—Certain water-soluble resins, when properly formulated with chromium compounds, may be applied to zinc surfaces by roller coat or other suitable means, such as dip and squeegee rolls. This may be done over a wide temperature range provided the film is properly baked or cured, or both, as required by the paint system to be applied. The resultant coating provides a corrosion-resistant film that increases the adhesion of applied paint films.

5.4 Method D, Acid-Bound Resinous Treatment (Vinyl Wash Primer) (See DoD-P-15328 and SSPC-Paint No. 27)—This surface treatment is based on the application of an acid-bound resinous film of approximately 0.3 to 0.5 mil (8 to 13 μ m) thickness. The treatment is based on three primary components: a hydroxyl-containing resin, a pigment capable of reacting with the resin and an acid, and an acid capable of

insolubilizing the resin by reacting with the resin, the pigment, and the zinc surface. The film is usually applied by spray, but may be applied by brush, dip, or roller coater. Under normal conditions it will dry sufficiently for recoating within 30 min, and within 8 h it will not be softened by organic solvents commonly used in paint coatings. The film has good adhesion to the metal substrate and promotes good adhesion of most subsequent organic coatings to itself. Two types of this treatment are available: (1) two-package material to be used the day it is mixed and (2) one-package material that has package stability and does not require daily preparation.

NOTE 3—It may be difficult to control the dry film thickness within the parameters of this specification when applied by brush, roller, or dip coater.

5.5 Method E, Annealing Heat Treatments—Under the controlled conditions obtainable in a mill, hot-dip galvanized surfaces may be converted and alloyed with the base metal to change the surface character of the zinc coating and make it more receptive to paint. This surface can be further improved by treating in accordance with Methods A, B, C, or D.

5.6 Method F, Amorphous Complex-Oxide Treatment—This surface treatment method consists of reacting the zinc surface in an alkaline solution containing heavy metal ions for a period of 5 to 30 s at 115 to 160°F (45 to 70°C). The surface of the zinc is converted to a nonmetallic, amorphous, complex-oxide coating that inhibits corrosion and increases the adhesion and durability of paint finishes. The treatment can be carried out by immersion or spray application.

Appendixes

(Nonmandatory Information)

X1. CLEANING OF ZINC SURFACES

X1.1 When zinc surfaces treated by Methods A through F have been soiled in fabrication, they should be cleaned before finishing. Alkali and acid cleaners should not be used without consulting the supplier of the treatment. Organic solvents will remove most soils but will not remove water-soluble salts unless specially selected. Proprietary solutions designed to clean zinc surfaces are available.

X1.2 New zinc-coated steel surfaces that cannot be treated in accordance with these methods prior to painting

can be exposed to the weather for at least 6 months prior to painting to allow the surface to oxidize.⁵

NOTE X1.1—There are special primers that obviate the need for weathering—U.S. Fed. Spec. TT-P-641 and CGSB, 1-GP-198 are examples.

⁵ Literature on painting zinc-coated steel surfaces may be obtained from the American Zinc Institute, 292 Madison Ave., New York, NY 10017, or from the National Paint, Varnish, and Lacquer Assoc., 15 Rhode Island Ave., N.W., Washington, DC 20005.

X2. IDENTIFYING THE PRESENCE OF AND REMOVING CHROMATE TREATMENTS USED AS WET-STORAGE (ALSO CALLED HUMID-STORAGE) STAIN INHIBITORS

X2.1 One of the inhibitors used by producers of zinc-coated steel is a hexavalent chromium solution. This treatment prevents Method D from working properly.

X2.2 If zinc-coated steel to be painted is galvanized to order, the order should prohibit the use of hexavalent chromium humid-storage stain treatments.

X2.3 Hexavalent chromium treatment can be removed

from galvanized surfaces by one of the following three methods:

X2.3.1 Weathering the surfaces for six months.

X2.3.2 Abrading the surfaces by sanding.

X2.3.3 Brush-off abrasive blast cleaning.

X2.4 The presence of hexavalent chromium on galvanized surfaces can be determined by spot testing with

diphenylcarbohydrazide solution. The spot test can also be used to evaluate the effectiveness of preparation to remove the treatment.

X2.5 Make the spot test solution as follows:

X2.5.1 Dissolve 0.5 g of 1,5-diphenylcarbohydrazide powder in a mixture of 20 mL acetone and 20 mL denatured ethanol. Heat the mixture in a warm water bath if necessary.

X2.5.2 Dilute 20 mL of concentrated phosphoric acid to 40 mL by slowly adding to 20 mL of distilled or deionized water.

X2.5.3 Add the dilute phosphoric acid to the acetone-alcohol solution.

X2.5.4 Store the solution away from light. Discard if it

becomes discolored. Preferably make fresh solution as needed using proportionally smaller amounts of ingredients.

X2.6 Conduct the spot test as follows:

X2.6.1 Degrease the test spot on the galvanized surface.

X2.6.2 Place several drops of the test solution on the galvanized surface.

X2.6.3 If no color develops in the solution within 10 s, hexavalent chromium is not present.

X2.6.4 If solution droplets turn a pink to purple color, then hexavalent chromium is present.

X2.6.5 Conduct the spot test on several representative spots on each individual piece of galvanized steel.

X2.6.6 Test every piece of galvanized steel that is to be treated for painting.

Standard Test Methods for Rheological Properties of Non-Newtonian Materials by Rotational (Brookfield) Viscometer¹

This standard is issued under the fixed designation D 2196; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^e) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense to replace Method 4287 of Federal Test Method Standard No. 141A. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

^{e1} NOTE—Section 24 was added editorially in August 1990.

1. Scope

1.1 These test methods cover the determination of the apparent viscosity and the shear thinning and thixotropic properties of non-Newtonian materials in the shear rate range from 0.1 to 50 s⁻¹.

1.2 This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Referenced Document

2.1 ASTM Standard:

E 1 Specification for ASTM Thermometers²

3. Summary of Test Methods

3.1 Test Method A consists of determining the apparent viscosity of coatings and related materials by measuring the torque on a spindle rotating at a constant speed in the material.

3.2 Test Methods B and C consist of determining the shear thinning and thixotropic (time-dependent) rheological properties of the materials.³ The viscosities of these materials are determined at a series of prescribed speeds of a rotational-type viscometer. The agitation of the material immediately preceding the viscosity measurements is carefully controlled.

4. Significance and Use

4.1 Test Method A is used for determining the apparent viscosity at a given rotational speed, although viscosities at two or more speeds better characterize a non-Newtonian material than does the single viscosity measurement.

4.2 With Test Methods B and C, the extent of shear

thinning is indicated by the drop in viscosity with increasing viscometer speed. The degree of thixotropy is indicated by comparison of viscosities at increasing and decreasing viscometer speeds (Test Method B), viscosity recovery (Test Method B), or viscosities before and after high shear (combination of Test Methods B and C). The high-shear treatment in Test Method C approximates shearing during paint application. The viscosity behavior measured after high shear is indicative of the characteristics of the paint soon after application.

5. Apparatus

5.1 Rotational-type viscometers having at least four speeds, such as:

5.1.1 Brookfield Viscometer,⁴ Model LVF, having four rotational speeds, or Model LVT having eight rotational speeds, with set of four spindles; or

5.1.2 Brookfield Viscometer, Model RVF, having four rotational speeds, or Model RVT having eight rotational speeds, with set of seven spindles.

5.2 Thermometer—ASTM thermometer having a range from 20 to 70°C and conforming to the requirements for Thermometer 49C as prescribed in Specification E 1.

5.3 Containers, round 1-pt (0.5-L) can, 3³/₈ in. (85 mm) in diameter, or 1-qt (1-L) can, 4 in. (100 mm) in diameter.

5.4 Shaker,⁵ or equivalent machine capable of vigorously shaking the test specimen.

6. Materials

6.1 Standard Oils,⁶ calibrated in absolute viscosity, millipascal seconds.

7. Calibration of Apparatus

7.1 Select at least two standard oils of viscosities differing by at least 5 P (0.5 Pa·s) within the viscosity range of the material being measured and in the range of the viscometer. Condition the oils as closely as possible to 25.0°C (or other

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.24 on Physical Properties of Liquid Paints and Paint Materials.

Current edition approved Aug. 29, 1986. Published October 1986. Originally published as D 2196 - 63 T. Last previous edition D 2196 - 81.

⁴ Brookfield viscometers are available from the Brookfield Engineering Laboratories, Inc., 240 Cushing St., Stoughton, MA 02072.

⁵ A reciprocating shaker may be obtained from the Red Devil Tools, 2400 Vauxhall Rd., Union, NJ 07083.

⁶ Absolute viscosity standards are available in 1-pt samples from The Cannon Instrument Co., P.O. Box 16, State College, PA 16801, or Brookfield Engineering Laboratories, Inc., 240 Cushing St., Stoughton, MA 02072.

agreed-upon temperature) for 1 h in a 1-pt (0.5-L) can, 3/8 in. (85 mm) in diameter. Measure the viscosities of each oil as described in Test Method B (Section 13) taking readings only at increasing speeds (13.7). Make certain that the spindle is centered in the container prior to taking measurements.

NOTE 1—The Brookfield LV and RV series viscometers are equipped with a spindle guard leg. The spindle/speed multiplying factors (Table 1) are designed for use with the guard leg in place except for the following conditions: RV series when the factors are the same with or without the guard leg for spindles No. 3 through 7; or LV series when the factors are the same with or without the guard leg for spindles No. 3 and 4.

7.1.1 Calibration in a 1-pt (0.5-L) can is always possible with the LV series viscometer with the guard leg attached. Calibration of the RV series viscometer in the 1-pt can must be done with spindles No. 3 through 7 without the guard leg. If the No. 1 or No. 2 spindles are to be used, calibration is carried out in the 1-qt (1-L) can with the guard leg attached.

7.2 Combining the tolerance of the viscometer ($\pm 1\%$, equal to the spindle/speed factor) and the tolerance of the temperature control (typically $\pm 0.5^\circ\text{C}$ at 25°C) it is reasonable to assume that a viscometer is calibrated if the calculated viscosities are within $\pm 5\%$ of the stated values (see Table 2 for examples of the considerable change in viscosity with temperature exhibited by standard oils). If measurements are not made at 25°C , then the stated viscosities should be corrected to the temperature at which they are measured. If the viscosities determined in 7.1 differ from the stated values of the viscosity standard by more than 5%, calculate new factors for each spindle/speed combination as follows:

$$f = V/s \quad (1)$$

where:

f = new factor for converting scale reading to viscosity, cP (mPa·s),

V = viscosity of standard oil, mPa·s, and

s = scale reading of the viscometer.

TABLE 1 Factors for Converting Brookfield Dial Readings to Centipoises (Millipascal Seconds)

7.3 Prepare a table of new factors similar to that furnished with the viscometer (Table 1) for the spindle/speed combinations worked out in 7.2. Spindle/speed factors vary inversely with speed.

8. Preparation of Specimen

8.1 Fill a 1-pt or 1-qt can with sample to within 1 in. (25 mm) of the top with the sample and bring it as close as possible to a temperature of 25°C or other agreed-upon temperature prior to test.

8.2 Vigorously shake the specimen on the shaker or equivalent for 10 min, remove it from the shaker, and allow it to stand undisturbed for 60 min at 25°C prior to testing (Note 2). Start the test no later than 65 min after removing the can from the shaker. Do not transfer the specimen from the container in which it was shaken.

NOTE 2—Shake time may be reduced if necessary, or as agreed upon between the purchaser and manufacturer, but, in any case, should not be less than 3 min.

TEST METHOD A—APPARENT VISCOSITY

9. Procedure

9.1 Make all measurements as close as possible to 25°C , or other agreed-upon temperature.

9.2 Place the instrument on the adjustable stand. Lower the viscometer to a level that will immerse the spindle to the proper depth. Level the instrument using the attached spirit level.

9.3 Tilt the selected spindle (Note 3), insert it into one side of the center of the surface of the material, and attach the spindle to the instrument as follows: Firmly hold the upper shaft coupling with thumb and forefinger; screw left-hand thread spindle coupling securely to the upper shaft coupling being very careful when connecting to avoid undue side pressure which might affect alignment. Avoid rotating the dial so that pointer touches the stops at either extreme of the scale.

NOTE 3—Select the spindle/speed combination that will give a minimum scale reading of 10 but preferably in the middle or upper portion of the scale. The speed and spindle to be used may differ from this by agreement between user and producer.

9.4 Lower the viscometer until the groove (immersion mark) on the shaft just touches the material. Adjust the viscometer level if necessary. Move the container slowly in a horizontal plane until the spindle is located in approximately the center of the container so that the test will be run in a region undisturbed by the lowering of the spindle.

9.5 Turn on the viscometer. Adjust the viscometer to the rpm selected (Note 3) for the material under test. Allow the viscometer to run until the pointer has stabilized (Note 4). After the pointer has stabilized, depress the clutch and switch

TABLE 2 Viscosity Variation of Cannon Viscosity Standards About the 25°C Temperature Point

Cannon Viscosity Standard	Viscosity at 25°C , cP (mPa·s)	Viscosity Change With $\pm 1^\circ\text{C}$ at 25°C , cP (mPa·s)
S-600	1 400	87.7 (6.26 %)
S-2000	4 900	332 (6.77 %)
S-8000	20 000	1462.3 (7.31 %)

off the motor so that when it stops, the pointer will be in view (Note 5).

NOTE 4—In thixotropic paints, the pointer does not always stabilize. On occasion it reaches a peak and then gradually declines as the structure is broken down. In these cases, the time of rotation or number of revolutions prior to reading the viscometer should be agreed to between user and manufacturer.

NOTE 5—Always release the clutch while the spindle is still immersed so that the pointer will float, rather than snap back to zero.

10. Calculation

10.1 Calculate the apparent viscosity at each speed, as follows:

$$V = fs$$

where:

V = viscosity of sample in centipoises, mPa·s,

f = scale factor furnished with instrument (see Table 1), and

s = scale reading of viscometer.

11. Report

11.1 Report the following information:

11.1.1 The Brookfield viscometer model and spindle,

11.1.2 The viscosity at the spindle/speed utilized,

11.1.3 The specimen temperature in degrees celsius, and

11.1.4 The shake time and rest period, if other than specified.

12. Precision and Bias

12.1 *Precision*—See Section 23 for precision, including that for measurement at a single speed.

12.2 *Bias*—No statement of bias is possible with this test method.

TEST METHOD B—VISCOSITY UNDER CHANGING SPEED CONDITIONS, DEGREE OF SHEAR THINNING AND THIXOTROPY

13. Procedure

13.1 Make all measurements with the Brookfield viscometer as close as possible to 25°C, or other agreed upon temperature.

13.2 Adjust the instrument and attach the spindle as in 9.2 through 9.4.

13.3 Set the viscometer at the slowest rotational speed (Notes 5 and 6). Start the viscometer and record the scale reading after ten revolutions (or other agreed-upon number of revolutions).

NOTE 6—When the eight speed viscometers (RVT and LVT) are used, lower or higher speeds than that permitted by the four speed viscometers may be used upon agreement between producer and user.

13.4 Increase the viscometer speed stepwise and record the scale reading after ten revolutions (or equivalent time for each spindle/speed combination) at each speed. After an observation has been made at the top speed, decrease the speed in steps to the slowest speed, recording the scale reading after ten revolutions (or equivalent time) at each speed.

NOTE 7—It is preferable to change speed when the motor is running.

13.5 After the last reading has been taken at the slowest speed, shut off the viscometer and allow it and the specimen to stand undisturbed for an agreed-upon rest period. At the

end of the rest period, start the viscometer at the slowest speed and record the scale reading after ten revolutions (or other agreed-upon number of revolutions).

14. Calculations and Interpretation of Results

14.1 Calculate the apparent viscosity at each speed as shown in Section 9.

14.2 If desired, determine the degree of shear thinning by the following method:

14.2.1 *Shear Thinning Index* (sometimes erroneously called the thixotropic index)—Divide the apparent viscosity at a low rotational speed by the viscosity at a speed ten times higher. Typical speed combinations are 2 and 20 rpm, 5 and 50 rpm, 6 and 60 rpm but selection is subject to agreement between producer and user. The resultant viscosity ratio is an index of the degree of shear thinning over that range of rotational speed with higher ratios indicating greater shear thinning.

14.2.2 A regular or log-log plot of viscosity versus viscometer speed in rpm may also be useful in characterizing the shear-thinning behavior of the material. Such plots may be used for making comparisons between paints or other materials.

14.3 If desired, estimate the degree of thixotropy (under conditions of *limited* shearing-out of structure) by one of the following methods:

14.3.1 Calculate the ratio of the slowest speed viscosity taken with increasing speed to that with decreasing speed. The higher the ratio, the greater the thixotropy.

14.3.2 Calculate the ratio of the slowest speed viscosity taken after the rest period to that before the rest period. The higher the ratio, the greater the thixotropy.

15. Report

15.1 Report the following information:

15.1.1 The Brookfield viscometer and spindle,

15.1.2 The viscosities at increasing and decreasing spindle speeds,

15.1.3 The rest period time and the viscosity at the end of that time,

15.1.4 The specimen temperature in degrees celsius, and

15.1.5 The shake time if other than that specified.

15.2 *Optional Reporting*:

15.2.1 *Degree of Shear Thinning*—Shear thinning index and speeds over which it was measured (14.2).

15.2.2 *Estimated Degree of Thixotropy* (under conditions of shearing-out of structure)—Ratio of the lowest speed viscosities, for both increasing and decreasing speeds; or ratio of the lowest speed viscosities before and after the rest period, and speed at which they were measured (14.3).

16. Precision and Bias

16.1 *Precision*—See Section 23 for precision, including that for measurement of the shear thinning index (ratio of viscosity at 5 r/min to that at 50 r/min). It has not been possible to devise a method for determining precision for viscosities at increasing and decreasing speeds other than as individual measurements. No attempt was made to determine the precision of the measurement of the degree of thixotropy because this parameter is dependent on the material, the time of the test, and other variables.

16.2 *Bias*—No statement of bias is possible with this test method.

TEST METHOD C—VISCOSITY AND SHEAR THINNING OF A SHEARED MATERIAL

17. Apparatus

17.1 High-speed laboratory stirrer with speeds of at least 2000 rpm and equipped with a 2-in. (50-mm) diameter circular dispersion blade.⁷

18. Preparation of Specimen

18.1 Insert the 2-in. (50-mm) blade into the center of the can (4.3) so that the blade is about 1 in. (25 mm) from the bottom. Run the mixer at 2000 rpm (Note 8) for 1 min.

NOTE 8—Materials may be sheared at other speeds using other size blades upon agreement between producer and user.

19. Procedure

19.1 Immediately insert the same spindle used in Test Method B into the sheared material in the same manner as in Section 9.

19.2 Start the viscometer and adjust to the highest speed used in Test Method B (13.5). Record the scale reading after ten revolutions (or other agreed-upon number of revolutions).

19.3 Decrease the viscometer speed (Note 7) step-wise and record the scale readings at each speed down to the lowest speed used in Test Method B, recording the scale reading after ten revolutions at each speed (or other agreed-upon number of revolutions).

20. Calculations and Interpretation of Results

20.1 As in Test Method B, calculate the viscosities at each decreasing speed.

20.2 If desired, calculate the degree of shear thinning by the method given in Test Method B, 14.2. The measured viscosity behavior after shearing is essentially that of the paint immediately after application (disregarding changes in solids).

20.3 If desired, estimate the degree of thixotropy (under conditions of complete shearing-out of structure) by calculating the ratio of the lowest speed viscosities before and after shear. The lowest speed before-shear viscosity is taken from Test Method B, 14.1, at the lowest increasing speed. The lowest speed after-shear viscosity is taken from 20.1. The higher the ratio, the greater the thixotropy.

21. Report

21.1 Report the following information:

- 21.1.1 The Brookfield viscometer model and spindle,
- 21.1.2 The viscosities at decreasing spindle speeds,
- 21.1.3 The specimen temperature in degrees celsius, and
- 21.1.4 The speed of the high-speed mixer, size of blade, and time of mixing if different from method.

21.2 Optional Reporting:

21.2.1 *Degree of Shear Thinning*—Shear thinning index and speed over which it was measured (14.2).

21.2.2 *Estimated Thixotropy*—Ratio of lowest speed viscosities before and after shear and the speed at which they were measured.

22. Precision and Bias

22.1 *Precision*—The precision for individual viscosity measurements is the same as for Test Method A in Section 23. No attempt has been made to determine the precision of the shear thinning index or degree of thixotropy for Test Method C for the reasons given in 16.1.

22.2 *Bias*—No statement of bias is possible with this test method.

23. Summary of Precision

23.1 In an interlaboratory study of Test Methods A and B, eight operators in six laboratories measured on two days the viscosities of four architectural paints comprising a latex flat, a latex semi-gloss, a water-reducible gloss enamel, and an alkyd semi-gloss, that covered a reasonable range in viscosities and were shear thinning. Measurements at increasing speeds of 5, 10, 20, and 50 r/min (equivalent to eight operators testing 16 samples) were used to obtain the precision of Test Method A. The within-laboratory coefficient of variation for Test Method A (single speed) was found to be 2.49 % with 121 degrees of freedom and for Test Method B (Shear Thinning Index) 3.3 % with 31 degrees of freedom. The corresponding between-laboratories coefficients are 7.68 % with 105 degrees of freedom and 7.63 % with 27 degrees of freedom. Based on these coefficients the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

23.1.1 *Repeatability*—Two results obtained by the same operator at different times should be considered suspect if they differ by more than 7 % relative for single speed viscosity and 9.5 % relative for shear thinning index.

23.1.2 *Reproducibility*—Two results obtained by operators in different laboratories should be considered suspect if they differ by more than 21.6 and 22.1 % relative, respectively, for the same two test methods.

Standard Test Method for Adhesion of Organic Coatings by Scrape Adhesion¹

This standard is issued under the fixed designation D 2197; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This method has been approved for use by agencies of the Department of Defense to replace Method 6303 of Federal Test Method Standard No. 141C and for listing in the DoD Index of Specifications and Standards.

^{e1} NOTE—Keywords were added editorially in July 1991.

1. Scope

1.1 This test method covers the determination of the adhesion of organic coatings such as paint, varnish, and lacquer when applied to smooth, flat (planar) panel surfaces.

1.2 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 609 Methods for Preparation of Steel Panels for Testing Paint, Varnish, Lacquer, and Related Products²

D 823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels²

D 1005 Test Methods for Measurement of Dry-Film Thickness of Organic Coatings Using Micrometers²

D 1186 Test Methods for Nondestructive Measurement of Dry-Film Thickness of Nonmagnetic Coatings Applied to a Ferrous Base²

D 1400 Test Methods for Nondestructive Measurement of Dry Film Thickness of Nonconductive Coatings Applied to a Nonferrous Metal Base²

3. Summary of Test Method

3.1 The materials under test are applied at uniform thickness to flat panels, usually sheet metal of uniform surface texture. After drying, the adhesion is determined by pushing the panels beneath a rounded stylus or loop that is loaded in increasing amounts until the coating is removed from the substrate surface.

4. Significance and Use

4.1 Coatings to perform satisfactorily must adhere to the substrates on which they are applied. This test method has been found useful in differentiating the degree of adhesion of coatings to substrates. It is most useful in providing relative

ratings for a series of coated panels exhibiting significant differences in adhesion.

5. Apparatus

5.1 *Application Equipment*, as described in Test Methods D 823.

5.2 *Film-Thickness Measuring Apparatus*, as described in Test Methods D 1005, D 1186, or D 1400.

5.3 *Balanced-Beam, Scrape-Adhesion Tester* (Fig. 1),³ consisting of a balanced beam to which is secured a platform for supporting weights, and a rod at an angle of 45° that holds the scraping loop. The rod shall be set so that the scraping loop contacts test surfaces directly below the weights. The loop shall be 1/16-in. (1.6-mm) diameter rod, bent into a "U" shape with an outside radius of 0.128 ± 0.002 in. (3.25 ± 0.05 mm) and hardened to Rockwell HRC 56 to 58, and shall be chromium plated and polished.

6. Preparation of Specimens

6.1 Apply the materials under test to panels of the composition and surface condition on which it is desired to determine adhesion. The panel material (6.1.1), surface preparation, thickness, and number of coats shall be specified or agreed upon by the seller and the purchaser. Apply uniform coatings and air dry or bake under conditions of humidity and temperature mutually agreeable to the seller and purchaser. Either mask the panel or remove material after application, so that 1/2 in. (13 mm) at one end of the panel is uncoated.

6.1.1 The surface of the panel must be hard enough that it will not be damaged by the scraping loop. If no panel material is specified, use 0.032-in. (0.8-mm) cold-rolled carbon steel prepared in accordance with Methods B or C of Methods D 609.

7. Conditioning and Number of Tests

7.1 Condition the test panels for at least 48 h at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity, and test in the same environment, or immediately on removal therefrom, unless otherwise specified or agreed by the seller and the purchaser. Test at least two replicate specimens of each material.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.23 on Physical Properties of Applied Paint Films.

Current edition approved Aug. 29, 1986. Published October 1986. Originally published as D 2197 - 63 T. Last previous edition D 2197 - 85.

² Annual Book of ASTM Standards, Vol 06.01.

³ The tester is available from BYK-Gardner, Inc., Gardner Laboratory, 2435 Linden Lane, Silver Spring, MD 20910. Other apparatus of demonstrated equivalency may be used.

FIG. 1 Balanced-Beam Scrape-Adhesion Tester

8. Procedure

8.1 When using the instrument shown in Fig. 1, level the base plate of the apparatus and place it so that the weight holder is toward the operator. This places the beam release on the operator's right and allows freedom to move the test specimen manually under the weighted scraping element (loop). Adjust the main bearing support so that the beam is balanced in the horizontal plane when the loop is just touching the specimen surface.

8.2 Raise the beam and lock it. Wipe the loop with clean cloth or chamois. Place a test panel on the sliding platform so that it may be moved away from the operator and the uncoated portion is toward the main beam support. Place weights on the weight support using an initial amount that is estimated to be appropriate for the particular coating. Carefully lower the beam until the loop rests on the uncoated portion of the test specimen and the full load is applied, then slowly (1 to 2 s/in.) push the sliding platform away from the operator for a distance of at least 3 in. (75 mm). If the coating is removed, continue the testing, using successively smaller loads (0.5-kg increments) until the coating is not removed. If the coating is not removed by the initial scrape, continue the testing, using successively larger loads (0.5-kg increments) until the coating is removed or until the maximum load of 10 kg has been applied. Use a new area of the test surface each time a scrape is made.

8.3 When the critical load has been approximately located, repeat the test five times at each of three loadings: above, below, and at the load determined in the first trial. Apply the different loads in random fashion so that all scrapes at one load are not made in succession or on one panel.

8.3.1 Periodically examine the loop to ensure that the

original smooth surface is intact. If the contacting surface is worn, reverse the loop. When both sides are worn, replace with a new loop.

8.4 For each applied load, tabulate the number of times the coating was removed or adhered. The load where the scrape results change from mainly adhering to mainly removed, ignoring the first ½ in. (13 mm) of the scratch if the coating was removed, is the adhesion failure end point.

9. Report

9.1 Report the following information:

- 9.1.1 Load in kilograms at the adhesion failure end point.
- 9.1.2 Panel material and surface preparation.
- 9.1.3 Dry-film thickness.
- 9.1.4 Any deviation from the specified procedure.

10. Precision

10.1 *Correlation*—This method was developed when correlation with other methods of assessing adhesion was considered to be of equal importance to the agreement between results obtained in the same or different laboratories. It was established that when materials differing widely in hardness and adhesion were evaluated by a number of experienced personnel in several laboratories, the adhesion results obtained using this method correlated well with those obtained with several other methods.

10.2 *Precision*—If sufficient cooperators can be obtained, an interlaboratory study will be conducted to establish precision.

11. Keywords

11.1 adhesion, scrape; balanced-beam scrape adhesion tester

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Stain Removal From Multicolor Lacquers¹

This standard is issued under the fixed designation D 2198; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^e) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Editorial changes were made throughout in April 1989.

1. Scope

1.1 This test method covers a procedure for the removal of pencil, crayon, and grease stains from multicolor lacquer films that have been applied to primed steel panels.

NOTE—Due to the nature of the test, comparable results can be obtained only when exactly the same materials and apparatus are used. In this test method it has not been found possible to describe the materials and apparatus adequately in more than general terms.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

- D 609 Methods for Preparation of Steel Panels for Testing Paint, Varnish, Lacquer, and Related Products⁴

2.2 U. S. Federal Specifications:⁵

- Fed. Spec. EE-0-451C Specification for Oleo (Margarine)
- Fed. Spec. TTV-121C Specification for Varnish, Spar, Water Resisting
- Fed. Spec. VV-0-551 Specification for Oil, Lubricating, Marine and Engine, Mineral
- Fed. Spec. VV-P-236 Specification for Petrolatum

2.3 U. S. Military Specification:⁵

- MIL-P-11414A Specification for Primer Coating, Lacquer, Rust Inhibiting

3. Summary of Test Method

3.1 Three 6½ by 17-in. (165 by 430 mm) primed steel panels are sprayed with multicolor lacquer and allowed to dry for 24 h. Varnish is then applied to the ends of the panels

and allowed to dry 72 h. The three stains are applied by a mechanical apparatus and removed by washing.

4. Significance and Use

4.1 The procedure described in this test method is intended as an aid in evaluating the ease of removal for surface stains encountered by surfaces coated with multicolor lacquers.

5. Apparatus and Materials

5.1 *Steel Panels*, 6½ by 17 in. (165 by 430 mm), 20-gage cold-rolled steel conforming to Specification A 109 or Specification A 366.

5.2 *Washability Machine*.⁶

5.3 *Lacquer Primer*, conforming to MIL-P-11414A.

5.4 *Drafting Pencil*.

5.5 *China Marking Crayon*.

5.6 *Wetting Agent*.⁷

5.7 *Amorphous Silica*.

5.8 *Diaper Cloth*.

5.9 *Varnish*, clear and waterproof, conforming to Fed. Spec. TT-V-121C or equal cut in mineral spirits.

5.10 *Carriage*, for mounting pencil and crayon.

5.11 *Arm*, extendible, for mounting mohair roller.

5.12 *Mohair Roller*, 1½ in. (40 mm), for application of grease stain.

5.13 *Glass Plate*, 4 by 7 in. (100 by 175 mm), for holding grease stain.

5.14 *Grease*—The grease shall consist of the following ingredients:

5.14.1 *Lanolin*, anhydrous, 50 g,

5.14.2 *Petrolatum*, 50 g, conforming to Fed. Spec. VV-P-236,

5.14.3 *Margarine*, 30 g, conforming to Fed. Spec. EE-0-451C,

5.14.4 *Mineral Oil*, 10 g, conforming to Fed. Spec. VV-0-551, and

5.14.5 *Lampblack*, 5 g, conforming to Specification D 209.

6. Preparation of Panels

6.1 Prepare three 6½ by 17-in (165 by 430-mm) steel panels in accordance with Methods D 609. Spray a 0.5-mil

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.55 on Factory-Applied Coatings on Preformed Products.

⁶ Gardner Model AG8100, available from Byk-Gardner, Inc., Gardner Laboratory, 2435 Linden Ln., Silver Spring, MD 20910, has been found suitable for this purpose.

⁷ Triton X-100, available from Rohm and Haas Marketing Services, Independence Mall West, Philadelphia, PA 19105, has been found suitable for this purpose.

(13- μ m) film of the lacquer primer and air dry for 24 h at normal room temperature. With the primer reduced 100 % with the recommended thinner, one wet coat will give approximately 0.5 mil.

6.2 Spray two coats of multicolor lacquer over the primer with the atomization pressure adjusted to get complete covering and allow 1 h between coats for flash off.

6.3 To protect the end of the panels in handling and scrubbing, brush one coat of varnish on the 5 in. (125 mm) of the end of each panel after 24 h of drying of the multicolor. Leave 7 in. (175 mm) of exposed test lacquer in the center of the panels and allow the varnish to dry 72 h before staining the panels. Test within 1 to 2 h after staining.

7. Procedure

7.1 Application of Stains:

7.1.1 *Pencil and China Marking Crayon*—Make both the pencil lead and the crayon flat by rubbing over fine sandpaper before application of pencil and crayon stains. Mount the pencil vertically in the carriage so that it rests with its own weight on the surface to be stained. Add an additional weight so that the total is 40 g. Move the pencil over the panel 5 strokes perpendicular to the abrasion boat path. Repeat this procedure with the crayon. Stain three panels.

7.1.2 *Grease Stain*—Apply 1 g of grease to a 4 by 7-in (100 by 175-mm) glass plate and smooth with a rubber roller. Pass a 1½-in. (40-mm) mohair roller mounted on the extendible arm over the greased plate making three stripes and removing the grease down to the glass on each stripe so that the entire surface of the roller is uniformly coated. Then pass the roller over the panels coated with the lacquer under test. Make one stripe on the glass panel between the staining of each subsequent panel under test to maintain a uniform

amount of grease on the roller.

7.2 Removal of Stains:

7.2.1 Cut the diaper cloth into a strip 5⅞ by 6¾ in. (150 by 170 mm) and fold to three thicknesses to give 2 by 6¾ in. (50 by 170 mm), keeping the embossed side out and the raw edges in. Soak the folded cloth in water, squeeze out the excess water, and place on the 2-lb (900-g) abrasion boat (load boat with weight if necessary). Place 2 g of No. 22 silica wet with 2 mL of a 5 % wetting agent solution and smear this paste uniformly on the scrubbing area of the cloth with a spatula.

7.2.2 Start the scrubbing test using the Gardner Washability Machine and record the number of cycles required to remove completely each of the three stains. If any of the stain is not removed after 100 cycles, add 1 mL of 5 % wetting agent solution to rewet the cloth and continue the test. Repeat at 100-cycle intervals stopping after 500 cycles. Rinse the panel in running water and allow to dry.

8. Report

8.1 Record the results as the number of cycles (double strokes) needed to remove each stain completely. Describe any stain that is not removed after 500 cycles as the percent of stain remaining on each of three panels and record the mean of the three panels.

9. Precision

9.1 Because of the variations that can arise from the application of the stains, meaningful estimates of precision cannot be given. In round robin tests fairly good agreement was obtained by the cooperators when the method of application of stains was the same.

10. Keywords

10.1 stain removal; multicolor lacquers; lacquer

Standard Method for Measurement of Plasticizer Migration From Vinyl Fabrics to Lacquers¹

This standard is issued under the fixed designation D 2199; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This method covers an accelerated test for the measurement of a tendency for plasticizers in finished vinyl fabric to be transferred to coatings with which they come in contact.

NOTE—Age of fabric sample may affect results of test. To ensure most reliable results, test with fabric sample closest in age to what will be coated.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Summary of Method

2.1 A small sample of vinyl fabric is placed on a conditioned coating film under a pressure of $\frac{1}{2}$ psi (3.45 kPa). The assembly is placed in an oven for 3 days at elevated temperature. At the end of that time, the coating is examined for marring or softening. For coatings that may block or print at 50°C or lower, a lower test temperature and a longer test time may have to be used.

3. Significance and Use

3.1 Plasticizers in finished vinyl fabric can be transferred to coatings with which they come in contact. When this takes place, objectionable marring and softening occur. This method covers an accelerated test for measurement of this tendency.

4. Apparatus

4.1 *Drawdown Blade*, 5-mils (125- μ m) clearance to provide a wet film of approximately 2.5 mils (63 μ m) in thickness.

4.2 *Plate Glass Panels*.

4.3 *Window Glass*, 2 by 2-in. (51 by 51-mm) square, double strength.

4.4 *Sponge Rubber*, 2 by 2-in. (51 by 51-mm) square by $\frac{1}{4}$ in. (6.3 mm) thick.

4.5 *Weights*, flat-bottom, sufficient to place a total weight of 2 lb (910 g) on each test sample.

4.6 *Forced-Convection Oven*, thermostatically controlled to $\pm 2^\circ\text{C}$.

4.7 *Photograph Roller*.²

4.8 *Aluminum Foil*.

5. Procedure

5.1 Apply the coating to the glass panel with the drawdown blade to provide a uniform film with an area of at least a 2-in. (51-mm) square and a dry thickness of at least 1 mil (25 μ m) or as agreed upon. Dry the coating in accordance with the recommendations of the manufacturer or for a minimum of 24 h at room temperature and 2 h at 50°C.

5.2 Preheat the glass plate bearing the coating, the 2 by 2-in. glass square, and the weights for 30 min at 50°C. Place the square of vinyl fabric on the coating with care and ensure intimate contact by rolling with the photographic roller. Cover the fabric with foil, sponge rubber, glass, and weight in that order. The total weight shall be 2 lb (910 g).

5.3 Place the assembly in the forced convection oven at a temperature of 50°C for 72 h. After removal from the oven and cooling, remove the weight, sponge rubber, and aluminum foil, and carefully remove the vinyl fabric. Note and report any resistance to removal. Wipe the surface of the fabric with a soft rag dampened with heptane and examine for removal of exuded plasticizer.

6. Rating

6.1 Rate the degree of migration by viewing the surface of the coating at a low angle against the light within 2 h after termination of heating and within 15 min of removal of the fabric.

7. Report

7.1 Report marring or softening, or both, on the scale of no change, faint imprint, severe imprint, or marring.

7.2 If plasticizer is evident when the surface is wiped, this shall be reported.

8. Precision

8.1 This method does not result in a numerical value for precision but repeated tests have demonstrated that several laboratories will assign the same rating to various coating fabric combinations. Also, replicate tests by one laboratory are in good agreement.

¹ This method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.55 Factory-Applied Coatings on Preformed Products.

Current edition approved Oct. 29, 1982. Published January 1983. Originally published as D 2199 - 63 T. Last previous edition D 2199 - 78.

² A squeegee-type roller is satisfactory.

Standard Pictorial Surface Preparation Standards for Painting Steel Surfaces¹

This standard is issued under the fixed designation D 2200; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 The visual surface preparation standards consist of a series of color prints available as separate publications. Two different sets of photographs are described in this standard, designated as Method A (ISO/Swedish Standard²) and Method B (SSPC Standard³). The two methods differ in the depiction of the initial surface, in the definition and depiction of the cleaning conditions, and in the number of cleaning methods included. Because of these differences, the specifier should state whether Method A or Method B should be used.

The colored visual surface preparation standards represent different conditions of hot rolled steel before and after surface preparation. Prior to cleaning, there are four rust grades, A to D, that cover the range from intact mill scale to 100 % rusted and pitted steel. The standards then depict the appearance of the four grades after cleaning by one or more methods (for example, blast cleaning) to various degrees of thoroughness.

2. Referenced Documents

- 2.1 *Adjuncts:*
Pictorial Surface Preparation Standards²
Surface Cleanliness Definitions³

3. Terminology

3.1 Definitions:

3.1.1 The cleanliness definitions for the Method A visual surface preparation standard appear in the text of the pictorial surface preparation standards publication.² The definitions for Method B are found in a separate publication.³

¹ This standard is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.46 on Industrial Protective Coatings.

The pictorial standards described were prepared by the Swedish Corrosion Inst. and have been jointly approved by ASTM, the Steel Structures Painting Council (Vis 1), and the Swedish Standardizing Commission.

Current edition approved Sept. 15, 1991. Published November 1991. Originally published as D 2200 - 66. Last previous edition D 2200 - 85 (1989).

² The pictorial surface preparation standards are available from ASTM Headquarters (request Adjunct No. 12-422000-00); the Steel Structures Painting Council, 4400 Fifth Ave., Pittsburgh, PA 15213; and Sveriges Standardiseringskommission, Box 3295, Stockholm 3, Sweden.

³ The Visual Standards Method B and surface cleanliness definitions are available from the Steel Structures Painting Council, 4400 Fifth Avenue, Pittsburgh, PA 15213.

4. Significance and Use

4.1 The appearance of the various degrees of blast cleaning are influenced by the initial rust grades of the steel being cleaned. The standards aid visually in judging and evaluating the degree of rusting before cleaning and the degree of cleaning of steel surfaces prior to painting.

4.2 Two methods for visual standards have evolved because of differences in the practice of using visual standards throughout the world. In Europe, the visual standards (Method A) are used as the primary means of determining the degree of cleaning. In the US, the SSPC written definitions take precedence with the visual standards used as a supplement. The visual standards of Method B comply with the SSPC definitions.

5. Procedure and Interpretation

Method A—ISO/Swedish Standard

5.1 Determine the method of cleaning to be used (for example, hand/power tool cleaning, abrasive blast cleaning, or flame cleaning).

5.2 Determine the initial condition of the steel in accordance with four initial grades (A, B, C, or D).

5.3 Following the cleaning operation, compare the surface prepared with the photographs showing the degree of thoroughness for that particular initial condition. Select the degree that most closely corresponds to the prepared surface.

5.4 Repeat the procedure for representative areas of structure and record all three items (initial condition, method of cleaning, and degree of thoroughness achieved).

Method B, SSPC Visual Standard

5.5 Determine the degree of blast cleaning to be employed.

5.6 Determine the initial condition of steel in accordance with photographs A, B, C, and D.

5.7 Following the cleaning operation, compare the prepared surface with the photographs showing the degree of thoroughness for that particular initial condition. Select the degree that most closely corresponds to the prepared surface.

5.8 Repeat for all representative areas of structure and record for each area the initial condition and degree of thoroughness achieved.

5.9 When abrasives other than silica sand are used for

blast cleaning, consult the photographs in the appendix of the SSPC Standard for possible variations in appearance created by the abrasive type.

NOTE 1—Different steel surfaces show differences in shade, color, tone, pitting, flaking, mill scale, etc. To some extent, these differences

between the actual steel surface and the visual standard can be reconciled between the painting contractor and the inspector.

Standard Test Method for Preparation of Hot-Dipped Nonpassivated Galvanized Steel Panels for Testing Paint, Varnish, Lacquer, and Related Products¹

This standard is issued under the fixed designation D 2201; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon, (e) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Footnote 1 and Note 4 were corrected editorially in October, 1987.

1. Scope

1.1 This test method describes the preparation of a type of hot-dipped, nonpassivated, galvanized steel panel to be used for testing paint, varnish, lacquer, conversion coatings, and related products.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

A 525 Specification for General Requirements for Steel Sheet, Zinc-Coated (Galvanized) by the Hot-Dip Process²

D 2092 Practice for Preparation of Zinc-Coated (Galvanized) Steel Surfaces for Painting³

2.2 U.S. Federal Test Specifications:

O-T-634a Type II Trichloroethylene⁴

O-P-191a Perchloroethylene⁴

3. Test Panels

3.1 The test panels shall be prepared from galvanized sheet that has not been subject to any kind of treatment for the purpose of passivating (Note 1) and shall be completely free from any visible signs of storage stain or white rust. The gage shall be No. 20 (0.0396 in.) (1 mm) unless otherwise agreed upon between the manufacturer and the purchaser, but in no case lighter than No. 24 gage (0.0276 in.) (0.7 mm). The galvanizing shall be of the 1.25-oz class conforming to Specification A 525, known as "commercial (full spangle)."

NOTE 1—This test panel is designed for referee testing and is not typical of galvanized material normally stocked in commercial ware-

houses. Specified panels may be obtained from standard panel suppliers.

3.2 The zinc coating shall have been applied by a continuous galvanizing method, using an aluminum-bearing zinc. Galvanized steel is customarily shipped from the mills uncoiled; however, galvanized steel that has been oiled with a nonreactive rust preventative oil shall be acceptable under this specification.

3.3 After cutting, the panels shall be cleaned in organic solvents or vapor degreased and wrapped in clean paper having a neutral pH and sealed in vaporproof bags or envelopes. The use of alkali cleaners shall not be permitted. The panel size shall be not less than 2¾ by 5⅞ in. (70 by 150 mm) and all corners and edges shall be smooth and uniformly rounded.

4. Solvents and Reagents

4.1 *Solvent Mixture*—Prepare a solvent mixture consisting of either equal volumes of Varnish Makers' and Painters' (VM&P) naphtha and xylene or of 3 volumes of VM&P naphtha and 1 volume of ethylene glycol monoethyl ether (2-ethoxyethanol).

4.2 *Stabilized Trichloroethylene or Perchloroethylene.*

NOTE 2—Perchloroethylene and trichloroethylene shall conform to and be maintained in accordance with the Federal Specification for Trichloroethylene (O-T-634a Type II) or Perchloroethylene (O-P-191a).

5. Procedure A—Galvanized Steel Test Panels Without Chemical Treatment

5.1 Wipe the corrosion-free panels vigorously on both sides with a cloth wet with the solvent to remove the gross film of oil. Clean the panels by either solvent spray or vapor degreasing, as described in 4.2 and 4.3.

5.2 *Solvent Spray Cleaning*—Spray the solvent mixture (3.1) downward at an acute angle to the panel surface using a spray gun operated with the fluid tip wide open and the atomizing tip almost completely closed. Preferred practice is to support the panels on a rack at an angle of approximately 25° from the vertical and to hold the spray gun so that the jet is directed vertically downward. The bottoms of the panels should rest upon projections, such as nails, which permit the solvent to drain from the bottom edge. Direct the solvent over the surface of the panel in an oscillating rinsing manner, moving the spray progressively from the top to the bottom of the panel until all soluble and loosely adhering soil has been washed off. The minimum treatment shall consist of five

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.27 on Accelerated Testing.

oven and uniformly heat at 350°F (177°C) for 10 min. After heating, remove the panels from the oven, and allow them to cool to room temperature and coat them immediately with the paint system (Note 3). Do not touch the panels with the fingers during the entire process of preparation.

6.1 Clean standard, corrosion-free panels, without sanding or abrasion, in accordance with Procedure A. Coat the panels with a phosphate coating or other conversion coating representative of production performance (Note 4). The conditions of treatment shall be agreed upon between the manufacturer and the purchaser. Paint the treated panels immediately or store in a vacuum desiccator until needed. If panels are stored in a vacuum desiccator, upon removal from the desiccator, place the panels in an oven and uniformly heat at 350°F (177°C) for 10 min. After heating, remove the panels from the oven, allow them to cool to room temperature, and coat them immediately with the paint system (Note 3). Do not touch the panels with the fingers during the entire process of preparation.

5.3 Vapor Degreasing—Suspend the panels in a vapor phase-type degreaser containing stabilized trichloroethylene or perchloroethylene and allow them to remain above the boiling solvent until they attain the temperature of the vapor, at which time condensation on the panels no longer occurs. Allow the panels to cool to room temperature and rub briskly with a clean, lint-free cloth. Place the panels in an

Standard Guide for Selection of Tests for Traffic Paints¹

This standard is issued under the fixed designation D 2205; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Sections 12 and 13 were editorially changed in March 1990.

1. Scope

1.1 This guide covers the selection and use of procedures for testing traffic paints in the laboratory and in the field.

1.2 This guide covers the testing of a ready-mixed paint product of sprayable consistency that shall be suitable for use as a reflecting traffic guide on paved roadways.

1.3 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

5. Conditions Affecting Traffic Paint

5.1 Practical requirements for traffic paint may vary with:

5.1.1 Substrate type, such as portland cement and asphaltic concretes, and the various coarse aggregates used therein.

5.1.2 Climatic conditions, both generally and specifically, at the time of paint application.

5.1.3 Service density, such as heavy traffic areas in cities versus lightly traveled rural highways and parking lots.

5.1.4 Traffic type, whether light passenger cars or heavy trucks and airplanes.

5.1.5 Presence of foreign matter on the road surface, such as oil, old paint, skid marks, sand, salt, concrete curing compound, etc.

5.2 New portland cement concrete surfaces have a greater degree of moisture and alkalinity than older surfaces and thereby adversely affect paint adhesion. Paint adhesion is also affected by the ratio of cement to fine aggregate, coarse aggregate, and mixing water, as well as by the surface character of the aggregate that can range from impervious smooth quartz to irregular, porous slag.

LIQUID PAINT PROPERTIES

6. Skinning

6.1 Paints containing a binder that dries by oxidation are subject to skin formation in a partially filled can or by diffusion of air into a filled can. Since skins are insoluble in the paint they must be removed before use. The referenced test employs a partially filled container to indicate the tendency of a paint to skin. A typical minimum time for skinning is 18 to 24 h.

6.2 Examine the original sample for skins both on the surface and in the mass. Using a well-mixed, skin-free portion of the sample, perform a skinning test in accordance with Guide D 154, except use a 1-pt (0.5-L) friction-top can instead of an 8-oz (0.25-L) jar.

7. Coarse Particles

7.1 Paints must be free of oversize particles and foreign matter to avoid clogging application equipment, a typical maximum being 1 % by weight of total paint. The referenced test with a 325-mesh (45- μ m) screen gives the percent of this material in the paint.

7.2 Determine coarse particles in accordance with Test Methods D 185.

NOTE 1—This test is not used for traffic paint containing pre-mixed glass beads.

8. Fineness of Dispersion

8.1 The more finely a pigment is dispersed, the more efficiently it is being used. One method for measuring the degree of dispersion (commonly referred to as "fineness of grind") is to draw the material down a calibrated, tapered groove in a hardened steel block with the groove varying in

depth from 4 to 0 mils (100 to 0 μ m). The point at which continuous groupings of particles or agglomerates, or both, protrude through the surface of the liquid is taken as the fineness reading. Lower readings in mils or micrometres or higher reading in Hegman units indicate better fineness of dispersion.

8.2 Fineness of grind is not generally specified for traffic paint but some application equipment may require a limit of 1 to 2 Hegman units (3 to 3.5 mils, 75 to 90 μ m). If additional assurance is needed that the paint will not clog application equipment, determine the fineness in accordance with Test Method D 1210 after reducing the traffic paint with mineral spirits, or compatible aromatic solvent with a similar evaporation rate, to keep the film wet long enough to determine the end point more easily. When a premix traffic paint is being tested, conduct the test on the paint before addition of the beads.

9. Density or Weight per Gallon

9.1 Density as measured by weight per unit volume is not a performance characteristic but is used to check product uniformity from batch to batch. A calibrated weight per gallon cup is used.

9.2 For an unbeaded paint, determine the density in accordance with Test Method D 1475.

9.3 For beaded paints, use a special weight-per-gallon cup¹⁰ having a modified cap so that the beads do not interfere with a snug fit of the cap to the cup. Proceed in accordance with Test Method D 1475.

10. Consistency

10.1 Paints of a given type should fall within a stated consistency range as agreed upon between the purchaser and the seller. Consistency is used mainly to ensure product uniformity. Improper consistency, however, can adversely affect application properties, and in turn, paint performance.

10.2 Determine consistency using the Stormer viscometer in accordance with Test Method D 562. If the requirement is in Krebs units, Table 1 of Test Method D 562 permits changing seconds to KU.

11. Package Stability

11.1 Since paints are not normally used immediately after manufacture, they must remain stable in the can for some time, which for traffic paints does not generally exceed 6 months. Although package stability can usually be determined by alternatively heating and cooling a specimen, occasionally the results do not coincide with storage at normal temperature. The referenced methods determine the degree of pigment settling after 2 weeks cycling or after 6 months storage at room temperature. These are usually sufficient as it is difficult to rate numerically the ease of redispersing an aged traffic paint.

11.2 Determine the degree of pigment settling in the accelerated test in accordance with Test Method D 1309. Determine the degree of pigment settling and ease of

¹⁰ A satisfactory modified cup is available from BYK-Gardner, Inc., Gardner Laboratory, 2435 Linden Lane, Silver Spring, MD 20910.

APPLICATION AND APPEARANCE PROPERTIES

12. Drying Time

12.1 The drying time of a traffic paint is particularly important because it determines how quickly a lane can be opened to free flow of traffic without the paint being transferred to adjacent pavement.

12.2 Though no-pick-up time as determined by Test Method D 711 has no direct correlation with field application, it is employed as a quality control test.

13. Bleeding

13.1 Bleeding refers to the passage of colored matter such as bitumen from an asphalt pavement through the traffic paint film. It is a function of the age of the asphalt, its compatibility with the paint, and the speed of drying of the paint. Typical traffic paints give results of 6 to 10 on an arbitrary scale of photographic standards where 10 is no bleeding and 2 is considerable bleeding. Determine bleeding in accordance with Test Methods D 868 and D 969.

14. Hiding Power

14.1 Hiding power or opacity is a measure of the ability of a paint to hide the substrate. It varies, naturally, with the thickness of the applied film that may be influenced by the flow and application properties of the paint.

14.2 Determine the dry hiding power of traffic paints in accordance with Procedure A, Method 4121 of U.S. Federal Test Method Standard 141B. (This method is being rewritten in ASTM form.)

15. Color and Color Difference

15.1 The color of a paint may be determined precisely by means of a spectrophotometer. However, the exact color is not usually as important as how closely a paint matches a standard. Color difference between a product and a standard can be determined visually or with less elaborate instruments than for color measurement. Visual comparison of color is fast and often acceptable although numerical values are not obtained. Color difference instruments, while not more sensitive than the eye, provide numerical values that can be subsequently compared to later measurements.

15.2 If required, determine the color in terms of tristimulus values or chromaticity coordinates in accordance with Method E 308.

15.3 Determine color difference by visual comparison against standard color chips¹¹ in accordance with Practice D 1729. This practice covers the spectral photometric, and geometric characteristics of light source, illuminating and viewing conditions, size of specimens, and general procedures to be used in the visual evaluation of color differences of opaque materials.

15.4 Determine color difference instrumentally in accordance with Test Method D 2244. The method covers the

instrumental measurement of small color differences observable in daylight illumination between nonfluorescent, non-metameric, opaque surfaces.

16. Reflectance

16.1 Reflectance is a measure of the light reflected from the surface of a paint. It determines which of two specimens appears lighter when viewed in average daylight at an angle that eliminates gloss effects.

16.2 Determine the green filter reflectance in accordance with Test Method E 97.

17. Night Visibility or Retroreflectance of Beaded Paints at Low Angles

17.1 This property is important to traffic paint but visibility at night is not related to daylight reflectance. The retroreflectance evaluation of test panels coated with traffic paint should be in accordance with Test Method D 4061. Such panels can serve as controls in monitoring the application of traffic paint and can be helpful in correlating visual ratings with absolute values.

PROPERTIES OF THE DRIED FILM

18. Resistance to Wear

18.1 Resistance to wear is a measure of the ability of the dried film to withstand wear from traffic and from objects rolled or pulled across the surface. In the referenced method abrasive is poured onto a dry film on a glass panel until the paint is removed. A typical value for traffic paint is 65 L of sand for removal of a 3-mil (75- μ m) dry film. Determine resistance to wear in accordance with Test Method D 913.

18.2 Using unbeaded traffic paint, determine the abrasion resistance to falling sand or silicon carbide in accordance with Test Methods D 968.

19. Elongation

19.1 Elongation is a measure of the flexibility of a paint film. Traffic paints may have difficulty in meeting the referenced test if they are over-pigmented to obtain high reflectance.

19.2 Using unbeaded traffic paint, determine the flexibility in accordance with Test Method D 1737 but using 30-gage (0.32-mm) tin plate in place of the specified steel panel.

19.2.1 As the thickness and curing conditions are not specified in Test Method D 1737, one of the following alternatives should be used for testing traffic paint:

19.2.1.1 Apply a 15-mil (380- μ m) wet film, allow to air dry 18 h, bake 2 h at 50°C, and let cool before conducting the test with a 1/2-in. (12.7-mm) mandrel.

19.2.1.2 Apply a 10-mil (250- μ m) wet film, allow to air dry 24 h, bake 1 h at 65°C, cool, and use a 1/4-in. (6.4-mm) mandrel.

19.2.1.3 Apply a 6-mil (150- μ m) wet film, bake 6 h at 100°C, cool, and use a 1/4-in. (6.4-mm) mandrel.

20. Water Resistance

20.1 This property is important to traffic paints because they are frequently exposed to rain or condensation on bridges. The immersion test time is quite short in relation to

¹¹ Standard yellow color chips may be obtained from the Traffic Control Systems Div., HTO-20, Office of Traffic Operations, Federal Highway Administration, Washington, DC 20590.

actual exposure so that the test detects only paints with poor water resistance.

20.2 Using unbeaded paint, determine water resistance in accordance with either Practice D 870 or Test Methods D 1647.

20.3 As Practice D 870 specifies steel panels but not the immersion time, while Test Methods D 1647 requires tin plate and an immersion of 18 h, the following should be used for testing traffic paint: apply a 5-mil (130- μ m) wet film to a clean glass panel, allow to air dry for 72 h, immerse in reagent water for 24 h, and allow a recovery period of 2 h before examining.

ANALYSIS OF PAINT

21. Chemical Analysis

21.1 If a specification requires certain raw materials or certain components in a given amount, then chemical analysis is necessary to determine whether the specified materials are present in the required amounts. Analysis does not necessarily establish paint quality that can also be greatly affected by manufacturing techniques. Select test procedures from Methods D 215 and other ASTM methods that are pertinent to the components of traffic paints.

NOTE 2—No single schematic analysis is comprehensive enough to cover the wide variety of traffic paint compositions.

22. Nonvolatile Content (Paint)

22.1 The percent nonvolatile matter indicates the amount of material remaining after the solvent evaporates and is a measure of the film solids. Determine the nonvolatile content in accordance with Test Methods D 1644 using a larger specimen size in the case of beaded paint. It is suggested that the methods be selected as follows:

22.1.1 *Test Method A*—3 h at 105°C for paints where the nonsolvent components decompose at 149°C, and

22.1.2 *Test Method B*—10 min at 149°C for most paints where the nonsolvent components are reasonably stable at 149°C.

23. Pigment Content

23.1 Pigment gives paint its hiding and color and influences many other properties. Determine the percent pigment in accordance with Test Method D 2371.

24. Binder Content

24.1 The nonvolatile vehicle is that portion of the film-forming solids in a paint other than the pigment. It is not to be confused with the nonvolatile portion of the vehicle. Subtract the pigment content from the nonvolatile content to obtain the nonvolatile vehicle content. If desired, separate the vehicle for further analysis in accordance with Method D 2372.

FIELD EVALUATIONS

25. Road Service Test

25.1 Whereas numerous laboratory tests in the previous

sections indicate general suitability of traffic paint, and also batch-to-batch uniformity, these tests cannot predict performance under all possible end uses. Accordingly, the test paint should be applied in a repeatable manner under carefully stated conditions of end use and then tested, observed, and evaluated at stated times throughout the useful life of the paint.

25.2 Proceed in accordance with Practice D 713, being careful to record the value of each variable stated.

26. Retroreflectance

26.1 Since there is no acceptable instrumental method of evaluating the retroreflectance in the field of the glass spheres on (in) the traffic paint stripe (Note 4), the following two visual methods are extensively used: (1) rating longitudinal stripes from a car traveling at approximately 20 to 35 mph and requiring a test line 50 ft (15 m) long, and (2) rating transverse test stripes in the wheel tracks with tungsten illumination from the side of the road with eye and light source (held chest high) and separated by a distance that corresponds to the observation angle of a driver viewing the stripes on a highway.

26.1.1 These ratings are based on a scale of 10 (complete (100 %) retroreflectance) to 0 (no retroreflectance).

NOTE 3—The wheel track is the area extending 9 in. (230 mm) to each side of the point of greatest wear.

NOTE 4—An instrumental method with much greater precision is being developed.

27. Durability

27.1 The test line rating is based on the paint film remaining at the time of inspection when estimated by close observation with the unaided eye. The rating is on the scale from 0 to 10, the latter representing 100 % remaining, a rating of 9 representing 90 % remaining, etc.

28. Appearance

28.1 This is the complete impression conveyed when the test stripe is viewed at a distance of at least 10 ft (3 m). Any discoloration of the surface due to bleeding, dirt collection, darkening, fading, mold growth, etc. will affect the rating that is also on the scale from 10 to 0.

29. Length of Useful Life

29.1 The length of useful life is the length of time (in days) between application of the test lines and when the weighted rating first reaches a value of 4, or when any specific quality (appearance, durability, or night visibility) first reaches the numerical rating of 3, whichever is the lesser number of days.

29.2 When it is necessary to calculate the "length of useful life," calculate as follows (Practice D 713):

$$L = D \times (10 - 4) / (10 - R) = 6D / (10 - R)$$

where:

L = length of useful life,

D = number of days the test stripe has been on the road, and

R = weighted rating at time of calculation.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. Standard Test Method for Freeze-Thaw Resistance of Water-Borne Coatings¹

This standard is issued under the fixed designation D 2243; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This test method has been approved for use by agencies of the Department of Defense to replace Method 3012 of Federal Test Method Standard No. 141 and for listing in the DoD Index of Specifications and Standards.

1. Scope

1.1 This test method covers the determination of the extent to which water-borne coating retain their original properties free of detrimental changes.

1.2 *This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 562 Test Method for Consistency of Paints Using the Stormer Viscometer²

D 2196 Test methods for Rheological Properties of Non-Newtonian Materials By Rotational (Brookfield) Viscometer²

3. Apparatus

3.1 **Test Chamber**—A suitable cabinet, room, or enclosure space large enough to contain the specimens to be tested permitting at least 1 in. (25 mm) of air space between the sides of adjacent cans and capable of being maintained continuously at a temperature of 0°F (−18°C).

NOTE 1—Although a variation of the test chamber temperature of $\pm 3.5^\circ\text{F}$ ($\pm 2^\circ\text{C}$) is allowed, the test chamber temperature should be maintained as near 0°F (−18°C) as practicable and the amount of variation should be recorded and reported.

3.2 **Viscometer**—A Stormer viscometer with paddle type rotor as described in Test Method D 562 or a Brookfield viscometer as described in Test Methods D 2196.

3.3 **Test Charts**—Smooth surface paper charts having adjacent black and white areas, and coated with a suitable varnish or lacquer to render the surface impermeable to paint liquids.

3.4 **Paint Brush**, 1 in. (25 mm).

4. Preparation of Sample and Specimens

4.1 Prepare specimens for testing by filling 1-pt (500 mL) resin-lined, friction-top cans two thirds full. Ensure that the bulk sample from which the cans are filled is well stirred and uniform, that the containers used are clean, and that the lids

are applied promptly to the cans to prevent evaporation losses. Two such specimens are required for each test.

5. Exposure to Test Conditions

5.1 Store one can at room temperature and identify this as the control specimen.

5.2 Place the second can, the paint under test, identified as the "test specimen", in the chamber maintained at 0°F (−18°C) in such a manner that it does not touch the walls or bottom of the chamber and so that free circulation of air around it is permitted. The placing of cans on racks that raise them off the bottom of the chamber or upon pieces of insulating board resting on the bottom is suggested. In the case of several test specimens, maintain a minimum of 1 in. (25 mm) of air space between adjacent cans and between cans and the chamber walls. Keep the test specimen in the chamber for 17 h and then remove and allow to stand for 7 h undisturbed at room temperature, adjacent to the control specimen, for a complete freeze-thaw cycle of 24 h.

5.3 Repeat 5.2 for additional freeze-thaw cycles, as many as agreed on between cooperating laboratories or buyer and seller (One to five cycles are usual.).

6. Examination

6.1 After completion of the agreed or specified number of cycles, before stirring, examine both specimens for condition in the can, observing and rating any evidence of settling, gelation, coagulation, lumpiness, etc. as slight, moderate or pronounced.

6.2 Then stir the specimens and determine their viscosities in accordance with Test Method D 562 or Test Methods D 2196, and record the temperature of measurement.

NOTE 2—Stir specimens by hand in their can using a stainless steel paint spatula with a blade measuring approximately 5 by $\frac{3}{4}$ in. (125 by 20 mm). Stir carefully so as to avoid air entrainment and foam.

NOTE 3—In carrying out consistency determinations using Test Method D 562, specimens should be maintained in 77°F (25°C) until two successive readings agree within 5 g. As is the case with all non-Newtonian fluids, viscosity variation is dependent to a degree upon intensity and duration of agitation. Utmost care should be taken that control and test specimens receive identical treatment during all stirring operations.

6.3 Immediately following the viscosity determinations, apply both specimens of paint to a test panel (3.3) by means of a clean 1-in. (25-mm) brush. Allow to dry at least 24 h, then compare the test specimen with the control. Note any changes in hiding power, gloss, speckiness, agglomeration, coagulation, or color as slight, moderate or pronounced.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.42 on Architectural Finishes.

Current edition approved Oct. 26, 1990. Published December 1990. Originally published as D 2243 - 64 T. Last previous edition D 2243 - 82 (1987)¹.

7. Report

7.1 Report on the condition of the paint in the can, in accordance with 6.1.

7.2 Report the viscosities of the test and control specimens, and the temperature of measurement, in accordance with 6.2.

7.3 Report comparatively on the visible dry film characteristics of the test and control specimens, in accordance with 6.3.

8. Precision

8.1 The precision of this test method in regard to viscosities is as specified in Test Methods D 562 or D 2196, whichever is employed.

8.2 No precision statement is made in regard to the other properties, because of the subjective nature of the observations.

9. Keywords

9.1 freeze-thaw resistance; package stability

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Calculation of Color Differences From Instrumentally Measured Color Coordinates¹

This standard is issued under the fixed designation D 2244; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

^{ε1} NOTE—Superscript for b^2 in 6.4 was editorially corrected in December 1990.

INTRODUCTION

This test method originally resulted from the consolidation of a number of separately published methods for the instrumental evaluation of color differences. As revised in 1979, it included four color spaces in which color-scale values could be measured by instruments, many of which were obsolete, and the color differences calculated by ten equations for different color scales. The sections on apparatus, calibration standards and methods, and measurement procedures served little purpose in the light of modern color-measurement technology. The present revision omits these sections, and limits the color spaces and color-difference equations considered, to the three most widely used in the paint and related coatings industry.

1. Scope

1.1 This test method covers the calculation, from instrumentally measured color coordinates based on daylight illumination, of small color differences between nonfluorescent, nonmetameric, opaque specimens such as painted panels. (Where it is suspected that the specimens may be metameric, that is, possess different spectral curves though visually alike in color, Practices D 1729 and D 4086 should be used to verify instrumental results.) The color differences determined by these procedures are expressed in terms of approximately uniform visual color perception in CIE 1976 CIELAB opponent-color space (1),² Hunter L_H , a_H , b_H opponent-color space (2), and the Friele-MacAdam-Chickering (FMC-2) color space (3).

1.2 For product specification, the permissible color difference between test specimen and reference and the procedure for calculating the color difference shall be agreed upon by the purchaser and the seller. Specific color tolerances may be required for each material and condition of use since other appearance factors (for example, proximity, gloss, and texture) may affect the correlation between the magnitude of a measured color difference and its commercial acceptability.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish*

appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

6.1

3.2.1.2 *color difference (computed)*—the magnitude and direction of the difference between two psychophysical color stimuli defined by tristimulus values, or by chromaticity coordinates and luminance factor, as computed by means of a specified set of color-difference equations.

4. Summary of Test Method

4.1 The differences in color between a reference and a test specimen are determined from measurements made by use of a spectrophotometer or a colorimeter. Reflectance readings from such instruments are converted by computations to color-scale values, or these color-scale values may be read directly from instruments that automatically make the computations. Color-difference magnitudes are computed, from differences in these color-scale values, that represent the perceived color differences between the reference and the test specimen.

5. Significance and Use

5.1 The original CIE color scales based on tristimulus values X , Y , Z and chromaticity coordinates x , y are visually nonuniform. Each subsequent color scale based on CIE values has had weighting factors applied to provide some degree of uniformity so that color differences in various regions of color space will be more nearly comparable. On the other hand, color differences obtained for the same specimens evaluated in different color-scale systems are not likely to be identical. To avoid confusion, color differences among specimens should be compared only when they are obtained for the same color-scale system. There is no simple factor that can be used to convert accurately color differences in one system to differences in another system for all colors of specimens.

