

Dear Sir,

I am a student at San Jose State College, studying Ceramics under Dr. Herbert Sanders. I was told that you had information concerning tests leading to the amounts of free lead left in a glaze after firing. I use large amounts of PbO and am very concerned as I make dinnerware. To this date I have not used any lead glazes on my dinnerware but would like to if I knew it was safe. I am interested in information of simple tests that I could use to see the amount, and exactly what the amount is, to make the difference between being deadly or safe.

Thank-you Michelle Griffoul