5.2 For uniformity of practice, the CIE recommended in 1976 the use of two new improved color scales, of which the CIELAB scale, with its associated color-difference equation, has found wide acceptance in the coatings and related industries. However, it has not completely displaced the use of the Hunter L_H , a_H , b_H and the FMC-2 scales, which are still utilized to allow comparison with earlier results and because of their familiarity to those responsible for interpreting them. Therefore, all three scales are included in this method as the most widely used in industrial laboratories.

5.3 Users of color differences have found that, in each system, summation of three vector color-difference components into a single scalar value is useful for determining whether a specimen color is within a specified tolerance from a standard. However, for control of color in production, it is necessary to know not only the magnitude of the departure from standard but also the direction of this departure. Information on the direction of a color difference is easily included by giving the three instrumentally determined components of the color difference.

5.4 Selection of color tolerances based on instrumental values should be carefully correlated with a visual appraisal of the acceptability of differences in hue, lightness, and saturation obtained by using Practice D 1729.

6. Description of Color-Difference Equations

6.1 CIE 1931 and 1964 Color Spaces—The daylight

colors of opaque specimens are represented by points in a space formed by three rectangular coordinates representing the lightness scale Y and chromaticity scales x and y , where:

$$x = \frac{X}{X + Y + Z}$$

$$y = \frac{Y}{X + Y + Z}$$

$$Y = Y$$

where X , Y , and Z are tristimulus values for either the 1931 CIE standard observer (2° observer) or the 1964 CIE supplementary standard observer (10° observer) and standard illuminant C , D_{65} , or another of daylight quality. These scales do not provide a perceptually uniform color space. Consequently, color differences are seldom if ever computed directly from differences in x , y , and Y .

6.2 CIE 1976 $L^* a^* b^*$ Uniform Color Space and Color-Difference Equation (1, 4)—This approximately uniform color space is a simplified version of the Adams-Nickerson color-scale system (5–7). It is produced by plotting in rectangular coordinates the quantities L^* , a^* , b^* , calculated as follows:

$$\begin{aligned} L^* &= 116(Y/Y_n)^{1/3} - 16 \\ a^* &= 500[(X/X_n)^{1/3} - (Y/Y_n)^{1/3}] \\ b^* &= 200[(Y/Y_n)^{1/3} - (Z/Z_n)^{1/3}] \end{aligned}$$

$$X/X_n, Y/Y_n, Z/Z_n > 0.01$$

The tristimulus values X_n , Y_n , Z_n define the color of the normally white object-color stimulus. Usually, the white object-color stimulus is given by the spectral radiant power of one of the CIE standard illuminants, for example, C , D_{65} or another of daylight quality, reflected into the observer's eye by the perfect reflecting diffuser. Under these conditions, X_n , Y_n , Z_n are the tristimulus values of the standard illuminant with Y_n equal to 100.

6.2.1 The total difference ΔE_{ab}^* between two colors each given in terms of L^* , a^* , b^* is calculated as follows:

$$\Delta E_{ab}^* = [(\Delta L^*)^2 + (\Delta a^*)^2 + (\Delta b^*)^2]^{1/2}$$

NOTE 1—The color space defined above is called the CIE 1976 $L^* a^* b^*$ space and the color-difference equation the CIE 1976 $L^* a^* b^*$ color-difference formula. The abbreviation CIELAB is recommended.

6.2.2 The CIE 1976 ($L^* a^* b^*$) space fails to approximate uniform color spacing when one or more of the ratios X/X_n , Y/Y_n , and Z/Z_n is less than 0.01. In calculating L^* , values of Y/Y_n less than 0.01 may be included if the normal formula is used for values of Y/Y_n greater than 0.008856, and the following modified formula is used for values of Y/Y_n equal to or less than 0.008856.

$$L^* = 903.3(Y/Y_n) \quad Y/Y_n \leq 0.008856$$

6.2.3 In calculating a^* and b^* , values of X/X_n , Y/Y_n , Z/Z_n less than 0.01, may be included if the normal equations are replaced by the following modified equations for all calculations of a^* and b^* :

$$\begin{aligned} a^* &= 500[f(X/X_n) - f(Y/Y_n)] \\ b^* &= 200[f(Y/Y_n) - f(Z/Z_n)] \end{aligned}$$

where:

$$\begin{aligned} f(X/X_n) &= (X/X_n)^{1/3} & X/X_n > 0.008856 \\ f(X/X_n) &= 7.787(X/X_n) + 16/116 & X/X_n \leq 0.008856 \\ f(Y/Y_n) &= (Y/Y_n)^{1/3} & Y/Y_n > 0.008856 \end{aligned}$$

$$f(Y/Y_n) = 7.787(Y/Y_n) + 16/116 \quad Y/Y_n \leq 0.008856$$

$$f(Z/Z_n) = (Z/Z_n)^{1/3} \quad Z/Z_n > 0.008856$$

$$f(Z/Z_n) = 7.787(Z/Z_n) + 16/116 \quad Z/Z_n \leq 0.008856$$

NOTE 2—To compare values of $\Delta E(AN40)$ calculated by means of the Adams-Nickerson (AN40) equation with ΔE_{ab}^* , multiply $\Delta E(AN40)$ values by the factor 1.1 to facilitate the comparison.

6.2.4 The magnitude, ΔE_{ab}^* , gives no indication of the character of the difference since it does not indicate the relative quantity and direction of hue, saturation, and lightness differences.

6.2.5 The direction of the color difference is described by the magnitude and algebraic signs of the components ΔL^* , Δa^* , and Δb^* :

$$\Delta L^* = L_1^* - L_0^*$$

$$\Delta a^* = a_1^* - a_0^*$$

$$\Delta b^* = b_1^* - b_0^*$$

where L_0^* , a_0^* , and b_0^* refer to the reference, and L_1^* , a_1^* , and b_1^* refer to the test specimen. The signs of the components ΔL^* , Δa^* , and Δb^* have the following approximate meanings (8):

$$+\Delta L^* = \text{lighter}$$

$$-\Delta L^* = \text{darker}$$

$$+\Delta a^* = \text{redder (less green)}$$

$$-\Delta a^* = \text{greener (less red)}$$

$$+\Delta b^* = \text{yellow (less blue)}$$

$$-\Delta b^* = \text{bluer (less yellow)}$$

6.2.6 For judging the direction of the color difference between two colors, it is useful to calculate their CIE 1976 hue angles h_{ab} and CIE 1976 chromas C_{ab}^* as follows:

$$h_{ab} = \tan^{-1}(b^*/a^*)$$

$$C_{ab}^* = [(a^*)^2 + (b^*)^2]^{1/2}$$

Differences in hue angle Δh_{ab} between the test specimen and reference can be correlated with differences in their visually perceived hue, except for very dark colors (9). Differences in chroma ΔC_{ab}^* can similarly be correlated with differences in visually perceived chroma.

6.2.7 For judging the relative contributions of differences in lightness, chroma, and hue to the total color difference between two colors, it is useful to calculate the CIE 1976 hue difference ΔH_{ab}^* between them as follows:

$$\Delta H_{ab}^* = [(\Delta E_{ab}^*)^2 - (\Delta L^*)^2 - (\Delta C_{ab}^*)^2]^{1/2}$$

where ΔE_{ab}^* is calculated as in 6.2.1 and C_{ab}^* is calculated as in 6.2.6; then the equation

$$\Delta E_{ab}^* = [(\Delta L^*)^2 + (\Delta C_{ab}^*)^2 + (\Delta H_{ab}^*)^2]^{1/2}$$

contains terms showing the relative contributions of lightness difference ΔL^* , chroma difference ΔC_{ab}^* , and hue difference ΔH_{ab}^* to the total color difference ΔE_{ab}^* .

6.3 Hunter L_H , a_H , b_H Color Space and Color-Difference Equation (2)—This approximately uniform color space is produced by plotting in rectangular coordinates the quantities L_H , a_H , b_H calculated as follows:

$$L_H = 10(Y)^{1/3}$$

$$a_H = 17.5(1.02X - Y)/(Y)^{1/3}$$

$$b_H = 7.0(Y - 0.847Z)/(Y)^{1/3}$$

where X , Y , and Z are tristimulus values for the CIE 1931 standard observer and standard illuminant C.

NOTE 3—The subscript L was used to denote Hunter in previous issues of this method.

6.3.1 The total difference ΔE_H between two colors each given in terms of L_H , a_H , b_H is calculated as follows:

$$\Delta E_H = [(\Delta L_H)^2 + (\Delta a_H)^2 + (\Delta b_H)^2]^{1/2}$$

6.3.2 The magnitude and direction of the color difference are described by considerations similar to those found in 6.2.4 and 6.2.5, respectively.

6.4 Friele-MacAdam-Chickering Color Space and Color-Difference Equation (3, 10)—This color space is more nearly perceptually uniform than the CIE 1931 space in terms of the MacAdam chromaticity-difference values (11). It is produced by a linear transformation of CIE 1931 tristimulus values X , Y , Z into tristimulus values P , Q , S as follows:

$$P = 0.724X + 0.382Y - 0.098Z$$

$$Q = -0.48X + 1.37Y + 0.1276Z$$

$$S = 0.686Z$$

Approximate lightness difference ΔL_{FMC-2} and chromatic differences ΔC_1 ("yellow-blue") and ΔC_3 ("red-green") are calculated as follows:

$$\Delta L_{FMC-2} = 0.279K_2(P\Delta P + Q\Delta Q)/aD$$

$$\Delta C_1 = K_1S(P\Delta P + Q\Delta Q)/bD^2 - K_1\Delta S/b$$

$$\Delta C_3 = K_1(Q\Delta P - P\Delta Q)/aD$$

where:

$$a^2 = 17.3 \times 10^{-6}(P^2 + Q^2)/[1 + 2.73P^2Q^2/(P^4 + Q^4)]$$

$$b^2 = 3.098 \times 10^{-4}(S^2 + 0.2015Y^2)$$

$$D = (P^2 + Q^2)^{1/2}$$

$$K_1 = 0.55669 + 0.049434Y - 0.82575 \cdot 10^{-3}Y^2$$

$$+ 0.79172 \times 10^{-5}Y^3 - 0.30087 \cdot 10^{-7}Y^4$$

$$K_2 = 0.17548 + 0.027556Y - 0.57262 \cdot 10^{-3}Y^2$$

$$+ 0.63893 \times 10^{-5}Y^3 - 0.26731 \cdot 10^{-7}Y^4$$

NOTE 4—The correlations between ΔL_{FMC-2} and perceived lightness, between ΔC_1 and perceived yellowness-blueness, and between ΔC_3 and perceived redness-greenness, are not well established and should not be used unless confirmed by visual observations.

NOTE 5—When $K_1 = K_2 = 1$, the FMC-1 equations are obtained.

6.4.2 The total difference ΔE_{FMC-2} between two colors is calculated as follows:

$$\Delta E_{FMC-2} = [(\Delta L_{FMC-2})^2 + (\Delta C_1)^2 + (\Delta C_3)^2]^{1/2}$$

7. Test Specimens

7.1 This method does not cover preparation techniques. Unless otherwise specified or agreed, prepare specimens in accordance with Practice D 3964.

8. Procedure

8.1 Select appropriate geometric conditions for color measurement in accordance with Guide E 179.

8.2 Operate the instrument in accordance with the manufacturer's instructions.

8.3 Standardize the instrument with a working standard. Restandardize at sufficient intervals to minimize the effects of instrumental drift.

8.4 When a spectrophotometer is used, obtain the reflectance values of the reference specimen and test specimens, in turn, at a sufficient number of wavelength intervals to permit accurate calculation of CIE tristimulus values. See Method E 308.

8.5 When a reflectance-reading filter colorimeter is used, obtain the reflectance values of the reference specimen and test specimens, in turn, with each of the filters.

8.6 When a color-scale-reading colorimeter is used, obtain scale values of the reference and test specimens, in turn.

8.7 For any instrument used, remeasure the working standard to determine whether instrumental drift has occurred during measurement. Compensate for instrumental drift, if observed, or remeasure specimens.

8.8 Measure at least three portions of each specimen surface to obtain an indication of uniformity. Record the location where these measurements were made on the specimen.

9. Calculation

9.1 Calculate color-scale values L^* , a^* , b^* , or L_H , a_H , b_H , or tristimulus values P , Q , S , if not obtained automatically.

9.2 Calculate color differences ΔE_{ab}^* , ΔE_H , or ΔE_{FMC-2} and their components, if not obtained automatically, as described in 6.2, 6.3, or 6.4, respectively.

10. Report

10.1 Report the following information:

10.1.1 Total color difference ΔE_{ab}^* , ΔE_H , or ΔE_{FMC-2} , of each test specimen from its reference.

10.1.2 For CIELAB color differences, L^*_0 , a^*_0 , b^*_0 for the reference, ΔL^* , Δa^* , Δb^* , and if desired Δh_{ab}^* , ΔC_{ab}^* , and ΔH_{ab}^* for each specimen.

10.1.3 For Hunter color differences, $L_{H,0}$, $a_{H,0}$, $b_{H,0}$ and ΔL_H , Δa_H , Δb_H for each specimen.

Standard Test Method for Finishes on Primed Metallic Substrates for Humidity-Thermal Cycle Cracking¹

This standard is issued under the fixed designation D 2246; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method describes conditions for testing an organic coating on a primed metallic substrate for cracking from humidity-thermal cycling or from loss of plasticizer, or both.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 ASTM Standard:

D 609 Methods for Preparation of Steel Panels for Testing Paint, Varnish, Lacquer, and Related Products²

3. Summary of Test Method

3.1 The tendency of an organic coating to develop cracking from humidity-thermal cycling or from loss of plasticizer, or both, is measured by alternate exposure in the humidity cabinet and in the cold box. At the end of the exposure period, the panels are rated for their degree of cracking.

4. Significance and Use

4.1 This test method provides an accelerated means of determining the tendency of an organic coating to fail by cracking when exposed to humidity-thermal cycling.

5. Apparatus

5.1 *Humidity Cabinet*, of such design and construction as to maintain a relative humidity of 100 % with condensation on the test specimens at all times and a temperature of $100 \pm 1^\circ\text{F}$ ($38 \pm 0.5^\circ\text{C}$).

5.2 *Cold Box*, of such design and construction that a temperature of $-10 \pm 3^\circ\text{F}$ ($-23 \pm 1.5^\circ\text{C}$) can be maintained.

NOTE—Most commercial household freezers are capable of maintaining this temperature.

5.3 *Rack*, as shown in Fig. 1, for supporting test specimens at an angle of 0 to 30° from the vertical position in

such a manner as to prevent contact between them during the test procedure.

5.4 *Grid*, of thin wires 3 by $8\frac{1}{2}$ in. (75 by 215 mm) constituting one hundred and two $\frac{1}{2}$ -in. (13-mm) squares, held in a frame $\frac{1}{2}$ in. wide, with outside dimensions 4 by $9\frac{1}{2}$ in. (100 by 240 mm).

6. Test Specimens

6.1 The test specimens shall be either samples of metallic products, prepared and coated in accordance with the specified production schedule, or coated metallic panels. The recommended panel size is 4 by 12 in. (100 by 305 mm).

7. Preparation of Test Specimens

7.1 The test specimens shall consist of steel meeting the requirements of Methods D 609, cleaned and prepared for coating in accordance with Procedure A of Method D 609. If desired, the metal panels selected for coating with organic coatings may be of any selected composition and may be cleaned and prepared according to commercial practice or by any procedure that is mutually agreed upon.

7.2 After coating, the specimens shall not be cleaned, and they shall be handled only by the edges.

8. Procedure

8.1 Support panels or specimens so that they will be held in a position 0 to 30° from the vertical in such a manner as to prevent contact between the panels during the test.

8.2 Place the panels in a humidity cabinet at 100°F (38°C) and 100 % relative humidity for a period of $24 \pm \frac{1}{2}$ h. Then transfer them to the cold box at $-10 \pm 3^\circ\text{F}$ ($-23 \pm 1.5^\circ\text{C}$) allowing a maximum of 30 s for the transfer. Leave the panels in the cold box for a period of $20 \pm \frac{1}{2}$ h. Remove the panels and allow to remain at room temperature for a period of $4 \pm \frac{1}{2}$ h, during which time rate them. This constitutes one cycle. Run the test for 15 cycles or as mutually agreed upon. During any interruption of the normal cycling, as on weekends, always leave the panels in the cold box.

9. Evaluation of Test Specimens

9.1 Lay the specimen upon a horizontal surface, finish side up, with the framed grid (5.4) placed upon it so that the bottom $8\frac{1}{2}$ in. (225 mm) is covered by mesh. (The frame itself excludes the first $\frac{1}{2}$ in. (13 mm) from edges of the specimen which may have been handled, or which may otherwise not be representative of the general area.) Make an evaluation by counting the number of grid squares within which one or more cracks is visible. This number shall constitute the rating.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.27 on Accelerated Testing.

Current edition approved May 29, 1987. Published July 1987. Originally published as D 2246 - 64 T. Last previous edition D 2246 - 65 (1981)¹.

² Annual Book of ASTM Standards, Vol 06.01.

FIG. 1 Aluminum Rack for Supporting Test Specimens

9.2 If the specimen is necessarily smaller than 4 by 12 in. (100 by 305 mm), or is irregular in outline, handle in accordance with 3.4 and 9.1, and assign as the rating the percentage of those grid squares under which the specimen lies, that contain one or more cracks.

9.3 It is recommended that coatings be evaluated by comparison with a coating system known to have acceptable performance. For referee tests this coating system should be included in each test.

Standard Practice for Testing Water Resistance of Coatings in 100 % Relative Humidity¹

This standard is issued under the fixed designation D 2247; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

1. Scope

1.1 This practice covers the basic principles and operating procedures for testing water resistance of coatings by exposing coated specimens in an atmosphere maintained at 100 % relative humidity so that condensation forms on the test specimens.

1.2 This practice is limited to the methods of obtaining, measuring, and controlling the conditions and procedures of tests conducted in 100 % relative humidity. It does not specify specimen preparation, specific test conditions, or evaluation of results.

NOTE 1—Alternative practices for testing the water resistance of coatings include Practices D 870, D 1735, and D 4585.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

D 3359 Test Method for Measuring Adhesion by Tape Test²

D 3363 Test Method for Film Hardness by Pencil Test²

D 4585 Practice for Testing Water Resistance of Coatings Using Controlled Condensation²

3. Summary of Practice

3.1 Coated specimens are placed in an enclosed chamber containing a heated, saturated mixture of air and water vapor. The temperature of the chamber is usually maintained at 100°F (38°C). At 100 % relative humidity (RH), a very small temperature difference between the specimen and the surrounding vapor causes the formation of condensation on the specimens. The exposure condition is varied by selecting the duration of the test. Water permeates the coating at rates that are dependent upon the characteristics of the coating. Any effects such as color change, blistering, loss of adhesion, softening, or embrittlement are observed and reported.

4. Significance and Use

4.1 Water can cause the degradation of coatings, so knowledge of how a coating resists water is helpful in predicting its service life. Failure in tests at 100 % relative humidity may be caused by a number of factors including a deficiency in the coating itself, contamination of the substrate, or inadequate surface preparation. This practice is therefore useful for evaluating coatings alone or complete coating systems.

4.2 Tests at 100 % relative humidity are used for specification acceptance, quality control, and research and development of coatings and substrate treatments. These tests usually result in a pass or fail determination but the degree of failure may also be measured. A coating system is considered to pass if there is no evidence of water-related failure after a period of time.

4.3 Results obtained from the use of 100 % humidity tests in accordance with this practice should not be represented as being equivalent to a period of exposure to water in the natural environment, until the degree of quantitative correlation has been established for the coating or coating system.

4.4 The test chamber can be a small laboratory cabinet or a room large enough to hold an automobile or a truck. Some automobile manufacturers test completed vehicles in rooms maintained at 100 % relative humidity. Corrosion tests can be conducted, as the condensate dripping off the test articles is not recirculated.

5. Apparatus

5.1 *Test Chamber*, constructed of corrosion-resistant materials with supports for the test specimens.

- 0—Angle of lid, 90 to 125°
- 1—Hinged top, hydraulically operated, or counterbalanced
- 2—Water seal
- 3—Constant-level water tank unheated with overflow/outlet and equalizer connection
- 4—Heater water tank for supplying heat and humidity to cabinet
- 5—Immersion heater
- 6—Water temperature limit control
- 7—Thermostatic controller for room temperature. Primary limit control for immersion heater (5)
- 8—Water line
- 9—Insulation if necessary (see A1.3)
- 10—Temperature recorder (optional)
- 11—Drain

FIG. A1.1 Humidity Cabinet

5.2 *Heated Water Tank*, within the test chamber, a water supply, and a water level control.

5.3 *Thermostatic Control*, for the water heater with the sensor located adjacent to the specimen holders.

5.4 *Thermometer*, with sensor located adjacent to the specimen holders.

5.5 Diagrams and details of the apparatus are shown in the Annex.

6. Test Specimens

6.1 This practice does not cover the preparation of test specimens. The substrate composition and surface preparation, specimen preparation, and the number of specimens should be agreed upon prior to testing.

NOTE 2—Applicable methods for the preparation of test panels and substrates are given in Method D 609 and Practices D 1730. Test Methods D 823 cover application techniques for the production of uniform films.

7. Procedure

7.1 Fill the water tank with reagent water conforming to Type IV of Specification D 1193. Tap water may be used, but this will result in the accumulation of residues in the water tank over a period of time.

7.2 Adjust the temperature of the saturated air and water vapor mixture to $38 \pm 1^\circ\text{C}$ ($100 \pm 1^\circ\text{F}$).

NOTE 3—Due to heat loss to the specimens and the walls of the chamber, the temperature of the water in the tank will be above the temperature of the air and water vapor mixture.

7.3 Support the specimens approximately 15° from the vertical. Slotted wood supports are suitable for flat specimens. Provide for formation of condensation on the speci-

mens by spacing them at least 30 mm apart. Space the specimens so they do not touch each other, any metallic material, or any material capable of acting as a wick. Arrange specimens so that condensate from one specimen cannot drip on other specimens.

7.4 Droplets of condensation should be visible on the specimens at all times if the chamber is operating properly. Operate the test continuously with the test chamber closed unless otherwise specified. Short interruptions to inspect or remove specimens are permitted.

7.5 Conclude the test after a specified period of time or after effects from exposure to water are observed.

7.6 Wipe the test specimens dry. Rate specimens for changes in color, blistering, etc. Evaluate specimens no less than 5 min and no more than 10 min after removal from test, as the effects from water exposure can change within a short time. Remove only as many specimens as can be rated within the specified time.

NOTE 4—The 0 to 10 scale described in ASTM STP 500⁶ is preferred for rating. Relevant procedures for evaluating water effects are described in Test Methods D 610, D 714, D 2616, D 3359, and D 3363.

7.6.1 If possible, rate the specimens again after they have been removed from the test for a recovery period long enough that moisture absorbed within the specimens dries out and the specimens reach moisture equilibrium with room air. A recovery period from 12 to 24 h is generally sufficient. The post-recovery rating allows evaluation of the permanent effects of the exposure as distinct from the transient effects, and is especially important for evaluation of color and gloss.

8.1.2 Results of the evaluation(s).

8.1.3 Reference to Practice D 2247.

8.1.4 Hours of test duration.

8.1.5 Test temperature.

8.1.6 Special conditions of test or any deviations in test procedure.

ANNEX

(Mandatory Information)

A1. Apparatus

A1.1 The apparatus must be constructed so that heated water vapor is generated at the bottom of the chamber. This saturates the air immediately above the water tank with water vapor. The saturated mixture of water vapor and air

temperature rises and then cools below the dew point, causing condensation on the specimens.

A1.2 The area of the heated water tank should be limited to no more than 25 % of the floor area of the chamber. The use of a large heated water tank would tend to make the temperature within the chamber uniform, and thus inhibit or prevent the formation of condensate on the specimens. The water temperature will be approximately from 10 to 20°F (5 to 10°C) above the vapor temperature when the water tank and chamber are properly proportioned.

A1.3 Insulation of the enclosure is not required and can possibly interfere with the formation of condensate by reducing the temperature differential within the chamber. It is difficult to produce condensation with small chambers because the temperature differential is slight.

A1.4 Large walk-in chambers may require more than one heated water tank to generate the convective currents needed to cause condensation at all points within the chamber. Circulating fans should be used with caution as their use may reduce the temperature differential and limit condensation.

A1.5 In a properly operating chamber, condensation is observed on the specimens or parts when the chamber is opened for inspections. It may be necessary to avoid placing specimens in the lower portion of the chamber as the temperature differentials at the lower levels may be too small to induce condensation.

A1.6 In the event that enough condensation does not occur, or condensation does not form at all the desired points, it is possible to increase condensation by:

A1.6.1 Opening the chamber to allow the temperature to drop,

A1.6.2 Turning off the water heater periodically to cause temperature fluctuations, or

A1.6.3 Removing the specimens to allow them to cool down to room temperature.

A1.7 Many variations in the design of the apparatus are possible in the use of this practice. Two typical designs are shown in Figs. A1.1 and A1.2.

- 1—Temperature recorder
- 2—Fiberglass door with magnetic closers and rubber seal; inward sloping sill
- 3—Light switch
- 4—Thermostatic controller for room temperature. Primary limit control for immersion heater (6)
- 5—Heated water tank for supplying heat and humidity to room
- 6—Immersion heater
- 7—Water temperature limit control
- 8—Constant level water tank unheated with overflow outlet
- 9—Equalizer connection
- 10—Floor drain

NOTE—The chamber shall feature waterproof construction with insulation and vaporproof fixtures on the interior, lighting may be accomplished with a fluorescent fixture above insulating glass sealed in the ceiling. Polyvinyl chloride pipe and flanges shall be used for sleeves through walls.

FIG. A1.2 Walk-in Humidity Chamber

Standard Practice for Detergent Resistance of Organic Finishes¹

This standard is issued under the fixed designation D 2248; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers the determination of the resistance to failure, in an accelerated manner, of organic finishes when immersed in a detergent solution.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

D 2244 Test Method for Calculation of Color Differences From Instrumentally Measured Color Coordinates²

3. Significance and Use

3.1 Any effects such as color change, blistering, loss of adhesion, softening, or embrittlement are observed and noted.

4. Apparatus

4.1 **Container**—A corrosion-resistant container equipped with the means to control the solution temperature within the range specified and to control the liquid level at $\pm 3/16$ in. (5 mm). Agitation may be required to maintain temperature uniformity.

4.2 **Cover**—The container shall be provided with a cover to retard evaporation and to contain the test specimens completely.

5. Test Specimens

5.1 Unless otherwise specified, the test specimens shall be 4 by 12 in. by 20 gage (100 by 300 by 0.9 mm) in size. The test specimen composition, surface preparation, and number of test specimens shall be agreed upon by the purchaser and the seller.

NOTE 1—Applicable test panel description and surface preparation methods are as follows:

Methods D 609, Practices D 1730 and D 2092.

6. Coating of Test Specimens

6.1 The method of application, film thickness, curing, and conditioning of the test surface shall be agreed upon by the purchaser and the seller.

NOTE 2—Application and film thickness measurement methods are given as follows:

Test Methods D 823, D 1005, D 1186, and D 1400.

6.2 The backs, cut edges, and those areas containing identification marks or in contact with the supports, shall be protected with a suitable coating that is stable under the conditions of test.

7. Detergent Solution

7.1 Composition, concentration, and temperature of detergent solution shall be agreed upon by the purchaser and the seller.

7.2 A typical solid detergent composition is as follows:

Parts by Weight	
Tetrasodium pyrophosphate ($\text{Na}_4\text{P}_2\text{O}_7$), anhydrous	53.0
Sodium sulfate (Na_2SO_4), anhydrous	19.0
Sodium metasilicate (Na_2SiO_3), anhydrous	7.0
Sodium carbonate (Na_2CO_3), anhydrous	1.0
Sodium salt of a linear alkylarylsulfonate (90 % flake grade)	20.0
Total	100.0

A suggested temperature of the detergent solution is $165 \pm 2^\circ\text{F}$ ($74 \pm 1^\circ\text{C}$).

8. Procedure

8.1 *Immersion*—Suspend the test specimens vertically in the container so that at least one half of the surface area is submerged in the detergent solution. Separate the test specimens so that they are not in contact with any metal and are no closer together than 1 in. (25 mm) at any point in the bath. Replace the detergent solution with fresh detergent solution every 168 h. If successive tests are to be correlated, use reference panels coated with a control paint.

8.2 *Examination of Specimens*—When the specimens are ready for examination, carefully remove, gently wash or dip in clean running water not warmer than the temperature of the detergent solution to remove the detergent from the surface, and then carefully dry by blowing with air or blotting with absorbent paper. During the progress of the test, examine for deterioration of the film immediately. If reimmersion is necessary, do not allow the specimens to remain out of the liquid in excess of $\frac{1}{2}$ h, unless otherwise specified. Examine the test coating for the failures specifically agreed upon by the purchaser and the seller.

NOTE 3—The following methods of evaluating finish degradation in this method are applicable:

Test Methods D 523, D 714, D 1474, and D 2197, and Methods D 610, D 1654, and D 2244.

8.3 *Length of Test*—The length of test and the intermediate examination periods shall be as designated by the specification covering the organic finish being tested or as mutually agreed upon by the purchaser and the seller.

9. Precision and Bias

9.1 Precision data are based on a round robin in which

three finishes applied to two substrates were tested in six laboratories with each laboratory making two runs of five replicates of each variation. Blister failure was reported by all cooperators using Test Method D 714. To simplify the evaluation of blistering data the blister ratings were converted to single numerical values by the formula $\text{Frequency Number} \times \text{Size} \div 10 = \text{Numerical Value}$. The Frequency Numbers assigned were as follows:

No blistering	10
Very few	9
Few	8
Few medium	6
Medium	5
Medium dense	4
Dense	2

By this system, few Size 8 blistering would have a numerical value of 6.4. The adequacy of precision depends upon the purpose of the test and should be determined by the user from the data supplied.

9.1.1 Using these numerical values the standard deviations for the three finishes were as follows (rounded to nearest-tenth):

Finish	Within Laboratory	Between-Laboratory
1	0.8	1.4
2	0.4	0.6
3	1.3	2.6

9.1.2 Repeatability:

Finish	Difference
1	2.8
2	1.5
3	4.5

9.1.3 Reproducibility:

Finish	Difference
1	4.9
2	2.2
3	9.0

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. Standard Practice for Specifying Properties from Liquid Through Cured State for Coatings Factory Applied to Wood Products¹

This standard is issued under the fixed designation D 2336; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Keywords were added editorially in August 1991.

1. Scope

1.1 This practice summarizes the test methods that may be used to assist in quality control during application and in specifying pigmented coatings that shall be used in factory finishing of wood products.

1.2 This practice is not intended for use by the consumer of coated wood products in specifying such coated wood products.

1.3 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2.2 U.S. Federal Test Method:

141b/3011 Condition in Container⁶

3. Significance and Use

3.1 Control of the parameters that are measured by the test methods outlined in this practice has been found to be the primary determinant of coating quality and reproducibility in the package, during coating application and on the coated product. Accurate measurement is essential if such control is to be achieved.

4. Characteristics in the Package

4.1 *Skinning, Settling, and Condition in the Container:*

4.2 Settling is determined in accordance with Test Method D 869, and by Federal Test Method No. 141b, Method 3011 which also covers condition in the container. Both of these methods are designed for trade sales type paints rather than industrial coatings, but could be adapted satisfactorily.

4.3 Skinning can occur in a partially filled container. Remove insoluble skins and perform a skinning test on a well-mixed portion in accordance with Guide D 154.

4.4 *Consistency*—Consistency of a paint varies considerably depending upon the type of instrument used to measure it. Consistency is determined in accordance with Test Method D 562 and Test Method D 1200. For most coatings there is not a straight line relationship between Stormer viscosity, a rotational method, and Ford cup viscosity, an efflux method. (The Zahn efflux cup and the Brookfield Rotational Viscometer (Test Methods D 2196) are also used widely by the paint industry.)

4.4.1 Most factory wood finishing is done with airless spray, curtain coating, or roller coating techniques. It is doubtful that any single method of viscosity measurement is truly indicative of the ability of coatings to be applied by production methods or, more especially, to be applied satisfactorily by curtain coating.

4.4.2 These methods are useful in that once a certain formula has been established, control of the viscosity by either method helps to ensure subsequent reproduction of that formula. In this way, they would be useful in specifying previously qualified coatings for factory finishing of wood products.

4.5 *Fineness of Dispersion*—The fineness of dispersion determined in accordance with Test Method D 1210, is based on visual observation of a few of the largest size particles remaining in a coating after dispersion. In itself, the test does not indicate the degree of dispersion of the bulk of the pigment in the coating except that when batches are dispersed in similar equipment the ratio of large particles remaining in the coating to the dispersion of the bulk of the pigment tends to remain constant. Therefore, if in an enamel with satisfactory gloss no particles remain that are above a size of 0.5 mil (7 Hegman dispersion), then successive batches of that coating having a similar Hegman rating can be said to have a good enamel grind. Hiding power and color control along with fineness of dispersion control should be adequate to ensure proper dispersion.

4.6 *Weight per Gallon*—Weight per gallon is determined in accordance with Test Method D 1475 to ensure batch-to-batch and composition product uniformity. This method is not related to the quality of the coatings per se.

4.7 *Nonvolatile Content*—Non-volatile content is determined in accordance with Test Methods D 1644 as another measure of coating uniformity and of the amount of film-forming material provided.

4.8 *Volatile Organic Content (VOC)*—VOC is determined in accordance with Practice D 3960 both to ensure coating uniformity and to comply with governmental regulation where required.

4.9 *Flash Point*—Flash point is determined in accordance with Test Methods D 3278 as a measure of the degree of

flammability or fire hazard of a coating material.

5. Coating Characteristics During and Immediately After Application

5.1 *Flow*—Flow is a property related to consistency, but it is influenced by other factors such as rate and order of solvent release. Visual observation of the leveling of a coating film during and after drying and the tendency of the film to sag during application and drying are usually adequate to determine flow. However, Test Method D 2801 may be used if desired.

5.2 *Gloss*—Specular gloss may be determined in accordance with Test Method D 523.

5.3 *Hiding Power*—Hiding power determined in accordance with Test Method D 2805 is a measure of the ability of a paint to hide the substrate. It is dependent upon uniform film thickness which is influenced by flow and leveling.

5.4 *Wet Film Thickness*—The thickness of a wet paint film is determined in accordance with Test Methods D 1212 as a rapid indication that the required amount of coating has been applied.

6. Coating Characteristics During and Immediately After Curing

6.1 *Curing Temperature*—The temperature of a coating film during the curing cycle is an important quality control parameter and should be monitored. Practice D 3259, discusses several infrared measuring instruments that can be used for such monitoring. Infrared measuring instruments can be based on the measurement of carefully filtered narrow bands of infrared energy emitted from test surfaces and can be unaffected by surface color or gloss. Thermocouples have been used but are subject to the defects that metals are good heat conductors and do not necessarily absorb heat from infrared radiation at the same rate as the paint film. Better results are obtained with portable pyrometers if they are preheated slightly above the operating temperature. Papers impregnated with wax powders of varying melting points have been suggested also. These tend to absorb infrared energy faster than most wet paint films and, therefore, give higher temperatures than actual.

6.2 *Film Thickness*—Measurement of film thickness in accordance with Test Methods D 1005, is designed for use on plane rigid surfaces such as metal or glass. It can be adapted to forest products by the simple use of an auxiliary panel of metal or glass placed alongside the wood substrate and coated in the identical way that the wood substrate is coated. Test Methods D 1400 or D 1186 also could be adapted to the forest products industry in a similar manner. This is a simpler but perhaps less accurate method. This adaptation leads to a measurement of application rate rather than to a true measurement of film thickness of the coating on a wood product because of the possibility of penetration by the coating into the wood product. Test Methods D 2691 gives a method for measuring the actual film thickness present on a wood products substrate.

6.3 *Hardness*—The measurement of hardness of coating films by means of an indenter, as described in Test Methods D 1474, calls for the measurement of film hardness on smooth, rigid substrates such as glass or metal. There may be some question as to its applicability on films applied to some

of the softer forest products substrates. However, if the films are thick enough (1.5 mils or greater), it should be applicable on the harder forest products substrate.

6.4 Color Difference—Color difference between a product and the standard can be measured instrumentally. Generally, the tolerance is agreed upon by the purchaser and the seller and may also be required if a product specification is involved. Although color instruments are not more sensitive than the eye, and Practice D 1729 may be used for visual evaluation of color differences, color instruments do provide numerical values that can be subsequently compared to later measurements. Test Method D 2244 covers the instrumental determination of small color differences observable in daylight illumination between nonfluorescent, nonmetameric, or opaque surfaces such as coated specimens. If metamerism is suspected, visual evaluation should be used to verify the results.

6.5 Adhesion—There are no available ASTM test methods

directly applicable to measuring adhesion on forest products substrates. It has been found that the available test methods have poor precision even on hard, smooth substrates. They would probably be even less satisfactory on wood substrates. Two methods that might give some indication of adhesion are Test Methods D 2197 and D 3359.

6.6 Blocking—Many coated wood products are immediately stacked after curing. Often they are subject to "blocking" or sticking together if improperly coated or cured. Test Method D 2793⁷ may be used to detect and quantify the degree of blocking. It may be used as a control test to detect this condition during the coating operation.

7. Keywords

7.1 cured properties; factory application; wood coatings; wood products

⁷ Subcommittee D01.52 is developing a revision to Test Method D 3003 to replace Test Method D 2793.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Freeze-Thaw Stability of Multicolor Lacquers¹

This standard is issued under the fixed designation D 2337; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the extent to which multicolor lacquers resist coagulation and coalescence when subjected to freezing and subsequent thawing.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

- 2.1 *ASTM Standard:*
D 562 Test Method for Consistency of Paints Using the Stormer Viscometer²

3. Summary of Test Method

3.1 Specimens of multicolor lacquers are placed in a chamber maintained at a temperature between -10 and -15°F (-23 and -26°C) and allowed to remain 24 h. The specimens are removed from the chamber and allowed to remain at room temperature for 24 h to reach thermal equilibrium. After the specimens are mixed and the viscosity adjusted, they are then sprayed and allowed to dry before comparing with the control standard sprayed from the original specimen.

4. Significance and Use

4.1 Waterborne coatings, when subjected to cycles of freezing and thawing, can undergo detrimental changes in application and performance characteristics. This test method evaluates the ability of multicolor lacquers to resist these changes.

5. Apparatus and Materials

5.1 *Cabinet, Room, or Enclosed Space*, large enough to contain the specimens to be tested and allowing at least 1 in. (25 mm) of air space between the sides of adjacent cans. It should be capable of being maintained at a temperature between -10 and -15°F (-23 and -26°C).

5.2 *Stormer Viscometer*, with paddle-type rotor.

5.3 *Spray Gun*, pressure-feed internal-mix type, tip 0.086 in. (2 mm) in diameter with wide-spray nozzle.

5.4 *White Paper Stock*, minimum size 8 by 11 in. (200 by 280 mm).

6. Preparation of Samples

6.1 For all gloss and semigloss multicolor lacquers, prepare ten 1-qt (1-L) specimens and for flat multicolor lacquers four 1-qt specimens for testing. Mix the sample from which the specimens are filled well by boxing so that it is of a uniform consistency and appearance. After recording the consistency reading as determined with a Stormer viscometer (in accordance with Test Method D 562 fill all samples in baked varnish-lined containers and apply the lids promptly to prevent evaporation loss).

7. Preparation of Control Standard

7.1 Prepare a control standard by spraying from one of the 1-qt (1-L) specimens of each product to be tested. Use a coated white paper stock and spray on a sheet at least 8 by 11 in. (200 by 280 mm) in size. Adjust the fluid and atomizing pressures to give a spreading rate of 150 to 200 ft^2/gal (3.7 to 4.9 m^2/L) for complete covering and 200 to 300 ft^2/gal (4.9 to 7.35 m^2/L) for scatter coat application.

8. Exposure of Samples to Test Conditions

8.1 Place nine specimens of all gloss and semigloss multicolor lacquers and three specimens of all flat multicolor lacquers under test in the chamber that is maintained between -10 and -15°F (-23 and -26°C). Place the specimens on racks in such a manner that they do not touch the walls or bottom of the chamber and so that there is at least 1 in. (25 mm) of air space between adjacent specimens. On each cycle allow all specimens to remain in the chamber for 24 h before removal. Remove from the chamber all specimens of each multicolor lacquer and let them come to thermal equilibrium by allowing them to remain at room temperature (77°F (25°C)) for 24 h. Mix these specimens to a uniform consistency by boxing. Run a minimum of three specimens and all specimens shall pass the test for multicolor to be acceptable.

9. Examination of Samples and Spray After Test

9.1 Check the consistency of all specimens on the Stormer viscometer after each test cycle and adjust if necessary by adding water to the viscosity of the original before testing. Spray three specimens after each cycle on white paper stock using the same equipment and adjustments of the spray gun that were used to spray the control standard. Allow the sprayed panels to dry thoroughly (16 h) and compare with the control standard in each case for color, particle size, and pattern of the background as well as the accent colors.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.55 on Factory-Applied Coatings on Preformed Products.

Current edition approved Nov. 14, 1984. Published January 1985. Originally published as D 2337 - 65 T. Last previous edition D 2337 - 68 (1979) ϵ 1.

² *Annual Book of ASTM Standards*, Vol 06.01.

10. Report

10.1 Report significant change in color, particle size, or tendency to show coalescence or coagulation when compared with the control standard. To be considered satisfactory for freeze-thaw resistance, all gloss and semigloss multicolor lacquers shall show a satisfactory appearance after three cycles and all flat multicolor lacquers shall show a satisfactory appearance after one cycle.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

11. Precision

11.1 It is recognized that the seller has no control over the conditions under which the purchaser will apply multicolor lacquer finishes and, therefore, meaningful estimates of precision cannot be given. In round-robin tests fairly good agreement was obtained by the cooperators as long as the same equipment was used to spray the multicolor before and after the test.

Standard Test Method for Determining Particle Size of Multicolor Lacquers¹

This standard is issued under the fixed designation D 2338; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Editorial changes were made throughout, including the title, in April 1989.

1. Scope

1.1 This test method employs photographic reference standards to evaluate the particle size of multicolor lacquers.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Adjuncts:*
Grain Sizes (5 photos)²

3. Summary of Test Method

3.1 The samples to be tested are mixed by pouring from one container to another until they are uniform in consistency before spraying on coated white paper stock. After the lacquers are dry they are compared with photographic reference standards to determine the particle size.

4. Significance and Use

4.1 This test method provides a uniform nomenclature for the producer and user in the identification of the various particle sizes used in the manufacture of nitrocellulose-type multicolor lacquers.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.55 on Factory-Applied Coatings on Preformed Products.

Current edition approved Aug. 31, 1984. Published January 1985. Originally published as D 2338 - 65 T. Last previous edition D 2338 - 68 (1979)^{e1}.

² Glossy prints of the photographic reference standards showing various particle sizes are available at nominal charge from ASTM Headquarters. Request Adjunct No. 12-423380-00.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

5. Reference Standards

5.1 The photographic reference standards² were prepared by photographing actual sprayed panels of multicolor lacquers that were made in the five particle sizes normally used in commercial multicolor lacquers. The standard designations are as follows (Figs. 1 (a), (b), (c)): fine, small, medium, large, and extra large, and represent the correct nomenclature for properly applied multicolor lacquer.

6. Apparatus

6.1 *Spray Gun*, pressure-feed internal-mix type, tip 0.086 in. (2.2 mm) in diameter with wide-spray nozzle.

7. Procedure

NOTE—The particle size of multicolor lacquer is dependent upon the spray conditions during the application procedure. In order to get uniform results the exact spray conditions should be agreed upon between the purchaser and the seller.

7.1 Spray the lacquer on a coated white paper panel with the fluid and atomizing pressures adjusted to give a spreading rate of 150 to 200 ft²/gal (3.7 to 4.9 m²/L) for complete covering and 200 to 300 ft²/gal (4.9 to 7.35 m²/L) for scatter coat application. After the sprayed lacquer is thoroughly dry, determine the particle size on the panel by comparing it to the photographic reference standards.²

8. Precision

8.1 This test method entails the use of visual judgment and as such does not readily lend itself to a precision statement.

8.2 In general there has been good agreement between operators in judgment of particle size.

9. Keywords

Standard Test Method for Arsenic in Paint¹

This standard is issued under the fixed designation D 2348; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of less than 0.5 % arsenic in whole paint.

1.2 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 ASTM Standard:

D 1193 Specification for Reagent Water²

3. Summary of Test Method

3.1 The specimen of liquid paint is prepared for analysis by acid-digestion. The arsenic content of a distillate from the acid-digested sample is determined by titration with KBrO_3 solution.

4. Significance and Use

4.1 The permissible level of toxic elements in certain coatings is specified by governmental regulatory agencies. This test method provides a documented procedure for determining low concentrations of arsenic present in whole paint to determine compliance.

5. Apparatus

5.1 *Kjeldahl Flask*, 800-mL, with standard-taper 24/40 joint.

5.2 *Condenser Delivery Tube*, with standard-taper 24/40 joint.

5.3 *Mechanical Shaker*.

5.4 *Gas Burner*, suitable for heating Kjeldahl flask.

5.5 *Glass or Disposable Syringes*, 2 mL capacity.

5.6 *Erlenmeyer Flasks*, 250 and 500 mL capacity.

5.7 *Pipets*, 10 mL capacity.

6. Reagents

6.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chem-

ical Society, where such specifications are available.³ Other grades may be used, provided it is ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

6.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent grade water conforming to Type II of Specification D 1193.

6.3 *Arsenous Oxide, Standard Solution*—Dissolve 0.3241 g of arsenous oxide (As_2O_3) in 25 mL of sodium hydroxide (NaOH) solution (100 g/L). Make slightly acid with sulfuric acid (H_2SO_4 , 1+8), and dilute to 1.0 L with water.

6.4 *Hydrazine Sulfate-Potassium Bromide Solution*—Dissolve 20 g of hydrazine sulfate ($\text{N}_2\text{H}_4 \cdot \text{H}_2\text{SO}_4$) and 23 g of potassium bromide (KBr) in 200 mL of concentrated hydrochloric acid (HCl , sp gr 1.19) (Precaution—see 7.1) and dilute to 1 L.

6.5 *Methyl Orange Indicator Solution*—Dissolve 0.1 g in 100 mL water.

6.6 *Nitric Acid* (sp gr 1.42)—Concentrated nitric acid (HNO_3) (Precaution—see 7.1).

6.7 *Potassium Bromate, Standard Solution*—Dissolve 0.18 g of potassium bromate (KBrO_3) in water and dilute to 1 L with water. Standardize as follows: Transfer 10.0 mL of standard arsenous oxide solution by pipet to a 250-mL flask. Add 100 mL of water and 25 mL of HCl (sp gr 1.19). Heat to 90°C and titrate with KBrO_3 as described in 8.5. Calculate the standardization factor, F , as follows:

$$F = (0.0032410 \times 0.7574) / V$$

where:

0.0032410 = As_2O_3 in 10.0 mL of solution, g,

0.7574 = factor converting As_2O_3 to As, and

V = KBrO_3 required for the titration, mL.

6.8 *Sodium Chloride* (NaCl).

6.9 *Sulfuric Acid* (sp gr 1.84)—Concentrated sulfuric acid (H_2SO_4) (Precaution—see 7.1).

7. Hazards

7.1 Handling concentrated acids can be hazardous. Refer to their individual Material Safety Data Sheets (MSDS).

8. Procedure

8.1 Mix the sample until it is homogeneous, preferably on a mechanical shaker.

8.2 Weigh to 1 mg from a glass syringe, 1.0 g of whole paint directly into the 800-mL Kjeldahl flask, being careful

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Material.

Current edition approved Oct. 15, 1991. Published December 1991. Originally published as D 2348 - 65 T. Last previous edition D 2348 - 85.

² *Annual Book of ASTM Standards*, Vols 06.03 and 11.01.

³ "Reagent Chemicals, American Chemical Society Specifications," Am. Chemical Soc., Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY and the "United States Pharmacopeia."

not to get any on the sides of the flask. Add approximately 10 boiling aids.

8.3 Digest by adding the following: 40 mL of HNO_3 (allow to stand 20 min) and 25 mL of H_2SO_4 (allow to stand 5 min). Boil; when charring occurs, add HNO_3 cautiously until the solution becomes clear and begins to reflux within the flask. The flask should be at about a 45° angle while digesting. Cool, carefully add 150 mL of water, and boil to sulfur trioxide (SO_3) fumes.

8.4 Add 100 mL of water and a thermometer to an Erlenmeyer flask. After the solution in the Kjeldahl flask has cooled, add 25 mL of water, 25 g of NaCl, and 25 mL of the hydrazine sulfate-potassium bromide solution, and connect the distillation tube so that the delivery end is immersed in the receiving water. Quickly heat the Kjeldahl flask over a small, well-protected flame, and distill into the Erlenmeyer flask (Note 1). Adjust the flame so that the temperature of the distillate solution will rise to 80°C in 9 to 11 min, and then discontinue distillation by first removing the thermometer, lifting the distillation tube out of solution slightly and turning the heat off.

NOTE 1—Although it may be necessary to boil the solution, heating is primarily to bring about evolution of hydrogen chloride (HCl) gas, which carries over the arsenic trichloride (AsCl_3). Absorption of evolved HCl gas by water causes a rise in temperature which indicates progress of distillation. If distillation proceeds further, or if a larger quantity of H_2SO_4 than specified is used in digestion, sulfur dioxide (SO_2) will be distilled and titrated as arsenic.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

8.5 Titrate the distillate at once with KBrO_3 solution, using 3 drops of methyl orange indicator solution. Toward the end of the titration add the KBrO_3 solution very slowly with constant agitation to prevent a local excess. The end point is reached when a single drop of the KBrO_3 just destroys the final tinge of red. Correct the results for the volume of KBrO_3 used in a blank determination (digest 5 g of pure sucrose, using the same reagents and procedure).

NOTE 2—The blank titration should not exceed 0.7 mL of KBrO_3 solution. The method is accurate down to variations in the blank, which should not exceed 0.1 mL when reagents from the same lot are used.

9. Calculation

9.1 Calculate the percent of arsenic in the sample as follows:

$$\text{Arsenic, \%} = [(V - B) \times F] / S \times 100$$

where:

V = KBrO_3 solution required for the sample, mL,

B = KBrO_3 solution required for the blank, mL,

S = sample used, g, and

F = factor as calculated in 6.7.

10. Precision and Bias

10.1 Precision and bias of this test method have not been determined.

Standard Test Method for Qualitative Determination of Nature of Solvent Composition in Solvent-Reducible Paints¹

This standard is issued under the fixed designation D 2349; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the nature of solvent in solvent-reducible house paints containing only hydrocarbon solvents.

1.2 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

- D 215 Methods of Chemical Analysis of White Linseed Oil Paints²
- D 233 Methods of Sampling and Testing Turpentine³
- D 1193 Specification for Reagent Water⁴

3. Significance and Use

3.1 This test method provides a procedure for determining qualitatively the composition of solvent in paints containing only hydrocarbon solvents.

4. Reagents

4.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁵ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

4.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water conforming to Type IV of Specification D 1193.

4.3 *Antimony Pentachloride* (SbCl_5).

4.4 *Chloroform*.

4.5 *Nitric Acid* (sp gr 1.42)—Concentrated nitric acid (HNO_3).

4.6 *Sulfuric Acid* (sp gr 1.84)—Concentrated sulfuric acid (H_2SO_4).

5. Preparation of Sample

5.1 Mix and prepare the sample in accordance with Methods D 215.

6. Nature of Solvent

6.1 Transfer approximately 150 g of the paint to a 500-mL flask fitted with a 2-hole cork stopper carrying a spray trap connected with a suitable condenser. Through the other hole in the stopper pass an influx tube for steam. (This tube should dip below the surface of the paint.) Heat the flask in an oil or air bath at 100°C and pass through it a current of steam; with the steam still passing through, raise the temperature of the bath to 130°C. Catch the distillate in a small separatory funnel; continue distillation until 300 mL of water have been obtained. Portions of this water may be drawn from the cock of the separatory funnel from time to time, but care must be taken not to draw out any of the volatile solvent.

6.2 Let the distillate stand until it separates into two layers, then draw off the water and filter the volatile solvent through a dry filter paper into a dry flask. If the solvent is apparently turpentine, examine the distillate in accordance with Color, Odor, Specific Gravity, Refractive Index and Distillation sections of Methods D 233. If the solvent is a mixture of turpentine and petroleum spirits, an approximate determination of the amount of turpentine may be made in accordance with the Polymerization sections of Methods D 233. (It should be noted that turpentine is slightly soluble in water, about 0.3 to 0.4 mL/100 mL of water.)

6.3 To test for benzene, add a few drops of the distillate to a small quantity of a mixture of HNO_3 (sp gr 1.42) and H_2SO_4 (sp gr 1.84) and heat cautiously. The characteristic odor of nitrobenzene will be noted if benzene is present.

NOTE 1—Toluene may give a similar odor.

6.4 If the solvent is apparently all petroleum spirits, no further examination is necessary unless further information is desired.

6.5 When the amount of turpentine in the solvent is so small that its presence is questionable, it may be detected by placing 2 drops of the distillate and 2 to 3 mL of chloroform in a dry test tube and adding 1 drop of SbCl_5 . A slow or slight change in color indicates the absence of turpentine. A rapid change in color to a dark red or purple indicates the possibility of turpentine. The iodine number for turpentine

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Materials.

Current edition approved May 25, 1990. Published July 1990. Originally published as D 2349 - 65 T. Last previous edition D 2349 - 72 (1984)⁶.

**Standard Test Method for
Flow Ratings of Organic Coatings Using the Shell Flow
Comparator**

This test method covers the determination of the flow rating, in terms of flow-out characteristics or degree of film smoothness, of an organic film applied to a flat substrate.
Formerly under the jurisdiction of Committee D-1 on Paint and Related Coatings and Materials, this test method was discontinued in 1992.

Standard Test Method for Accelerated Testing of Moisture Blister Resistance of Exterior House Paints on Wood

This test method covers only an accelerated evaluation of the resistance to moisture blistering of exterior house paints for use on wood substrates.

Formerly under the jurisdiction of Committee D-1 on Paint and Related Coatings and Materials, this test method was discontinued in 1989.

Refer to Practice D 4585¹.

¹ *Annual Book of ASTM Standards*, Vol 06.01.

Standard Test Method for Volatile Content of Coatings¹

This standard is issued under the fixed designation D 2369; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This test method has been approved for use by agencies of the Department of Defense to replace Method 404 1.1 of Federal Test Method Standard No. 141. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

1. Scope

1.1 This test method describes a procedure for the determination of the weight percent volatile content of solvent-reducible and water-reducible coatings. Test specimens are heated at $110 \pm 5^\circ\text{C}$ for 60 min.

NOTE 1—The coatings used in these round-robin studies represented air-dried, air-dried oxidizing, and heat-cured baking systems.

1.2 Sixty minutes at $110 \pm 5^\circ\text{C}$ is a general purpose test method based on the precision obtained with both solvent-reducible and water-reducible coatings (see Section 9). These coatings (single package, heat cured) are commonly applied in factories to automobiles, metal containers, flat (coil) metal and large appliances, and many other metal parts.

NOTE 2—Testing at $110 \pm 5^\circ\text{C}$ for 20 min was utilized for the establishment of the original test method in 1965. Precision data are not available and may not have been properly generated at the time. The nine paints tested then were all solvent-reducible. These conditions, 20 min at $110 \pm 5^\circ\text{C}$, are no longer satisfactory for the determination of the volatile content of many coatings being tested at the present time. Water-reducible and solvent-reducible coatings were tested in the development of Test Method D 2369 using $110 \pm 5^\circ\text{C}$ for 60 min and 20 min for which precision data have been generated. See Appendix X1 for precision statements on the 20-min oven residence time.

1.3 This test method does not cover multi-package coatings wherein one or more parts may, at ambient conditions, contain liquid coreactants that are volatile until a chemical reaction has occurred with another component of the multipackage coating.

NOTE 3—Committee D-1 is running round-robin studies on the volatiles of multicomponent paint systems. The only change in procedure is to premix the weighed components in the correct proportions and allow the solvent reduced specimens in the aluminum pans to stand at room temperature for 1 h prior to placing them into the oven. Preliminary results with these changes appear to show that this test method is viable for multicomponent systems.

1.4 This test method may not be applicable to all types of coatings such as some printing inks (see Test Method D4713), and other procedures may be substituted with mutual agreement of the producer and user.

NOTE 4—If unusual decomposition or degradation of the specimen occurs during heating, the actual time and temperature used to cure the coating in practice may be substituted for the time and temperature

specified in this test method, subject to mutual agreement of the producer and user.

1.5 *This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For a specific hazard statement see Note 6.*

E 180 Practice for Determining the Precision Data of ASTM Methods for Analysis and Testing of Industrial Chemicals⁷

3. Summary of Test Method

3.1 A designated quantity of coating specimen is weighed into an aluminum foil dish containing 3 mL of an appropriate solvent, dispersed, and heated in an oven at $110 \pm 5^\circ\text{C}$ for 60 min. The percent volatile is calculated from the loss in weight.

4. Significance and Use

4.1 This test method is the procedure of choice for determining volatiles in coatings for the purpose of calculating the volatile organic content in coatings under specified test conditions. The inverse value, nonvolatile, is used to determine the weight percent solids content. This information is useful to the paint producer and user and to environmental interests for determining the volatiles emitted by coatings.

5. Apparatus

5.1 *Aluminum Foil Dish*, 58 mm in diameter by 18 mm

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Materials.

Current edition approved Sept. 12, 1990. Published November 1990. Originally published as D 2369 - 65 T. Last previous edition D 2369 - 87 ϵ 2.

⁷ Annual Book of ASTM Standards, Vol 15.05.

high with a smooth (planar) bottom surface. Precondition the dishes for 30 min in an oven at $110 \pm 5^\circ\text{C}$ and store in a desiccator prior to use.

5.2 *Forced Draft Oven*, Type IIA or Type IIB as specified in Specification E 145.

5.3 *Syringe*, 5-mL, capable of properly dispensing the coating under test at sufficient rate that the specimen can be dissolved in the solvent (see 7.2).

5.4 *Test Tube*, with new cork stopper.

5.5 *Weighing or Dropping Bottle*.

6. Reagents

6.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁸ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

6.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean Type II of Specification D 1193.

6.3 *Toluene*, technical grade, Specification D 362.

6.4 *2-Ethoxyethyl Acetate*, technical grade, Specification D 343.

7. Procedure

7.1 Mix the sample, preferably on a mechanical shaker or roller, until homogeneous. If air bubbles become entrapped, stir by hand until the air has been removed.

7.2 Using an appropriate weighing container (5.3, 5.4, or 5.5, with the syringe preferred for highest precision), weigh to 0.1 mg, by difference, a specimen of 0.30 ± 0.10 g for coatings believed to have a volatile content less than 40 weight % or a specimen of 0.50 ± 0.10 g for coatings believed to have a volatile content greater than 40 weight %, into a tared aluminum foil dish (5.5) into which has been added 3 ± 1 mL of suitable solvent (6.2, 6.3, or 6.4). Add the specimen dropwise, shaking (swirling) the dish to disperse the specimen completely in the solvent. If the material forms a lump that cannot be dispersed, discard the specimen and prepare a new one. Similarly prepare a duplicate.

NOTE 5—If the specimen cannot be dispersed in the solvents listed (6.2, 6.3, or 6.4) a compatible solvent may be substituted provided it is no less volatile than 2-ethoxyethyl acetate (6.4).

⁸ "Reagent Chemicals, American Chemical Society Specifications," Am. Chemical Soc., Washington DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY and the "United States Pharmacopeia."

7.3 Heat the aluminum foil dishes containing the dispersed specimens in the forced draft oven (5.2) for 60 min at $110 \pm 5^\circ\text{C}$.

NOTE 6: *Precaution*—In addition to other precautions, provide adequate ventilation, consistent with accepted laboratory practice, to prevent solvent vapors from accumulating to a dangerous level.

7.4 Remove the dishes from the oven, place immediately in a desiccator, cool to ambient temperature, and weigh to 0.1 mg.

8. Calculation

8.1 Calculate the percent volatile matter, V , in the liquid coating as follows:

$$V = 100 - [(W_2 - W_1)/S] \times 100 \quad (1)$$

where:

W_1 = weight of dish,

W_2 = weight of dish plus specimen after heating, and

S = specimen weight.

8.2 The percent of nonvolatile matter, N , in the coating may be calculated by difference as follows:

$$N = 100 - V \quad (2)$$

9. Precision and Bias

9.1 The precision estimated for tests at 60 min at $110 \pm 5^\circ\text{C}$ are based on an interlaboratory study⁹ in which 1 operator in each of 15 laboratories analyzed in duplicate on 2 different days 7 samples of water-based paints and 8 samples of solvent-based paints containing between 35 and 72 % volatile material. The paints were commercially supplied. The results were analyzed statistically in accordance with Practice E 180. The within-laboratory coefficient of variation was found to be 0.5 % relative at 213 degrees of freedom and the between-laboratories coefficient of variation was 1.7 % relative at 198 degrees of freedom. Based on these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level.

9.1.1 *Repeatability*—Two results, each the mean of duplicate determinations, obtained by the same operator on different days should be considered suspect if they differ by more than 1.5 % relative.

9.1.2 *Reproducibility*—Two results, each the mean of duplicate determinations, obtained by operators in different laboratories should be considered suspect if they differ by more than 4.7 % relative.

9.2 *Bias*—Bias has not been determined.

10. Keywords

10.1 nonvolatile determination; VOC baking temperature; VOC in paints; volatile determination

⁹ Supporting data are available from ASTM Headquarters. Request RE D01-1026.

APPENDIX

(Nonmandatory Information)

X1. PRECISION STATEMENT FOR 20-MIN OVEN RESIDENCE

X1.1 Oven residence time of 20 min for the paint test specimen at $110 \pm 5^\circ\text{C}$ was the original procedure for this test method. For information purposes, the precision statements for 20-min residence time are as follows:

- (1) X1.1.1 The precision estimates are based on an interlaboratory study in which 1 operator in each of 15 laboratories analyzed in duplicate on 2 different days 7 samples of water-based paints and 8 samples of solvent-based paints containing from 35 to 72 % volatile material. The paints were commercially supplied. The results were analyzed statistically in accordance with Practice E 180. The within-laboratory coefficient of variation was found to be 1.1 %

relative at 193 df and the between-laboratory coefficient of variation was 2.5 % relative at 178 df. Based on these coefficients the following criteria should be used for judging the acceptability of results at the 95 % confidence level.

(a) *Repeatability*—Two results, each the mean of duplicate determinations, obtained by the same operator on different days, should be considered suspect if they differ by more than 2.9 % relative.

(b) *Reproducibility*—Two results, each the mean of duplicate determinations, obtained by operators in different laboratories, should be considered suspect if they differ by more than 7.1 % relative.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Tensile Properties of Organic Coatings¹

This standard is issued under the fixed designation D 2370; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This method has been approved for use by agencies of the Department of Defense to replace Method 6224.1 of Federal Test Method Standards No. 141A. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

^{e1} NOTE—Paragraph 12.1.2 was editorially changed in November 1987.

^{e2} NOTE—Keywords were added editorially in July 1991.

1. Scope

1.1 This method covers the determination of the elongation, tensile strength, and stiffness (modulus of elasticity) of organic coatings when tested as free films.

1.2 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* Specific hazard statements are given in Section 7.

2. Referenced Documents

2.1 ASTM Standards:

- D 823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels²
- D 882 Test Methods for Tensile Properties of Thin Plastic Sheeting³
- D 1005 Test Methods for Measurement of Dry-Film Thickness of Organic Coatings Using Micrometers²
- D 3980 Practice for Interlaboratory Testing of Paint and Related Materials²

3. Summary of Method

3.1 Free unsupported films of the materials to be tested are prepared. The tensile properties of the free films are determined by means of a tensile testing apparatus.

4. Significance and Use

4.1 Tensile properties determined by this method are of value in studying the behavior of coatings subjected to environmental stresses, such as those produced by aging and weathering. (See Refs. (1) through (10).)⁴

4.2 Tensile properties may vary with specimen thickness, method of preparation, gage length, rate of load application,

tensile tester response, and type of grips used. Consequently, where precise comparative results are desired, these factors must be carefully controlled.

5. Description of Terms

5.1 *tensile strength (nominal)*—the load per original unit area at which a specimen fails or yields in a tension (pull) test.

5.2 *elongation*—the increase in specimen length from the point of initial load application to the point of film rupture in a tension test.

5.3 *stress-strain curve*—the curve resulting from a plot of tensile load against the distance of jaw separation (elongation of specimen).

5.4 *stiffness (modulus of elasticity)*—the load per unit area required to elongate the film 1 % from the first point in the stress-strain curve where the slope becomes constant.

5.5 *gage length*—the initial length of the test specimen between the jaws of the tensile tester.

6. Apparatus

6.1 Equipment for applying films of uniform thickness as described in Test Methods D 823.

6.2 *Micrometer Film Thickness Gage* as described in Method D 1005.

6.3 *Tensile Tester* of the constant rate of jaw separation type, equipped with load cells having capacities of 0.2 to 4.4 lb (100 to 2000 g), and equipped with an indicating device such as an electronic constant speed chart recorder, a digital device that displays numerical values, or a printer that records the numerical values.⁵

6.4 *Precision Specimen Cutter* having a double blade with a foot to hold the sample in place.⁶

6.5 *Alternative Substrates* on which test material can be deposited.

6.5.1 *Dental Tin Foil*, preferably 1 mil (25 μ m) thick.⁷

¹ This method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.23 on Physical Properties of Applied Paint Films.

Current edition approved June 25, 1982. Published September 1982. Originally published as D 2370 - 65 T. Last previous edition D 2370 - 68 (1973).

⁹ Dry lubric Chemical Co., I

6.5.2 *Sheet of FEP* (fluorinated ethylene-propylene),⁸ preferably 2 mils (50 μm) thick, coated with a dry lubricant.⁹

NOTE 1—Other substrates that may be suitable are 10-mil (250- μm) thick polyethylene (7), photographic paper (8), polished steel (9), and fluoropolymer coated metal panels.

7. Hazards

7.1 *Mercury*—Mercury is a toxic metallic liquid. Its vapors are extremely hazardous. Small amounts of spilled mercury can vaporize sufficiently at room temperature to exceed the TLV of the vapor. Use with adequate ventilation (in a hood) and clean up spills immediately. Wear gloves when handling mercury. Containers should be kept closed. Droplets of mercury can be picked up by using a small glass pipet connected to a suction flask with a rubber hose.

8. Test Specimens

8.1 The test specimens shall be free films having a width that is between $\frac{1}{2}$ and 1 in. (13 and 25 mm). No specimen shall vary by more than $\pm 2\%$ in width along its entire length. The length shall be at least 2 in. (50 mm) longer than the gage length selected for the test.

8.2 Prepare the free films by one of the following procedures:

8.2.1 Dental Tin Foil Substrate:

8.2.1.1 Apply each material to be tested to a strip of dental tin foil. First, mount the foil on a smooth glass plate on which there may be placed a small pool of high-boiling liquid, which may be useful in holding the foil in close contact with the glass. Spread the foil out to a smooth flat surface by means of a rubber squeegee. Apply a uniform coating of the material on the foil by automatic spray or drawdown procedures given in Test Method D 823.

NOTE 2—Use a liquid that is known to have little or no effect on the test coating. In many cases a light mineral oil would be suitable.

8.2.1.2 Dry the applied films at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity or bake under conditions mutually agreeable to producer and user. Dry film thicknesses must not vary by more than $\pm 5\%$ of the average film thickness. Most films with a thickness of less than 2.0 mils (50 μm) are very difficult to handle.

8.2.1.3 When required for further treatment such as weathering, remount the coated foil on a convenient smooth, flat substrate such as a glass or steel panel. In this case, a high boiling liquid (Note 2) may be used to hold the foil in close contact with the substrate over extended periods of time.

8.2.1.4 Age or expose the coated foil to conditions mutually agreed upon. At the end of the specified or agreed upon period, remove the foil-backed film from the glass or metal substrate and cut the specimens to size using the precision specimen cutter.

NOTE 3—A precision specimen cutter must be used to ensure nick-free edges on the specimens. Even with this instrument, it is necessary to cut each specimen independently, allowing at least $\frac{1}{4}$ in. (6 mm) of waste between specimens.

⁸ Teflon FEP 2-mil film thickness (Card No. 03111, Item #29499) from E. I. du Pont de Nemours & Co., Inc., Wilmington, DE 19898, is satisfactory.

⁹ Dry lubricant (MS-122 Fluorocarbon Release Agent) from Miller-Stephenson Chemical Co., Danbury, CT 06810, is satisfactory.

8.2.1.5 Place the foil-backed specimen film side up on a pool of mercury to remove the foil by amalgamation.

NOTE 4—Care should be exercised at all times to prevent the high-boiling liquids used in mounting the foil from coming in contact with the test film as these liquids may soften the film. For instance, the foil should be cleaned before amalgamation since any liquid remaining on the back of the foil and the test film will float on the bath of mercury.

8.2.1.6 After amalgamation is completed, pick up an end of the floating film with tweezers, and carefully brush the unsupported film free of mercury and amalgam with a soft camel hair brush.

8.2.2 FEP Sheet Substrate:

8.2.2.1 Apply each material to be tested to a sheet of FEP. First, cover a smooth, flat, polished glass plate with a sheet of FEP. Coat the sheet uniformly with a dry fluorocarbon lubricant and allow to dry for 24 h at standard conditions. Then apply a uniform coating of the test material on the sheet by automatic spray or drawdown procedures given in Method D 823.

8.2.2.2 Dry the applied films at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity or bake under conditions mutually agreeable to producer and user. Dry film thicknesses must not vary by more than $\pm 5\%$ of the average film thickness. Most films with a thickness of less than 2.0 mils (50 μm) are very difficult to handle.

8.2.2.3 When required for further treatment such as weathering, remount the coated sheet on a convenient smooth, flat substrate such as a glass or steel panel.

8.2.2.4 Age or expose the coated sheet to conditions mutually agreed upon. At the end of the aging or exposure period, remove the sheet-backed film from the glass or metal substrate, and cut the specimens to size using the precision specimen cutter (see Note 3). Carefully strip the coating film from the sheet substrate.

9. Calibration

9.1 Balance, zero, and calibrate the load weighing and recording system of the tensile tester in accordance with methods specified by the manufacturer.

10. Conditioning

10.1 Unless otherwise agreed upon between the producer and the user, condition the test specimens for at least 24 h at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and 50% relative humidity and test in the same environment.

11. Procedure

11.1 Select a mutually agreed upon gage length in the range of 1 in. (25 mm) to 5 in. (125 mm).

11.2 Prepare 10 test specimens for each material to be evaluated. These specimens should not exhibit any nicks or flaws. Measure the thickness of each specimen to ± 0.1 mil (2.5 μm) with a micrometer in accordance with Test Methods D 1005, taking five measurements within the gage length area.

11.3 Set the jaw separation of the tensile tester at the gage length selected. Place the test specimen in the grips of the testing machine, taking care to align the long axis of the specimen with an imaginary line joining the points of attachment of the grips to the machine. Tighten the grips evenly and firmly to the degree necessary to minimize

slipping of the specimen during test.

NOTE 5—Mounting is facilitated by the use of air activated jaws. Line-type jaws will minimize slippage and breakage. The application of pressure-sensitive cloth to the ends of the film can improve jaw grip.

11.4 Select a mutually agreed upon rate of elongation (strain rate) that is in the range of 5 to 100 %/min. Set the crosshead speed of the tensile tester to provide this rate for the gage length chosen.

NOTE 6—A rate of elongation should be selected that is optimum for testing the types of materials to be evaluated. For relatively brittle films, elongation rates of 5 to 20 % are suggested. For relatively extensible films, elongation rates of 50 to 100 % are suggested. (Refer to Test Methods D 882 for relation of elongation rate to elongation at break).

11.5 Elongate the test specimen until rupture of the film occurs and evaluate the stress-strain curve as follows:

11.5.1 Determine the specimen elongation by measuring the increase in jaw separation from the point of original load application to the point of rupture.

11.5.2 Measure the tensile pull in pounds (kg) required to rupture the film.

11.5.3 If stiffness is desired, determine the tensile pull in pounds (kg) to elongate the film 1 % from the first point in the stress-strain curve where the slope becomes constant.

11.6 Using the procedures in sections 11.1 through 11.5, run ten test specimens for each material under test.

12. Calculations

12.1 For each specimen compute the following:

12.1.1 The elongation E , in percent from the following equation:

$$E = 100 \left(\frac{\Delta L}{L} \right)$$

where:

ΔL = increase in specimen length to break, and

L = initial specimen length (gage length).

12.1.2 The tensile strength, T.S., in pounds per square inch, from the equation:

$$\text{T.S.} = (P_R)/(TW)$$

where:

P_R = tensile pull to rupture, lb (kg),

T = thickness of test specimen, in. (mm), and

W = width of test specimen, in. (mm).

12.1.3 The stiffness (modulus of elasticity), S , from the following equation:

$$S = (P_E)/(TW)$$

where:

P_E = pull in pounds (kg) to elongate the film 1 % from the first point in the stress-strain curve where the slope remains constant,

T = thickness of test specimen, in. (mm), and

W = width of test specimen, in. (mm).

12.2 Examine the uniformity of the tensile strength and elongation results obtained for the ten specimens measured for a material. Choose one of the following procedures for discarding spurious values and calculate the mean of the remaining results:

12.2.1 Use the results from those five specimens showing the highest tensile strength in evaluating all three properties, discarding those from the remaining five. This is done on the basis that the expected errors (nicks or flaws in the specimen, breaks within the jaw, slippage in the jaw, etc.) would all tend to produce results on the low side.

12.2.2 Discard the values for those specimens where the tensile strength and elongation values are significantly lower than those for most of the specimens. Use the test for outliers given in Practice D 3980.

13. Report

13.1 Report the mean values obtained with the test specimens for:

13.1.1 Tensile strength,

13.1.2 Elongation, and

13.1.3 Stiffness (modulus of elasticity), if desired.

13.2 Report the conditions of the test.

13.2.1 Procedure for preparation of free films,

13.2.2 Rate of elongation in percent per minute,

13.2.3 Specimen size (length, width, and thickness),

13.2.4 Temperature and relative humidity during test and treatment, and

13.2.5 Aging and treatment given the specimens.

14. Precision

14.1 An interlaboratory test of this method was conducted in which three coatings (representing a brittle film, a film with limited elasticity, and a very elastic film) were tested by five laboratories. The test was conducted with an Instron tensile tester operated at two elongation rates (10 and 100 %) with a specimen gage length of 2 in. (50 mm) and specimen thicknesses of 2.5 to 3.5 mils (65 to 90 μm). The between laboratory coefficients of variation were found to be 30 % for percent elongation and 18 % for tensile strength. Based on these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

14.1.1 *Reproducibility*—Two results for percent elongation obtained by operators in different laboratories should be considered suspect if they differ by more than 118 % of their mean. Two results for tensile strength obtained by operators in different laboratories should be suspect if they differ by more than 70 % of their mean.

15. Keywords

15.1 elongation; organic coatings; stiffness; tensile properties; tensile strength

Standard Test Method for Pigment Content of Solvent-Reducible Paints¹

This standard is issued under the fixed designation D 2371; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Section 10 was added editorially in May 1990.

1. Scope

1.1 This test method covers the procedure for the quantitative separation of the vehicle from the pigment in solvent-reducible coatings.

1.2 This test method has been proven to be applicable to the following types of paints: white linseed oil outside house paint, white soya and phthalic alkyd enamel, white linseed *o*-phthalic alkyd enamel, red lead primer, zinc chromate primer, flat white inside enamel, white epoxy enamel, white vinyl toluene modified alkyd, and white amino modified baking enamel. It is considered to be applicable to most solvent-reducible paints.

1.3 *This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* Specific precautionary statements are given in Section 6.

2. Referenced Document

2.1 ASTM Standard:

D 2698 Test Method for Determination of the Pigment Content of Solvent-Reducible Paints by High-Speed Centrifuging²

3. Significance and Use

3.1 This test method is suitable for setting specifications for the pigment content of solvent-reducible paints as well as for monitoring manufacturing quality control.

3.2 This test method provides the isolated pigment fraction from solvent-reducible paints that may be used for pigment analysis.

4. Apparatus

4.1 *Centrifuge*, explosion-proof, capable of developing 1000 to 2000 g.

NOTE 1—The centrifuge should be equipped with a suitable head to take the proper size trunnion cups necessary for use of the 90-mL tubes or 4-oz (120-mL) bottles. A two, four, or six-place head can be used with the bottles and an eight-place head can be used with the tubes.

4.2 *Centrifuge Tube*, 90-mL, heavy-walled. In place of the

90-mL centrifuge tube a 4-oz (120-mL) screw cap bottle with vinyl-lined screw cap may be used.³

4.3 *Laboratory Oven*, vented and capable of maintaining a temperature of $105 \pm 2^\circ\text{C}$.

4.4 *Syringe*, 5-mL.

4.5 *Water Bath*.

5. Solvents

5.1 *Ethyl Ether or Petroleum Ether*: (Warning—See 6.1).

5.2 *Extraction Mixture*—Mix 10 volumes of ethyl ether, 6 volumes of benzene or toluene, 4 volumes of methyl alcohol, and 1 volume of acetone (Warning—See 6.2, 6.3, and 6.4).

6. Hazards

6.1 *Ethyl Ether and Petroleum Ether*—Flammable. Vapor is harmful. May be fatal if inhaled or swallowed. Use only with adequate ventilation. Avoid prolonged contact with skin. Avoid contact with flame, hot surface, or sparks. Do not get in eyes, on skin, or on clothing. Refer to suppliers' Material Safety Data Sheet.

6.2 *Acetone*—Flammable. Vapor is harmful. May be fatal if inhaled or swallowed. Use only with adequate ventilation. Avoid prolonged contact with skin. Avoid contact with flame, hot surface, or sparks. Do not get in eyes, on skin, or on clothing. Refer to suppliers' Material Safety Data Sheet.

6.3 *Methyl Alcohol*—Flammable. May be fatal or cause blindness if swallowed. Cannot be made nonpoisonous. Harmful if inhaled. Keep away from heat, sparks, or open flame. Avoid breathing vapor. Use only with adequate ventilation. Refer to suppliers' Material Safety Data Sheet.

6.4 *Benzene* has been declared carcinogenic.

6.4.1 *Benzene and Toluene*—Flammable. Vapors and liquid are harmful and may be fatal if swallowed. Keep away from heat, sparks, or open flame. Keep in a well-closed container. Avoid breathing vapor. Avoid contact with eyes, skin, or clothing. Refer to suppliers' Material Safety Data Sheet.

7. Procedure

7.1 Mix the sample until it is homogeneous, preferably on a mechanical shaker.

7.2 Weigh to 1 mg from a syringe, 5 to 10 g of sample into a tared 90-mL centrifuge tube with a screw-type glass stirring rod (the rod is tared with the centrifuge tube), or a glass bottle as described in 4.2. The weight of the specimen is the

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paint and Paint Materials.

Current edition approved May 31, 1985. Published July 1985. Originally published as D 2371 - 65 T. Last previous edition D 2371 - 73 (1979)^{e1}.

² *Annual Book of ASTM Standards*, Vol 06.01.

³ Bottles and caps that have been successfully used may be obtained from the Sargent Welch Scientific, 7300 N. Linder Ave., Skokie, IL 60076 and are designated as follows: Cat. No. S9185C, 4-oz bottles.

weight of syringe and paint minus the weight of the syringe after transferring the specimen to the tube or bottle.

7.3 Add 60 mL of extraction mixture (5.2) and stir well with the glass, screw-type stirring rod, preferably using a power stirrer. Wash the rod clean with a stream of extraction mixture into the tube, and reserve the rod. If the glass bottle is used, mixing may be accomplished by hand, shaking vigorously, or by use of a mechanical shaker.

7.4 Centrifuge at 1000 to 2000 *g* (Note 2) until the pigment is clearly separated. A faster speed may cause the pigment to pack too hard for future mixing. (See Test Method D 2698.)

NOTE 2—Calculate the gravity developed by the centrifuge as follows:

$$g = 1.118 \times 10^{-6} \times r \times n^2 \quad (1)$$

where:

r = rotating radius, mm, and

n = rotating speed, r/min.

7.5 Discard the upper layer by decantation.

7.6 Repeat the extraction twice as described in 7.3, 7.4, and 7.5, making certain that the settled pigment is sufficiently stirred or shaken so that no lumps can be seen sticking to the side of the centrifuge tube or bottle and all pigment can easily be washed from the stirring rod into the tube. It may be necessary to break up the pigment cake before stirring. The bottle and contents may be mixed by tapping at an angle on a cloth pad on a bench top to break up the pigment cake and then shaking vigorously to complete the pigment dispersion in the extraction mixture.

7.7 Make a fourth extraction using ethyl ether or petro-

leum ether following the same precautions noted in 7.6. Decant the upper layer. Drive off the ether by heating (gently at first to avoid spattering) on a steam bath in a hood away from open flames or sparks. The pigment should be broken up by tapping the tube or bottle on a cloth pad on a bench top. Dry the tube or the bottle at $105 \pm 2^\circ\text{C}$ for 2 h.

7.8 Cool and weigh the tube (including stirring rod) or bottle, plus pigment.

8. Calculation

8.1 Calculate the percent of pigment, *P*, as follows:

$$P = [(W_1 - W_2)/S] \times 100 \quad (2)$$

where:

*W*₁ = weight of the tube (including stirring rod) plus pigment, g,

*W*₂ = weight of the tube (including stirring rod), g, and

S = weight of paint sample used, g.

NOTE 3—All pigment obtained using this test method has minute amounts of vehicle adsorbed on the pigment. However, this will not significantly affect the precision of this test method.

9. Precision

9.1 Data are not available to determine the precision of this test method. There are no plans at present to obtain such data. This test method has been in use for several years and is considered acceptable.

10. Keywords

10.1 high speed centrifuging; pigment content; pigment separation; solvent-reducible paint

Standard Practice for Separation of Vehicle From Solvent-Reducible Paints¹

This standard is issued under the fixed designation D 2372; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

^{ε1} NOTE—Section 6 was added and the title was changed editorially in May 1990.

1. Scope

1.1 This practice covers the procedure for the separation of the vehicle from the pigment in solvent-reducible paint.

1.2 In the development of the practice the following material were tested: white soya and white fish oil isophthalic alkyd semi-gloss enamels, white linseed oil paint, white soya and white linseed *o*-phthalic alkyd enamels. It is considered to be applicable to similar materials.

1.3 *This standard does not purport to address the safety problem associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

reducible paints is required in order to characterize paint vehicles by chemical, spectroscopic, or chromatographic techniques. Characterization of vehicles is important since they play a major role in the performance of coatings.

4. Apparatus

4.1 *Centrifuge*, high-speed, capable of developing in excess of 10 000 g.

NOTE 1—Calculate the gravity developed by the centrifuge as follows:

$$g = 1.118 \times 10^{-6} \times r \times n^2$$

where:

r = rotating radius, mm, and

n = rotating speed, r/min.

5. Procedure

NOTE 2—If the percent of pigment is desired, see Test Method D 2371 and Test Method D 2698.

5.1 Mix the sample until it is homogeneous, preferably on a mechanical shaker.

5.2 Centrifuge about 20 mL of the whole paint on a high-speed centrifuge in excess of 10 000 g (Note 1) for 30 min or until separation is completed. If difficulty is encountered, add 10 mL of a suitable solvent (Note 3). Mix with the vehicle layer in the centrifuge tube and centrifuge as before. Pour off the supernatant liquid into a bottle and stopper under nitrogen for further use.

NOTE 3—If quantitative work must be done on the vehicle, the weight of the paint specimen and of the added solvent must be known.

6. Keywords

6.1 centrifuge; paint vehicle separation; solvent-reducible paint

Standard Test Method for Slump of Face Glazing and Bedding Compounds on Metal Sash¹

This standard is issued under the fixed designation D 2376; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers face glazing or bedding compounds, or both, used on exterior steel, aluminum, and other metal sash.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Summary of Test Method

2.1 A triangular bead of glazing or bedding compound is tooled into a steel channel and then placed in a $122 \pm 4^\circ\text{F}$ ($50 \pm 2^\circ\text{C}$) oven for 7 h and then visually inspected for slump.

3. Significance and Use

3.1 This test method provides an accelerated means for predicting slump of such glazing compounds.

4. Apparatus

4.1 *Number 28 U.S. Gage Steel Channel* (smooth, unpainted), 1 in. (25.4 mm) wide, $\frac{1}{2}$ in. (12.7 mm) deep, and 8 in. (203 mm) in length. The flanges of the channel shall be approximately at right angles with the web of the channel. The fillet at the bottom of the channel shall have an internal radius of no more than $\frac{1}{16}$ in. (1.6 mm).

4.2 *Gravity Convective Oven*, having a temperature controlled at $122 \pm 4^\circ\text{F}$ ($50 \pm 2^\circ\text{C}$).

4.3 *Putty Knife*.

5. Reagent

5.1 *Solvent*, such as methyl ethyl ketone or ethylene dichloride.

6. Sampling

6.1 Thoroughly mix the entire contents of a full, previ-

FIG. 1 Slump Test Diagram

ously unopened container on a clean, nonabsorptive surface, and take from this the sample to be tested.

7. Conditioning

7.1 Condition both the channel and the mixed compound (in a closed container) for at least 5 h at $73.4 \pm 3.6^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$).

8. Procedure

8.1 Thoroughly clean the channel with solvent.

8.2 Apply a portion of the thoroughly mixed compound to the channel in a triangular shape with a putty knife as illustrated in Fig. 1(a).

8.3 When the channel is so filled, set it in an oven with the flanges horizontal, as shown in Fig. 1(a), with the mass of the material toward the top, and maintain the temperature at $122 \pm 4^\circ\text{F}$ ($50 \pm 2^\circ\text{C}$) for 7 h.

9. Report

9.1 The report shall indicate if there was sagging or slumping of the compound at the top towards the bottom, as illustrated in Fig. 1(b).

9.2 Any sagging or slumping from the original configuration, Fig. 1(a), shall be construed as failure.

10. Precision and Bias

10.1 No statement is made about the precision or bias for measuring slump since the result merely states whether there is conformance to the criteria for success in the procedure.

¹ This test method is under the jurisdiction of ASTM Committee C-24 on Building Seals and Sealants and is the direct responsibility of Subcommittee C24.12 on Oil and Resin Base Glazing and Caulking Compounds.

Current edition approved Nov. 30, 1984. Published January 1985. Originally published as D 2376 - 65 T. Last previous edition D 2376 - 74 (1979).

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Standard Practice for Determining the Effect of Overbaking on Organic Coatings¹

This standard is issued under the fixed designation D 2454; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers the determination of the time-temperature effect of overbaking on the physical and chemical properties of organic coatings.

1.2 *This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* Specific hazard statements are given in Section 7.

3. Terminology

3.1 Definition:

3.1.1 *overbaking*—an exposure of the coating to a moderately higher temperature or to a longer period of baking, or both, than recommended by the manufacturer of the coating for normal curing. This condition is in contrast to "heat resistance" which is a parameter relating to the service life of a coating.

4. Summary of Practice

4.1 Four panels are prepared and baked at the schedule normally recommended for the coating. Two of the panels are then removed and the remaining two are subjected to an additional overbake in which the time and temperature are mutually agreed upon between the purchaser and the seller. The sets of panels, after a suitable conditioning interval, are then evaluated for the properties that are compatible with the substrate. Among these are gloss, color, flexibility, adhesion, impact resistance, and resistance to reagents. Note that glass substrates should not be tested for impact, and zinc-coated substrates can influence both flexibility and impact.

5. Significance and Use

5.1 Most coatings are designed for a specific baking time and temperature. For a variety of reasons (line stoppages, rerouting back through ovens, oven overheating, etc.) the prescribed time or temperature, or both, of the bake is often exceeded. This practice has been found to be useful in evaluating the effects of overbakes on coatings.

6. Materials

6.1 *Standard Baking-Type Coating* mutually agreed upon between the purchaser and the seller.

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.27 on Accelerated Testing.

Current edition approved Feb. 22, 1991. Published April 1991. Originally published as D 2454 - 66 T. Last previous edition D 2454 - 84a.

² Annual Book of ASTM Standards, Vol 06.01.

³ Annual Book of ASTM Standards, Vol 14.02.

⁴ Annual Book of ASTM Standards, Vols 02.05 and 06.01.

7. Hazards

7.1 The flash points of most solvents used in many organic coatings and related products are low enough that adequate ventilation is needed to avoid exceeding 25 % of the lower explosive limits of the solvents when test panels are being prepared and baked. As these materials are considered toxic, take care to avoid inhalation of solvent vapor and unnecessary contact of solvent with the skin.

8. Procedure

8.1 Application of Organic Coating:

8.1.1 Apply coatings to steel panels prepared in accordance with Methods D 609.

8.1.2 Apply coatings to zinc-coated surfaces prepared in accordance with Practices D 2092, when zinc has been applied by the hot-dip method or by electroplating.

8.1.3 Apply coatings to nonpassivated galvanized steel prepared in accordance with Test Method D 2201, when the zinc is applied by a continuous galvanizing method using an aluminum-bearing zinc.

8.1.4 Apply coatings to aluminum surfaces on all-aluminum materials prepared in accordance with Practices D 1730.

8.1.5 Apply coatings to hot-dip aluminum coated surfaces prepared in accordance with Practices D 1731.

8.1.6 In cases where a primer is used in practice under the topcoat, apply the entire system to the panels. The film thickness of each coat shall be mutually agreed upon between the purchaser and seller, but, in the absence of such agreement, the total thickness shall be 2 ± 0.2 mils (50 ± 5 μm).

8.1.7 In instances where clear coatings are to be tested, they may be applied to aluminum or white carrara glass, one side of which has been polished to a smooth, high-gloss finish. Other selected substrata previously agreed upon between the purchaser and the seller may also be used. In the absence of a specific agreement between the purchaser and the seller in regard to film thickness, apply the coatings by automatic spray. (Refer to Test Methods D 823, Method A) at a dry film thickness of 2 ± 0.2 mils (50 ± 5 μm). Multiple coats may be used to obtain this film thickness where necessary due to the nature of the coating material (Note 1). Manual spray application or the drawdown method with wire-wound draw bars may be used when automatic equipment is not available.

NOTE 1—Dry film thickness should be measured in accordance with Test Methods D 1005, D 1186, or D 1400, whichever is applicable. The adhesion, flexibility, and color can vary considerably with thickness.

8.2 Baking:

8.2.1 The baking schedule for each coating including primer, topcoat, and primer/topcoat systems shall be mutually agreed upon between the purchaser and the seller and shall include the following:

8.2.1.1 *Normal Baking Schedule (Time and Temperature)* recommended for the development of optimum film properties, and

8.2.1.2 *Overbaking Cycle*—This cycle shall be within practical limits in order to simulate conditions that might be encountered in actual production where baking oven or conveyor lines, or both might malfunction temporarily due to mechanical or electrical failure.

8.3 Prepare four panels of each coating or coating system and bake them at the schedule normally recommended to obtain optimum properties. Conduct the baking of these panels in a mechanical recirculating air oven set to $\pm 2^\circ\text{F}$ ($\pm 1^\circ\text{C}$) of the specified baking temperature. At the end of the specified time remove two panels from the oven and subject the remaining two to the overbake cycle by:

8.3.1 A continuation of the normal bake but for a previously agreed upon time, for example, 50 or 100 % increase in time, or

8.3.2 Resetting the oven temperature to the agreed overbake temperature and then continuing the bake for a specified period of time after the overbake temperature has been reached, or removing the panels until the overbake temperature is reached and then baking them for the agreed upon time.

NOTE 2—The conditions described in 8.3.2 are not usually reproducible between laboratories or different ovens because of variations in the heating characteristics of ovens.

8.3.3 After the sets of panels have been baked according to the mutually agreed upon baking cycles, place them in a suitable rack and condition for 24 h at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and 50 ± 5 % relative humidity (see Test Methods D 1640) prior to testing.

9. Test Methods

9.1 Determine the properties of both sets of panels in accordance with the following ASTM methods:

9.1.1 *Gloss*—Test Method D 523.

9.1.2 *Color*—Practice D 1729 (Visual) or Practice E 805 (instrumental), or both

9.1.3 *Flexibility*—Test Method D 522 (conical mandrel and cylindrical mandrel).

9.1.3.1 Heat-aged flexibility values should be determined in accordance with a baking cycle that is in agreement between the purchaser and the seller.

9.1.4 *Adhesion*—Test Methods D 2197 (mechanical) or D 3359 (tape), or both.

9.1.5 *Impact Resistance*—Test Method D 2794.⁵

9.1.6 *Hardness*—Test Method D 3363 (pencil test).

9.1.7 *Exposure to Reagents*—If this test is desired, the choice of materials to which the coating is to be exposed shall be governed by the ultimate use of the coating and shall be agreed upon between the purchaser and the seller. The general procedure to be followed in this test is given in Test Method D 1308 or Practice D 1540.

10. Report

10.1 Report the following information:

10.1.1 Substrate employed, including type and thickness,

10.1.2 Type of coating,

10.1.3 Film thickness, including primer, if any,

10.1.4 Normal bake schedule, or schedules,

10.1.5 Overbake cycle,

10.1.6 Test methods employed, and

10.1.7 Values determined, including the measured changes between the normal and overbake cycles.

⁵ It is suggested that impact resistance be determined by use of the Gardner Variable Impact Tester obtainable from the Gardner Laboratory, Inc., Bethesda, MD.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Methods for Evaluating Coatings For High Temperature Service¹

This standard is issued under the fixed designation D 2485; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 These test methods cover the evaluation of the heat-resistant properties of coatings designed to protect steel surfaces exposed to elevated temperatures during their service life. Two test methods are described as follows:

Method A—Interior Service Coatings

Method B—Exterior Service Coatings

1.2 *This standard does not purport to address the safety problems, if any, associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* Specific hazard statements are given in Section 5.

3. Summary of Test Methods

3.1 Panels suitably coated with the material under test are

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.27 on Accelerated Testing.

Current edition approved May 15, 1991. Published July 1991. Originally published as D 2485 - 66 T. Last previous edition D 2485 - 84.

² Annual Book of ASTM Standards, Vol 01.04.

³ Annual Book of ASTM Standards, Vols 03.02 and 06.01.

⁴ Annual Book of ASTM Standards, Vol 06.01.

⁵ Annual Book of ASTM Standards, Vol 14.02.

evaluated under one or both of two test methods depending on the intended usage.

3.1.1 *Test Method A, Interior Service Coatings*—Coated panels are heated for 24 h in a muffle furnace at a temperature agreed upon between the purchaser and the seller. One panel is plunged into water and the other cooled and then subjected to a bend test.

3.1.2 *Test Method B, Exterior Service Coatings*—Coated panels are subjected to temperatures that increase in steps from 400 to 800°F (205 to 425°C). One panel is subjected to salt spray for 24 h, and one is exposed outdoors for 12 months.

3.2 When tests are completed, the panels are examined for evidence of film degradation including rust formation, blistering, loss of adhesion, dulling, and chalking.

4. Significance and Use

4.1 Some coating systems are developed for use over steel that is exposed to high temperatures during service life. This method provides an accelerated means of determining the performance of these coating systems. Testing of coatings designed for interior service and of coatings designed for exterior (weather-exposed) service is included.

5. Apparatus

5.1 Automatic spray equipment as described in Test Methods D 823 (Method A) or any other suitable method that will give the required uniformity of film and film thickness.

5.2 Muffle furnace capable of maintaining the temperatures described in 7.2 and 7.3.

5.2.1 *Precaution:* Due to the high temperatures involved in operating the muffle furnace, extreme caution should be used.

5.3 Salt spray apparatus as described in Method B 117.

6. Panel Preparation

6.1 *Type*—Panel dimensions shall be established by prior agreement between the purchaser and the seller. Use panels of 1/4 in. (6.4 mm) hot-rolled steel conforming to Specification A 36/A 36M or Specification A 283/A 283M, or when appropriate, Specification A 285/A 285M for the water quench test in Test Method A and for all tests under Test Method B. For the bend test in Test Method A, the panels must be thin and soft enough to be bent as described in Test Methods D 552.

6.2 *Cleaning*—Clean the panels for both test methods in accordance with Methods D 609, Methods B or D. Then, using a fine silica sand (graded to pass through a No. 40 (425- μ m) sieve), blast the panels for Method B to "white" metal (removing all mill scale and rust) so that the panels

comply with grade A SP-5 of Standard D 2200. Other blast media and blast methods are acceptable if agreed upon between the buyer and the seller. Blast-cleaned panels cannot be subjected to the bend test because they are too thick to bend.

6.3 Coatings Applications—Apply the coatings by automatic spray, Method A of Test Methods D 823, or by any other suitable method that will assure the required uniformity of film thickness. The number of coats, technique, and cycle for drying between coats of multicoat systems, limits of dry film thickness, and drying time before exposure shall be established by prior agreement between the purchaser and the seller. Determine dry film thickness in accordance with Test Methods D 1186. Allow coatings that air dry at ambient temperature to dry a 168 h at a temperature of $75 \pm 5^\circ\text{F}$ ($24 \pm 2.5^\circ\text{C}$) prior to exposing to test conditions. Bake coatings that require heat conversion in accordance with the recommendation of the supplier.

7. Procedure

7.1 Sampling—When panels have been coated at another location, select at random from different packages two specimens for each method of each type of coating under investigation.

7.2 Test Method A:

7.2.1 Place one panel each of the two types described in 6.1 and 6.2 coated with each paint under test in a muffle furnace maintained at the test temperature mutually agreed upon between the purchaser and the seller, and allow to remain for 24 h. At the end of this time plunge one of the panels immediately into water maintained at $70 \pm 5^\circ\text{F}$ ($21 \pm 2.5^\circ\text{C}$). After removing from the water, examine the coating film for evidence of film failure including dulling, blistering, cracking, and loss of adhesion. Allow the second panel to cool at a room temperature of $75 \pm 5^\circ\text{F}$ ($24 \pm 2.5^\circ\text{C}$) for 1 h, then rapidly bend double over a $\frac{1}{2}$ -in. (12.7-mm) diameter steel mandrel with coated side uppermost in accordance with Test Methods D 522, Method B. Examine this panel for evidence of film degradation such as cracking and loss of adhesion.

7.3 Test Method B:

7.3.1 Expose duplicate coated panels finished with the materials under test to the elevated temperature test schedule mutually agreed upon between the purchaser and the seller. In the absence of such a specified schedule use the following:

7.3.2 Place the panels in a muffle furnace maintained at 400°F (205°C) for 8 h, then increase the temperature to 500°F (260°C) for 16 h. Increase the temperature in 100°F (55°C) increments, alternating the time periods indicated, to the final temperature maximum previously agreed to between the purchaser and the seller. Thus the schedule would be:

400°F (205°C) for 8 h
500°F (260°C) for 16 h
600°F (315°C) for 8 h
700°F (370°C) for 16 h
800°F (425°C) for 8 h

NOTE—Many high temperature paints depend upon service conditions to provide the extreme heat required to cure or sinter their films. If these paints are never exposed to the extreme heat, they may be found to be unsuitable. Consequently, it is good practice to make observations also at temperatures less than the expected service temperatures.

7.3.3 Remove the test panels and make a visual inspection following exposure at each temperature level for evidence of failure, including peeling, cracking, blistering, abnormal discoloration, or loss of adhesion, using ASTM standards where possible. Disregard such failures up to $\frac{1}{4}$ in. (6.4 mm) in from the edges of the test panels.

7.3.4 At the end of the complete exposure, remove the panels from the oven or muffle furnace and allow to air cool at ambient temperature for a minimum period of 1 h. As described in 7.3.3, inspect for evidence of failure due to the high temperature exposure.

7.3.5 If both panels of each pair pass the heat test satisfactorily, use them, respectively, for salt spray (fog) testing and exterior exposure testing.

7.3.5.1 Place one panel of each pair in a salt spray cabinet operated in accordance with the requirements of Method B 117, for a period of 24 h. At the conclusion of the exposure period, examine each panel for rusting or any evidence of corrosive attack.

7.3.5.2 Expose the second panel of each pair on an insulated-type rack, as described in Practice G 7, or as agreed upon between the purchaser and seller, for a period of 12 months. Make a visual inspection after 6 months and after termination of the exposure. The site to conduct the test and the angle of the exposure rack should be agreed upon between the purchaser and the seller and should relate to the end-use application of the coating.

8. Report

8.1 Report the following information:

8.1.1 Description of substrates, substrate preparation, and application conditions used.

8.1.2 Air drying versus baking schedule used.

8.1.3 Details of outdoor exposure when applicable, including:

8.1.3.1 Exposure site, type (insulated rack, black box, open rack, etc.) and angle of exposure,

8.1.3.2 Date of exposure start,

8.1.3.3 Radiation data in terms of kilojoule per square metre or langley's during exposure period, and

8.1.4 Any defects or changes as described under Section 7.

9. Precision

9.1 Four operators in four laboratories tested six materials covering a range of heat-resistant properties and were able to rank products in order of their heat-resisting qualities. Since rankings were of a qualitative nature, no mathematical statement of reproducibility was established.

10. Keywords

10.1 heating tests, paints; resistance, heat; temperature tests, elevated

Standard Test Method for Scrub Resistance of Interior Latex Flat Wall Paints¹

This standard is issued under the fixed designation D 2486; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers an accelerated procedure for determining the resistance of latex flat wall paints to erosion caused by scrubbing.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D4213 Test Method for Wet Abrasion Resistance of Interior Paints²

3. Summary of Test Method

3.1 The test paint is applied to a black plastic panel. After aging, the coated panel is placed over a 1/2-in. by 10-mil (12.7 by 0.25-mm) shim and held in place on a glass plate in a washability machine by means of a gasketed frame. It is then scrubbed with a nylon bristle brush and an abrasive scrub medium until failure occurs over the shim.

4. Significance and Use

4.1 Interior wall paints often become soiled especially near doorways, windows, and in work and play areas. This test method covers determination of the relative resistance of different wall paints to erosion when repeatedly scrubbed to remove the stains during the life of the paint.

4.2 Results developed by use of this test method do not necessarily represent the scrub resistance of aged paint films.

4.3 This test method measures scrub resistance by the traditional scrub-to-failure concept. Test Method D 4213 is a more precise method that measures essentially the same property by a weight-loss technique and reports it as a volumetric film erosion rate. Test Method D 2486 is maintained as an ASTM standard along with the newer Test Method D 4213 because it has served the paint industry usefully for many years, its techniques are familiar, and its results are meaningful. To discard it as a standard would be to minimize a great deal of significant past experience.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.42 on Architectural Finishes.

Current edition approved March 6, 1989. Published May 1989. Originally published as D 2486 - 66 T. Last previous edition D 2486 - 79.

5. Apparatus

5.1 Washability Machine.³

5.1.1 Accessory Apparatus: (Fig. 1).

5.1.1.1 Nylon Bristle Brush, Rubber Mat, and Holder (total weight 454 g).

5.1.1.2 Glass Plate, measured to fit.

5.1.1.3 Shim, 1/2-in. by 10-mils (12.7- by 0.25-mm).

5.1.1.4 Gasketed Frame and Clamps.

5.2 Film Caster,⁴ having 7-mil (0.18-mm) clearance.

6. Reagents and Materials

6.1 Black Plastic Panels.⁵

6.2 Masking Tape.

6.3 Flannel Cloth.

6.4 Detergent.⁶

6.5 Scrub Medium⁷ (Note 1), consisting of the following:

	grams
Water, distilled or deionized	49.7 ⁴
Hydroxyethyl cellulose ⁸	1.0
Ammonium hydroxide, 28 %	0.1
Detergent ⁶	2.0
Trisodium phosphate, anhydrous	2.0
Silica ⁹	45.0
Acetic acid (glacial)	0.2 ^B
Preservative ¹⁰	0.1
	100.0

⁴ Adjust to achieve viscosity of 110 to 120 Krebs Units before use.

^B Vary to achieve a pH of 9.5 to 10.0.

NOTE 1—When a referee test is made, prepare fresh medium or use standardized scrub medium⁷ from a previously unopened container that is no more than 1 year old.

6.5.1 Slowly add the hydroxyethyl cellulose to the water while stirring mechanically. Stir until uniform, then continue stirring for an additional 5 min. Then slowly add 3 drops of

³ The Gardner washability machine Model M-105A and accessory apparatus, available from the Gardner Laboratories, Inc., 5521 Landy Lane, Bethesda, MD 20014, has been found satisfactory for this purpose. Other straight-line wash testers may be adapted to meet the requirements of this test method.

⁴ The Dow film caster, available from the Gardner Laboratories, Inc., has been found satisfactory for this purpose.

⁵ Leneta P-121-10N dull black plastic panels 6 1/2 by 17 in. by 10 mils (165 by 432 by 0.25 mm) in size (production tolerance: ± 1 mil), obtainable from the Leneta Co., P.O. Box 576, Ho-Ho-Kus, NJ, are suitable for the purpose.

⁶ Octyl phenoxy polyethoxy ethanol has been found satisfactory. Triton X-100 obtainable from Rohm & Haas Co., Independence Sq., Philadelphia, PA, is representative of this product.

⁷ Laboratory standardized scrub medium is available from the Leneta Co.

⁸ Cellosize QP-4400, obtainable from Union Carbide Corp., Chemicals Div., 270 Park Ave., New York, NY, has been found satisfactory for this purpose.

⁹ Silica No. 22, obtainable from Whittaker, Clark, & Daniels, Inc., 100 Church St., New York, NY 10007, has been found satisfactory for this purpose.

¹⁰ 1,3,5-triethyl hexahydro-sym-triazine (Vancide TH) obtainable from R. T. Vanderbilt Co., 230 Park Ave., New York, NY 10017, has been found satisfactory.

28 % ammonium hydroxide while mixing, and continue mixing until solution turns clear. In the order given, add the other ingredients separately, employing mechanical stirring. Be sure that each item is uniformly dispersed before adding the next one. The addition of the silica should take about 5 min to ensure uniform dispersion. Finally, add the preservative and adjust the pH with glacial acetic acid.

7. Preparation of Apparatus

7.1 Washability Machine—The washability machine should be leveled before use and operated at 37 ± 1 counts per minute. Before each test check the tightness of the motor belt or chain drive, alignment of the pulleys and cables in both horizontal and vertical planes, and tautness of the cable.

7.2 Brush—The bristles, if new, must be leveled before use to permit uniform wear on the paint surface. Leveling is accomplished by running the brush over 100 or 120-mesh aluminum oxide close grain sandpaper or emery cloth attached lengthwise on the glass plate in the washing machine. The total number of cycles required will vary from 1000 to 5000. Additional weight, up to 454 g, may be used to expedite the procedure. Change the sandpaper or emery cloth if it becomes clogged. Tape down the edges if any tearing is observed. Replace brush when bristles have worn to extend less than $\frac{5}{8}$ in. (16 mm) from block.

7.3 Brush Holder—Screws on the brush holder shall be removed and not used. Instead, insert a $\frac{1}{8}$ -in. (3.2-mm) thick rubber mat in the holder above the brush block. When in operation, this mat allows the brush to ride evenly on the paint surface without tilting (Fig. 1). The brush must fit loosely in the holder.

8. Procedure

8.1 Clean the top of the glass plate (or preferably suction plate) and both sides of the black plastic panel to be sure they are free of specks. Place the black panel on the plate and tape one end to the plate. Smooth the panel along the plate by rubbing with flannel, creating static electricity which improves adhesion to the plate.

8.2 Stir the test paint thoroughly and strain to remove all skins and particles. Draw down the paint on the panel using the 7.0-mil (0.18-mm) side of the film caster, starting from the taped end of the panel. The time for application should be fairly slow—3 to 4 s from end to end—to prevent formation of pinholes or holidays in the film. Air dry in a horizontal position for 7 days in an open room kept at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and 50 ± 5 % relative humidity.

8.3 Clean the plate and set it in the pan of the washability machine. Be sure that the shim is smooth and free of burrs and placed across the center of the plate. Wipe the test panel carefully and place it on top of the shimmed plate with the painted side up. Be sure that there are no defects in the film above the shim and that the test area is level. Prewet the gasket of the frame and wipe it dry before use. Place the frame over one half of the drawdown, being sure that the entire gasket is on the painted surface. (The other half can be used for a second test if desired.) Clamp the gasket in place. The clamps should be tight enough to ensure close contact, but not tight enough to cause warping of the panel.

8.4 Soak the brush in a 1 % solution of detergent⁶

FIG. 1 Accessory Apparatus for Scrub Test

overnight. Remove the brush and shake it vigorously to remove any excess. Mount the brush in the holder being sure that the mat is in place above the brush block and that the brush is always in the same position. (Mark both brush and holder beforehand.) Stir the scrub medium and spread 10 g evenly on the brush bristles. Place the brush at one end of the path and attach the guide cables. Wet the panel with 5 mL of reagent water in the path of the brush.

8.5 Set the cycle counter at zero. Start the test. After each 400 cycles before failure remove the brush (do not rinse); add 10 g of stirred scrub medium; replace the brush, being sure that brush and holder are in the same position with relation to each other and in the machine. Place 5 mL of water on the path before continuing.

8.6 Record the number of cycles to remove the paint film fully in one continuous line across the $\frac{1}{2}$ -in. (12.7-mm) width of the shim. Stop the machine and wipe off the area to determine the end point.

8.7 Make three drawdowns of each specimen. Test two and average them if they are within 25 % repeatability. If they are not, test a third and average the three, unless one of the results is obviously discrepant, in which case it should be discarded. According to the 90 % confidence limits specified herein, the running of a third test will be required, on the average, only one out of ten times for normal results.

9. Report

- 9.1 Report the mean number of cycles to failure (see Section 10).
- 9.2 Outline any deviations from standard procedure.

10. Precision

- 10.1 The following criteria should be used for judging the acceptability of results of scrub resistance tests at a 90 % confidence level.

10.1.1 *Repeatability*—Duplicate results by a single operator should be considered suspect if they differ by more than 25 % of their mean value.

10.1.2 *Reproducibility*—Two results (each the mean of duplicate measurements) obtained by operators in different laboratories should be considered suspect if they differ by more than 50 % of their mean.

11. Keywords

- 11.1 Scrub resistance; abrasion resistance

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Guide for Testing Wood Furniture Lacquers¹

This standard is issued under the fixed designation D 2571; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This Guide covers the evaluation of gloss or flatted, unpigmented lacquers designed for use on wood substrates. This Guide is to be used in conjunction with Test Methods D 333. Also included are several methods of special relevance to the application of lacquer on wood. The selection of the tests to be used for any given product or system must be governed by experience and by the requirements agreed upon by the producer and user.

1.2 The tests on films apply to those films applied in sufficient quantity to form a continuous film. It is recommended that reports include the thickness of the film under test.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

¹ This Guide is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.55 on Factory-Applied Coatings on Performed Products.

Current edition approved March 25, 1988. Published September 1988. Originally published as D 2571 - 67. Last previous edition D 2571 - 81(1987).

² Annual Book of ASTM Standards, Vol 06.03.

³ Annual Book of ASTM Standards, Vol 06.01.

⁴ Annual Book of ASTM Standards, Vols 06.01, 06.02 and 06.03.

⁵ Annual Book of ASTM Standards, Vols 14.02 and 06.03.

3. Significance and Use

3.1 This Guide is intended to compile as well as provide screening tests in evaluating wood furniture coatings both high gloss and flatted type, as used by the furniture industry.

3.2 Each wood finishing system may vary from a simple two-step operation to a complex operation consisting of as many as 15 steps.

3.3 The substrate is a complex and varied substrate that does absorb moisture from the surrounding environment. Variation in the moisture content of the wood before and after coating and during the testing affects the test results. Grease, dirt and foreign matter also affect the test results.

3.4 Results from these various tests are not necessarily useful in evaluating performance of all different types of furniture finishing systems.

4. Test Panels and Panel Preparation

4.1 Test panels should be regular production finish panels.

4.2 If regular production finish panels are not available, the producer and the user should agree on the substrate to be used and on the complete finishing system.

5. Nonvolatile Matter

5.1 Test for nonvolatile matter in accordance with Test Methods D 333.

6. Self-Lifting Properties

6.1 Apply a second coat after the first top-coat has been applied and air dried for 1, 6, and 24 h. Report any tendency of self-lifting.

7. Color

7.1 Test color of the liquid lacquer in accordance with Test Method D 1544.

8. Rubbing Properties

8.1 In the absence of a specified procedure, air dry the lacquer 18 h, sand with No. 320 W/D sandpaper wetted with mineral spirits, and then rub with 3-F pumice and paraffin oil (white mineral oil, U.S.P. heavy, or other suitable rubbing compound).

8.2 Examine the rubbed surface immediately and after 24 h, or the time agreed upon by the producer and the user, in a

standard atmosphere, for example, $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and 50 % relative humidity, and report any difference in appearance.

9. Print Test

9.1 Test for resistance to imprinting in accordance with Test Method D 2091.

10. Cold Check Test

10.1 Test for resistance to checking and cracking in accordance with Test Method D 1211 on a substrate agreed upon by the producer and the user. Report any difference in appearance.

11. Resistance to Oils, Greases, Cosmetics, and Other Household Chemicals

11.1 Test for resistance to the agents in 11.2 to 11.5. For other household chemicals test in accordance with Test Method D 1308.

11.2 *Cosmetic Stain*—Apply to the finished surface a heavy smear of lipstick of indelible type and place the panel in a 125°F (50°C) oven overnight. Remove the lipstick with mineral spirits meeting the requirements of Specification D 235, and evaluate.

11.3 *Alcohol Resistance*—Place 0.5 mL of 50 % ethanol (by weight) in water on the lacquer film and trap with a 2-in. (50-mm) watch glass. Pure, undiluted ethyl alcohol or denatured alcohol conforming to Formula 2-B of the U.S. Bureau of Internal Revenue are considered equivalent for this test. One hundred proof vodka may be used in place of 50 % ethanol. After at least 6 h, remove the watch glass and allow the alcohol to evaporate. Report whitening or spotting that cannot be removed with light polishing using a dry cotton pad.

11.4 *Boiling Water Resistance*—Pour 25 mL of boiling distilled or deionized water on the leveled panel and allow to cool to room temperature. Dry and examine. Report graying, spotting, softening, or other film deterioration.

11.5 *Coffee Stain Resistance*—Prepare coffee by each of the following methods:

11.5.1 Dissolve 1 teaspoon (5 cm^3) of instant coffee, 1 teaspoon of sugar, and 1 teaspoon of powdered cream substitute in 8 fl oz (240 mL) of at least 180°F distilled or deionized water.

11.5.2 Dissolve 1 teaspoon (5 cm^3) of instant coffee and sufficient synthetic sweetener (dry or liquid) to supply 5 mg of saccharin in 8 fl oz (240 mL) of at least 180°F distilled or deionized water.

11.5.3 Place 1 mL of each type of hot coffee on the panel and cover with 2-in. (50-mm) watch glasses. After 2 h, remove the watch glasses, and allow to evaporate. Wash the panel with a rag moistened with water. Report how readily the residue is removed.

12. Light Exposure

12.1 Test for the effect of light exposure in accordance with all methods except 1, 2, and 3 of Practice G 23, but operated without water spray. Report method used and results.

13. Tape Marring

13.1 Press a strip of cellophane tape, on the test panel, rolling it down with a 70 to 80 durometer hardness rubber roller. Allow the tape to remain on the panel for 30 min. Slowly remove the tape. After 30 min recovery, report any visible marring.

14. Tape Adhesion

14.1 Test for tape adhesion in accordance with Test Methods D 3359.

15. Resistance to Plasticizer Migration

15.1 Test and rate plasticizer migration in accordance with Test Method D 2199.

16. Accelerating Aging by Humid-Dry Cycling

16.1 Evaluate and report the accelerated aging in accordance with Test Method D 3459.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Resistance of Emulsion Paints in the Container to Attack by Microorganisms¹

This standard is issued under the fixed designation D 2574; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the resistance of emulsion paints against attack in the container by microorganisms.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Significance and Use

2.1 Spoilage of paint in the container can result in putrefaction, lowered pH, gas formation, and decrease in viscosity. This test method provides a standard procedure for the evaluation of the resistance of emulsion paints to microbial deterioration. The results should enable: (1) the paint manufacturer to select an effective preservative and (2) the supplier of preservatives to evaluate the performance in emulsion paints of competitive and developmental preservatives.

2.2 This test method should preferably be used by persons who have had basic microbiological training.

3. Apparatus

- 3.1 Refrigerator, maintained at 10 to 13°C.
- 3.2 Balance, accurate to 0.1 g.
- 3.3 Swabs, sterile cotton.
- 3.4 Screwcap Borosilicate Test Tubes, 125 by 15-mm.
- 3.5 Borosilicate Flasks, 1-L.
- 3.6 Screwcap Bottles, 150-mL.
- 3.7 Autoclave, capable of producing 15 psi (103 kPa) of steam pressure at 120°C and maintaining it for a minimum of 15 min. An autoclave is not necessary if prepared agar slants are used.

4. Materials

- 4.1 Culture of *Pseudomonas aeruginosa*.²
- 4.2 1 U.S. qt (945 mL) of Paint Under Test.
- 4.3 1 U.S. qt (945 mL) of paint identical to 4.2, but containing no microbiocide.

4.4 Dehydrated Tryptone-Glucose Extract Agar.³

4.5 Beef Extract.^{4,5}

4.6 Tryptone.^{4,5}

4.7 Glucose.^{4,5}

5. Preparation of Materials

NOTE—Observe conventional microbiological techniques in making these tests. Handle all materials so as to avoid contamination from the air, fingers, or work surfaces.

5.1 Preparation of Tryptone-Glucose Extract Agar Slants:

5.1.1 Add 12 g of tryptone-glucose extract agar to 500 mL of cold distilled water in a 1-L flask. Heat to boiling with frequent agitation to dissolve the medium completely.

5.1.2 Distribute 10 mL of the dissolved medium into each of 50 test tubes.

5.1.3 Autoclave tubes (with caps loose) for 15 min at 15 psi (103 kPa) and a temperature of 120°C.

5.1.4 Upon removal from the autoclave, tighten caps and place the tubes at an approximate 30° angle position to cool, making a slope about 2 in. (50 mm) long.

5.1.5 Store agar slants in a refrigerator at 10 to 13°C until needed.

5.2 Preparation of Tryptone-Glucose Extract Broth:

5.2.1 Add 1.5 g of beef extract, 2.5 g of tryptone, and 0.5 g of glucose to 500 mL of cold distilled water in a 1000-mL flask. Heat to boiling to dissolve the medium completely.

5.2.2 Distribute 10 mL of the dissolved medium into each of 50 test tubes.

5.2.3 Autoclave tubes (with caps loose) for 15 min at 15 psi (103 kPa) and a temperature of 120°C.

5.2.4 Upon removal from the autoclave, allow the tubes to cool to room temperature, tighten the caps, and store until needed.

5.3 Inoculation of Tryptone-Glucose Extract Broth With *Pseudomonas Aeruginosa*:

5.3.1 To an agar culture of *Pseudomonas aeruginosa*, add 3 mL of the tryptone-glucose extract broth prepared in 5.2. Using a sterile cotton swab, remove bacterial growth from the surface of the agar and mix with the broth.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.28 on Biodeterioration.

Current edition approved May 30, 1986. Published July 1986. Originally published as D 2574 - 67 T. Last previous edition D 2574 - 73 (1980).

² Suitable culture may be obtained from the American Type Culture Collection, Washington, DC.

³ Tubed tryptone-glucose extract agar slants available from Difco Laboratories, Inc., Detroit, MI 48201, Baltimore Biological Laboratories, Baltimore, MD 21218, or equivalent are suitable for use by those who do not have the necessary equipment for preparation of their own media.

⁴ Available from Difco Laboratories, Inc., Detroit, MI 48201, Baltimore Biological Laboratories, Baltimore, MD 21218, or equivalent.

⁵ Tryptone-glucose extract broth may be prepared by dissolving a commercially produced tablet in water. Suitable tablets may be obtained from Consolidated Laboratories, Chicago Heights, IL.

5.3.2 Remove the cotton swab soaked with broth and place in a tube of sterile tryptone-glucose extract broth. Transfer the inoculated broth to the sterile broth by pressing the swab against the inside wall of the tube.

5.3.3 Remove the cotton swab and incubate the broth culture at 27 to 28°C for 24 h.

5.3.4 Soak a second sterile cotton swab in the broth added to the culture of *Pseudomonas aeruginosa* described in 5.3.1. Remove the cotton swab soaked with broth and transfer the inoculated broth to the surface of a tryptone-glucose extract agar slant prepared in 5.1 by pressing the swab gently on top of the agar surface. Incubate slant at 27 to 28°C for 24 h or until luxuriant colony growth is observed on the agar surface. Label as culture of *Pseudomonas aeruginosa* ATTC No. 10145 and store in a refrigerator at 10 to 13°C until 5.3.1 is repeated for a future test.

5.3.5 Soak a sterile cotton swab in the inoculated broth culture following the incubation period described in 5.3.3.

5.3.6 Remove the swab and prepare a second broth culture by repeating 5.3.2 and 5.3.3.

5.3.7 Following the incubation period, use the broth culture prepared in 5.3.6 to proceed as described in Section 6.

6. Procedure

6.1 Preparation of Spoiled Paint:

6.1.1 Transfer the well-shaken broth culture prepared in 5.3.6 to the 1-qt (945-mL) sample of paint (see 4.3). Shake the inoculated paint well before proceeding.

6.1.2 Incubate the paint at 27 to 28°C for 1 week.

6.1.3 To determine whether or not the paint contains bacteria at the end of the incubation period, use a sterile cotton swab to transfer a specimen of paint to the surface of a tryptone-glucose agar slant. Incubate agar slant at 27 to 28°C for 72 h. If colonies of *Pseudomonas aeruginosa* appear on the agar surface, paint is satisfactory for use as spoiled paint in 6.4.1. If colonial growth of *Pseudomonas aeruginosa* does not appear on the surface, repeat 6.1.1 and 6.1.2.

6.2 Preliminary Examination of Paint Under Test:

6.2.1 Examine the can for evidence of swelling. If the can is swollen, exercise caution in removing the lid.

6.2.2 Remove the lid and smell the contents of the can. Deterioration of paint by microorganisms is often characterized by distinct odors. Such odors may be either putrefactive or fermentative.

6.2.3 Observe the contents of the can for the presence of stringy structures characteristic of the presence of certain microorganisms.

6.2.4 Observe the contents for noticeable losses in viscosity. This physical change frequently occurs as the result of microbiological deterioration.

6.3 Determination of Presence or Absence of Living Microorganisms in Paint Under Test:

6.3.1 Soak a sterile cotton swab in the paint under test. Remove excess paint by pressing gently against inside of container.

6.3.2 Transfer the test paint to the surface of a tryptone-glucose agar slant by pressing the swab gently on the agar surface.

6.3.3 In order to obtain duplicate agar slants, repeat 6.3.1 and 6.3.2.

6.3.4 Incubate the inoculated agar slants at 27 to 28°C for a minimum of 1 week.

6.3.5 If colonial growth of bacteria is observed on the agar surface at the end of the incubation period, the test is complete and may be reported in accordance with Section 7.

6.3.6 If colonial growth of bacteria is not observed on the agar surface at the end of the incubation period, continue the test as described in 6.4.

6.4 Challenging Test Paint by Inoculation:

6.4.1 To 100 g of the paint under test, add 1 g of paint spoiled in 7.1.

6.4.2 Incubate the paint for 6 weeks at 27 to 28°C.

6.4.3 At the end of 24, 48, 72 h and 1 week of incubation and once each succeeding week throughout the incubation period, soak a sterile cotton swab in the paint. Remove excess paint by pressing against the side of the container and transfer the paint to the surface of a tryptone-glucose agar slant.

6.4.4 Incubate the agar slant at 27 to 28°C for 1 week and observe the presence or absence of colonial growth of bacteria.

6.4.5 At the end of 6 weeks add an additional 1 g of paint spoiled in 6.1. Incubate for 2 weeks at 27 to 28°C and repeat 6.4.3 and 6.4.4.

7. Report

7.1 Report the following information:

7.1.1 Results of observations noted under 6.2.

7.1.2 Presence or absence of living microorganisms in the paint as received, and after it has been inoculated (or reinoculated) with a sample of spoiled paint.

7.1.3 If living microorganisms are found in the paint as received, or after inoculation (or reinoculation), the paint shall be reported as "not resistant in the container to attack by microorganisms."

7.1.4 If living organisms are not found, the paint shall be reported as "resistant in the container to attack by microorganisms."

8. Precision and Bias

8.1 No statement is made about either the precision or bias of this test method for measuring the resistance of emulsion paints in the container to attack by microorganisms, since the result merely states observations of the paint under test and presence or absence of living microorganisms in the paint as received or after inoculation.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. Standard Test Method for Light Stability of Clear Coatings¹

This standard is issued under the fixed designation D 2620; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the discoloration of clear coatings by sunlight through glass.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D1729 Practice for Visual Evaluation of Color Differences of Opaque Materials²

D1925 Test Method for Yellowness Index of Plastics³

G24 Practice for Conducting Natural Light Exposures Under Glass²

3. Summary of Method

3.1 The effect of sunlight on discoloration of clear coatings is determined by exposing under glass, coated panels masked at one end, to natural sunlight for a specified time. At the end of the exposure, the mask is removed and the panels evaluated for degree of discoloration.

4. Significance and Use

4.1 Color change, particularly yellowing, is not generally acceptable to users of coatings when it is readily noticeable. In designing clear coating systems for interior use on various substrates, it is of interest to know how well the clear coats will resist color change caused by ambient light. This test method permits the evaluation of the effect of natural indoor light on the color stability of clear coatings.

5. Apparatus

5.1 *Exposure Cabinet* as described in Practice G 24.

6. Test Specimens

6.1 For each clear coating under test, use one test panel approximately 3 by 5 in. (75 by 125 mm) of white carrara glass or other specified substrate material.

NOTE 1—Other materials that may be considered for this purpose include: (1) White ceramic tile. (2) A white pigmented, light-stable

coating which would not be lifted by the clear topcoat. (A baking enamel with the composition of 30 % melamine formaldehyde resin and 70 % of the phthalic anhydride/coconut alkyd resin with 3 lb/gal (1.36 kg/L) of titanium dioxide per gallon has been found satisfactory.) (3) The substrate intended for use with the clear coating. The light stability of the substrate may be determined by including an extra test panel without a clear topcoat.

6.2 Prepare specimens of the test materials by applying the coatings on the test panels to a dry film thickness of 2 ± 0.2 mil (50 ± 5 μ m).

6.3 Prepare a reference specimen, representing a material of known performance in this test, with each set of test specimens.

6.4 Record the panel preparation details: method of coating application, baking conditions, film thickness, etc. These details will be established by mutual agreement between purchaser and seller in accordance with the type of product and its intended use.

7. Conditioning

7.1 Unless otherwise specified, condition the coated panels at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and 50 ± 5 % relative humidity for 48 h if baked, or 7 days if air dried.

8. Procedure

8.1 Prior to exposure, mask one-half of each test panel with aluminum foil to exclude sunlight from the other half of the coating.

NOTE 2—The tape used to attach the mask to the panel should not extend over the edge of the mask but should extend beyond the ends of the mask and stick to the rear of the panel, thereby holding the mask in position. This will prevent contact between the tape and the finish and eliminate the possibility of staining from the tape.

8.2 Mount the test specimens in the glass-covered exposure cabinet continuously 24 h a day for the specified period of exposure. It is recommended this period should be approximately 5 weeks, since longer periods of exposure do not significantly change the results.

NOTE 3—In cooperative tests, exposure of nitrocellulose lacquers, cellulose acetate butyrate lacquer, and low-bake alkyd enamel for 22 weeks did not show significantly greater discoloration than after exposure for 5 weeks.

9. Interpretation of Results

9.1 Visual ratings of the degree of discoloration may be made. However, it is preferred that an instrumental method be used as described in Test Method D 1925, (see Test Method D 1729).

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.55 on Factory-Applied Coatings on Preformed Products.

Current edition approved May 29, 1987. Published July 1987. Originally published as D 2620 - 67. Last previous edition D 2620 - 68 (1981)⁴.

² *Annual Book of ASTM Standards*, Vol 14.02.

³ *Annual Book of ASTM Standards*, Vol 08.02.

10. Color Changes Not Caused by Light

10.1 In many cases atmospheric conditions (temperature, humidity, reactive gases) may produce significant color changes even without the presence of light. An indication as to whether or not side effects are operating may be obtained by retaining unexposed a duplicate set of specimens in the laboratory. A difference in color between the unexposed specimens and the covered portion of the exposed specimens indicates that the material has been affected by some agent other than light.

10.2 Further clarification regarding atmospheric effects may be obtained by simultaneously exposing a duplicate set of test specimens in another cabinet of the same type used in the light exposures but with the glass covered with an opaque material so that the light is excluded.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

11. Report

11.1 Report the following information:

- 11.1.1 Visual ratings or instrumental values for degree of discoloration of coatings or both,
- 11.1.2 Date and location of exposure,
- 11.1.3 Length of exposure,
- 11.1.4 Substrate used,
- 11.1.5 Details of panel preparation, and
- 11.1.6 Conditioning of panels prior to testing.

12. Precision

12.1 Because of the many variations in visual rating of discoloration, meaningful estimates of precision cannot be given. In cooperative tests, however, fairly good agreement was obtained by the various cooperators in the visual rating of the test panels.

Standard Test Method for Infrared Identification of Vehicle Solids From Solvent- Reducible Paints¹

This standard is issued under the fixed designation D 2621; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the qualitative characterization or identification of separated paint vehicle solids by infrared spectroscopy within the limitations of infrared spectroscopy.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

- D 1467 Guide for Testing Fatty Acids Used in Protective Coatings²
- D 1962 Test Method for Saponification Value of Drying Oils, Fatty Acids, and Polymerized Fatty Acids²
- D 2372 Method of Separation of Vehicle from Solvent-Reducible Paints³
- E 131 Definitions of Terms and Symbols Relating to Molecular Spectroscopy⁴
- E 275 Practice for Describing and Measuring Performance of Ultraviolet, Visible, and Near Infrared Spectrophotometers⁴

3. Definitions

3.1 For definitions of terms of symbols, refer to Definitions E 131.

4. Summary of Test Method

4.1 Infrared spectra are prepared from dried films of isolated paint vehicles. Vehicle types are identified by comparing the spectra to a collection of reference infrared spectra.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Materials.

Current edition approved June 26, 1987. Published August 1987. Originally published as D 2621 - 67 T. Last previous edition D 2621 - 69 (1981)⁴.

² Annual Book of ASTM Standards, Vol 06.03.

³ Annual Book of ASTM Standards, Vol 06.01.

⁴ Annual Book of ASTM Standards, Vol 14.01.

5. Significance and Use

5.1 The ability to qualitatively identify paint vehicles is useful for characterizing unknown or competitive coatings, for complaint investigations, and for in-process control.

6. Apparatus

6.1 *Spectrophotometer*—A recording double-beam infrared spectrophotometer with a wavelength range from at least 2.5 to 15 μm and a spectral resolution of at least 0.04 μm over that range. See Practice E 275.

6.2 *Demountable Cell Mount* with NaCl window.

6.3 *Vacuum Drying Oven* thermostatically controlled to operate at $60 \pm 2^\circ\text{C}$. A water aspirator vacuum source is satisfactory.

6.4 *Oven, Gravity or Forced Draft*, capable of maintaining temperature from 105 to 110°C.

7. Procedure

7.1 Place the vehicle, separated from the paint in accordance with Method D 2372, on a NaCl window and spread to form a uniform film. The thickness of the film should be such that when the infrared spectrum is recorded the transmittance of the strongest band falls between 5 and 15 % (Note). Dry the film in an oven at 105 to 110°C for 15 min and cool in a desiccator. Inspect the film visually for defects such as bubbles, wrinkles, contamination, etc. If defects are present, cast another film. If easily oxidizable substances are present such as tung, oiticica, or linseed oils, the film should be dried at $60 \pm 2^\circ\text{C}$ in a vacuum oven for 1 h. If solvents of low volatility such as cyclohexanone or isophorone are present, the film may need to be dried for several hours in a 60°C vacuum oven.

NOTE—Numerous procedures and variations may be used to obtain a film on which to prepare a suitable spectrum. These include liquid mounting between two NaCl plates, transmission through free films, and reflectance from highly polished surfaces.

7.2 Immediately record the infrared spectrum from 2.5 to 15 μm so that a spectral resolution of 0.04 μm is maintained throughout that range (methods for achieving this resolution will vary according to the directions of the manufacturer of the instrument used).

7.3 Compare the spectrum obtained with reference spectra prepared from nonvolatile vehicles of known composition (see Annex A1) or consult other published spectra available in the literature (Annex A3). Interpret the spectrum on the basis of available information, recognizing certain limitations of infrared spectroscopy, and qualifying the interpretation accordingly (Annex A2).

TABLE 1 Correlation of Absorption Bands in Alkyd Spectra

Wavelength, μm	Wavenumbers, cm^{-1}	Group Vibration
2.9	3448	O—H stretch
3.4 to 3.5	2941 to 2857	alkane C—H stretch
5.8	1724	ester, C=O stretch
6.2, 6.3, 6.6, 6.7	1613, 1587, 1515, 1493	skeletal in-plane aromatic C=C
6.9, 7.3	1449, 1369	aliphatic C—H bending
7.5 to 9.4	1333 to 1063	ester, C—O—C stretch (o-phthalate ester)
8.6	1163	ester, C—O—C stretch (fatty acid ester)
9.6, 13.5, 14.3	1042, 741, 699	out-of-plane aromatic C—H bending denoting o-disubstituted benzene ring.

ANNEXES

(Mandatory Information)

A1. INFRARED SPECTRA OF NONVOLATILE VEHICLES OF KNOWN COMPOSITION

A1.1 A set of reference infrared spectra on grating and prism is reproduced on the following pages.

A2. CONSIDERATIONS IN THE INTERPRETATION OF INFRARED SPECTRA OF NONVOLATILE VEHICLES SEPARATED FROM SOLVENT-TYPE PAINTS

INTRODUCTION

The infrared spectra of vehicles recovered from whole paint are presented in Annex A1. The aim of this compilation is to aid those using Test Method D 2621 in the practical interpretation of the spectra they obtain.

The spectra are compiled with one representative spectrum of each vehicle presented in both a prism and a grating format. In the discussion of the spectra, the general assignment refers to the first spectrum. The subsequent spectra discussion will include only those bands which aid in the identification of the particular modifications being illustrated. In addition, some practical information is provided where it is believed to be helpful to the analyst. In general, previously noted band assignments are not repeated.

The data compiled here were obtained from spectra prepared on very carefully calibrated instruments. In comparing them to spectra prepared in any given laboratory, it is expected that the wavelength values of absorption bands may differ slightly depending upon the calibration of the instrument used.

GROUP I-ALKYDS

A2.1 Spectrum 1: Ortho-Phthalic Alkyd, Medium Oil Length

A2.1.1 2.9- μm Region (3448 cm^{-1})—The 2.9- μm band in alkyds is due to the O—H stretching vibration. This is usually attributed to the unesterified hydroxyl OH on the polyhydric alcohol used in manufacturing the alkyd. This absorption is known to increase on drying of unsaturated oil modified alkyds due to oxidation of the double bonds. This absorption band can be used to determine the hydroxyl number of alkyds.

A2.1.2 3.3 to 3.6- μm Region ($3030\text{ to }2778\text{ cm}^{-1}$)—The bands in this area are all due to aromatic and aliphatic C—H stretching vibrations.

A2.1.3 5 to 6- μm Region ($2000\text{ to }1667\text{ cm}^{-1}$)—The 5.8- μm band in alkyds is due to the combined C=O stretch of the phthalate and fatty acid esters. Unreacted phthalic anhydride, if present, may be detected by the appearance of a sharp absorption band at approximately 5.6 μm (1786 cm^{-1}). Free carboxyl groups (due to unreacted fatty acid or

incompletely reacted phthalic acid) may often be detected by the appearance of a shoulder on the high wavelength (low frequency) side of the ester carbonyl band.

A2.1.4 6.2 to 6.4- μm Region ($1613\text{ to }1563\text{ cm}^{-1}$)—The doublet appearing in this region of the spectrum is due to vibrations associated with the double bonds in an aromatic ring. The band shape and position of this doublet is characteristic of non-oil modified, o-phthalic alkyds.

A2.1.5 6.8 to 6.9- μm Region ($1470\text{ to }1449\text{ cm}^{-1}$)—This absorption is produced by C—H bending vibrations of methylene (scissoring deformation) and methyl (asymmetrical deformation) groups in the alkyd. The intensity of this absorption band will vary with oil length.

A2.1.6 7.2 to 7.3- μm Region ($1389\text{ to }1370\text{ cm}^{-1}$)—This absorption band is due to the C—CH₃ symmetrical deformation vibration, and is produced by the methyl groups on the fatty acid chains.

A2.1.7 7.5 to 10.0- μm Region ($1333\text{ to }1000\text{ cm}^{-1}$)—The absorption bands in this region are due to the C—O—C

stretching vibrations of the phthalate ester. These absorptions are most strongly influenced by the acid portion of the ester rather than the alcoholic portion.

A2.1.8 13.5 and 14.2- μm Regions (741 and 704 cm^{-1})—These two bands are due to out-of-plane bending vibrations of ring hydrogens of aromatic compounds having four adjacent hydrogens (orthodisubstitution).

A2.1.9 Comments:

A2.1.9.1 Note that in oil-modified alkyds, the intensity of the absorption at 8.6 μm (1163 cm^{-1}) is indicative of the amount of oil modification or oil length of the alkyd. In unmodified alkyds, this band may be little more than a shoulder on the 8.9- μm (1124- cm^{-1}) C—O—C absorption. The correlation to oil length is only a very general one in that within a given group of alkyds one may say a sample is a "short," "medium," or "long" oil type.

A2.1.9.2 Alkyd spectra generally reveal little or no information concerning the type of combined oil or polyol present.

A2.1.9.3 Identification of polyol and unsaponifiables may usually be accomplished by infrared examination of saponification fractions. Identification of the oil acids used usually requires gas chromatographic analysis of the methylated fatty acids recovered by saponification. (For saponification procedures see Test Methods D 1467 and D 1962.)

A2.2 Spectrum 2: Ortho-Phthalic Alkyd, Long Oil Length

A2.2.1 8.6 μm (1163 cm^{-1}); fatty acid ester C—O—C

A2.2.2 Comments—Note the difference in the 8.6- μm (1163- cm^{-1}) peak compared to Spectrum 1, due to increased oil length.

A2.3 Spectrum 3: Ortho-Phthalic Alkyd, Tung Oil Modified

A2.3.1 10.12 μm (988 cm^{-1}); —C=C—C=C—C=C— Conjugated triene unsaturation

A2.3.2 Comments—Note the difference in band shapes in the 10 to 10.4- μm region (1000 to 962 cm^{-1}) compared to Spectra 1 and 2. Absorption due to conjugated unsaturation (in such oil types as tung, oiticica, dehydrated castor, and conjugated safflower) occurs here. Oil types used for alkyds 1 and 2 contain only isolated double bonds.

A2.4 Spectrum 4: Ortho-Isophthalic Alkyd

A2.4.1 7.8 μm (1282 cm^{-1}) isophthalate ester C—O—C

A2.4.2 8.2 μm (1220 cm^{-1}) isophthalate ester C—O—C

A2.4.3 8.9 μm (1124 cm^{-1}) isophthalate ester C—O—C

A2.4.4 13.7 μm (730 cm^{-1}) meta-disubstituted benzene ring

A2.4.5 Comments—The spectrum of this alkyd is typical of an isophthalic alkyd. The major band that identifies this as an isophthalate is the 13.7- μm (730- cm^{-1}) band. The presence of orthophthalic alkyd can be suspected by comparison to a straight isophthalic alkyd spectrum (see following) and noting the influence of the ortho-phthalate at 7.9 μm (1266 cm^{-1}), 9.0 μm (1111 cm^{-1}), 9.4 μm (1064 cm^{-1}), and at 14.2 μm (704 cm^{-1}).

A2.5 Spectrum 5: Ortho-Phthalic Alkyd, Benzoic Acid Modified

A2.5.1 14.0 to 14.1 μm (714 to 709 cm^{-1}); aromatic ring vibration where ring contains five adjacent hydrogens. Posi-

tion is characteristic of benzoate esters.

A2.5.2 Comments—The band at approximately 14.0 μm (714 cm^{-1}) is the identifying peak for this modification. Because of the *o*-disubstitution peak at 14.3 μm (699 cm^{-1}) present in *o*-phthalates, it is difficult to observe this band when the benzoic acid modification drops below 3 %.

A2.6 Spectrum 6: Ortho-Phthalic Alkyd, Para-Tertiary Butyl Benzoic Acid Modified

A2.6.1 8.4 μm (1190 cm^{-1}) C—O—C *p*-tert. butyl benzoate

A2.6.2 9.6 μm (1042 cm^{-1}) C—O—C *p*-tert. butyl benzoate

A2.6.3 9.8 μm (1020 cm^{-1}) C—O—C *p*-tert. butyl benzoate

A2.6.4 11.7 μm (855 cm^{-1}) aromatic ring substitution patterns

A2.6.5 12.9 μm (775 cm^{-1}) aromatic ring substitution patterns

A2.6.6 Comments—The characteristic bands for the identification of the paratertiary butyl benzoic acid modification are the 11.7- μm (855- cm^{-1}) and the 12.9- μm (775- cm^{-1}) bands. The other absorption bands, although sharp and distinctive, can tend to be lost in the background of the spectrum when the modification drops below 2 to 3 %.

A2.7 Spectrum 7: Ortho-Phthalic Alkyd, Tall Oil, Rosin Modified

A2.7.1 12.3 μm (813 cm^{-1}) abietic acid ring vibration

A2.7.2 Comments—The curve shows only a very slight depression at 12.3 μm (813 cm^{-1}). In general, the band is never very intense and, if suspected, the presence of rosin is readily confirmed by a Lieberman-Storch spot test. Note also the obscured nature of the 6.3 to 6.5- μm (1587 to 1538- cm^{-1}) region. This is most likely due to the salt or "soap" formation with the acids present in the system and the pigment used.

A2.8 Spectrum 8: Ortho-Phthalic Alkyd, *p*-Phenyl Phenol Modified

A2.8.1 11.4 μm (877 cm^{-1}) associated with substituted aromatic rings

A2.8.2 12.1 μm (826 cm^{-1}) associated with substituted aromatic rings

A2.8.3 13.1 μm (763 cm^{-1}) associated with substituted aromatic rings

A2.8.4 14.4 μm (694 cm^{-1}) associated with substituted aromatic rings

A2.8.5 Comments—The main identifying band is the 13.1- μm (763- cm^{-1}) band. The other bands are less distinctive, especially the 14.4- μm (694- cm^{-1}) area. It is always best to consider the positions of the 3 or 4 absorptions in the far end of the curve as a group in assigning the modifying structure.

A2.9 Spectrum 9: Ortho-Phthalic Alkyd, Styrene Modified

A2.9.1 6.7 μm (1493 cm^{-1}) aromatic ring vibration

A2.9.2 13.2 μm (758 cm^{-1}) monosubstituted aromatic (5 adjacent ring hydrogens)

A2.9.3 14.3 μm (699 cm^{-1}) monosubstituted aromatic (5 adjacent ring hydrogens)

A2.9.4 Comments—The very general forebroadening in the 13 to 13.3- μm (769 to 758- cm^{-1}) area of the ortho substitution band is characteristic of styrene modification. The 14.3- μm (699- cm^{-1}) absorption that obscures the normally present small 14.3- μm (699- cm^{-1}) band is the primary styrene absorption. Note also the sharp 6.7- μm (1493- cm^{-1}) peak which is associated with the presence of an aromatic.

A2.10 Spectrum 10: Ortho-Phthalic Alkyd, Vinyl Toluene Modified

A2.10.1 6.6 μm (1515 cm^{-1}) aromatic ring vibrations

A2.10.2 6.7 μm (1492 cm^{-1}) aromatic ring vibrations

A2.10.3 11.4 μm (877 cm^{-1}) meta-disubstituted aromatic

A2.10.4 12.3 μm (813 cm^{-1}) para-disubstituted aromatic

A2.10.5 12.8 μm (781 cm^{-1}) meta-disubstituted aromatic

A2.10.6 14.2 μm (704 cm^{-1}) meta-disubstituted aromatic

A2.10.7 *Comments*—The general pattern of peaks at the end of the spectrum is characteristic for vinyl-toluene modification. They arise from the meta-para mixed isomers.

A2.11 Spectrum 11: Ortho-Phthalic Alkyd, Acrylonitrile Modified

A2.11.1 4.5 μm (2222 cm^{-1}) C $\equiv$ N nitrile stretching vibration

A2.11.2 *Comment*—The 4.5- μm (2222- cm^{-1}) band is the outstanding feature characteristic of an acrylonitrile modification.

2.12 Spectrum 12: Ortho-Phthalic Alkyd, Bis-Phenol Epoxy Modified

A2.12.1 8.4 μm (1190 cm^{-1}) aromatic C—O—C

A2.12.2 10.9 μm (917 cm^{-1}) terminal epoxy grouping

A2.12.3 12.1 μm (826 cm^{-1}) para-disubstituted aromatic.

A2.12.4 *Comments*—The band at 10.9 μm (917 cm^{-1}) is due to the weakly absorbing terminal epoxy group. The 12.1- μm (826- cm^{-1}) absorption is due to the bis-phenol backbone of the epoxy polymer. The band at 8.4 μm (1190 cm^{-1}) is also always present in conjunction with the 12.1- μm (826- cm^{-1}) band.

A2.13 Spectrum 13: Ortho-Phthalic Alkyd, Urea-Formaldehyde Modified

A2.13.1 3.1 μm (3226 cm^{-1}) N—H stretching vibration.

A2.13.2 6.1 μm (1639 cm^{-1}) amide linkage band

A2.13.3 6.6 μm (1515 cm^{-1}) amide linkage band

A2.13.4 9.3 μm (1075 cm^{-1}) C—O—C ether

A2.13.5 13.0 μm (769 cm^{-1}) unknown (but present in all urea-formaldehyde resins).

A2.13.6 *Comments*—The presence of urea-formaldehyde in an o-phthalic alkyd can always be observed in the spectrum by its influence at the wavelengths listed above. The general curve shape is somewhat depressed throughout. The 3.1- μm (3226- cm^{-1}) absorption appears as a shoulder on the O—H stretch at 3.0 μm (3333 cm^{-1}).

A2.14 Spectrum 14: Ortho-Phthalic Alkyd, Melamine-Formaldehyde Modified

A2.14.1 6.5 μm (1538 cm^{-1}) C $\equiv$ N

A2.14.2 12.3 μm (813 cm^{-1}) triazine ring vibration

A2.14.3 *Comments*—A melamine modification is always distinguishable from the urea-formaldehyde modification in that it lacks the 6.1- μm (1639- cm^{-1}) absorption and contains the 12.3- μm (813- cm^{-1}) triazine ring vibration.

A2.15 Spectrum 15: Ortho-Phthalic Alkyd, Benzoguanamine-Formaldehyde Modification

A2.15.1 6.3 μm (1587 cm^{-1}) aromatic ring vibration

A2.15.2 6.5 μm (1538 cm^{-1}) C $\equiv$ N

A2.15.3 12.1 μm (826 cm^{-1}) characteristic band for benzoguanamine derived modification

A2.15.4 12.8 μm (781 cm^{-1}) characteristic band for benzoguanamine derived modification

A2.15.5 14.2 μm (704 cm^{-1}) characteristic band for benzoguanamine derived modification

A2.15.6 *Comments*—The C $\equiv$ N band occurs at a slightly lower wavelength than in the melamine resins. The band at 12.1 μm (826 cm^{-1}) rather than at 12.3 μm (813 cm^{-1}) also helps to distinguish between the two types of triazine based resins.

A2.16 Spectrum 16: Ortho-Phthalic Alkyd, Hexamethoxymethylmelamine Modified

A2.16.1 9.3 μm (1075 cm^{-1}) C—O—C ether

A2.16.2 *Comments*—The presence of hexamethoxymethylmelamine can be observed in the spectrum of an ortho-phthalic-alkyd by its influence at 6.5 μm (1538 cm^{-1}); 6.7 μm (1493 cm^{-1}); 9.3 μm (1075 cm^{-1}); 9.9 μm (1010 cm^{-1}); 10.9 μm (917 cm^{-1}); 11.5 μm (870 cm^{-1}); and 12.3 μm (813 cm^{-1}).

A2.17 Spectrum 17: Ortho-Phthalic Alkyd, Rosin-Maleic Adduct Modified

A2.17.1 5.4 μm (1852 cm^{-1}) C=O stretching vibrations associated with anhydrides

A2.17.2 5.6 μm (1786 cm^{-1}) C=O stretching vibrations associated with anhydrides

A2.17.3 *Comments*—The most characteristic absorptions are the ones listed above which cause multiple bands in the carbonyl area. The presence of the rosin-maleic adduct can also be seen at 10.6 μm (943 cm^{-1}); 10.9 μm (917 cm^{-1}); 11.7 μm (855 cm^{-1}); and 12.2 μm (820 cm^{-1}). These bands are generally found in all rosin-maleic adducts even if slightly changed in intensities.

A2.18 Spectrum 18: Ortho-Phthalic Alkyd, Vinyl Chloride-Acetate Modified

A2.18.1 7.0 μm (1428 cm^{-1}) —CH₂—

A2.18.2 8.0 μm (1250 cm^{-1}) —CH in —CHCl—

A2.18.3 14.5 μm (690 cm^{-1}) C—Cl

A2.18.4 *Comments*—The most characteristic features of this spectrum are the 8 to 8.1- μm (1250 to 1234- cm^{-1}) absorption and the very broad band peaking at approximately 14.5 μm (690 cm^{-1}). A general depression of the entire curve is noted between 7.0 μm (1428 cm^{-1}) and 10.0 μm (1000 cm^{-1}).

A2.19 Spectrum 19: Ortho-Phthalic Alkyd, Phenyl Siloxane Modified

- A2.19.1 7.0 μm (1429 cm^{-1}) aromatic silicon bond
 A2.19.2 8.8 μm (1136 cm^{-1}) Si—O—Si
 A2.19.3 10.0 μm (1000 cm^{-1}) aromatic silicon bond
 A2.19.4 14.4 μm (694 cm^{-1}) mono-substituted aromatic
 A2.19.5 *Comments*—The general influence of the presence of silicone is seen in the depressed area from 8.8 μm (1136 cm^{-1}) to 10.0 μm (1000 cm^{-1}).

A2.20 Spectrum 20: Ortho-Phthalic Alkyd, Methyl Siloxane Modified

- A2.20.1 7.9 μm (1266 cm^{-1}) —Si—CH₃
 A2.20.2 12.5 μm (800 cm^{-1}) —(CH₃)₂—Si

A2.21 Spectrum 21: Ortho-Phthalic Alkyd, Nitrocellulose Modified

- A2.21.1 6.1 μm (1639 cm^{-1}) R—O—NO₂ stretching vibration
 A2.21.2 7.8 μm (1282 cm^{-1}) R—O—NO₂ stretching vibration
 A2.21.3 9.5 μm (1053 cm^{-1}) general C—O—C ether from the cellulose ring
 A2.21.4 11.9 μm (840 cm^{-1}) low-frequency vibrations associated with R—O—NO₂
 A2.21.5 *Comments*—The most prominent absorptions are the 6.1- μm (1639 cm^{-1}) band and the very broad 11.9- μm (840 cm^{-1}) peak. An additional reliable feature of

nitrocellulose is the ether linkage which causes a general depression in the mid-section of the spectrum.

A2.22 Spectrum 22: Ortho-Phthalic Alkyd, Urethane Modified

- A2.22.1 5.8 μm (1724 cm^{-1}) R—NH—CO—OR amide I band
 A2.22.2 6.3 μm (1587 cm^{-1}) aromatic vibration (in aromatic di-isocyanate systems)
 A2.22.3 6.5 μm (1538 cm^{-1}) amide II band, C—N
 A2.22.4 12.3 μm (813 cm^{-1}) 1,2,4 tri-substitution (in systems with toluene di-isocyanate)

A2.23 Spectrum 23: Isophthalic Alkyd, Medium Oil Length

- A2.23.1 6.2 μm (1613 cm^{-1}) ring unsaturation
 A2.23.2 13.8 μm (725 cm^{-1}) meta-disubstitution band
 A2.23.3 *Comments*—Note the change from a doublet in the 6.2- μm (1613 cm^{-1}) region to the singlet. The 13.8- μm (725 cm^{-1}) band is characteristic for isophthalic alkyds.

A2.24 Spectrum 24: Tere-Phthalic Alkyd, Medium Oil Length

- A2.24.1 8.6 μm (1163 cm^{-1}) C—O—C
 A2.24.2 9.8 μm (1020 cm^{-1}) C—O—C
 A2.24.3 *Comments*—The tere-phthalate spectrum is identified mainly by the 8.6- μm (1163 cm^{-1}) and 9.8- μm (1020 cm^{-1}) peaks combination in conjunction with a 13.8- μm (725 cm^{-1}) peak position.

A2.25 Spectrum 25: Ortho-Phthalic Alkyd, Chlorendic Acid Modified

- A2.25.1 *Comments*—The overall appearance of the absorption band pattern in this spectrum is characteristic of this modification.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Methods for Microscopical Measurement of Dry Film Thickness of Coatings on Wood Products^{1,2}

This standard is issued under the fixed designation D 2691; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

1. Scope

1.1 These test methods cover the measurement of film thickness of dried coatings applied to a plane rigid substrate of wood or a wood-base material. These test methods apply to both opaque and clear coatings. They are not recommended for metal or glass substrates. Test Method A uses a razor blade and Test Method B a microtome for cross sectioning.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Significance and Use

2.1 This test method provides a precise, quantitative measurement of the thickness of a dried coating. It may be used for quality control or monitoring of the production of coated wood products.

3. Apparatus

3.1 *Calibrated Monocular Compound Microscope*, equipped with an optical system sufficient to provide sharp resolution of the cross section to be examined. One system, consisting of a 16-mm objective and a 10-power filar micrometer eyepiece, resulting in a magnification of approximately 100 diameters, has been found satisfactory. Other combinations of objectives and eyepieces and other magnifications may also be suitable, although magnifications above 200 diameters may result in distortion of the viewed cross section.

3.2 *Tool for Extracting Test Specimens*—The tool may be similar in design to an ordinary cork borer, except that it shall be made of thicker walled tubing, hard enough to hold a keen cutting edge, and be fitted with a head suitable for pounding with a hammer (Fig. 1). A leather punch has been found satisfactory for this use. The tool shall make a circular cut approximately $\frac{1}{2}$ in. (12.7 mm) in diameter and $\frac{1}{8}$ in. (3.2 mm) deep through the coating and into the substrate. A sidewise movement of the punch while firmly embedded in the substrate will dislodge the specimen and allow its

FIG. 1 One Type of Tool for Extracting Coated Wood Specimens

removal intact within the punch.

3.3 *Source of Oblique Illumination.*

3.4 *Hand Microtome (Method B).*

4. Test Specimens

4.1 Specimens for microscopical measurement shall be extracted from the punch tool by means of a push rod inserted through the hollow shaft of its tube. The end of the push rod should be tipped with felt or other soft material so that the coated surface of the disk will not be damaged during extraction.

5. Procedure

5.1 Prepare disks for microscopical examination and measurement by either Method A or Method B. Either method of preparation will expose a cross section of coating and substrate, including the extremes in film thickness resulting from variations in the wood surface or method of application.

5.2 *Method A, Cross Sectioning with Razor Blade*—With a sharp razor blade carefully slice away parallel to the coated surface the substrate adhering to the coating until the disk is approximately $\frac{1}{16}$ in. (1.6 mm) thick. Place the disk coated face down on a smooth, hard surface and cut in half by means of a slicing stroke with a fresh razor blade (Fig. 2). Cut in a direction perpendicular to the grain of the wood substrate and at right angles to the coated surface.

5.3 *Method B, Cross Sectioning with Microtome:*

5.3.1 With a sharp razor blade carefully slice away parallel to the coated surface the substrate adhering to the coating until the disk is approximately $\frac{1}{16}$ in. (1.6 mm) thick.

5.3.2 Embed the thinned disk in molten paraffin³ which is

¹ These test methods are under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.52 on Factory-Coated Wood Products.

Current edition approved March 29, 1988. Published May 1988. Originally published as D 2691 - 68. Last previous edition D 2691 - 70 (1981)⁴.

² This test method is presently under study for revision or replacement with an improved microscopical film thickness method.

³ Paraplast, available from Fischer Scientific, 191 South Gulph Road, P.O. Box J, King of Prussia, PA 19406 melting point about 50 to 60°C, has been found satisfactory for this purpose. For clear films the addition of 0.5 g of Indigo to 200 mL of paraffin improves optical definition.

allowed to harden in a small mold to form a block which surrounds the disk on all sides. (The disk may also be dipped successively in the molten paraffin until a reasonably heavy deposit of wax is obtained.)

5.3.3 Trim the paraffin block with razor blade until the sides are parallel to the woodcoating surface.

5.3.4 Mount the trimmed block in a sliding-knife hand microtome⁴ in such a manner that the embedded disk is vertical with its cross-sectional edge facing and perpendicular to the oncoming knife edge. Cut perpendicular to the grain or to the machine direction of the specimen. The block should be firmly clamped between the jaws of the microtome chuck so that approximately one third of the diameter of the embedded disk protrudes.

5.3.5 Make successive cuts with a single sliding movement of the knife, raising the block by small increments after each cut. Continue sectioning until the clamped paraffin block protrudes no more than 1/16 in. (1.6 mm) above the jaws of the microtome chuck and the embedded disk is sectioned to approximately one half its diameter.

5.3.6 Examine the exposed cross section of the embedded disk with a hand lens to ascertain that a smooth cut has been obtained. If not, resume sectioning until this is accomplished.

6. Microscopical Measurement

6.1 Mount the cross-sectional disk for microscopical examination by carefully mounting in parallel clamps, modeling clay, or in clean sand held in a small container such as a petri dish (Fig. 3). Examine the edge-on view of the specimen by oblique overstage illumination. A focusable microscope lamp and a rotatable microscope stage are recommended for obtaining optimum viewing conditions.

6.2 Determine thickness of the coating above the substrate at ten randomly selected points on the cross section.

Do not measure within 1/32 in. (0.8 mm) of the edges of the disk, nor in areas where obvious deformation of the coating or substrate has occurred.

7. Report

7.1 Report the average film thickness computed from the ten random measurements as well as the maximum and minimum thicknesses measured to the nearest 0.1 mil (2.5 μm).

7.2 If a more extensive sampling procedure is employed, the report shall show the number of disks examined and the number of measurements per disk, in addition to the maximum, minimum, and average film thickness computed from all measurements.

8. Precision

8.1 Opaque Coatings:

8.1.1 *Test Method A*—On the basis of an interlaboratory test of this method in which operators in six laboratories tested 12 materials covering a wide range in film thickness, the within-laboratory standard deviation was found to be 0.26 mils with 72 degrees of freedom, and the between-laboratory standard deviation was found to be 1.03 mils with 60 degrees of freedom. Based on these standard deviations, the following criteria should be used for judging the acceptability of results at the 95% confidence level:

8.1.2 *Repeatability*—Two results obtained by the same operator should be considered suspect if they differ by more than 0.7 mils.

8.1.3 *Reproducibility*—Two results, each the mean of duplicate measurements, obtained by operators in different laboratories should be considered suspect if they differ by more than 3 mils.

8.1.4 *Test Method B*—On the basis of an interlaboratory test of this method in which operators in three laboratories tested 12 materials covering a wide range in film thickness, the within-laboratory standard deviation was found to be 0.28 mils with 36 degrees of freedom and the between-laboratory standard deviation was found to be 0.66 mils with 24 degrees of freedom. Based on these standards deviations, the following criteria should be used for judging the acceptability of results at the 95% confidence level.

8.1.5 *Repeatability*—Two results obtained by the same operator should be considered suspect if they differ by more than 0.8 mils.

TABLE 1 Laboratory Standard Deviations of Opaque Coatings

Substrate	Standard Deviation			
	Between		Within	
	Method A	Method B	Method A	Method B
Wood	0.97	0.66	0.30	0.34
Hardboard or overlaid plywood	1.09	0.25	0.22	0.21

TABLE 2 Repeatability

Substrate	Method A	Method B
Wood	0.8	1.0
Hardboard or overlaid plywood	0.6	0.6

⁴ A Spencer microtome (Catalog No. 900), available from American Optical, Warner-Lambert Co., Reichert Scientific Instrument Division, 201-T Tabor Rd., Morris Plains, NJ 07950 has been found suitable for this purpose.

8.1.6 *Reproducibility*—Two results, each the mean of duplicate measurements, obtained by operators in different laboratories should be considered suspect if they differ by more than 2 mils.

8.2 *Clear Coatings*:

8.2.1 *Test Method B*—On the basis of an interlaboratory test of this method in which operators in six laboratories tested 16 materials covering a wide range in film thickness, the within-laboratory standard deviation was found to be 0.07 mils with 96 degrees of freedom, and the between-

laboratory standard deviation was found to be 0.10 mils with 80 degrees of freedom. Based on these standard deviations, the following criteria should be used for judging the acceptability of results at the 95% confidence level:

8.2.2 *Repeatability*—Two results obtained by the same operator should be considered suspect if they differ by more than 0.2 mils.

8.2.3 *Reproducibility*—Two results, each the mean of duplicate measurements, obtained by operators in different laboratories should be considered suspect if they differ by more than 0.3 mil.

Standard Test Method for Volume Nonvolatile Matter in Clear or Pigmented Coatings¹

This standard is issued under the fixed designation D 2697; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^e) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Keywords were added editorially in January 1991.

1. Scope

1.1 This test method is believed to be applicable to the determination of the volume of nonvolatile matter of a variety of coatings. An interlaboratory study to establish the precision of this test method included a water-reducible exterior latex paint and three automotive coatings that included a solvent-reducible primer surfacer, water reducible primer surfacer, water reducible enamel topcoat, and acrylic dispersion lacquer topcoat. Earlier collaborative studies included a gloss enamel, a flat wall paint, a gloss house enamel, an industrial baking enamel, an interior latex paint, and an exterior latex paint.

1.2 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

- D 1475 Test Method for Density of Paint, Varnish, Lacquer, and Related Products²
- D 2369 Test Method for Volatile Content of Coatings²
- D 3925 Practice for Sampling Liquid Paints and Related Pigmented Coatings²
- D 3980 Practice for Interlaboratory Testing of Paint and Related Materials²

3. Summary of Test Method

3.1 The weight and volume of a stainless steel disk are determined. After the disk is coated with the material being tested, the weight and volume of the disk plus dried coating is determined by weighing in air and then by weighing in a liquid of known density, the volume being equal to the quotient of the weight loss of the coated disk (due to the Archimedes buoyancy effect) divided by the density of the liquid displaced. The liquid may be water, organic liquid such as low-solvency mineral spirits or kerosine, or with special modifications not covered specifically in this method, mercury. The choice of liquid depends upon the nature of the coating tested.

NOTE 1—Distilled water is suitable for most paints. Exceptions are coatings that contain ingredients that are readily leached out of the dry film by the water and low-gloss coatings, the surface of which is poorly wet by water even with surfactant added. (Note 2) Low-solvency hydrocarbon solvent (KB below 36) is also practical for most paints and is preferred by some workers.³ It is considered to be particularly good for paint films not readily wet by water. Analogously, organic solvents must not be used if the coating to be tested contains ingredients that will be dissolved readily by the solvent. Lacquers containing monomeric plasticizers would be examples where hydrocarbon solvents should definitely not be used. Coatings formulated much above the CPVC present a special problem, where mercury might be the desired "suspending" liquid (Note 3), and for solvent-reducible paints hydrocarbon solvent might be considered the poorest (unless it is the objective to obtain values closer to "theoretical" spaces between pigment particles not filled with binder, becoming partially filled with solvent during the test).

Note 2—Concentration of surfactant must be kept very low or literature values for the density of the water cannot be used.

Note 3—Details of the mercury displacement techniques can be found in the literature.⁴

3.2 From the measured weights and volumes of the disk before and after coating, the weight and volume of the dried coating film are calculated. Based on the density of the liquid coating and the weight percent nonvolatile matter, the volume of the liquid coating deposited on the coated disk is calculated. The volume of the dried coating divided by the volume of liquid coating, multiplied by 100, provides the volume percent nonvolatile matter in the total liquid coating.

4. Significance and Use

4.1 This test method is intended to provide a measure of the volume of dry coating obtainable from a given volume of liquid coating. This value is useful for comparing the coverage (square feet of surface covered at a specified dry film thickness per unit volume) obtainable with different coating products.

4.2 For various reasons the value obtained may not be equal to that predicted from simple additivity of the weights and volumes of the raw materials in a formulation. One reason is that the volume occupied by a solution of resin in solvent may be the same, greater, or less than the total volume of the separate ingredients: such contraction or expansion in resin solutions is governed by a number of factors, one of which is the extent and direction of spread

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Materials.

Current edition approved April 25, 1986. Published June 1986. Originally published as D 2697 - 68. Last previous edition D 2697 - 73 (1979).

⁴ Cole, R. J., *Journal, Oil Colour Chemists' Assn.*, Vol. 45, 1962, p. 776.

between solubility parameters of the resin and solvent.

4.3 The spatial configuration of the pigment particles and the degree to which the spaces between the pigment particles are filled with the binder also affect the volume of a dry coating formulation. Above the critical pigment volume concentration, the apparent volume of the dry film is significantly greater than theoretical due to the increase in unfilled voids between pigment particles. The use of volume nonvolatile matter values in such instances should be carefully considered as the increased volume is largely due to air trapped in these voids.

5. Apparatus

5.1 Analytical Balance.

5.2 *Steel Disk*, preferably stainless steel, 2½ in. (60 mm) in diameter and 22 gage (0.65 mm) in thickness with a small hole near the circumference. A fine wire, such as Chromel A, 28 gage (0.32 mm), is attached through the hole and made the appropriate length for subsequent suspension of the disk in a liquid. The wire should have a small loop on the upper end so the disk and wire can be hung by this loop on the balance.

NOTE 4—Instead of steel disks, some analysts use aluminum tubes. In the round-robin results, essentially no difference was found in the precision obtained by both methods. Source and dimensions of these tubes are described in the annex.

5.3 *Counterweight*, to be placed on the balance stirrup after hanger bow and pan are removed.

5.4 *Beaker, 1-L*—For easier manipulation during the weighing of disk in liquid it is advisable to cut the beaker to a height of 4½ in. (115 mm).

5.5 Support for holding the beaker under the balance stirrup without jamming the pan damper in the floor of the balance. A cork or neoprene ring is suitable when a single-pan balance is used.

5.6 *Weight per Gallon Cup*, acrometer, or other suitable means for determining the density of the coating material and the suspending liquids if not known.

6. Volume Determination of Uncoated Disks

6.1 Dry the disk in an oven at $110 \pm 5^\circ\text{C}$ for 10 min. Cool and weigh the disk in air.

6.2 Weigh the disk in the liquid to be used for suspension of the coated disk. If water is used as the suspending liquid, a few drops of wetting agent (Note 2) added to the liquid will help to ensure rapid and thorough wetting of the disk. Be careful that no air bubbles form on the disk or wire. Mark the level of liquid in the 1-L beaker necessary for complete immersion of the disk which should be at least ¾ in. (20 mm) above the disk. Maintain this level in subsequent weighings when the disk is coated.

6.3 Record the temperature of the liquid. Obtain the density of the liquid at the temperature used, from a table, such as is found for pure water in *Handbook of Chemistry and Physics*,⁵ or determine it to 0.001 g/mL.

6.4 Calculate the volume of the disk, G , in millilitres as follows:

$$G = (w_1 - w_2)/D$$

where:

w_1 = weight of disk in air, g

w_2 = weight of disk in liquid, g, and

D = density of liquid at temperature of test, g/mL.

7. Procedure

7.1 Take a representative sample of the liquid coating in accordance with Practice D 3925. Mix thoroughly before taking specimens for the individual tests.

7.2 Determine the weight nonvolatile of the liquid coating by drying 1 h at $110 \pm 5^\circ\text{C}$ in accordance with Test Method D 2369.

NOTE 5—If this method does not apply, then the method used should be agreed upon between producer and user.

7.3 Determine to 0.001 g/mL the density of the liquid coating in accordance with Test Method D 1475.

7.4 Dip the disk in the liquid coating and allow the liquid to come up on the wire a distance from ¼ to ½ in. (5 to 15 mm). Allow about 10 min for draining, and blot the coating material off the bottom edge of the disk so that beads or drops do not dry on the bottom edge of the disk.

NOTE 6—In some cases the paint or varnish may be of such consistency that the amount of solid matter remaining on the disk after drying is too small for an accurate volume determination. The use of a flat pan with a sidewall about 10 mm in height in place of the disk enables the operator to obtain a more desirable volume of solid matter. However, extra care must be observed to prevent trapping of air at the point where the sidewall meets the bottom of the pan. In no case should bubbles be allowed to be present in cast films. This procedure has not been evaluated and no precision statement is available.

7.5 When beads or drips stop forming, hang the disk in the oven for 1 h at 110°C (Note 5). Remove and cool. Weigh the coated disk in air.

7.6 Weigh the coated disk in the chosen medium in the same manner as for the uncoated disk, recording the temperature of the liquid at the time of the test.

8. Calculations

8.1 Calculate the volume of the coated disk, H , in millilitres, as follows:

$$H = (w_3 - w_4)/D$$

where:

w_3 = weight of coated disk in air, g,

w_4 = weight of coated disk in liquid, g, and

D = density of liquid at temperature of test.

8.2 Calculate the volume of the dried coating, F , in millilitres, as follows:

$$F = H - G$$

8.3 Calculate the volume of wet coating, V , in millilitres, from which the dried coating was obtained, as follows:

$$V = (w_3 - w_1)/(w \times \rho)$$

where:

w = nonvolatile matter in 1 g of wet coating, g, and

ρ = density of liquid coating material.

8.4 Calculate the percent volume nonvolatile content in a liquid coating as follows:

$$(F/V) \times 100$$

NOTE 7—The displacement liquid used should be reported with volume percent nonvolatile results. The method of drying the films should also be stated if different from that specified.

⁵ CRC Press, Inc., West Palm Beach, FL, 1986.

9. Precision⁶

9.1 *Precision (In accordance with Practice D 3980)*—In an interlaboratory study of this test method in which one operator in each of five laboratories analyzed in duplicate on two days four coatings (two solvent-reducible and two water-reducible) with nonvolatile contents ranging from 24 to 35 volume %, the pooled within-laboratory standard deviation was found to be 0.444 % with 17 degrees of freedom (DF) and the pooled between-laboratories standard deviation 1.195 % with 16 DF, after discarding one day's results from two laboratories on one sample, one day's results from one laboratory on another sample, and one

duplicate result from one laboratory on a third sample. Based on these standard deviations the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

9.1.1 *Repeatability*—Two results, each the mean of duplicates, obtained by the same operator on different days should be considered suspect if they differ by more than 1.32 % absolute at volume nonvolatile contents of 24 to 35 %.

9.1.2 *Reproducibility*—Two results, each the mean of duplicates, obtained by operators in different laboratories should be considered suspect if they differ by more than 3.59 % absolute at the same levels.

9.2 *Bias*—Bias has not been determined.

⁶ Supporting data are available from ASTM Headquarters. Request RR:D01-1052.

10. Keywords

10.1 volume nonvolatile content

ANNEX

Nonmandatory Information

A1. Aluminum Tubes

A1.1 Aluminum tubes,⁷ uncoated, plain with no cap or liner, #16 neck and orifice, 1¼ by 6¼ in., (32 mm by 160 mm).

A1.2 Cut two 3-in. (75 mm) lengths of tube from the aluminum tubing. Make a ¾-in. (20 mm) cut on the flattened end of the tube about ¼ in. (6 mm) from the end. Slip the tube over a short length of 1 in. (25 mm) inside diameter electrical conduit and return the tube to a round condition. Remove the tube from the pipe and press 1 in. wide strip at an end of the tube toward the center to serve as a hangar attachment.

⁷ Tubes manufactured by Teledyne; 2290 W. Townsend St., Chester, PA 19016, have been found satisfactory for this purpose.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. Standard Test Method for Determination of the Pigment Content of Solvent-Reducible Paints by High-Speed Centrifuging¹

This standard is issued under the fixed designation D 2698; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This test method has been approved for use by agencies of the Department of Defense to replace Methods 4022, 4032, 4052 of Federal Test Method Standard No. 141. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

1. Scope

1.1 This test method covers the separation of pigment from solvent-type paints and the calculation of the percent pigment from the results of nonvolatile determinations on the total paint and the separated vehicle.

NOTE 1—This test method has been proven to be applicable to most solvent-type paints, the exception being those paints containing severely bleeding pigments or pigments such as carbon black that are very difficult or impossible to centrifuge.

1.2 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

- 2.1 *ASTM Standard:*
D 2369 Test Method for Volatile Content of Coatings²

3. Significance and Use

3.1 This test method describes a rapid method for separating pigment from solvent-reducible paints.

3.2 This test method is used by paint producers and consumers for product acceptance and process control.

4. Apparatus

- 4.1 *Laboratory Centrifuge*, capable of developing 32 000 g or higher.³

5. Procedure

5.1 Shake the sample for 10 min on a mechanical shaker, stir with a paddle to loosen any caked pigment, and shake again for 10 min. If necessary, repeat until there are no lumps present and the sample is thoroughly mixed.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Materials.

Current edition approved May 25, 1990. Published July 1990. Originally published as D 2698 - 68. Last previous edition D 2698 - 73 (1984)⁴.

² *Annual Book of ASTM Standards*, Vol 06.01.

³ A Sharples supercentrifuge or an International centrifuge equipped with a high-speed head have been found satisfactory for this purpose. Any centrifuge capable of developing 32 000 g and having facilities for sealing the specimen to prevent solvent loss should also prove to be satisfactory.

To calculate the gravities developed by a particular centrifuge use the following calculation:

$$g = \text{rotating radius, cm} \times r/\text{min}^2 \times 1.118 \times 10^{-5}$$

5.2 Add the mixed paint to the centrifuge container until sufficient paint is added to permit the recovery of 25 mL minimum of clear vehicle. Revolve the bowl at 32 000 g or higher for 15 min or until a clear vehicle is obtained.

5.3 Transfer the vehicle carefully, so as not to dislodge any of the pigment from the walls, into a jar that is immediately capped to prevent any solvent losses by evaporation. Use this vehicle for the determination of the nonvolatile content of the separated vehicle.

6. Percent Paint and Vehicle Solids

6.1 Determine the percent nonvolatile content of the original paint and the separated vehicle in accordance with Test Method D 2369.

7. Calculation

7.1 Calculate the weight percent pigment of paint, P , as follows:

$$P = (A - B) \times 100/100 - B$$

where:

A = nonvolatile content of paint, %, and

B = nonvolatile content of separated vehicle, %.

8. Recovery of Pigment for Analysis

8.1 The pigment may be completely recovered from the centrifuge bowl and washed to remove residual vehicle. This may be done either by a Soxhlet extraction or washing the pigment with a suitable solvent and recentrifuging.

NOTE 2—It has been noted that the removal of the pigment from the bowl of a Sharples supercentrifuge can be facilitated by lining the bowl with a piece of polyester film prior to adding the sample and subsequently just slipping the polyester film along with the pigment out of the bowl.

9. Precision and Bias

9.1 *Precision*—The precision estimates are based on an interlaboratory study of this test method in which air drying materials were analyzed in duplicate or triplicate. The following criteria should be used for judging the acceptability of results at the 95 % confidence level:

9.1.1 *Repeatability*—The difference between two results, each the mean of duplicate determinations obtained by the same operator, will approximate 0.1 % absolute. Two such values should be considered suspect if they differ by more than 0.25 % absolute.

9.1.2 *Reproducibility*—The difference between two results, each the mean of duplicate determinations obtained by

oper
abso
they
9.
reac
appr
abso
9.

operators in different laboratories, will approximate 0.25 % absolute. Two such values should be considered suspect if they differ by more than 0.5 % absolute.

9.1.3 This precision pertains to air-drying materials. Heat-reactive vehicles will have a repeatability and reproducibility approximately twice as large, that is, 0.5 % and 1.0 % absolute.

9.1.4 It should be noted that when the solvent content of

the total paint is very low (15 % or less) the precision of this test method will not be satisfactory unless the nonvolatile determination is precise to the second decimal place.

9.2 Bias—Bias has not been determined for this test method.

10. Keywords

10.1 high speed centrifuging; pigment content; solvent-reducible paint

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practices for Uniformity of Traffic Paint Vehicle Solids by Spectroscopy and Gas Chromatography¹

This standard is issued under the fixed designation D 2743; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 These practices provide general information on the instrumental techniques available for detecting adulteration or nonuniformity of the chemical nature of the vehicle solids in purchased lots of traffic paints by means of the individual or combined use of infrared and ultraviolet spectroscopy and gas chromatography. The procedures given are applicable when traffic paint is selected and purchased on the basis of pre-qualification laboratory or road performance tests, or both, and a *reference sample* of the original paint so evaluated and selected is retained and compared with test samples representative of subsequent purchased and delivered lots of such paint and which are required to be the same as the original reference sample.

1.2 Although not specifically provided for in these practices, the methods given may also be applied, with appropriate modification, to evaluating the acceptability of traffic paints that have been purchased on the basis of composition specifications. In such cases, application is limited to the vehicle solids as before, as well as the availability of a suitable standard or range of standards representative of the vehicle solids that are acceptable and with which samples of subsequent delivered lots will be compared.

1.3 The techniques provided are wholly adequate for detecting gross adulteration of the vehicle solids where completely different drying oils, resins, or polymers, or combinations of these have been substituted for those originally contained in the reference sample. In cases of lesser adulteration or modification, these methods have been found adequate for detecting vehicle solids, adulterations, or modifications as low as 5 weight % of the vehicle solids.

1.4 These techniques have been developed on the basis of cooperative work with alkyd, chlorinated rubber-alkyd, and poly(vinyl toluene) type paints involving the detection of nonuniformity when such extraneous materials as rosin, fish oil, hydrocarbon resin, and chlorinated paraffin have been added. The procedures given may be, but are not necessarily completely applicable to all other types of vehicle solids or extraneous additions, or both.

1.5 The methods provided appear in the following order:

	Section
Method A—Infrared Spectral Analysis of Total Vehicle Solids.	10 to 12
Method B—Infrared Spectral Analysis of Unsaponifiable Matter from Vehicle Solids	13 to 15

¹ These recommended practices are under jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and are the direct responsibility of Subcommittee D01.44 on Traffic Coatings.

Current edition approved Aug. 15, 1968. Published October 1968.

Method C—Gas Chromatographic Analysis of Oils and Oil Acids Separated from Vehicle Solids	16 to 18
Method D—Ultraviolet Spectral Analysis of Total Vehicle Solids	19 to 21

1.6 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 For definitions of terms and symbols, refer to Definitions E 131.

4. Summary of Methods

4.1 Each of the methods given requires both a reference and a test sample of traffic paint and a preliminary separation and removal of the pigment component in each.

4.2 *Method A* involves infrared spectral analysis of cast films of the total vehicle solids to detect spectral differences between the reference and test samples caused by gross or minor adulteration of the test sample.

4.3 *Method B* involves infrared spectral analysis of cast films of the unsaponifiable matter that has been separated from the vehicle solids in order to detect spectral differences between the reference and test samples caused by lesser

adulteration readily evident by 4.4 Method A.

prepared from the differences either gross or with extraneous evident by 4.5 Method B.

analysis of spectral graphs to detect the adulteration be readily apparent.

5. Selection

5.1 All test samples between the test sample and the reference sample. It is not possible to use as a guide to the ratio of the reference sample to the test sample in order to determine the nature of the adulteration causing the difference.

5.2 *Method A* procedures for nonuniformities from indication of other methods is sufficient vehicle solid content spectral sample is corrected for drying oil, addition of resins, and characteristic cases it is by Methods B and C.

5.3 *Method B* unsaponifiable matter that has escaped adulteration in strong spectral differences of the vehicle solids precluding spectroscopic conclusions cause its spectral differences to be evident, failure to

adulterations of an unsaponifiable nature and which was not readily evident when using Method A.

4.4 Method C involves gas chromatographic analysis of prepared methyl esters of the separated fatty acids obtained from the vehicle solids in order to detect chromatographic differences between the reference and test samples caused by either gross or lesser adulteration of the drying oil fraction with extraneous drying oils which may not have been readily evident by the use of Methods A and B.

4.5 Method D involves quantitative ultraviolet spectral analysis of the total vehicle solids dissolved in a nonaromatic spectral grade solvent to give precise concentrations in order to detect ultraviolet spectral absorbance differences between the reference and test samples caused by minor or sophisticated adulterations of the vehicle solids and which may not be readily detected by Method A. Method D is to be used as an alternative to Methods B and C.

5. Selection of Test Methods and Significance and Use

5.1 All of the methods provided involve comparisons between the spectra or chromatograms of the reference and test samples to determine if they show significant differences. It is not possible at this time to establish quantitative limits as a guide to whether a spectral or chromatographic difference is truly significant. Certainly the presence or absence of a moderate or strong peak in the test sample which is not evident in the reference is significant. A persistent difference in the ratios of two peaks of one spectrum as compared to the reference sample is significant. On the whole, some judgment must be exercised in this respect and it is advisable to refer to published data on infrared or gas chromatography in order to establish, where feasible, the possible overall nature of the adulterant or its functional group which might be causing the comparison spectra to differ.

5.2 Method A is rapid and the most convenient of the procedures given. It should be utilized first in order to detect nonuniformity of the test sample. Significant spectral differences from that of the reference sample can be taken as an indication of adulteration and in such cases the use of the other methods is not necessary. As a general rule, Method A is sufficient to detect gross or major adulteration of the vehicle solids. However, where Method A shows no significant spectral differences, it cannot be assumed that the test sample is completely acceptable since changes in the type of drying oil, polyol, and certain dibasic acids in alkyd resins, addition of certain aliphatic or nonfunctional hydrocarbon resins, and many minor adulterations may not always show characteristic infrared spectral differences. Therefore, in such cases it is best to proceed to additional tests as given in Methods B and C or else alternatively directly to Method D.

5.3 Method B is useful in detecting adulterations that are unsaponifiable or else have an unsaponifiable component that has escaped detection in Method A only because the adulterant may have been small in amount and therefore its strong spectral peaks may have been masked over by the rest of the vehicle solids. Some care should be taken in interpreting spectral differences in Method B to avoid an erroneous conclusion that the test sample is unacceptable because its spectrum is different. Apparent but unreal differences can occur as a result of incomplete saponification, failure to remove all saponifiable material, and varying

degrees of contamination of the unsaponifiable fraction with sterols, etc., present in the vehicle solids. After it has thus been firmly established that a real spectral difference does exist, further tests are unnecessary, except that it is wise to resort again to the published literature on infrared to attempt to identify the possible nature of the adulterant. Where Methods A and B indicate acceptability of the test sample, it is still not always possible to rule out adulteration caused by changes or modifications in the saponifiable portion, that is, the type of fatty acid, dibasic acids, and polyol. In such cases, it is best to continue on to Method C for determination of the oil acids, and to other gas chromatographic methods for the polyol and dibasic acids when such equipment is available.

5.4 Method C is extremely sensitive in detecting adulterations and changes that have been made in the oil or fatty acid portion of the vehicle solids. It can, for example, detect whether linseed, coconut, oiticica, etc., has been substituted for soya oil and vice versa, or whether fish or tall oil has partially or wholly replaced some other drying oil, etc. Consequently, when the results of Methods A and B suggest that the test sample is acceptable and where a drying oil component is known to be present, Method C should be used additionally for more complete assurance of product uniformity. Where the results from Method C along with those from Methods A and B indicate product uniformity, it is a fairly safe assumption that the product has not been significantly altered.

5.5 Method D is intended as an alternative to Methods B and C and where the results from Method A indicate apparent product acceptability. Method D, by the use of quantitative ultraviolet spectral absorbance data, is an extremely sensitive procedure for the detection of complete or even partial adulteration of the test sample. However, considerable caution must be exercised in the preliminary pre-drying of the vehicle solids since it is at this stage that the components are extremely sensitive to oxidative changes. Even minor oxidative changes can seriously affect the absorbance data obtained in ultraviolet spectral analysis and may give an impression that the two samples being compared are different when in fact they are the same. When these considerations are provided for, and the comparison spectra are identical in Method D as well as in Method A, then it can be assumed that the sample is acceptable. Significant differences in the spectra from Method D would indicate nonuniformity of the product even though Method A may fail to reveal such nonuniformity.

6. Reference Sample

6.1 The reference sample of traffic paint should be at least ½ pt (250 mL) and should be truly representative of the initial paint found acceptable in pre-qualification laboratory or field service tests, or both, and which paint is subsequently specified for purchase.

6.2 In cases where paint is purchased on the basis of formulation specifications and it is desired to utilize these procedures to detect adulteration in delivered lots of paint, reference samples may be synthetically prepared to represent the extremes of the range that will be permitted in the formulation.

7. Test Sample

7.1 The test samples of the traffic paint should be at least ½ pt (250 mL) and should be representative of each delivered lot of paint that was specified for purchase and which is intended to be the same as the initial reference paint used in the pre-qualifications acceptance tests from which a reference sample was retained.

8. Sampling Reference and Test Samples

8.1 Test and reference samples of the traffic paint should be obtained in accordance with Recommended Practice E 105.

9. Preparation of Samples

9.1 Separate the vehicle from the pigment by centrifuging the paint in accordance with Method D 2372. Transfer and preserve the vehicle in a well-stoppered amber bottle.

METHOD A—INFRARED SPECTRAL ANALYSIS OF TOTAL VEHICLE SOLIDS

10. Apparatus

10.1 *Infrared Spectrophotometer*, recording double-beam, and accessory equipment as described in Test Method D 2621.

11. Procedure

11.1 Obtain the infrared spectra of a cast film of the vehicle solids of both the test and reference samples by utilizing the procedure referred to in 10.1. In all cases, however, the spectral intensity of both samples should be well matched (by adjusting the film thickness) to within 5 % transmission of each other at the strongest peak, and the transmission of this peak shall be between 5 and 15 %. It is also desirable to obtain additional spectra on thicker films or else ordinate scale expansion if available, to bring out spectral differences in the weak to moderate peak areas. Here again, the same degree of care should be taken as above to match the film thickness and thereby the overall spectral intensities of the two samples. If desired, an aid in comparison is to run the test sample against the reference sample in the reference beam in order to show significant differences by means of a single differential spectrum. Considerable caution is required in the use and interpretation of differential spectra as well as proper adjustments of gain, speed, and slit programs.

12. Interpretation of Results

12.1 Compare the companion spectra from the test and reference samples for identity by visual inspection preferably over a light box. Note particularly the presence of an extraneous peak or peaks in one which is (are) not in the other. Also note the ratio of intensities of two adjacent or pairs of peaks on one spectra and determine whether this ratio is similar on the comparison spectra. Any significant difference should be considered as an indication of lack of uniformity between the reference and test samples. Attempt to ascribe this difference to some extraneous component or formulation difference between the comparison samples by referring to available infrared literature and published spectra. Where it is evident that the comparison spectra are significantly different, no further tests are necessary. When

the spectra are identical, proceed to Methods B and C or alternatively to Method D for a fuller evaluation of possible minor or more sophisticated adulteration.

METHOD B—INFRARED SPECTRAL ANALYSIS OF UNSAPONIFIABLE MATTER FROM VEHICLE SOLIDS

13. Apparatus

13.1 Same as in 10.1.

14. Procedure

14.1 Treat a portion of the separated vehicle from both the sample and reference paints so as to obtain an ether solution of the unsaponifiable matter in accordance with Test Method D 1397. Take care to ensure rigorous quantitative separations and similar handling and exposure of the comparison samples. Determine the percentage of unsaponifiable matter. Obtain infrared spectra of cast films of the dried unsaponifiable matter in a manner similar to that described in 11.1.

15. Interpretation of Results

15.1 Compare the percentages of unsaponifiable matter. Compare the spectra and interpret the results in a similar manner as in 12.1. Care should be taken to avoid an erroneous conclusion that the materials are different when in fact they are the same. Such a misinterpretation could be caused by incomplete removal of oil acids and varying degrees of sterol contamination, solvent residues, etc. If it is firmly established that the companion samples are truly different, then further tests are unnecessary. If, on the other hand, the spectra and unsaponifiable contents are identical and the results from Method A were similar, then proceed to Method C to determine adulteration of the oil fraction or by oils if such is present or suspected of being present.

METHOD C—GAS CHROMATOGRAPHIC ANALYSIS OF OILS AND OIL ACIDS SEPARATED FROM VEHICLE SOLIDS

16. Apparatus and Reagents

16.1 Same as in Method D 2245.

17. Procedure

17.1 Proceed as in Method D 2245 utilizing a portion of the vehicles separated from both the test and reference samples.

18. Interpretation of Results

18.1 Compare the two recorded chromatograms and the calculated percentages of individual fatty acids for similarity. Note particularly the absence or presence of extraneous peaks in one and not the other as well as the percentages of individual fatty acids and polymers in one sample as

and C or of possible

portion of reference

ns and the similarity. extraneous entages of sample as

compared to the other. Any significant difference should be taken as an indication of test sample adulteration or lack of uniformity.

METHOD D—ULTRAVIOLET SPECTRAL ANALYSIS OF TOTAL VEHICLE SOLIDS

19. Apparatus

19.1 *Spectrophotometer*, recording double-beam, suitable for use in the ultraviolet region of the electromagnetic spectrum from 190 to 350 nm.

20. Procedure

20.1 On a portion of the previously separated vehicles of the test and reference samples, determine the nonvolatile content by means of Test Method D 1259. On the basis of this determination, quantitatively weigh out, by difference, from the stoppered bottles of the total vehicle, samples to yield 0.2 ± 0.0005 g of vehicle solids and place in a 100-mL beaker. Take care to avoid weighing errors caused by evaporation of solvent in the stoppered bottle during the weighing process.

20.2 Evaporate the volatile material by placing the beaker over an even heat source maintained at 60 to 65°C and under a constant blanket of dry, inert gas, preferably nitrogen, fed through a bell jar in which the beaker is placed. The bell jar should also be fitted with a stoppered separatory funnel with its delivery tube directly over the beaker. Evaporate until all the solvent is completely removed but avoid excessive exposure to these conditions much beyond this point. With the inert gas flow uninterrupted, transfer about 25 to 30 mL of spectral grade cyclohexane to the beaker through the assembled separatory funnel. Remove the beaker and immediately stir to dissolve all the solid material in the solvent. Quantitatively transfer to a 50-mL volumetric flask and fill to mark with additional spectral solvent. This yields a 0.4 % stock solution (wt/vol) of the vehicle solids in solution. If solution is not complete, try gentle warming or else start over using another suitable spectral grade nonaromatic solvent with an ultraviolet cut-off point at least as low as 220 or 230 nm.

20.3 With appropriate calibrated pipets or hypodermic syringes, volumetric flask, and the same lot of solvent used before, prepare several dilute quantitative solutions from aliquots of each stock solution that will enable quantitative measurements of all peak heights in the subsequent ultraviolet analysis (Note 1). In all cases, a specific quantitative dilution of the reference sample should be matched by exactly the same dilution of the test sample. For each such

matched dilution, use the exact same pipet for the test sample as was used for the reference sample to avoid dilution errors of comparison samples.

NOTE 1—The concentrations and numbers of dilute solutions necessary to obtain all the spectral peaks characteristic of a material will vary with the type of vehicle solids under examination. Generally, three dilutions of each stock solution to yield 0.03, 0.01, and 0.005 % solutions should suffice.

20.4 Within 24 h, and after making certain that the dilute solution is perfectly clear and without sediment and insolubles, record the ultraviolet absorbance spectrum of the dilute solution using a 1-cm stoppered quartz cell against the solvent blank in a reference cell. Obtain all absorbance peaks for each material that may occur between 200 and 300 nm. By appropriate use of the various dilutions of each sample, the spectral peaks should be made to fall between 0.3 and 0.8 absorbance unit. In all cases, record the exact absorbance value for each of the peaks for both test and reference samples. For each peak at a specific wavelength, the concentrations used for both the test and reference samples should be identical. It is wise to prepare several replicate standard stock and dilute solutions for each concentration independently of each other in order to obtain an idea of the range in each peak absorbance of the standard sample that might be expected in this procedure, especially as a result of the preliminary removal of original solvent by heating and its possible oxidative effects.

21. Interpretation of Results

21.1 Compare the nature and shape of the ultraviolet absorption curves obtained for both the test and reference samples. Any significant difference is an indication of adulteration or nonuniformity. Also compare the absorbance value of each peak given by the test sample with that given by the comparison reference sample. Any significant difference should be an indication of adulteration or nonuniformity. It is difficult to fix precise criteria for spectral differences that apply to all materials. As a general guide, the following criteria may be useful for evaluating comparable absorbance peaks. Comparison peaks should be within 0.05 absorbance units when occurring between 220 and 350 nm, and within 0.08 at lower wavelengths.

22. Report

22.1 Indicate uniformity or lack of uniformity of the vehicle solids of the test sample with respect to the reference sample and the method or methods (A, B, C, and D) used for this judgment. If possible, attempt to report the nature of possible adulterant(s) present or the cause of the nonuniformity.

Standard Test Method for Solvent and Fuel Resistance of Traffic Paint¹

This standard is issued under the fixed designation D 2792; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method describes a laboratory test for determining the resistance of a dried film of traffic paint to the action of a specified hydrocarbon solvent or gasoline fuel test fluid.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 471 Test Method for Rubber Property—Effect of Liquids²

2.2 Federal Standard:

TT-S-735 Standard Test Fluids for Hydrocarbons³

3. Summary of Method

3.1 The test paint is applied to a specified, properly prepared, tin panel. After aging, the coated panel is immersed in the hydrocarbon test fluid for a specified period of time at a specified temperature. The paint is examined for blistering, wrinkling, and loss of adhesion immediately upon removal and for complete hardness after a specified recovery time.

4. Significance and Use

4.1 Traffic paints must have good resistance to motor oil and fuel drippings on the highway. This test method describes the procedure necessary to measure the resistance of traffic paint to reference test fluids in order to simulate this type of action.

5. Apparatus

5.1 *Tin Panel*—Panels shall be cut from bright tin plate weighing not more than 25 g and not less than 19 g/dm² (0.51 to 0.39 lb/ft²). The panel should be about 75 by 130 mm (3 by 5 in.).

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.44 on Traffic Coatings.

Current edition approved Oct. 3, 1969. Published December 1969.

² *Annual Book of ASTM Standards*, Vol 09.01.

³ Available from Standardization Documents Order Desk, Bldg. 4 Section D, 700 Robbins Ave., Philadelphia, PA 19111-5094, Attn: NPQDS.

5.2 *Film Applicator*, which will produce a 3 or 6-mil (0.003 or 0.006-in.) (76 or 142- μ m) wet film thickness.

6. Reagents and Materials

6.1 *Test Liquid*—The testing liquid shall be specified by the purchaser and shall be selected from the following, dependent on the paint tested:

6.1.1 Type I of Federal Specification TT-S-735 which is the same as ASTM Reference Fuel A (ASTM Test Method D 471).

6.1.2 Type III of Federal Specification TT-S-735 which is the same as ASTM Reference Fuel B (Test Method D 471).

7. Procedure

7.1 Clean the tin panels thoroughly with a suitable solvent, and buff lightly with fine steel wool. Prepare at least 3 panels for each paint to be tested.

7.2 Examine the test paint, remove any skins that are present, stir with a paddle to loosen any settled pigment, and mix thoroughly.

7.3 Draw down the material on the panels using a film applicator that will produce a 3 or 6-mil (76 or 142- μ m) wet film as specified by the purchaser.

7.4 Air dry the coating for the time specified by the purchaser (usually 90 h) and then immerse the panels to half their length in the test liquid contained in a covered glass beaker at the temperature specified by the purchaser (generally 70 to 90°F (21 to 32°C)). Use a separate beaker for each paint tested.

7.5 At the end of the specified time (usually 4 to 18 h, depending on the type of paint) remove the panels and examine immediately for blistering, wrinkling, and loss of adhesion.

7.6 Allow the panels to dry at normal temperatures for the purchaser-specified time (generally 24 h), and examine for film defects and softening in comparison with the unimmersed portion of the panels.

8. Report

8.1 Report whether blistering, wrinkling, or loss of adhesion is evident immediately upon removal of panel from the test fluid as determined in 7.5.

8.2 Report whether any softening of the film is evident after the panel has recovered as determined in 7.6.

9. Precision

9.1 No statement of precision, in terms of percentages, can be made, although repeatability and reproducibility are exceptionally good.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

Standard Test Method for Block Resistance of Organic Coatings on Wood Substrates¹

This standard is issued under the fixed designation D 2793; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This method covers the determination of the block resistance of organic coatings on wood and wood-based substrates. Block resistance is the ability of a coating to resist sticking to another surface and to resist any change in appearance, when it is pressed against that surface for a prolonged period of time.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Summary of Method

2.1 The coatings to be tested are applied to the desired substrate. They are cured in a manner duplicating the condition of end use as much as possible. Then a stack of these painted substrates is formed and subjected to a specified pressure for a sufficient time to develop any sticking tendencies that exist. The pressure is released and the painted surfaces are examined for any signs of sticking. If blocking (forming a block by panels sticking together) occurs, the material is unsatisfactory. If no sticking or damage to the film surface occurs, the material is satisfactory.

2.2 When the conditions of production finishing are established and known, the method of application, the substrate, film thickness, and cure of the film should duplicate those conditions as closely as possible.

2.3 When the conditions of storage and shipment are established and known, the temperature, relative humidity, duration, and pressure used for the test should duplicate those conditions as closely as possible.

3. Apparatus

3.1 *Rigid Platens*, 4-in. (100-mm) square, capable of being maintained at $120 \pm 2^\circ\text{F}$ ($49 \pm 1^\circ\text{C}$).

4. Test Specimens

4.1 For those cases where the intended use conditions are not established or known, the following specifications or some set of specifications agreed upon by the purchaser and seller apply: The test coating shall be applied by normal spray, using air, to a 4 by 4-in. (100 by 100-mm) panel. The panel shall be a piece of $\frac{1}{4}$ -in. (6.4-mm) SIS (smooth one

side) standard hardboard. The dry film thickness of pigmented coatings shall be 1.5 ± 0.2 mils ($38 \pm 5 \mu\text{m}$), and of clear coatings shall be 1.2 ± 0.2 mils ($30 \pm 5 \mu\text{m}$). Cure of the coating shall be as agreed and should be standardized for each coating.

NOTE 1—Film thickness can be measured by weight difference before and after painting, but this requires careful conditioning of the substrate under standard temperature and humidity conditions prior to each weighing. Film thickness can also be determined by using an aluminum tab alongside the test panel and measuring the film thickness with a standard eddy-current gage or using a steel panel with a magnetic film thickness gage.

5. Procedure

5.1 After 90 s cooling under ambient conditions or as agreed upon, make a stack of six panels and place under a uniform pressure of 35 ± 2 psi (240 ± 20 kPa) for Class I, 20 ± 1 psi (140 ± 10 kPa) for Class II, and $5 \pm \frac{1}{4}$ psi (35 ± 1.7 kPa) for Class III. These classes are arbitrary and simply designate three groups of coatings or possibly three groups of end uses. Stack the panels in the following order from the top to the bottom:

- (a) Face down.
- (b) Face down
- (c) Face up.
- (d) Face down.
- (e) Face down.
- (f) Face up.

This provides for two face-to-face contacts and two face-to-back contacts. Apply the load through rigid 4-in. square (100-mm square) pressure plates. Apply the load for a minimum of 24 h. Other pressures, types of pressure plates, and times may be used if agreed between the purchaser and seller. Conduct the test under ambient conditions but use press platens heated to $120 \pm 2^\circ\text{F}$ ($49 \pm 1^\circ\text{C}$). Slip sheets should not be used unless they are known to be used during storage of shipment.

NOTE 2—The most difficult portion of this test method to standardize on intelligently is the proper pressure to employ. Stacking pressure in production would be calculated as follows:

$$(DHA_1/A_2) \times F$$

where:

D = board density,
 H = height of stack,
 A_1 = area of stack,
 A_2 = area of support, and
 F = safety factor.

The area of support is difficult to establish. In some instances board is stacked smoothly on the floor while in other instances the stack is supported on 2 by 4 or 4 by 4 stringers which cut the support to very

¹ This method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials.

appear

small areas. It has been found that pressures of 20 to 50 psi (140 to 340 kPa) are suitable on hardboard substrates while 2 to 5 psi (14 to 35 kPa) are suitable on solid wood surfaces.

NOTE 3—Many coatings are plasticized if they are contaminated with water. If possible, therefore, it is advisable to run blocking tests at as high relative humidities as might be encountered in production of warehousing.

NOTE 4—Blocking tests shall be run with panels wet with water, if water quenching is used for cooling the boards and the boards are wet when stacked in production.

5.2 At the end of the test period remove the pressure and pick up the stack in such a way that first the bottom panel, then the next to the bottom panel, and eventually all of the panels are free to fall of their own weight. This falling free is considered as passing the test if there also is no change in the appearance of the coated surfaces of any of the panels.

6. Report

6.1 This is a go/no-go test for both face-to-face and face-to-back conditions. In addition to the separate statement of satisfactory or not satisfactory under both of these conditions, the nature of the failure should be reported. The report should also include the particulars of the test as follows:

- 6.1.1 Type of substrate,
- 6.1.2 Method of application,
- 6.1.3 Curing cycle,
- 6.1.4 Film thickness,
- 6.1.5 Temperature, humidity, and pressure of the blocking test,
- 6.1.6 Type of stacking including identification and type of slip sheets if any, and
- 6.1.7 Duration of test.

7. Precision

7.1 A round robin will be made to establish precision.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. Standard Test Method for Resistance of Organic Coatings to the Effects of Rapid Deformation (Impact)¹

This standard is issued under the fixed designation D 2794; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers a procedure for rapidly deforming by impact a coating film and its substrate and for evaluating the effect of such deformation.

1.2 This test method should be restricted to testing in only one laboratory when numerical values are used because of the poor reproducibility of the method. Interlaboratory agreement is improved when ranking is used in place of numerical values.

1.3 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 609 Practice for Preparation of Steel Panels for Testing Paint, Varnish, Lacquer, and Related Products²

D 823 Test Methods for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels²

D 1186 Test Methods for Nondestructive Measurement of Dry Film Thickness of Nonmagnetic Coatings Applied to a Ferrous Base²

3. Terminology

3.1 Description of Term Specific to This Standard:

3.1.1 *impact resistance, of a coating*—the number of inch-pounds (kilogram-metres) required to produce cracking in the deformed coating.

4. Summary of Test Method

4.1 The organic coatings under test are applied to suitable thin metal panels. After the coatings have cured, a standard weight is dropped a distance so as to strike an indenter that deforms the coating and the substrate. The indentation can be either an intrusion or an extrusion. By gradually increasing the distance the weight drops, the point at which failure usually occurs can be determined. Films generally fail by cracking, which is made more visible by the use of a magnifier, by the application of a copper sulfate (CuSO_4)

solution on steel, or by the use of a pin hole detector.

5. Significance and Use

5.1 Coatings attached to substrates can exhibit cracking when subjected to rapid deformation, produced by impacts of objects during manufacturing and service. This test method has been very useful in evaluating attached coatings for their ability to resist cracking caused by impacts.

6. Apparatus

6.1 *Tester*, consisting of a vertical tube to guide a cylindrical weight that is dropped on a punch resting on the test panel.³

6.1.1 *Guide Tube*, 24 to 48 in. (0.6 to 1.2 m) long mounted vertically in a base plate. A slot is cut lengthwise on one side of the tube to act as a guide for a cylindrical weight that fits inside the tube. Graduations are marked in inch-pounds along the slot. The base is constructed so that a thin flat panel can be inserted at 2 in. (50 mm) below the tube.

6.1.2 *Weight*, metal cylinder, made to fit inside the guide tube. A pin is fitted into one side of the weight to act as a guide by riding in the slot of the tube and to serve as a handle by which the weight can be raised and released and serve as the indicator of inch-pounds (kilogram-metres).

6.2 *Indenter*—A steel punch with a hemispherical head having a diameter of either 0.500 in. (12.7 mm) or 0.625 in. (15.9 mm). The head rests on the test panel and the punch is held vertically by a guide ring.

6.3 *Panel Support*—A steel fixture with a 0.64-in. (16.3-mm) diameter cylindrical hole centered under the indenter for supporting the test panel.

6.4 *Magnifier*.

6.5 *Pin Hole Detector*.⁴

7. Reagents

7.1 An acidified copper sulfate (CuSO_4) solution prepared by dissolving 10 g of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ in 90 g of 1.0 N hydrochloric acid (HCl).

8. Test Specimens

8.1 Apply uniform coatings of the material to be tested to

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.23 on Physical Properties of Applied Paint Films.

9.1 Unless otherwise specified and the user, at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$). Conduct the test on removal of

10. Procedure

10.1 Install or agreed upon coated side of the test panel. Ensure the panel indenter is lightly placed on the tube so that weight up to failure will occur. indenter.

10.2 Remove the indenter and observe the test panel. If cracking is evident, creasing is observed, retest slightly above the first trial. Test one height at

10.3 Examine the following

10.3.1 Use

10.3.2 Heat

acidified copper

24-gage (0.025 in. or 0.63 mm) steel panels treated with a conversion coating in accordance with Procedure A of Practice D 609, unless otherwise specified. Prepare a minimum of four coated panels for the material.

NOTE 1—The coatings should be applied in accordance with Test Methods D 823, or as agreed upon between the producer and the user. Other gage steel panels may be used if agreed upon between the producer and the user.

8.2 Cure the coated panels under conditions of humidity and temperature agreed upon between the producer and the user.

NOTE 2—The thickness of the dry coatings should be measured in accordance with Test Methods D 1186.

9. Conditioning

9.1 Unless otherwise agreed upon between the producer and the user, condition the coated test panels for at least 24 h at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity. Conduct the test in the same environment or immediately on removal therefrom.

10. Procedure

10.1 Install the punch having the head diameter specified or agreed upon. Place the test panel in the apparatus with the coated side either up or down as specified or agreed upon. Be sure the panel is flat against the base support and that the indenter is in contact with the top surface of the panel. Lightly place the weight on the indenter and adjust the guide tube so that the lifting pin is at the zero mark. Raise the weight up the tube to a height where it is expected that no failure will occur. Release the weight so that it drops on the indenter.

10.2 Remove the test panel from the apparatus and observe the impact area for cracks in the coating. If no cracks are evident, repeat the procedure at a greater height, increasing 1 in. (25 mm) at a time. Once visible cracks are observed, repeat the test five times at each of three heights; slightly above, slightly below, and at that determined in the first trial. Test in a random fashion so that all impacts from one height are not made in succession or on one panel.

10.3 Examine the impacted areas for cracking by one of the following methods:

10.3.1 Use a magnifier to examine the area for cracks.

10.3.2 Hold a white flannel-type cloth saturated with the acidified copper sulfate (CuSO_4) solution (7.1) over the

impacted areas for at least 15 min. Remove the cloth and examine both the test areas and cloth for evidence of copper deposition or iron-rust staining respectively.

NOTE 3—The copper sulfate solution will not perform properly on zinc-phosphate-treated metal unless the conversion coating cracks.

10.3.3 To detect breaks in the film with a pin hole detector, first connect the ground lead from the instrument to the bare substrate and connect the instrument to an electrical power source. Moisten the probe sponge with tap water and slowly draw the probe over the impact area. The presence of cracks will be indicated by an audible alarm.

10.4 For each inch-pound (kilogram-metre) level, tabulate the number of times the coating passed or failed. The value where the results change from mainly passing to mainly failing is the impact failure end point.

11. Report

11.1 Report the following for each coating tested:

11.1.1 The inch-pounds (kilogram-metres) at the impact failure end point,

11.1.2 Whether intrusion or extrusion was used,

11.1.3 Diameter of the punch used,

11.1.4 Thickness of coating,

11.1.5 Substrate thickness and type of metal,

11.1.6 Method of panel preparation, and

11.1.7 Atmospheric conditions under which the coated panels were conditioned and tested.

NOTE 4—Because of the poor reproducibility of this method, the reporting of inch-pounds (kilogram-metres) in comparing coatings for impact resistance should be restricted to one laboratory. For interlaboratory comparisons, rankings of coatings for impact resistance should be reported.

12. Precision

12.1 On the basis of an interlaboratory test in which operators in six laboratories tested three paints having a broad range of impact resistance on two metal substrates, the between-laboratories coefficients of variation were found to be as follows:

	Coefficient of Variation	
	Intrusion, %	Extrusion, %
Brittle coating (less than 6 in.-lb)	25	100
Average coating (between 6 and 140 in.-lb)	80	100
Flexible coating (more than 140 in.-lb) (0.625 in.-diameter punch)	10	25

Standard Test Method for Leveling Characteristics of Paints by Draw-Down Method

This method covers the laboratory determination of the relative leveling characteristics of liquid water-reducible or solvent-reducible coatings in white and light tints.

Formerly under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials, this test method was discontinued in 1990.

1. Scope

1.1 This method covers the susceptibility of the coating to leveling.

1.2 This method covers whether the coating will level after application.

1.3 This method covers the leveling characteristics of the coating, and addresses all the responses appropriate to the application of the coating.

Standard Test Method for Filiform Corrosion Resistance of Organic Coatings on Metal¹

This standard is issued under the fixed designation D 2803; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This method covers two procedures for determining the susceptibility of organic-coated metal substrates to formation of filiform corrosion.

1.2 This method is limited to the determination of whether filiform corrosion will occur between the organic coating and substrate.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

 E 104 Practice for Maintaining Constant Relative Humidity by Means of Aqueous Solutions⁵
 2.2 *International Standard:*
 ISO 4623 Paint and Varnishes—Filiform Corrosion Test on Steel⁶

3. Summary of Method

3.1 Coated metal specimens are scribed and placed in a

corrosive atmosphere to initiate corrosion. The specimens are then exposed to controlled temperature and humidity conditions known to be conducive to filiform corrosion.

3.2 In Procedure A, panels are subjected to a preliminary exposure in the salt spray cabinet to initiate corrosion, rinsed, and placed in a humidity cabinet. In Procedure B, based on ISO 4623, panels are either exposed to salt spray or dipped in a salt solution but not rinsed before placing in the humidity cabinet operated at a higher temperature than in Procedure A.

4. Significance and Use

4.1 Some organic coatings applied to metal substrates exhibit filiform corrosion when there is a break in the coating film and the relative humidity is in the 70 to 95 % range.

4.2 This method can be used to determine the susceptibility of organic coated metal substrates to the formation of filiform corrosion.

5. Definitions

5.1 *filiform corrosion*—a special type of corrosion that occurs under coatings on metal substrates that is characterized by a definite threadlike structure and directional growth. Filiform corrosion usually occurs between 70 and 95°F (20 and 35°C), with a corresponding relative humidity range of 60 to 95 %; above 95 % humidity, blistering rather than filiform corrosion may occur.

6. Apparatus

6.1 *Salt-Spray Chamber* as described in Method B 117, for salt-spray (fog) testing.

NOTE 1—The preferred initiator of corrosion at the scribe is the salt-fog atmosphere described in Method B 117. Exposure of the specimens for 2 to 4 h in a closed cabinet to the atmosphere above a 1 % acetic acid solution is an acceptable alternative.

6.2 *Humidity Cabinet*—Any cabinet with suitable temperature and humidity controls with air circulation may be used. The size and detailed construction of the apparatus are optional, provided the conditions meet the requirements of this method.

7. Test Specimen

7.1 The composition, surface preparation, and number of test specimens shall be agreed upon between the producer and the user. Steel is the preferred substrate, but other metals such as aluminum, copper, and stainless steel may be used. Zinc and zinc-coated steel are not recommended because filiform corrosion generally does not occur on zinc.

NOTE 2—Applicable test panel description and surface preparation methods are given in Method D 607 and Practices D 1730.

7.2 *Preparation of Test Specimens*—The method of application, film thickness, curing, and conditioning shall be agreed upon between the producer and user.

¹ This method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.27 on Accelerated Tests for Protective Coatings.

Current edition approved June 25, 1982. Published September 1982. Originally published as D 2803 - 69 T. Last previous edition D 2803 - 70 (1974).

⁶ Available from American National Standards Institute, 11 W. 42nd St., 13th Floor, New York, NY 10036.

NOTE 3—Test Methods D 823 gives application methods that can be used to produce films of uniform film thickness.

NOTE 4—Test Methods D 1005, D 1186, and D 1400 give procedures that can be used for measurement of dry film thickness.

7.3 Scribe the test specimen in accordance with Method D 1654 or as agreed upon between the producer and user.

7.4 The back and edges of the panel should be protected with an anti-corrosion coating or tape, unless edge failure is being evaluated.

8. Procedure A

8.1 Expose the test specimens to the salt-fog atmosphere in accordance with Method B 117 for at least 4 h and not more than 24 h, or as agreed upon between the producer and user.

8.2 Remove from the salt-fog cabinet and thoroughly rinse with distilled or demineralized water. Do not permit specimens to dry before placing in the humidity cabinet.

8.3 Place the specimens in the humidity cabinet so they are no closer together than 1.5 in. (40 mm) and not in contact with any metal. Operate the cabinet at $77 \pm 3^\circ\text{F}$ ($25 \pm 2^\circ\text{C}$) and $85 \pm 2\%$ relative humidity unless otherwise agreed upon between the producer and user.

NOTE 5—The recommended means of maintaining the specified relative humidity is to utilize trays of saturated potassium chromate solution (650 g/L). Recommended Practice E 104 describes other methods for maintaining relative humidity, but they may affect the degree and rate of filiform corrosion.

8.4 Inspect the specimens at intervals of approximately 168 h for development of threadlike filaments from the scribe. Exercise care to maintain wetness of specimens during inspection, since drying stops the original pattern of filiform corrosion. New filiform may develop on continued exposure but at different points.

8.4.1 Filiform corrosion will be noted as threadlike filaments (see Note 6), initiating at the scribe. A standard method of rating failure due to filiform is not available. The uniformity of filament growth in direction, width, height and frequency precludes a precise rating system. Photographs of filiform failure are preferred for recording test results. Otherwise, a brief description of the filament growth and their frequency can be made.

NOTE 6—The nature of grinding and grain direction on panels can influence the direction of filiform growth.

8.5 The normal test period is 6 weeks (1008 h). Other periods may be used at the option of the producer and user.

9. Procedure (ISO 4623)

9.1 Two alternative initiations of corrosion are available, based on initiation by dipping in sodium chloride solution (see Note 7) or exposure to salt fog. The dipping technique is

generally preferable for air drying and low-durability materials. For high-durability systems such as automotive finishes applied to phosphated steel, the dipping technique may not produce filiform corrosion and for these systems, it is preferable to adopt the salt-fog technique. In such cases, the necessary period of exposure to salt fog depends on the durability of the material under test but should rarely need to exceed 24 h.

NOTE 7—Sodium chloride 0.1 % (w/v) solution (for dipping technique) is prepared by dissolving 1 g of reagent grade sodium chloride (NaCl) in 1 L of distilled or demineralized water. Place this solution in a vessel suitable for complete immersion of the test panel.

9.2 Dipping Technique:

9.2.1 Immerse the scribed specimen for 30 to 60 s in the sodium chloride solution (see Note 7).

9.2.2 Take the specimen out of the solution and remove any drops of liquid adhering to it, taking care not to remove the solution from the scribed marks.

9.2.3 Place the specimen in a humidity cabinet maintained at $104 \pm 3.5^\circ\text{F}$ ($40 \pm 2^\circ\text{C}$) and $80 \pm 5\%$ relative humidity.

9.2.4 Repeat the immersion procedure every 3 or 4 days until the end of the test cycle (21 days) or as agreed upon between the producer and the user.

9.3 Salt-Fog Technique:

9.3.1 Expose the scribed test specimen to the salt-fog atmosphere in accordance with Method B 117 for at least 4 h or not more than 24 h or as agreed upon between the producer and the user.

9.3.2 Remove the test specimen from the salt-fog cabinet and remove any drops of liquid adhering to it, taking care not to remove the solution from the scribed marks.

9.3.3 Place the specimen in a humidity cabinet maintained at $104 \pm 3.5^\circ\text{F}$ ($40 \pm 2^\circ\text{C}$) and $80 \pm 5\%$ relative humidity for the specified period agreed upon between the producer and the user.

9.4 Follow the procedures in 8.4 and 8.4.1.

10. Report

10.1 The report shall include the following:

- 10.1.1 Initiation procedure,
- 10.1.2 Humidity cabinet operating temperature,
- 10.1.3 Exposure period, and
- 10.1.4 Rating of coatings as described in 8.4.1.

11. Precision

11.1 *Procedure A*—Twelve laboratories, using three types of corrosion initiations, three coatings and three substrates, were in excellent agreement in their ranking of the susceptibility to filiform corrosion by this procedure.

11.2 *Procedure B*—Has been judged reproducible by Working Group 2 of ISO/TC35/SC9.

Standard Test Method for Hiding Power of Paints by Reflectometry¹

This standard is issued under the fixed designation D 2805; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reappraisal. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reappraisal.

INTRODUCTION

Using equations derived from Kubelka-Munk turbid media theory (1-4)², the reflectance of a coating can be predicted for any film thickness from measurements made at only one. On this basis several easy and accurate test methods (5,7) have been developed for determining hiding power. In the past such test methods have been considered difficult due to complexities, apparent and actual, in the treatment of data. The present test method has been simplified in this respect, primarily by adapting it fully for computer calculations.

Although the use of broad-band reflectometry makes this test method theoretically valid only for nonchromatic (white or gray) colors, good agreement has been obtained with chromatic paints as well. This is undoubtedly because the experimental measurements are made fairly close to the hiding power end point so that the Kubelka-Munk extrapolation and thus any associated error is relatively small.

This test method is therefore recommended without restriction as to color.

1. Scope

1.1 This test method covers the determination, without reference to a material paint standard, of the hiding power of air dry coatings with Y tristimulus values greater than 15 %. With appropriate modification, it can also be used to test baking finishes.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

E 284 Definitions of Terms Relating to Appearance of Materials⁵

3. Terminology

3.1 *Definitions*—For definitions used in this test method, see Definitions E 284.

3.2 Descriptions of Terms Specific to This Standard:

3.2.1 *contrast ratio*—the ratio of the reflectance of a film on a black substrate to that of an identical film on a white substrate.

3.2.1.1 C_W —the contrast ratio with a white substrate of reflectance W .

$$\text{Thus: } C_W = R_0/R_W$$

3.2.1.2 C —the contrast ratio with a white substrate for which $W = 0.80$.

$$\text{Thus: } C = R_0/R_{0.80}$$

3.2.2 *reflectance*—the daylight luminous diffuse reflectance factor (specular reflection excluded). Also referred to in this test method as the Y-tristimulus value. This value may be expressed as a percent or a decimal fraction, the latter being preferred and usually required for mathematical calculations.

3.2.2.1 *reflectivity*, R_∞ —the reflectance of film thick enough to have the same reflectance over both a black and a white substrate.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.26 on Optical Properties.

Current edition approved March 25, 1988. Published May 1988. Originally published as D 2805 - 69 T. Last previous edition D 2805 - 85.

² The boldface numbers in parentheses refer to the list of references at the end of this standard.

³ *Annual Book of ASTM Standards*, Vol 06.01.

⁴ *Annual Book of ASTM Standards*, Vols 06.01 and 14.02.

⁵ *Annual Book of ASTM Standards*, Vol 14.02.

3.2.2.2 R_0 —the reflectance of a film on a black surface with a reflectance of 1 % or less, which is effectively zero for the purpose of this test.

3.2.2.3 W —the reflectance of a white substrate.

3.2.2.4 R_w —the reflectance of a film applied on a white substrate of reflectance W .

3.2.2.5 $R_{0.80}$ —the reflectance of a film applied on a substrate having a reflectance of 80 %, which is the standard white-substrate reflectance in paint technology.

3.2.3 *scattering coefficient, S* —the ability of a material to internally scatter and thereby reflect light; expressed in this test method in the same units as spreading rate.

3.2.4 *spreading rate, H* —film area per unit volume of coating, in this test method expressed in square metres per litre (m^2/L). It is also frequently expressed in square feet per gallon (ft^2/gal).

3.2.4.1 *spreading rate, H_x* —an experimentally determined value of H .

3.2.4.2 *spreading rate, H_C* —value of H at a specified contrast ratio C .

3.2.4.3 *hiding power, $H_{0.98}$* —the spreading rate at the contrast ratio $C = 0.98$.

NOTE 1—It should be emphasized that this contrast ratio does not represent visually complete hiding, nor does it indicate that the same contrast ratio holds at every wavelength.

4. Summary of Test Method

4.1 The reflectivity R_∞ of the coating is determined from reflectance measurements on black and white hiding power charts.

4.2 The scattering coefficient S of the coating is determined from R_∞ and the reflectance R_0 and spreading rate H_x of a film applied on black glass.

4.3 The hiding power, $H_{0.98}$ of the coating is calculated from the reflectivity R_∞ and the scattering coefficient S .

4.4 As an optional procedure the contrast ratio C at a specified spreading rate H_C is calculated from R_∞ and S .

5. Significance and Use

5.1 This is a precise instrumental method giving results having an absolute physical significance without reference to a comparison paint. It should be used when maximum precision and minimum subjectivity are required, as in testing specification coatings or evaluating the hiding efficiency of pigments.

5.2 Hiding power Test Method D 344 is visual instead of instrumental, and gives results that are relative to a material standard instead of absolute. It is less precise than Test Method D 2805 but more closely aligned with practical painting procedures.

6. Apparatus and Materials

6.1 Substrates:

6.1.1 *Black Glass Panels*,⁶ minimum size 200 by 200 mm, and approximately 13 mm thick.

⁶ Black Vitrolite and Carrara structural glasses were used originally and may still be obtainable from some local glaziers but, in general, have been replaced with black float glass. If this is not available from local glaziers it may be purchased from The Leneta Co., Box 86, Ho-Ho-Kus, NJ 07423.

6.1.2 *Black and White Paper Charts*⁷—The surface shall be smooth and level, and impervious to paint liquids. The black area shall have a maximum reflectance of 1 % and the white area a minimum reflectance of 76 %.

6.2 *Balance*, accurate to 0.1 mg.

6.3 *Glass Slides*⁸—Round or square plates of thickness similar to that used for microscope specimen slides, with a minimum area of 40 cm^2 .

6.4 *Reflectance-Measuring Instrument*—One that allows only diffusely reflected, radiant flux to be incident upon the measuring element. It shall employ a photometric system, including source, filters, and receptor, that provides a response closely similar to the product of the spectral luminous efficiency function of the CIE standard observer and source C . It shall provide readings to at least the third decimal place and permit estimation to the fourth.

6.5 *Template*,⁹ with a film area approximately 100 cm^2 determined to the nearest tenth. Record the exact value on Line C of the worksheet shown in Fig. 1.

6.6 *Doctor Blade Film Applicators*, width 150 mm, clearances 50, 75, 100, 125, 150, 175, and 200 μm .

NOTE 2—With doctor blades made in the United States, estimate 25 mm/in. and 25 $\mu m/mil$. Bird-type applicators are usually marked with their half clearance.

6.7 *Computer and Software*,¹⁰ for solving the relevant Kubelka-Munk equations.

7. Procedure

7.1 General Instructions:

7.1.1 *Film Application*—Drawdowns should be made manually with a smooth uniform motion, at the rate of about 6 cm/s. Paper charts should be held flat by a vacuum plate or other suitable device while making drawdowns.

7.1.2 *Reflectance Measurements*—Measure the reflectance of each test area at a minimum of three locations, reading or estimating to four decimal places and calculating mean values to the same. Charts should be placed over a white surface and black glass over a black surface while measurements are being made.

7.1.3 *Record Keeping*—All data should be recorded on a copy of the worksheet form specified in Fig. 1. Typical data entries are shown in Fig. 2.

7.1.4 *Weight Measurements*—Make all weighings to 0.1 mg on the analytical balance.

7.2 *Paint density, D* —Determine the density in g/mL to four decimal places in accordance with Test Method D 1475 and record on Line A of the worksheet (Fig. 1). If the density is first determined in pounds per gallon, divide by 8.3454 to obtain it in grams per millilitre.

7.3 *Nonvolatile Content, N* —Sandwich 0.3 mL of paint (dispensed with a 1-mL syringe) between two previously

⁷ Leneta Form 3B, available from The Leneta Co., has been found satisfactory for this purpose. An equivalent may be used.

⁸ If glass slides of this type are not readily available, use clear or translucent plastic slides instead. Leneta Form P420NV, available from the Leneta Co., have been found satisfactory for this purpose.

⁹ A template available from Precision Gage and Tool Co., 28 Volkenand Ave., Dayton, OH 45410, has been found suitable for this purpose. An equivalent may be used.

¹⁰ Most computers can be programmed with the relevant equations. A small pre-programmed computer is available from The Leneta Co.

weighed slides, squeezing them together so that the paint spreads to a diameter of about 45 mm. Reweigh to obtain the weight of paint sample. Separate the slides, allow the films to dry, and weigh a third time to determine the dry weight. Then calculate the nonvolatile content of the paint as a decimal fraction to four places. Run in duplicate and report the mean value to three decimal places on Line B of the worksheet (Fig. 1).

7.4 *Applicator Selection*—Make trial drawdowns on black and white charts at clearances of 100, 150, and 200 μm. Allow them to dry overnight and measure their contrast ratios. Based on the results select the best applicator for a contrast ratio of 0.97 ± 0.01 , which may be one of the trial applicators or one of intermediate clearance. If it seems necessary, make an additional trial drawdown to confirm the correct applicator.

7.5 *Drawdowns on Glass and Charts*—Using the applicator selected from 7.4, make four drawdowns each on black glass and on black and white charts in accordance with 7.1.1.

Leave enough of the white area of each chart uncoated to permit measurement of the reflectance W .

7.6 *Drying of the Films*—Immediately after application place each drawdown horizontally in a well-ventilated dust-free location, with all drawdowns in close proximity to one another to assure identical drying conditions, and allow to dry a minimum of 40 h before testing.

7.7 *Reflectance Measurements*—On the second or third day after application measure the reflectances on all of the drawdowns within as brief a time span as possible, alternating the measurements between charts and glass rather than doing first all one and then the other. Enter the values of R_0 , R_w , and W for charts into Section D of the worksheet, and the values of R_0 for glass into Section E.

7.8 *Weight of Dry Film, M* —After all of the reflectances are measured, position the template on the glass panels, each in its turn, and scrape off the surplus paint with a razor blade, to leave film areas defined by the template. If the template area is not already specified, measure one of the

resultant films carefully to determine its area in square centimeters to the nearest tenth. Record this value on Line C of the worksheet (Fig. 1) as the characteristic area of the template. Then scrape off each paint film carefully into a weighing dish, weight to 0.1 mg, and record the weights M in Section E of the worksheet, each value entered adjacent to the corresponding value of R_0 for the same glass panel.

8. Calculation

8.1 In general, calculations should be made and recorded to four significant figures and final report values to three. Enter calculated results in the worksheet (Fig. 1). Typical entries are shown in Fig. 2.

8.2 Contrast Ratio C_w and Reflectivity R_∞ —From the data entered in Section D of the worksheet calculate C_w and R_∞ for each of the four charts, thus:

$$C_w = R_0/R_w \quad R_\infty = f(R_0, R_w, W) \quad (\text{A1.1})$$

Enter the values, as they are calculated, in the appropriate columns of Section D, then calculate and likewise enter their means.

8.3 Spreading Rate H_x —From the data recorded in the worksheet on Lines A, B, and C and in Section E, calculate the spreading rate $H_{0.98}$ for each of the four glass panels, thus:

$$H_x = \frac{A \times N \times D}{10M}$$

where:

- H_x = spreading rate, m²/L,
 A = template area, cm²,
 N = nonvolatile content of the paint,
 D = density of the paint, g/mL, and
 M = dry film weight, g.

and enter the values in the appropriate column of Section E.
 8.4 Scattering Coefficient S and Hiding Power $H_{0.98}$ —Continuing on Section E of the worksheet (see Fig. 1), and

using the mean value of R_{∞} from Section D, calculate for each of the glass panels, first S and then $H_{0.98}$ in square millimetres per litre as follows:

$$S = f(R_0, R_{\infty}, H_X) \quad (A1.2)$$

$$H_{0.98} = f(S, C, R_{\infty}) \text{ given } C = 0.98 \quad (A1.3)$$

Enter the values as they are calculated in the appropriate columns of Section E, then calculate and likewise enter their means.

8.5 *Contrast Ratio C at a Specified Spreading Rate H*—If desired, calculate the contrast ratio at a specified spreading rate using the mean values of R_{∞} and S from worktable Sections D and E, of the worksheet (Fig. 1), thus:

$$C = f(S, H, R_{\infty}) \quad (A1.4)$$

9. Report

9.1 Enter the following information on the indicated line in Fig. 1, Section G:

9.1.1 *Hiding Power, $H_{0.98}$* —Enter the mean value of $H_{0.98}$ from Section E, rounded to the second decimal place, onto Line G(1). If desired, multiply this value by 40.746 to obtain the value in square feet per gallon to the nearest whole number and enter it on the same line.

9.1.2 *Reflectivity, R_{∞}* —Enter the mean value of R_{∞} from Section D, rounded to three significant figures, onto Line G(2).

9.1.3 *Scattering Coefficient, S* —Enter the mean value of S from Section E, rounded to three significant figures, onto Line G(3).

9.1.4 *Applicator Clearance*—On Line G(4) enter the clearance of the applicator, expressed in μm and if desired also in mils.

9.1.5 *Contrast Ratio, C_W* —Enter the mean value of C_W from Section D, rounded to the third decimal place, onto Line G(5).

9.1.6 On Line G(6) enter the identification and brief description of the coating.

9.1.7 On Line G(7) enter the identification and description of the reflectometer employed.

9.2 *Alternative Hiding Power Report: Contrast Ratio at a Specified Spreading Rate*—Enter the specified spreading rate H and the value of C calculated from 8.5, into Section H of the worksheet. This report may be in addition to or instead of conventional hiding power $H_{0.98}$.

10. Precision

10.1 *Precision*—The precision values given for this test method are based on two series of interlaboratory tests. For gray and chromatic paints (6), five operators in five laboratories tested four gloss enamels covering a broad range of colors. For white paints (5), five operators in five laboratories tested three white finishes covering the range of gloss to flat. The between-laboratory coefficients of variation were found to be those shown in Table 1.

11. Index Terms

11.1 This test method is indexed under the following terms: hiding power (of paints/coatings); spreading rate; contrast ratio; scattering coefficient.

TABLE 1 Precision of Hiding Power, $H_{0.98}$

	Coefficient of Variation	Maximum Acceptable Differences for Two Results	
		Repeatability	Reproducibility
Gray, and chromatic gloss finishes, %	3.5	<10.4	10.4
White finishes:			
Gloss, %	1.2	<4.7	4.7
Semigloss and flat, %	5.0	<16.3	16.3

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Durability and Compatibility of Factory-Primed Wood Products with Representative Finish Coats¹

This standard is issued under the fixed designation D 2830; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method provides for the determination of the relative durability and compatibility of factory-primed wood and wood-based substrates with representative finish coats when exposed to the weather.

1.2 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2.2 U. S. Federal Standards:³

- TT-P-96b
- TT-P-102

3. Summary of Test Method

3.1 This test method consists of the atmospheric exposure of at least three types of conventional exterior white house paints applied to panels of factory-primed wood or wood-base substrates that have been exposed to atmospheric

weathering conditions for periods of 0, 3, and 6 months.

3.2 The finish coats are applied by brush.

3.3 An additional panel of original factory-primed substrate, without finish coat, is exposed for the duration of the test.

4. Significance and Use

4.1 This test method is useful for evaluating the weathering performance of factory-applied primers on wood or wood-based substrates overcoated with a field-applied topcoat.

4.2 This test method is useful for evaluating the weathering compatibility of commercial topcoats over factory-applied primers on wood or wood-based substrates.

5. Apparatus

5.1 A vertical (90° from horizontal) test fence constructed in accordance with requirements of Practice D 1006.

6. Materials

6.1 Exterior Finishes:

6.1.1 *Paint, Oil, Alkyd*, fume resistant, conforming to Federal Specification TT-P-102.

6.1.2 *Resin Latex Paint, Synthetic*, of the emulsion type designed for use on exterior wood surfaces (such as TT-P-96b).

6.1.3 *Flat Alkyd, Solvent-Thinned, Exterior*.

6.1.4 Any other type of exterior finish paint mutually agreed upon.

6.2 *Bristle Brush (Natural or Synthetic)*.

7. Procedure

7.1 The minimum length of panel is 3 ft (910 mm) with a minimum width of 6 in. (150 mm) of a particular preprimed substrate.

7.2 Mark off one third of the panel area (in a manner which will not damage the prime coat) and apply by brush to the right one third panel area a single coat of one of the white finishes at a spreading rate as recommended by the manufacturer or by the appropriate Federal specification. Paint the panel and dry indoors for 7 days under prevailing conditions of temperature and humidity, taking care to avoid exposure to drafts or excessive heat.

7.3 Determine the spreading rate of the finish paints by the weight difference method or other suitable methods. Record the spreading rate, film thickness, and method used.

7.4 Fasten the panel to a south exposure rack.

NOTE 1—Panel mounting should be the same as normal practice for the mounting of a particular substrate.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.52 on Factory-Coated Wood Building Products.

Current edition approved Oct. 15, 1991. Published December 1991. Originally published as D 2830 - 69. Last previous edition D 2830 - 82 (1987).

³ Available from Standardization Documents Order Desk, Bldg. 4 Section D, 700 Robbins Ave., Philadelphia, PA 19111-5094, Attn: NPODS.

7.5 After 3 months (± 1 week) of exposure of the panel, coat the center one third section adjacent to the section already coated with exterior finish as specified in 7.2.

NOTE 2—If possible, the application should be made in the laboratory as in 6.2. No washing or cleaning should be done to the surface to be coated.

7.6 At completion of 6 months (± 1 week) of exposure to the weather, apply finish coat to the final third section of the panel as specified in 7.2.

7.7 Examine each section of the panels visually for appearance, mildew, and film failure at intervals of not more than 3 months (preferably 1 month) beginning 1 month after initial exposure.

7.8 At the end of each 6 months exposure of a topcoated section, test for intercoat adhesion between the factory-applied primer and the topcoat as follows:

7.8.1 Cut a small "X" in the film with a sharp knife or razor blade. The cuts should penetrate the substrate slightly but not distort the film unduly. Apply pressure-sensitive tape⁴ so that it crosses the "X" in the direction of the acute angles. Press the tape on carefully with the flat surface of the

finger nail or with a rubber eraser. Remove the tape with a quick yank, at a 90° angle to the surface.

7.9 Exposure of the topcoated preprimed substrate may be terminated 12 months after application of the finish coat to the third section. Additional exposure may be agreed upon between buyer and seller.

8. Report

8.1 Report the following properties:

8.1.1 Chalking—Method D 659.

8.1.2 Checking—Test Method D 660.

8.1.3 Cracking—Test Method D 661.

8.1.4 Erosion—Test Method D 662.

8.1.5 Flaking—Test Method D 772.

8.1.6 Blistering—Test Method D 714.

8.1.7 Intercoat Adhesion—Test Methods D 3359.

8.1.8 Mildew—Test Method D 3274.

9. Precision and Bias

9.1 Varying weather conditions from year to year and at several exposure sites preclude development of precision and bias data.

10. Keywords

10.1 adhesion; factory primed wood; primer performance; topcoat compatibility; weathering

⁴ 3-M Company's No. 600 Cellophane Tape has been found satisfactory. Tape shall be stored in an airtight container and shall not be more than 6 months old.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Guide for Determining Volatile and Nonvolatile Content of Paint and Related Coatings¹

This standard is issued under the fixed designation D 2832; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{ε1} NOTE—Keywords were added editorially in June 1991.

1. Scope

1.1 This guide is intended to aid in the selection of the proper ASTM standard for determining the volatile and nonvolatile content of paint and related coatings.

NOTE—Test methods for determining the composition of the volatile fraction are not covered by this guide.

1.2 The standards included are as follows:

Type of Coating	Section	ASTM ² Designation
Aerosol coatings	4.1	D 3062
Architectural wall coatings, interior, high performance	4.3	D 1644
Asphalt roof coatings	4.4	D 2823
Asphalt roof coatings, aluminum-pigmented	4.5	D 2824
Bitumens, emulsified	4.6	D 2939
Bleached lac varnish	4.7	D 1650
Coil coatings	4.8	D 1353
		D 2697
Electrical insulation varnishes	4.9	D 115
House paints, gloss	4.10	D 2697
Industrial baking enamel	4.10	D 2697
Lacquers, clear and pigmented	4.11	D 1644
		D 333
Latex paint, exterior	4.10	D 2697
Latex paint, interior	4.10	D 2697
Magnet wire enamels	4.12	D 3288
Plastics, coatings for	4.13	D 1644
Powder coatings	4.14	D 3451
Shellac varnish, orange	4.7	D 1650
Solvent-reducible coatings	4.2	D 2369
Traffic paints	4.15	D 2205
Varnishes	4.16	D 1644
Wall and trim enamels, interior semigloss, solvent-based	4.17	D 2697
Wall paints, flat	4.10	D 2697
Water-reducible coatings	4.2	D 2369

1.3 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Significance and Use

3.1 The nonvolatile content of paint and related coatings is useful to producers and users and to environmental and health and safety interests in comparing the coverage of competing products and in estimating the volatile organic content.

4. Procedure

4.1 *Aerosol Coatings*—Test Method D 3062 covers the determination of solids content (weight %) in aerosol coatings.

4.2 *Volatile Content of Coatings (Test Method D 2369)*—This test method covers the determination of the volatile content of coatings. It is considered to be applicable to most

⁵ Annual Book of ASTM Standards, Vol 06.02.

⁶ Annual Book of ASTM Standards, Vol 04.04.

⁷ Annual Book of ASTM Standards, Vol 15.09.

⁸ Annual Book of ASTM Standards, Vol 10.02.

solvent-reducible and water-reducible paints.

4.3 High Performance Interior Architectural Wall Coatings (HIPAC)—Determine the nonvolatile content of HIPAC coatings in accordance with Test Methods D 1644. Calculate the volatile content (weight %) by difference.

4.3.1 Method A—3 h at 105°C for paints with nonsolvent components that decompose at higher temperature.

4.3.2 Method B—10 min at 149°C for most paints with nonsolvent components that are reasonably stable at 149°C.

4.4 Asphalt Roof Coatings—Determine the nonvolatile content (weight %) of asphalt roof coatings of brushing or spraying consistency in accordance with 8.2 of Specification D 2823.

4.5 Aluminum-Pigmented Asphalt Roof Coatings—The nonvolatile content (weight %) of asphalt-based aluminum roof coatings suitable for application to roofing or masonry surfaces by brush or spray is determined in accordance with 8.2 of Specification D 2824.

4.6 Emulsified Bitumens Used as Protective Coatings—Section 8 of Test Methods D 2939 contains a method for determining residue by evaporation (weight %) of emulsified bitumens used in relatively thick films as protective coatings for metals and built-up roofs.

4.7 Shellac Varnish—Determine the nonvolatile matter in orange shellac and bleached lac varnishes in accordance with Sections 14 through 16 of Methods D 1650.

4.8 Coil Coatings—Although stated to be for solvents, determine the nonvolatile matter (weight %) in accordance with Test Method D 1353. Determine volume solids in accordance with Test Method D 2697.

4.9 Electrical Insulation Varnishes:

4.9.1 Sections 18 through 22 of Methods D 115 on nonvolatile matter by weight, are applicable to the following classifications of varnishes used for electrical insulation: alcohol-soluble varnishes, oxidizing air-drying varnishes, thermosetting varnishes, oxidizing baking varnishes, air-drying asphaltic varnishes, silicone varnishes, and thermosetting laminating varnishes.

4.9.2 Determine nonvolatile matter in electrical insulating varnishes intended for electrical equipment operating at 180°C and above in accordance with Methods D 115 except that the temperature used shall be $275 \pm 5.5^\circ\text{F}$ ($135 \pm 3^\circ\text{C}$) or at a temperature agreed upon between the producer and the user.

4.10 Volume Nonvolatile Matter in Clear or Pigmented Coatings (Test Method D 2697)—This test method is applicable to the determination of the volume nonvolatile matter of coatings. A gloss enamel, a flat wall paint, a gloss house paint, an industrial baking enamel, an interior latex paint,

and an exterior latex paint included in formal collaborative studies of this test method.

4.11 Lacquer Coatings—Determine the nonvolatile content of clear and pigmented lacquers as described in Test Methods D 1644. As an additional requirement, the specimen shall be reheated and reweighed until the weight is constant to within 1 mg. Method A of Test Methods D 1644 is preferred since Method B is potentially dangerous when used with lacquers.

4.12 Magnet Wire Enamels—Sections 17 through 23 of Test Method D 3288 cover the determination of nonvolatile content (weight %) in magnet wire enamels.

4.13 Coatings for Plastics—Determine nonvolatile matter in clear and pigmented coatings designed for use on rigid or semirigid plastic substrates in accordance with Test Methods D 1644.

4.14 Polymeric Powders and Powder Coatings—Determine nonvolatile content (weight %) in accordance with Section 12 of Practices D 3451. Determine volatile content at baking or fusion temperature in accordance with Section 13 of Practices D 3451.

4.15 Traffic Paints—Determine the nonvolatile content of traffic paints, ready-mixed, of spraying consistency of the premix, drop-in, or combination type in accordance with Test Methods D 1644, and state any necessary larger specimen size for beaded paint. Either of the two methods can be used as follows:

4.15.1 Method A—3 h at 105°C for paints with nonsolvent components that decompose at higher temperature.

4.15.2 Method B—10 min at 149°C for most paints with nonsolvent components that are reasonably stable at 149°C.

4.16 Varnishes—Nonvolatile content (weight %) of varnishes is determined using Test Methods D 1644. These test methods may give high results due either to incomplete elimination of volatile matter or to absorption of oxygen by oxidizing-type varnishes.

4.17 Solvent-Based Interior Semigloss Wall and Trim Enamels—Use Test Method D 2369 to determine volatile content. Volume nonvolatile matter is determined in accordance with Test Method D 2697.

5. Precision

5.1 Some of the referenced ASTM standards have precision limits. Reference to the individual standards for precision statements is recommended.

6. Keywords

6.1 nonvolatile content of paints and related coatings; volatile content of paints and related coatings

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Standard Index of Methods for Testing Architectural Paints and Coatings¹

This standard is issued under the fixed designation D 2833; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This index is provided for reference in the selection of procedures, test methods, and specifications to be used in the evaluation of architectural paints and coatings designed for application in the field. Composition specifications and analytical methods in general, also tests on raw materials, are not included, the scope being limited to procedures required in the evaluation of finished coatings.

1.2 Methods suitable for both interior and exterior coatings of either the water-thinned or solvent-thinned type are listed by ASTM designation primarily. Where comparable (but not necessarily identical) methods exist in U.S. Federal Test Method Standard No. 141, the Federal Method numbers are also listed.

1.3 Where more than one test method is listed for the same characteristic in this index, no attempt is made to indicate superiority of one test method over another. Selection of the test methods to be followed must be governed by experience and the requirements in each individual case,

¹ This index is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.42 on Architectural Finishes.

Current edition approved March 31, 1989. Published May 1989. Originally published as D 2833 - 69. Last previous edition D 2833 - 83.

together with agreement between the purchaser and the seller.

2. Precision and Bias

2.1 If available, precision for any procedure or test method selected is given in the latest issue of the subject standard.

3. Test Categories

3.1 For convenience in selection, the procedures, methods, and specifications listed in this index are classified into three groups and three classes. The category of each listing is indicated in a column preceding the reference. The classifications are as follows:

3.1.1 *Group I—Applicable to Either Water- or Solvent-Reducible Coatings:*

Class A—For both interior and exterior products.

Class B—For interior products only.

Class C—For exterior products only.

3.1.2 *Group II—Water-Thinned Coatings:*

Class A—For both interior and exterior products.

Class B—For interior products only.

Class C—For exterior products only.

3.1.3 *Group III—Solvent-Thinned Coatings:*

Class A—For both interior and exterior products.

Class B—For interior products only.

Class C—For exterior products only.

Standard Test Method for Qualitative Tests for the Presence of Water Repellents and Preservatives in Wood Products^{1,2}

This standard is issued under the fixed designation D 2921; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method describes simple qualitative field or laboratory tests to determine water repellency or the presence of chlorinated phenol³ preservative chemicals in wood products that are specified to be water repellent preservative treated.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 U.S. Federal Specification:

TT-W-572 Wood Preservative Water-Repellent⁴

2.2 NIST Standard:

262-63 Water Repellent Preservative Non-Pressure Treatment for Mill Work⁵

3. Significance and Use

3.1 Although chlorinated phenol-treated wood has become less common due to environmental concerns, repellent-treated wood is commonly specified in construction. This test method provides a means to verify the presence of a significant level of water repellent protection.

4. Apparatus

4.1 *Eyedropper*, plastic squeeze bottle or similar means for metering drops of water.

4.2 *Flame Source*, such as bunsen burner, butane torch, or alcohol burner.

4.3 *Copper Wire Coil Specimen Holder (or Other Suitable Copper Holder)*—A suitable copper wire coil can be made by using a lead pencil as a mandrel to form a helix using copper wire of about $\frac{1}{16}$ to $\frac{3}{32}$ in. (1.6 to 2.4 mm) in diameter. Leave a space of approximately the diameter of the wire between each loop. The helix should be $\frac{3}{4}$ to 1 in. (19 to 25 mm) in length. Leave a pigtail of about 6 in. (152 mm) of wire at one end of the helix and form a loop of approxi-

mately 1 in. (25 mm) in diameter to be used as a holder for the coil.

4.4 *Sharp Knife*.

5. Water Repellent Test

5.1 Place uncut wood items to be tested so that the end grain is exposed as a horizontal surface. If the end grain cannot be so positioned, comparisons can be made on the flat grain.

5.2 With an eyedropper, or similar device, allow several drops of water to fall from about $\frac{1}{2}$ in. (13 mm) on the end grain of the wood. Wait 5 min and then observe the degree of penetration. With flat grain or vertical grain surfaces, waiting periods of 10 to 15 min may be necessary.

5.3 Water drops that immediately flatten out, penetrate and darken the wood, indicate that the wood has not been treated with a water repellent.

5.4 Water drops that "bead-up" and remain as spheres, with little or no color change or penetration, indicate that the wood has been treated with a water repellent. Water repellent preservatives, meeting Fed. Spec. TT-W-572 and NBS Standard 262-63, impart sufficient water repellency to the end grain of wood to cause water drops to bead up and form spheres.

6. Preservative Test

6.1 Chlorinated phenol based wood preservatives emit a characteristic green flame upon pyrolysis within a ventilated copper envelope due to the release of chlorine and its consequent reaction with copper (Beilstein's test). Untreated wood produces a yellow-orange flame but any chlorine containing compound will give a positive test.

6.2 Using the copper wire specimen holder, described in 3.3, hold the coil portion in the flame until it burns with a characteristic yellow-orange color. This preheated coil is then allowed to cool.

6.3 With a knife, cleaned by heating after each use, cut a splinter from the specimen of wood to be tested. Samples should be taken near the end of the wood items where end grain is exposed and where normal concentration of the preservative chemicals is greatest. The size of the wood sample should be smaller than the length and inner diameter of the coil.

6.4 With the copper coil held horizontally, place the splinter in the center of the coil. Put the copper coil with wood splinter in the flame and burn. If chlorinated phenols are present, the characteristic green flame is produced. Untreated wood produces the yellow-orange flame.

7. Accuracy

7.1 The tests are less accurate on flat grain and the

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.52 on Factory-Coated Wood Products.

Current edition approved March 25, 1988. Published May 1988. Originally published as D 2921 - 70. Last previous edition D 2921 - 70 (1979)⁶.

² An improved quantitative test method for water repellents is under development by Subcommittee D01.42.

³ Pentachlorophenol, tetrachlorophenol and other chlorinated phenols.

⁵ Available from the National Institute of Standards and Technology, Gaithersburg, MD 20899.

heartwood of some wood species, so that end grain and sapwood should be used whenever possible.

7.2 Tests on both a known untreated sample and a treated sample of the same wood species will provide comparison standards for the operator and will improve the accuracy of the tests.

7.3 Test results are improved if tests are made with wood samples taken from the center of a stack or from a protected area where the possibility of contamination is least. Untreated items which come in physical contact with pre-

servative treated products during handling and shipping may show slight evidence of the preservative chemical.

7.4 More than one wood sample obtained from different areas from the unknown piece should be tested.

8. Precision and Bias

8.1 No numerical statement of precision is possible in this qualitative test method. One hundred percent agreement was obtained in a round-robin test.

8.2 Bias—Bias has not been determined.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

Standard Guide for Testing Latex Flat Wall Paints¹

This standard is issued under the fixed designation D 2931; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—The title was editorially changed in March 1989.

1. Scope

1.1 This guide covers the selection and use of procedures for testing flat latex paints for use on interior walls. The test methods included are listed in Tables 1 and 2.

1.2 This guide applies to ready-mixed flat latex paints for application by brushing, roller coating, spraying, or other means, on plaster, masonry surfaces, wood, wallboard, previously painted surfaces and other interior architectural surfaces.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Definitions

3.1 For definition of terms used in this practice, refer to Definitions D 16 and D 1554.

4. Conditions Affecting Latex Wall Paints

4.1 *Substrate Type*—The substrate to be painted can affect not only the application properties and the physical properties of a latex paint, such as sheen and uniformity, but may also be a factor in determining the type of latex paint to be used. For instance, a latex paint with good sealing properties may be required for porous surfaces, such as new dry wall, bare plaster, new wood or porous masonry surfaces.

4.2 *Substrate Condition*—Dirty, chalky, alkaline, or water-soluble surfaces may affect the practical requirements and performance of interior latex flat paints.

4.3 *Application Properties*—The application properties of interior latex paints are affected by temperature, humidity, and the texture and porosity of the surface to be painted. Application will also depend upon the type and quality of equipment used.

4.4 *Physical Requirements*—The type of latex wall paint to be used will depend not only upon the surface to be painted, but also upon the desired physical properties of the finish. For instance, if maximum light diffusion and uniformity of appearance are the prime requirements, such as when painting ceilings, then a low sheen paint should be used. However, if cleanability or stain removal properties are desired for walls that become soiled, then a nonporous paint should be used.

5. Selection of Tests

5.1 It has been pointed out that there are many conditions that affect interior latex wall paints so that different types of latex paints have been developed specifically to meet the requirements of these various conditions. Although the recommended test methods presented in Tables 1 and 2 cover most of the properties of interior latex wall paints, all of these tests may not be required for each paint. If a paint is to be used only in a warm climate, for instance, then freeze-thaw tests or low temperature coalescence tests need not be considered.

5.2 The purchaser should first determine which properties a latex paint must have and then select only those test methods that will measure or evaluate these properties. After selecting the desired tests, the purchaser should determine which of these properties are the most important and then establish the requirements or specifications of these tests to get the most desired properties. Since some paint properties tend to oppose each other, such as low sheen versus good cleanability, or high viscosity versus good leveling, some properties may need to be attenuated if others are to be accentuated. This balance of properties must be considered when selecting the tests and establishing the requirements of these tests. The properties that these tests measure and the normal range of values have been presented for many of the tests, however.

5.3 Some tests cannot be selected as being more impor-

tant than others and specific values for each test cannot be recommended since the properties that are important to one purchaser may not be important to another.

6. Sampling

6.1 Prior to sampling, the condition of the container should be established since damage to it may cause evaporation, skinning, or other undesirable effects in the coating. Determine the condition of the coating in accordance with 7.1 and 7.2.

6.2 Sample in accordance with Practice D 3925. Determine the weight per gallon in accordance with Test Method D 1475. Repeat this procedure until successive readings agree within 0.2 lb (90 g) or as agreed upon between the purchaser and the seller. Samples for testing may then be taken.

6.3 Specify the amount of sample, the package sizes, and identification codes to assure a representative sample. A

1-gal (4-L) sample is usually sufficient for the recommended tests, but for guidance in selecting a sampling plan, consult Recommended Practice E 105.

7. Liquid Paint Properties

7.1 Condition in Container—Thickening, settling, and separation are undesirable and objectionable if the paint cannot be reconditioned with a reasonable amount of stirring. The referenced method covers procedures for determining changes in properties of paints after storage. Determine the condition in the container in accordance with Method 3011 of Federal Test Method Standard No. 141.

7.2 Coarse Particles and Foreign Matter:

7.2.1 Paints must be free of coarse particles to form uniform films of good appearance, a typical maximum being 2 weight % of total paint. The specified test with a 325-mesh (45- μ m) screen and water as the wash liquid gives the percent of these particles in a latex paint. Determine coarse particles and foreign matter in accordance with Test Methods D 185.

7.2.2 Another test method used in industry to determine whether coarse particles are present in a dry film is to scrape the surface of the film with a spatula or metal edge of a ruler.

Any particles larger than 325 mesh can be clearly seen after the surface has been scraped.

7.3 Density (Weight per Gallon)—The density as measured by weight per gallon (kilograms per litre) is used to assure product uniformity from batch to batch. It does not necessarily measure the quality of a paint. In the referenced method, the density is expressed as the weight in pounds of 1 U.S. gal (kg/L) of the paint at a specified temperature. Most interior flat latex paints have densities of about 10 to 12 lb/gal (1.2 to 1.4 kg/L). Determine density in accordance with Test Method D 1475.

7.4 Fineness of Dispersion:

7.4.1 The more finely a pigment is dispersed, the more efficiently it is being used. One method for measuring the degree of dispersion (commonly referred to as "fineness of grind") is to draw the material down a calibrated tapered groove varying in depth from 4 to 0 mils (100 to 0 μ m). The point at which continuous groupings of particles or agglomerates, or both, protrude through the surface of the liquid is taken as the fineness reading. Lower readings in mils or micrometres or higher readings in Hegman units indicate better fineness of dispersion.

7.4.2 The referenced method was designed primarily for coatings with good fineness of dispersion, such as enamels. Most interior flat latex paints have finenesses of about 70 to 90 μ m (1 to 2.5 Hegman). Although these paints may contain pigments so coarse that it is impractical to measure the fineness with a grind gage, most of the pigments are so finely dispersed that particles or agglomerates cannot be seen by the unaided eye or felt on the surface of the dry film. In addition, the fast drying of some flat latex paints may make it difficult to make accurate measurements of fineness of dispersion.

7.4.3 Determine fineness of dispersion with Test Method D 1210.

7.5 Odor—One of the advantages of latex paints is that they do not have odors characteristic of solvent-based coatings. However, other ingredients, such as ammonia, may be used which might also be objectionable in confined spaces. Thus, interior latex paints should be tested for odor acceptability. Although there is no adequate ASTM test method to measure odor for nonorganic solvent paints, test methods are used by industry to measure this property. Examine to determine if the paint has an unpleasant or irritating odor during application or drying.

7.6 Consistency (Viscosity)—Paints of a given type should fall within a stated consistency for satisfactory reproduction of a specific formula. While consistency is an important property it does not determine the quality of a paint and should be used mainly to assure product uniformity. In the referenced method, consistency is defined as the load in grams to produce a specified rate of shear. Although the consistency of most latex wall paint is about 150 to 300 g/100 revolutions, a much wider range is possible because of the wide variations in rheological properties of these paints. Also two paints of the same consistency may have quite different rheological properties. Determine the consistency in accordance with Test Method D 562.

7.7 Rheological Properties, Non-Newtonian Liquids—Rheological properties are related to application and leveling properties of the liquid paint. The referenced method covers

the determination of rheological properties and is particularly suited for use with paints that display thixotropic characteristics. It actually measures viscosity under varying conditions of time and rotational speed of the spindle. Determine rheological properties in accordance with Test Methods D 2196.

7.8 pH—Latex paints with low (acidic) pH may corrode the container. pH may vary from about 5 to 10 depending upon the type of latex used and the general formulation. pH does not determine the quality of a latex paint and should only be used to assure product uniformity. A change in pH during storage may indicate poor stability or a change in properties of a latex paint. Determine pH in accordance with Test Method E 70.

7.9 Color Compatibility—A test method to determine how well colorants can be dispersed in a paint so that the paint will have uniformity of color when applied is now in preparation and will be included in this guide when adopted by ASTM.

7.10 Freeze-Thaw Stability—Water-based paints may be subjected to freezing conditions during shipping and storage. Suitably stabilized paints will resist several cycles of freezing and thawing without showing deleterious changes such as coagulation, graininess, or excessive viscosity increase. Many latex paints will increase in viscosity but can still be considered usable if other properties, which may be affected by a higher viscosity, such as leveling and brushability, are satisfactory. Determine freeze-thaw stability in accordance with Test Method D 2243.

7.11 Package Stability—Since paints cannot normally be used immediately after manufacture, they must remain stable in the can for some time. At normal temperatures, most latex paints can be stored for over a year with little change in properties. Although package stability can usually be determined in several weeks at an elevated temperature such as 122°F (50°C), occasionally the results of the accelerated test do not coincide with those of prolonged room temperature storage. The referenced method covers the change in consistency and in certain other properties in packaged latex paint when stored at temperatures above freezing. Determine package stability in accordance with Test Method D 1849.

7.12 Microorganism Resistance—Bacteria in a latex paint can cause gassing, putrefactive, or fermentative odors and loss of viscosity. Determine if the paint contains living bacteria or if it is resistant to attack by bacteria in accordance with Test Method D 2574.

8. Paint Application and Film Formation

8.1 Application Properties—Determine the ease with which a paint can be applied to various wall surfaces with brush, roller, or spray equipment, in accordance with Method 4541 of Federal Test Method Standard 141. Application properties are generally compared to a standard, or described by requirements in a product specification.

8.1.1 Brushing Properties—The specified method covers the determination of the brushing properties of coatings. The test is quite subjective although someone experienced in the art can produce quite consistent results, particularly in the evaluation of "drag" properties. Determine brushing proper-

ties in accordance with Method 4321 of Federal Test Method Standard No. 141.

8.1.2 Roller Application—Determine the ease with which a paint can be roller applied in accordance with Method 2112 of Federal Test Method Standard 141. Since roller foam and roller spatter are often serious problems when latex paints are roller applied, these properties can also be determined in the test method for roller application. The amount of foam produced, the time that it takes for the bubbles to break, and the number of craters that remain after the bubbles have broken can be determined by visual examination of the test panel. Roller spatter can be determined by placing a strip of paper or a panel at the bottom of the test panel to catch the paint spatters from the roller. The degree to which a paint will spatter when roller applied can be determined by the density of the paint spatter.

8.1.3 Sprayed Film Application—Interior latex paints are sometimes applied by spray. Determine the spray application properties in accordance with Method 2131 of Federal Test Method Standard No. 141. The method can be modified to include application by airless spray equipment.

8.2 Drying Time—The drying time of an interior latex paint is important in determining when a freshly painted room can be put back to use. Under average conditions most flat latex paints are dry to touch in 1 or 2 h when the water has evaporated from the film. They can usually be recoated from within a few hours to 18 h. Curing to obtain the ultimate properties may take only a few days for some latex paints while others may require 1 or 2 weeks depending upon the composition. Determine drying time in accordance with Test Methods D 1640.

8.3 Flow and Leveling—These properties are usually evaluated by visually examining the test panel after a paint has been applied by brush or roller to see if any brush or roller marks can be seen in the dry film. Determine the ability of the paint to flow out after application in accordance with Test Method D 4062.

8.4 Low-Temperature Coalescence of Paints—Determine how well the latex particles in a paint will fuse together or coalesce, to form a continuous film at low temperatures in accordance with Test Method D 4062.

8.5 Producing Films of Uniform Thickness—The following method covers the preparation of various films of uniform thickness essential in conducting tests. Prepare films in accordance with Test Methods D 823.

8.6 Touch-Up—Although there is no test method published in Federal Test Method Standard 141 to measure touch-up, test methods are used by the paint industry. The usual method is to apply the test paint to a small section of a test panel that has previously been painted with the test paint and allowed to dry. The touch-up area is usually applied with a small brush. When the touch-up area has dried, it is examined to see if there is any difference in color or sheen between the touched-up area and the initial coat of paint.

9. Appearance of Dry Film

9.1 Color Differences of Opaque Materials by Visual Evaluation—Visual comparison of color is fast and often acceptable although numerical values are not obtained. The referenced method covers the spectral, photometric, and geometric characteristics of light source, illuminating and

viewing conditions to be used of opaque materials in accordance with Practice 9.2 Color D

9.2 Color D Evaluation—Color standard can tolerance is agreed upon. Although color eye, they frequently compare method covers differences of nonfluorescent coated specimens (9.1) standard instrumental method

9.3 Hiding—Measure of the hiding power, however, depends upon practical test thickness is usually as affected by film paint. Test method precise and accurate standard. Paint the effects of measured, determine hiding in accordance with D 2805.

9.4 Specular—85° geometric appearance of 85° sheen of uniformity of paints with sheen, this should not be determined in D 523.

9.5 Uniformity—Method 4541 examine the color or sheen

10. Properties

10.1 Efflorescence—method measures itself, not efflorescence of formulations of ter sufficient soil deposit on the surface in accordance with

viewing conditions, size of specimens, and general procedures to be used in the visual evaluation of color differences of opaque materials. Determine color difference in accordance with Practice D 1729.

9.2 Color Differences of Opaque Material by Instrumental Evaluation—Color difference between a product and the standard can be measured by instrument. Generally, the tolerance is agreed upon by the purchaser and the seller and may also be required if a product specification is involved. Although color instruments are not more sensitive than the eye, they provide numerical values which can be subsequently compared to later measurements. The referenced method covers the instrumental determination of small color differences observable in daylight illumination between nonfluorescent, nonmetameric, opaque surfaces such as coated specimens. If metamerism is suspected, visual evaluation (9.1) should be used to verify the results. Make instrumental measurement of color difference in accordance with Method D 2244.

9.3 Hiding Power (Dry Opacity)—Hiding power is the measure of the ability of a paint to hide the substrate. It is, however, dependent upon uniform film thickness which is influenced by flow and leveling. Test Method D 344 is a practical test in which paint is applied with a brush, film thickness is approximately measured, opacity is evaluated visually as compared to a standard paint, and results are affected by flow and leveling application properties of the paint. Test Method D 2805 is considered to be a more precise and accurate test that does not need a material paint standard. Paint is applied with an applicator bar to minimize the effects of flow and leveling, film thickness is rigorously measured, and opacity is instrumentally evaluated. Determine hiding power in accordance with Test Methods D 344 or D 2805.

9.4 Specular Gloss (Sheen)—The method given, using the 85° geometry, is useful in characterizing the low angle appearance of flat paints. Most flat latex wall paints have an 85° sheen of about 1 to 10. Although paints with good uniformity of appearance are often paints of lower sheen and paints with good cleanability are often ones with higher sheen, this is not always the case, and the sheen of a paint should not be used as a measure of other paint properties. Determine the 85° gloss in accordance with Test Method D 523.

9.5 Uniformity of Appearance—Apply the paint as in Method 4541, Federal Test Method Standard 141, and examine the dry paint to see if there is any nonuniformity of color or sheen.

10. Properties of Dry Film

10.1 Efflorescence of the Paint Film—The referenced method measures efflorescence that comes from the paint itself, not from the substrate. Few interior latex paints effloresce due to improvements in latex and latex paint formulations. Salt formation is produced by specific conditions of temperature and humidity if a paint contains sufficient solid water-soluble material to cause a noticeable deposit on the film. Determine efflorescence resistance in accordance with Test Method D 1736.

10.2 Efflorescence from Substrate—Cementitious substrates may contain sufficient solid water-soluble materials to

cause a surface deposit through leaching and evaporation. Determine if a latex paint applied over an alkaline masonry surface will allow soluble salts to pass through the film in accordance with Test Method D 2831.

10.3 Elongation—Elongation is a measure of the flexibility of a paint film. Most interior latex paints can be bent over a ¼ in. (6.4-mm) mandrel without affecting the film. Determine elongation in accordance with Test Methods D 522 or D 1737.

10.4 Film Porosity—The more porous a paint is, the worse will be its cleanability and enamel holdout. Determine the film porosity in accordance with Test Method D 3258.

10.5 Scrubbability—The ability of an interior finish to resist scrubbing is an important property. The referenced method provides a measure of the wet abrasion resistance of a film. However, wet abrasion resistance is not necessarily a measure of how well soils or stains can be removed since some paints have good scrubbability but poor stain cleanability because they are porous. The scrubbability of interior latex flat paints can vary from less than 100 to more than 1000 cycles. Determine the scrubbability in accordance with Test Method D 2486. A control paint should always be tested at the same time because of the variability of the method.

10.6 Stain Removal (Cleanability)—The ability to remove marks satisfactorily without damaging the film is an important property of interior finishes. A test method to determine how well stains and soils can be removed from a cured paint film is now in preparation and will be included in this guide when it is approved by ASTM. Test methods used by the paint industry consist of applying various household soils or stains to the cured paint film and attempting to remove these soils or stains by means of a washing or scrubbing operation. The attempted removal of the soils or stains can be done by hand or with a mechanical apparatus. Determine the relative ease of removal of soil from the dried film by washing with either an abrasive or nonabrasive cleaner in accordance with Test Method D 3450.

10.7 Wet Abrasion Resistance (Weight Loss Method)—This method differs from Test Method D 2486, scrub resistance (10.5), in that the loss in weight or volume of the paint film is recorded for each 100 scrub cycles. In Test Method D 2486 the number of scrub cycles required to wear through the paint film is recorded. Determine the wet abrasion resistance of the paint in accordance with Test Method D 4213.

11. Analysis of Paint

11.1 Chemical Analysis—If a specification requires certain raw materials or certain components in a given amount, then chemical analysis is required to determine whether the specified materials are present and in what amounts. Analysis does not necessarily establish paint quality which can also be greatly affected by manufacturing techniques. Most ASTM analytical methods apply to solvent-based coatings. However, some of them can be adapted for analysis of latex paints.

11.2 Volatile Content—The amount of volatile material in a paint cannot be used as an indication of the quality of a paint. This value is useful, however, in determining the

similarity of two samples. Determine volatile content in accordance with Test Method D 2369.

12. Field Testing

12.1 Although the recommended test methods attempt to

duplicate actual conditions under which latex flat wall paints are applied, it is not possible to duplicate all possible conditions. It is therefore necessary to test latex flat wall paints under actual existing conditions for a final evaluation of the quality of a paint.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Guide for Testing Exterior Solvent-Reducible House and Trim Coatings¹

This standard is issued under the fixed designation D 2932; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

¹ NOTE—Editorial changes were made throughout, including the title, in October 1988.

1. Scope

1.1 This guide covers the selection and use of procedures for testing exterior solvent-reducible house paints and trim coatings in the laboratory and in the field. The test methods included are listed in Tables 1 and 2. All of these tests may not be required for each paint. Selection of the test methods to be followed must be governed by experience and the requirements in each individual case, together with agreement between the purchaser and the seller.

1.2 This guide covers the testing of ready-mixed solvent-reducible house paint or trim coatings for application by brush, roller, or spray on exterior surfaces. The paint may be any of the following types:

1.2.1 *Type I Paint, Oil*—Titanium, lead, zinc, and oil, nonfume-resistant, white and colors. For general exterior use, particularly on wooden structures.

1.2.2 *Type II Paint, Oil*—Titanium, zinc, and oil, fume-resistant, white and colors. Suitable for use on exterior surfaces such as wood and primed steel or sealed concrete, where resistance against discoloration from hydrogen sulfide is required.

1.2.3 *Type III Paint, Oil-Alkyd*—Combination of oil and alkyd in the vehicle and pigments, composed of chalk-resistant and chalking titanium dioxide, white and colors. For general exterior use, particularly on wooden surfaces, trim, primed steel, or sealed concrete.

1.2.4 *Type IV Paint, Miscellaneous Vehicles*—Combination of pigments and vehicle, white and colors. Suitable for use on exterior wooden surfaces, trim, primed steel, or sealed concrete.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Definitions

3.1 For definition of terms used in these practices, refer to Definitions D 16, D 1554, and D 1038.

4. Conditions Affecting Solvent-Based House and Trim Coatings

4.1 Practical requirements and performance for solvent house or trim paints may vary with:

4.1.1 Substrate type, such as type and quality of wood or hardboard; type of grain of wood; knots; and type, quality, and alkalinity of concrete substrates.

4.1.2 Condition of previously painted substrates such as degree of chalk, adhesion of film, dirt, mold, and general condition of old coating.

4.1.3 Type and quality of primer and time before topcoating.

4.1.4 Climatic conditions at the time of coating application and immediately after application.

sampling, stir the paint as in 4.21 of Method 1021. Determine the weight per gallon (or kilograms per litre) in accordance with Test Method D 1475. Stir again and recheck the weight per gallon. The two readings should agree within 0.10 lb (45 g).

5.3 Specify the amount of sample, the package sizes, and identification codes to assure a representative sample. A 1-gal (4-L) sample is usually sufficient for the recommended tests but for guidance in selecting a sampling plan consult Recommended Practice E 105.

6. Liquid Paint Properties

6.1 *Skinning*—Paints containing a binder, that dries by oxidation are subject to skin formation in a partially filled can or by diffusion of air into the can. Since skins are insoluble in the paint, they must be removed before use. This test in a partially filled container indicates the tendency of a paint to skin. Examine the original sample for skins, both on the surface and in its mass. Using a well-mixed, skin-free

portion of the sample, perform a skinning test in accordance with Guide D 154.

NOTE 1—A typical minimum time for skinning in accordance with Guide D 154 is 48 h.

6.2 *Condition in Container*—After storage, paints should be suitable for application with minimum stirring. Characteristics that are undesirable and objectionable in a stored paint are given in the referenced test method. Determine condition in container in accordance with Method 3011.1 of Federal Test Method Standard No. 141.

6.3 *Coarse Particles and Foreign Matter*—Paints must be free of oversize particles and foreign matter to form a uniform film of good appearance. This test, with a 325-mesh (45- μ m) screen, gives the percent of these particles in the paint. Determine coarse particles and foreign matter in accordance with Test Methods D 185.

NOTE 2—A typical maximum for coarse particles and foreign matter is 1 weight % of total paint.

6.4 *Density or Weight per Gallon*—The density of a paint as measured by weight per gallon (or kilograms per litre) provides a check against the theoretical weight calculated from the formula and is useful for determining similarity of two samples. The density is expressed as the weight in pounds of 1 U. S. gal (or kilograms per litre) of the liquid at a specified temperature. A calibrated weight per gallon cup is used. Determine weight per gallon in accordance with Test Method D 1475.

6.5 *Fineness of Dispersion*—The more finely a pigment is dispersed the more efficiently it is being utilized. One method for measuring degree of dispersion is to draw a paint down a tapered groove in a hardened steel block with the groove varying in depth from 4 to 0 mils ((100 to 0 μ m) 0–8 Hegman units). The point at which continuous groupings of particles or agglomerates protrude through the surface of the wet film is taken as the dispersion reading. Higher readings (Hegman units) indicate better dispersion. Determine the fineness of dispersion in accordance with Test Method D 1210.

NOTE 3—A typical reading for house paint is 60 μ m (approximately 2½ mils) and for trim paint 25 μ m (1 mil). Several arbitrary scales and modifications of the gage are used by industry. The approximate relationship of these scales to micrometre and mil readings is shown in Test Method D 1210.

6.6 *Consistency (Viscosity)*—Paints of a given type should fall within a stated consistency range for satisfactory reproduction of a specific formula. While consistency is an important property, it does not determine the quality of a paint and should be used mainly to assure product uniformity. In the referenced method consistency is defined as the load in grams to produce a specified rate of shear. Although the consistency of most solvent-based house and trim coatings is about 150 to 300 g/100 revolutions, a much wider range is possible because of the wide variations in rheological properties of these paints. Also two paints of the same consistency may have quite different rheological properties. Determine the consistency in accordance with Test Method D 562.

6.7 *Dilution Stability*—Dilution with a specified thinner shows whether the materials are compatible and whether the reduced paint is stable. The referenced test is a measure of

the stability of paint that has been reduced to a desired viscosity, for example, for spray application. The diluent suggested for reduction should be readily incorporated into the paint without excessive stirring or shaking. Determine dilution stability in accordance with Method 4203 of Federal Test Method Standard No. 141.

6.8 Rheological Properties of Non-Newtonian Liquids—Rheological properties are related to application and flow properties of the liquid coating. The referenced test method covers the determination of the rheological properties of a paint and is particularly suited for use with paints that display thixotropic characteristics. It actually measures viscosity under varying conditions of time and rotational speed of the spindle. Determine rheological properties in accordance with Test Methods D 2196.

6.9 Absorption—On porous surfaces, binder penetration can result in pigment volume concentration changes as the film dries. This may cause performance to vary. The referenced method provides a rapid means for measuring the relative penetration of the binder into a porous surface. It provides a rough measure of the wetting and penetrating quality of liquid materials. Determine the absorption in accordance with Federal Test Method Standard No. 141, Method 4421.

6.10 Flash Point—When the flash point of a material is required for shipping information, use Test Methods D 93, Part B, or D 3278.

7. Paint Application and Film Formation

7.1 Working Properties—Working properties of a paint are generally compared to a standard or described by requirements in the product specification. Test working properties in accordance with Method 4541 of Federal Test Method Standard No. 141.

7.2 Application by Brush—Brushed films should be smooth and free of seeds and on vertical surfaces should show no sagging, streaking, or excessive brush marks. For proper method of application of a brushed film for test purposes, refer to Method 2141.1 of Federal Test Method Standard No. 141.

7.3 Application by Spray—This method covers application of a paint by spray, which is sometimes used for house and trim paint. Refer to Method 2131 of Federal Test Method Standard No. 141.

7.4 Drying Properties—The drying time of a coating is determined by its composition and by atmospheric conditions during drying. Insufficient drying may result in dirt or insect pickup resulting in a poor appearance, or a nonuniform appearance caused by dew or rain falling on the paint film. Testing a paint for the required drying properties can determine whether the paint has lost its drying properties through aging or whether insufficient drier was included in the product at the time of manufacture. The specific category of drying should be selected to suit the types of house paint being tested, since drying times vary widely. Determine the drying time in accordance with Test Methods D 1640.

8. Appearance of Dry Paint Film

8.1 Color Difference of Opaque Materials, Visual Evaluation of—Visual comparison is fast and often acceptable although numerical values are not obtained. The referenced

practice covers the spectral, photometric, and geometric characteristics of light source, illuminating and viewing conditions, sizes of specimens, and general procedures to be used in the visual evaluation of color differences of opaque materials. Determine the color difference in accordance with Practice D 1729.

8.2 Color Difference of Opaque Materials, Instrument Evaluation of—Color difference between a product and the standard can be tested by instrument. Generally the tolerance is agreed upon between the purchaser and the seller, and may also be required if a product specification is involved. Determine the color difference in accordance with Method D 2244.

8.3 Directional Reflectance—This property is a measure of light reflected from the surface of the paint. It usually is assigned a value in specifications for white and pastel shades. Determine daylight directional reflectance in accordance with Test Method E 97.

8.4 Gloss (60-deg Specular)—Determine the specular gloss in accordance with Test Method D 523. Oil house paints are typically in a gloss range from 30 to 70, while trim enamels are in a gloss range from 70 to 90.

8.5 Hiding Power (Dry Opacity)—Hiding power is the measure of the ability of a paint to hide the substrate. It is, however, dependent upon uniform film thickness which is influenced by the flow and leveling. Test Method D 344 is a practical test in which paint is applied with a brush, film thickness is approximately measured, opacity is evaluated visually as compared to a standard paint, and results are affected by flow and leveling application properties of the paint. Test Method D 2805 is considered to be a more precise and accurate test that does not need a material paint standard. Paint is applied with an applicator bar to minimize the effects of flow and leveling, film thickness is rigorously measured, and opacity is instrumentally evaluated. Determine hiding power in accordance with Test Methods D 344 or D 2805.

9. Properties of Dry Paint Film

9.1 Elongation (Flexibility)—Elongation is a measure of flexibility of a paint film. Generally, gloss house paints and trim paints will have no problem in passing a mandrel bend test. Flat house paints, however, may fail a sharp bend. Determine elongation in accordance with Test Methods D 1737 or D 522.

9.2 Moisture Blister Resistance—Blister resistance is related to the ability of a dry paint film to resist the formation of blisters caused by water from the wood substrate. The water can come from either the interior of the home or from structural defects that permit entry of the water behind the wood. Moisture blister resistance can be qualitatively evaluated in a laboratory test. Determine resistance to moisture blistering in accordance with Test Method D 2366.

9.3 Fume Resistance—Fume resistance is the ability of a dry paint film to resist discoloration in a moist hydrogen sulfide atmosphere. This type of atmosphere may be present near industrial or other polluted areas and can cause paint to yellow or darken in as little time as overnight exposure. There are no ASTM or Federal test methods for evaluating this property, but one procedure used by the industry is as follows:

ability of a st hydrogen y be present use paint to it exposure. r evaluating ndustry is as

9.3.1 Apply a sufficient number of coats of the paint to two glass plates to hide the surface completely, allow to dry for 6 h and expose one of the plates in a moist atmosphere of hydrogen sulfide for 18 h. Compare the color with the unexposed plate. The exposed plate should be practically no darker than the unexposed one. The color difference should not exceed that between plates that have been coated with a paint made with titanium dioxide pigment, lead-free zinc oxide, raw or refined linseed oil, and sufficient cobalt added for drying, and which has been similarly treated.

9.4 *Exterior Exposure Resistance*—In conducting exterior exposures, refer to Practice D 1006.

9.4.1 *Wood Panel Description*—In establishing exposure performance, use the panels as described in Specification D 358.

9.4.2 *Chalk-Resistance Ratings*—Determine chalk-resistance rating using Method D 659.

9.4.3 *Checking-Resistance Ratings*—Determine checking-resistance rating using Method D 660.

9.4.4 *Cracking-Resistance Ratings*—Determine cracking-resistance rating using Test Method D 661.

9.4.5 *Erosion-Resistance Ratings*—Determine erosion-resistance rating using Test Method D 662.

9.4.6 *Flaking-Resistance Ratings*—Determine flaking-resistance rating using Test Method D 772.

10. Analysis of Paint

10.1 *Chemical Analysis*—If a specification requires specific ingredients, chemical analysis may be required. Select test procedures from Methods D 215, and other ASTM

methods that are pertinent to the components of exterior house paints.

NOTE 5—No single schematic analysis is comprehensive enough to cover the wide variety of house paint compositions.

10.2 *Volatile Content*—Thinner is removed from the paint at 110°C. The percentage of volatile matter calculated from this loss in weight indicates the thinner loss from the film as the paint dries. Determine volatile content of the paint in accordance with Test Method D 2369.

10.3 *Pigment Content*—The pigment gives paint its hiding and color and influences many other properties of the paint. Determine the percent pigment in accordance with Test Method D 2371.

10.4 *Pigment Analysis*—The analysis of pigment may be required if the product is covered by a specification, or upon agreement between the purchaser and the seller. Determine analysis of pigments in accordance with the selected test procedure from Method D 215.

10.5 *Nonvolatile Vehicle Content*—The nonvolatile vehicle is that portion of the film-forming solids in a paint other than the pigment. Water, volatile thinner, and pigment are determined and the sum subtracted from the total weight to give the nonvolatile vehicle content. Determine the nonvolatile vehicle content in accordance with Method D 215. Separate the vehicle for further analysis in accordance with Method D 2372.

10.6 *Identification of Vehicle Solids*—Determine identity of vehicle solids in accordance with Methods D 2621.

10.7 *Identification of Oils*—Determine identity of oils in accordance with Methods D 2245.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Corrosion Resistance of Coated Steel Specimens (Cyclic Method)

This test method is intended for use in determining the resistance to failure of coatings of paint, varnish, lacquer, and related products on steel surfaces when exposed cyclically to salt spray, humidity, and cold to induce coating failure more representative of the type found in outdoor corrosive environments.

Formerly under the jurisdiction of Committee D-1 on Paint and Related Coatings and Materials, this test method was discontinued in 1992.

Standard Practice for Evaluation of Coatings for Plastics¹

This standard is issued under the fixed designation D 3002; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice is intended for the evaluation of clear and pigmented coatings designed for use on rigid or semi-rigid plastic substrates. Coated film and sheeting are not covered by this practice.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint, and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.55 on Factory-Applied Coatings on Preformed Products.

Current edition approved Oct. 30, 1981. Published December 1981. Originally published as D 3002 - 71. Last previous edition D 3002 - 78.

² Annual Book of ASTM Standards, Vol 06.01.

³ Annual Book of ASTM Standards, Vols 06.01, 06.02, and 06.03.

⁴ Annual Book of ASTM Standards, Vol 14.02.

3. Significance and Use

3.1 This practice is designed to set up a series of screening tests that will indicate the performance level to be expected of a coating or coating system on a given plastic substrate.

3.2 Rigid and semirigid plastic substrates vary widely in their acceptance characteristics for a given coating.

3.3 Surface cleaning or preparation prior to application of the coating can be critical to the proper performance of the coating.

4. Precaution

4.1 This standard may involve the use of hazardous materials, operations, and equipment. It is the responsibility of whoever uses this standard to establish appropriate safety practices and to determine the applicability of regulatory limitations prior to use.

5. Test Panels and Panel Preparation

5.1 Unless directed otherwise, conduct performance tests on coatings of specified thickness applied to a normally molded sample of the designated plastic. Applied coatings cannot correct surface defects from improper molding procedures.

5.2 Preparation of test samples shall include any cleaning, metalizing, or priming operations agreed upon by the producer and the user.

5.3 Air-dry or bake the system according to the established schedule and aged as agreed between the producer and the user.

6. Nonvolatile Matter

6.1 Test for nonvolatile matter in the coating material in accordance with Test Methods D 1644.

7. Color

7.1 *Clear (on liquid sample)*—Determine the Gardner color in accordance with Test Method D 1544.

7.2 *Pigmented (on dry film)*—Evaluate color differences visually in accordance with Practice D 1729 and instrumentally in accordance with Method D 2244.

8. Gloss

8.1 Test in accordance with Test Method D 523.

9. Print Test

9.1 Test in accordance with Test Method D 2091.

10. Hardness

10.1 Apply a film to a clean steel panel at a thickness agreed upon by the purchaser and the seller. Test in accordance with Test Methods D 1474.

11. Tape Adhesion

11.1 Test for tape adhesion in accordance with Methods D 3359.

12. Resistance to Plasticizer Migration

12.1 Test in accordance with Test Method D 2199. Time and temperature may be varied as agreed between the producer and the user.

12.2 If migration from a plastic substrate into a coating is being determined, the vinyl contact pad should be omitted.

13. Resistance to Temperature-Humidity Cycling

13.1 Expose the finished panel in accordance with Test Method D 2246.

13.2 After the number of cycles agreed between the producer and the user, determine whether adhesion (Section 11) and appearance (Sections 7 and 8) have changed.

14. Resistance to Continuous 100 % Humidity

14.1 Expose the finished panel in accordance with Practice D 2247.

14.2 After exposure for the length of time agreed between the producer and the user, determine whether adhesion (Section 11) and appearance (Sections 7 and 8) have changed.

15. Resistance to Household Chemicals

15.1 Test in accordance with Test Method D 1308.

16. Wear Resistance

16.1 Conduct an abrasion test in accordance with Test Method D 658 or Test Methods D 968 and determine the abrasion coefficient.

17. Light Stability Test

17.1 Expose to sunlight in accordance with Recommended Practice G 24. Duration of test and maximum acceptable change in color shall be as agreed between the producer and the user.

18. Weather Resistance

18.1. Expose panels in Florida or other area agreed between the producer and the user, 45° South for 12 months and determine changes in appearance (Sections 7.2 and 8.1), and adhesion (Section 11).

19. Resistance to Chipping

19.1 Using the plastic, pretreatment, primer, and topcoat system agreed between the producer and the user, test with the gravimeter in accordance with Test Method D 3170.

20. Effect on Substrates

20.1 Determine the physical properties of the substrate such as hardness, tensile strength, flexibility, or surface smoothness before and after applying the coating under test. Select the appropriate tests for the substrate from Volumes 08.01, 08.02, and 08.03 of the *Annual Book of ASTM Standards*.

21. Precision

21.1 The precision of this practice is described by each individual method cited.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Pressure Mottling and Blocking Resistance of Organic Coatings on Metal Substrates¹

This standard is issued under the fixed designation D 3003; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This method covers determination of the pressure mottling and sticking, or blocking resistance of organic coatings applied to coil-coated or factory-coated metal prior to postformed.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Summary of Method

2.1 The coated metal is cut into suitably sized panels. A stack of these panels is then subjected to a specified pressure and temperature for a specified time to permit any pressure mottling and sticking or blocking to develop. The heating elements of the test apparatus are turned off and, after cooling, the specimens are examined for any signs of sticking or blocking, and mottling. The results are rated on the 0 to 10 scale and may be used in accepting or rejecting the coating according to standards established by the purchaser and the seller.

3. Description of Terms

3.1 *pressure mottling*—film distortion or uneven pattern giving a change of gloss and nonuniform appearance. It is usually caused by pressures within a painted coil or stacked painted sheets or other painted products.

3.2 *blocking or sticking*—the condition wherein coated surfaces adhere to each other.

4. Apparatus²

4.1 A suitable hydraulic or mechanical press or vise may be used. The equipment shall be capable of producing the required test pressure in pounds-force per square inch (or kilopascals) and be equipped with a suitable device for measuring the force applied.

5. Test Specimens and Conditions

5.1 At least four, and preferably six, flat panels shall be cut from the coated stock, the age of which shall be within the limits agreed upon by the purchaser and the seller.

5.2 Panels should be at least 4 by 2.5 in. (100 by 70 mm) to provide an adequate area for assessing the results. Where the equipment does not provide adequate pressure, smaller panels may be used. The minimum recommended size is 2 by 2 in. (50 by 50 mm).

5.3 Use only flat panels. If necessary, file the edges smooth to ensure maximum contact between the surfaces. When the equipment permits, panels larger than the pressure plates may be used, thus eliminating any effect from uneven edges. With this method, the pounds-force per square inch (or kilopascals) is calculated using only the panel area within the pressure plates.

5.4 The film thickness of the coating under test shall be as specified or agreed upon by the purchaser and the seller.

5.5 The coated stock shall be tested under the conditions of pressure, temperature, and time mutually agreed upon by the purchaser and the seller. Pressures ranging from 110 to 350 psi (750 to 2400 kPa), temperatures from 110 to 140°F (43 to 60°C), and times of 2 to 16 h have been used.

5.6 In the absence of agreed or specified test conditions, a pressure of 110 ± 5 psi (750 ± 35 kPa), a temperature of $110 \pm 3^\circ\text{F}$ ($43 \pm 1.5^\circ\text{C}$), and a time of 16 h shall be used.

5.7 The total force applied is measured by a suitable gage and the pounds-force per square inch (or kilopascals) is calculated by dividing the force (pounds-force or newtons) by the area in square inches (or square millimetres) of one side of one panel.

6. Procedure

6.1 Stack the panels face to back as used in production with both face and back coatings applied. Limit the number of panels in the test to the quantity that can be heated rapidly to and maintained at the correct panel temperature throughout the test.

6.2 For presses having heating units, place the test panels in the press and bring the heating platens in contact but with light pressure. Turn on the electrical heating unit, and heat the panels to the required test temperature. When this temperature is reached, the indicating light will shut off. Apply the required pressure and maintain it for the specified time (6.4).

6.3 Where the apparatus does not have built-in heating units, preheat the mechanical press or vise. Place the panels in the press at room temperature with very light contact and heat the unit in an oven to the required temperature. Then

¹ This method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.53 on Factory-Precoated Strip Metal.

Edition effective Dec. 22, 1971.

² Suitable equipment includes Pasadena or Studebaker Hydraulic Presses; Gardner Laboratories Cam-activated Pressure Mottling Tester; and drill press vises modified for use with a torque wrench if agreed between purchaser and seller (Hensley, W. L., "Pressure Mottling Test," *Journal of Paint Technology*, Vol. 40, No. 517, February 1968, p. 544).

TABLE 1 Classification

NOTE 1—Intermediate grades are permissible to distinguish small differences.

NOTE 2—Reasonable force is defined as that which can be exerted by the fingers only, using the fingernails as the only prying instrument.

NOTE 3—The transfer of components of one coating onto or into another coating is also known as offsetting or pickoff.

Grade	Sticking or Blocking	Grade	Mottling
10	Panels fall apart—no sticking.	10	No mottling immediately after separation.
8	Slight tackiness or panels pull apart easily.	8	No mottling after 24 h separation.
6	Panels pull apart with effort. No flexing or prying required to aid separation.	6	Light permanent mottling after 24 h separation.
4	Panels pull apart using reasonable force. Flexing may be required (Note 2).	4	Heavy permanent mottling after 24 h separation.
2	Panels require prying apart with a spatula or similar instrument.	2	Light pickoff or transfer of one or both coatings (Note 3).
0	Panels block together so they cannot be separated with a spatula or similar instrument, without using extreme force.	0	One or both coatings show heavy pickoff down to the metal or basecoat; or block together (Note 3).

apply the proper pressure and return the unit to the oven for the specified time.

6.4 Record the time only after the specified temperature and pressure are reached. Check the temperature and pressure at intervals during the test.

6.5 At the end of the specified time, turn off the heat and allow the panels to cool to room temperature under pressure before removal and separation.

6.6 After removal from the press, grade the panels separately for both sticking or blocking and mottling in accordance with Table 1. In assessing the results ignore effects due to sharp or uneven edges.

6.7 Maintain panels that are to be reaccessed after a recovery period at $75 \pm 5^\circ\text{F}$ ($24 \pm 3^\circ\text{C}$).

6.8 For both properties assign each coating a grade which is the arithmetic mean of all panels tested.

7. Report

7.1 Report the following data for each coating:

7.1.1 Equipment used,

7.1.2 Number of panels tested,

7.1.3 Pressure,

7.1.4 Temperature and heating process (built-in or oven),

7.1.5 Time,

7.1.6 Grade for sticking or blocking, and

7.1.7 Grade for mottling.

8. Precision

8.1 In an interlaboratory test of this method, two operators in each of seven laboratories tested two different coatings, subjected to two treatments (pressure, temperature, and duration) and rated them for sticking, and pressure mottling. The within-laboratory and between laboratory pooled standard deviations were found to be as follows:

Rating Parameter	Pooled Standard Deviations	
	Within-Laboratory	Between Laboratory
S	0.42	1.10
PM	0.38	1.06
Average	0.40	1.08

Based on these results the following criteria should be used in judging the acceptability of results at the 95 % confidence level.

8.1.1 *Repeatability*—Two results, each the mean of the two sets of panels, obtained by the same operator should be considered suspect if they differ by more than 1 to 2 units.

8.1.2 *Reproducibility*—Two results, each the mean of two sets of panels, obtained by operators in different laboratories should be considered suspect if they differ by more than 3.7 units.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Determination of Resistance of Factory-Applied Coatings on Wood Products to Stains and Reagents¹

This standard is issued under the fixed designation D 3023; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

- 1.1 This practice covers evaluation of clear factory-applied coating systems on wood substrates.
- 1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

- 2.1 *ASTM Standards:*
D 235 Specification for Mineral Spirits (Petroleum Spirits) (Hydrocarbon Dry Cleaning Solvent)²
D 333 Test Methods for Clear and Pigmented Lacquers³
D 2571 Guide for Testing Wood Furniture Lacquers³

3. Significance and Use

3.1 When used in conjunction with Methods D 333, this practice will provide a comprehensive evaluation of resistance to stains caused by chemical reagents and household chemicals.

3.2 This practice applies only to coatings applied in sufficient quantity to form a continuous film. It is recommended that the dry film thickness of the coating under test be reported.

3.3 Results from stain tests conducted in accordance with this practice distinguish differences between coatings.

4. Reagents

4.1 *Code for Applicability of Reagents*—V = Vertical, any surface that may be vertical as on a dresser front. H = Horizontal, any surface that may be horizontal as on a table top. L = Laboratory, any surface that may be used for laboratory furniture (Section 9).

4.2 Water:

4.2.1 *Tap Water*, V, H, L

4.2.2 *Boiling Water* (test in accordance with the Boiling Water Resistance section of Guide D 2571): H, L

4.3 Alcohol:

4.3.1 *Ethyl Alcohol* (test in accordance with the Alcohol Resistance section of Guide D 2571): V, H, L

4.4 Aliphatic:

4.4.1 *Mineral Spirits*: L (Specification D 235, Type III)

4.4.2 *Perchloroethylene*: V, H, L

4.5 Ketone:

4.5.1 *Methyl Ethyl Ketone*: L

4.6 Acetate:

4.6.1 *Amyl Acetate*: H, L

4.7 Inorganic Acid:

4.7.1 *Hydrochloric Acid (3 N)*—Dilute 258 mL of 12 N (36 %) HCl to 1 L: L

4.8 Organic Acid:

4.8.1 *Acetic Acid (3 N)*—Dilute 172 mL of 99 % acetic acid to 1 L: V, H, L

4.8.2 *Grape Juice* (unsweetened): V, H

4.8.3 *Lactic Acid (5 % solution)*: V, H

4.9 Bases:

4.9.1 *Unscented Mild Soap* (saturated solution): V, H, L

4.9.2 *Potassium Tripolyphosphate* (saturated solution containing 0.5 % sodium *N*-methyl-*N*-oleyl laurate (Igepon T-73): V, H, L

4.9.3 *Ammonium Hydroxide (3 % solution)*: L

4.9.4 *Trisodium Phosphate* (saturated solution): V, H, L

4.9.5 *Urea (6.6 % solution)*: V, H, L

4.10 Disinfectant:

4.10.1 *Cresols (5 % solution)*: V, H, L

4.11 Ink:

4.11.1 *Washable Ink*: V, H, L

4.11.2 *Permanent Ink*: V, H, L

4.11.3 *Ball-Point Ink*: V, H, L

4.12 Dye:

4.12.1 *Coffee* (test in accordance with the Coffee Stain Resistance section of Guide D 2571): V, H

4.13 Wax:

4.13.1 *Wax Crayons, Red, Blue, and Yellow*: V, H

4.13.2 *Lipstick* (test in accordance with the Cosmetic Stain section of Guide D 2571): V, H

4.14 Shoe Polish:

4.14.1 *Liquid Shoe Polish, tan*: V, H

4.15 Oil:

4.15.1 *Corn Oil or equivalent*: V, H

4.15.2 *Hair Oil*: V, H

4.16 Miscellaneous:

4.16.1 *Mustard*: V, H

4.16.2 *Tincture of Merthiolate (1+1000)*: V, H (see Section 5)

4.16.3 *Sodium Hypochlorite (6 % solution)*: V, H, L

4.16.4 *Tincture of Iodine*—Wet 50 g of potassium iodide (KI) with water, weigh into the wet KI 70 g of iodine, let stand 1 h to dissolve the iodine, and make up to 1 L with alcohol: V, H, L

³ *Annual Book of ASTM Standards*, Vol 06.01.

4.17 *Staining Solutions*, unless otherwise specified, are water solutions.

5. Selection of Staining Agents for Testing Stain Resistance of Coatings

5.1 The producer and the user shall select staining agents from the reagents in Section 4. Selection of staining agents should depend on end use, such as wall, ceiling, horizontal surface, or floor.

5.2 In the absence of agreement between the producer and the user, the suggested staining reagents for each intended use are indicated in Section 4 by V, H and L.

5.3 It is not necessary that all finishes pass all tests.

6. Test Specimen

6.1 Test panels shall be of regular production finish.

6.2 If regular production finished panels are not available, the producer and the user shall agree upon the following variables: face veneer or wood surface, filler or filler stain, primer coat, topcoat, and dry film thickness for each coating material.

7. Panel Conditioning

7.1 Before testing, panels must be aged for a time and by a method agreed upon between the producer and the user.

8. Procedure

8.1 Conduct the test with panel surfaces horizontal at room temperature unless a different temperature is specified.

8.2 Place 0.5 mL of each staining agent on the finish surface and allow to stand uncovered for 18 h (or a time agreeable to the producer and the user) except for staining agents 4.3 to 4.6. On these put a 1-in. (25-mm) square of double-acid-washed quantitative filter paper. The purpose of the filter paper is to maintain a longer wet contact of volatile reagents with the surface of the finish.

8.3 After 18 h exposure, or other time period agreed to by the producer and the user, wash the surface with water, rinse with ethanol (1+1) and dry with a paper towel. Place the panel in a vertical position with a diffuse light source and view (Note) from a distance of 2 to 3 ft (0.6 to 0.9 m). Examine the surface for graying, spotting, wrinkling, discoloration, or other film defects and report.

NOTE—This method of viewing panels gives the best correlation of staining damage between laboratories. However, the following information should be noted: (1) When viewing panels across the grain at a low angle that is being varied, many more stains will appear visible than would appear visible perpendicular to the surface. These additional stains are superficial stains only. (2) When viewing with and against the grain, there appears to be an even greater number of superficial stains than would appear when viewing perpendicular to the surface or across the grain.

9. Interpretation of Results

9.1 Each product finish differs greatly in stain resistance requirements. The key, in general, is that the resistance to staining must be adequate for that finish's end use when first used in place and throughout the expected life span of the specific product.

9.2 The end use choice of resistance to staining should be agreed upon between the producer and the user.

10. Precision

10.1 Agreement between laboratories by visual comparison varied according to how samples were viewed.

10.1.1 Stains viewed perpendicular with a diffused light source at a distance of 2 to 3 ft (0.6 to 0.9 m) for graying, spotting, wrinkling, discoloration, or other film defects gave complete agreement between laboratories.

10.1.2 The same test stains viewed both with and across the grain at a low angle resulted in many more superficial stains being evident, depending upon the eyesight and judgment of the observer.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Guide for Testing Exterior Latex House Paints¹

This standard is issued under the fixed designation D 3129; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide covers the selection and use of procedures for testing exterior latex house paints and trim paints in the laboratory and in the field. The test methods included are listed in Tables 1 and 2. All of these may not be required for each paint. Selection of the test methods to be followed must be governed by experience and the requirements in each individual case, together with agreement between purchaser and seller.

1.2 This guide covers the testing of a ready-mixed latex house or trim paint for application by brush, roller, or spray on exterior surfaces.

1.3 *This standard does not purport to address the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

4. Conditions Affecting House Paint Topcoats

4.1 Practical requirements and performance of latex house paint may vary with:

4.1.1 Substrate type, such as type and quality of wood or hardboard, grain of wood, knots, pitch, etc., type and quality of masonry, ratio of cement to aggregate, alkalinity, etc.

4.1.2 Substrate weathering. Weathering of wood before painting will probably adversely affect the performance. Some weathering of masonry surfaces before painting may have beneficial effects on the performance.

4.1.3 The type, quality, and suitability of primer, undercoat, conditioner, etc., used under the topcoat and the time between coats.

4.1.4 Environmental conditions such as temperature at the time of application and during drying. As these paints contain water as a thinner, surfaces do not have to be completely dry before application. However, low temperature during drying may cause poor film formation.

4.1.5 Contaminants on the surface of the substrates.

4.1.6 Condition of previously painted substrates such as degree of chalk, adhesion of film, dirt, mold, general condition of substrate paint.

5. Sampling

5.1 Prior to sampling, the condition of the container should be established since damage to it may cause evaporation, skinning, or other undesirable effects in the coating. Determine the condition of the paint in accordance with 6.1 and 6.2.

5.2 Sample in accordance with Practice D 3925. Determine the weight per gallon in accordance with Test Method D 1475. Repeat this procedure until successive values agree within 0.1 lb (45 g) or as agreed upon between the purchaser and the seller. Samples for testing may then be taken.

5.3 Specify the amount of sample, the package sizes, and identification codes to assure a representative sample. A 1-gal (4-L) sample is usually sufficient for the recommended tests, but for guidance in selecting a sampling plan, consult Practice E 105.

6. Liquid Paint Properties

6.1 *Condition in Container*—Thickening, settling, and separation are undesirable and objectionable if a paint cannot be reconditioned and made suitable for application with a reasonable amount of stirring. The referenced method covers procedures for determining changes in properties of paints after storage. Determine the condition in the container in accordance with Method 3011 of Federal Test Method Standard No. 141.

6.2 *Coarse Particles and Foreign Matter*—Paints must be free of coarse particles to form uniform films of good appearance, a typical maximum being 1 weight % of total paint. The specified test with a No. 325 (45- μ m) sieve gives the percent of these particles in a paint. Determine coarse particles and foreign matter in accordance with Test Method D 185.

6.3 *Density or Weight per Gallon*—The density as measured by weight in pounds per gallon or kilograms per litre is used to assure product uniformity from batch to batch. In the referenced method the density is expressed as the weight in pounds of 1 U.S. gal (kg/L) of the paint at a specified

temperature. Determine the density in accordance with Test Method D 1475.

6.4 *Nonvolatile*—The amount of nonvolatile in a coating is not necessarily an indication of performance. It is, however, useful for determining similarity of two samples. Determine nonvolatile solids in accordance with Test Method D 2369.

6.5 *Fineness of Dispersion*—The more finely a pigment is dispersed, the more efficiently it is being used. One method for measuring the degree of dispersion (commonly referred to as "fineness of grind") is to draw the material down a calibrated, tapered groove in a hardened steel block with the groove varying in depth from 4 to 0 mils (100 to 0 μ m) and calibrated Hegman 0–8. The point at which continuous groupings of particles or agglomerates, or both, are visible through the surface of the liquid is taken as the fineness reading. Lower readings in mils or micrometres or higher readings in Hegman units indicate better fineness of dispersion. Determine fineness of dispersion in accordance with Test Method D 1210.

NOTE—The fast drying of latex paints makes it difficult to make accurate measurements of this type. Low-gloss paints do not generally require dispersion finer than a 1 to 2 Hegman reading.

6.6 *pH*—Latex paints with low (acidic) pH may corrode the container. Changes in pH during storage may indicate poor stability of a latex paint. Determine pH in accordance with Test Method E 70.

6.7 *Consistency*—Paints of a given type should fall within a stated consistency range for satisfactory reproduction of a specific formula. In the referenced method, consistency is defined as the load in grams required to produce a specified rate of shear. Although the consistency of most latex paints is about 150 to 300 g/100 revolutions, a much wider range is possible because of the wide variations in rheological properties of these paints. Also two paints of the same consistency may have quite different rheological properties. Determine the consistency of the product in accordance with Test Method D 562.

6.8 *Rheological Properties of Non-Newtonian Liquids*—Rheological properties are related to application and leveling properties of the liquid paint. The referenced methods cover the determination of rheological properties and are particularly suited for use with paints that display thixotropic characteristics. They actually measure viscosity under different shear rates. Determine rheological properties in accordance with Test Methods D 2196 or D 4287, or both.

6.9 *Freeze-Thaw Stability*—Water-based paints may be subjected to freezing conditions during shipping and storage. Suitably stabilized paints will resist several cycles of freezing and thawing without showing deleterious changes such as coagulation, graininess, or excessive viscosity increase. Many latex paints will increase in viscosity but can still be considered satisfactory if other properties which may be affected by a higher viscosity such as leveling and brushability are satisfactory. Determine the extent of change in several properties in accordance with Test Method D 2243.

6.10 *Microorganism Resistance*—Bacteria in a latex paint can cause gassing, putrefactive or fermentative odors, and loss of viscosity. Determine if the paint contains living

bacteria and if it is resistant to attack by bacteria in accordance with Test Method D 2574.

7. Paint Application and Film Formation

7.1 Drying Properties—Under average conditions most flat latex paints are dry-to-touch in 1 to 2 h when the water has evaporated from the film. Slow drying of the film may result in dust pickup, poor appearance and, when used on an exterior surface, rain or dew may cause a nonuniform appearance. They can usually be recoated from within a few hours to 18 h. Curing to obtain the ultimate properties may take only a few days for some latex paints, while others may require 1 to 2 weeks depending on composition. Determine drying time in accordance with Test Methods D 1640.

7.2 Producing Films of Uniform Thickness—Methods D 823 covers the preparation of coating films of uniform thickness essential in conducting tests.

7.3 Application Properties—Application properties of a paint are generally compared to a standard or described by requirements in the product specification. Determine application properties in accordance with Method 4541 of U.S. Federal Standard No. 141.

7.3.1 Brush Application—For proper method of application of a brushed film for test purposes refer to Method 2141 of U.S. Federal Test Method Standard No. 141.

7.3.2 Spray Application—House and trim paints are sometimes applied by spray. Determine the spray application properties in accordance with Method 2131 of U.S. Federal Test Method Standard No. 141.

7.4 Touch-Up Uniformity—After a paint has dried, areas where less material was applied sometimes become noticeable. If the paint has suitable touch-up properties, additional material can be applied to these areas only, instead of refinishing the complete wall. The color, gloss, and leveling of the touched-up areas and the previously coated area should be uniform. Differences in these properties are often caused by short wet-edge time, poor leveling on recoat, and pigment orientation or flotation during and after application. Determine touch-up properties in accordance with Test Method D 3928.

8. Appearance of Dry Paint Film

8.1 Color Differences by Visual Comparison—Visual comparison of color is fast and often acceptable although numerical values are not obtained. The referenced method covers the spectral, photometric, and geometric characteristics of light source, illuminating and viewing conditions, sizes of specimens, and general procedures to be used in the visual evaluation of color differences of opaque materials. Determine color difference in accordance with Practice D 1729.

8.2 Color Differences Using Instrumental Measurements—The differences in color between a product and its standard can be measured by instrument. Generally, the tolerance is agreed upon by the purchaser and the seller and may also be required if a product specification is involved. Color instruments provide numerical values that can be compared to subsequent measurements. The referenced method covers the instrumental determination of small color differences, observable in daylight illumination, between nonfluorescent, nonmetameric, opaque surfaces such as paint specimens. If metamerism is suspected, visual evalua-

tion (8.1) should be used to verify the results. Calculate in accordance with Test Method D 2244 the color differences that have been measured instrumentally.

8.3 Directional Reflectance—This property is a measure of the appearance of lightness of a coating. It is usually assigned a value in specifications for white and pastel shades, a typical minimum reflectance being 86 % for white wall paint. In the referenced method, the direction of illumination and viewing is specified so as to eliminate the effect of gloss. Determine daylight directional reflectance in accordance with Test Method E 97.

8.4 Gloss 60°—Gloss level can affect dirt pickup and washability. Exterior latex house paints and trim paints may vary in gloss. A typical range would be from 5 to 60 units. Determine the specular gloss in accordance with Test Method D 523.

8.5 Hiding Power (Dry Opacity)—Hiding power is the measure of the ability of a paint to hide the substrate. It is, however, dependent upon uniform film thickness which is influenced by flow and leveling. Test Method D 344 is a practical test in which paint is applied with a brush, film thickness is approximately measured, opacity is evaluated visually as compared to a standard paint, and results are affected by flow and leveling application properties of the paint. Test Method D 2805 is considered to be a more precise and accurate test that does not need a material paint standard. Paint is applied with an applicator bar to minimize the effects of flow and leveling, film thickness is rigorously measured, and opacity is instrumentally evaluated. Determine hiding power in accordance with Test Method D 344 or D 2805.

9. Properties of Dry Paint Film

9.1 Flexibility—Elongation is a measure of flexibility of a paint film. Generally house paints will have no problem in passing a mandrel bend test. Most latex paints can be bent over a 1/4-in. (6.4-mm) mandrel without affecting the film. Determine elongation in accordance with Test Method D 522.

9.2 Moisture Blister Resistance—Moisture blister resistance is a necessary property of a house and trim paint. It can be evaluated by an accelerated laboratory test. Determine resistance to moisture blistering in accordance with Practice D 4585.

9.3 Fume Resistance—Fume resistance is the ability of a dry paint film to resist discoloration in a moist hydrogen sulfide atmosphere. This type of atmosphere may be present near industrial areas and can cause paint to yellow or darken in as little time as overnight exposure. There are no applicable ASTM or Federal test methods for fume resistance, but one method used in industry is as follows:

9.3.1 Apply a sufficient number of coats of the paint to two glass plates to hide the surface completely, allow to dry for 6 h, and expose one of the plates in a moist atmosphere of hydrogen sulfide for 18 h. Compare the color with the unexposed plate. The exposed plate should be no darker than the unexposed one.

9.4 Exterior Exposure Resistance—In conducting exterior exposures, refer to Practice D 1006.

9.4.1 Wood Panel Description—In establishing exposure

perform
D 358.

performance, use the panels described in Specification D 358.

9.4.2 *Degree of Chalking*—Determine the rating using Test Method D 4214.

9.4.3 *Degree of Checking*—Determine the rating using Test Method D 660.

9.4.4 *Degree of Cracking*—Determine the rating using Test Method D 661.

9.4.5 *Erosion Resistance*—Determine the rating using Test Method D 662.

9.4.6 *Flaking Resistance*—Determine the rating using Test Method D 772.

9.4.7 *Mildew Resistance*—All exterior latex paints are subject to microbiological discoloration that will occur on the surface of the coating over a period of time. This is especially true in warm, moist climates. Determine mildew resistance using Practice D 3456.

9.4.8 *Stain Resistance*—There is neither an ASTM nor a Federal test method available for evaluating stain resistance of exterior latex paints. There are, of course, different kinds of stain such as the water-soluble extractives in wood substrates, the formation of lead or mercury sulfides, and run-down from metal surfaces of oxides that stain. Different kinds of test methods are required for the various stains.

9.4.9 *Efflorescence Resistance*—Exterior latex paints can contain sufficient solid water-soluble material to cause a noticeable deposit on the film through leaching by water and subsequent evaporation. Determine the tendency of the paint to effloresce in accordance with Test Method D 1736.

9.4.10 *Fade Resistance*—Exterior latex paints usually have good color retention because of their good chalk resistance. However, the use of improper latex, pigment volume concentration, or pigments can lead to fading. There are no applicable ASTM or Federal test methods for fade resistance. One method on the evaluation of chalk-fade has been published in the literature.⁹

9.4.11 *Dirt Pickup*—Low-gloss exterior latex paints generally have good resistance to dirt pickup. Gloss or semigloss latex paints may be more subject to this type of disfigurement. Exterior exposure particularly under an overhang will

⁹ Daiger, W. H., and Madson, W. H., "Chalk-Fade Evaluation of Pigmented Finishes by Use of Instrumentation and Computer Analysis," *Journal of Paint Technology*, Vol 39, No. 510, 1967, p. 399.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

indicate a paint's tendency for this property in a relatively short time (about 1 year). Determine degree of dirt collection in accordance with Test Method D 3719.

9.4.12 *Adhesion to Chalky Surfaces*—Latex paints generally have little ability to penetrate porous substrates. Therefore they do not adhere well to chalky substrates unless they are modified with some liquid that does penetrate and can bind a layer of chalk. (However certain latices do exist that are designed to adhere well to chalky surfaces. These could be considered without the need for a modifying liquid.) There are no directly applicable ASTM or Federal test methods for adhesion to chalky substrates. The industry generally uses a pressure-sensitive tape for testing this property. The tape is pressed firmly onto the dried latex film (fresh dry films do not adhere as well as aged dry films) and then removed rapidly by pulling back upon itself. Method 6301 of U.S. Federal Test Method Standard No. 141 describes a similar method but includes water exposure.

9.4.13 *Wet Adhesion*—Determine the wet adhesion of exterior latex paints in accordance with Method 6301 of U.S. Federal Standard Test Method No. 141.

10. Analysis of Paint

10.1 *Chemical Analysis*—If a specification requires certain raw materials or certain components in a given amount, then chemical analysis is required to determine whether the specified materials are present, and in what amounts. Analysis does not necessarily establish paint quality that can be also greatly affected by manufacturing techniques. Most ASTM analytical methods apply to solvent-reducible coatings. However, some of these can be adapted for analysis of water-reducible paints.

10.2 *Volatile Content*—The percent of volatile matter indicates the thinner loss from the film as it dries. This quantity subtracted from 100 % gives the nonvolatile content. Determine the volatile content in accordance with Test Method D 2369.

10.3 *Pigment Analysis*—The analysis of pigment may be required if the product is covered by a specification, or if it is agreed between the purchaser and the seller. Analyze the pigment in accordance with selected test procedures from Methods D 215.

Standard Test Method for Quantitative Determination of Cellulose Nitrate in Alkyd Lacquers by Infrared Spectrophotometry¹

This standard is issued under the fixed designation D 3133; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Editorial changes were made throughout in March 1989.

1. Scope

1.1 This test method covers the quantitative determination of the content of cellulose nitrate (also known as nitrocellulose) in lacquers containing alkyd resins.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For a specific hazard statement, see Note 1.*

2. Referenced Documents

2.1 ASTM Standards:

- D 1644 Test Methods for Nonvolatile Content of Varnishes²
- D 2372 Method of Separation of Vehicle from Solvent-Reducible Paints²
- E 168 Practices for General Techniques of Infrared Quantitative Analysis³
- E 275 Practice for Describing and Measuring Performance of Ultraviolet, Visible, and Near Infrared Spectrophotometers³

3. Summary of Test Method

3.1 The method of standard additions is employed. Increments of cellulose nitrate, in solution, are added to aliquots of the sample. Absorbance measurements are made of the band at 848 cm^{-1} ($11.8\text{ }\mu\text{m}$) for each addition. The original content is then calculated from absorbance versus concentration.

4. Significance and Use

4.1 Coating compositions based on a mixture of synthetic resins and cellulose nitrate dissolved in organic solvents are quantitatively analyzed for the cellulosic derivative without isolating it. The test method is applicable to lacquers for which the grade of nitrocellulose is known and available. Other cellulose, alkyd resins, many vinyl resins, and solvents do not interfere. Components, such as acrylic resins

and some vinyl polymers, that absorb infrared near 848 cm^{-1} ($11.8\text{ }\mu\text{m}$) interfere with the determination. High boiling ester solvents, in particular methyl cellosolve acetate, may also interfere with the determination if not removed in the evaporation procedure (see 8.3).

5. Apparatus

5.1 *Infrared Spectrophotometer*, automatic recording, double-beam. Most infrared spectrophotometers operate from 4000 to 650 cm^{-1} (2.5 to $15\text{ }\mu\text{m}$), but in this test method only the range between 1000 and 750 cm^{-1} (10 to $14\text{ }\mu\text{m}$) is used. See Practices E 168.

5.2 *Absorption Cells*, sealed, with sodium chloride (NaCl) windows, 0.1-mm path length, one pair approximately matched.

5.3 *Film Vacuum Evaporator*, rotary thin or equivalent apparatus, to obtain redissolvable lacquer solids without decomposition of the cellulose nitrate.

5.4 *Oven*, vacuum drying, thermostatically controlled to operate at $65 \pm 2^\circ\text{C}$.

6. Reagents

6.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁴ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

6.2 *Cellulose Nitrate*, of the same grade as in the sample.

6.3 *N,N-Dimethylacetamide (DMA)*, spectrograde quality.

6.4 *Nitrogen Gas*, dry.

7. Standard Solution

7.1 Thoroughly dry a quantity of cellulose nitrate at 65°C , in the vacuum oven (Note 1). Transfer 4000 g , weighed to 0.1 mg , to a 200-mL volumetric flask. Add DMA, shake to dissolve the cellulose nitrate, and dilute to volume with DMA. One millilitre of solution is equivalent to 20 mg of

¹ This method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.55 on Factory-Applied Coatings on Preformed Products.

cellulose nitrate.

NOTE 1: Warning—Every precaution must be exercised in the handling and drying of cellulose nitrate because of its explosive nature. No more than 15 g should be dried at any one time.

8. Procedure

8.1 If the material is pigmented, remove the pigment quantitatively in accordance with Method D 2372, and proceed with the determination on the vehicle.

8.2 Determine the nonvolatile content of the clear lacquer, on the vehicle, in accordance with Test Methods D 1644.

8.3 Transfer, by any convenient means, 10.000 g of unpigmented material to a 50-mL volumetric flask. Attach the flask to the rotary evaporator and evaporate off the bulk of the solvents. Detach the flask, dissolve the lacquer solids in DMA, and dilute to volume with DMA. If the presence of methyl cellosolve acetate is suspected in the solvents, care must be taken to evaporate off the solvents as completely as possible.

8.4 Pipet 10.0 mL aliquots of this solution into each of three 25-mL volumetric flasks. To each, in turn, add 0, 5.0, and 10.0 mL of the standard solution. Dilute to volume with DMA.

8.5 Infrared Analysis:

8.5.1 Schedule the operating parameters of the infrared spectrometer to attain highly accurate absorbance values (refer to the directions of the manufacturer of the instrument). To accomplish this, set for lengthier scanning time and high signal-to-noise ratio, in accordance with Practice E 275.

8.5.2 Place one cell, containing DMA, in the reference beam. Place the other cell, filled in turn, with each of the solutions (Note 2), in the sample beam. Record the spectrum between 1000 and 750 cm^{-1} (10 and 14 μm) three times for each solution. Rinse the cell with DMA, and purge with dry nitrogen gas after each solution has been examined.

NOTE 2—To facilitate the transfer of the solutions to the cell, a small glass syringe fitted with a 3-in. (75-mm) hypodermic needle may be used.

8.5.3 Measure the difference in absorbance, ΔA , between

FIG. 1 Plot of ΔA versus Cellulose Nitrate Additions

the maximum absorbance at 848 cm^{-1} (11.8 μm) and the minimum at 813 cm^{-1} (12.3 μm). Determine the mean ΔA for the three runs on each solution.

9. Calculation

9.1 Plot the absorbance difference, ΔA , versus the cellulose nitrate additions and extrapolate the curve to zero absorbance. The intersection of the curve with the abscissa (concentration axis) gives the original cellulose nitrate content in the diluted sample. See Fig. 1.

9.2 *Alternative Method*—Solve for C in the three simultaneous equations derived from the expression for the Beer-Bourguier law, $A = abc$

$$\Delta A_0/(C + 0.0) = \Delta A_{0.1}/(C + 0.1) = \Delta A_{0.2}/(C + 0.2)$$

where:

C = original concentration of cellulose nitrate, in grams per 25 mL and the subscripts for ΔA correspond to the amounts of cellulose nitrate added in grams per 25 mL. Calculate the mean of C .

9.3 Calculate the weight percent of cellulose nitrate E in the original lacquer as follows:

$$E = (C \times D \times 100)/S$$

where:

D = dilution factor,

S = weight of specimen, and

C = grams of cellulose nitrate in 25 mL.

9.4 Calculate weight percent cellulose nitrate E in nonvolatile portion of original lacquer as follows:

$$E = (C \times 5 \times 100 \times 100)/(S \times N)$$

where:

N = nonvolatile content (see 8.2).

10. Precision

10.1 On the basis of a study in which four laboratories analyzed two different samples for percent of cellulose nitrate relative to the total samples, T , and relative to the nonvolatile matter, NVM , the within and between laboratory standard deviations were found to be:

Percent Relative to	Standard Deviations	
	Within	Between
T	0.14	0.12
NVM	0.39	0.64

Based on these standard deviations the following criteria should be used in judging the acceptability of results at the 95 % confidence level.

10.1.1 *Repeatability*—Two results obtained by one operator on one instrument should be considered suspect if they differ by more than the following:

Relative to	Percent
T	0.48
NVM	1.34

10.1.2 *Reproducibility*—Two results obtained by operators in different laboratories should be considered suspect if they differ by more than the following:

Relative to	Percent
T	0.71
NVM	2.51

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Standard Practice for Qualitative Identification of Polymers in Emulsion Paints¹

This standard is issued under the fixed designation D 3168; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{ε1} NOTE—Sections 6 to 10 were renumbered and Section 11 was added editorially in May 1990.

1. Scope

1.1 This practice describes a procedure for the qualitative identification in emulsion paints of most types of polymers present as major components of the paint vehicle. Limitations are discussed in Sections 5 and 10.

1.2 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D16 Terminology Relating to Paint, Varnish, Lacquer, and Related Products²

D1193 Specification for Reagent Water³

D2621 Test Method for Infrared Identification of Vehicle Solids from Solvent-Reducible Paints²

E 275 Practice for Describing and Measuring Performance of Ultraviolet, Visible, and Near Infrared Spectrophotometers⁴

3. Terminology

3.1 *Definitions*—For definitions of terms, refer to Definitions D 16.

4. Summary of Practice

4.1 The vehicle is extracted from the dried paint and after filtering is cast on a salt plate. The infrared spectrum is obtained and compared with reference spectra for identification of major components.

4.2 The paint is applied to a filament and pyrolyzed to depolymerize the vehicle. An internal standard is added and the pyrolyzate is separated into its components by gas-liquid chromatography. Monomers are identified by comparison of relative retention times.

5. Significance and Use

5.1 Identification of specific acrylic polymers in emulsion paints is often difficult or impossible by infrared alone. This

is particularly true when the acrylic is present in a small amount as a comonomer with vinyl acetate, or when blended with alkyds or other ester systems. If identification of an acrylic component is required in such a system, it may often be accomplished by gas-liquid chromatographic analysis of the pyrolyzed paint film. The presence of a number of other polymers may often also be confirmed by pyrolysis since they produce characteristic and reproducible pyrograms.

5.2 The pyrograms obtained from unknown samples vary in complexity according to the sample composition. It is necessary to establish the presence or absence of as many components as possible from a study of the infrared spectra obtained in the first part of this practice. The gas-liquid chromatography results may then be used to help identify any unknown components present and to confirm identifications made by infrared.

6. Interferences

6.1 Dibutyl maleate and dibutyl fumarate monomers are not successfully recovered by this procedure. If their presence is suspected as comonomer in a vinyl acetate copolymer system, *n*-butyl alcohol should be found in the pyrolyzate. This evidence, together with the absence of butyl acrylate or butyl methacrylate monomer peaks, is an indirect indication of the presence of one or both of these monomers.

6.2 The presence of relatively low quantities of copolymerized acids may not be successfully established by this procedure, due to some unavoidable decomposition of acrylate and methacrylate esters to acrylic or methacrylic acid and the corresponding alcohols during the pyrolysis. The infrared spectrum and an acid number determination, both run on the polymer solids, may usually be relied upon to establish the presence or absence of acid groups in the polymer.

6.3 In the case where the polymer being analyzed is simple (such as a vinyl acetate-alkyl ester copolymer, or a single acrylate-methacrylate copolymer), it might be advantageous to examine the total pyrolyzate directly by infrared (as a solution in carbon disulfide).

7. Apparatus

7.1 *Spectrophotometer*, recording, double-beam, infrared, with a range from at least 2.5 μm to 15 μm and a spectral resolution of at least 0.04 μm over that range. For checking the performance of the infrared spectrophotometer, see Practice E 275.

7.2 *Cell Mount*, demountable.

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Materials.

Current edition approved Oct. 25, 1985. Published December 1985. Originally published as D 3168 - 73. Last previous edition D 3168 - 73 (1979)^{ε1}.

² Annual Book of ASTM Standards, Vol 06.01.

³ Annual Book of ASTM Standards, Vols 06.03 and 11.01.

⁴ Annual Book of ASTM Standards, Vol 14.01.

7.3 *Halide Salt Crystals*, for use with demountable cell mount.

7.4 *Oven*, gravity or forced-draft, maintained at $105 \pm 2^\circ\text{C}$.

7.5 *Linear Programmed Temperature Gas Chromatograph*, equipped with a thermal conductivity detector.

7.6 *Pyrolysis Accessory*—Any suitable apparatus for achieving pyrolysis external to the chromatograph, that results in the recovery of sufficient pyrolyzate for identification purposes. The apparatus described in the Annex has been found to meet these requirements.

7.7 *Gas Chromatographic Column*, 10 ft (3 m) in length, $\frac{1}{4}$ in. (6.4 mm) in outside diameter copper tubing packed with 10 % silicone resin⁵ on 80 to 100-mesh acid-washed, dimethyl-dichlorosilane treated calcined diatomaceous earth.⁶

7.8 *Steam Bath or Low-Temperature Hot Plate*.

7.9 *Flask*, small Dewar.

8. Reagents

8.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁷ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

8.2 *Purity of Water*—Unless otherwise indicated, reference to water shall be understood to mean reagent water conforming to Type II of Specification D 1193.

8.3 *Extraction Solvent Mixture*—Equal volumes of *o*-dichlorobenzene, dimethylformamide, and tetrahydrofuran.

8.4 *Liquid Nitrogen*.

8.5 *Petroleum Ether* (30 to 60°C boiling range) or heptane.

9. Procedure—Infrared Analysis

9.1 Transfer 1 to 2 g of emulsion paint to a 100-mL borosilicate glass beaker. Add approximately 2 mL of water and swirl or use a clean glass rod to spread the paint uniformly over the bottom of the beaker.

9.2 Place the beaker in an oven at $105 \pm 2^\circ\text{C}$ for at least 2 h, breaking up any skins that form so that complete drying is ensured.

9.3 Add 50 mL of water, cover with a watchglass, and place on a steam bath or low-temperature hotplate for 1 h. This process removes emulsifiers, protective colloids, and other water-soluble components that might interfere with interpretation of the infrared spectrum. Decant off the clear water layer and discard. If the addition of the distilled water

to the dried paint film produces a milky dispersion, the drying step in 9.2 was not complete and should be repeated.

NOTE 1—If there is an interest in characterization of the emulsifier system used, the water should be filtered through a fine-texture filter paper and taken to dryness. The solids may then be examined by infrared.

9.4 Dry for 15 to 20 min in an oven at $105 \pm 2^\circ\text{C}$. Add 50 mL of petroleum ether or heptane, cover with a watchglass, and bring to a slow boil for approximately 5 min. This process removes most emulsified plasticizers, oils, and other water insoluble, nonpolymeric organic materials, which might also interfere with the interpretation of the infrared spectrum. Decant off the solvent and discard.

NOTE 2—If there is an interest in characterizing the water-insoluble petroleum ether-soluble fraction, it should also be filtered through fine-texture paper, taken to dryness, and examined by infrared.

9.5 Add 10 mL of the extraction solvent mixture (8.3) and place on a steam bath or low-temperature hotplate for approximately 1 h. Filter, while still hot, through a fine-texture filter paper. If the polymer solution is viscous, it may be diluted further with extraction solvent mixture and warmed prior to filtration. Alternatively, the pigment may be removed from the polymer solution by centrifuging. Evaporate the solution on the steam bath or hotplate to a volume of 1 mL or less.

9.6 Place the concentrated polymer solution on a halide salt crystal and spread to form a uniform film. The thickness of the film should be such that when the infrared spectrum is recorded, the transmittance of the strongest band falls between 5 and 15 %. Dry the film in an oven at $105 \pm 2^\circ\text{C}$ for 1 h and cool in a desiccator.

9.7 Record the infrared spectrum from 2.5 to $15 \mu\text{m}$ so that a spectral resolution of $0.04 \mu\text{m}$ is maintained throughout that range. (Methods for achieving this resolution will vary according to the directions of the manufacturer of the instrument used.)

9.8 Compare the spectrum obtained with reference spectra prepared in a similar manner from emulsion paints of known composition or with published collections of polymer spectra such as Test Method D 2621. Other sources are listed in the references (1 to 7).⁸

10. Procedure—Pyrolysis-Gas Liquid Chromatography

10.1 Coat the resistance wire filament of the pyrolysis unit by dipping it into the original paint sample to be tested. Remove the volatiles either by drying the filament in an oven for about 30 min at $105 \pm 2^\circ\text{C}$ or by heating it electrically with the power supply set at 1 or 2 A (100 to 200°C) for approximately 10 min. If a larger volume of pyrolyzate is required than would be produced by the initial amount of sample deposited, additional layers of coating may be added by repeating the dipping and drying steps.

10.2 Place the coated filament-vial cap assembly in a small beaker. Extract with water, followed by petroleum ether or heptane, as outlined in 9.3 and 9.4.

10.3 Add a few drops of liquid nitrogen to the vial or flush with nitrogen gas to prevent oxidation reactions from

⁵ Silicone resin SE-30 produced by General Electric Co., has been found satisfactory for this purpose.

⁶ Chromosorb W, manufactured by Manville Sales Corp., Filtration and Minerals, P.O. Box 5108, Denver, CO 80217-5108, has been found satisfactory for this purpose.

⁷ "Reagent Chemicals, American Chemical Society Specifications," Am. Chemical Soc., Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY, and the "United States Pharmacopeia."

⁸ The boldface numbers in parentheses refer to the list of references at the end of this practice.

occurring during the pyrolysis.

NOTE 3—If the infrared spectrum obtained in 9.8 shows poly(vinyl acetate) or poly(vinyl chloride) to be present, the pyrolysis step should be modified to prevent the acetic or hydrochloric acid formed from degrading other monomers that may be present in the pyrolyzate. Addition of a drop of concentrated ammonium hydroxide to the vial just prior to pyrolysis, neutralizes the acid as it is formed. The pyrolyzate may then be recovered by dissolving in diethyl ether just before sampling.

10.4 Tightly screw the coated filament-cap assembly onto the glass vial and connect the filament leads to the power supply.

10.5 Submerge the entire vial in liquid nitrogen contained in a small Dewar flask. Allow to equilibrate for several minutes, then apply a predetermined current for approximately 10 to 15 min.

NOTE 4—The optimum temperature which varies for different polymer types may be determined experimentally from known polymer systems. Six amperes (approximately 600°C) has been found to be close to optimum for the types tested. A study of the pyrolysis of acrylic polymers showed that heating times varying from 10 to 30 min produced no significant differences in the composition of the pyrolyzate.

10.6 Turn off the power supply and allow the filament to cool for several minutes. Remove the vial from the liquid nitrogen and substitute a standard screw cap for the filament-cap.

10.7 Using a syringe, add *n*-butyl acetate to the pyrolyzate equal to approximately 20% of the pyrolyzate volume.

10.8 Install the silicone resin column in the chromatograph and allow it to condition to 200°C. Set up the following conditions on the chromatograph:

Temperatures, °C	
Injection port	270
Detector block	270
Column (programmed):	
Initial	70
Final	200
ΔT, °C/min	6
Carrier gas:	
Flow rate, mL/min	helium
Detector current, mA	60
	150

10.9 Inject 5 μL of pyrolyzate into the chromatograph, engage the chart drive, and start the temperature programmer. Attenuate as necessary during the run.

NOTE 5—The use of the method described minimizes the tendency of pyrolysis products to undergo secondary reactions while still in the vapor state. This simplifies the chromatograms obtained, making interpretation easier.

TABLE 1 Relative Retention Times^a

Monomer or Alcohol	Relative Retention
Methanol	0.13
Ethanol	0.16
Acrylonitrile	0.25
Vinyl acetate	0.37
Methyl acrylate	0.45
Isobutanol	0.48
<i>n</i> -Butanol	0.57
Ethyl acrylate	0.66
Methyl methacrylate	0.72
Ethyl methacrylate	0.93
<i>n</i> -Butyl acetate	1.00
Isobutyl acrylate	1.15
<i>n</i> -Butyl acrylate	1.29
Styrene	1.33
Hydroxyethyl acrylate	1.38
Isobutyl methacrylate	1.43
Butyl methacrylate	1.55
Vinyl toluene	1.64
2-Hydroxyethyl methacrylate	1.64
2-Ethylhexanol	1.72
2-Ethylhexyl acrylate	2.31
2-Ethylhexyl methacrylate	2.56

^a Relative retention times listed are meant to serve as a guide for identification purposes. It should be understood, however, that the numbers listed are not absolute, and will vary somewhat from laboratory to laboratory and from instrument to instrument. For maximum accuracy in making identifications from retention time data, each analyst should prepare his own table by running the monomers of interest under the same conditions used for the analysis of the pyrolyzate.

10.10 Calculate retention times relative to the *n*-butyl acetate internal standard peak for each major peak obtained. Compare relative retention times obtained with known values for monomers of interest (see Table 1).

10.11 If any doubt remains concerning an identification based on the pyrogram obtained, it is recommended that the peak of interest be trapped as it is eluted from the chromatograph for subsequent positive identification by infrared spectroscopy or mass spectrometry.

10.12 Burn off any remaining organic residue by applying 8 or 9 A for a few seconds. Disconnect the filament from the power supply; then clean off any adhering pigment by gently brushing with a test tube brush while holding the filament under running water. The same filament may be reused many times.

11. Keywords

11.1 emulsion paints; gas chromatography; infrared analysis; paint vehicle; polymers; pyrolysis

ANNEX

(Mandatory Information)

A1. PYROLYSIS ACCESSORY

A1.1 Fig. A1.1 shows 12.5 in. (320 mm) of 20 gage Nichrome wire wound in a helix configuration. The characteristics of the filament have been chosen so that the current in amperes $\times 100$ closely approximates the temperature of the filament in degrees Celsius. Two 0.6-in. (15-mm) lengths of 0.05 in. (1.3 mm) outside diameter. Number 18 stainless steel hypodermic tubing is crimped onto the filament ends and inserted through snugly fitting holes drilled through the cap of a 1-dram (15 by 45-mm) vial (see drawing for detail). The hypodermic tubing, which functions as a heat sink to prevent pyrolysis of the plastic cap, may be firmly fastened to the cap by means of an epoxy cement.

A1.2 The tubing ends are connected by means of alligator clips to the leads of a suitable power supply.

FIG. A1.1 Pyrolysis Accessory

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Chipping Resistance of Coatings¹

This standard is issued under the fixed designation D 3170; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^e) indicates an editorial change since the last revision or reapproval.

This test method has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

^{e1} NOTE—Keywords were added editorially in March 1991.

1. Scope

1.1 This test method covers the determination of the resistance of coatings to chipping damage by stones or other flying objects.

NOTE 1—This test method is similar to SAE J-400.

1.2 This standard does not purport to address the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3. Summary of Test Method

3.1 Standardized road gravel is projected by means of a controlled air blast at the coated specimens. Generally the test conditions are made more severe by performing the test at low ambient temperatures. The resultant chipping effect is evaluated by comparison with a set of photographic standards that appear in the Pictorial Standards Coating Defects.

4. Significance and Use

4.1 Chipping of coatings, particularly on the leading faces and edges of automobile surfaces, is considered unacceptable by owners. In formulating a coating or coating system to meet service requirements, the resistance to chipping damage by flying objects such as gravel is one of the properties of importance since it can vary considerably as other properties are adjusted. Since resistance to chipping decreases at lower temperatures partly as the result of decreased flexibility, the test may be more directly related to service conditions by performing it at a low temperature. This test method is designed to produce a controlled amount of impact by the media on the coated panel in order to enhance reproducibility.

5. Apparatus

5.1 *Gravel-Projecting Machine*, constructed according to the design specifications shown in Fig. 1.⁶

5.2 *Gravel*—Water-eroded alluvial road gravel⁷ passing through a 3/8-in. (16-mm) space screen but retained on a 3/16-in. (9.5-mm) space screen. Note that mesh screen is not a substitute for a space-screen. It is important to remove the small pieces of gravel before reusing the gravel.

5.3 *Masking Tape*, 4 in. (100 mm) wide.⁸

5.4 *Temperature-Conditioning Equipment (alternatives):*

5.4.1 A cold room or freezer of sufficient size in which the gravel-projecting machine and test specimens can be maintained at the specified temperature of testing.

5.4.2 A freezer or cooler in which the test panels can be cooled 10°F (5°C) below the specified test temperature.

5.5 *Chipping Rating Standards*—A set of photographic standards depicting size and number of chips in each

⁶ A suitable apparatus meeting these specifications can be obtained from Q-Panel Co., 26200 First St., Westlake, OH 44135.

⁷ Gravel meeting these specifications can be obtained from Q-Panel Co., 26200 First St., Westlake, OH 44135.

⁸ No. 202-2 masking tape manufactured by the 3M Co., St. Paul MN 55101, has been found satisfactory for this purpose.

ISOMETRIC - COMPONENTS
SCALE 1"=1'-0"

category (see 2.3). The photographs in Fig. 2 are for illustration purposes only and should not be used for evaluation(s).

6. Test Specimens

6.1 The composition, surface preparation, and size of specimens shall be agreed upon between the purchaser and the seller. Test panels of 4 by 12 in. (102 by 305 mm) are most suitable for this test.

6.2 The number, type, method of application, and aging of coatings shall be agreed upon between the purchaser and the seller.

NOTE 2—Application, metal preparation, and film thickness measurement methods are given in the following ASTM methods: D 609, D 823, D 1005, D 1186, D 1400, D 1733, and D 2201.

7. Procedure

7.1 Condition the specimens for a minimum of 1 h at the specified test temperature in the equipment specified in 5.4. Make certain the test specimens are separated and have free access to the conditioning environment so that optimum heat transfer occurs.

7.2 Adjust the air pressure on the gravel apparatus to 70 ± 3 psi (480 ± 20 kPa) with the air valve open. Keep the lid to the gravel chamber on the apparatus closed during this operation as a safety precaution.

7.3 After adjusting the air pressure, shut off the air valve, open the lid to the gravel chamber and collect 1 pt (550 mL) of graded gravel (approx 250 to 300 stones) in a suitable container. Collect the gravel by scraping across the screen to allow fines to fall through.

7.4 Place the panel in the apparatus.

NOTE 3—the apparatus should be closed after the test begins.

7.5 After the apparatus is placed, place the panel in the apparatus.

7.6 After the gravel is collected, return the gravel to the chamber.

7.7 Shut the chamber, return to moisture level.

7.8 Cover the masking tape and pull off the tape.

FIG. 2 Reference Photographs (Illustration Purpose Only)

FIG. 2 Reference Photographs (Contd)

7.4 Place one test specimen at the desired test temperature in the panel holder with the coated side facing the front of the apparatus and close the lid to the gravel chamber.

NOTE 3—Due to space limitations, it may not be possible to operate the apparatus at the desired test temperature. In this event, the panels should be cooled below the desired test temperature by 10°F (5°C) and the test begun within 10 s of removal from the cooler.

7.5 *Automatic Gravel Feed*, with automatic feed apparatus, place one pt of the gravel in the vibrating hopper. Opening the air valve automatically feeds the gravel into the air stream over approximately a 10-s interval.

7.6 *Manual Gravel Feed*, with a manual feed, slowly pour the gravel into the funnel over approximately a 10-s interval.

7.7 Shut off the air valve, open the lid to the gravel chamber, and remove the tested panel. Allow the panel to return to room temperature and remove any condensed moisture by wiping dry with a cloth.

7.8 Cover the test panel with a 4-in. (100 mm) strip of masking tape. Press the tape down firmly by rubbing; then pull off slowly to remove any loose chips of paint.

7.9 Determine the degree of chipping by comparison with the photographic standards.

8. Report

8.1 Report the substrate composition, type and age of coating, test temperature, and chipping rating.

9. Precision

9.1 Since the rating scale consists of a combination letter and number, no standard deviation value is obtainable from the supporting test results. It is the judgment of those familiar with this test method that the following precision statements are representative:

9.1.1 *Repeatability*—Results of tests within a laboratory differing by more than one letter or number unit should be considered suspect.

9.1.2 *Reproducibility*—Results of tests between laboratories differing by more than two letters or number units should be considered suspect.

10. Keyword

10.1 chip resistance

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. Standard Test Method for Porosity of Paint Films¹

This standard is issued under the fixed designation D 3258; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{ε1}NOTE—Editorial changes were made throughout in May 1987.

1. Scope

1.1 This test method covers the determination of the porosity of a white or near white mineral spirits insoluble paint film to indicate the degree to which a subsequent coat will penetrate.

1.2 The texture of the film can affect cleanup that will influence the results of the test. A stain applied to a high-hiding paint will not lower the reflectance as much as the same stain applied to a low-hiding paint of equal porosity. These points must be considered in comparing different paints.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 ASTM Standard:

E 97 Test Method for Directional Reflectance Factor, 45-deg 0-deg, of Opaque Specimens by Broad-Band Filter Reflectometry²

3. Summary of Test Method

3.1 The test paint is applied to a nonporous surface, air dried, then measured for reflectance. A special colored penetrating medium is applied, the excess removed in a specified manner, and reflectance measured again. The difference between the two readings indicates the degree of porosity; the smaller the difference, the lower the porosity of the film and the greater its ability to resist penetration.

4. Apparatus and Materials

4.1 *Film Applicator*, 6 in. (150 mm) wide with a clearance of 12 mils (300 μ m).³

4.2 *Film Applicator*, 5½ in. (140 mm) wide with a

clearance of 10 mils (250 μ m).⁴

4.3 *Reflectometer*, meeting the requirements of Test Method E 97.

4.4 *Vacuum Drawdown Plate*.

4.5 *Camelhair Brush* (approximately ½ in. (13 mm) wide).

4.6 *Plastic Wash Bottle*, containing odorless mineral spirits (about 16 oz (500 mL)).

4.7 *Test Panel*—Smooth nonporous panel such as sealed white, cardboard chart, or white plastic sheet.

4.8 *Penetrating Medium*—A composition of pigment and dark-colored dye dispersed in organic liquid vehicle.⁵

4.9 *Filter Paper*.

5. Procedure

5.1 Place the test panel on the vacuum plate and apply the paint under test with the 12-mil (30- μ m) clearance drawdown blade. Remove the test panel from the vacuum plate and air dry 48 h under standard conditions of 73 $\pm$ 3.5°F (23 $\pm$ 2°C) and 50 $\pm$ 5 % relative humidity.

5.2 Determine the percent reflectance of the dry film using the green filter on the reflectometer. When making this reading, back up the panel with a flat rigid opaque object and mark the area on which the reading was made.

5.3 Place the panel containing the dry paint film on the vacuum plate. Using the 10-mil (25- μ m) clearance blade, apply the penetrating medium over the test paint, covering the area marked as above and drawing the applicator blade in the same direction as before.

5.4 After 5 min $\pm$ 15 s wash off excess penetrating medium. To do this, hold the panel vertically and remove the medium using the camelhair brush wet with odorless mineral spirits. Repeat the process until most of the excess is removed. Then continue to remove more of the excess by applying mineral spirits directly from the wash bottle to the area above the stain so that it flows across the stained area. Pause to observe the bead that forms at the bottom of the panel. If the bead is not clear, continue washing with mineral spirits until the bead is essentially clear. Test with filter paper to be sure no dye remains in the bead.

5.5 Hang the panel in a vertical position and air dry for 3 h. As before, read the percent reflectance over the same area

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.42 on Architectural Finishes.

Current edition approved Oct. 14, 1980. Published December 1980. Originally published as D 3258 - 73. Last previous edition D 3258 - 79.

porosity,

standard

Nomina
in Refl

of the panel with the same flat rigid opaque object behind the panel.

6. Report

6.1 Report the difference between the percent reflectance of the untested film and that of the penetrated film.

7. Precision

7.1 On the basis of an interlaboratory study of this test method in which one operator in each of ten laboratories tested paint films of two nominally different levels of porosity, the within-laboratory and between-laboratories standard deviations were found to be:

Nominal Difference in Reflectance, %	Standard Deviations	
	Within-Laboratory	Between-Laboratories
7	0.27	1.26
35	0.60	4.22

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Based on these standard deviations the following criteria should be used to judge the precision or results at the 95 % confidence level:

7.1.1 *Repeatability*—Duplicate results, obtained by a single operator, should be considered suspect if they differ by more than 0.8 % relative for difference in reflectance levels of about 7 % and more than 1.8 % relative for difference in reflectance levels of about 35 %.

7.1.2 *Reproducibility*—Two results, each the mean of duplicate measurements obtained in different laboratories should be considered suspect if they differ by more than 4.0 % relative for difference in reflectance levels of about 7 % and 14 % relative for difference in reflectance levels of about 35 %.

8. Index Terms

8.1 This test method is indexed under the following terms: porosity; resistance—penetration (into paint films).

Standard Practice for Infrared Determination of the Temperature of Applied Coatings on Wood Products During the Curing Cycle¹

This standard is issued under the fixed designation D 3259; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^e) indicates an editorial change since the last revision or reapproval.

^{e1} NOTE—Section 5 was editorially changed in May 1990.

1. Scope

1.1 This practice is intended to serve as a guide in measuring with infrared instruments the temperature during the curing process of coatings applied to wood products.

1.2 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Significance and Use

2.1 The forest products finishing industry has encountered difficulties in measuring the temperature of painted surfaces during the curing process. The use of thermocouples is not entirely satisfactory because the thermocouple wires tend to conduct heat away too rapidly from the area where the temperature is being measured. Infrared radiation thermometers that are simple to operate can circumvent this difficulty. After calibration they are aimed at the surface, switched on, and the temperature read directly from an indicating gage.

NOTE 1—Temperature-sensitive crayons, papers, and pellets may be successfully used to measure only the highest temperature reached by painted surfaces during the curing cycle.

2.2 There are several different types of infrared radiation thermometers, including those based on lead sulfide or thermistor sensors and those that are simple thermal voltaic transducers. As such they respond to different wavelengths of infrared radiation and have different areas of applicability. Only instruments that have been evaluated are included in this practice.

3. Apparatus

3.1 *Lead Salt Types²* (Note 2)—Two lead salts are commonly used. Lead sulfide that responds to wavelengths between 1.0 and 3.0 μm and lead selenide that responds to wavelengths between 15 and 4.5 μm .

3.2 *Thermistor Type*—Thermistors are sensitive to longer wavelength infrared of 3 to 20 μm . Instruments may be

designed with a narrow or broad band pass and may compensate for changes in ambient temperatures. One instrument³ with the latter feature has a band pass of 8 to 14 μm . Another instrument⁴ that must be rezeroed to compensate for changes in ambient temperatures has a band pass of 3 to 20 μm . However, this instrument can be completely portable and requires essentially no warm up time.

3.3 *Thermalvoltaic Type⁵*—These instruments are equipped with collection chambers for radiated energy that then heat a thermocouple to the temperature of the surface measured. As such, they require a minimum target area of 1 in. (25 mm) in diameter and have a delay time that averages about 1.5 s.

3.4 Instrumentation is available for on-line process monitoring control of product temperatures. These units have long term stability that permits operation in varying ambients encountered in plants or mills without periodic calibration. The instruments also have output signals to operate recorders and controllers.

4. Procedure

4.1 *Calibration*—Calibrate each instrument according to the instructions of the manufacturer. A standard blackbody capable of being controlled at various temperatures is almost essential for calibration. One such blackbody⁶ is a modified hot plate with a 1/2-in. (13-mm) thick aluminum plate and a ventilated cowling to minimize the effects of ambient drafts. A dial thermometer with its stem within the aluminum plate serves to monitor the temperature of the blackbody.

4.2 Operation:

4.2.1 Detailed instructions on the operation of each instrument are not included in this practice. Unless otherwise agreed follow the manufacturer's instructions in operating the equipment.

4.2.2 One general precaution is that the instrument must observe only the surface being measured and not stray radiation from infrared heaters, sunlight, electric lights, or other sources. The permissible distance from the surface to the sensor depends upon the area of surface, the viewing

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of D01.52 on Factory Coated Wood Products.

Current edition approved Aug. 31, 1984. Published January 1985. Originally published as D 3259 - 73. Last previous edition D 3259 - 73.

Standard Test Method for Acid and Mortar Resistance of Factory-Applied Clear Coatings on Extruded Aluminum Products¹

This standard is issued under the fixed designation D 3260; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the evaluation of the mortar and acid resistance of clear protective coating factors applied to extended aluminum substrates.

2. Referenced Documents

2.1 ASTM Standards:

C 207 Specification for Hydrated Lime for Masonry Purposes²

D 823 Test Method for Producing Films of Uniform Thickness of Paint, Varnish, and Related Products on Test Panels³

3. Summary of Test Method

3.1 Panels that have been buffed, cleaned, neutralized, and coated with the material being evaluated are exposed to freshly prepared mortar and to a hydrochloric acid solution.

4. Significance and Use

4.1 This test method will provide differentiation between types of coatings for acid and motor resistance providing the coating is applied in a uniform continuous film with a specified film thickness.

5. Reagents

5.1 *Acid*—Ten volume percent solution of commercial grade hydrochloric acid (31.4 to 31.8 % HCl, 20°Bé) in distilled water.

5.2 *Cleaning Solution*—An alkaline cleaner⁴ in the concentration recommended by the manufacturer, usually 6 to 8 oz/gal (45 to 60 g/L) of water. The pH of the solution should be between 11.4 and 12.2.

5.3 *Lime*—Building lime complying with Specification C 207.

5.4 *Neutralizing Solution*—Prepare from a stable free-flowing, granular material having a chromate base⁵ as recommended by the supplier, usually at a concentration of

12 to 16 oz/gal (90 to 120 g/L) of water.

5.5 *Sand*—Dry sand capable of passing through a 10-mesh wire screen.

6. Test Panels

6.1 Panels of extruded aluminum alloy No. 6063-T5 with dimensions 6 by 3 by ¼ in. (150 by 75 by 6.3 mm) shall be used for the test.

7. Procedure

7.1 Preparation of Test Panels:

7.1.1 Buff the aluminum panels and remove the buffing compound with an organic solvent.

7.1.2 Immerse the panels in cleaning solution (5.2) for 1 h at a temperature of 200°F (93°C).

7.1.3 Rinse the panels in tap water having a pH of 6.5 to 7.5 until the surface is free of water break. Use reagent water for rinsing if the pH of the tap water is outside the specified limits. The panels shall be free from evidence of corrosion or surface attack.

7.1.4 Immerse the panels in neutralizing solution (5.4) at 75 ± 2°F (24 ± 1°C) for 30 s to neutralize any retained alkalinity and to promote adhesion of the applied coatings.

7.1.5 Rinse the panels in reagent water and allow them to dry a minimum of 1 h before coating.

7.2 Coating of Test Panels:

7.2.1 Apply the coatings being evaluated to the test panels in a uniform continuous film by automatic spray equipment in accordance with Method A of Test Method D 823.

7.2.2 For the mortar test, spray two panels on one side with two or more full wet coats to produce a minimum dry film thickness of 0.6 mils (15 µm) and two panels with one or more full wet coats to produce a minimum dry film thickness of 0.3 mils (7.5 µm).

7.2.3 For the acid test, spray two panels with two or more full wet coats, on both sides, to produce a minimum dry film thickness of 0.6 mils (15 µm) and two panels with one or more full wet coats on both sides to a minimum dry film thickness of 0.3 mils (7.5 µm).

7.2.4 Allow the panels to dry for 7 days at 73 ± 3.5°F (23 ± 2°C) and 50 ± 5 % relative humidity.

7.3 Mortar Test:

7.3.1 Prepare freshly mixed mortar by dry mixing 75 g of building lime (5.3) and 225 g of sand (5.5) and adding sufficient reagent water while stirring to make a soft paste that can be formed into a firm mortar patty approximately 1½ in. (40 mm) in diameter and ¼ in. (6 mm) thick.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.55 on Factory-Applied Coatings on Preformed Products.

Current edition approved Oct. 29, 1982. Published January 1983. Originally published as D 3260 - 73. Last previous edition D 3260 - 73 (1978).

7.4.

7.3.2 Apply the mortar to the top and bottom areas of the test panels and, without drying, immediately expose them for 7 days at 95 to 98 % relative humidity at a temperature of $70 \pm 3.5^\circ\text{F}$ ($21 \pm 2^\circ\text{C}$) in an automatically controlled cabinet.

7.3.3 At the end of 7 days take the panels from the test cabinet and immediately dislodge the mortar patties from the panels using a damp cloth to remove any residue.

7.3.4 View the surface of the panels perpendicular to the surface under a diffused light source providing a minimum light intensity at the surface of 200 ft-candles (2150 lx). Examine for blistering, peeling, lifting, crazing, flaking, or discoloration of the coating, and for corrosion of the coated part of the aluminum panel. Three observers shall evaluate each panel and the majority assessment shall govern.

7.4 Acid Test:

7.4.1 Apply a mixture of 50 parts beeswax and 50 parts

paraffin to protect the raw edges to a distance of $\frac{3}{8}$ in. (10 mm).

7.4.2 Immerse the panels in the acid bath (5.1) at $70 \pm 3.5^\circ\text{F}$ ($21 \pm 2^\circ\text{C}$) for 6 h. Remove the panels, rinse in water, and allow to dry.

7.4.3 Examine and evaluate as in 7.3.4.

8. Precision

8.1 The effect of acid and mortar on the coatings is expressed in terms of appearance and numerical values are not generally assigned.

8.2 In a cooperative test program, consistent results were obtained by all cooperators when all of the test variables were controlled closely. The success of the procedure depends particularly on having a continuous film of the coating on the panels, the proper pH value when rinsing the panels, and proper protection of the edges of the panels in the acid test.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. Standard Practice for Direct Injection of Solvent-Reducible Paints Into a Gas Chromatograph for Solvent Analysis¹

This standard is issued under the fixed designation D 3271; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice describes the techniques used to inject whole paint samples directly into a gas chromatograph to obtain a chromatogram from which the solvent composition may be established.^{2,3}

1.2 This practice is not designed to be quantitative.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. A specific hazard statement is given in 6.1.*

2. Referenced Document

2.1 *ASTM Standard:*

E 260 Practice for Packed Column Gas Chromatography⁴

3. Summary of Practice

3.1 A suitable aliquot of whole paint is injected, by means of a syringe, into a gas chromatographic column in order to separate the solvents.

4. Significance and Use

4.1 Gas chromatographic separation of solvents present in whole paints is the preferred first step for identifying and quantitating solvent compositions, using auxiliary procedures and techniques.

5. Apparatus

5.1 *Gas Chromatograph*—Any instrument with temperature programming capability may be used. It should be equipped with either a thermal conductivity or flame ionization detector (see Practice E 260).

5.2 *Recorder*—A 1 to 10-mV recorder with a full-scale response time of 2 s or less and a maximum noise of $\pm 0.03\%$ of full scale.

5.3 *Column*—The resolution of the column must be such that under the operating conditions selected the distance from the base line to the depression between two adjacent peaks must be not more than 50 % of the smaller peak. Columns may be either packed or capillary.

6. Reagents and Materials

6.1 *Carrier Gas*—Helium or hydrogen for use with thermal conductivity detector units; and nitrogen, helium or argon for use with flame ionization detector units.

NOTE 1: Precaution—When hydrogen is used, special precautions should be taken to prevent gas leakage from causing a possible explosion.⁵

6.2 *Column Packing Material*, meeting requirements in 5.3. The following materials have been used satisfactorily:

6.2.1 Polyethylene glycol, molecular weight 20 000,⁶ and diisodecyl phthalate as liquid phases on a solid support of 60 to 80 mesh (250 to 175 μm) diatomaceous earth.

6.2.2 Porous beads of ethylvinylbenzene and divinylbenzene copolymer,⁷ 60 to 80-mesh (250 to 177- μm) have also been successfully used as column material.

6.3 *Liquid Charging Devices*, such as micro syringes.⁸ Disposable type is preferred.

6.4 *Septum Sample Vials*, PTFE-fluorocarbon-faced.⁹

7. Procedure

7.1 Protect the injection port from the nonvolatile portion of the paint by using a borosilicate glass injection port sleeve (Note 2), glass wool plug, or by any other suitable means. If the whole paint sample is of sufficiently low viscosity, draw an aliquot directly into the syringe. When the whole paint sample is too viscous, dilute with a suitable solvent (Note 3) that will not interfere with the analysis. In order to minimize solvent losses due to evaporation, the whole paint sample

Standard Practice for Vacuum Distillation of Solvents From Solvent-Reducible Paints For Analysis¹

This standard is issued under the fixed designation D 3272; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^e) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

^{e1} NOTE—Editorial changes were made throughout, including the title, in February 1988.

1. Scope

1.1 This practice covers a vacuum distillation procedure that separates the solvents from the nonvolatile portion of paints so they may be analyzed.

1.2 An alternative procedure for the analysis of solvents in paints is described in Practice D 3271.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 ASTM Standard:

D 3271 Practice for Direct Injection of Solvent-Reducible Paints into a Gas Chromatograph for Solvent Analysis²

3. Summary of Practice

3.1 The sample of whole paint with added tricresyl phosphate is heated by means of a silicone oil bath. The distillation is allowed to proceed for a period of time and then vacuum is applied. Finally dry air is passed through the system to facilitate the removal of any high-boiling solvents present.

4. Apparatus

4.1 Apparatus³ is shown in Fig. 1. It is essential in assembling this apparatus, that the volume of the portion preceding the flask be kept to a minimum by using diameters of connections and distances as small as possible. Include a gage in the assembly for measuring pressure.

4.2 *Vacuum Pump*, capable of pulling 2 mm Hg or less of vacuum pressure.

4.3 *Septum Sample Vial*, PTFE-fluorocarbon-faced.⁴

4.4 Safety Shield.

5. Reagents

5.1 *Methylene Chloride or Acetone.*

5.2 *Silicone Oil.*⁵

5.3 *Tricresyl Phosphate.*

6. Procedure

6.1 Immerse the receiver in a bath containing dry ice with methylene chloride or acetone of sufficient depth that the liquid reaches to the bottom level of the rubber stopper.

6.2 Pour approximately 15 g of the whole paint sample into the 50-mL distillation flask. Immediately follow with 10 mL of tricresyl phosphate and without delay mix the contents of the flask.

6.3 Assemble the apparatus and close the needle valve and stopcock attached to the capillary tubing. Immerse the distillation flask by raising a silicone oil bath preheated to 155 to 160°C (Warning—see Note 1) until it reaches the side arm (Note 2). Allow the distillation to proceed for 15 min without vacuum.

NOTE 1: Warning—Care should be taken to prevent the temperature of the silicone oil exceeding 160°C because of possible formation of explosive mixtures of air and solvents from the sample being analyzed.

NOTE 2—The liquid level in the oil bath should be as high as is practical.

6.4 After 15 min apply vacuum slowly and carefully to avoid bumping or rapid distillation until 2 mm Hg is reached. This step should take approximately 10 to 15 min. Next, carefully open the stopcock. After bubbling subsides, adjust the needle valve so as to regulate the flow of air at a rate of 60 to 80 bubbles per minute (at the bubble counter). Pass air through the system for a total of 30 min while keeping the dry ice bath at a minimum low temperature.

6.5 At the end of the 30-min period release the vacuum very slowly with air flowing to prevent back-up of the paint. Remove the receiver containing the solvents and warm the contents only to the temperature of cold running tap water. Transfer the isolated solvents promptly to an airtight septum faced vial for subsequent analysis.

¹ This practice is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.21 on Chemical Analysis of Paints and Paint Material.

Current edition approved Oct. 29, 1976. Published December 1976. Originally published as D 3272 - 73 T. Last previous edition D 3272 - 73 T.

Standard Test Method for Resistance to Growth of Mold on the Surface of Interior Coatings in an Environmental Chamber¹

This standard is issued under the fixed designation D 3273; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

^{ε1} NOTE—Keywords were added editorially in July 1991.

1. Scope

1.1 This test method describes a small environmental chamber and the conditions of operation to evaluate reproducibly in a 4-week period the resistance of a paint film to surface mold growth in a severe interior mold environment. The apparatus is designed so it can be easily built or obtained by any interested party and will duplicate results obtained in a large tropical chamber.

1.2 Temperature and humidity must be effectively controlled within the relatively narrow limits specified in order for the chamber to function reproducibly during the short test period. Severity and rate of mold growth on a film is a function of the moisture content of both the film and the substrate. A relative humidity of 95 to 98 % at a temperature of $90 \pm 2^\circ\text{F}$ ($32.5 \pm 1^\circ\text{C}$) is necessary for test panels to develop rapidly and maintain an adequate moisture level to support mold growth.

1.3 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Document

2.1 ASTM Standard:

D 3274 Test Method for Evaluating Degree of Surface Disfigurement of Paint Films by Microbial (Fungal or Algal) Growth or Soil and Dirt Accumulation²

3. Significance and Use

3.1 An accelerated test for determining the resistance of interior coatings to mold growth is useful in estimating the performance of coatings designed for use in interior environments that promote mold growth and in evaluating compounds that may inhibit such growth and the aggregate levels for their use.

3.2 This test method should preferably be used by persons who have had basic microbiological training.

4. Apparatus

4.1 *Environmental Chamber*, capable of maintaining a relative humidity of 95 to 98 % at a temperature of $90 \pm 2^\circ\text{F}$ ($32.5 \pm 1^\circ\text{C}$) while providing a continuous inoculation of the surface of exposed panels with mold spores. The chamber should be kept in a room controlled to 70 to 75°F (21 to 24°C) so that heat loss from the cabinet is insignificant and that 95 to 98 % relative humidity is readily obtained at the test temperature. Alternatively the cabinet must be insulated with suitable materials to minimize heat loss.

4.2 *Small Cabinet*, suitable for holding about twenty-five 3 by 4-in. (75 by 100-mm) test panels under these conditions can be constructed as follows (Fig. 1):

4.2.1 *Tank*, polypropylene or polyethylene, with an offset shoulder at the top rim is used as the chamber.³ A pitched top with straight sides should be constructed out of acrylic plastic so moisture condensation will run down the sides and be recirculated instead of dripping onto the panels.

4.2.2 *Heating Coil*,⁴ 125-W, regulated by a controller⁵ and installed in the bottom of the chamber by connections through the end wall. It is so placed that it is immersed when there are 2 to 3 in. (50 to 75 mm) of water in the bottom of the chamber. A 90°F (32.5°C) thermostat should be installed in the chamber in the area by the test panels to regulate the heat input through the controller to the heating coil in the water.

4.2.3 *Tray*, stainless steel or plastic, approximately 1 in. (25 mm) smaller than the inside dimensions of the chamber and 1 to 3 in. (25 to 75 mm) deep with a noncorrodible metal⁶ mesh bottom should be supported 1 in. (25 mm) above the water level and centered in the chamber. One layer of fine plastic or fiberglass screen should be placed over the metal mesh for holding soil.

4.2.4 *Small Fan*,⁷ mounted through the end wall perpen-

³ Dynalab Corp., Rochester, NY, and Cole Parmer Instrument Co., Chicago, IL have tanks of this type available in dimensions approximating 27 by 18 and 18 in. (686 by 457 and 457 mm) high.

⁴ The Chromalox® heating coil manufactured by the Wiegand Div., Emerson Electric Co., Pittsburgh, PA has been found satisfactory for this purpose.

⁵ The Lumenite Electronic Level Control has been found satisfactory for this purpose.

⁶ Monel has been found satisfactory for this purpose.

⁷ 1/250-hp fan operating at 300 r/min with a 1.5-in. blade, obtained from Dayton Electric Manufacturing Co., or equivalent, has been found satisfactory for this purpose.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.28 on Biodeterioration.

Current edition approved May 30, 1986. Published July 1986. Originally published as D 3273 - 73 T. Last previous edition D 3273 - 82^{ε1}.

² Annual Book of ASTM Standards, Vol 06.01.

FIG. 1 Environmental Cabinet Assembly

pendicular to and just above the surface of the soil bed in the tray (4.2.3) to provide dispersion and circulation of the mold spores to achieve continuous inoculation of the surfaces of the painted panels.

4.2.5 *Series of Wood Bars*, suspended across the width of the chamber at a height and spacing that allows the use of test panels 3 by 4 in. (75 by 100 mm), hung vertically, with approximately 3-in. (75-mm) clearance above the inoculated soil with a suitable method of fastening. Screw eyes are used with the wooden panels while a wire frame or a large clip is used with the gypsum board panels. Other support systems may be utilized.

NOTE 1—Other angles of exposure may be used but may alter the rate and severity of mold growth.

4.3 *Psychrometer*, for measuring relative humidity in the test area.

5. Reagents and Materials

5.1 *Soil*—A good quality greenhouse-grade potting soil, suitable for plant propagation, containing 25 % peat moss. pH of the soil should fall from 5.5 to 7.6. Do not allow soil to become compacted.

5.2 *Cultures*:

5.2.1 *Aureobasidium pullulans*,⁸ ATCC 9348

5.2.2 *Aspergillus niger*,⁸ ATCC 6275

5.2.3 *Penicillium*,⁸ Sp. 12667 or ATCC 9849

5.3 *Test Panels*:

5.3.1 *Ponderosa Pine* (*Pinus ponderosa* Laws) *Sapwood Panels*, ½ in. (12.7 mm) thick, 3 by 4 in. (75 by 100 mm), free of excessive resins, knots, growth rings or other abnormalities, surfaced smooth on four sides. Wood shall be kiln dried after sawing to avoid infestation of wood-rotting fungi and any wood showing evidence of such infestation shall be eliminated as test material. Wood shall be weighed after conditioning at room temperature in a dry room to 15 % moisture content. Calculated weight shall fall between 6.0 and 7.0 g/in.³ (365 and 425 kg/m³). Panels containing heartwood areas should not be used as they will inhibit mold growth under test conditions.

5.3.2 *Gypsum Board Panels*, ½ in. (12.7 mm) thick, 3 by 4 in. (75 by 100 mm).

NOTE 2—Other substrates may be used but may result in a different rate or severity of mold growth.

6. Preparation of Apparatus

6.1 Place greenhouse soil in the tray in the cabinet and add water to the tank chamber to the desired depth. Allow the cabinet to equilibrate for 24 h before inoculating the soil with the specified mold suspensions.

6.2 Prepare mold slants of all three cultures and age 10 to 14 days or purchase prepared mold slants⁸ of all three cultures. Prepare mold suspensions from each type of mold slant by the following procedure: Add one drop of 25 % nonionic surfactant⁹ solution to 95 to 100 mL sterile deionized or distilled water and shake. Pipet 5 mL of this solution onto the mold slant. Scrub the surface of the slant with a sterile cotton swab to remove as much spore and mycelial growth as possible without digging up the surface of the agar. Pour the water from the scrubbed slant back into the surfactant-sterile water mixture for dilution. Shake gently for 15 to 20 min to break up clumps of mold. Use a pipet to distribute the mold suspensions evenly over the surface of the greenhouse soil in the tray in the cabinet.

6.3 Allow two weeks of continuous operation for the mold to sporulate and equilibrate with the environment before starting a test. It should not be necessary to recontaminate continually the chamber of panels after sufficient microorganism growth has built up in the soil, if the chamber is maintained in continuous operation.

6.4 Viability of the mold growth in the cabinet can be checked by placing several malt agar or potato dextrose agar plates,¹⁰ open and face up, at several locations on the panel support rods. After 1 h, cover plates and place in incubator at 90 ± 2°F (32.5 ± 1°C) for 3 days. If an incubator is not available, leave the covered plates in the cabinet. Mold

⁸ Suitable cultures can be obtained from American Type Culture Collection, 12301 Parklawn Dr., Rockville, MD 20852. Cultures can be maintained on malt agar or potato dextrose agar. Prepared slants can be obtained from Difco Laboratories, Inc., Detroit, MI 48232; Baltimore Biological Laboratories, Baltimore, MD 21218 or from equivalent sources.

⁹ Triton X100, Rohm & Haas, Igepal CA-630, G.A.E., or equivalent.

¹⁰ Prepared agar plates can be obtained from Difco Laboratories, Inc., Detroit, MI 48232; Baltimore Biological Laboratories, Baltimore, MD 21218, or from equivalent sources.

growth should be medium-heavy to heavy and cover the complete surface of the agar plate.

7. Procedure

7.1 Preparation of Test Panels—Wear disposable plastic gloves or utilize other techniques when handling panels to avoid fingerprints. Prepare triplicate panels by applying two coats of the material under test to both faces and to all edges of the panels at a spreading rate of approximately 450 ft²/gal (11 m²/L) per coat or as specified by the coating manufacturer, allowing 1 day between coats unless otherwise specified. Condition the panels at 73.5 ± 3.5°F (23 ± 2°C) and 50 ± 5 % relative humidity for 4 days after application of the last coat before placing in the test chamber for start of environmental exposure.

7.2 Exposure—Hang the panels vertically with the bottom approximately 3 in. (75 mm) above the surface of the inoculated soil and with sufficient spacing to allow free circulation of air and to prevent contact between panels or with wall surfaces. Place triplicate panels randomly in the cabinet. Include uncoated control panels in all tests. If the cabinet is operating properly, unpainted panels should develop a 4 to 6 mold growth rating within 2 to 3 weeks. If this growth is not obtained, the cabinet conditions are not satisfactory or there is some interfering treatment on the panel.

7.3 Rating—Rate the panels for mold growth each week for 4 weeks on a 0 to 10 rating scale using photographic standards (Test Method D 3274). The 50 and 100 magnification photographic standards for types of fungal or dirt disfigurement (Test Method D 3274) should be used to confirm the presence of mold as the cause of discoloration.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

8. Report

8.1 Report the results at the end of the 4-week exposure giving the mean and range of the three panels. The result from any panel that differs by more than 2 rating units from either of the others can be considered manifestly faulty and discarded and the mean of the remaining two panels reported. If all panels in a set differ by more than 2 units in their ratings, discard all results and repeat the test.

9. Precision and Bias

9.1 On the basis of an interlaboratory study of this test method in which one operator, in each of seven laboratories, rated resistance to mold growth of interior paints at seven levels of resistance by visual comparison with photographic standards, the standard deviations within and between laboratories were found to be:

	Standard Deviations
Within laboratories	0.4 units
Between laboratories	0.7 units

Based on these deviations the following criteria should be used to judge the precision of results at a 95 % confidence level:

9.1.1 Repeatability—Two ratings, each the mean of a set, obtained by a single operator should be considered suspect if they differ by more than 1 unit.

9.1.2 Reproducibility—Two ratings, each the mean of a set, obtained in different laboratories should be considered suspect if they differ by more than 2 units.

9.2 Bias—No bias has been determined for this test method.

Standard Test Method for Evaluating Degree of Surface Disfigurement of Paint Films by Microbial (Fungal or Algal) Growth or Soil and Dirt Accumulation¹

This standard is issued under the fixed designation D 3274; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

^{ε1} NOTE—Editorial changes were made throughout, including the title, in October 1988.

1. Scope

1.1 The photographic reference standards available for use with this test method provide a numerical basis for rating the degree of fungal and algal growth or soil and dirt accumulation on paint films.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Significance and Use

2.1 The growth of fungi and algae in and on the surface of paint films represents a major cause of discoloration or disfigurement of painted surfaces. Because of their dark pigmentation, it is frequently difficult to distinguish fungi and algae from soil or dirt particles. The use of magnification of as much as 100 $\times$ affords easy distinguishability among fungal spores, fungal mycelia, algae, and dirt and is recommended in cases where such difficulty is apparent.

3. Types of Fungal and Algal Growth

3.1 Two types of fungal growth may be observed:

3.1.1 *Spores*—Spherical bodies, gray black in color, observed singly or in clusters. May or may not be associated with fungal mycelia. Spores are the reproductive form of fungi. Spores of *Pullularia pullulans* magnified 100 $\times$ are shown in Fig. 1.

3.1.2 *Hyphae*—Thread or filament structures, gray to black in color, that make up the mycelium or vegetative form of fungi. Hyphae may appear alone or with spores attached. Hyphae of *Pullularia pullulans*, magnified 50 $\times$ are shown in Fig. 2.

3.2 Amorphous growth typical of an alga such as *Chlorococcum* Sp. appears in Fig. 3 at a magnification of 39 $\times$. Terrestrial algae can appear green to dark brown in color.

FIG. 1 Spores of *Pullularia pullulans*, Magnified 100 $\times$

FIG. 2 Hyphae of *Pullularia pullulans*, Magnified 50 $\times$

4. Soil or Dirt Particles

4.1 Soil or dirt particles may range from light brown to black. The particles, viewed at 50 $\times$ to 100 $\times$ magnification, are generally amorphous and are frequently translucent. Soil particles on paint magnified 100 $\times$ are shown in Fig. 4.

5. Use of Photographic Standards²

5.1 The photographic reference standards that are part of

¹ This method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.28 on Biodeterioration.

Current edition approved Oct. 29, 1982. Published December 1982. Originally published as D 3274 - 73 T. Last previous edition D 3274 - 76.

² Available from ASTM Headquarters (Request PCN 12-432740-00). Copies of the pictorial photographic standards are contained in the publication *Pictorial Standards of Coating Defects*, which may be obtained from the Federation of Societies of Coating Technology, 492 Norristown Rd., Blue Bell, PA 19422.

FIG. 3 Amorphous Algal Growth, Magnified 39x

this test method are for illustration purposes only and should not be used for evaluation.

5.2 The photographic standards illustrated in Fig. 5 rate the disfigurement of paint films from 0 to 8. A rating of 10 would indicate a film totally absent of disfigurement by particulate matter.

6. Procedure

6.1 Compare each specimen with the photographic standards associated with this test method to determine which most closely matches the degree of disfigurement on the specimen. When the degree is intermediate between two adjacent standards select the intermediate odd number as the disfigurement rating.

6.2 The density of fungal or algal growth as well as dirt

FIG. 4 Soil Particles on Paint, Magnified 100x

accumulation may vary over the painted surface being evaluated. This variation may be the result of the location of the surface (that is, under an eave of a house *versus* an exposed area), nonuniformity of the substrate, film thickness or other factors. Such variation should be noted when reporting the rating assigned to specimen under test. In examining test specimens for fungal, algal, or dirt disfigurement, the possibility of failure due to the wood substrate should be recognized and reported.

6.3 When microbial disfigurement is detected (or established), distinguish between algal and fungal growth. For the latter, estimate whether spores or mycelia predominate.

7. Report

7.1 Report the numerical disfigurement rating as defined in 5.1 and the predominant type, that is, fungi, algae, or soil.

FIG. 5 Disfigurement Ratings

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Guide for Painting Inspectors (Metal Substrates)¹

This standard is issued under the fixed designation D 3276; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide is intended as an information aid to painting inspectors in carrying out their task efficiently. It includes the key elements of surface preparation, coatings application, and final approval for both field and shop work. The items should be selected that are pertinent to the specification of a particular job.

NOTE 1—For additional helpful information, refer to the following documents:

*Manual of Coating Work for Light-Water Nuclear Power Plant Primary Containment and Other Safety-Related Facilities*²
*New Concepts for Coating Protection of Steel Structures*³

3. Significance and Use

3.1 This guide is intended as a reference for those concerned with the inspection of industrial coating work. A punch list for use in the field is included as an appendix. Many of the details covered may be in a specification for a particular project. A specification for coating projects should

include the coatings to be used. The various items are explained in detail in the appendix.

4. Preparation for Inspection

4.1 The guide describes the duties of the inspector and discusses inspection methods, both visual and instrumental, that can be used to determine that the specification requirements have been met by the painting contractor.

4.2 Before painting is started the project engineer must provide the inspector with information from the official plans and specifications as to coating type, thinner to be used, mixing ratios to be used, recommended application thickness, recommended primer, tie coat, topcoat, time between coats, surface preparation, method of application, and any special precautions to be followed such as limits on ambient conditions. These details should be recorded in an inspector's record book to eliminate any misunderstanding between the inspector and the contractor.

5. Field and Shop Inspection

5.1 *Surface Preparation* is one of the most important factors affecting the performance of coatings. The specifier should determine the proper level in accordance with the expected service life and type of coating specified.

5.1.1 *Pictorial Standard D 2200 (SSPC-Vis 1)* should be provided to the inspector on a job involving painting of structural steel. The standard is used by the inspector to determine whether the degree of surface preparation specified in a contract has been attained by the contractor. For large jobs it is recommended that before work starts, an actual steel sample of adequate size be blasted to the satisfaction of the project engineer. This blasted surface should be protected by a clear acrylic coating or encased in plastic and used for reference purposes as the work progresses.

5.2 *Factors Affecting Coating Performance*—There are a number of factors that must be considered to ensure a proper painting job.

5.2.1 *Cleanliness*—Many materials if not removed from the surface will affect the life of the coating. These include oil, grease, soil, weld spatter, and slag that make it impossible to obtain proper adhesion to the metal surface. Deposits of salts (such as chlorides and sulfates) must be removed or long-term coating performance will be seriously affected. The Steel Structures Painting Council (SSPC) issues detailed surface preparation specifications that cover methods for solvent cleaning and hand and power tool cleaning as well as the various methods of blast cleaning.

5.2.2 *Mill Scale*, the bluish-black oxide resulting from the hot-rolling process, is a constant source of trouble leading to coating failure. This scale is very hard and can crack or loosen from temperature changes both in fabricating and weathering in the field.

5.2.3 *Surface Profile*—The texture of the metal surface has a significant effect on the performance of coatings since it increases the surface area to which the coating can develop adhesion. In fact, the term "anchor pattern" is sometimes used to describe the depth of profile required. This varies both with the type and size of the abrasive used. Coarser abrasives generally produce a coarser and deeper profile. Deep profiles are advantageous for adhesion but require

Dry-Film
sters⁵

⁶ Annual Book of ASTM Standards, Vols 02.05 and 06.01.

⁷ Annual Book of ASTM Standards, Vols 01.06 and 03.03.

⁸ Available from Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402.

more coating to fill in the valleys and cover the peaks of the profile; they cannot be used with low-build coatings that do not cover the peaks even when several coats are applied. A general recommendation is that the surface profile should be one quarter to one third of the dry film thickness of the coating system but does not apply in every case if the resulting profile would be too great.

5.3 Cleaning Procedures—Safety precautions are not addressed separately for each of the following cleaning methods. Each has its own safety-related hazards, and U.S. Occupational Health and Safety Administration regulations should be followed. Material Safety Data sheets (MSDS) for the solvents and cleaning compounds provided by the manufacturer should also be consulted for proper worker protection.

5.3.1 Chemical Cleaning—Solvents are used to remove oil, grease, and related materials. The solvent is applied to the surface by wiping or scrubbing with rags or brushes. The contaminants must be removed (not simply spread out) by a thorough wiping of the affected areas with cloths saturated with clean solvent. Contaminated cloths must not be dipped into clean solvent. The cleaning should be repeated with clean rags and fresh clean solvent. Emulsions, cleaning compounds, steam cleaning, or similar methods and materials may also be used. Where emulsion cleaners, soaps, or detergents are used, they must be removed completely by washing with clean hot water. SSPC SP-1 covers cleaning procedures using these materials.

5.3.1.1 Solvent Vapor Cleaning is a procedure that can be adapted to a production line or a piecework operation. Vapor cleaning removes all soluble contaminants but does not disturb the natural oxide film. If this film must be removed, mechanical cleaning will be necessary as well. The part to be cleaned is placed in the saturated vapor above the heated solvent so that the solvent vapor condenses on the metal surface. Vapor degreasing does not remove particulate matter and parts must be wiped to remove any insoluble soils. Vapor degreasing has the advantage over solvent wiping in that hot solvents are used and the solvent condensation removes soils without recontamination.

5.3.2 Hand Tool Cleaning is the method used for the removal of loose mill scale, loose rust, loose or otherwise defective coating, weld flux, slag and spatter from metal surfaces by hand brushing, hand sanding, hand chipping or scraping using wire, fiber, or bristle brushes, sandpaper, steel wool, hand scrapers or chisels, and chipping hammers. The surface is then cleaned to the condition St 2 given in Method D 2200 (SSPC-Vis 1). SSPC also provides a detailed specification, SSPC-SP 2.

5.3.2.1 Hand tool cleaning requires that all tar, oil and grease, weld flux, and other greasy contaminants be removed

first by solvent cleaning (5.3.1).

5.3.2.2 Wire brushes should be rigid enough to clean the surface thoroughly and shaped to penetrate into all corners and joints. Brushes should be kept free of all materials that may clog the wires of the brush. Hand scrapers should be made of tool steel, tempered and ground to a sharp edge and should be of the proper size and shape to enable cleaning to be done as specified. Scrapers should be kept sharp at all times.

5.3.3 Power Tool Cleaning is a method used for the removal of loose mill scale, loose rust, loose or otherwise defective coating, and weld flux from metal surfaces by power wirebrushes, power impact tools, power grinders, power sanders, or by a combination of these methods. The surface is cleaned to the condition St 3 given in Pictorial Surface Preparation Standards D 2200. SSPC-SP 3 is the detailed specification for power tool cleaning.

5.3.3.1 Power Tool Cleaning requires that all oil, grease, weld flux, and other contaminants be removed first by solvent cleaning (SSPC-SP 1). Hand tool cleaning in accordance with 5.3.2 may be used prior to power tool cleaning.

5.3.3.2 All equipment must be suitable for the configuration of the work to be cleaned and maintained free of material that clogs the wire or disks making them ineffective. All impact tools should be kept sharp.

5.3.4 Blast Cleaning is used to remove foreign materials from a metal surface and to provide a roughened surface by striking the surface with a stream of small, hard abrasive particles such as (dry) sand, grit, or shot.

5.3.4.1 One method utilizes compressed air, special blast nozzles, and abrasive. In another method used in a fabricating shop, wheels propel the abrasive centrifugally against the work. The minimum and maximum particle size of the abrasive may be specified as a means of controlling the surface profile. Water may be injected into the air stream to control dust. Occasionally a high-pressure water blast, either with or without an abrasive injected into the stream, is used as an alternative to open blasting since it reduces the release of dust into the atmosphere.

5.3.4.2 Blast cleaning requires that all oil, grease, and weld flux be removed by solvent cleaning. The compressed air used for blast cleaning should be free of condensed water or oil by making certain that separators and traps are in working order.

5.3.4.3 Blast-cleaning operations should be performed so that no damage is done to the completed portion of the work. Blast cleaning is often performed from the top to bottom of the structure and should only be carried on downwind from any recently painted areas. Dry blast cleaning operations should not be conducted on surfaces that will be wet after blasting and before painting. Dew point must be at least 5°F (3°C) above the steel temperature.

5.3.4.4 The degree of blast cleaning required should at least be equal to the appropriate SSPC surface preparation specification and the applicable pictorial standard shown in Pictorial Surface Preparation Standards D 2200 (SSPC-Vis 1) or National Association of Corrosion Engineers (NACE) as shown in Table 1.

5.3.4.5 Blast cleaned surfaces must be examined for any traces of oil, grease, or smudges; where present, the contaminants must be removed by solvent cleaning (see 5.3.1).

TABLE 1 Comparison of Surface Preparation Specifications

Preparation Grade	SSPC	ASTM D 2200	NACE
Blast cleaning to white metal	SSPC-SP 5	Sa 3	1
Blast cleaning to near-white	SSPC-SP 10	Sa 2 ½	2
Commercial blast cleaning	SSPC-SP 6	Sa 2 ^A	3
Brush-off blast cleaning	SSPC-SP 7	Sa 1	4

^A Pictorial standard B Sa 2-½ shows mill scale and conflicts with the SSPC definition of commercial blast (SP6) which does not allow mill scale.

Surfaces that have been dry blasted should be brushed with clean brushes, blown with compressed air free of oil and moisture, or vacuum cleaned to eliminate any traces of blast products, dust, or dirt from the surface. This also serves to remove abrasive from pockets and corners.

5.3.4.6 Blast cleaned surfaces should be further treated, primed or painted as specified on the same day they are blasted, preferably within 8 h, or in any event before any visible rerusting occurs. Reblasting will be necessary on any surface if rust bloom forms before the coating can be applied.

5.4 *Cleaning and Preparation of Various Surfaces*—Before application of any coating, all surfaces to be coated must be thoroughly cleaned and properly prepared to the requirements of the specification. All dust, dirt, oil, grease, moisture, soot, tars, or other contaminants should be removed from unpainted surfaces. Previously painted surfaces should be similarly cleaned of all foreign matter; all deteriorated coating must be removed as well. Mortar or cement drippings from earlier repairs must be removed by mechanical or chemical means. Tree limbs or other growth obstructing the structure should be cut away to provide ready access.

5.4.1 *Steel Surfaces*—Removal of rust and scale must be done in the manner and to the degree specified, that is, hand, power tool, or blast cleaned.

5.4.1.1 On bridges, all dirt and debris must be cleaned from around bearing plates, shoes, and other components. The entire surface of the beam or truss seat on each unit of the structure should be cleaned. On truss spans particular attention should be paid to removal of dirt and debris from pockets and crevices. Open steel grid-type decking should be cleaned by use of a detergent steam-water-type jet that will clean painted surfaces without softening or removing tightly adhering coating. The machine manufacturer's recommended solution should be used. Surfaces should then be rinsed with a clear water jet.

5.4.2 *Galvanized Surfaces* that are to be painted should be cleaned and treated in accordance with Method A or D of Practices D 2092. Alternatively, the surface may be allowed to weather a minimum of 6 months before cleaning and painting.

5.4.3 *Aluminum Surfaces*:

5.4.3.1 Complete removal of oil and grease and, for unanodized aluminum, treatment is essential. Vapor degreasing or immersion in an alkaline or acid cleaning solution are commonly used in shop work. In the field a water wash followed by solvent cleaning is a good starting point.

5.4.3.2 Vinyl wash primer is one of the metal pretreatments commonly used on unanodized aluminum. The material is described in Practices D 1730, Type B, Method 8 and is covered by SSPC Paint 27. For exterior work an inhibitive primer is required over this pretreatment. Lead pigmented primers should never be used over aluminum surfaces. The minimum treatment for aluminum is Type B, Method 3 of Practices D 1730, which describes the use of an alcoholic phosphoric acid cleaner.

5.4.4 *Precautions in Preparing Unpainted and Previously Painted Surfaces*—Cleaning should proceed by sections, bays, or other readily identifiable parts of the work. The cleaning of each section, bay, or part of the work must be

entirely completed, inspected, and accepted before any coating is applied. The system of alternately cleaning and painting short sections by one workman is not good practice.

5.4.4.1 If, in the opinion of the project engineer, traffic, or any other source produces an objectionable amount of dust, it is customary for the contractor, at his own expense, to control the dust by using tarpaulins, etc., for a sufficient distance around the structure and take any other precaution necessary to prevent dust and dirt from coming into contact with the cleaned or freshly painted surfaces. It may sometimes be necessary between the various coats to clean newly coated surfaces using some of the specified methods.

5.4.4.2 Some areas to be painted or repainted are exposed to chemical fumes and should be washed with water before painting. Washing may also be necessary between coats of paint. If there is reason to suspect the presence of chemicals, the surfaces should be tested before applying subsequent paints.

5.4.4.3 Residual contaminants present on pitted steel can be a problem. Chloride from deicing salts or a marine environment and sulfate contamination from air pollution have recently been recognized as one of the main factors in premature breakdown of coating systems. High-pressure water blasting is often used to remove these contaminants.

5.5 *Inspection of Surfaces Prior to Field Painting*:

5.5.1 *New Construction*—It must be emphasized that the first coat should be applied to the cleaned surfaces before any soiling or deterioration can occur. If painting is done out of doors, the cleaned areas should receive the first protective coat well before nightfall brings lower temperatures and possible moisture condensation on the surfaces. When surface preparation and painting are carried on indoors, overnight delays between cleaning and painting may be permissible except on blast-cleaned surfaces.

5.5.1.1 Shop-coated steel that has been shipped to the erection site should be stored on blocks to prevent contact with the ground and where it is least likely to be marred, scratched, or subjected to harmful contamination by grease, oil, salts, etc. Insofar as practicable, the steel should be stored to avoid the formation of waterholding pockets. If outdoor storage lasts for several months, the inspector should check the integrity of the coating from time to time, and have any deficiencies corrected. Correction of these deficiencies may require complete blast cleaning and repriming in the field if the shop primer has weathered so long as to make touch up too extensive. The length of time between shop priming and erection and subsequent topcoating should be kept to a minimum to avoid the problem of intercoat adhesion.

5.5.1.2 Immediately before applying the first field coat, the shop-coated surfaces should be cleaned of dust. If necessary to remove grime and oil substances, they are wiped with solvents selected so as not to soften the film appreciably. Miscellaneous scratches and breaks in the shop coat, including those occasioned by field welds, bolts, or rivets, should be cleaned and touched-up as specified before the steel receives the first overall field coat.

5.5.1.3 The inspector must ensure that field rivets have been cleaned of slag and weld spatter. It is important that every coat of the system be applied over dry, soil-free surfaces, and that all previous coats be free of mechanical damage. Great care should be exercised to prevent trapping

corrosive salts under or between coats.

5.5.1.4 The inspector should determine whether the specifications are being followed with reference to the painting or prohibition of painting of contact surfaces in bolted or riveted surfaces of construction. He must ensure that surfaces not in contact but that will be made inaccessible by assembly or erection, have received the full number of specified coats before they become inaccessible.

5.5.2 *Maintenance Repainting*—In most cases, maintenance painting will consist of spot-cleaning and priming of small isolated areas of deterioration followed by application of one overall new finish coat to all surfaces of the structure. The inspector of maintenance painting must be alert for several conditions not encountered in the painting of new work.

5.5.2.1 Sound coating not intended to be removed should not be damaged by cleaning operations on adjacent areas. This is particularly important with spot-blast cleaning.

5.5.2.2 The junctions between sound coating and spot-cleaned areas should present a smooth, feathered appearance. The application of coating to spot-cleaned areas should overlap the old, adjacent coating to a slight extent in order to assure full coverage of the cleaned areas. Before the overall finish coat is applied, the inspector must ensure that oil, grime, dust, and other contaminants are cleaned from the old coating surfaces.

5.5.2.3 Before work has progressed too far, adhesion of the newly applied coat to the old coating should be carefully checked. Under the direction of the engineer the inspector may explore beneath the surface of the existing or new coating film for covered-over rust or loosening of the old film, and where he discovers such conditions, require that the surface be cleaned and repainted.

5.5.2.4 The effect of any newly applied coating on the old underlying coating should be noted. Any coating that shows curling, lifting, or excessive wrinkling should be reported to the engineer immediately since it may have to be removed and the area repainted. If the defects are general, rather than existing in a few isolated areas, use of a different type of coating may be necessary.

6. Inspection Equipment

6.1 *General*—Visual observation is the most important part of inspecting coating application. There are, however, instruments and mechanical aids that are of considerable help to the inspector. They make the painter aware that his work can be checked during progress and even after completion. The different instruments that can be used are described in this section.

6.1.1 *Surface Profile Gages*—The inspector can determine the surface profile of blast-cleaned steel substrates using Test Methods D 4417 to assure an adequate "tooth" is obtained for the specified material. Some of the common instruments are:

6.1.1.1 Surface profile comparator⁹ for visual comparisons of the profile against a reference disk for sand, grit, and shot blast-cleaned steel.

6.1.1.2 Depth micrometers with conical points to project into the valleys to determine profile depth.

6.1.1.3 Tape,¹⁰ to create an exact replica of the profile on a special material. The tape is measured in the field using a spring micrometer to determine average maximum profile height.

6.1.2 *Adhesion of Existing Coating*—The inspector should carry a pocket knife that can be used to determine the soundness of existing paint where there might be blistering or underfilm corrosion. This is a subjective test and its value depends upon the inspector's experience. The cross-cut test, Methods D 3359, is more reproducible.

6.1.3 *Portable Pull-off Adhesion Testers* are available. The apparatus measures the force required to remove a metal stud that has been cemented to the coated surface as described in Method D 4541.

6.2 *Field Inspection Equipment* in good working order should be available to the inspector so that he may perform his function properly.

6.2.1 *Drying and Curing Times*—These are both important considerations since drying time and curing time can both be affected. Minimum temperatures are required for reactive and water-borne coatings while too high a temperature can make application difficult. Inorganic zinc-rich primers and moisture-cure urethanes require certain minimum humidity conditions for proper cure. The manufacturer's recommendations must be followed.

6.2.1.1 *Thermometers*—The paint inspector may need several types of thermometers and should have at least an accurate pocket thermometer with a range from about 0 to 150°F (−18 to 65°C) for measuring the ambient air temperature. The same thermometer or a floating dairy thermometer may be used to determine the temperature of liquid coating, solvent, etc. The pocket thermometer may also be used for determining the temperature of metal surfaces by placing it against the metal while shielding the outer (away from the metal) side of the bulb by means of putty or similar material, so that the reading is not affected by the ambient temperature. Flat surface-temperature thermometers are also available for this purpose.

6.2.1.2 *Dew Point*—A psychrometer containing a wet- and dry-bulb thermometer for determining relative humidity and dew point is a useful inspection tool. Hand-held sling or electrical types are available as well as a direct reading digital type.

6.2.2 *Coating Consistency* is an important characteristic since durability is related to film thickness and whether a film of the proper thickness can be applied is partly controlled by consistency.

6.2.2.1 *Consistency Cups*—There are occasions, such as on-site thinning, when it is necessary to check paint consistency during field application. While giving only partial information about the viscosity of a coating, the Zahn cup is a portable device for checking quickly the approximate consistency of coatings and other liquids. It consists of a bullet-shaped, stainless steel cup with an orifice in the bottom. Attached to the cup is a looped handle with a small

ring at the top to align the cup in a vertical position when withdrawing it from the liquid being tested. To operate, the cup is completely immersed in the liquid to fill it and is then withdrawn rapidly and completely. The time in seconds for the liquid to escape through the orifice is an expression of viscosity, that is, Zahn Cup No. ____ () seconds. It should be noted that Zahn cups are not suitable for all coatings and have poor reproducibility (agreement between different cups is poor—see Test Method D 4212).

6.2.3 Weight-per-Gallon Cup—There are times when the inspector may wish to check the weight-per-gallon of the paint in the field. If the value is low compared to the paint specification, it indicates that unauthorized thinning has been done, while differing values from the same container show that the coating has not been thoroughly mixed for application. The weight-per-gallon cup holds a given quantity of water when filled at 77°F (25°C) or other specified temperature. It is made of corrosion-resistant material and has a closely fitted lid with a small hole in it. In use, the cup is filled with liquid slightly below the specified temperature. As the contents warm up, the excess escapes through the hole and is removed. The filled cup is wiped clean on the outside and weighed. A relatively inexpensive balance having a sensitivity of 0.1 g provides sufficient accuracy. The difference between the full and empty weights divided by 10 is the weight in pounds of 1 gal of the paint. Complete instructions for the procedure are given in Test Method D 1475.

6.2.4 Wet-Film Thickness Gages—This type of instrument is designed to measure the thickness of a wet film of paint *immediately* after it is applied to a surface. Note that erroneous readings may result when using the gage on fast-drying paints such as inorganic zinc. If a wet-film gage is used to determine the thickness of coats subsequent to the first, great care must be taken that partially hardened undercoats are not indented by the gage, thus giving high readings. If the coat being measured has an appreciable softening effect on the previous coat, a wet-film gage cannot be used with accuracy. It is very important to record test results and send a copy to the engineer.

6.2.4.1 Interchemical Gage—This instrument is rolled over the newly applied wet film on a *smooth* flat portion of the surface and the thickness read directly in mils (micrometres). Complete details are given in Method A of Methods D 1212.

6.2.4.2 Notched Gage—This device has a series of calibrated steps for measuring thin to heavy coats. The gage with the proper face is placed squarely on the fresh, wet film. It is then withdrawn perpendicularly *without a sliding movement*. The true wet-film thickness lies between the highest step coated and the next highest which was not coated. The procedure is described in Practice D 4414.

6.2.5 Dry-Film Thickness Gages—Dry-film thickness measurements are of great importance because the protection of the substrate is directly related to the thickness of the coating. There are two ways of making the measurements, nondestructively or destructively. The latter involves penetrating or cutting through the film to the substrate with a needle or blade and measuring by some means the distance between the top and bottom of the film. Because the dimensions are so small, some cuts are made at an angle in an attempt to increase the accuracy of the measurement.

This type of gage destroys the film at the inspection points, necessitating touch up with primer and finish to prevent corrosion at these spots. One kind of cutting gage is described in 6.2.5.1.

6.2.5.1 Tooke Gage—The Tooke inspection gage is designed to measure coating film thickness by microscopic observation of a cut into the film. The tungsten carbide cutting tip is specially shaped to slice a precise narrow groove through a film and into the substrate at an angle to the surface. Thickness of coating on any type of stable substrate may be determined and individual coats may be measured separately providing they are distinguishable, for example, by color. The coating cannot be too brittle or soft, otherwise the cutting tip will tear rather than precisely cut through the coating, making accurate readings impossible.

6.2.6 Nondestructive Film Thickness Gages are widely used for field and shop inspection. For ferrous metals they are based on magnetism, and for nonmagnetic metals on inductance and eddy currents. There are no satisfactory nondestructive methods for wood or other nonmetallic substrates. All of the different types require calibration with standards the thickness of which is known and in the same range as the coating to be measured. The calibration must be made on metal of the same kind, temper, thickness, and contour as that beneath the coating. Test Methods D 1186 and 1400 describe procedures. Measurements on relatively rough surfaces, such as a surface blasted to a high profile, may be misleading unless the instrument is calibrated on an identical surface.

6.2.6.1 Magnetic-Type Gages¹¹—Use either an electromagnet requiring a power supply or a permanent magnet. The principle of the method is that a nonmagnetic coating changes the magnetic force between the magnet and the magnetic base or the magnetic flux between the poles of the magnet. As the change is a function of distance from the metal, the gage can be made to read film thickness directly. Magnetic gages may be affected by the mass of the steel, or if electric welding is being carried out on a structure, for example, a ship's hull, at the time of measurement. Test Methods D 1186 describe the procedure for using magnetic gages. The method is also described in SSPC-PA 2 which includes instructions on the number of measurements for different areas and tolerances on the required film thickness.

6.2.6.2 Nondestructive procedures based on inductance and eddy current techniques are described in Test Method D 1400.

7. Coating Storage and Handling

7.1 Storage of Coating and Thinner—All coatings and thinners should be stored in areas or structures that are well-ventilated and not subject to excessive heat, open flames, electrical discharge, or direct rays of the sun. Storage should be in compliance with applicable regulations. Materials susceptible to damage at low temperatures must be stored in heated areas. If a coating is stocked for a consider-

¹¹ Type 1—Pull-off gages (such as Mikrotest, Inspector Thickness Gage, and the Pencil Pull-Off Gage, or Tinsley type gage); and Type 2—Fixed Probe Gages (such as Elcometer Thickness Gage, Minimeter, General Electric Type B Thickness Gage, Verimeter, Permascope, Dermatron, Positector, Certotest, Accuderm and Minitest) have been found suitable for this purpose.

able length of time (several months), it is desirable to invert the containers at monthly intervals. This will prevent hard settling and thus make mixing quicker and easier when the coating is to be used.

7.1.1 Coating containers should remain unopened until needed and the oldest should be used first. The manufacturer's written instructions should be followed regarding shelf life. Coatings that have livered, gelled, or otherwise deteriorated during storage should not be used. If a particular material is in question, do not use it until it has been tested by the manufacturer or independent laboratory and found to be satisfactory.

7.1.2 Where a skin has formed in the container, the skin should be cut loose from the sides of the container, removed and discarded. If it is felt that the skins are thick enough to have a practical effect on the composition, the remaining paint should not be used until it has been tested and found to be satisfactory.

7.2 *Mixing of Coatings*—All coatings must be thoroughly and completely mixed in clean containers before use. Where there is noticeable settling and mixing is done either by power stirrers or by hand, most of the vehicle should be poured off into a clean container. The pigment is then lifted from the bottom of the container with a clean broad, flat paddle, lumps broken up and the pigment thoroughly mixed with the vehicle present. The poured-off vehicle should be returned slowly to the original container with simultaneous stirring. It is also useful at this point to mix or pour repeatedly from one container to another (boxing) until the composition is uniform. The bottom of the original container should be inspected for unmixed pigment. The coating should not be mixed or kept in suspension by means of an air stream bubbling under the coating surface.

7.2.1 Some coatings may require straining after mixing to ensure homogeneity and to remove skins and foreign matter. The strainers should be of a type to remove only skins, etc., but not to remove pigment. For example, a 150-mesh (105- μ m) strainer is normally satisfactory for most coatings unless some specific size is required in the specification. Coatings should not remain in buckets, spray pots, etc., overnight, but be gathered into a container and remixed before use, provided the manufacturer's stated pot life will not be exceeded. Containers must be covered when not in use, to reduce volatile losses and skinning.

7.2.2 Coatings should be agitated enough during application to ensure homogeneity. Some materials may even require constant agitation during use.

7.3 *Thinning*—Some specifications permit field thinning of laboratory-accepted coatings while others do not. This section describes some commonly accepted procedures when thinning is permitted.

7.3.1 *Initial Samples*—When thinning on the job site is permitted and unless other arrangements have been made, (for example using manufacturer-supplied thinner from unopened containers and complying with manufacturer's written thinning instructions), the painting inspector may need to submit to an agreed-upon testing laboratory a 1-qt (1-L) sample from each batch to be thinned, together with a 1-qt sample of the thinner to be used using clean sample containers in both cases. With these samples a request is submitted for advice on the proper thinning rate for the

conditions prevailing and the consistency limits of the thinned coating.

7.3.2 *Thinning of Coating*—All additions of thinner must be made in the presence of the inspector and no other amounts or types of thinner than those permitted by the specification or manufacturer, or both, may be added. Thinning is carried out by pouring about half of the thoroughly mixed coating into an empty, clean container. The required thinner is then added and the two portions are boxed to obtain a homogeneous mixture.

7.3.3 *Sampling of Thinned Coating*—During the work, additional samples need not be submitted for testing unless a deviation is noted in the coating consistency or if it is suspected that there has been a change in the thinner.

7.3.3.1 When an inspector is qualified and has the necessary equipment available at the field office, arrangements may be made for on-site inspection of thinning and of the thinned coating. This speeds acceptance of a coating and lightens the laboratory workload. The inspector must keep a record of all paint modifications, amount of thinning, weight per gallon, and viscosity. Where dry-film thickness is specified, the inspector must calculate the new wet thickness necessary to obtain the desired dried thickness with the thinned coating. He should make frequent checks of wet-film thickness as work progresses, however compliance with the specification should be based on dry-film thickness where possible.

7.3.3.2 To determine the wet-film thickness of the thinned coating required to obtain the specified dried-film thickness, the percent volume of nonvolatile (solids) in the original coating must be known. This figure is readily obtained from the manufacturer. With this information the calculation may be made as follows:

$$W = D (1.0 \pm T)/S$$

where:

W = wet-film thickness,

D = desired dry-film thickness,

S = percent by volume of coating solids, and

T = percent by volume of thinner added.

7.4 *Heating of Coating*—Coatings as delivered in the manufacturer's containers and mixed thoroughly, are ready for use, unless the specification permits on-site thinning of high-viscosity material. Should the coating temperature be low, that is, 50°F (10°C) its consistency may increase to the point where application is difficult. Where thinning is not permitted, the coating may be heated. Should the contractor wish to reduce the viscosity by heating to make application easier, the containers may be warmed in hot water, on steam radiators, or by other acceptable indirect heating processes. In-line heaters are also available for application equipment. Direct application of flame to the containers is forbidden by fire regulations. It should be noted, however, that heating of the coating alone will not compensate for ambient or surface temperatures, or both, that are below the minimum specified for that material.

8. Weather Considerations

8.1 *Drying*—It is well known that most coatings, particularly those for structures, will not dry properly at low temperatures and high relative humidities, nor will they

protect if applied over wet surfaces.

8.2 Low Temperature—Many specifications indicate temperature limits between which painting may be undertaken either in the shop or in the field. The minimum ambient temperature is usually 40°C (5°C) or for cold-curing epoxy systems 50°F (10°C) with the temperature of the substrate above freezing. The requirements may state further that painting should not be undertaken when the temperature is dropping. However, some authorities believe that many solvent-borne coatings may be applied at (or below) 32°F (0°C) without adverse effects. Within the limitations of the composition of the coating, this may be satisfactory depending upon the type of coating and providing the surface is dry. Painting over ice or frost will result in early adhesion failure of the coating.

8.3 High Temperature—The maximum reasonable surface temperature for application is 125°F (50°C). A surface that is hot may cause the coating solvents to evaporate so fast that application is difficult, blistering takes place, or a porous film results. To keep the temperature down it is desirable, where practical, to paint under cover at a shop or to protect the surfaces from the sun with tarpaulins.

8.4 Moisture—Painting should not be undertaken in rain, snow, fog, or mist, or when the temperature of the metal surface is below the dewpoint. This is especially true in the spring and fall when days are warm and nights are cool. Wet surfaces should not be painted unless the coatings are specifically designed for that condition. Relative humidity is usually a good index of the acceptability of air conditions and specifications often contain an 85 % upper limit. If it is suspected that the temperature and humidity conditions are such that moisture is condensing upon the surface, the inspector may make the following test: Use a psychrometer to determine the actual relative humidity and dew point; compare the dew point with the metal temperature measured with a surface temperature thermometer. It is generally accepted that the surface temperature should be at least 5°F (3°C) higher than the dew point. A less accurate test is to lightly moisten a small area with a damp cloth and observe evaporation and drying; if the dampness decreases and evaporates within 15 min, the surface is considered satisfactory for the application of coating from the standpoint of dampness and condensation at that particular time.

8.4.1 When coatings must be applied in damp or cold weather, the substrate should be painted under cover, or protected from the surrounding air, and the steel heated to a satisfactory temperature. The steel should remain under cover until dry or until weather conditions permit its exposure in the open.

8.4.2 Applied coatings exposed to freezing, excessive humidity, rain, snow, or condensation should be permitted to dry. Damaged areas of coating should then be removed, the surface again prepared and painted with the same number of coats of the same kind as the undamaged area.

8.5 Wind—The wind direction and velocity must be considered when applying coatings in areas where airborne overspray could damage automobiles, boats, and structures nearby. Heavy winds result in considerable loss of coating and in excessive drying of the droplets reaching the surface. This results in an inability of the film to flow together and create a continuous barrier free of "holidays." Such condi-

tions can also create excessive amounts of dry spray that can interfere with adhesion of the applied or subsequent coats. These problems can be avoided by utilizing brush or roller application methods instead of spray, or scheduling the work at the less windy times of day, changing materials to the dry-fog types that do not adhere or damage adjacent property, scheduling the work so that if dry spray becomes attached to adjacent components it will not create a quality problem because it is attached to the final coat.

9. Coating Application

9.1 Residual Contaminants—Visually inspect the surface immediately prior to painting to ensure that spent abrasive, dust, and debris have been completely removed. Dust removal shall be considered satisfactory when the path left by a gloved hand wiped over the surface is barely discernible when viewed from a distance of 3 ft (1 m). During this inspection, also ensure that any oil or grease contamination that may have become deposited on the surface is completely removed. This is accomplished by solvent cleaning in accordance with SSPC-SP1.

9.2 Quality Assurance—The inspector must ensure that: (1) coatings received at the fabricators or in the field meet the description of the products acceptable under the requirements of the specification; (2) they are properly mixed and thinned (where allowed); (3) colors match a visual standard provided that proper precautions have been taken to prevent damage to adjacent areas from cleaning and painting operations; (4) working practices are so scheduled that damage to newly applied coating is minimized; (5) application equipment (brushes, spray) is acceptable for type, cleanliness, and usability; (6) weather conditions are acceptable under the requirements of the specification; (7) field-testing equipment on hand is in satisfactory working order ready for use; and (8) only the methods of application permitted under the specification are used and that their use is in accordance with 9.2.1 and 9.3 through 9.7. SSPC-PA1 is a specification for application of coating.

9.2.1 Film Defects—All coats should have nearly smooth, streamlined surfaces relatively free of dryspray, overspray, orange peel, fish eyes, pinholes, craters, bubbles, or other significant defects. Show through, insufficient hiding skips, and misses are not acceptable. Runs and sags should be brushed out during application. Abrasive, dirt, or other debris that becomes embedded in the paint film should be removed prior to the application of subsequent coats.

9.3 Brush Application—Painting by brush must be done in a neat, workmanlike manner to produce a smooth coat as uniform in thickness as possible. Coating should be worked into all irregularities in the surface, crevices, and corners. Runs, sags, or curtains should be brushed out. Surfaces that are inaccessible for painting with brushes and on which spraying is not permitted should have coating applied by means of sheepskin daubers. To provide adequate film thickness on places prone to premature breakdown, it is recommended that edges and corners of all metal work, rivet heads, bolts and nuts, and all individual members, bars, shapes, and plates should be striped by brush painting in advance of the application of coating to other parts.

9.3.1 Brushes must be of good quality with pliable bristles. They should not exceed 4 in. (100 mm) in width and the

bristle length should be no less than 3½ in. (90 mm). When not in use, the brushes should be kept in a clean, acceptable condition. The inspector may prohibit the use of any brush not in an acceptable condition.

9.4 Spray Application—Spray application may or may not be allowed. Often it is acceptable in fabricating shops but, because of the possibility of damaging surrounding property or coating films from overspray, it may not be permitted in the field. The inspector should be familiar with the different kinds of spraying, which are compressed air spray, airless spray, hot spray, and hot airless spray.

9.4.1 The equipment should be suitable for the intended purpose, capable of properly atomizing the coating to be applied, and be equipped with suitable pressure regulators and gages. The equipment must be kept in a suitably clean condition to permit proper coating application without depositing dirt, dried coating, and other foreign materials in the film. The air supply for conventional and hot spray application should be free of moisture or oil. Airless spray equipment should be properly grounded. Any solvents left in the equipment should be completely removed before applying coating to the surface being painted.

9.4.2 Coating ingredients must be kept properly mixed in spray pots or containers during coating application, either by continuous mechanical agitation or by intermittent agitation. Coating should be applied in a uniform layer, with overlapping at the edge of the spray pattern. The spray pattern should be adjusted so that the coating is deposited uniformly. During application the gun should be held at right angles (perpendicular) to the surface (not arced or fanned) and at a distance that will ensure that a wet layer of coating is deposited on the surface. The trigger of the gun should be released at the end of each stroke. Poor spray technique resulting in excessive overspray (or sand-like finish) should not be tolerated. All runs, sags, or curtains must be brushed out immediately or the coating will have to be removed and these areas repainted.

9.4.3 Usually brush striping of edges and other vulnerable locations as described in 9.3 is required. Brush or sheepskin daubers are used to coat all areas inaccessible to the spray gun and brushes and are used to work coating into cracks, crevices, and blind spots not adequately spray painted.

9.4.4 Particular care should be observed with respect to type and amount of thinner, coating temperature, and operating techniques in order to avoid depositing coating that is too viscous, too dry, or too thin when it reaches the surface.

9.5 Roller Application—Rollers that are clean and of a material not soluble in the coating to be applied should be used. Roller covers are available in a variety of diameters, lengths, type of fabric, and fiber lengths. The nap (length) used on metal surfaces generally varies from ¼ to ¾ in. (25 to 75 mm). The longer fibers hold more coating but do not provide as smooth a finish. Therefore their use is generally restricted to rougher surfaces and faster drying coatings. There are also specialized rollers available for use on pipes, fences, and even pressure rollers that continually feed the coating to the roller cover.

9.5.1 The roller cover should be dipped into the coating until it is saturated and then rolled along the tray ramp until the coating is completely wetted in. The first load of coating

on the roller should be applied to scrap material to force out air bubbles trapped in the nap. Proper roller technique requires application in the form of a V or W depending on the size of the area involved. The coating should then be cross-rolled to fill in the square created by the boundaries of the initial application. Only moderate pressure should be used as heavy pressure can cause foaming and possible cratering by entrapped air. Application should be finished with light perpendicular strokes in one direction (usually vertical) to provide the smoothest, most uniform finish.

9.6 Miscellaneous Methods—Methods such as pads, mitts, and squeegees or trowels are used for specialized products or in situations where the conventional methods are not suitable due to the location or configuration of the work.

9.6.1 Painter's pads generally consist of a roller-type synthetic fabric attached to a foam pad. The size is generally 4 by 7 in. (100 by 175 mm) and the fiber length is ¾ in. (5 mm). Application technique with a pad on large surface areas is similar to that used with a roller.

9.6.2 Painter's mitts are lamb skin gloves that are dipped into the coating and are rubbed across the surface. They are ideal for application of coatings to odd-shaped surfaces such as pipes and railings.

9.6.3 Squeegee or trowel application is generally used for heavy-bodied thick-film coatings that cannot be applied by spray.

9.7 Rate of Application—Properly written specifications require certain minimum and maximum dry-film thicknesses for each coat. The requirements should be augmented with wet-film thickness figures calculated from the composition of the coating so that the proper dry-film thickness is obtained. (Equation shown in 7.3.3.2.) Wet-film thickness figures are useful to the inspector since he can often check as the work progresses to determine reasonably well that the desired amount of coating is being applied. Later, when the films are dry, the inspector should make spot checks with a dry-film measuring gage to ascertain acceptability of the coatings. Film thickness measurements are more informative than visual inspection, which may show only obvious nonuniform application. Instruments for measuring film thickness and the procedures for their use are described in 6.2.5 and 6.2.6. Nondestructive dry-film thickness gages and measurements are applicable to metal substrates only.

9.7.1 Thickness or coverage requirements apply to the whole structure, not some specific part. It is important that the painting inspector check all areas and determine the film thickness for each coat. For instance, if the "shop coat" requires a minimum of 2 mils (50 µm) dry film, the inspector should ensure that it is obtained within the tolerances permitted in SSPC-PA2. The areas tested should be identified and recorded so that the dry thickness of added coating can be also determined. With nondestructive measuring instruments a 50-ft (15-m) long and 6-ft (1.8-m) high I-beam can be tested in 30 min and low areas if any, properly marked and recorded in the inspector's book. Because the shop prime coat inspector may not be the person doing the field coat application inspection, it is very important to record test results and send a copy to the field inspector in order to better determine thicknesses of subsequently applied coats.

10. Additional Considerations

10.1 *Ventilation*—It is essential when painting in enclosed spaces that adequate ventilation is provided for removal of solvents.

10.2 *Shopcoat Repair*—Normally after erection work, such as riveting, bolting, welding, straightening, etc., has been completed satisfactorily, areas of the shopcoat will be found to have been damaged. Damaged or bare areas must be thoroughly cleaned, prepared, and covered with one new coat of shop or field primer. In addition, crevices and small cracks should be thoroughly cleaned and spot-primed. After drying, the crevices and cracks should be filled with an acceptable caulking compound as required by the specification. The specified field coats should then be applied over the entire structure.

10.3 *Painting Schedule*—As indicated in 5.4.4, painting should proceed by sections, bays, or parts of the work, and each coat on each section should be applied entirely and accepted by the inspector before a succeeding coat is applied. Except for any shop coat touch ups made necessary by welding, etc., none of the metal that will be exposed to view in the completed structure is to be field-painted until all concrete has been placed. Care must be taken by the contractor during painting operations to protect concrete from being stained by the coating being applied. Any stained concrete surface must be restored to its intended color without damage to the concrete.

10.4 *Film Integrity*—Each coat should be applied as a continuous film of uniform thickness, free of holidays and

pores. Any thin spots or areas missed in the application should be repainted and permitted to dry before the next coat is applied.

10.5 *Recoat Time*—Each coat must be dried throughout the full thickness of the film before application of the succeeding coat. Coating is considered dry for recoating when the next coat can be applied without the development of any detrimental film irregularities such as wrinkling, lifting, or loss of adhesion of the previous coat. For most coatings the time to dry for recoat, even under optimum conditions varies with their composition and that of the subsequent coat. Thus, an oil-based coating may take 2 to 4 days to harden sufficiently to be overcoated with a coating of the same type. However, it may take 3 or 4 months to harden to be satisfactorily overcoated with a vinyl coating or other type of coating containing strong solvents. The coating manufacturer's literature should be consulted for recoat times.

10.6 *Coating System Failure*—Failure of completed coating work may be the result of several factors. Most obvious is noncompliance with the specifications indicating insufficient inspection of surface preparation, coating quality, coating application, or conditions during application and drying/curing. On the other hand, failure may be due to improper specification of coatings for the intended use. Defective coatings should be removed in their entirety, the surface recleaned, and the specified coatings, or their alternatives, applied.

APPENDIX

Nonmandatory Information

X1. INSPECTION CHECKLIST

X1.1 The checklist in Fig. X1.1 lists the key elements to be used for inspection of industrial coating work. Many of the details covered may be in a specification for a particular

project. A job specification for painting should include the coatings to be used. The various items are explained in detail in the text of this guide.

TASK

I Surface Condition Examination 1 Condition of edges, weld splatter 2 Grease or oil, or both 3 Chalk, mildew 4 Protective coverings in place 5 Air temperature 6 Surface temperature 7 Wind direction, velocity 8 Dew Point, RH 9 Visible moisture	I Surface Condition: 1 Visual observation and touch 2 Visual observation and clean white rag 3 Visual observation and magnifying glass 4 Visual observation 5 Air thermometer 6 Surface thermometer 7 Current weather report 8 Sling psychrometer 9 Direct observation	I Cleanliness —Many materials if not removed from the surface will affect the life of the coating. These include oil, grease, soil, weld spatter and slag which make it impossible to obtain proper adhesion to the metal surface (5.2.1, 5.4). Careful observation is the key to making certain that a sound surface is available for painting. Factors are listed which will affect job quality (9.1).
II Safety on the Job: Protective clothing Respirator Safety glasses Ear protection	II Safety on the Job: OSHA Hazard Communication Standard Product MSD sheets Municipal and state regulations	II There are a number of hazards associated with any painting operation; safety regulations must be observed and unsafe conditions or practices should be reported promptly to management (1.2, 5.3).
III Blast Cleaning: 1 Type and size abrasive 2 Clean and dry abrasive 3 Recycled abrasive test 4 Compressed air check 5 Nozzle air pressure	III Blast Cleaning: 1 Sieve analysis and visual observation 2 Visual observation 3 Water test 4 White blotter 5 Pressure gage	III Blast cleaning is used to remove foreign materials from a metal surface and to provide a roughened surface by means of a dry sand, grit, or shot blast impinging the surface with hard abrasive particles impelled by air (5.3.4). The minimum and maximum particle size of the abrasive are specified as a means of controlling the surface profile. Precautions must be taken that blasting equipment is operated properly (5.2.3).
IV Surface Preparation: 1 Dust and abrasive removal 2 Degree of cleanliness	IV Surface Preparation: 1 Visual observation 2 <i>Pictorial Standard D 2200</i> should be used by the inspector on a job involving painting of structural steel to determine whether the degree of surface preparation specified in a contract has been attained by the contractor (5.1.1).	IV Surface preparation is one of the most important factors affecting the performance of paint. The specifier will determine the proper level according to the expected service life of the structure and type of paint specified (5.1). <i>Surface Profile</i> —The texture of the metal surface has a significant effect on the performance of coatings since it increases the surface area to which the coating can develop adhesion.
3 Profile measurement	3 Keane-Tator comparator for visual comparisons of the profile against a reference disk for sand, grit, and shot-blast-cleaned steel (6.1.1). Testex Press-O-Film tape is used to create an exact replica of the profile on a special material. The tape is measured in the field using a spring micrometer to determine average maximum profile height.	
4 Magnetic base reading	4 Magnetic thickness gage (6.2.6)

- 4 Visual observation
- 5 Record
- 6 Visual observation
- 7 Visual observation
- 8 Record coatings batch numbers mixing procedure
- 9 Visual observation
- 10 Visual observation
- 11 Film thickness gages

Wet (Notched Gage)—This device has a series of calibrated steps for measuring thin to heavy coats. The true wet-film thickness lies between the highest step coated and the next highest that was not coated. This method is not as accurate as the interchemical gage.

Interchemical Gage—This type of instrument is designed to measure the thickness of a wet film of paint.

Nondestructive Film Thickness Gages are widely used for field and shop inspection. For ferrous metals they are based on magnetism, and for nonmagnetic metals, inductance and eddy currents. See guide for discussion of types.

Dry (Tooke Gage)—The Tooke paint inspection gage is designed to measure paint film thickness by microscopic observation of a cut into the paint film.

- 12 Record time application completed
- 13 Tape test D 3359
- 14 Holiday detector

VI Recordkeeping:

Inspector's log book

V Many factors are important in ensuring proper application of coatings. The details are covered in this guide (Section 9). In particular, note: Dry-film thickness measurements are of great importance because the protection of the substrate is directly related to the thickness of the coating. There are two ways of making the measurements, nondestructively or destructively (6.2.5).

VI Maintenance of a record book containing all transactions between the inspector and the contractor is essential to eliminate contract disputes. Details of the many steps involved in proper coatings application must be recorded (Section 4).

FIG. X1.1 Inspection Checklist (continued)

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Test Method for Formability of Attached Organic Coatings with Impact-Wedge Bend Apparatus¹

This standard is issued under the fixed designation D 3281; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method describes a method of evaluating the formability of organic coatings intended for application to strip metal substrates by coil-coating or other factory application methods.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Significance and Use

2.1 This test method is designed to provide a uniform procedure for determining the degree of flexibility and adhesion of factory-applied organic coatings on strip metal.

2.2 It should be recognized that some metal substrates will crack during forming and that the organic coating may crack accordingly.

3. Apparatus

3.1 *Impact-Type Wedge Bend*, assembly illustrated in Fig. 1.² The instrument contains a 4-lb (1.82-kg) impactor rod with one flat end that slides in a vertical slotted guide and serves as a falling weight to hammer the wedge mandrel with the flat end. A knurled cover inserted in the wedge mandrel impact test hole serves as the impact point. When positioned properly the lifting knob on the impactor coincides with the zero mark on the guide tube. The spacer block is removed from the front edge of the wedge mandrel so that the taper is 0 to $\frac{1}{8}$ in. (0 to 3.2 mm) front to back.

3.2 *Cellulose Adhesive Tape*, $\frac{3}{4}$ in. (20 mm) wide.

4. Test Specimens

4.1 Suitable substrates for the test specimen (including thickness) shall be employed and agreed upon between the purchaser and the seller (Note 1). The dimensions of the base metal panel shall be 4 in. (100 mm) in width, with a maximum length of 12 in. (300 mm). The surface preparation of the base metal shall be agreed upon between the

purchaser and the seller. Prior to application of the coating, edges of the specimens that will be bent in the test shall be rounded slightly to remove burrs in order to eliminate effects associated with cracking of a sharp metallic edge when bent.

NOTE 1—When metal thickness exceeds 0.025 in. (0.64 mm), complete compression of the bend may not occur with a single impact.

4.2 The coating under test shall be applied to the clean base metal after the agreed-to surface preparation of the metal substrate has been completed. The coating shall be applied to one or both sides of the metal (as specified) in a manner that will provide a uniform coating thickness. The dry film thickness shall not vary more than 0.1 mil ($\pm 2.5 \mu\text{m}$) from the specified thickness agreed upon between the purchaser and the seller. The method of application, the cure of the film, the time between the application of the coating and the testing of the specimen, as well as the temperature and humidity environment used for aging the film during this period, shall be agreed upon between the purchaser and the seller.

5. Conditioning and Number of Tests

5.1 Test at least three replicate specimens under the conditions of temperature and humidity mutually agreed upon between the purchaser and the seller. Unless otherwise specified by the purchaser and the seller, make measurements at $73.5 \pm 3.5^\circ\text{F}$ ($23 \pm 2^\circ\text{C}$) and $50 \pm 5\%$ relative humidity after equilibrating at these conditions for at least 24 h.

6. Procedure

6.1 Place the specimen, coated side down, under the $\frac{1}{8}$ -in. (3.2-mm) cylindrical mandrel. Slide the specimen to the rear of the mandrel platform until the edge is flush with the two studs located at the rear of the platform.

NOTE 2—Since the test is usually more severe if the panel is bent parallel to the original rolling direction of the base metal, the direction of the bend with respect to the "grain" of the base metal should be agreed upon between the purchaser and the seller and reported.

6.2 Raise the remainder of the panel at a uniform velocity to bend the specimen 170 to 180° in a time not to exceed 5 s.

6.3 Slide the spacer located under the impact platform to the extreme front of the tester and tighten it in place with the adjustment screws provided. This allows the impact platform to create a wedge that provides stress angles between 170 and 180° .

NOTE 3—The end of the specimen with the 180° stress angle is defined as having a zero T (OT) bend.

6.4 Center the bent specimen under the impact platform. Place the longest segment of the specimen downward.

¹ This test method is under the jurisdiction of ASTM Committee D-1 on Paint and Related Coatings and Materials and is the direct responsibility of Subcommittee D01.53 on Coil Coated Metal.

Current edition approved April 27, 1984. Published December 1984. Originally published as D 3281 - 73. Last previous edition D 3281 - 73 (1979).

² The Gardner Coverall Impact Tester available from BYK-Gardner, Inc., Gardner Laboratory, 2435 Linden Lane, Silver Spring, MD 20910, has been found satisfactory for this purpose. Use of other equipment should be agreed upon by the purchaser and seller.

6.5 Predetermine the load required to result in a OT bend (180°) and run all tests using the same substrate at this load. The wedge bend required shall be obtained with a single impact representing the minimum force to obtain a OT bend.

6.6 After impact, remove the specimen and visually inspect without magnification the bent portion for cracking and adhesion loss, starting at the most severe bend and progressing outward.

6.7 Measure the distance fractured (cracking) from the edge of the most severe bend outward to the edge with the least severe bend in inches or millimetres.

NOTE 4—Disregard heavy beads of coating on the edges.

6.8 Determine film adhesion loss by firmly applying the adhesive tape to the entire bend area and then removing the tape in a uniform rapid motion. The time between the first bending of the specimen and removal of tape shall not be less than 1 nor more than 5 min. Start removal from the edge of most extreme bending (OT edge) and remove the tape rapidly in a motion parallel to the surface of the longitudinal edge of the bend, such that the tape is pulled back upon itself.

6.9 Examine the taped area and measure the amount of film removed. It should be noted that the primary concern of this rating is the maximum distance of adhesion failure.

7. Precision

7.1 On the basis of an interlaboratory study of this test method in which two operators in each of five laboratories measured two replicates on two days for cracking and adhesion, the standard deviations within and between laboratories were found to be as follows:

	Standard Deviation	
	Cracking, mm	Adhesion, mm
Within laboratory	2.0	3.9
Between laboratory	4.7	10.0

Based on these standard deviations, the following criteria should be used to judge the precision of results at the 95 % confidence level:

FIG. 1 Coverall Impact Tester

7.1.1 *Repeatability*—Two measurements obtained by the same operator should be considered suspect if they differ by more than

Cracking, mm	5.8
Adhesion, mm	11.4

7.1.2 *Reproducibility*—Two measurements, each the mean of duplicate measurements, obtained in different laboratories should be considered suspect if they differ by more than

Cracking, mm	16.8
Adhesion, mm	35.7

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Practice for Testing Primers and Primer Surfacer Over Preformed Metal¹

This standard is issued under the fixed designation D 3322; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers the selection and use of procedures for testing primers and primer surfacers. The test methods included are listed in Table 1.

1.2 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

D3359 Test Methods for Measuring Adhesion by Tape Test⁵

D3456 Practice for Determining by Exterior Exposure Tests the Susceptibility of Paint Films to Microbiological Attack⁵

2.2 Federal Test Methods:¹⁰

141B/6011 Immersion Resistance

141B/6271.1 Mildew Resistance

141B/6321 Sanding Characteristics

2.3 U.S. Military Specification:

MIL-P-46105¹⁰

3. Terminology

3.1 Definitions:

3.1.1 *primer*—the first of two or more coats of paint, varnish, or lacquer system (same as in Terminology D 16).

3.1.2 *primer surfacer*—a pigmented coating for filling minor irregularities which is sanded to obtain a smooth uniform surface preparatory to applying finish coats. A primer surfacer is not usually applied over a primer.

4. Significance and Use

4.1 Primers and primer surfacers may be used over many

different surfaces top coated with one or more of a variety of coatings and subjected to many kinds of wear and exposure.

4.2 The selection of the tests to be used for any given product or system must be governed by experience and by the requirement agreed upon between producer and user.

5. Panel Preparation

5.1 *Treatment of Substrate*—Preparation of test panels should include any cleaning treatment agreed upon between purchaser and seller or one of the following ASTM Practices: D 609, D 1730, D 1731, D 1732, D 1733 and D 2092, and Test Method D 2201.

5.2 *Substrate, Film Thickness and Application Means*—Conduct performance tests on the specified substrate on coatings having a film thickness agreed upon between the purchaser and seller. Primers are generally applied to a dry film thickness of 0.3 to 1.5 mils (8 to 38 μ m) and primer surfacers to film thickness of 0.7 to 2.0 mils (17 to 50 μ m). Unless otherwise agreed upon, apply primers and primer surfacers in accordance with Test Method D 823.

5.3 *Measurement of Film Thickness*—Since the properties of the primer or primer surfacer can vary considerably with the thickness of the coating, it is important to know the film thickness. Measure the film thickness in accordance with Test Methods D 1400, D 1005, or D 1186.

5.4 Drying of Primer or Primer Surfacers:

5.4.1 Before tests are run, air dry or bake the primer or primer surfacer according to the schedule and temperature and age as agreed upon between the purchaser and seller.

5.4.2 Overbake the primer or primer surfacer to determine the time/temperature effect on the physical and chemical properties. Do this in accordance with Practice D 2454.

5.4.3 It may be desirable for some reason (handling, stacking, etc) to determine the various stages and rates of film formation in the drying or curing of primers and primer surfacers at room temperatures. Do this as described in Test Method D 1640.

6. Physical Properties of The Dry Film

6.1 Primers and primer surfacers are usually (but not always) topcoated. Therefore, many of the following tests should be run on the complete system (substrate/primer or primer surfacer/topcoat). Some of the tests however are for the untopcoated primer or primer surfacer. The properties required of a primer or primer surfacer depend on the intended end use and the tests to be used should be selected on the basis of experience and agreed upon between the purchaser and seller.

6.2 *Abrasion Resistance*—Determine the abrasion resistance as described in either Test Method D 658 or D 968.

6.3 Adhesion:

6.3.1 The primer or primer surfacer of a specified substrate as agreed upon by the purchaser and seller is subjected to an adhesion test to determine the degree of attachment the coating has to the substrate.

6.3.2 Determine the adhesion of the primer or primer surfacer as described either in Test Methods D 2197 or D 3359.

6.3.3 The above methods, in addition to measuring the adhesion of the coating to the substrate, can also be used to determine the intercoat adhesion between the topcoat and

¹⁰ Available from Standardization Documents Order Desk, Bldg. 4 Section D, 700 Robbins Ave., Philadelphia, PA 19111-5094.

the primer or primer surfacer.

6.4 Chemical Resistance:

6.4.1 Coating systems frequently come into contact with various chemicals that may have an effect on the properties of the system. Failure when it occurs is usually in the form of discoloration, change in gloss, blistering, softening, swelling, dissolving, or loss of adhesion. Unless a primer is to be left untopcoated in actual service, primers and primer surfacers should be topcoated with the appropriate product before undergoing chemical resistance tests.

6.4.2 *Household Chemical Resistance*—Determine the effect of chemicals in accordance with Test Method D 1308.

6.4.3 *Detergent Resistance*—Determine the resistance to failure under conditions of immersion in a detergent solution in accordance with Practice D 2248.

6.4.4 *Hydrocarbon Resistance*—Test hydrocarbon resistance in accordance with Method 6011 of U.S. Federal Test Method Standard No. 141B.

6.5 *Chip Resistance*—The chip resistance of a primer or primer surfacer is the ability of a film to withstand sudden impact from stones, gravel, etc, without being loosened from the substrate. Determine chip resistance by Test Method D 3170.

6.6 *Color Difference-Pigmented Dry Film*—The color differences between two similarly homogeneously colored, opaque film such as those formed by primers or primer surfacers may be determined using visual evaluating techniques or by instrumental means. Determine color differences visually using Practice D 1729. Determine color differences instrumentally using Test Method D 2244.

6.7 *Cracking Resistance*—A test for resistance to temperature and humidity changes, or a cold cracking test as it is sometimes called, is designed to give an indication of the resistance of a coating system to cracking or checking caused by temperature and humidity changes and also by aging. The degree of correlation between accelerated crack results and long term room temperature aging varies with the types of coating. The industry uses the test widely and it is felt that a system showing good cold crack resistance will perform satisfactorily in service. Some factors that can affect results are type of substrate, substrate thickness, primer, primer surfacer, topcoat, and film thickness of the different coatings. Determine cracking resistance in accordance with Test Method D 2246.

6.8 *Elongation*—An elongation test may be used as an indication of the flexibility of an attached primer or primer surfacer. It can also show whether there is any change during aging. Determine elongation by Test Methods D 522 or D 1737.

6.9 *Filiform Corrosion Resistance*—Filiform corrosion is a type of corrosion that occurs under coatings on metal substrates and is characterized by a definite thread-like structure and directional growth. Determine the susceptibility of organic films over metal substrates to this type of corrosion by Test Method D 2803.

6.10 *Gloss*—Determine the gloss of primers and primer surfacers in accordance with Test Method D 523.

6.11 *Hardness*—Determine the film hardness of primers and primer surfacers in accordance with Test Methods D 1474, using either Test Method A (Knoop indentation hardness) or Method B (Pfund indentation hardness) as

agreed upon by the purchaser and seller. Other methods of determining hardness may be used as agreed between purchaser and seller.

6.12 *Holdout*—Holdout is the ability of a primer or primer surfacer to give a smooth (nonporous), uniform appearance when topcoated. This property can be evaluated visually or by instrumental means. One method of measuring for holdout is described in Test Method C 540.

6.13 *Mildew Resistance*—Test mildew resistance in accordance with Method 6271 of U.S. Federal Test Method Standard No. 141B or Practice D 3456.

6.14 Outdoor Exposure:

6.14.1 Primers and primer surfacers can have an important effect on the durability of any paint system destined for exterior use. While the accelerated tests given in other sections of this recommended practice are intended to enable one to predict performance, actual outdoor exposure should be made. Usage of paint systems is so varied that no one set of conditions (length of exposure or place of exposure) can be given in this practice to cover all situations. These conditions as well as the type of substrate, substrate preparation, etc should be agreed upon between the purchaser and the seller. However, it is suggested that, unless otherwise agreed upon, prepare panels for outdoor exposure in accordance with Section 4 of this practice.

6.14.2 Many properties of organic coating systems should be evaluated periodically throughout the outdoor exposure period. Where failures occur on a topcoated system, experience is required to determine whether or not the primer or primer surfacer is involved. Properties most likely to involve the primer or primer surfacer may be evaluated as follows: Blistering, Test Method D 714; Cracking, Test Method D 661; Rusting, Test Method D 610; Checking, Test Method D 660.

6.15 *Print Resistance*—A print test can be used to determine the degree of thermoplasticity or solvent retention of a film and hence whether the product can be safely stacked or packaged and, in the case of a thermoplastic film, at what temperature the film prints or mars. A print test can also be used to determine the degree of marring due to pressure. Determine the imprinting and thermoplasticity of primer or primer surfacer films as described in Test Method D 2091.

6.16 *Salt Spray Resistance*—Salt spray testing of coatings is helpful in determining their resistance to failure in service under conditions of high humidity and salt concentrations. Under accelerated conditions of laboratory testing the temperature, the pH, the concentration of the salt solution and other physical properties can be controlled. The selection of the substrate, the application technique, the choice of the topcoat, the manner in which the coating is scribed, the location or position of the panels within the cabinet, the length of the test, the inspection of panels and the method of reporting results must be agreed upon between the purchaser and seller. Test for salt spray resistance in accordance with Method B 117.

6.17 Sanding Properties:

6.17.1 Sanding properties are normally expected of primer surfacers only. Method 6321 of U.S. Federal Test Method Standard No. 141B covers this property.

6.17.2 Prepare and dry a film of the material to be tested as specified in the product specification. Scuff the surface of

the dried film manually with 400 softback sandpaper. Examine the film for gouging and deep scratches and determine whether there has been any clogging of the sandpaper. Depending on the end use of the primer surfacer involved, other methods of sanding may be used as agreed upon by the purchaser and seller.

6.18 Water Resistance:

6.18.1 Testing of coating systems with water is helpful in determining their resistance to failure under conditions of high humidity or water immersion. Failure in water tests is usually evidenced by blistering, dulling, softening or loss of

adhesion which does not disappear or recover upon evaporation of the absorbed water.

6.18.2 Determine the resistance to failure under conditions of high humidity in accordance with Practice D 1735.

6.18.3 Determine the resistance to failure under conditions of water immersion in accordance with Practice D 870. This test is best suited for coating systems that will actually be soaked in water during service.

6.19 Weldability—In some instances it is necessary to weld metal that has been primed. The welding characteristics of a primer or primer surfacer may be tested in accordance with U.S. Military Specification MIL-P-46105 (MR), Section 4.4.11.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Guide for Testing Interior Solvent-Reducible Flat Wall Paints¹

This standard is issued under the fixed designation D 3323; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

^{ε1} NOTE—Editorial changes were made throughout, including the title, in October 1988.

1. Scope

1.1 This guide covers the selection and use of procedures for testing interior solvent-reducible flat wall paints, such as alkyd or other solvent-thinned finishes. The test methods included are listed in Tables 1 and 2. All of these test methods may not be required for each paint. Selection of the test methods must be governed by experience and the requirements in each individual case, together with agreement between the purchaser and seller.

1.2 This guide covers the testing of ready-mixed finish coats for application by brushing, roller coating, spraying, or other methods, on wood, plaster, wallboard, masonry, previously painted surfaces, and other interior architectural surfaces.

3. Definitions

- 3.1 For definitions of terms in these practices, refer to Definitions D 16 and D 1554.

4. Conditions Affecting Solvent-Thinned Flat Wall Paint Topcoats

- 4.1 Practical requirements and performance of solvent-thinned flat wall paints may vary with:
 - 4.1.1 *Substrate Type*, such as type and quality of wood or

hardboard, wallboard and joint cement systems, alkalinity, type and quality of plaster, and type and quality of old paint.

4.1.2 *Substrate Conditions*—Smoothness of substrate and quality of topcoat will affect spreading rate, final appearance, and texture.

4.1.3 Type and quality of primer and the time before topcoating.

4.1.4 Environmental conditions, such as temperature and humidity, at the time of paint application and during drying.

5. Sampling

5.1 Prior to sampling, the condition of the container should be established since damage to it may cause evaporation, skinning, or other undesirable effects in the coating. Determine the condition of the paint in accordance with 6.1 and 6.2.

5.2 Sample in accordance with Section 4.2.1 of Method 1021 of Federal Test Method No. 141. Determine the weight per gallon in accordance with Test Method D 1475. Repeat this procedure until successive values agree within 0.1 lb (45 g) or as agreed upon between the purchaser and the seller. Then take samples for testing.

5.3 Specify the amount of sample, the package sizes, and identification codes to assure a representative sample. A

Volatile content	10.2	D 2369	4041, 4042
Washability	9.2.2	...	6141
Water content	10.3	D 1208	4081
Weight per gallon	6.5	D 1475	4184
Working properties	7.7	...	4541
Yellowness index	9.5	E 313	6131

1-gal (4-L) sample is usually sufficient for the recommended tests, but for guidance in selecting a sampling plan, consult Recommended Practice E 105.

6. Liquid Paint Properties

6.1 Skinning—Paints containing a binder which dries by oxidation are subject to skin formation in a partially filled can. Since skins are insoluble in the paint, they must be removed before use. This test in a partially filled container indicates the tendency of a paint to skin. Examine the original sample for skins, both on the surface and in its mass. On a well-mixed, skin-free portion of the sample, perform a skinning test in accordance with Guide D 154.

6.2 Condition in Container—Thickening, settling, and separation are undesirable and objectionable if the paint cannot be reconditioned with a reasonable amount of stirring. The referenced method covers procedures for determining changes in properties of paints after storage. Determine the condition in the container in accordance with Method 3011 of U.S. Federal Test Method Standard No. 141.

6.3 Coarse Particles and Foreign Matter—Paints must be free of coarse particles and foreign matter to form a uniform film of good appearance, a typical maximum being 1 weight % of the total paint. Determine the percent of coarse particles and foreign matter in accordance with Test Method D 185.

6.4 Fineness of Dispersion—The more finely a pigment is dispersed the more efficiently it is being utilized. One method for measuring the degree of dispersion (commonly referred to as "fineness of grind") is to draw the product

down a tapered groove varying in depth from 4 to 0 mils (100 to 0 μ m). The point at which continuous groupings of particles or agglomerates, or both, protrude through the surface of the wet film is taken as the dispersion reading. Higher readings in Hegman units or lower readings in mils or micrometres indicate better dispersion. Determine the fineness of dispersion in accordance with Test Method D 1210.

6.5 Weight per Gallon—The density of a paint as measured by weight per gallon or kilograms per litre is used to assure product uniformity, batch to batch, and provides a check against the theoretical weight calculated from the formula. The density is expressed as the weight in pounds avoirdupois of 1 U.S. gal of the paint at a specified temperature. Determine weight per gallon or kilograms per litre in accordance with Test Method D 1475, using a calibrated weight per gallon cup.

6.6 Consistency—Paints of a given type should fall within a stated consistency range for satisfactory reproduction of a specific formula. In the referenced test method, consistency is defined as the load in grams required to produce the specified rate of shear. Determine consistency in accordance with Test Method D 562.

6.7 Flash Point—When the flash point of a material is required for shipping information, use Test Methods D 1310, D 3278, or D 93.

6.8 Color Acceptance—This method gives an indication of the ability of the paint to be tinted with tinting systems in common use. Determine color compatibility as agreed upon between the purchaser and seller.

6.9 Rheological Properties of Non-Newtonian Materials—Rheological properties are related to application and flow

properties of the liquid paint. The referenced test method covers the determination of the rheological properties and is particularly suited for use with paints that display thixotropic characteristics. Determine the rheological properties in accordance with Test Method D 2196.

6.10 *Absorption*—This method provides a rapid determination of the relative penetration of the binder into the surface. It provides a rough measure of the wetting and penetrating properties of liquid materials. Loss of binder and the resultant change in pigment volume, as the film dries, are indicated by this test. Determine the absorption in accordance with Method 4421 of U.S. Federal Test Method Standard No. 141.

7. Paint Application and Film Formation

7.1 *Application of Brushed Films*—Refer to Method 2131 or 4321 of U.S. Federal Test Method Standard No. 141 to determine the brushing properties of a coating. Method 4321.1 is quite subjective although someone experienced in the art can obtain consistent results, particularly in the determination of the "drag" properties.

7.2 *Applications of Sprayed Films*—Refer to Method 2131 or 4331 of U.S. Federal Test Method Standard No. 141 to determine the spraying properties of a coating. Method 4331 is very subjective and should be performed by an individual skilled in the art of using spray equipment.

7.3 *Drying Time*—The drying time of an interior finish is important in determining when a freshly painted room can be put back to use. The test can also be used to determine whether or not the drying properties of a paint have changed during storage. Any one or several of the test methods that cover the determination of the various stages and rates of film formation in the drying or curing of organic coatings may be used. For example, if two coats are specified, the determination of "dry-to-recoat" times will be important. Determine the appropriate drying time in accordance with Test Method D 1640.

7.4 *Leveling Properties*—Leveling is an important factor when smooth surfaces are to be produced. The referenced test method covers the laboratory determination of the relative leveling characteristics of liquid coatings. Determine leveling characteristics in accordance with Test Method D 2801.

7.5 *Producing Films of Uniform Thickness*—Method D 823 covers the preparation of coating films of uniform thickness essential in conducting tests.

7.6 *Roller Coating Properties*—The referenced method outlines a procedure for making an evaluation of a material's characteristics when applied by a roller. Determine roller coating properties in accordance with Method 4335 of U.S. Federal Test Method Standard No. 141.

7.7 *Working Properties*—Working properties of a paint are generally compared to a standard or described by requirements in the product specification. Determine working properties in accordance with Method 4541 of U.S. Federal Test Method Standard No. 141.

8. Appearance of Dry Paint Film

8.1 *Color Difference of Opaque Materials by Visual Comparison*—Visual comparison of color is fast and often acceptable. The referenced practice covers the spectral,

photometric, and geometric characteristics of light source, illuminating and viewing conditions, sizes of specimens, and general procedures to be used in the visual evaluation of color differences of opaque materials. Determine color difference in accordance with Practice D 1729.

8.2 *Color Differences of Opaque Materials by Instrument Evaluation*—Color difference between a product and the standard can be measured by instrument. The referenced method covers the instrumental determination of small color differences, observable in daylight illumination, between nonfluorescent, nonmetameric, opaque surfaces such as paint specimens. If metamerism is suspected, visual evaluation (8.1) should be used to verify instrumental results. Determine the color difference in accordance with Method D 2244.

8.3 *Specular Gloss (Sheen)*—The test method given, using the 85° geometry, is useful in characterizing the low angle appearance of flat paints. Determine 85° gloss in accordance with Test Method D 523.

8.4 *Hiding Power*—Hiding power is a measure of the ability of a coating to hide the substrate. It is, however, dependent on uniform film thickness which is influenced by the flow, leveling, and application properties of the enamel. Test Method D 344 uses brush application and compares the enamel to a standard. Test Method D 2805 uses an applicator bar and is more reproducible and measures smaller differences than D 344. Determine hiding power in accordance with Test Methods D 344 or D 2805.

9. Properties of Dry Paint Film

9.1 *Adhesion*—Measure the adhesion of the paint by testing in accordance with Test Method D 2197.

9.2 *Cleanability*—The ability to remove marks satisfactorily without damaging the film is important with interior finishes.

9.2.1 *Scrub Resistance*—The test for scrub resistance of interior latex flat wall paint can be applied to the solvent-thinned type. Use Test Method D 2486.

9.2.2 *Washability*—The referenced method determines the washability of a paint by subjecting a soiled film of the dried paint to the cleaning action of a wet sponge and cake grit soap. Determine the washability in accordance with Method 6141 of U.S. Federal Test Method Standard No. 141.

9.3 *Elongation*—Elongation is a measure of flexibility of a paint film. Determine elongation in accordance with Test Methods D 1737 or D 522.

9.4 *Fume Resistance*—Some paints exhibit a change in appearance (usually color) when subjected to foul atmospheres, for example, air containing certain sulfur compounds. There is no standard test method for determining the ability of a paint to resist this change.

9.5 *Yellowness Index*—The referenced test method is used for white or near white specimens to determine color departure from white toward yellow or color change towards yellow on exposure or treatment. Determine the yellowness index in accordance with Test Method E 313.

10. Analysis of Paint

10.1 If a specification requires certain raw materials or certain components in a given amount, then chemical

analysis is required. Chemical analysis determines whether the specified components are present and if they are, in what amounts. It does not necessarily establish paint quality which can be greatly affected by manufacturing techniques. No single schematic analysis is comprehensive enough to cover the wide variety of materials used in paint compositions.

10.2 Volatile Content—The percent of volatile matter indicates the thinner loss from the film as it dries. The referenced test method covers the determination of the volatile content of solvent-type paints. The quantity determined subtracted from 100 % gives the nonvolatile content of the coating. Determine the volatile content in accordance with Test Method D 2369.

10.3 Water Content—The referenced test method covers the determination of water in paint and related materials by distilling the sample with a volatile solvent. Determine water content in accordance with Test Method D 1208.

10.4 Pigment Content—Pigment provides the hiding and color and influences many other properties of a coating. The referenced test method describes the procedure for the quantitative separation of the vehicle from the pigment in solvent-type coatings. It is used to determine the weight percent pigment in the paint. Determine the pigment content in accordance with Test Method D 2371.

10.5 Separation of Vehicle—The recommended procedure describes the separation of vehicle from certain solvent-type paints. The separated vehicle is subjected to further analysis. Separate the vehicle in accordance with Method D 2372.

10.6 Identification of Vehicle Solids—The suggested method covers the qualitative characterization or identification of separated paint vehicle solids by infrared spectroscopy. It is useful in detecting uniformity, batch to batch, and the presence of adulterants. Characterize vehicle solids in accordance with Method D 2621.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

1. Scope

1.1 This standard covers the determination of volatile matter, water, pigment, and vehicle content in liquid coatings by gravimetric methods. It is not applicable to solid coatings. It is not applicable to coatings that require the use of reagents.

1.2 This standard covers the determination of volatile matter, water, and lacquer content in liquid coatings that are applied to a surface.

1.3 This standard covers the determination of volatile matter, water, and lacquer content in liquid coatings that are applied to a surface.

1.4 This standard covers the determination of volatile matter, water, and lacquer content in liquid coatings that are applied to a surface.

1.5 This standard covers the determination of volatile matter, water, and lacquer content in liquid coatings that are applied to a surface.

Designation: D 3335 - 85a (Reapproved 1991)^{e1}

Standard Test Method for Low Concentrations of Lead, Cadmium, and Cobalt in Paint by Atomic Absorption Spectroscopy¹

This standard is issued under the fixed designation D 3335; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (^e) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

^{e1} Note—Keywords were added editorially in June 1991.

1. Scope

1.1 This test method covers the determination of lead² contents between 0.01 and 5 %, cadmium contents between 50 and 150 ppm (mg/kg), and cobalt contents between 50 and 2000 ppm (mg/kg) present in the nonvolatile portion of liquid coatings or contained in dried films. There is no reason to believe that higher levels of all three elements could not be determined by this test method, provided that appropriate dilutions and adjustments in specimen size and reagent quantities are made.

1.2 Only pigmented coatings were used for evaluating this test method, but there is no reason to believe that varnishes and lacquers could not be analyzed successfully, provided that appropriate precautions are taken.

1.3 This test method is not applicable to the determination of lead in samples containing antimony pigments (low recoveries are obtained).

1.4 If lead is present in the sample to be analyzed in the form of an *organic* lead compound at a concentration greater than 0.1 %, small losses of lead may occur, resulting in slightly poorer precision than shown in Section 12.

1.5 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. Specific hazard statements are given in Section 7.*

³ *Annual Book of ASTM Standards*, Vols 06.03 and 11.01.

⁴ *Annual Book of ASTM Standards*, Vol 06.01.

3. Summary of Test Method

3.1 The specimen of liquid coating or dried film is prepared for analysis by dry ashing. The content of lead, cadmium, or cobalt of an acid extract of the ash is determined by atomic absorption spectroscopy.

4. Significance and Use

4.1 The permissible level of heavy metals in certain coatings is specified by governmental regulatory agencies. This test method provides a fully documented procedure for determining low concentrations of lead, cadmium, and cobalt present in both water and solvent-reducible coatings to determine compliance.

5. Apparatus

5.1 *Atomic Absorption Spectrophotometer*, consisting of an atomizer and either a single- or three-slot burner; gas pressure regulating and metering devices for air and acetylene; lead, cadmium, and cobalt source lamps⁵ with a regulated constant-current supply; a monochromator and associated optics; a photosensitive detector connected to an electronic amplifier; and a readout device.

5.2 *Muffle Furnace*, capable of maintaining $500 \pm 10^\circ\text{C}$.

5.3 *Crucibles*, wide-form, porcelain, glazed inside and outside except for the outside bottom surface, approximately 30-mL capacity, 50-mm rim diameter and 31-mm height.⁶

5.4 *Hot Plate*, with variable surface temperature control over the range from 70 to 200°C .

5.5 *High-Silica Glass Beakers*,⁷ 100 and 250-mL.

5.6 *Volumetric Flasks*, 50, 100, and 1000-mL.

5.7 *Dropping Bottles*, $\frac{1}{4}$ or $\frac{1}{2}$ -oz (7 or 15-mL) capacity.

5.8 *Glass or Disposable Syringes*, 5 or 10-mL capacity.

5.9 *Pipets*, 1, 2, 5, and 10-mL capacity.

5.10 *Paint Shaker*.

5.11 *Paint Draw-Down Bar*.

6. Reagents

6.1 *Purity of Reagents*—Reagent grade chemicals shall be

⁵ Both hollow cathode lamps and electrodeless discharge lamps have been found satisfactory for this purpose.

⁶ Coors No. 25007 crucibles, or equivalent, have been found satisfactory for this purpose.

⁷ Vycor beakers manufactured by the Corning Glass Co. have been found satisfactory for this purpose.

used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.⁸ Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

6.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent grade water conforming to Type II of Specification D 1193.

6.3 *Ammonium Acetate Solution* (50 % weight/volume)—Dissolve 500 g of ammonium acetate ($\text{NH}_4\text{C}_2\text{H}_3\text{O}_2$) in water and dilute to 1 L.

6.4 *Ammonium Acetate Diluting Solution*—Add 50 mL of HNO_3 (sp gr 1.42) to 150 mL of 50 % weight/volume ammonium acetate solution and dilute to 1 L.

6.5 *Cadmium Standard Stock Solution* (1 mg/mL)—Dissolve 2.1032 g of cadmium nitrate ($\text{Cd}(\text{NO}_3)_2$) in 10 mL of water, add 10 mL of HNO_3 (sp gr 1.42), and dilute to 1 L.

6.6 *Cobalt Standard Stock Solution* (1 mg/mL)—Dissolve 4.9387 g of cobalt nitrate hexahydrate ($\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$) in 10 mL of water, add 10 mL of HNO_3 (sp gr 1.42), and dilute to 1 L.

6.7 *Lead Standard Stock Solution* (1 mg/mL)—Dissolve 1.5980 g of lead nitrate ($\text{Pb}(\text{NO}_3)_2$) in 10 mL of water, add 10 mL of HNO_3 (sp gr 1.42), and dilute to 1 L.

NOTE 1—10.00 mg/mL concentrations of cadmium, lead, silver and zinc are available as SRM 2121; and the same concentration of cobalt, copper, iron and nickel as SRM 2124 from: Office of Standard Reference Materials, Room B-311, Chemistry Building, NIST, Washington, DC 20234.

6.8 *Nitric Acid* (sp gr 1.42)—Concentrated nitric acid (HNO_3).

6.9 *Nitric Acid* (1+1)—Add 1 volume of HNO_3 (sp gr 1.42) to 1 volume of water.

7. Hazards

7.1 Concentrated nitric acid is corrosive and may cause severe burns of the skin or eyes; the vapor is irritating to mucous membranes. Use care in handling this acidic substance. Refer to suppliers' Material Safety Data Sheet.

7.2 Use only a rubber bulb aspirator for pipetting liquids.

8. Calibration and Standardization

8.1 Prepare 100-mL quantities of at least four standard solutions bracketing the expected lead, cadmium, or cobalt concentration in the sample to be tested. To suitable aliquots add 5 mL of HNO_3 (sp gr 1.42) and 15 mL of 50 % ammonium acetate solution. Dilute to 100 mL with water.

8.2 Operational instructions for atomic absorption spectrophotometers vary with different models. Consult the manufacturer's literature for establishing optimum conditions for the specific instrument used.

8.3 Turn the instrument on and set the wavelength to the

⁸ "Reagent Chemicals, American Chemical Society Specifications," Am. Chem. Soc., Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY, and the "United States Pharmacopoeia."

NOTE 4—Ashing at temperatures in excess of 500°C may result in the loss of some lead by volatilization.

9.6 When the ashing appears to be complete (do not exceed 1 to 2 h), remove the crucible or beaker from the

preheated muffle furnace and ash at 475 to 500°C.

9.5 After charring is complete, place the container in a hot plate until the material chars.

9.4 When the specimen appears to be dry or when starting with a dried film, gradually increase the temperature of the

9.3 Place the crucible (or beaker) containing the liquid coating on a hot plate and slowly increase the temperature until the material is dried. With some types of coatings, an initial oven-drying at 105°C may be necessary to remove solvents without incurring losses due to spattering.

NOTE 3—Recover dried paint films from previously coated substrates (being careful not to remove any underlying material from the substrate) or prepare in the laboratory from liquid samples. For the laboratory preparation, flow some of the well-mixed sample onto a clean glass plate. The use of a paint draw-down bar is recommended to obtain uniform wet film thickness not exceeding 2 mils (50 µm). Allow the film to dry in an oven at 105°C for a minimum of 1 h. Scrape the dried film off the glass plate, preferably with a single-edge razor blade.

NOTE 2—The specimen size called for will give a concentration of approximately 10 to 20 µg/mL lead in the final diluted solution for paints containing approximately 500 ppm (mg/kg) lead, based on the solids. If the material is estimated to contain more or less than 500 ppm lead, the quantity taken should be adjusted accordingly. In the event that significantly less than 500 ppm lead is expected, a 250-mL high-silica beaker may be used in place of the crucible to accommodate specimen weights up to 10 g. The size specified will give a concentration of approximately 2 to 4 µg/mL cadmium in the final diluted solution for paints containing approximately 100 ppm cadmium, based on the solids. The size specified will give a concentration of approximately 10 to 20 µg/mL cobalt in the final diluted solution for paints containing approximately 500 ppm cobalt, based on the solids.

NOTE 2—The specimen size called for will give a concentration of approximately 10 to 20 µg/mL lead in the final diluted solution for paints containing approximately 500 ppm (mg/kg) lead, based on the solids. If the material is estimated to contain more or less than 500 ppm lead, the quantity taken should be adjusted accordingly. In the event that significantly less than 500 ppm lead is expected, a 250-mL high-silica beaker may be used in place of the crucible to accommodate specimen weights up to 10 g. The size specified will give a concentration of approximately 2 to 4 µg/mL cadmium in the final diluted solution for paints containing approximately 100 ppm cadmium, based on the solids. The size specified will give a concentration of approximately 10 to 20 µg/mL cobalt in the final diluted solution for paints containing approximately 500 ppm cobalt, based on the solids.

9.2 Prepare at least two replicate specimens by weighing by difference from a dropping bottle or syringe approximately 2 to 3 g of the mixed liquid coating, or by directly weighing approximately 1 to 2 g of dried paint film, into a 30-mL porcelain crucible. Weigh to 0.1 mg.

NOTE 2—The specimen size called for will give a concentration of approximately 10 to 20 µg/mL lead in the final diluted solution for paints containing approximately 500 ppm (mg/kg) lead, based on the solids. If the material is estimated to contain more or less than 500 ppm lead, the quantity taken should be adjusted accordingly. In the event that significantly less than 500 ppm lead is expected, a 250-mL high-silica beaker may be used in place of the crucible to accommodate specimen weights up to 10 g. The size specified will give a concentration of approximately 2 to 4 µg/mL cadmium in the final diluted solution for paints containing approximately 100 ppm cadmium, based on the solids. The size specified will give a concentration of approximately 10 to 20 µg/mL cobalt in the final diluted solution for paints containing approximately 500 ppm cobalt, based on the solids.

9. Procedure

9.1 If the sample is a liquid coating, mix it until homogeneous, preferably on a mechanical shaker. Determine the nonvolatile content in accordance with Guide D 2832.

9.2 Prepare at least two replicate specimens by weighing by difference from a dropping bottle or syringe approximately 2 to 3 g of the mixed liquid coating, or by directly weighing approximately 1 to 2 g of dried paint film, into a 30-mL porcelain crucible. Weigh to 0.1 mg.

NOTE 2—The specimen size called for will give a concentration of approximately 10 to 20 µg/mL lead in the final diluted solution for paints containing approximately 500 ppm (mg/kg) lead, based on the solids. If the material is estimated to contain more or less than 500 ppm lead, the quantity taken should be adjusted accordingly. In the event that significantly less than 500 ppm lead is expected, a 250-mL high-silica beaker may be used in place of the crucible to accommodate specimen weights up to 10 g. The size specified will give a concentration of approximately 2 to 4 µg/mL cadmium in the final diluted solution for paints containing approximately 100 ppm cadmium, based on the solids. The size specified will give a concentration of approximately 10 to 20 µg/mL cobalt in the final diluted solution for paints containing approximately 500 ppm cobalt, based on the solids.

NOTE 2—The specimen size called for will give a concentration of approximately 10 to 20 µg/mL lead in the final diluted solution for paints containing approximately 500 ppm (mg/kg) lead, based on the solids. If the material is estimated to contain more or less than 500 ppm lead, the quantity taken should be adjusted accordingly. In the event that significantly less than 500 ppm lead is expected, a 250-mL high-silica beaker may be used in place of the crucible to accommodate specimen weights up to 10 g. The size specified will give a concentration of approximately 2 to 4 µg/mL cadmium in the final diluted solution for paints containing approximately 100 ppm cadmium, based on the solids. The size specified will give a concentration of approximately 10 to 20 µg/mL cobalt in the final diluted solution for paints containing approximately 500 ppm cobalt, based on the solids.

NOTE 2—The specimen size called for will give a concentration of approximately 10 to 20 µg/mL lead in the final diluted solution for paints containing approximately 500 ppm (mg/kg) lead, based on the solids. If the material is estimated to contain more or less than 500 ppm lead, the quantity taken should be adjusted accordingly. In the event that significantly less than 500 ppm lead is expected, a 250-mL high-silica beaker may be used in place of the crucible to accommodate specimen weights up to 10 g. The size specified will give a concentration of approximately 2 to 4 µg/mL cadmium in the final diluted solution for paints containing approximately 100 ppm cadmium, based on the solids. The size specified will give a concentration of approximately 10 to 20 µg/mL cobalt in the final diluted solution for paints containing approximately 500 ppm cobalt, based on the solids.

muffle furnace and allow it to cool to room temperature. Break up the ash into fine particles with a glass stirring rod, leaving the rod with the container through the filtering step.

9.7 Add 10 mL of HNO_3 (1+1), taking care to avoid losses due to spattering in case the ash reacts vigorously with the acid. Heat carefully on a hot plate until 2 to 3 mL of solution remain. Add an additional 10 mL of HNO_3 (1+1) and continue heating on the hot plate until less than 5 mL of the solution remains.

9.8 Filter the solution through medium-porosity filter paper into a 50-mL volumetric flask. If the filtrate is not clear, refilter through fine-porosity filter paper. Wash the container three times with 2.5 mL of hot ammonium acetate solution (6.3), each time transferring the washings to the filter paper. Wash the filter paper several times with water. Adjust the volume to 50 mL with water and mix.

9.9 Aspirate the test solution and determine the absorbance in the same manner in which the instrument was calibrated. Determine the concentration of lead, cadmium, or cobalt in micrograms per millilitre from the calibration curve. If the absorbance is above the range covered by the calibration curve, dilute an aliquot of the sample solution to a suitable volume with ammonium acetate diluting solution.

NOTE 5—For maximum accuracy, calibration and standardization (Section 8) should be completed just prior to aspirating the sample solution.

NOTE 6—The method of standard additions may be used to improve the accuracy of the analysis. This method is particularly recommended for use with unknown samples where matrix effects may be potentially significant. For a detailed description of the procedure and calculations used in the method of standard additions, consult a standard text on atomic absorption spectroscopy or the instruction manual provided by the instrument manufacturer.

10. Calculation

10.1 Calculate the mean concentration of lead, cadmium, or cobalt in the nonvolatile portion of the sample as follows:

$$\text{lead, cadmium or cobalt, ppm (mg/kg) in nonvolatile} = (C \times F \times 5000)/(NV \times S)$$

where:

C = concentration of lead, cadmium, or cobalt in the aspirated specimen solution, ($\mu\text{g/mL}$),

F = dilution factor from 9.9 (volume diluted to/volume of aliquot),

5000 = factor derived from multiplying the 50-mL volume obtained in procedure in 9.8 by 100 (to convert NV used to a whole number) and 10^6 (to obtain ppm), then dividing by 10^6 (to convert grams of sample to μg),

NV = percent nonvolatile of paint sample (use 100 if sample was a dried film), and

S = sample, g.

11. Report

11.1 Report the lead, cadmium, or cobalt content of the nonvolatile content of the sample and whether the analysis was conducted on a liquid coating or a dried film.

12. Precision and Bias⁹

12.1 The precision estimates are based on an inter-laboratory study in which seven different laboratories analyzed in duplicate, on two different days, four samples of water-reducible paints and four samples of solvent-reducible paints containing from 0.01 to 5 % lead, 50 to 150 ppm (mg/kg) cadmium, and 50 to 2000 ppm cobalt. The within-laboratory coefficient of variation was found to be 3.4 % relative at 24 degrees of freedom for lead, 3.7 % relative at 15 degrees of freedom for cadmium, and 3.3 % relative at 21 degrees of freedom for cobalt. The between-laboratory coefficient of variation was 9.3 % relative at 20 df for lead, 8.9 % relative at 11 df for cadmium, and 5.5 % relative at 17 df for cobalt. Based on these coefficients, the following criteria should be used for judging the acceptability of results at the 95 % confidence level:

12.1.1 *Repeatability*—Two results, each the mean of duplicate determinations, obtained by the same operator on different days should be considered suspect if they differ by more than 11 % relative for all three metals.

12.1.2 *Reproducibility*—Two results, each the mean of duplicate determinations, obtained by operators in different laboratories should be considered suspect if they differ by more than 28 % relative for lead or cadmium or by more than 17 % relative for cobalt.

12.2 Bias:

12.2.1 The true value for the amount of lead present in the solids of a coating should be between 97 and 111 % of the experimental value.

12.2.2 The true value for the amount of cadmium present in the solids of a coating should be between 77 and 143 % of the experimental value.

12.2.3 The true value for the amount of cobalt present in the solids of a coating should be between 96 and 120 % of the experimental value.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Standard Guide for Testing Water-Borne Floor Paints¹

This standard is issued under the fixed designation D 3358; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been approved for use by the Department of Defense.

1. Scope

1.1 This guide covers the selection and use of procedures for testing water-borne floor paints. The test methods included are listed in Tables 1 and 2.

NOTE—Where no ASTM test method exists or there is a comparable (but not necessarily identical) method in Federal Test Method Standard, No. 141, the Federal Method number is listed. However, the Federal Method shall not be considered approved by ASTM.

1.2 The guide covers the testing of ready-mixed finish coats applied by brush or roller on surfaces subjected to traffic, such as floors, decks, platforms, stairs, and adjacent surfaces such as stair risers and railings.

1.3 Floor paints may be intended for interior use only or may also be suitable for use on exterior surfaces exposed to the weather, such as decks, porches, porch steps, and carport floors. Paints intended for both exterior and interior use require certain test procedures not applicable to paints intended for interior use only. Selection of test methods must be governed by the requirements in each individual case, together with agreement between the purchaser and the seller.

3. Conditions Affecting Performance of Water-Borne Floor Paints

3.1 Practical requirements affecting and performance of water-thinned floor paints may vary with:

3.1.1 Substrate type, such as type and quality of wood, concrete, metal, or composition flooring. The use of water-borne floor paints is generally restricted to previously painted surfaces or unpainted concrete.

3.1.2 Substrate conditions such as porosity, hardness, smoothness, or in the case of unpainted concrete, alkalinity. Cleanliness is very important as traces of oily contaminants can cause water-borne floor paints to peel.

3.1.3 Environmental conditions such as temperature and humidity at the time of application and during drying. As these paints contain water as a thinner, the floor does not have to be completely dry before application. However, low temperature during the drying period may cause poor film formation.

3.1.4 *Substrate Aspects*—If construction defects are such that excessive moisture makes its way through the substrate, or if the substrate is in direct contact with damp ground, blistering, flaking, or peeling may result.

4. Definitions

4.1 For definitions of terms used in this guide, refer to Definitions D 16.

5. Sampling

5.1 Prior to sampling, the condition of the container should be established since damage to it may cause evaporation, skinning, or other undesirable effects in the coating. Determine the condition of the paint in accordance with 6.1 and 6.2.

5.2 Sample in accordance with Section 4.2.1 of Method 1021 of Federal Test Method No. 141. Determine the weight per gallon (or kilograms per litre) in accordance with Test Method D 1475. Repeat this procedure until successive values agree within 0.1 lb (45 g) or as agreed upon between the purchaser and the seller. Samples for testing may then be taken.

5.3 Specify the amount of sample, the package sizes, and identification codes to assure a representative sample. A 1-gal sample is usually sufficient for the recommended tests, but for guidance in selecting a sampling plan, consult Practice E 105.

TABLE 1 List of Test Methods by Properties

Test Method	Section	ASTM Method	Federal Test Method Standard No. 141
Liquid Paint Properties:			
Condition in container	6.1	...	3011

6. Liquid Paint Properties

6.1 *Condition in Container*—Thickening, settling, and separation are undesirable and objectionable if a paint cannot be reconditioned and made suitable for application with a reasonable amount of stirring. The referenced methods covers procedures for determining changes in properties of paints after storage. Determine the condition in the container in accordance with Method 3011 of Federal Test Method Standard No. 141.

6.2 *Coarse Particles and Foreign Matter*—Paints must be free of coarse particles to form uniform films of good appearance, a typical maximum being 1 weight % of total paint. The specified test with a No. 325 (45- μ m) sieve gives the percent of these particles in a paint. Determine coarse particles and foreign matter in accordance with Test Methods D 185.

⁷ Annual Book of ASTM Standards, Vol 15.05.

TABLE 2 Alphabetical List of Test Methods

Test Method	Section	ASTM Method	Federal Test Method Standard No. 141
Abrasion resistance	9.1	D 658, D 968	...
Adhesion	9.3	D 2197	...
Application of brushed films	7.1	...	2141
Brushing properties	7.2	...	4321
Chalk resistance	9.5.3	D 659	...
Checking resistance	9.5.4	D 660	6421
Chemical analysis	10.1	...	...
Coarse particles and foreign matter	6.2	D 185	...
Color differences of opaque materials, instrumental evaluation of	8.2	D 2244	...
Color differences of opaque materials, visual evaluation of	8.1	D 1729	4249
Condition in container	6.1	...	3011
Conducting exterior exposures	9.5.1	D 1006	...
Consistency	6.5	D 562	...
Cracking resistance	9.5.5	D 661	6471
Density or weight per gallon	6.3	D 1475	...
Drying properties	7.4	D 1840	...
Elongation	9.2	D 522, D 1737	6221
Erosion resistance	9.5.6	D 662	...
Exterior exposure	9.5	...	...
Fineness of dispersion	6.4	D 1210	...
Flaking resistance	9.5.7	D 772	...
Freeze-thaw resistance	6.7	D 2243	...
Gloss	8.3	D 523	...
Hiding power	8.4	D 2805, D 344	...
Leveling properties	7.5	D 4062	...
Package stability	6.8	D 1849	...
pH measurement	6.6	E 70	...
Pigment analysis	10.3	D 215	...
Producing films of uniform thickness	7.6	D 823	...
Reporting paint film features, characteristic of exterior latex paints	9.5.1	D 1848	...
Resistance to microorganisms	6.9	D 2574	...
Resistance to chemicals	9.4	D 1308	...
Roller coating properties	7.3	...	4335
Volatile content	10.2	D 2369	...
Wood panel description	9.5.2	D 358	...

6.3 Density or Weight per Gallon—The density as measured by weight in pounds per gallon (kilograms per litre) is used to assure product uniformity from batch to batch. In the referenced method, density is expressed as the weight in pounds of 1 U.S. gal (or kilograms per litre) of the paint at a specified temperature. Determine density in accordance with Test Method D 1475 using a calibrated cup.

6.4 Fineness of Dispersion—The more finely a pigment is dispersed, the more efficiently it is being used. One method for measuring the degree of dispersion (commonly referred to as "fineness of grind") is to draw the material down a calibrated, tapered groove in a hardened steel block with the groove varying in depth from 4 to 0 mils (100 to 0 μm) and calibrated Hegman 0-8. The point at which continuous groupings of particles or agglomerates, or both, are visible through the surface of the liquid is taken as the fineness reading. Lower readings in mils or μm or higher readings in Hegman units indicate better fineness of dispersion. Determine fineness of dispersion in accordance with Test Method D 1210.

6.5 Consistency—Consistency is important, relating to application and flow, and should fall within a range agreed

upon. In the referenced method consistency is defined as the load in grams required to produce a specified rate of shear and also expressed in Krebs units. Other methods may be used as agreed upon between the purchaser and the seller. Determine consistency in accordance with Test Method D 562.

6.6 pH—The pH of a water-thinned paint depends on the type of latex used and the general formulation. It may vary from about 5 to 10. pH does not determine the quality of the paint and should not be used to assure product uniformity. A change in pH during storage may indicate poor stability or a change in properties of a water-thinned paint. Determine pH in accordance with Test Method E 70.

6.7 Freeze-Thaw Resistance—Water-thinned paints may be subjected to freezing conditions during shipping and storage. Suitably stabilized paints resist several cycles of freezing and thawing without showing deleterious changes. The referenced method covers the determination of the extent to which water-thinned floor paints, utilizing synthetic latices or synthetic resin emulsions as vehicles, retain their original properties when subjected to freezing and subsequent thawing. Determine freeze-thaw resistance in accordance with Test Method D 2243.

6.8 Package Stability—Since paints cannot normally be used immediately after manufacture, they must remain stable in the can for some time. At normal temperatures, most water-thinned floor paints can be stored for over a year with little change in properties. The referenced method covers the change in consistency and in certain related properties that may take place in packaged latex paint when stored at temperatures above freezing. Determine package stability in accordance with Test Method D 1849.

6.9 Resistance to Microorganisms—Bacteria in a water-borne floor paint can cause gassing, putrefactive or fermentative odors, and loss of viscosity. Determine if the paint contains living bacteria and if it is resistant to attack by bacteria in accordance with Test Method D 2574.

7. Paint Application and Film Formation

7.1 Application of Brushed Films—Brushed films should be smooth and free of seeds, color streaking, and brush marks. Test brush application in accordance with Method 2141 of Federal Test Method Standard No. 141.

7.2 Brushing Properties—The specified method covers a means for determining the brushing properties of coatings. The test is quite subjective; however, someone experienced in the art can produce quite consistent results, particularly in the determination of "drag" qualities. Floor paints are generally applied to horizontal surfaces but evaluation on vertical surfaces may be necessary to determine performance on stair risers, railings, posts, baseboards, etc. Determine the brushing properties in accordance with Method 4321 of Federal Test Method Standard No. 141.

7.3 Roller Coating Properties—Floor paints are frequently applied by roller. The referenced method outlines a procedure for evaluating a material's characteristics when applied by a roller. Determine roller coating properties in accordance with Method 4335 of Federal Test Method Standard No. 141.

7.4 Drying important in stair may be result in dust exterior surf appearance.
